In [12], the authors predicted the passing rates of the students using support vector machine (SVM) and decision tree (DT). While the others authors predicted the passing rate using simple algorithms, the authors in this research work predicted using optimized support vector machine decision which was optimized using grid search. The results had shown better accuracy. Around 92% accuracy is achieved by using the optimized support vector machine and this also proves that the parameter tuning of algorithms has significant impact on performance of algorithms. The dataset taken was from UCI data repository which included the performance of secondary school students in the subject of Mathematics and Portuguese language.

In [13], the authors preprocessed the student data to perform feature extraction on the basis of Bloom's taxonomy and category. The data of students was gathered in a serious game to perform extraction on the basis of Bloom's Taxonomy and category. It was seen that there was decrease in execution time and there was improvement in level of accuracy. With comparison to traditional Fuzzy C-Means, execution time was 2.2-2.7 seconds lesser for the proposed FCM approach and the level of accuracy was improved up to 2.3-4.7%. Also, in comparison to traditional Fuzzy C-Means approach, the performance was enhanced when the features were extracted using Bloom's taxonomy-based extraction and Category-based extraction. Weights were added to features for improving the proposed methods.

In [14], the authors presented a comparison among four techniques namely neural networks, decision tree, support vector machine and naive bayes and their performance was analyzed using F-measure performance metric. The authors had firstly studied the effects of data preprocessing on the algorithms and compared them with the results achieved without data preprocessing. Secondly, the authors had studied the effects of fine tuning of parameters of algorithms on the classification techniques and comparing them with the results achieved without fine-tuning of parameters of algorithms. It was found that support vector machine performs well in both the cases and there is a significant effect of both fine-tuning and data preprocessing on the performance of the algorithms. The students who were enrolled in introductory programming courses in Brazilian Public University by distance learning and by on-campus courses were considered as the dataset and on these datasets the performance of algorithms is tested.

In [15], the author proposed a knowledge flow model using all five different classifiers namely REPTree, J48, SMO, MLP, Naïve Bayes. The analysis was done on the basis of prediction accuracy. It was seen that around 93% of accuracy was reached in case of Multilayer Perceptron (MLP). All the analysis was done on WEKA tool. The attributes didn't consider socio-economic attributes of students. The performance of Multilayer Perceptron was greater among all the five classifiers used in this research. The model could be useful for the students who are new to the introductory programming so that they can be helped with special attention.

In [16], the authors studied the performance of undergraduate students by utilizing data mining techniques. There was a detailed focus on the two important aspects of the performance of students. The academic achievement of the students was predicted at the end of 4 years of study program initially. Further, the typical progressions were studied and the prediction results were combined along with them secondly. Low and high achieving students were the two important groups of students that had been recognized. A timely warning was provided and low achieving students were supported so that their performance could be improved by focusing on fewer numbers of courses which were affecting performance.

In [17], the authors proposed and validated a predictive GPA model by Maximum Weight Dependency Tree. A relatively small-sample experiment was used for determining the set of self-regulatory learning behaviors. For every constituent of the generated model, the predictability was quantified and its relevance was calculated. Utilizing the constructed models for designing the intervention strategies that helped students when the academic failure was at risk was the major objective of grade prediction. The basic interventions were defined and the interventions which were of help to students having minimum GPA were identified by this application framework. Around 65% of accuracy was achieved by the proposed algorithm.

In [18], the authors analyzed the progress of students, their performance and their potentials using the multiple analysis tools. Initially, Student Attribute Matrix (SAM) formulated the student model. The analysis performed further could be utilized as the student attributes quantified by SAM. The BP-NN algorithm was applied secondly, for providing student performance estimation tools. The prior knowledge of students and their performance attributes were used to estimate the attributes of students further. For describing the progress of students related to different aspects along with the casual relationships, the BP-NN was used to propose the student progress indicators and attributes thirdly. The level at which a

factor would affect the performance of student could be known by these indicators and predictor. It was thus possible to train up the students. For the evaluation of student achievement and development, a student potential function was proposed at the end of this paper. The real academic performance data which was gathered from 60 high school students was used to check the performance of these analysis tools. Correct and highly accurate results were achieved by applying the proposed tools as per the evaluation results.

III. Dataset Preprocessing and Feature Extraction

In this section, we have described the dataset used in this research, hardware and software used, process of data preprocessing and relevant attributes selection using Exploratory Data analysis.

A. Dataset Description

After exploring various data sources, the dataset is taken from UCI data repository. The dataset consists of performance of secondary school students of two Portuguese schools in the subject of mathematics [19].The dataset includes various attributes related to students such as mother's education, father's education, previous period grades and other social, demographic attributes [20].There is 32 attributes in the dataset and the dependent or response variable is G3 and it has a strong correlation with G1 and G2 i.e. period 1 and period 2 scores. There are in total 395 records of different students in the dataset. All the attributes which are present in the dataset is shown in the Table I.

TABLE I. Attributes Description of Student Performance Dataset

Attribute	Description (Domain)
sex	student's sex (binary: female or male)
age	student's age (numeric: from 15 to 22)
school	student's school (binary: *Gabriel Pereira* or *Mousinho da Silveira*)
address	student's home address type (binary: urban or rural)
Pstatus	parent's cohabitation status (binary: living together or apart)
Medu	mother's education (numeric: from 0 to 4[a])
Mjob	mother's job (nominal[b])
Fedu	father's education (numeric: from 0 to 4[a])
Fjob	father's job (nominal[b])
guardian	student's guardian (nominal: mother, father or other)
famsize	family size (binary: ≤ 3 or > 3)
famrel	quality of family relationships (numeric: from 1 – very bad to 5 – excellent)
reason	reason to choose this school (nominal: close to home, school reputation, course preference or other)
traveltime	home to school travel time (numeric: 1 – < 15 min., 2 – 15 to 30 min., 3 – 30 min. to 1 hour or 4 – > 1 hour).
studytime	weekly study time (numeric: 1 – < 2 hours, 2 – 2 to 5 hours, 3 – 5 to 10 hours or 4 – > 10 hours)
failures	number of past class failures (numeric: n if $1 \leq n < 3$, else 4)
schoolsup	extra educational school support (binary: yes or no)
famsup	family educational support (binary: yes or no)
activities	extra-curricular activities (binary: yes or no)
paidclass	extra paid classes (binary: yes or no)
internet	Internet access at home (binary: yes or no)
nursery	attended nursery school (binary: yes or no)
higher	wants to take higher education (binary: yes or no)
romantic	with a romantic relationship (binary: yes or no)
freetime	free time after school (numeric: from 1 – very low to 5 – very high)
goout	going out with friends (numeric: from 1 – very low to 5 – very high)
Walc	weekend alcohol consumption (numeric: from 1 – very low to 5 – very high)
Dalc	workday alcohol consumption (numeric: from 1 – very low to 5 – very high)
health	current health status (numeric: from 1 – very bad to 5 – very good)
absences	number of school absences (numeric: from 0 to 93)
G1	first period grade (numeric: from 0 to 20)
G2	second period grade (numeric: from 0 to 20)
G3	final grade (numeric: from 0 to 20)

a 0 – none, 1 – primary education (4th grade), 2 – 5th to 9th grade, 3 – secondary education or 4 – higher education.
b teacher, health care related, civil services (e.g. administrative or police), at home or other.

B. Hardware & Software

We have used the Python language version 3.7.0 to carry out the whole research work. The IDE on which work is carried out is Jupyter Notebook version 4.4.0. The processor is Intel Pentium N3710 with 4GB random access memory and 64-bit operating system.

C. Data Preprocessing

After appropriate dataset selection, the data pre-processing is an important step in making machine learning model. Firstly, dataset is loaded as a comma separated values file. Then, null values are checked. After that the final score which is a numeric variable is converted into categorical variable. For the students who scored marks in the range of 15 to 20 are categorized as good performing students, students who scored marks in range of 10 and 14 are categorized as average performing students and students having marks less than or equal to 9 are categorized as low performing students. Student's final grade after categorization is shown in Fig. 1. All the nominal attributes such as mother's occupation, father's occupation etc. were converted into numeric attributes through 1-hot-encoding technique.

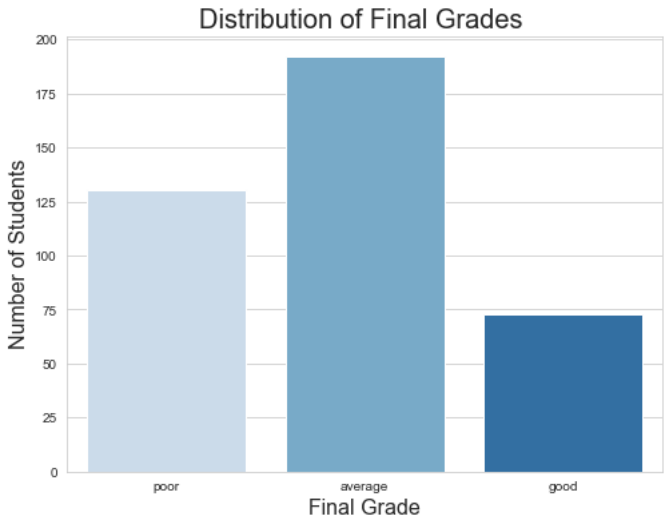

Fig. 1. Distribution of final grades.

D. Attributes Selection

The selection of relevant attributes which are affecting the prediction result is done using exploratory data analysis. The seaborn library of python is used to generate the correlation heatmap. The range varies from -1 to 1. The attributes which are having negative value has a negative correlation with other variable and attributes which are having positive value has a positive correlation with another variable. Positive correlation can be explained through an example in our dataset, if mother's education is high then there is a high chance that final grade of student is higher. Negative correlation can be explained through example of failures in our dataset. For example, if failures of a student increase, then there is a high chance that final grade of that student decreases. The correlation heatmap of our dataset is shown in Fig. 2. The values which are close to zero whether positive or negative has no significant correlation with other variables. These attributes can be dropped from the dataset without any loss in performance. After analysing the correlation heatmap, the feature which is selected for model is as follows: failures,

desire of getting higher education, mother's education, father's education, weekend alcohol consumption, absences, first period score, second period score and the target variable final score. All the other attributes are dropped out from the dataset.

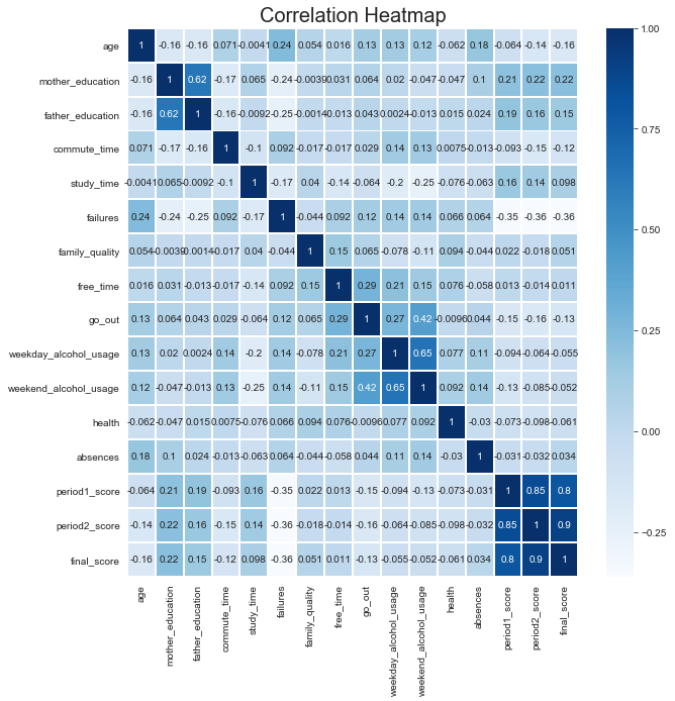

Fig. 2. Correlation Heatmap

IV. Proposed Methodology

Machine learning tasks can be divided into broadly three categories namely supervised learning, unsupervised learning and semi-supervised learning. In this research work, supervised learning is used to build the model as multiclass classification of student performance is done in this research work. In supervised learning, a mathematical model is built by the algorithm from a set of training data that contains both the inputs and the desired outputs. For example, in this research work the task is to determine whether the student is a good performer, average performer or poor performer, the training data includes each student record with all the student related attributes and output variable i.e. the performance of students. The screenshot of training dataset is shown in the Table II. After building the model through supervised machine learning approach, the model is tested by giving new student records without giving the output label i.e. performance of students and their performance is predicted. After that performance of applied algorithms is evaluated. The proposed methodology is shown in Fig. 3.

Appropriate attributes selection is done through correlation heatmap and preprocessing of data is also done by converting output variable into categorical value and by checking for null values, the next step is to split the data in to training and testing. Then different algorithms are fine-tuned with respect to certain parameters. The process of fine tuning and training the algorithms is discussed below with respect to every algorithm:

A. *Decision Tree*

Decision Tree Classifier uses a decision tree to get a decision about the target value. Tree based learning are consider to be one the best and mostly used supervised machine learning algorithms. Firstly, decision tree classifier is trained using the training data then the performance of the classifier is checked using testing data as shown in Table III. Then the decision tree classifier is tuned with respect to minimum samples leaf and applied on extracted features, the dataset obtained in the previous step. Again, tuned classifier is trained using the features extracted data and accuracy is calculated with respect to testing data. Minimum samples leaves specifies the minimum number of samples required to be at a leaf node. The result has shown a significant improvement in terms of accuracy and weighted average of precision, recall, F-measure and decrease in execution time as shown in Table IV.

B. *Random Forest Classifier*

Random forest classifier is a special type of Bootstrap Aggregation. Random forest classifier generates a set of decision trees from randomly selected subset of training set. The final class of the test object is found out by aggregating the votes of different decision trees. Random forest classifier is trained using the training data and then the accuracy of the classifier is checked using testing data as shown in Table III. After this, the random forest classifier is tuned with respect to minimum samples leaf, number of estimators and tuned classifier is applied on extracted features dataset obtained in the previous step. Again, tuned classifier is trained using the dataset consisted of extracted features and accuracy is checked with respect to testing data. Minimum samples leaves specifies the minimum number of samples required to be at a *leaf* node while number of estimators controls the number of trees to be used in the forest. The result has shown a significant improvement in terms of accuracy and weighted average of precision, recall, F-measure and decrease in execution time as shown in Table IV.

TABLE II. Screenshot of Training Data

	school	sex	age	address	family_size	parents_status	mother_education	father_education	mother_job	father_job	...	free_time	go_out
0	GP	F	18	U	GT3	A	4	4	at_home	teacher	...	3	4
1	GP	F	17	U	GT3	T	1	1	at_home	other	...	3	3
2	GP	F	15	U	LE3	T	1	1	at_home	other	...	3	2
3	GP	F	15	U	GT3	T	4	2	health	services	...	2	2
4	GP	F	16	U	GT3	T	3	3	other	other	...	3	2

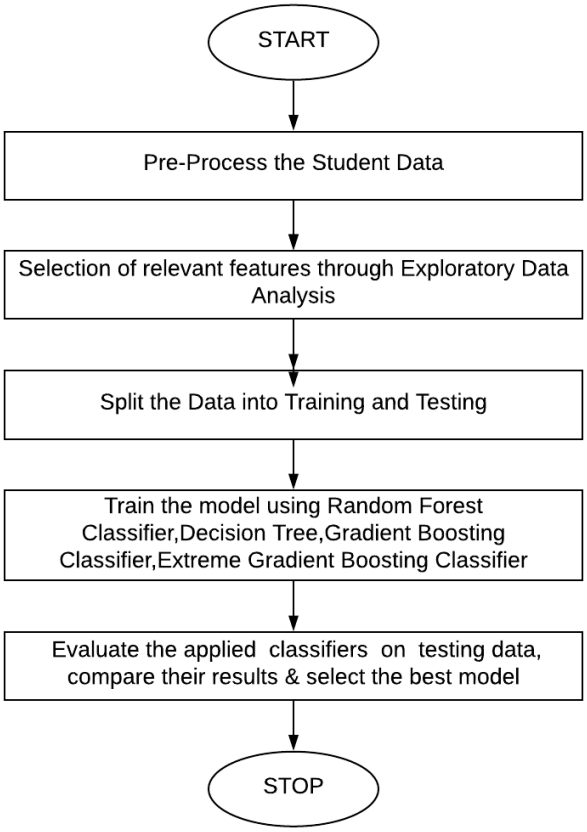

Fig. 3. Proposed Methodology

C. Gradient Boosting Classifier

Gradient Boosting Classifier is an ensemble method of combine's weak learners into strong learners. Gradient boosting helps in automatically reducing the bias. Gradient boosting classifier is trained using the training data then the accuracy of the classifier is checked using testing data as shown in Table III. Then the gradient boosting forest classifier is tuned with respect to minimum samples leaf, number of estimators and tuned classifier applied on featured extracted dataset obtained in the previous step. Again, tuned classifier is trained using the feature extracted data and accuracy is checked with respect to testing data. However, after parameter tuning and feature extraction significant increase in terms of performance parameters is not shown in case of gradient boosting classifier as shown in Table IV. The classifier parameters are tuned with respect to two parameters i.e. minimum sample leaf and n estimators. Number of estimators specifies the number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance. Minimum samples leaf specifies the minimum number of samples required to be at a leaf node.

TABLE III. PERFORMANCE METRICS WITHOUT FINE TUNNING AND ATTRIBUTE SELECTION

Prediction Technique	**Performance Metrics**				
	Accuracy	***Precision***	***Recall***	***F-measure***	***Execution Time (in second)***
Decision Tree	84	84	84	84	0.249
Random Forest	73	75	73	73	1.5
Gradient Boosting	92.4	92	92	92	1.256
Extreme Gradient Boosting	**91.6**	**92**	**92**	**92**	**0.70**

D. Extreme Gradient Boosting Classifier

Extreme gradient boosting classifier is designed to increase the speed of gradient boosting classifier and it has inbuilt cross validation feature. It is a faster version of gradient boosting classifier in which cross validation is inbuilt. Without any parameter tuning and feature extraction this classifier outperforms all other classifiers when both accuracy and execution time are considered as shown in Table III. Extreme gradient classifier is faster in terms of execution time. After, parameter tuning and feature extraction significant increase in terms of performance parameters is not shown in case of extreme gradient boosting classifier as shown in Table IV. Two parameters were tuned i.e. minimum sample leaf and number of estimators. Number of estimators specifies the number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting, so, a large number usually results in better performance. Minimum samples leaves specify the minimum number of samples required to be at a leaf node.

TABLE IV. PERFORMANCE METRICS WITH FINE TUNNING AND ATTRIBUTE SELECTION

Prediction Techniques	***Performance Metrics***				
	Accuracy	***Precision***	***Recall***	***F-measure***	***Execution Time (in second)***
Decision Tree	92.4	93	92	93	**0.015**
Random Forest	**95**	**95**	**95**	**95**	**0.20**
Gradient Boosting	93.27	94	93	93	0.420
Extreme Gradient Boosting	**93.27**	94	93	93	**0.111**

V. RESULTS & DISCUSSION

The four algorithms were evaluated on various performance metrics like accuracy, precision, recall, F-measure and execution time. Accuracy is the ratio of correctly

predicted class to the total number of observations. A comparison of accuracy of different techniques with and without parameter tuning and attribute selection is shown in Fig. 4. Precision is the ratio of correctly predicted positive observations to the total predicted positive observations. Recall can be defined as the ratio of correctly predicted positive observations to the all observations in actual class. F1 Score is the weighted average of Precision and Recall. Therefore, this score takes both false positives and false negatives into account. Execution time is the time required for the algorithm on training and testing data. Results have shown that without any parameter tuning and feature extraction, extreme gradient boost outperforms all other classifiers in terms of accuracy and execution time. But after fine tuning and feature extraction, random forest outperforms all other classifier in terms of accuracy, precision, recall, F-measure with respect to other prediction techniques.

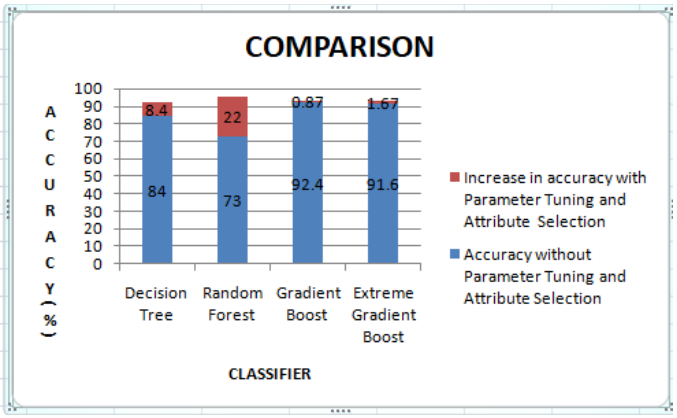

Fig. 4. Comparison of accuracy of different techniques with and without parameter tuning and attribute selection

VI. Conclusion & Future Work

It has been concluded from the research work that proposed machine learning approaches is better in terms of accuracy and other performance parameters when parameter tuning and attributes selection is done. Random forest classifier outperforms all the applied classifiers. Also, the multiclass analysis will give a better analysis to teachers, students, administrators to classify students on the basis of their performance and they can take necessary steps to help students to improve their performance. This prediction models will act like an alarming system to the students. Also, dataset includes not only the academic attributes but also socio-economic attributes. In the future work, a more enhanced dataset including behavioral attributes also along with other student attributes can be considered and parameter tuning can be applied on other algorithms to further increase the accuracy.

***Abstract*— Narrated instructions videos are the rich source of information. The problem of automatically extracting the procedures that are narrated in the video and to summarize the important steps to reduce the time and provide the information to the user is addressed. Natural Language Processing Technique is used for extracting the summarization of the narrated task in the given video. The input video dataset contains real world interactions between a human and machine to explain the procedure to complete a certain task. The given data set is analyzed, processed, and finally a list of important steps are extracted which will help in achieving the given task. Procedure identification or Procedure Extraction is useful for a variety of applications including intelligent tutoring systems, representation learning, transfer learning and video understanding.**

Keywords— video data set; procedure extraction; Natural Language Processing; Summarized instructions; Achieve the given task.

I. INTRODUCTION

Procedural videos are the narrated instructional videos that guide the viewer to tackle an unfamiliar situation. Internet remains a huge source of information media. It provides a large number of videos for a particular task. These videos are made with an intention to teach viewers about the task. Example if a viewer needs to know how to make a coffee as he is new to the field he will seek the help of internet to tackle his situation. We get a lot of results for the phrase "How to make coffee" out of which the best one which explains in a easy understandable way and to the fullest need to be chosen.

This task can be made less time consuming by summarizing the necessary steps to a easy readable format. The proposed work deals with this intention. Unsupervised machine learning technique is followed to retrieve the summary. The challenging task was to deal with the linguistic expressions that are the way the information is conveyed through the language. Even though we considered only English subtitle videos we could find people using different phases to convey information. Example "put coffee, pour coffee, serve coffee all mean the same but used in different videos . But we cannot just neglect them though they mean the same .There is a situation that some videos may vomit some steps thinking it is minor, but it also should be considered for a full information delivery.

In this work we use clustering of text to automatically identify sequence of steps .Videos and its subtitle files are studied to identify keywords to automatically build a Annotation file which is the input for the clustering algorithm which will filter the duplicates and align the text to form sequence.

II. Related work

Procedural Knowledge is also known as imperative knowledge is the knowledge exercised in performing a task according to cognitive science [1]. Processing the images and videos automatically to describe their contents to the viewer more clearly has become popular in recent years using natural language processing [2]. Usually a procedural video is guided by human experts who demonstrate a way to accomplish a task e.g. A woman who could be a beautician can demonstrate steps of applying a makeup, A lecturer teaching steps to solve a problem or a Chef instructing for a tasty recipe preparation. Observing the similarities in the demonstrations and recording them remains a key step in building a model is a challenging problem [3]. Video Captioning problem had a rapid progress due to the availability of large-scale of dataset on the internet [4][5].

Most Recently "flipped" classroom have become very popular , it believes that videos remain a effective approach to teach imperative knowledge as long as the content is proper[6][7].Video demonstrations can be used to create a model that will learn from human explanation. But automatic learning of tasks is a challenge as it requires the pre-learning of the relation between tasks and which steps remain important for the final result summarization.

In this work we have concentrated on finding a way to retrieve the main steps first through the text and then through the video. The main steps are summarized after applying the clustering method repeatedly till all the steps are obtained. Unsupervised machine learning approach is used as we could

not label the classes as the videos may differ in using the sentences even though they are meaning or explaining the same task. In this work, we learn the flow in which we can extract sequence of events from a set of narrated instruction videos of a task on the Internet. Such data contains the detailed descriptions of the event they are illustrating but is not structured and contains more amount of noise and disturbance when compared to the original set [15, 16]. Interpretation of a narrated instruction video set has been recently addressed in the following reference [17]. From the related work we were able to find that we could complete our paper in two different ways one, is to read from subtitles file and other is to go through the Annotation files. Going through the Annotation files is better as compared to the subtitles files as the English usage differ from video to video in the given set. If we go for subtitles file it will not be as effective as it could be hence we decide on doing with Annotation file.

III. PROPOSED WORK

A. *Obtaining the Dataset*

The dataset being used is collected by searching through the YouTube with a specific keyword say "making coffee" or "changing tire". As we all know that over internet we can find a lot of things as in these days internet is a very large source for finding any information that is required, this is the reason we get ample amount of options if we search for a thing over any internet platform. In the same way we were listed up with too many videos for the search we made relating to a particular task. The top 30 videos having English subtitles are chosen. The selection of videos are done on the basis of 2 important things, one is that the subtitles are clearly visible to the user seeing them, and the other is that, in all videos there is a human present physically present who is explaining the steps he has been performing in the video to achieve the specified task. These 30 videos set having the aim of making coffee and changing tire are considered as the data set for this paper. The subtitles are extracted from these videos present in YouTube using automatic speech recognition system (ASR). The extracted subtitles are once manually checked to verify there are no spelling mistakes. The average length of each videos considered in the set is about 2 minutes approximately.

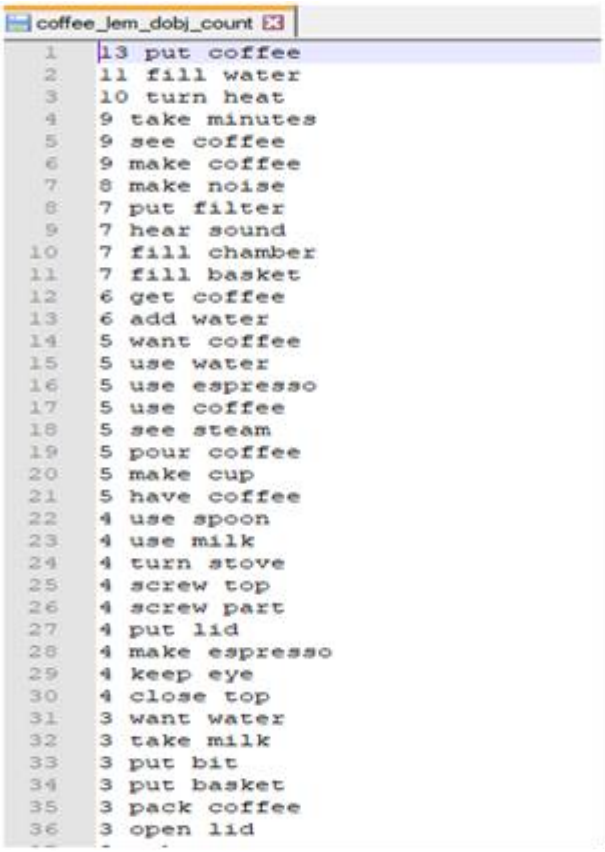
B. *Obtaining a Annotation file*

Once the textual data from the videos are extracted and stored as a text file now the next step in the paper is to analyze the subtitles file to extract important steps from it. The extracted words are written on a new file. This new file can be used to create an annotation file. An annotation file is a text file consisting of important steps – that are extracted from subtitles – along with the number of subtitle files in which that particular step has been mentioned in the given set of subtitles.

Obtaining the annotation file stands as the preprocessing work relating to this paper. An Annotation file is a text file containing the set of important steps that are considered after analyzing the video files. As it may seem what is the use of important steps when that whole set of instructions are readily available with us in the subtitle files. Yes the whole set of instructions are available but as said earlier the videos are considered from YouTube. Even though, the task each narrator is planning to achieve is the same at last, the set of words used to one of the narrators in one video can be different from the words used by other narrator. For example assume the task to be state as "raise the car by using Jack", this step can be explained by one narrator as "place the jack under car and raise the car". The other narrator can say it like "Use the jack to raise car". In both the steps the narrator wants the user to raise the car up, but the sentences used are different. Hence the important step that can be extracted from here is that "put jack", "place jack", "raise car", "use jack" and so on.

The steps are noted down on a separate text file. This text file is an input file to an automation tool that is being used in this paper. The automation tool that we are using is a free license automation tool called as the AutoIT. The automation tool takes in 2 input files, one is the file that we recently created which contains the important steps, and the other file is the subtitle file.

Fig 1: The obtained annotation file.



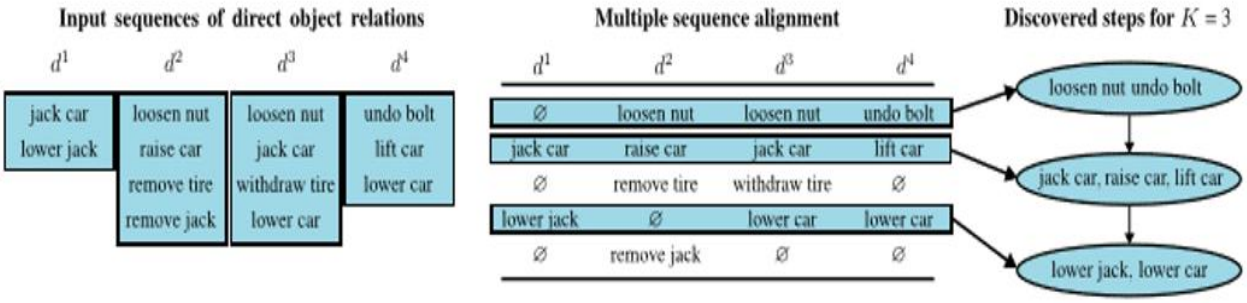


Figure 2: This shows the process of analyzing and clusters of data into groups.

The automation tool works as follows, it reads the data line by line from the file containing the important steps, compares the words with the data present in the subtitles file. Whenever there is a match of words in both the files a counter is incremented. The AutoIt tool will scan over all the 30 subtitle files and finally will give us the result which contains the total number of files that contains the given important step. This number is appended with the specified step and both are written on to a new file.

This newly generated file is named as the annotation file in this paper. Consider an example as shown in figure 1. This is the annotation file that has been created for the task of making coffee. It can be seen that in line 6 the important step that is noted down as "make coffee" is appended with a value 9. This means to state that the step "make coffee" is used in 9 files among the given set of 30 files. Similarly consider line 13 as seen in figure 1, the step is "add water" this has been appended with 6 which indicates that the step "add water" is present in 6 subtitle files.

Figure 3 shows the input file that is given to the AutoIt tool that will be compared with the subtitles files to give an annotation file similar to the figure as shown in Figure 1.

The point to note down here is that the step "add water" could have been used in the subtitle files in many ways say for example: "then add little water", "now we will add little bit of water to vessel", "we are adding water now", and so on.

In the similar fashion the annotation file is created inclusive of all the important steps.

C. Processing the Annotation file

Once the annotation file is received, move to the next step in the paper processing the received annotation file. In this step we analyze the annotated file in order to group the similar important steps.

The Annotation file is processed through a Natural Language Processing (NLP) algorithm. "Matlab" software is used for the processing of the annotation file and for clustering of the similar steps. It takes some iterations to completely sort all the necessary steps and give a summarized form. In the paper the maximum numbers of iterations are taken to be 15. This can be any number but after some trial and error methods we summed the number of iterations to be 15. The Annotation file contains raw information as discussed in the previous section. The instructions may contain repeated keyword for example say 'lower car', 'lower jack' both points to the same operation of lowering the car. This does not mean that we can consider one of the two and neglect the other. Both are equally important. In such a case both the steps are combined together and written under same step.

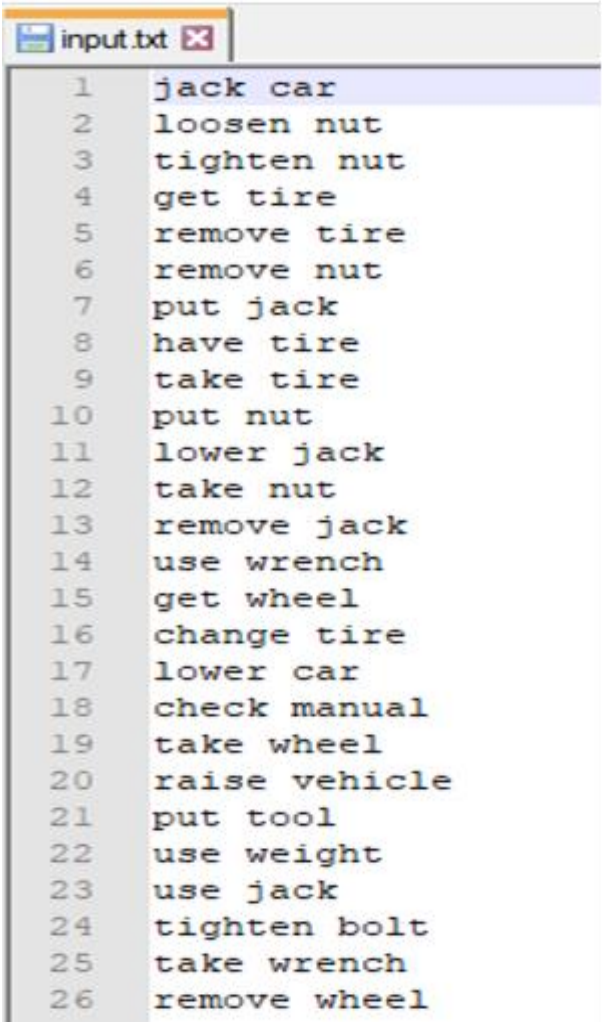

Figure 3: The input file that is given as input to AutoIt automation tool.

The processing of the same can be seen in figure 2. Multiple sequence alignment is done to cluster the similar text. The steps are recognized as a direct object relation which means we consider the steps by a pair of a verb and a object. Example Under step 3 it can be seen that the steps "loosen nut", "undo bolts" have been considered. The algorithm implemented will cluster the text based on the similarity between the keywords as shown in the middle part of figure 2 which is later clustered onto a single step say A1. Similarly "jack car", "raise car" and "lift car" onto group A2.

This clustering of files take part under different iterations and finally as described at the iteration number 15 we get the complete list of sorted summarized steps for achieving the given task.

IV. Results

The primary goal that this paper is trying to portray is on clustering of verbal descriptions present in any of the video set into a sequence of necessary important steps required to achieve the specified task. From the obtained results of the above processing can now be used to analyze the steps for the given task. In our case the given tasks are "Making coffee" and "Changing a tire".

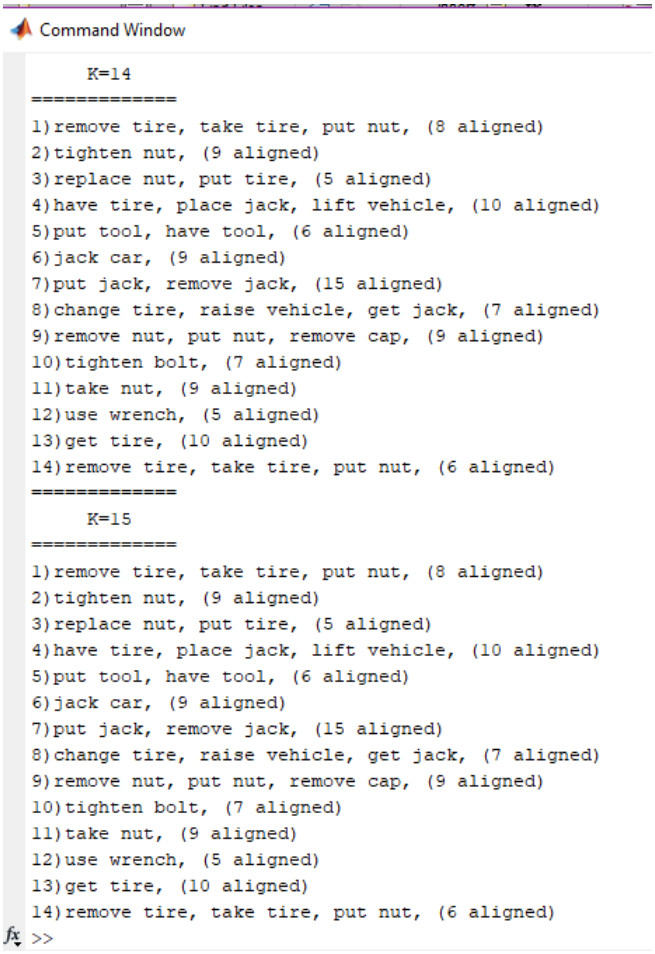

Figure 4. The obtained result after the data is sorted for "Making Coffee".

Now a days people prefer referring to the summarized data rather than going through the whole content. In such a case this procedure can be used to summarize the contents into steps.

The process that is addressed in this paper can be state as multiple sequence alignments problem. In the paper an approach of trying to align a set of instructions present in the given set of data into a set of steps which can be referred instead of going through the whole video.

Figure 4 and figure 5 explains the result that was obtained for 2 data sets. As seen in figure 4 the final output shows the sequence obtained for "Making coffee". Similarly the figure 5 shows the necessary steps when any one wants to change the flat tire of a car. The steps are so clear to understand.

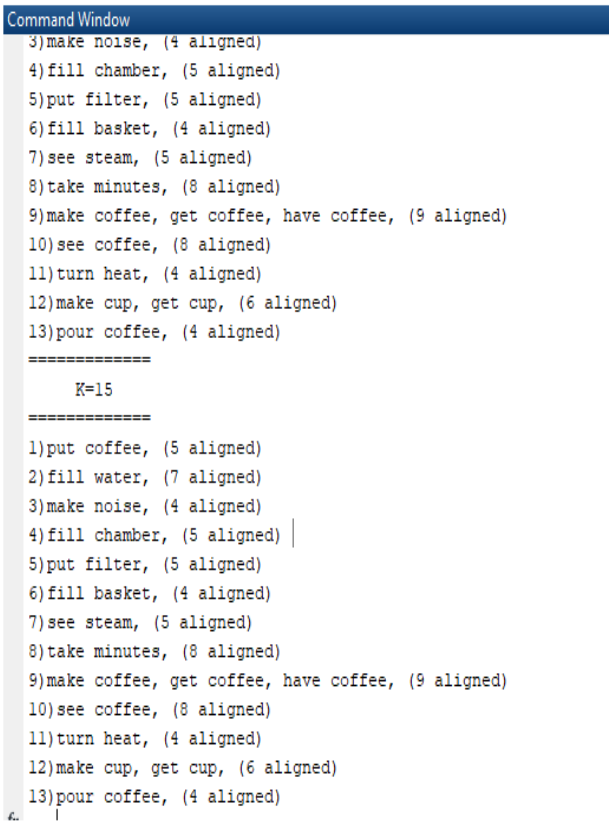

Figure 5: The obtained result after the data is sorted for "Changing Tire".

V. Conclusion

The goal of the arriving at the summary of the important steps of a procedural videos is achieved finally by the use of clustering of data. Before clustering the input is to be clear for this purpose pre-processing was done on the dataset which was a set of videos from the dataset obtained by taking into account that the videos should involve the live demonstration from a human and should include steps to achieve the task and care was also taken to get the videos all explaining the same task with a length not more than 2 minutes. The dataset involved the subtitles file was also the main observation done through which it will be able to pick important keywords easily and done as a text file. This text file is input to automation tool to know the

number of occurrences of each keyword in the videos which further helped us in alignment of the steps in sequence. The output file of the automation is the input for the algorithm which automatically gives us the summary of steps. This work could be further extended to integrate with videos and make the final presentation more colorful and justified.

***Abstract*— In this paper a single band beam steering antenna is designed using corporate feed network and feed this network at the output ports of the branch line coupler and it obeys the property of phase shifting of the radiation pattern in both positive and negative direction. A microstrip patch antenna is designed at Industrial Scientific and Medical ISM Band III (24 GHz) which is an unlicensed band and at the same resonance frequency coupler is also designed using Roger RT-Duroid 5880 substrate having relative permittivity (ϵ_r) of 2.2 and its dissipation factor (tanΔ) is 0.0009. After feeding the corporate feed network at output ports of coupler the phase of the beam is varying to ± 55° after feeding excitation at port 1 and port 2 simultaneously. All design and simulations have performed in HFSS software tools.**

Keywords*— Beam Steering, Corporate Feed Network, Branch Line Coupler (BLC), Antenna Array, ISM Band III.

I. INTRODUCTION

Beam steering is all about changing the pattern of the beam at the respective phase angle. It is achieved by different methods such as by using a phase shifter method and switching it by using PIN diode[1], by using branch line coupler beam forming network i.e. BFN [2] is designed and assigning feed at input port one by one and phase is varying at some extent angle. The Beam also steer mechanically by implementing drivers and motors in the system which steers the antenna and beam starts steering respectively in earlier days. Now we design the system which steers the beam electronically where driver elements are used to steer the beam. A new approach to create beam steering for the circularly polarized (CP) antenna array without phase-shift circuits is recommended [3]. It is found that in a spherical coordinate system (r, θ, φ), for any constant r and θ, as φ varies from 0 to 2π, the phase of the CP antenna's co-polarized far field will progress linearly by 2π, and the magnitude is constant [3]. All-metal beam steering antenna founded on the concept of Risley prism is presented in this communication. The antenna is composed of a feed antenna and two metal lenses. A Mechanically rotate two lenses along the same axis independently can steer the radiation beam in both azimuth and elevation planes [4]. If we design an antenna for a band and by changing the size of the patch at different frequencies it will operate, so we steer the beam by this method also [5]. The circular array beam steering scheme using Orbital Angular Momentum (OAM) to resolve the different challenges by providing means to steer an axial beam using RF phase-shifters and RF hybrid couplers [6].The beam is also steered by using Linear Polarized (LP) metalines and Circular Polarized (CP) metalines for discerning the LP beam steering antenna and CP beam steering antenna [7]. Without using phase shifter beam steering is also possible by using three-element phase array antenna, the center or driven patch is fed by an RF source and two neighboring antennas are excited through the mutual coupling from the center antenna [8]. Silicon based electronic integrated circuits (EICs), Photonic integrated circuits (PICs) and antenna-on-chip (AoC) is another advanced process involves in beam-steering [9].

In this paper, we design a rectangular microstrip antenna which operates at 24 GHz and a Branch Line Coupler at the same band. Basically, we need to steer the beam so we design a beam forming network. The designed antenna is used to form a corporate feed network and at the output ports of the coupler is feeded. Different phase is obtained by exciting each port alternatively. Beam steer antenna is broadly used in a current communication network such as Radar network, point to point or multipoint networks and as well as in satellite communication. This beam steering antenna is highly efficient for the ISM Band III applications.

II. ANTENNA DESIGN

As the defined band is ISM band III i.e. 24 GHz and at that frequency, we proposed an antenna which is a rectangular microstrip patch antenna having feed line and its dimension is calculated at 50 ohm impedance value.

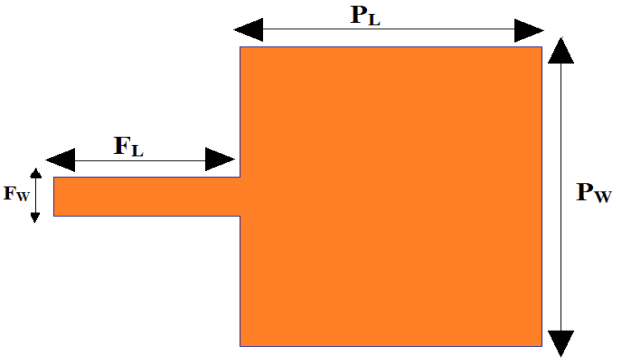

Fig. 1. Designed antenna for ISM Band III

The proposed antenna is shown in Fig 1.with its simulated response in Fig 2. The detailed dimension of the proposed antenna parameters are tabulated Table I. The radiation pattern for the designed antenna is shown in Fig.3 at phi =0 deg. The reflection coefficient (|S11|) for the designed antenna is -46.07 dB and total dimension of the antenna is 5.74mm × 3.9mm (L × W) and designed at the height of 0.79 mm using Roger RT-Duroid 5880substrate. The peak Gain

TABLE I. ANTENNA PARAMETERS

Parameter	Values
P_l	3.55mm
P_w	3.9mm
F_l	2.19mm
F_w	0.5mm

of the single feed antenna is 7 dB and beamwidth of single feed antenna is 58.45° at -3dB down.

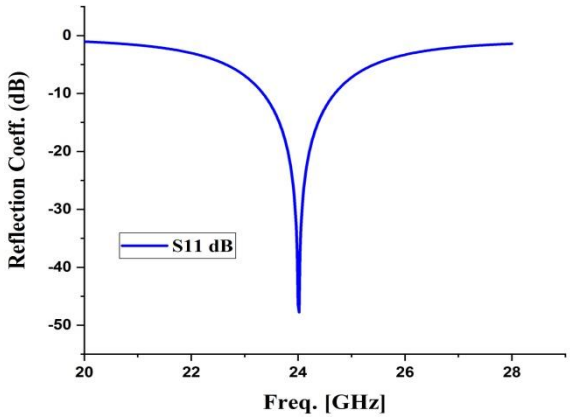

Fig. 2. Simulated response of the designed antenna

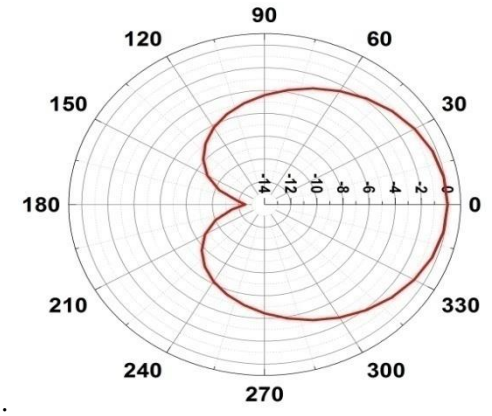

Fig. 3. Radiation Pattern for the designed antenna

III. BRANCH LINE COUPLER DESIGN

Branch Line Coupler is also called the quadrature coupler and having one input port, two output port, and an isolated port as shown in Fig. 4. As branch line coupler has two output ports and there is a phase shift of 90° so, it is used to shift the phase of the beam at some angle. The Coupler is designed at the ISM Band III for proper matching with antenna and it is shown in Fig. 5. The parametric table for this coupler is shown in Table II and all values derive at 50 ohm characteristic impedance (Z_0) value. The value that we calculated for the performed mode of Coupler design for 9 GHz which also resonate of higher order mode at 24 GHz because Coupler having large Bandwidth (B.W) so we design any coupler at lower band and make it also to resonate at a higher frequency. The reason to do so because when we calculate the values of arms of the coupler at 24 GHz it becomes very small and there is an overlap between the arms. We simulate the Coupler at 9 GHz and its simulated result in Fig. 8(a) and after switching it to 24 GHz the

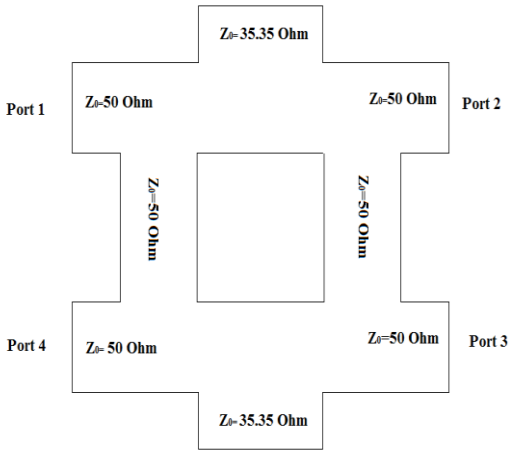

Fig. 5. The basic structure of Branch Line Coupler.

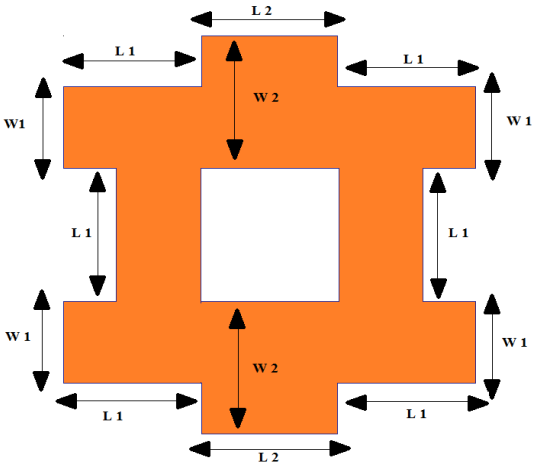

Fig. 6. Designed Branch Line Coupler for ISM Band III.

simulated result is shown in Fig. 8 (b). The phase shift occurs at output ports i.e. Port 2 and port 3 and simulated phase changes is shown in fig. 7 with |S21| for port 2 and |S31| for port 3 respectively. The simulated response for the same coupler at 9 GHz and 24 GHz is not similar, the response of coupler at 9 GHz obeys the defined characteristic of the coupler means at output ports transmission coefficient is same as |S21| and |S31| as shown in Fig. 7(b) and for 24 GHz |S21| and|S31| are totally different from the simulated response for 9 GHz and it happens because the higher frequency is putting at a lower frequency designed coupler.

TABLE II. COUPLER PARAMETERS

Parameter	Values
Length [L1] (Z_0= 50Ω)	4.49mm
Width [W1] (Z_0= 50 Ω)	2.34mm
Length [L2] ($Z_0/\sqrt{2}$ =35.35Ω)	4.41mm
Width [W2] ($Z_0/\sqrt{2}$ =35.35Ω)	3.81mm

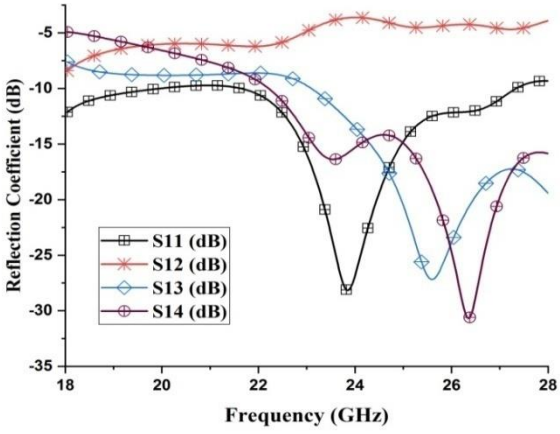

Fig. 8 (b). Simulated response at 24

IV. RESULTS AND DISCUSSIONS

By using branch line coupler and 2×4 corporate feed networks a beam forming network is designed with different feed lines. At Z_0=50Ω a feed line is designed and another one is designed at Z_0=70.7Ω.The designed beam forming network is shown in fig.9. At port 1 excitation is given and

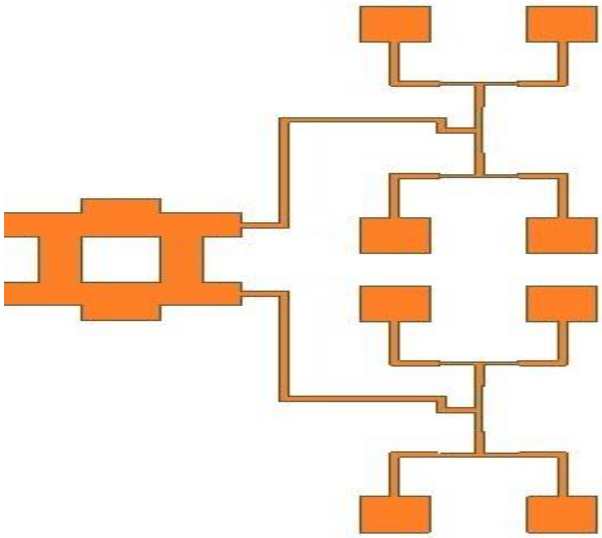

Fig. 9. Beam forming network design

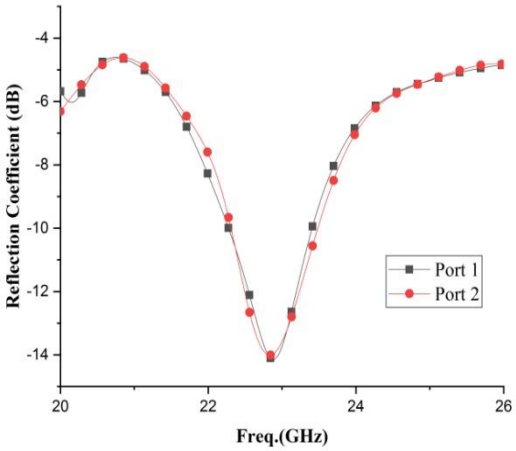
terminating the port 2 the radiation pattern is formed at +55°. After exciting port 2 and terminating port 1 the beam is forming at -55°. The simulated reflection coefficient for each port is similar and it is shown in fig.10. The simulated value of S11 is -14.86dB for port 1 and port 2 respectively. The single microstrip antenna can also feed at the output ports and beam-steering may occur but the gain of the antenna is also desirable. The simulated response at each port is not wide means bandwidth is narrow. The purpose to design this beam forming network is to increase the antenna gain and increase the bandwidth. Without corporate feed network antenna's peak gain is 7dB but with corporate feed network antenna's peak gain is 11 dB. The radiation pattern at port 1 is shown in fig.11 (a) and at port 2 is shown in fig.11 (b).



GHz Fig.10. Simulated reflection Coefficient at each port

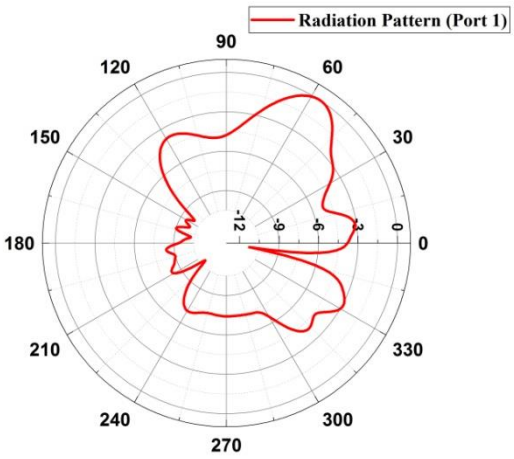


Fig. 11 (a). Radiation pattern at port 1

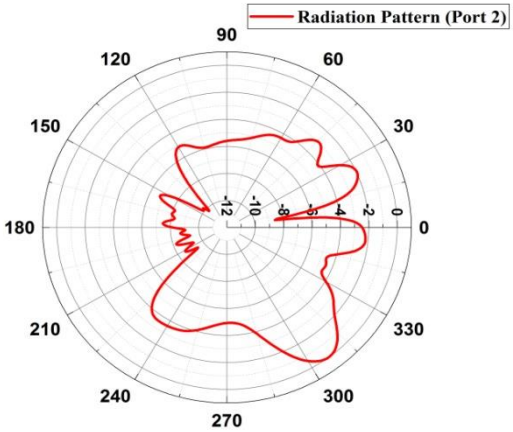

Fig.11(b). Radiation pattern at port 2

The current density distribution at each port is observed at designed network. For port 1 simulated response of current distribution is shown in fig. 12(a) and for port 2 is fig. 12(b). The current density distribution shows the intensity of current flowing from excited port to the feeded antennas. At each port the intensity of current is good and it shows the distributed power in the designed beam forming network.

CONCLUSION

In this paper a novel, innovative, new beamforming network using corporate feed is proposed. For achiveing radiations at particular directional its always difficult to move antenna every time. So we use beam forming networks. Here also our beams are stearing from +55° to -55 ° after exitation of port 1 and port 2 respectively.The dimension of the proposed system is also very small and with good impedence matching, high peak gain and very directive radiation pattern at different angles are achived.We can apply beamforming in different applications like satelite communication, Telecommunication and in radar technology.

Abstract— Physical Unclonable Functions (PUFs) are extensively used to generate the cryptographic keys from the Integrated circuits(ICs),by utilizing the uncontrollable and unavoidable process variations during fabrication process. Arbiter PUFs are emerged to be a one of the strong delay based PUFs having exponential number of challenges and used in commercial and critical security applications. In this paper we proposed 8-stage decoder-multiplexer based arbiter PUF, simulated on cadence spectre using CMOS 90nm technology and measured its security metrics such as reliability(92.56%), uniqueness(48%) and uniformity(47.36%) respectively.

Keywords— Physical Unclonable Functions(PUFs),Arbiter PUF, Hardware security, machine learning attacks.

I. INTRODUCTION

As a continuous growth of the complex digital devices, it is very much necessary to enhances the authenticity, confidentiality, and trustworthiness of each and electronic device. Over the past decade in the field of intrinsic security, several methods being developed to generate the secret keys such as True Random Number Generator(TRNG),pseudo random number generator(PRNG) etc and stored in Non-Volatile Memories(NVMs). Storing the confidential keys in Non-volatile memories are vulnerable to side-channel attacks and also occupies the huge area. Hence to mitigate the above problem Physical Unclonable Functions (PUFs) are emerged to be a one of the promising hardware cryptographic primitive.PUF is a small piece of an electronic circuit which generates an efficient and reliable volatile secret keys by utilizing the unavoidable semiconductor process variations during the manufacturing process[1]. Therefore, these random variations will make each IC will acts as an individual physical fingerprint. The response of a PUF is always the function of the input challenge and random structure of the electronic circuit. Typically, the applied challenge and resulting response are termed to be a Challenge-Response pair(CRP), it can be expressed as Response=PUF(Challenge). Due to its inherent nature and intractably behavior, each challenge can trigger an unpredictable response.Fig.1,depicts an outline of the PUF[2][3]. The generated set of responses from an IC is mainly dependent on two statistical sources such as global mismatches and local mismatches[4](Fig.2,). Global mismatches occur during the fabrication process and factors which are mainly due to oxide thickness, channel length, diffusion depth, impurity concentration, etc, are significantly responsible for on-chip secret keys. On the other hand local mismatches such as supply voltage, temperature, aging can affect the performance of the PUF circuit. The outcome of any PUF circuit is a combination of these mismatches and it can be expressed by (1).

$$M_{Total} = M_{Global} + M_{Local} \quad (1)$$

The rest of the paper is organized as follows in section 2 describes the background and preliminaries of strong PUFs(ring oscillator and arbiter PUF). Section 3 delivers the proposed decoder-mux based arbiter PUF and its results. Finally, section 4&5 describes the conclusion and future scope.

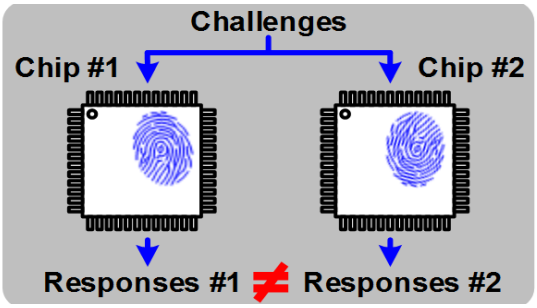

Fig. 1,Challenge response behavior of PUF circuit.

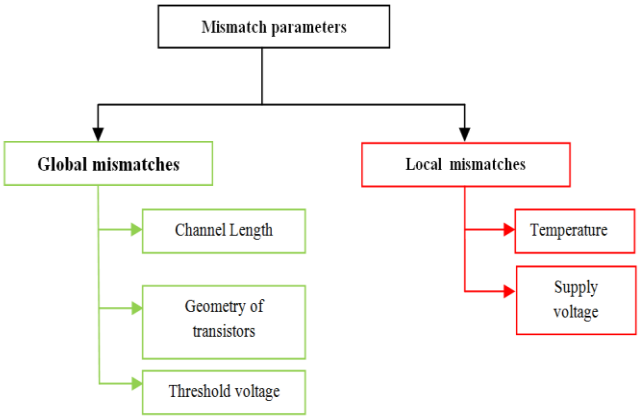

Fig. 2, Classification of mismatches for CMOS PUFs.

II. BACKGROUND AND PRELIMENRARIES

By taking advantage of the mismatches occurred in CMOS ICs, Many constructions have been performed. Depending upon the number of CRPs researchers can be broadly classified PUFs into two categories such as strong PUFs and weak PUFs[5][6]. Weak PUFs are the PUFs having a limited number of CRPs, Signatures obtained from PUF are stable and robust against the environmental variations. Responses are highly unpredictable and strongly depends on fabrication process variations. Weak PUFs such as SRAM PUF, butterfly PUF, etc. On the other hand, strong PUFs differ from weak PUFs, the properties acquired by strong PUFs such as a large set of CRPs, responses can be stable over a wide range of temperatures. Strong PUFs such as arbiter PUFs, ring oscillator PUFs, etc. Depending upon type of application different PUFs being used in each scenario. The main objective of this paper is to discuss the different types of strong PUFs (Multiplexer based PUFs)

corresponding advantages and relatively compare the performance metrics with the proposed PUF. Basically there two different types of strong PUFs are widely used in the device authentication and cryptography such as ring oscillator PUF and arbiter PUF respectively.

A. Ring oscillator PUF

The basic architecture of the ring oscillator PUF as shown in Fig.3, It consists of N-identical delay loops (ring oscillators) are placed on the silicon-Chip[7][8][9]. The minute fabrication variations in the silicon layers of the semiconductor device can results, a slit frequency difference in each pair of delay loops. when a set of input challenge being applied to the PUF circuit depending upon a fixed set of frequency oscillations and process variations can produce the response either '1' or '0' respectively. Researchers have been proposed the several types of ring oscillators in order to improve the performance metrics of the PUF, out of those configurable ring oscillator is one type of the PUF, which enhances the reliability of the PUF.

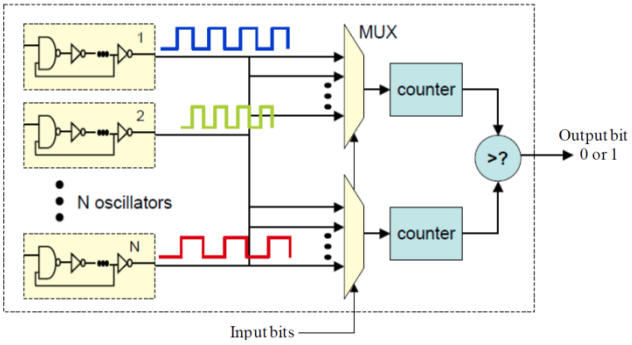

Fig. 3, Ring oscillator PUF.

B. Arbiter PUFs

Arbiter PUF can be coined as one of the strong delay-based PUF. It consists of N stages and two multiplexers are connected at the top and bottom of each stage. A pulse signal is applied as an input of the first stage and selection lines in each stage of the multiplexer will act as a challenge. Depending upon a set of challenges and intra-die variations lead to generate a unique set of responses. The last stage of two multiplexers is connected to the arbiter (DFF) which determines the final response '0' or '1' based on analogy delay difference. For an N-stage arbiter PUF having 2^N number of symmetrical paths and N-challenges. Fig. 4, depicts the linear arbiter PUF architecture [10][11]. One of the biggest issue associated with classical arbiter PUF relatively suffers from reliability and linearity. In order to overcome the above-mentioned issues researchers[12] have proposed several Non-linear arbiter PUFs such as feed-forward arbiter PUF, feed-forward cascade PUF, feed-forward separate, buffer-based PUFs, etc.

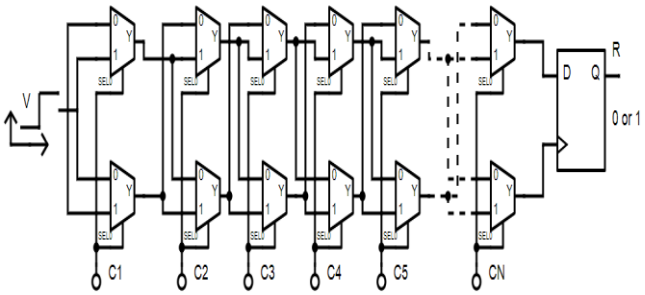

Fig. 4, Schematic of the linear N-stage arbiter PUF[13].

III. PROPOSED DECODER BASED ARBITER PUF

3.1 Operation of decoder PUF

Fig .5, depicts the basic block diagram of the decoder-mux based arbiter PUF. The architecture mainly consists of two stages such as delay network and arbiter network. Each individual stage of the delay network having two switching elements such as 2-4 decoder and transmission gate based multiplexer respectively. A pulse signal is applied as stimulus for the first stage of the delay network and selection lines of the top and bottom multiplexer will acts as the challenges for the first stage of the delay network. Depending upon the input challenges and minute process variations makes significant delay variations in each and individual stage. This process will be continuous until final stage of the delay network and Last stage of the delay network is fed to the arbiter(DFF),which decides the final response based on arrival of the signal. Fig.6 depicts the 8-stage decoder-mux based delay network and fig.7, represents Schematic of the arbiter.

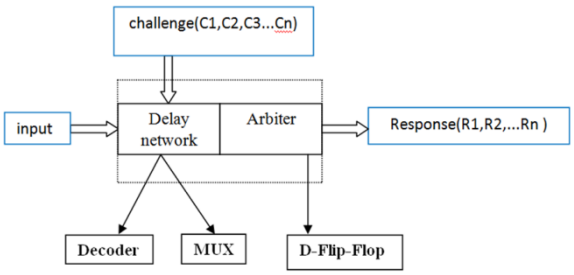

Fig. 5, Block diagram of decoder-Mux based PUF structure.

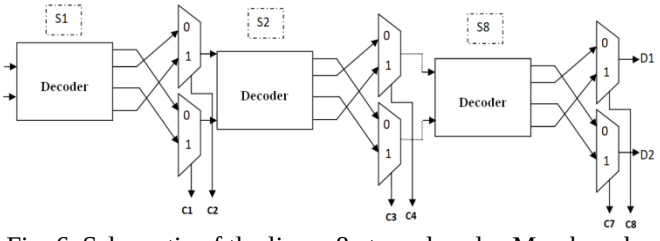

Fig. 6, Schematic of the linear 8-stage decoder-Mux based delay network.

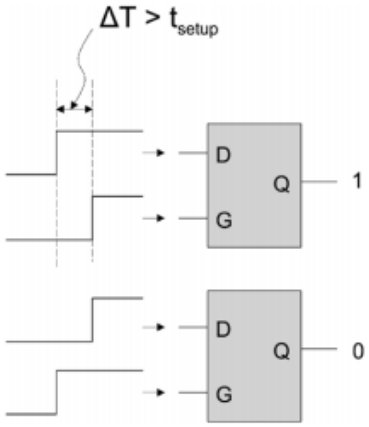

Fig. 7, Detection of final response by an arbiter with respect to delay difference

3.2 Simulation setup and Results

The proposed 8 stage decoder-MUX based PUF architecture being implemented and characterized using cadence spectre. The technology library used as CMOS 90nm process nodes. To study the effect of the process variations and environmental variations performed the Monte-Carlo (MC) simulation to analyze the statistical variations over 200 iterations and 150 samples. From the estimated results measured the security metrics and analyzed the final yield of the proposed PUF based on mean and standard deviation. The yield can be enhanced by each design by tweaking process variations. For any PUF architecture the performance can be estimated by using a set of metrics such as uniqueness, reliability, and uniformity. This can be discussed in a detailed manner in the below discussion.

A. uniqueness:

It is one of the important metric, which can be used to assess the similarity of the PUF responses over different instances. This can be measured by using the Inter-Hamming Distance(HD_{inter}), for any PUF the uniqueness should be very high, otherwise, the response could be predictable and not used for security applications. The ideal value for HD_{inter} is 50%. There are several measurements are employed to estimate the PUF response and most commonly used metric can be expressed by (2).

$$\text{uniquness} = \frac{2}{k(k-1)} \sum_{k}^{k-1} \sum_{j=i+1}^{k} \frac{HD(R_i, R_j)}{N} \times 100\% \quad (2)$$

'N' is the total number of PUF instances, R_i, R_j -is two dissimilar chips i and j.

In order to estimate the uniqueness of a PUF applied the MC analysis over 200 iterations and 25 random challenges. And measured Its mean and standard deviation from 3-sigma plot. The response could be taken at 25^0C and 1v.To achieve better uniqueness varied the threshold voltage(Vt) of the MOSFET were varied and measured its final response ate different intravels. The uniqueness could be measure at different corners such as typical typical(TT),slow slow(SS),slow fast(SF),fast slow(FS) and fast fast(FF). From the obtained results we estimated the maximum uniqueness could be 48% at TT corner. Fig 8(a),(b),(c),(d)and (e) depicts inter die HD variations at different corners.

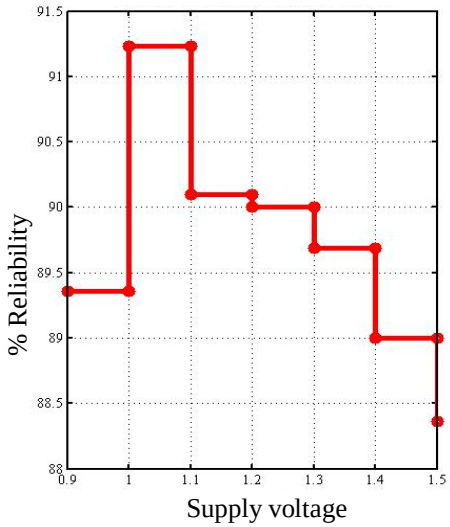
Fig. 8,Distribution of Hamming Distance at different corners(a)TT,(b)SF,(c)FS,(d)SS,(e)FF.

B. Reliability

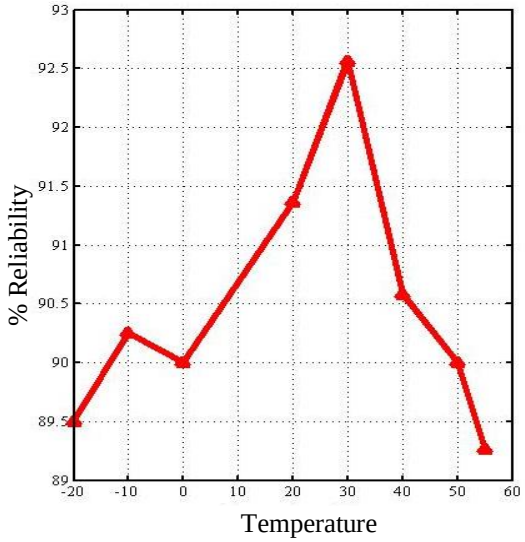
The ability of PUF which can recreates the same response under different environmental conditions such as temperature, voltage and ageing etc. Due to these effects the response of the PUF should be flipped. The ideal value of the reliability is 100%.This metric can be measured using Intra Hamming Distance(HD_{intra}).Mathematically it could be expressed by (3).

$$\text{reliability} = \frac{1}{s}\sum_{t=1}^{s}\frac{HD(R_i, R_{i,t})}{N} \times 100 \quad (3)$$

In order to estimate the reliability of the PUF, chosen as a reference response/golden response at 1v and 25^0c, then collected a set of 25 random challenges and measured its reliability by varying temperature from -20^0c to -55^0C and supply voltage ranging from 0.9V to 1.5V respectively. This process can be done for 200 iterations over 150 samples at each iteration. From the results we observed the maximum reliability 92.56% and minimum reliability is 89.36%. Fig 9(a) and (b) represents the reliability of proposed PUF at different nodes of voltage and temperature at different instances.



(a)



(b)

Fig. 9, % Reliability with respect to (a) Supply voltage and (b) temperature.

C. uniformity

It is a measure of unpredictability of the PUF response, even with the prior knowledge of circuit the generated response could be unpredictable for each and every challenge. The ideal value of the uniformity is 50%. This indicates that response having equal proportion of '1' and '0' respectively. Mathematically it could be expressed by equation (4).

$$\text{uniformity} = \frac{1}{n}\sum_{i=1}^{n} R_{i,l} \times 100\% \quad (4)$$

Fig.10, represents the distribution of the response of the PUF response over 150 number of samples. The test results indicates that maximum mean could be 47.36% respectively.

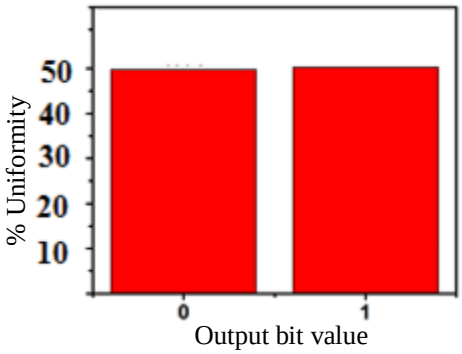


Fig. 10, Estimation of uniformity (% '0' and '1').

IV. CONCLUSION

In order to enhance the security of the PUF and avoided invasive, semi-invasive and side channel attacks proposed a non-linear complex decoder-mux based arbiter PUF. This architecture can satisfy the security metrics and suitable for the device authentication, identification, and IoT environment. The proposed architecture can be tested over the wide range of voltage and temperatures to estimate its reliability, uniqueness, and uniformity. It was observed that these values are very close to the ideal values. And there is

an improvement of reliability with respect to the non-linear MUX based PUFs

V. FUTURE SCOPE

Fabrication of proposed and thoroughly tested decoder-mux based strong PUF architecture can be considered for future work since it can be used in many real-time IoT authentication applications.

***Abstract*—Data acquisition of electric drive is very much relevant in the context of electric vehicles. Different data like IGBT temperature, diode temperature, coolant temperature, electric machine coolant temperature, motor torque, electric machine speed data etc. have to be acquired and analyzed in electronic control units. Data samples are processed in RAM using various algorithms and relevent information is extracted and transferred to ROM as various maps. These information are useful in life time estimation, failure analysis and optimum design of various electric drive components. Histograms and rainflow counting are conventionally adopted methods in data acquisition. Histograms may include irrelevant information and also require large memory space. Normal offline rainflow counting also demands large memory, which necessitates the need for an optimum memory consuming data acquisition algorithm. An online rainflow counting algorithm based on three point method can minimize the RAM space consumption by significant amount. The data counts remains same as in offline rainflow algorithm. Instead of using histograms for data like electric machine speed, data counts for only the relevant operating range can be stored, which minimizes memory requirement. Also level crossing counting is another algorithm which can be adopted where we are interested only in threshold crossings of the parameter acquired, for example the threshold crossing of inverter phase currents, which can cause serious damage to the system. Memory requirement minimization achieved by the above mentioned algorithms are validated by simulation.**

***Index Terms*—offline rainflow algorithm, online rainflow algorithm, level crossing counting, histograms.**

I. Introduction

Different data acquisition algorithms are used for processing and storing electric drive data. Histograms are conventionally used storage method, which consumes large memory space. Other advanced counting methods are used for filtering and storing input data without losing much granularity. Level crossing counting, as per ASTM standards is implemented, where preset threshold crossing information of acquired data is required[2]. In peak counting the peaks and valleys are counted based on a preset level. Peaks higher than the reference level and valleys lower than the reference level are counted[2]. Simple range counting and maximum edge counting are other conventionally used cycle counting methods[2].Rainflow counting is another widely implemented algorithm in cycle counting and fatigue analysis. Different variants of this algorithm is used. Rainflow algorithm based on pagoda roof analogy proposed by Endo and Matsuishi is the basis for all rainflow varients[3]. One of the most widely implemented rainflow algorithm was proposed by Downing and Socie. This three point algorithm was specified in ASTM E 1049-85[2]. Rainflow cycle counting algorithms provide means for comparing obtained variable amplitude load history with constant amplitude load pattern. Rainflow algorithm identifies closed hysteresis loops in the stress - strain plane and provides a method for treating open loops[4]. Other modern methods like Moshrefifar and Azamfar counting were later proposed, but rarely adopted due to complexity in the procedure[5]. In the above method rainflow counting is widely adopted and efficient method, but consuming lot of memory. An online rainflow counting based on the three point algorithm can considerably reduce the RAM consumption[6]. The input data samples are filtered and processed and relevant data is extracted at the instant when the input samples are obtained and the samples are discarded, reducing RAM memory consumption. The online three point rainflow algorithm can be used in data acquisition of various electric drive parameters like IGBT temperature, diode temperature, coolant temperature, electric machine speed etc. in the electric drive.

II. Offline Rainflow Algorithm

A. Algorithm

For a sample load-time history as in Fig. 1, let 'X' be the current range, 'Y' be previous range adjacent to 'X' and S be the Starting point in the history. The three-point offline algorithm as per ASTM E 1049-85[2] is specified below,

A) Read next valley or peak. If end of data then go to step F.
B) If the number of turning points is less than three then go to step A. Update X and Y with three most recent valleys & peaks that are not eliminated.
C) Check the magnitude of ranges Y & X.
    A) If X<Y, go to step A.
    B) If X>=Y, go to step D.

D) If Y includes S them go to step E, if not count Y as a full cycle and remove the turning points in Y & go to step B.
E) Range Y is counted as a half cycle and remove the initial point in Y and set next point in Y as starting point and go to step B.
F) Count remaining ranges as half cycles.

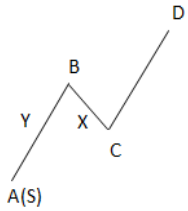

Fig. 1. Sample load history showing ranges and starting point.

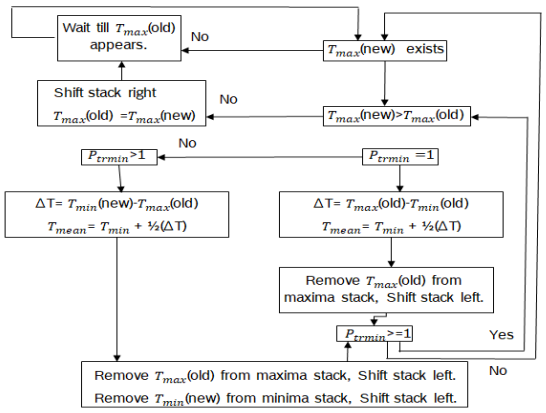

Fig. 2. Online Rain-Flow counting algorithm working on maximal values.

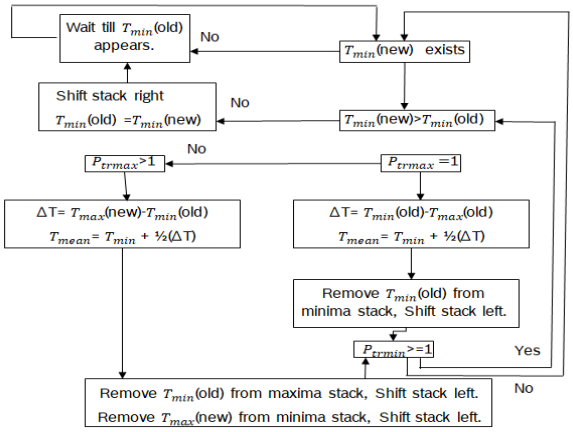

Fig. 3. Online Rain-Flow counting algorithm working on minimal values.

B. Challenges in implementing offline rainflow algorithm

The offline rainflow algorithm is not suitable for real time applications. The load history for significant time should be stored for proper cycle formation from the data. The algorithm cam be applied only on a stored load history. It have a buffer which accommodates the consequent turning points (minima & maxima). The buffer size should be determined before the algorithm is executed. For this the duration between successive usage of the rainflow algorithm, should be predetermined before the algorithm execution. The buffer should have the capacity of holding the entire loading range of the system under consideration. This involves large quantities of data demanding substantial computational resource to process the data during algorithm execution. In real-time applications, coding should be carefully done so that other real-time activities of the ECU are not interrupted.

III. Memory Optimizing Algorithms

A. Online Rainflow Algorithm

The turning points are processed as it occurs. Two buffers are used for this purpose. After processing, the turning points are discarded thus minimizing memory consumption. The load-time history need not be stored. Half and full cycles are extracted in a recursive manner, depending on the buffer contents. The procedure used for obtaining the full and half cycles is similar to the one used in offline rainflow method, and the cycle counts are therefore same for same loading sequences. Pre-ordering of input data points in ascending or decending order as in offline rainflow is not required. The online three point algorithm is depicted in fig. 2 and fig. 3, where, T_{max}-Element of maxima stack, T_{min}-Element of minima stack, P_{trmin}-Element of minima stack elements, P_{trmax}-Element of maxima stack elements. The MATLAB simulation of both online and offline three point rainflow on IGBT temperature input in the range, [20^oC-120^oC] and coolant tempearture input in the range, [20^oC-120^oC] gives similar maps, shown in fig. 4 and fig. 5 respectively, which implies there is no loss of data in the online method.

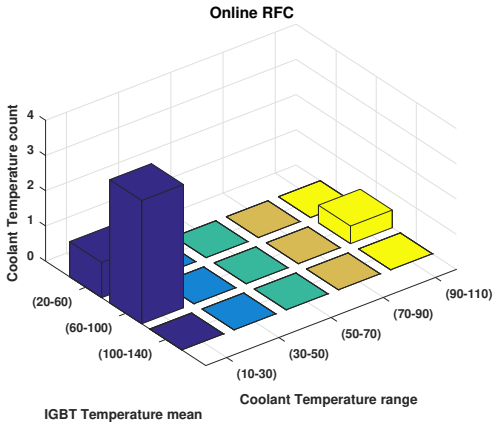

Fig. 4. Online rainflow counting(3D map).

B. Histograms

Histograms are used to represent the distribution of normal data accurately. It is the probability distribution estimate of a continuous variable (quantitative variable). For constructing

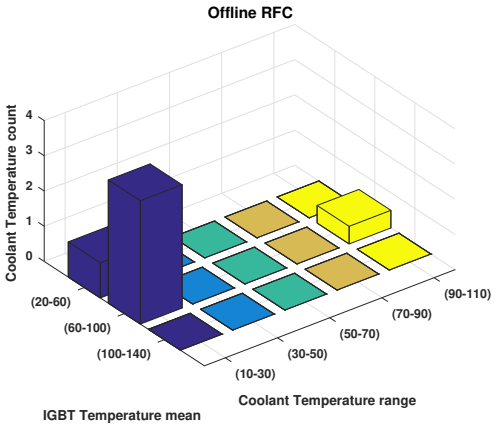

Fig. 5. Offline rainflow counting(3D map).

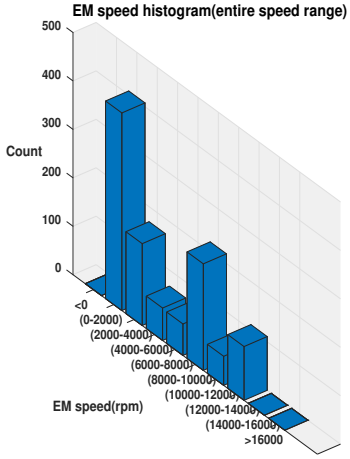

Fig. 7. EM speed histogram for entire speed range(1D).

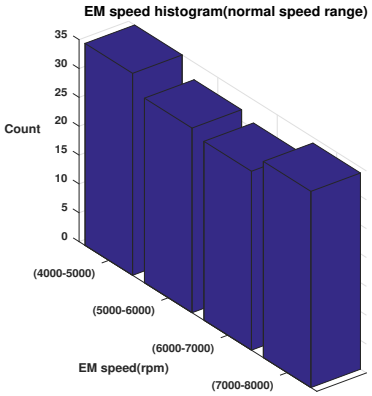

Fig. 8. EM speed histogram for entire speed range(1D).

histograms, the initial step is to make bins of input parameter's value ranges. This means, dividing full operating range of values to series of intervals and then counting how many values is lying in each interval. The bins should be consecutive and non - overlapping. Considering the electric motor speed histogram, the speed may be divided into ten sections as depicted in fig. 6, each section may require a four byte for the count. Thus a total of 40 bytes will be required for the entire histogram in the memory. For the normal driving speeds(40Kmph-160Kmph), the EM speed will be a factor (gear ratio) times the driving speed. This lies between a specific rpm range say, 4000rpm-8000rpm. Histogram for entire EM speed range will be having more sections than this one. Thereby the memory requirement is minimized and also the granularity of the map is now increased as depicted in fig. 6. Only four sections are present in this map. So for each sections of 4 bytes, a total of 16 bytes will only be required, saving 24 bytes of memory. Simulation results for electric motor speed inputs for three minutes are given in fig. 7 and fig. 8.

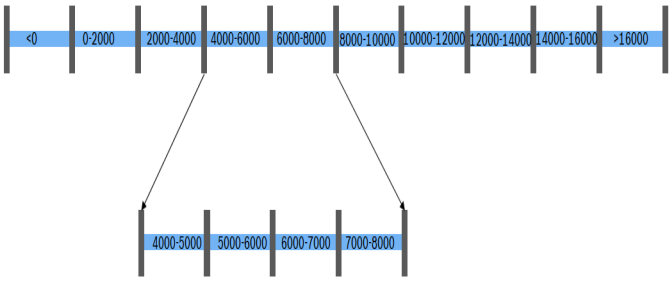

Fig. 6. EM speed histogram sectors for entire speed & normal speed ranges(rpm).

C. Level crossing counting

In level crossing counting, counts are registered when the input data exceeds preset levels. This method can be adopted where we are interested only in threshold crossings of a parameter, which may can have serious effect on the system under consideration. For example, Consider the scenario of a vehicle moving down hill, the electric motor's speed may increase beyond its rated limit which can have adverse effect on the machine. So recording such threshold crossings are of much significance. For such an application the level crossing counting can be used instead of recording a complete histogram. Simulation results of electric motor speed crossing of the rated limit, 16,000rpm for speed inputs for three minutes given in fig. 6 shows that it may require only a byte or two for storing the level crossing counts. Thus the memory requirement can be minimized by a considerable amount than in the case of storing the entire motor speed histogram which may be requring number of sections, having a larger memory requirement say, 4 bytes each.

IV. Conclusion

Different memory optimizing methods were identified for acquiring electric drive parameters. An online rainflow algorithm which minimizes the RAM memory requirement by

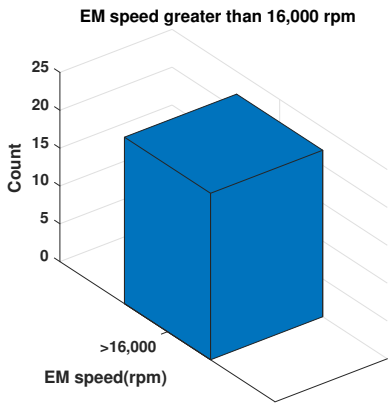

Fig. 9. Offline rainflow counting(3D map).

avoiding the requirement of load history storage can be used in storing parameters like IGBT temperature, diode temperature, coolant temperature etc. Instead of histograms for entire operating ranges , storing only map for normal operating ranges for parameters like electric motor speed memory requirement can be considerably minimized. Level crossing counting can be adopted where only threshold crossings of the acquired parameters are of interest, saving memeory space.

Data acquisition is very much relevant not only in automotive field but also in all areas where a stress cycle analysis is required, as in life time estimation of wind turbine parts, fatigue analysis of mettalic parts of different machines etc. In hybrid electric vehicles the data acquisition functionality will be handled by a particular electronic control unit (ECU) which will be handling other real time electic drive functionalities say, controlling the gate circuit of the electric motors inverter. For such other important real time functions to be performed un - disturbed and efficiently, sufficient memory should be free. So for a functionality like data acquisition, which take up large RAM and EEPROM space, the data acquiring algorithm should be carefully selected. Algorithms should be selected such that the acquired data should maintain maximum possible granularity and consuming minimum memory possible. So techniques with optimum memory usage in data acquisition is of great future scope.

[3]Professor, Department of Computer Science and Engineering
Adi Shankara Institute of Engineering and Technology

Abstract: **- The primary objectives of the project are "Node Congestion Management" and "Policy Settings". The secondary objective is to assess the congestion nodes and construct a graph based output so as to analyze the trends in traffic flow of Ernakulam district during 2 peak hours that is first peak hour from 7.00 am to 8.30 am and second from 4.00 pm to 6.30 pm. The traffic management and public works department under state government of Kerala can get various insights related to congestion nodes. One important intelligence that this project provides is the change in congestion rate of various congestion points with respect to a single road infrastructure project. Even a road-hump or a speed breaker would affect the congestion rate at various congestion points far away. This automated analysis based on machine learning would save public funds by preventing unnecessary allocation of funds. Also this system justifies allocation of funds for various useful projects. The traffic monitoring helps in long term decision making especially while formulating transport policies and budgets. It also guides the law enforcement agencies to properly understand the variations of such traffic and properly take precautionary measures like installation of security cameras and other control measures.**

Keyword: Smart city, smart transportation, IoT sensors, Big Data processing, Traffic congestion;

I INTRODUCTION

One of the desired outcomes while designing a Smart City [4], [13] [14], [15], [16], [19], [20] is to develop cities that provide necessary infrastructure and quality of life to citizens. It also promotes a clean and sustainable environment and application of 'smart' solutions. But the Smart Cities Mission announced by government of India still has its own challenges to face. Some of the difficulties are discussed below.

Smart Traffic management [9], [22] is very important for the success of smart city concept. With the low cost vehicle sensors and smart traffic management systems real-time monitoring and alert systems can be deployed to provide travelers better service. With the proper integration of IoT services, real-time Big Data analysis of traffic details and mobile applications for alerts, city planners can provide the citizens with effortless traffic service in the near future.

Internet of Things (IoT) has gained significant traction, leading to development of various types of sensors that are connected to the broad internet with the help of wired or increasingly wireless technologies. In the recent past, IoT devices have become extremely cheap even from developing world standards. This has enabled widespread deployment capabilities. The high levels of deployment have enabled collection of large amounts of data with the help of sensors connected to the internet. This data can be leveraged using latest data analytical techniques to extract useful information. Big Data from heterogeneous sources with high-volume with distributed and decentralized control, seeks to explore complex relationship among data. The infrastructure involving the combination of big data, cloud computing and internet of things (IoT) is utilized in the proposed paper. Currently there is increasing focus on using combination of these technologies to improve quality of life of common man [17], [23].

It has been recognized that urban cities are the focus for expansion and are drawing a million people every minute from rural areas. Based on expert opinion, [4] global urban population would double by 2050 as more and more people are moving towards cities at a steady pace every single day. It means adding an equivalent 7 New Delhi cities every single year.

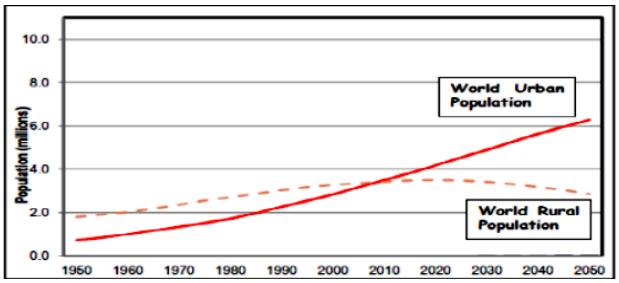

Fig.1 Urbanization trend (Source: [13])

Compared to China which has over 160 cities each with population above one million, India possess only 40 such cities. To meet these challenges drastic increase in the number of cities should be proposed. To support the development of newer cities challenges of urban transportation and mobility needs to be addressed immediately. A comprehensive and support policy framework for urban transportation needs to be developed for establishing new smart cities with sustainable urban spaces. Based on the report from the High Power Expert Committee on Investment Estimates in Urban Infrastructure [39], around Rs 44 thousand crores is the predicted cost to be earn-marked by the government for a period of twenty years. In the following sessions we propose an intelligent transportation system for arrival time prediction. Section II

analyses various existing systems related to vehicular traffic management. The limitations of the existing systems and the important current players in the area of smart transportation are discussed in section III. Section IV deals with the problem faced and motivations for the proposed system. The proposed architecture working is evaluated in Section V and the corresponding cluster analysis of congestion nodes in Section VI.

II RELATED WORKS

In today's world, In order to continued business success and growth automation and data are essential. Vehicle counters [2], [9] solve the issue of collecting both vehicle information and vehicle counting. Most companies and organizations have a general idea of the traffic in and out of their facilities, but they facing a big issue for make strategic decisions according the huge number. Sales and activity which help us to get a huge idea about what has happened throughout the day, week or month, but if we want to know about the traffic with the vehicle counters and analytics software, you must want to capture some knowledge on pattern, trends and opportunities.

Manual counts

One of the simplest methods is manual counting [10] of pedestrians and vehicles. It is a simple and accurate method of traffic counting, which comprises people manually counting vehicles. In this method the people who stand at the side of the road takes count using an electronic hand held counter or record data using tally sheet. Also most of them watch the recorded video and take the counting from that. A small sample data is collected over less than a day. For getting data over a season or year it is extrapolated. It provides 99% accuracy.

Video Vehicle Detection

Manual intensive is a major drawback of manual count method. There are number of systems which are used to analyze the video and detecting cars with a similar accuracy to that of people watching the video. This process automates the counting of vehicles. This method is not only cost effective, but it can also count vehicles in any direction. One of the advantages of this process is that it requires only one camera for several lanes.

Video is analyzed locally to get the count of vehicles and the count can be uploaded online. So, the bandwidth is minimized. The historical data is typically available online. It can be done throughout the year and hence we can get a precise count.

Pneumatic Road tube counting

Pneumatic road tube counting is a popular method used for vehicle sensing for many years. More than one rubber tubes are stretched across the road. One end of the rubber tube is connected to a data logger and other end is sealed. The air pressure in the tube is squashed when the vehicle hits the tube. The data logger records the time of the event.

Direction can be determined by identifying the first tube that was hit. It two vehicles hit simultaneously then the direction cannot be determined accurately. This is the drawback of this method.

Piezoelectric Sensor

Piezoelectric Sensor converts mechanical energy to electrical energy. This concept is used to collect information about the traffic. A groove is cut on the surface of the road and piezoelectric sensor [2] is mounted. The sensor is squeezed when a car drives above it. This mechanical pressure is converted to electrical voltage. The change in voltage levels can be detected and count can be recorded. The counting can be performed in this way. These sensors can be connected to a device which uploads the count to a database locally or to a cloud.

Inductive Loop

Inductive loop will detect moving magnet or alternating current. The principle is that an electric current is induced when a magnetic field is detected near an electric conductor. Vehicle acts as a magnetic field. The inductive loop placed on roads acts as conductor. When current is generated in the inductive loop, the count of the vehicle can be recorded.

Magnetic Sensor

Magnetic sensor detects the change in earth's magnetic field. The vehicle acts as a magnetic field and when it passes over the sensor there is change in magnetic field. This change is detected and vehicle count is updated. The sensor may be inserted on the road or kept on the roadside. The only drawback is that the vehicle close by each other cannot be detected clearly.

Acoustic detector

As the vehicle passes, a sound is created and the acoustic detector detects this sound and counts the vehicle. Acoustic detector is placed in such a way on the roadside poles so that they point towards the traffic. The benefit is that it can be used for different lanes. These detectors can communicate their counts wirelessly.

Passive Infrared

Passive Infrared Sensor detects the radiation, radiating from an object that comes in its view. Vehicle can be detected using this sensor. There is change in the radiation when a vehicle passes by and hence the count is increased. The limitation is that only one or two lanes can be detected.

Doppler and Radar Microwave Sensors

Doppler and Radar Microwave Sensor will transmit low-energy microwave signal. There is change in frequency, if there is vehicle in motion in its detection area. Hence moving vehicles can be detected.

Radar is capable of determining the position by detecting distant objects and speed of movement. The time delay of the return signal will be used to calculate the distance to the vehicle.

In the arrival time prediction system, Big Data analysis plays crucial role in producing real-time data. Some of the research works carried out in the segment of smart transportation is as follow. Big data for social transportation [28] is one of the major contributors for smart transportation

solutions. A study conducted by University of California [18] for traffic monitoring shows that a 2-3% penetration of GPS enabled mobile phones is enough for finding the speed of vehicular traffic. Other studies on GPS data were conducted by taxi calling service providers (UBER, Didi Taxi etc) while developing their software. The modeling employed for visualizing human mobility details is based on Origin destination (OD) matrix. Researchers can make use of existing traffic allocation patterns with OD matrix developed to reach out useful conclusions. Another source of datasets used for creating OD matrix is mobile phone data [12].

In China, to make sure maximum travelers reach the mega event- Shanghai World Expo 2010, a traffic prediction system based on mobile phone data was developed to broadcast to travelers the real-time traffic congestion information so that they can plan their trips accordingly. Crowdsourcing and data from public domains of social media websites are also good source for social transportation scheme.

In another related research which focused on improving the accuracy of arrival time prediction of buses [26], bus scheduling dataset, time point dataset, real-time transit feeds and crowd sourced data feeds were utilized. The proposed system employed clustering analysis and kalman filtering techniques for developing the prediction model. The arrival time prediction can be reduced by 25% if predicted an hour before and by 47% if predicted before 15 minutes.This is one of few research works where shared route segment is taken into account while calculating the arrival delay.

Graph-oriented smart ITS solutions [25] finds popularity among researcher in the field of smart city solutions. The system employed Giraph and Spark tool above Hadoop architecture to generate and process graphs. The traffic dataset is modeled on a directed and weighted road graph with three types of weights- distance between two vertexes (intersections), average speed of all vehicles from one intersection to another intersection and number of vehicles going from one intersection to another intersection. Decisions are made by parallel processing of sub-graphs. By analyzing the real-time traffic conditions the quickest road is found out by the proposed system.

A framework [24] for Smart Transportation using Big Data is proposed. The framework consists of 4 layers: Input layer, storage layer, analysis layer and communication layer. Input layer deals with all kinds of data read from sensors like RFID, GPS etc. The data in Storage layer is collected from heterogeneous sources. Data will be fetched from storage layer to analysis layer for analysis using different tools. Big Data technology can be used in smart transportation systems. Another study was conducted on smart transportation using Bluetooth devices in bus rapid system, Colombia [23]. The analytics was focused on the planning of bus rapid transit systems by using OD matrix using Bluetooth signals presents in the BRT systems. It is used by the administrative authorities for planning of BRT systems and utilized the NoSQL approach for storing the database in cloud. The system offers web based and mobile app based interaction with the clients. It also offers a reduced cost, high scalable, reliable and fast deployment platform for collecting reliable data for processing.

III CURRENT PLAYERS

- **CISCO**: report pointed out that the devices connected to Internet exceeds number of people on earth and it will reach 50 billion in 2020.
- **Redhat**: Fleet telematics solution (Italy), Smart toll collection system (EU roadway system).
- **Sensys Networks** developed a magnetic sensor based system and micro radar sensor systems for use in traffic intersections.
- **MIT and University of Sri Lanka**: Wireless sensors used to monitor the state of road surfaces.
- **Moovit app**: provides more accurate and live information regarding timing and routes. Other Apps: Offi, Bosch City App.
    - **Japan's broadband access**provides the facility of communication between people, people and devices, and devices to devices.
    - **South Korea's smart home** enables their people to access things remotely.
    - **FASTag (ICICI, AXIS bank and NHAI):** Itis part of **National Electronic Toll Collection** (NETC) enables automatic deduction of toll charges and hassle free trip on national highways.
    - **Delhi Integrated Multi-Modal Transit System Ltd:** Wireless Traffic Signal Controller (Wi-TraC) and Red Light-Stop Line Violation & Detection System.
    - **Some examples of Vehicular counting tools:**
    - The **COUNT cam** will record 360 hours of video without charging. It counts car, bikes, and pedestrians (Starting price $1000).
    - **Video Turnstile** people and vehicle traffic counting system: Using this system we can count vehicles moving in different directions.
- **PureTech's** Video-Based Vehicle Counting.

At present, traffic information is commonly shared between different traffic agencies by means of voice or data communications. For such data communication between management centers, a common language and a frame of reference is required. There are many possible ways to analyze traffic data like manually counting each vehicle or through image processing, video analytics and so on. Manual counting involves a team to count each vehicle travelling on the road and update the statistics and a separate team is required to analyze these results of statistics.

Limitations of the Existing System

- Requires very huge man power.
- Time consuming and cumbersome.
- Create unmanageable traffic jams.
- If there is no traffic, the team personnel still need to wait at junctions.

- Lack of traffic details to users: Present traffic systems fail to provide traffic information including busy/idle time and number of accidents happening.
- The expense involved in maintaining the field components used is also high.
- Setting up the framework initially is also difficult.

IV MOTIVATION

There are so many hurdles going to be faced to make the public transportation smarter. Presently there is lack of public domain data related to transportation in India. Researchers often finds hard to get human mobility details to perform data analytics. Few short comings in smart transportation in India are:

1.) No real-time arrival time predictor: Smart management of the traffic system with the provision of real-time information to the citizen based on the current traffic situation has a major impact on the citizen life.

2.) No major Intelligent Transportation System [ITS] in Kerala and other Tier-1 and tier-2 cities in India: The big data generated by the vehicular network and traffic system should be utilized to analyze different aspects of smart transportation to obtain smart city.

3.) Relationship between various congestion nodes needs to be analyzed before planning an infrastructure or after it's been installed. Consider a route segment which consists of n congestion nodes. Many research works been conducted for evaluating factors affecting congestion nodes. But due to lack of study on how different congestion nodes are related, either regression based or correlation, deteriorates the scope of enhancement of ITS.

4.) Difficulty in making algorithm for smart phone based application.

5.) Lack of research about last mile connectivity issues.

V PROPOSED ARCHITECTURE:

The proposed system uses big data analytics tools like Hadoop version 3 for studying stored historical data and Apache Spark for real-time data analytics. Apache spark and Apache Hadoop offers flexibility of using various programming languages like Java, Python and Scala etc. The proposed system emphasizes the importance of Big-data processing using Hadoop in IoT based applications. The combination of big data, cloud computing and internet of things (IoT) is utilized in the proposed design. Currently there is increasing focus on using combination of these technologies to improve quality of life of common man. Availability of cheap IoT devices has enabled collection of large amounts of data with the help of sensors connected to the internet. This data can be leveraged using latest data analytical techniques to extract useful information. Big data with large-volume, heterogeneous, autonomous sources with distributed and decentralized control, seeks to explore complex and evolving relationship among data. We initially propose to collect our data using RFID mechanism and GPS. With the substantial growth of location data, data analytics plays a significant role in analysing the data and in solving emerging problems in traffic management. We are planning to implement RFID and GPS modules in our college bus fleet and store the data using IoT module. The digital location data obtained from IoT module or GPRS module can be collected in real-time using a publicly accessible server. For this we need to put a server OS instance in listening mode linked with a public IP. The collected data can be used for performing various machine learning techniques. The storage data structure preferred is either multi-dimensional matrix or graphical representation.

The proposed system evaluated various congestion nodes in 4 bus routes (Table-1). The congestion nodes are then evaluated for 2 month period from March 1st 2019 to April 30th 2019. The proposed system helps in proper scheduling of buses. The graphical analysis helps to take decisions for deciding whether or not speed breakers or road bumpers are required by correlating the accident information with the day to day traffic analysis. The processed and analysed data shows interesting patterns of traffic. During Haj season, the traffic towards airport has spiked but other lane traffic remains almost constant. During Sabarimala season, the traffic towards Kottayam district and Thodupuzha district increased exponentially. The data collected helped local traffic officers better understand the traffic during day time and during various months. The proposed system gives directed design plans for laying funds in future infrastructure projects. The government agencies like public works department can get the fund allocated with authentic data without delays. The policy makers make use of such automated data collection system to get better idea about developing predictable models. The system can be effective if it can be integrated with cloud platform like Ubidot. Ubidot or other cloud platforms act as one of the future extension to the predictive automated counting system. Such integration gives better analytical decision making data in time for policy makers.

The data obtained from Ubidot is collected and analysed for getting a better idea about the daily as well as day to day traffic details. The sensor data collected are processed using Hadoop system to get further analytical information regarding future traffic prediction. R programming can also be employed for getting more futuristic analytical information regarding future traffic patterns.

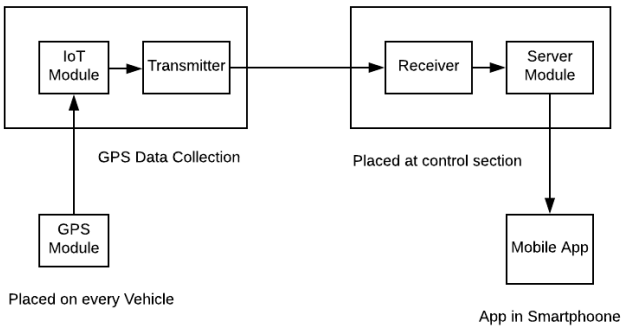

Fig.2 Proposed Smart Transportation System Architecture

Basically the proposed system consists of four modules:

- GPS module
- IoT module for GPS data collection.
- Server module for receiving data.
- Mobile App Development module

- The system will consist of a GPS module installed on every vehicle and receiver module installed on every control section.
- The data generated for a period of time is collected and analysed to discover the usual congested routes.
- Transmitter module transmits this information to control section. Control section along with software section processes the data.
- It assesses the congestion nodes and constructs a graph based output so as to analyse the trends in traffic flow.
- The useful information is made available to the end user through a mobile application.

VI. RESULTS:

The real-time datasets are provided by VTS (Vehicular Tracking System) systems implemented at Adi Shankara Institute of Engineering and Technology. We have evaluated four bus routes for our study covered by bus numbers: 10, 11, 12 and 13. The details of the route are shown in the table-1. The test dataset for neural network analysis is collected from the month of February and the training dataset is fetched from the month of March. Figures 3, 4, 5 and 6 reveals the congestion points (Heat maps) during peek traffic hours from 7:30 AM to 8:30 AM and from 4:00 PM to 6:30 PM. Red region represents heavy traffic, yellow regions represents moderate traffic and green regions represent normal traffic. The figures identified heavy congestion points at “Mattoor junction”, “Aluva bridge”, “Maradu junction”, “Kochi”, “Vytilla junction” and “Fort Kochi”. Our study identified moderate congestion points are “Aluva Metro Station” and “Kochi International Airport road”. We also extended our study using 4 bus routes as shown in figure-9.

The system we modelled using the VTS datasets can be automated bye connecting the VTS database with machine learning front-end application. The front-end can be easily programmed using Python machine learning libraries which gives real-time graphical output related to various congestion nodes and clusters so that decision makers in government level can make use of these evaluated results when making fund allocation as well as resource allocation. The proposed system when evaluated over a period of months starts producing real-time outputs in the google map showcasing whether signal light timings placed in one location needs to be decreased or not.

Table.1 Bus routes taken for neural network analysis

Bus no.	Route
10	Old NH47,Kumbalam north, Thoppumpadi to ASIET
11	Bypass road, Irinjalakuda, Thrissur to ASIET
12	Mulanthuruthy, Ernakulam to ASIET

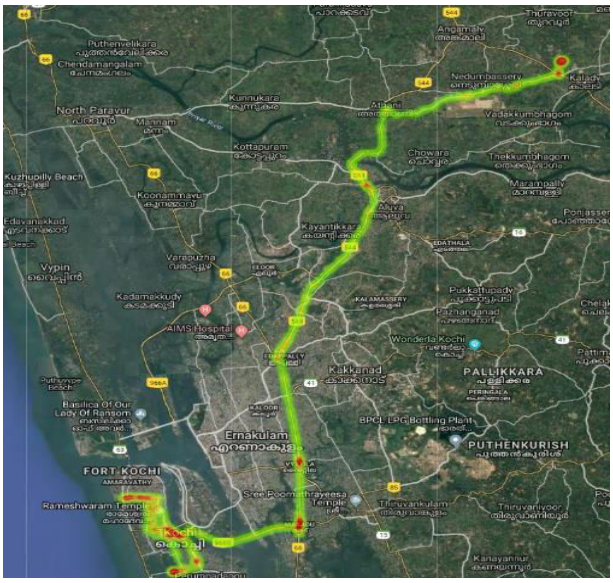

Fig.7 Ernakulam bus route congestion analysis

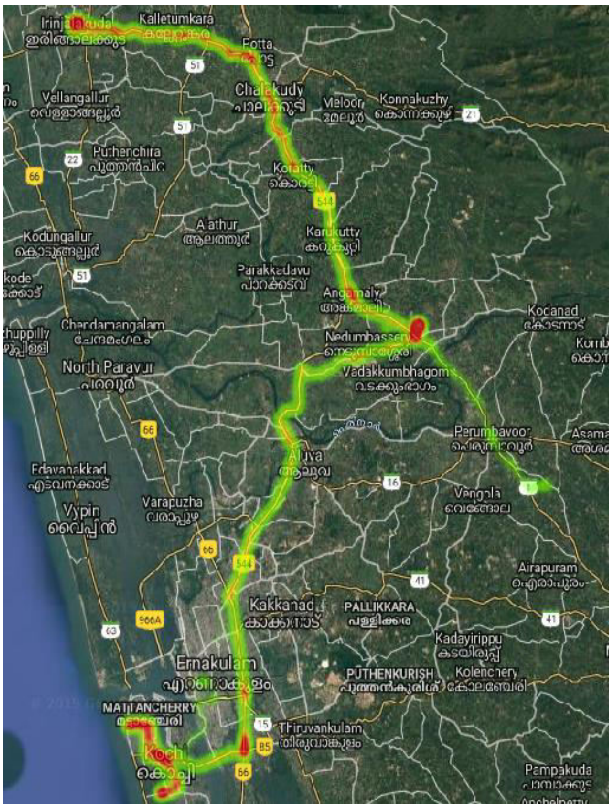

Fig.9 4 bus routes congestion analysis

VII. CONCLUSION

The proposed Machine learning based congestion prediction algorithm that used Logistic Regression gives a simple, accurate and early prediction of the traffic congestion for a given static road network which can be considered as a graph. The complexity of the algorithm mentioned above would be constant. So, this is can be effectively used by any devices which has a less computation capability and with less resources. As a future direction the traffic congestion prediction can be predicted using various Hybrid techniques which can give high accurate results.

Acknowledgement: We thank Management, Principal and Head of the Department-CSE & IT of Adi Shankara Institute of Engineering and Technology for giving permission to access database of college's vehicle monitoring system. We would like to extend our sincere thanks to all staff coordinators of Data Analytics Research Lab, ASIET, for providing all computing resources and for their whole-hearted efforts put in for the completion of our work.

Abstract: **In this paper a unique approach towards decision making process and better quality care through Machine Learning (ML) concepts as an alternative mode by identifying the characteristics and patient satisfaction (PS) in health care system is proposed. Extracting the information from raw data using some algorithmic approach is known as Data mining. In this a ML approach is used in determining the patient satisfaction in health care sector. Applied regression models to determine the patient satisfaction and also correlation methods is identified as an important attribute to be considered in determining the better quality in health care sets. The data set is taken based on the opinion on three types of data such as a) patient opinion towards hospital care b) nurse opinion towards workplace and c) Administrative aspects of healthcare. Our findings revealed high accuracy in Regression (88%), that helps in concluding by considering the administrative and workplace attributes related to patient satisfaction. The results are validated using traditional statistical methods like binomial correlation and linear regression.**

Keywords: Patient Satisfaction (PS), Machine learning(ML), Healthcare, Regression, correlation

1. INTRODUCTION

The recent trend in service sector evaluation is to consider end user satisfaction as one of the key constraint, as it is associated with satisfaction level in performance of business. In case of healthcare sector patient satisfaction plays a key role in evaluating the quality of service they provide. So far there is no clear picture on pre-defined data sets that has to be considered in evaluating the patient satisfaction, however each healthcare sector follows their own metric in evaluating this. Patient satisfaction is considered to be one of the key metric in evaluating quality of healthcare services and their decision making process, In turn this helps them to improvise their services in health care based on their marketing strategy and eventually targeting the patient satisfaction [1].

Pati

Patient satisfaction is considered to be one of the excellence that is linked with excellence of health care [2], as it is considered that mollified patient will have faith in the recommended cure that improves their life amongst others. The opinion from the patient helps the health care sector administration to measure and relate various departments, in progressing their existing services that they offer. The opinion also helps the doctors to treat the patients in a better way [3].

In various works different metrics are considered that predicts patient satisfaction in an incorrect mode as it is not directly related with quality of healthcare. The metrics that are considered in evaluation are communication with physician and nurses, waiting time, [4] timely services, access to the services [5]. Patient nurse ratio, working nature of attenders all related with the good quality of healthcare services that is associated with patient satisfaction. Maximum research works studies patient satisfaction using traditional statistical methods [5, 6]. Where there is limited data mining techniques are used in discovering healthcare services relating with patient's view. To understand patient healthcare choice it is better to compare the old methods with new data mining concepts. [7]

Data mining concepts is used to extract the needed information from big data that helps in decision making process both at organizational and medical fields. The main task in using this data mining technique is its type and diversity nature of the data along with omitted data. As many data is not available in the format needed for processing, it has

to be preprocessed to make it in a usable form (electronic form).

But this problem is reducing in recent days as many of the health care sector became digitalized with their data in both medical and organizational levels. In this paper we access three data sets like patient view towards health care, nurse view towards workplace and Managerial aspects of healthcare. Data mining techniques are applied to extract the information about patient satisfaction in different ways. We try to implement machine learning techniques as an alternative method in extracting managerial and operative features which affect the views of patients. The resulted information can be considered for decision making and deriving hypothesis [8, 9]. In healthcare sector it provides support in decision making for both administrative and clinical cure to improve the service that they offer. [10]

2. PATIENT SATISFACTION AND DECISION MAKING

This section is going to discover the factors related to patient satisfaction and the analysis of their results to administrative tactics for a health care services.

2.1 Patient Satisfaction:

When we think about patient care in health care sector, data plays a major role in analyzing personal experience factors that relates with patient satisfaction. Hush et al [11] mentioned in his work that the researchers used least squares regression models to evaluate the correlation between various parameters, like issues related to various facilities available and the way they communicate in obtaining patient satisfaction among different patients who had taken care during the past five years. Patient satisfaction is measured to be decidedly correlated to personal experiences as well as hopes. Further studies show that the relations of the therapist with the patient as well as his/her complete experience correspondingly contributing factor that is considered to be significant than the real consequence of the treatment [11].

2.2 Organization and Consumer Satisfaction healthcare sector is considered as a service oriented and the patients as consumer the organization tactics is tested to yield the satisfaction. By assuming this model, various administrations are inspiring the customers that it is based on the choice satisfaction. [12]. Many research has conveyed the message that more personalized communication between the consumer and the administration leads to more satisfying experience.

Additionally there is a demand from consumer related to the services offered has increased research area. Satisfaction plays a vital role in health care sector in determining their objectives related to both administrative and clinical aspects. The data obtained is used to decide and update the changes required in quality of service.

3. PROPOSED METHOD0LOGY

To obtain patient satisfaction from the given data sets we applied the known machine learning techniques. It is used to analyze huge data sets and their relationship between the data in turn it provides the meaningful information [13]. In this study we use Machine learning concepts which is dived into two categories as supervised and unsupervised learning. In supervised learning includes classification, regression prediction and time series analysis that helps in forming models that is used to classify new and unknown information. In unsupervised learning we use clusters in determining the different patterns and similarity between the data [14]. For our studies we used Regression concepts for analyzing the data the results are validated by linear regression and binomial correlation using traditional statistical method.

3.1 Regression:

Regression is a task used to predict the number such as Age, height, Income distance etc., It predicts the data where the target data is unrevealed. It is done by the statistical team by measuring the difference between the predicted and expected values. [15]

Most widely used statistical technique that estimates the relationship between the variables is Regression. This model provides easy structure for describing and testing the hypothesis between the explanatory variable and a response variable

Normally, a regression analysis is applied for (1) modeling the relationship between variables. (2) Predicting the target variable (forecasting). (3) Testing the hypotheses. Linear model is the very basic in regression analysis. It can be obtained by having n sets of observations {X1i, X2i, ..., Xpi, Yi}, i = 1, ..., n, that represents random sample from large dataset. It is expected that these observations satisfy a linear relationship

$Yi = \beta 0 + \beta 1X1i + \beta 2X2i + ...\beta pXpi + \varrho i$, $i = 1, \ldots, n$ where the β coefficients of unknown parameters, and the ϱi are random error terms.

3.2 Prediction is a method used in predicting the outcome based on available data by incorporating with unavailable data sets of future

4. RESULT ANALYSIS

The main objective of this study is to examine the parameters of patient satisfaction and to study the above objective, response from 80 respondents that collected through online source.

The opinion attitude towards Patient satisfaction consists of 5 determinants. These constructs are determined using Likert scale of 1 to 5 where 1 denotes strongly disagree and 5 denotes strongly agree. The descriptive statistics of predictive statistics are depicted from the table 1 and table 2.It is denoted by chart in Figure1 and figure 2.

The parameters of patient satisfactions (PS) are

1. PS1- Patient level of education
2. PS2- Patient care from nurses
3. PS3- Patient care from doctors
4. PS4- Patient opinion on hospital environment
5. PS5- Patient opinion during discharge.

Descriptive Statistics	PS1	PS2	PS3	PS4.	PS5
Mean	3.8250	3.9750	3.5125	3.7875	4.0250
Median	4.0000	4.0000	4.0000	4.0000	4.0000
Mode	4.0000	4.0000	4.0000	4.0000	4.0000
Std. Deviation	0.7424	0.7951	1.1691	1.0150	0.8855

Table 1. Descriptive Statistics of Patient Satisfaction

Predictor	Beta	Sig
PS1	0.093	0.00
PS2	0.193	0.00
PS3	0.245	0.00
PS4	.097	0.00
PS5	.490	0.00

Table 2. Predictive Statistics of Patient Satisfaction

Figure 1. Descriptive Statistics of Patient Satisfaction

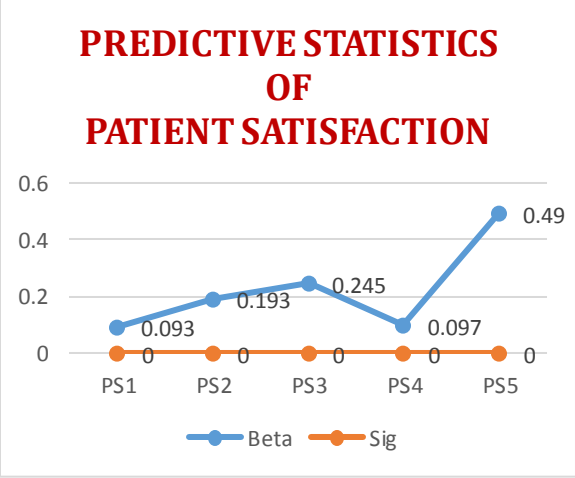

Figure 2 Predictive Statistics of Patient Satisfaction

From the correlation matrix it is evident that patient satisfaction is positively correlated with patient care from nurses, patient care from doctors and patient opinion during discharge. The correlation is significant from the above table. Linear regression is applied with dependent variable patient satisfaction and patient level of education, patient care from nurses, patient care from doctors, and patient opinion on hospital environment and patient opinion during discharge as predictor variable.

PARAMETERS	Pearson Correlation	Sig. (2-tailed)
Patient Satisfaction	1	0
PS1	0.093	0.411
PS2	0.193	0.086
PS3	0.245*	0.028
PS4	0.097	0.392
PS5	0.490**	0.000

Table 3. Prediction of Output Variable

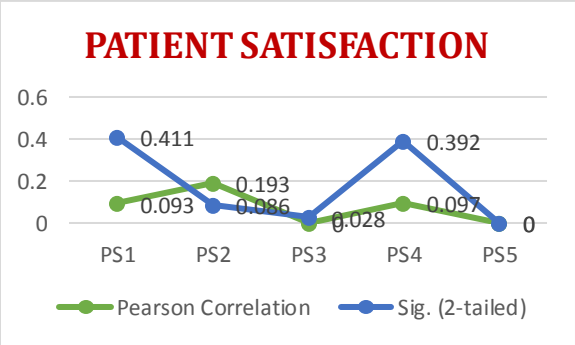

Figure 3. Prediction of Output Variable

From the Table 3 and Figure 3 it is evident that the r egression model statistically predicts the outcome var iable that is Patient satisfaction as p value is less than 0.05.Therefore we can conclude that the relationship between Patient satisfaction and different predictor v ariables is significant. Therefore we can conclude tha t there is linear relationship between patient satisfacti on and five predictor variables

5. CONCLUSION:

In this paper we discussed various parameters that is related to patient satisfaction in a hospital environment, from the perception of a consumer service model. In this we used the data available from various consumers to provide a valid view point to the organization in setting the services related to patient satisfaction. Here regression technique is used to derive the correlation factor using correlation the results are predicted with predicted variable by obtaining the significant result. It is thus concluded that the linear relationship is obtained between patient satisfactions correlating with predicted variable. In this we try to give a model that will help in decision making process of the organization focusing on the parameters specified in turn which builds a safe and support healthcare environment

***Abstract*— Wireless Sensor Networks(WSN) are characterized by highly application specific nature, stringent resource constraints, self-organizing, spatio-temporal traffic, and large dynamic topology with several contradicting design goals. Of these design goals, network life time and energy efficiency are considered as of paramount importance. Many existing research works have stressed on developing techniques to extend the network life time and achieve energy efficiency of WSN. Some of these techniques include the application of Tree as a data structure. The authors of this paper has made an attempt to present a critical study of research works which have applied different variants of Trees for extending network life time and energy efficiency. Also, the paper mainly tries to present the theoritical discussion on performance implications of application of variants of trees, advantages, and disadvantages alogn with the causes.. The paper further tries to articulate the possible feasibility of the application of Red Black Trees (RBL) in WSN and explain the major constriants in WSN which may bring issues in applying the concepts of RBLs in their original form.**

***Keywords*— Wireless Sensor Network (WSN), Tree Based Approaches, Red Black Tree, Network Life Time, Energy Efficiency**

I. INTRODUCTION

Wireless Senor network(WSN) is composed of thousands of sensor nodes spread across large geography, possibly, for monitoing phenomenon of the interest. Applications of WSN range from home automation to industrial and very specific uses like defence applications etc. However, WSN are characterized by serveral unique features like contradicting design goals, stringent resource constraints, and highly application specific nature. Due to these wide varying applications WSN are evolving as a new paradigm for information processing [1][2].

The contradicting constraints on resources lead to two very important design goals: improving network life time and energy efficiency.

The large number of sensor nodes and associated unique features & constraints make these wireless sensor networks to be unable to adapt to any kind of global addressing mechanisms and/or comon solutions [1].

In this regard, a novel architecture & design of WSN, its protocol stack, layer wise open issues have been discussed in detail, along with description of some of the existing WSN specific protocols as solutions to some of the open issues, in [1]. The need for self-organization and some solutions for the same have been presented elaborately in [3].

Thus, with the above general background about WSN, the motivation of this paper is to attempt to present a detailed survey of the various existing works which proposed application of Tree as a data structures and Chain concept from discrete mathematics for achieving energy efficiency and extended the network life time. For details on Chains one can refer to [53] or [54].

Further, the organisation of this paper is as follows: section II presents the detailed literature survey of research

works, the theoritical discussion on the implications of application of tree data structures is presented in section III, section IV presents discussion on feasibility & limitations in case of applying Red Black Trees in WSN, and the paper will be concluded in section V mentioning the scope for future research using red black trees.

II. Literature Survey

Wendi et al have proposed a work involving clustering for energy efficient communication resulting in severn times efficiency in energy [4]. Huang et al proposed an energy efficient routing scheme for WSN based on clustering with the use of minimum spanning trees degree constrained(CMST-DC)[6].

Z. Han et al proposed an efficient routing by constructing routing tree (GSTEB)[5]. Weighted Spanning Tree variant of LEACH (WST-LEACH) was proposed in [7] . Geographic and Energy Aware Routing (GEAR) algorithm, claimed to perform noticebaly better than any non-energy aware routing algorithms[8].

B. Krishnamachari et al[9] have discussed in detail about the infulence of source-destination placement, communication network density, and the energy costs on each other.

A. Boulis [12] proposed distributed estimation algorithm to explore energy-accuracy subspace for subclass of periodical data collection problems.

Y. Yu et al [13] explores energy-latency trade off to a great deal.

H. O. Tan and I. Korpeoglu[14] proposed a new work consisting of two new algorithms, with power efficiency as their major design goals, called as “Power Efficient Data gathering and Aggregation Protocol(PEDAP)”.

A near-optimal chain-based protocol with energy efficeint as its primary design goal, called Power-Efficient GAthering in Sensor Information Systems (PEGASIS), was proposed by [15]. Joanna Kulik et al [16] proposed Sensor Protocols for Information via Negotiation(SPIN) family of protocols , claiming 75% energy efficiency but incurr lot meta-data usage. T. He et al [17] proposed a research work by using feedback between sensor nodes.

Nahdia Tabassum et al[18] proposed a work which is energy aware version of periodical data collection. Further the same authors present two more improved works in [19] [20] which are based on ‘chain’ concept and claim to achieve 15-30% extended network life time and 90-95% energy efficiency K. Du et al [21] also present a similar chain-based improved algorithm for data gathering, called 'Chain Oriented SEnsor Network' (COSEN).

Heuristics based aggregation tree construction for data gathering had been discussed in detail in [22].

K. Kalpakis et al [23] attempted to propose a novel solution for extending life time of network for data gathering purposes. Another work intending to extend the life time of network for data aggregation is presented by B. Hong and V.K. Prasanna [24].

N. Sadagopan et al [25] focused on maximizing the data collected than so far considered parameters. However, F. Ordonez et al [26] presented a more interesting work concerning the same maximization of data collection but amidst of energy constraints while providing flexibility to choose trade off depending upon the design requirements.

Another research work intending to extend the life time of the network for data aggregation was presented by Y. Xue et al [27].

Kyung tae kim et al [28] proposed an idea of construction of trees for the purpose of data collection, which was termed by authors as Tree-Based Clustering (TBC). Further, authors claim that the proposed work outperforms when compared to PEGASIS and LEACH.

P. Parthasarathy and R.Karthickeyan [29] presented a research work to improve the life time of the network for data aggregation purposes.

Mohammad Abdus Salam and Tanjima Ferdous [30] present a detailed survey of Tree-based data aggregation works for WSN in detail. Dreef et al [31] focused on the

application of Tree as a data structure to achieve improved security.

Hussain, S et al [32] proposed a work for hierarchical clusters operating in distributed fashion. It was a modified version of Kruskal's minimum spanning tree (MST).

Gupta, S et al [33] analysed the issues with broadcast and convergecast trees and attempted to provide improved solution. Application of Spanning trees for energy-aware data aggregation was considered in the work by M. Lee et al [34].

Genetic Algorithms were also considered for the benefit of data aggregation with trees being used data structures in the works like [35] and [36].

The network life time maximization was attempted as an Linear Programming problem in[37] and was interested in studying the impact of multiple sinks.

Another application of tree data structure was found in the research work by OmPrakash Gnawali et al [38]. Further, two more improvements were suggested to the original CTP as presented in [41] and [42]. Research work presented in [43] attempts to evaluate the performance of CTP and other variants of it using Castalia simulator. Further, some improved versions of CTP were published in the works [44] & [45] .

III. Advantages, disadvantages, & Performance implications of application of tree data structures in WSN

Main advantage of MST and BST variants of trees is that they are easy and simple to implement. But, at the same time they have several disadvantages. In case of minimum spanning trees, they have varying path lengths along with many instances being applicable. Most frequently followed algorithms for constructing minimum spanning tree have been shown to run with complexity of O(m log n) where 'm' is the number of edges in the resultant spanning tree and 'n' is the number of nodes. Any other variants of binary trees are also having varying depths and operational costs (time complexity) depending upon the circumstances. For example, simple binary search tree may often show the performances for best case as *O(log n)* and for worst case can degrade to *O(n)* when it becomes unbalanced, where 'n' is the number of nodes in the tree. Thus, the time taken to perform operations is less if the height of the search tree is small; but if its height is large, their performance may be no better than with a linked list.

* highlight the issues of this delay in wsn.

Further, AVL trees impose rigid balance on the tree structure leading to slow and costly operations.

But, all the above discussed variants of tree data structure are not well suited for application in WSN. Major reasons for such infeasibility come from two aspects. First aspect of such infeasibility is that most often applied tree variants in the existing works are going to demonstrate the worst performance in case of frequent insert, delete and lookups in trees with arbitrarliy longer depths.

Second aspect of such infeasibility stems from some important unique features of WSNl ike highly dynamic topologies, frequent need for self-reconfiguration etc.

Further, normal datastructure algorithm for trees is different than trees in WSN. Because, in normal datastructure single system handles insertion, deletion of node along with building the tree. But in WSN, many things happens in parallel. For example, all nodes in one hop distance to sink node, may join sink node, sequentially, one after the other. For example, if 4 nodes are there in one hop distance to sink then it may take 4 x time required to join one node to sink, as the total time. However, the nodes in 2 hop distance to sink, will join the one hop nodes and it can happen parallelly. So the time calculation or algorithm complexity, in fact, varies depending on these parallel activities happening. It also varies based on sink position. Most often, many of these parallel activities will be affecting a particular parent in localized fashion. And, most influencing factor in WSN, while applying Tree data structures, is the number of hops or reachability to sink than hieght/length of tree/path.

IV. Red Black Trees(RBL): Feasibility, Potentials, and limitations for Application in WSN

Red Black Trees are a variant of self-balancing trees. The nodes in RBL are differentiated as red and black nodes. Further, every path in RBL from root to leaf has same number of black links. In RBL at most one red link in-a-row or path from root to leaf is permissible. Height of tree in case of RBL is less than *2 log (n + 1).*

These RBL trees have been proven to show best and constant performance where insertion, deletion and lookups are frequently performed. Because of this reason it may seem that the RBL are well suited for WSN where topological changes bring in frequent node insertion, deletion, and lookup. The only disadvantage is that they are comparatively difficult to be implemented. More details on these Red Black Trees can be found in references like [47][48][53].

However, RBL trees put a restriction that all parent nodes must have same number of leaf nodes. This restriction puts a difficulty in WSN, as the nodes can be deployed randomly which makes meeting this restriction infeasible most often. Additionally, in WSN topology creation depends on communication range too. Thus, several unqiue aspects of WSN may expect some variant of RBL, but not exactly the original RBL concept, to be applicable for improving network life time & energy efficiency. More research need to take place with focus on exploting the benefits of RBL towards improving the performance of WSN while circumventing the limitations imposed by RBL on WSN.

V. CONCLUSIONS

WSN have found wide spread application in different domains. The WSN are also characterised by peculiar features and conflicting design goals making them different from other types of networks. Various techniques like application of data structures etc have been considered in the earlier research works to improve the overall performance and specifically energy efficiency and network life time. In this regard, this article made an attempt to present, as far as possible, a critical study of existing research works which applied tree data structures for improving the energy efficiency and extending the network life time of WSN. Further, the theoritical discssion on the implications of applying different types of tree data structures on the overall performance and specifically towards the energy efficiency & network life time was also presented. Also, this artcile presented a brief discussion on the possible potentials for application of Red Black Tree as data structures for improving energy efficiency and network life time along with mentioning the design issues likely to be manifesting on the way in such attempt. The paper is concluded with stress on need for elaborated research in future in this regard. Authors of the paper are making research on the different novel approaches of using Red Black Trees in WSN and hopeful of presenting the research reseults to the research community soon.

Abstract. ***Due to recent development in technology, today's we are insisted to connect every object (device) with updated technology (i.e., which can run through connected via internet). Some examples like smart agriculture, smart homes, smart city, etc., are some applications of advancement in integration of Internet of Things together. Today's Internet of Things (IoT) or Internet Connected Things (ICT) are connected everywhere, with every-applications which is used to build a smart environment (with physical world). In general, these internet-connected devices (in integration) provide efficient services to users/ human. In other words, people life becomes easier to live with such devices in different applications (like smart transportation, smart cities, smart homes, smart grid, etc.). But, using these devices in their daily life, people are very much concern about "their personal information" or "their co-ordination/ location". So a question raised here: "Is it (personal information) safe with these (such) devices"? Do we know what is coming to our life/ in near future via leaking of privacy (or tracking our footprints) by these smart devices? When these devices are connected together, they build an ecosystem together for human being/ for many applications. A lot of data is being captured and transformed into valuable forms, which is used in future for increase productivity by firms/ organisation (in many application areas), ranging from automated home appliances, smart grids and high-resolution assets, to product management. This captured and collected data creates several issues, so it requires new/ useful strategies of enhancing the present status of IoT by incorporating (or overcoming) security and privacy into its current design, structure and implementation. Hence, this article explains such issues (in IoT) like privacy breaches, security vulnerability etc., in clear manner.***

Keywords **–** Internet of Things (IoTs), Internet Connected Things, Privacy, Security, Cyber- Attacks, and Internet of Thing's Applications.

I. Introduction

In the past decade, several security vulnerabilities are being found in Internet of Things/ Cyber-Physical Systems like robotics/ electronic power grid, intelligent transportation systems, and medical devices, and so on. The term 'Internet of Things (IoTs)' was first coined by the cofounder and Executive Director of MIT's Auto-ID lab, Kevin Ashton in the mid-1990s [1]. There are salient attributes across array of definitions, such as sensors, things, people, process, automation, data, network, connectivity, convergence, and intelligence. Hence, Internet of Things (or Internet Connected Things or Smart Things) can be defined as "Intelligent interactivity between human and things to exchange information and knowledge for new value creation". Billions and billions of devices are getting connected to the internet everyday as hardware is getting cheaper and smaller to fit into even the tiniest object. Manufacturers are connecting even the mundane kitchen gadgets to the internet to do some little work. Over a period of time, it is possible to turn the dumbest thing into a smart device. For example, a washing machine manufacturer collecting data to understand the product's wear and tear to build a better version in future (i.e., for future customers). However, a customer is always unaware from this kind of strategy of manufactures. So, in future we may expect a device to be unexpectedly smart. This scenario is the outcome of industries who are just thinking ways to make a device IoT enabled rather than thinking whether they should make a device IoT enabled or not. Interestingly it is not the consumer but the manufacturer who is benefitting by collecting data. Every manufacturer's primarily intention is to digitalize things to collect data. Manufacturer first aim is to attract many customers (with putting security risks at side), to make maximum profits and to stand in competitive market. Also, the customers wanted themselves to be updated with the latest technological innovations and are ignoring the associated security risks. A lot of data (called Big Data) is being generated by internet of Things (internet) and its integration. Also, this generated data is being collected on a cloud. On another side, cloud is the backbone for the Internet of Things, through which we can share resources anywhere, anytime. As IoT devices or this technology evolves, human being become more familiar with smart things/ these devices. So, we use these internet connected/ IoT devices for solving some real world's problems/ tasks related to real-time scenarios like self-driving cars or health care, etc. But as the data becomes more critical, we need more useful, sufficient analytics tool (approaches) to manage, store, secure and process information. Note that as data changes from critical to hyper-critical, we require more advanced security protocol systems. But a serious question arises here, who will fix these security issues in devices and at which level/ layer of communication/ implementation?

Internet of Things provides several benefits to users, and has the potential to change the ways that user's interact with technology. In near future, the Internet of Things is being integrating with virtual world with physical world (together), which is difficult to protect. From a security and privacy perspective, the predicted pervasive introduction of sensors and devices into currently intimate spaces like home, car, and with wearables and ingestible, even the body, it poses particular challenges. As physical objects are increasing in our daily life (according to our needs), then in future, detection and sharing of observations about us (by devices) will be increased automatically, i.e., we will require to protect our privacy. The IoT has the potential to connect 10X as many (28 billion) "things" to the Internet by 2020, ranging from bracelets to cars (in near future). Note that the Internet of Things (IoT) is emerging as the third wave in the development of the Internet, in 1990s' Internet wave was the first one, whereas in 2000s', mobile wave was the second one [2]. With decreasing prices/ cost of sensors, processing power and bandwidth to connect devices are enabling ubiquitous connections right now. Pervasive computing follows 6A's, authorized access to anytime-anywhere-any device-any network-any-data. Internet of Things (IoTs) makes a smart environment in integration of together [3], in this smart environment several smart things works together smartly, security, and efficiently. In the development of the Internet of Things (IoT) devices/ smart things, several issues like security, privacy, scalability, lack of standards, etc., (already) has been raised. Loopholes in security (badly configured devices) may provide a backdoor to unknown/ malicious users/hackers. Internet of Things devices are becoming more attractive to human beings (now days) than any other technologies (e.g., mobile phones), which access user's most sensitive information/ personal data, i.e., social security numbers and banking information. This is an essential issue overcome/ to received attention from research community.

A. Component of Internet of Things

With knowing total number of connected devices with Internet of Things (IoTs), we can derive the phenomenon of a network/ understand a network clearly (for which application IoTs are working). Here, IoT is "a complex eco-system encompassing all aspects of the Internet, including analytics, the cloud, application, security and much more" [1, 3]. In technical words, connecting

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

devices/ Things with Internet connected devices/ IoTs are the main causes in generating a lot of components, i.e., physical devices with sensors/ connected things, connection and infrastructure, and analytics and applications). The following enabling technologies with Internet of Things are included as:

- Radio-Frequency IDentification (RFID): They help in automatic identification of anything they are attached to acting as an electronic barcode.
- Wireless Sensor Networks (WSN): A sensor network consisting of a large number of intelligent sensors, enabling the collection, processing, analysis and dissemination of valuable information, gathered in a variety of environments. The components that make up the WSN monitoring network include: WSN hardware, WSN communication stack, Middleware and Secure Data aggregation.
- Addressing Schemes: Internet Protocol version 6 (IPv6) is used for identifying the IoT devices uniquely as it is a key aspect for controlling and monitoring the devices.
- Data Storage and analytics: Billions and Billions of IoT devices are producing continuous streams of data. In order to process the data collected and gain knowledge we require AI based machine learning algorithms. These algorithms need to be interoperable and adaptive.
- Visualization: Visualization is the key to the success of any IoT application. Visualization techniques help the end users in making quick decisions.

An IoT device can be classified further into two categories, i.e., Physical objects (i.e., smartphone, camera, sensor, vehicle, drone, and so on), and Virtual objects (i.e., electronic ticket, agenda, book, wallet, and so on). In simple terms, IoT is a combination of embedded technologies including wired and wireless communication sensors and actuator device and physical objects connected to the internet. An IoT system has four major constituents: a). Sensors that collect data from smart devices b). Input which activates the sensors c). Data analysis that is performed to extract useful information. d). A monitoring system for ensuring security and privacy of the information.

Hence, this section discusses about several things likes introduction and essential components of IoTs. Further, the organization of this paper is discussed as: Section 2 discusses a vision for future, i.e., how near future can be changed/ will be with Internet of Things and Machine Learning or intelligence together. Further, section 3 discusses about some current trends in IoTs technologies. Then several Threats to Internet of Things Ecosystem like human and cyber-attacks (also some vision of IoTs in future) are being discussed in section 4. Further, we will secure an IoT ecosystem using some preventive and cryptographic mechanisms in section 5. Then, security and Privacy Goals with internet of Thing's Devices (via a 360^0 view) have been discussed in section 6. Before conclusion, some challenges in IoTs devices/ with internet connected things have been discussed in section 7. In last, this work is concluded with some future work (scope) in section 8. Note that in this work, we have used terms 'Internet of Things' with 'Internet Connected Things' or 'Smart Things' interchangeably.

II. How Internet of Things is affecting User's Privacy?

Generally, Internet of Things enabled devices are physical gadgets with built-in Internet connectivity that allow data transmission [10]. But, a user is unaware what is happening in the background, i.e., a user have no indication that anything is happening in back-send. Are these devices are supporting users in a positive ways or in negative ways? For example, a movie named "Spy in the sky" was released in 2015.In this movie, user's location or movement was getting traced by drones (in form of/ like a bird). Such incidents are possible in real-world also. As another example, a hacker or antivirus companies have added some patches with their antivirus update, to get end-user activities. Even hackers can send malicious files to an end user which may control end user's systems/devices entirely. As discussed above, increases in data. Also, using devices by several people without knowing such technology/ device or having low security in respective devices are the main reason of losing their footprints to other users/ attacker/ hacker. IoTs are much helpful in building Cyber Physical Systems (CPSs), but providing automation to machines or every work may harm to society/ people via tracing their movements (or footprints). These are is no guarantee that these devices will not track user's movements or reveal this collected information to other user/ outside world. Internet of Things device are being used in several applications like industries/ industrial intent, personal medical devices, smart home, wearable, smart city, smart grid, connected car, smart retail, smart supply chain, smart farming, etc. [2]. Apart that, today's IoT devices are resilience to several attacks like TREsPASS attack, Distributed-Denial-of-Service, Falsification attack, Man-in-Middle attack. Hence, with such attacks, hacker/ attacker breach or track or interfere into user's personal life/ daily life. In summary, a user may be traced in public places by several devices or by his own devices (like smart phone, laptops, or nay internet connected devise, etc.). Also, he/ she can be traced by hackers/ machines/ robots (i.e., a cyber-physical system) in his/ her home. A robot can look to his owner, i.e., at what time which work he/ she is doing and so on. According to that, machine/ robot may use this information/ traces/ patterns against his owner (in future) only. For example, in a movie named "Edward Snowden" which was made on true incident. In respective movie, Central Intelligence Agency (CIA) looks into its citizen's life and traces every movement of its citizens. Together this, CIA read all messages through mails, phones, etc., of its citizens (also put surveillance on its citizens). Hence, there was no privacy protection mechanism, even companies made to bind to share their user's data with the respective government. As another example, in China (now a day) mobile companies have to share its user's data with respective governments (as a mandatory rule). Such examples are complete violation of personal privacy. Basically, a user's privacy need to be protected and kept preserved, because privacy a fundamental right for citizens of a country (e.g., India, USA, etc.).

Hence, major security issues in IoTs/ Internet Connected Devices are: handling data encryption, data authentication, IoT hardware issues, hardware testing (as inevitable), and managing updates (in devices). Also, major trust issues in IoT are: lack of security, leaking of privacy/ tracking footprints of users, safety (smart locks, etc.). To overcome such raised issues in IoTs, we need to fulfil some goals with respect to privacy and trust. Primary security goals in IoT are confidentiality, integrity, authentication and authorization, availability, accountability, auditing, non-repudiation. On the other hand, privacy goals in IoTs are: privacy in devices, privacy during communication, privacy in storage, privacy in processing, identity privacy and location privacy and building trust with respect to respective service provider (who own IoTs devices). Hence, this section discusses about how internet connected devices may affect user's privacy in a crowd places and non-crowded places. Now how IoTs can be useful to a human being can be discussed via two scenarios (see figure 1). Here, we need to discuss one day of a user with two different scenarios [4, 5], in that we are finding that intelligence or machine learning are much helpful/ in helping them to get ready for next day (for job/ work). Hence, what we noticed from the discussed scenarios (discussed in [4]]). We learned here, differences among life living with and without intelligence, and importance of Machine Learning or intelligence/ artificial intelligence in near future. For new users, no matter when a user gets up, shower and coffee are being ready without ever-getting the chance to waste water or warm or cold using intelligence with (in) IoTs devices. Smart things keep/ perform event in flow/ in manner (see figure 1). Above all tasks which were done by user only (in scenario 1), can be done in sequential or in parallelized way with Intelligence. But, depending more on technology also creates several problems like leaking of privacy/ personal information, storing information without user's permission, trust, safety, etc.

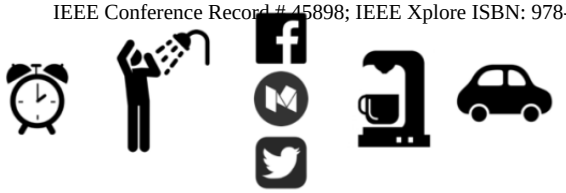

Figure 1: Flow of Events with Internet of Things and new Technology like Machine Learning, or Deep Learning [4]

Hence, this section discusses about internet connected things, i.e., how they (IoTs) are changing human's being life or making their life better. Later, this section also discusses uses of IoTs (with intelligence or machine learning) in human's being life with an example (i.e., with two scenario). Now next section will discuss about the technologies which are trending now and in near future.

III. Technologies Trending Now and in Near Future

As discussed above, most of the benefits (from cloud based IoTs) are coming with huge risks, like losing of privacy loss and security breaches. To secure the IoT devices (also to preserve privacy of user in IoTs), several novel ideas/ proposed work have been proposed by many researchers [6]. The Internet is the main backbone for making a communication among devices/ machines, also a platform to reveal people's information to malicious users/ hackers. In 1990, internet/ worldwide web (a method of publishing information on the Internet) created by Tim Berners-Lee [7, 8]. Today's Internet users are in billions, it is being in maximum devices (i.e., interlinked human and creates new generations of interactive experiences). In near future, Internet will be used with billions of IoTs/ IoT ecosystems (a world of networked smart devices equipped with sensors, connected to the Internet, all sharing information with each other without human intervention). It is because today Internet has a lot of information (due to having a large network of information). In simple terms, Internet became a bigger platform/ source of information (also it is due to large number of websites available on it).

Value Propositions: With the rise of internet connected devices and connected individuals, technology experts forecast four components like Big data, cloud, social media, and mobile devices/ things [4]. Interaction of these components (together) will fuel and shape the IoT to a new level. The 'Internet of Things' generate a lot of data (called as 'Big Data'), which is used by data scientists, researchers or organisations (or manufacturer) to do prediction/ make some decision for future. The volume of data attributable to the 'Internet of Things' is substantial. As sensors (embedded in IoTs) interact with the other things (or devices), 'Things' such as RFID tags generates huge and huge of data. In result, traditional tools fail to handle this large amount of data. Today's digital processing becomes a requirement of feasibility. The velocity of data associated with the 'Internet of Things', is compared with traditional transaction processing, explodes as sensors can continuously capture data. The variety of data is generated by 'Internet of Things' is also increasing/ changing frequently (due to using different types of sensors in different applications). The veracity of data in the 'Internet of Things' may also be improving as the quality of sensor and other data improves over time. For example, use of Radio Frequency Identification (RFID) tags generates much more reliable information than a decade ago. Such high volumes of data, coupled with an increasing velocity of data, along with an increased variety of data, illustrate the push by the 'Internet of Things' to generate 'Big Data'. Hence, a 360^0 view of IoTs Things/devices can be discussed in following applications:

- IoTs for manufacturing
- IoTs for retail
- IoTs for electronics
- IoTs for automotive
- IoTs for energy and utilities
- IoTs for insurance
- IoTs for industrial
- IoTs for aviation

Above discussed point and uses of IoTs in several applications has been discussed in [3]. Hence, this section discusses trending technology of Internet of Things (IoTs) in several applications. Now, next section will discuss several raised threat in an IoT ecosystem.

IV. Potential Threat to Internet of Things Ecosystem

As discussed in [1, 4], 'Internet of Things' Generates 'Big Data', above discussed points are four pillars (of technology), which are interconnected with each other and work efficiently (with respect to cost and accessing to find/ search records over records or a database). But, IoTs have different views/ aspects for these pillars, i.e., tracking or leaking information of user to malicious users (by malicious systems/ devices, for example, in a Hollywood movie "Eagle Eye", released in 2008, in that computer systems or army personal track a user or its location everywhere with the help of small drone) [4]. As many as devices are being with other smart devices (IoT), researchers require to test several security, scalability, critical concerns etc. Through this, researcher tells to world about possible security vulnerabilities (or key threat) in IoTs, i.e., not having proper *security measures for large network of IoTs*. The key threat vectors explained in [11], also discussed here in brief:

a) Threat Posed by Compromised Devices: As we all know IoT devices contain information and the attacker have the potential target to exploit that information, for example, User installs a security camera, it could expose personal information of user. This information can be hacked easily and the attacker can control and manage it [4, 11]. Can we put trust on these devices? If yes, then how much? This question is really a tricky one.

b) Threat over Communication Link: A network of connected IoT devices transmits a lot of data, during this transmission lots of attacks are possible which is too dangerous. Note that this communication can be intercepted, captured, or manipulated (or shared with others/ unknown users) during transmission. For example, an attacker may trace the footprints of a user via his/ her communication, on the other side, attacker may track energy usage to plan an attack on the entire smart system. Here, successful attacks may affect trust among user, devices, firms and manufactures (of such devices) with respect to data transmitted in IoT infrastructure.

c) Threat on the Master: This threat is against manufacturer and Cloud Service Provider (CSP) raises issues like safety, trust and privacy. Manufacturers and IoT cloud both contain trillions amount of data which is highly sensitive and a strategic asset because it is determined by analytics process. Note that this has higher competitive information in view of underground APT (Asia-Pacific Tele-community) group, if leaked/ intercepted. If the Master is compromised, it gives opportunity to an attacker to manipulate many devices at once, some of which may have already been deployed in the field.

Besides all the IoT application benefits, several security threats in IoTs are observed and discussed in [4, 11]. Note that the internet connected devices (or internet of things) or machines are extremely valuable to cyber-attackers for several reasons:

i. Most Internet Connecting (IoT) devices are operating by the users who have less knowledge of cybercrimes. Then, it is easy to gain physically access to smart device by an intruder (attacker).

ii. Most IoT components communicate over wireless networks where an attacker could obtain confidential information by eavesdropping.

iii. Most IoT components cannot support complex security schemes due to low power and computing resource capabilities.

a. Human Threats

Malicious human activity always is dangerous than natural systems/ computing device, for example, an employee (of an organisation) may try to tamper with or destroy or leak data [12]. Human is constantly trying to find new ways to annoy, steal, and harm. Human threats are categorized into the following:

- Unstructured threats consist of users which are less experienced and hack the data by using available hacking tools.
- Structured threats consist of users who can understand, develop and can exploit codes and scripts for example, structured threat, i.e., Advanced Persistent Threats (APT) [13]. Here, APT is defined as "a sophisticated network attack targeted at high-value information in business and government organizations, such as manufacturing, financial industries and national defense, to steal data" [14].

Hence due to weaknesses in security vulnerabilities or Rogue security software, malicious users can enter in another user's system and can steal their data.

b. Common Cyber-Attacks

Using malicious code, i.e., in form of worms, virus, etc., Cyber-attacks are being done to harm users or their data (which is a cybercrime due to stealing of information and identity theft of users). In general terms, Cyber-attack is an attack is "any attempt to expose, alter, disable, destroy, steal or gain unauthorized access to or make unauthorized use of an asset" [15]. Generally, cyber-attacks are socially or politically motivated on internet-connected systems/ things, i.e., stealing, altering, or damaging someone information on an internet connected system/ things. Today's several attacks have been performed or formed one thing/ computer (system) to another things/ computer (systems). Many attacks on these things (internet connected devices) have been detected in the past decade. Some of these Cyber-Attacks on IoTs are listed here as:

1. Physical attacks**:** It is the subset of physical threats. Attack means that there is some attacker and his intention to do attack and tempers with hardware components. Most of the devices typically operate in outdoor environments, which are highly vulnerable to physical attacks.
2. Reconnaissance attacks: It is unauthorized discovery and mapping of systems, services, or vulnerabilities, for example, scanning network ports [16], packet sniffers [17], traffic analysis, and sending queries about IP address information.
3. Denial-of-Service (DoS): A Denial of Service (DoS) attack happens when a service that would usually make a machine or network resource unavailable to its intended users. In this attack , the attacker (hacker) sends excessive messages asking the server to authenticate requests that have invalid return addresses
4. Access attacks: The attacker wants to gain to a system network, where the intruder has to find out the vulnerabilities or weaknesses in the network authentication, i.e., FTP and web services. This attack is of two types: Physical access and Remote access.
5. Attacks on Privacy: Privacy protection in Internet connecting things (like autonomous vehicles, intelligent/ smart vehicles, etc.) is always a challenging task in IoT because of the huge information is easily available (being collected by smart devices) through remote access. The most common attacks on user privacy are:
    - Data mining: The attacker can extract useful information and patterns from data in large databases.
    - Cyber espionage: The attacker use malicious software and cracking techniques to steal the secret information of the individuals, organizations or the government.
    - Eavesdropping: listening to a conversation between two parties [20].
    - Tracking: The attacker can track the movements of the user with the help of devices Unique Identification Number (UID), for example, mobile number.
    - Password-based attacks: Such attacks attempts by malicious users to duplicate a valid user password into two different ways via dictionary attack (making possible combinations of letters and numbers, i.e., guessing user passwords) and brute force attacks (using some hacking/ cracking tools to try all possible combinations of passwords to break user passwords).
6. Cyber-crimes: Now days, these smart devices are being used (using internet) for other uses rather on their actual uses, i.e., used to exploit users and data for materialistic gain, such as intellectual property theft, identity theft, brand theft, and fraud [18, 19, and 21].
7. *Destructive attacks: Space is used to create large-scale disruption and destruction of life and property. Examples of destructive attacks are terrorism and revenge attacks.*
8. *Supervisory Control and Data Acquisition (SCADA) Attacks: As any other TCP/IP systems, the SCADA [22] system is vulnerable to many Cyber-attacks [23, 24]. The system can be attacked in any of the following ways: i) Using denial-of-service to shut down the system. ii) Using Trojans or viruses to take control of the system. For example, in 2008 an attack launched on an Iranian nuclear facility in Natanz using a virus named Stuxnet [25].*

Some other cyber-attacks are: Phishing. Man-in-the-middle attack, Denial-of-service attack, SQL injection, Zero-day exploit, etc. We need to remember here that as the number of IoT devices are integrating together and becoming a reality to user's life, and then obviously several security threats also will be occurred. Everyday unfortunately, IoT devices are getting new attacks (with new mechanisms, code).

c. Vision of the Internet of Things

As discussed IoTs are being used everywhere now days. Also we find that several threats have been mitigated on IoTs devices. So, a manufacturer (of these devices) needs to build these devices in future with considering issues like privacy, safety, and quality of life (for other user/ firm, which will use it in a distributed multi-user system with internet). Internet of Things is being look at outer world in the following way

a) Large Scale Ubiquitous and Pervasive Connectivity: Today's in vision of the IoT, these devices are using in creating smart environments, i.e., to makes energy, transport, cities, etc., more intelligent [29]. Integration of IoTs makes an environment which provides efficient services to users anytime, anyplace (using optimal path). IoTs in near future will be used in several areas like businesses and industrial Internet (with creating an open, global network of people, data, and things).

b) Context-Aware Computing: It requires most in Internet of Things, i.e., users require awareness of the computing elements (to optimize their performance and to enable services customization). Also, creation of smarter environments, entertainment and business applications (which are beneficial to users) would require acquiring, analysing and interpreting important context information about users.

c) Seamless Connectivity and Interoperability: Internet Connected Things or IoT requires seamless connectivity and Interoperability, so that context information can be shared among heterogeneous devices.

d) Network Neutrality: Network neutrality (a part of vision of IoTs) states that "no bit of information should be prioritized over another". So the principle of connecting any device to other devices from anywhere at any-time

make most optimal physical path between sender and
IEEE Conference Record # 45338; IEEE Xplore ISBN: 978-1-7281-1261-9
the recipient in a network/ communication.

Hence, this section discusses about several threats notified in the IoT ecosystem. Also, this section discusses about human and cyber-attacks (including vision of IoTs things) in detail. Now, next section will discuss some mechanism to secure an IoTs ecosystem in detail.

V. Securing Internet Connecting Things Ecosystem

As we all know, IoT will be a game changer for the applications and business but it will raise issues like security and privacy on a large scale and requires attention from manufacturer. In general, IoT security depends on the ability to identify devices, protecting IoT hosting platform, and protecting data (collected by smart/ IoT devices) and share this data with Trusted IoT Device (a trusted device is required to be reliably identifiable and associated with a manufacturer/ provider. Sharing information with trusted entities only increase trust among users and on technology. Now, here we are discussing all necessary tasks/ components to require/ secure an IoT ecosystem.

a. Maintaining Data Integrity with Internet of Things/ Internet Connected Things

Internet of Things promises to open up new opportunities for businesses to offer exciting services. These days insurance companies are installing IoT devices in the vehicles to collect the data about health and driving details of user to take decisions about the insurance claims. To prevent the data from the malicious user, the data should be encrypted at network layer. Blockchain Technology (first time used in Bit coin: A Crypto- currency [30], in 2009) can be used to fulfil this wish, i.e., can provide higher security to a distributed, decentralized and centralized system.

b. Establishing Trusted Identity Internet of Things

As discussed above, Internet of Things is built on a network of uniquely identifiable devices, whereas, public key cryptography plays a biggest role in establishing trusted identities (in IoTs). Public key cryptography used a concept of using two different keys to share any information among systems/ users. Where one of the key is made public (i.e., public key) and the other is kept private (i.e., private key). Information can be read if both of the keys apply correctly on encrypted information. This process is done by a Certification Authority (CA). Also, trust can be built via creating blocks and storing encrypted information in blocks with consisting information with respect to previous and next block's records (i.e., a Blockchain concept) in an IoT environment.

c. Establishing a Public Key Infrastructure for Internet of Things

As discussed above, identity infrastructure is built on both/ combination of public and private keys. If a private key is not kept secure/ private, then credibility of respective key may get compromised. The secure generation and storage of these keys is paramount. Public Key need to be secured by a novel propped solution (which is properly implemented with some real world attacks) against tamper-resistant hardware / to protected stored data. Using this mechanism, we can easily mitigate an attacker/ attack in a network.

d. Protecting Aggregated Big Data with Encryption

The data collected, transmitted, and stored in clouds/ IoT can be protected using encryption mechanisms. We can use Blockchain technology to secure this data, i.e., storing this data in blocks (after encrypt) then make a connection with next blocks (according to data/ information). A data is situated in two forms (in a cloud/ IoTs communication) like data at rest (static) and data in motion (dynamic).

- Protection of Data at Rest: When IoTs devices are communicating, then they generating a lot of data, which is stored at several locations with secure mechanisms. Encrypting this data and keeping it at server side provides scalable, cost effective storage, and fast processing in near future. These encryption mechanisms provide availability, integrity and usage of respective collected data (i.e., accessible all time to users). Storing this data with protected manner and avoiding any possible entry point to any malicious users/insider is an essential issue to overlook/ focus in near future. To overcome this issue of protecting stored data, firms/ organizations need to use sufficient encryption mechanism (after compression of data)/ lock down sensitive data at rest in big data clusters (without affecting systems/ devices performance). For that, it requires transparent and automated file-system level encryption that is capable of protecting sensitive data at rest on these distributed nodes.
- Protection of Data in Motion: Encrypting communicated data presents a unique challenge because it has a high variety and increasing at a higher rate. As data moves from one location to another, it is highly vulnerable to attacks like fibre tapping attack, man in middle attack, etc. Note that an attacker can listen a communication (which is being with two parties/ devices) with tempering/ attaching a cable (with fibre coupling device) and no device (or mechanism) can detect it. In this, attacker can record all activity that runs across a network, and data is captured and stolen without the owner's knowledge (even sender and receiver's knowledge). In worst case, this type of attack can also be used to change data, and has potential to override the controls on the entire system. Note that encryption is also required at the back-end infrastructure level of manufacturers, cloud service providers, and IoT solution providers.

A data can also be protected using Blockchain concept. Security can be provided to any types of data via creating blocks and storing encrypted data/ information in blocks with consisting information with respect to previous and next block's records. This process is clearly impossible to compromise (except in case of covering majority of blocks) by any attacks. Note that Physical security is probably more of an issue, since these devices are usually out in the open or in remote locations and anyone can get physical access to it. Once someone has physical access to the device, the security concerns rise dramatically. Hence this work presents several suggestions or techniques to (provide security) securing an IoT or Cloud based IoT ecosystem. Now, next section will discuss several security and privacy required in IoTs (via 360^0 view).

VI. Security and Privacy Goals with internet of Thing's Devices (via a 360^0 view)

In above discussion (in section 5), storing or learning patterns of user's daily activities is ok, but it is critical when it is shared with unknown device/ users. It is a major and essential challenge (issue) to overcome. Privacy is a fundamental right, which needs to be protected. It can be protected with complete isolation from outside world/ Internet-world. A user starts to interact with other devices/ people; he/she starts sharing/ is willing to share information about itself with others. Hence, some privacy goals in IoT based Cloud are included as:

- Privacy in devices: When a user sends information from one device to another, then this personal/ sensitive information of users may be leaked to other devices (or users). It (privacy breaching) is also possible in case of device's theft or loss. In summary, it depends on physical and commutation privacy.
- Privacy during communication: When a device is connected to another device, it depends on availability, integrity and reliability of a device to reveal its service to another device. Here to reduce the breaching of

Information Privacy, #48882, IEEE Xplore ISBN: 978-1-7281-1261-9

with devices only when there is a need.

- Privacy in storage: In this, a device which is not in use or in its ends of life, then storage information in such devices (or IoTs) needs to be protected from reaching in hands of illegal users. Such information may use by attacker to blackmail the respective users (in future). It means data should be protected which is stored in such devices. Hence, a proper deletion and wipe off (of storage) of devices is required for avoiding any kind of attack.
- Privacy in processing: It depends on device and communication integrity [26]. Data (or information) should be disclosed to or retained from third parties without the knowledge of the data owner.
- Identity privacy: Every device has some unique identity which should be identified by the authorized person/ device only (to avoid any attacks like privacy breaching, etc.).
- Location Privacy: It is the geographical position of relevant device should only discovered by authorized entity (human/device) [27, 28].
- A user consists data, information, identity, location and genomic types of privacy in communication of/ with internet of things. Such types of privacy contain valuable and sensitive information, which require protection against malicious users. Similarly, some security protection required with IoTs as:
- Security of IoT devices: Security of IoT ecosystem need to be provided physically. When an IoT ecosystem is being like smart grid, then from we require some manpower/ human being to take care that site, i.e., protection site against any kind of damages. For example, organisations are hiring persons for taking care of their infrastructure (i.e., in telecom industry).
- Security in IoT devices: Proper encryption mechanism, efficient algorithms to collect data in a database, access control to known users, etc., are some essential components need to include when IoTs devices is being used.

Hence, this section discusses several security and privacy goals with respect to internet connected things via 360^0 view. In this, we find that privacy of information stored/ communicated in devices should be persevered and protected, also security of devices and enough level of security need to be provided in IoTs. Now, next section will discuss about some challenge in IoTs.

VII. Issues and Challenges in Internet Connected Things

In the past decade, several challenges have been investigated in IoTs. We need to focus on these challenges to encourage higher growth rate of IoT (in near future), and to provide opportunities to future researchers to do their research work. Industry also can consider these challenges to capture new competencies and capacities. These challenges (investigated in an IoT ecosystem) can be discussed as:

- Infrastructure: An Infrastructure is an environment which is interoperable, trustable, mobile, distributed, valuable, and powerful for provide services to human beings. An IoT ecosystem consist several emerging applications in it, i.e., like Smarter Cities, Smart Grid, Smart Building, Smart Home, Intelligent Transport Systems, and ubiquitous healthcare, etc. Due to that, large numbers of address schemes are required to provide address to each and every connected IoTs (to offer offers scalability, flexibility, tested, extended, ubiquitous, open, and end-to-end connectivity). Note that Addressing schemes are used to identify with respect to identify sender's identification/ location, to provide security to devices.
- Data and Information: Lots of data is being generated with these devices (in integration), which is a major challenges to handle, and analysis. Modern analytic tools/ new big data solutions are required (by service providers) to analyse data, and discover relevant trends and patterns for future purpose.
- Security and Privacy: The smart devices connected to the internet connected devices (ICD) helps consumers, or industries or service providers (in many ways) to increase business (or solve queries of users). Smart devices transmit data, with compiling it (in shorter form) to end users. Third parties users like researchers, health care providers, etc., can use this information for their research purpose. But again, leaking of privacy or breaching of privacy, trust issues will be arises in an IoT ecosystem.
- Ecosystem: The IoT revolution is on peak. Each city or machine is being embedded with smart devices or internet of things. 'Things' already have a lot of information of users. This information is being used to produce new facts/ information, communicate, and to become an integral, essential part of the Internet. In near future, the market for IoT will reach approximately £200bn a year (worldwide) with new and innovative business models, applications and services developing across different sectors of the economy. Such smart innovation in several areas will improve growth of respective areas (using efficient, better wireless connectivity, system integration and decision-support tools).

A. Challenges in Internet of Things

A key challenge in machine learning is "How to represent the Input Data and what are possible Security Attacks and System Vulnerabilities"? There has been a lot of work done in the scenario of IoT security up till now. The related work can be divided into system security, application security, and network security. Some few problems in this regard can be included as:

a) Design of Service oriented Architecture (SoA) for IoT: SoA needs to handle a large number of devices connected to the system which phrases scalability issues. Here in this challenges like: data transfer, processing, and management become a matter of burden.

b) Heterogeneity: IoTs is having a complicated heterogeneous network platform. This, in turn enhances the complexity among various types devices through various communication technologies showing the rude behaviour of network to be fraudulent, delayed, and non-standardized. The management of connected objects by facilitating through integration between devices, for example, hardware components and/or software services, and administering them after providing addressing, identification, and optimization at the architectural and protocol levels is a serious research challenge.

c) Lack of Service Description Language (SDL): In network services, a lack of a Service Description Language makes the service development, deployment, and resource integration difficult by extending the product dissemination time (due to/ causing loss in market). A Novel SDL may and change or solve several problems like product dissemination. We must identify a commonly accepted SDL, so powerful service discovery methods and object naming services need to be implemented.

d) Lack of a Unified infrastructure: IoT is designed with a traditional network/ IoT makes CT environment. This environment is affected by its connection. So, we require a unified information infrastructure to connect large number of IoTs devices (to produce real-time data).

e) Handling Large Data base: Today's existing/ Traditional Data Base Management System (DBMS) cannot handle the originated data, because of the huge data (generated or collected). The current fault tolerance system is in capable of managing the high speed generated data. A new IoT based data centric architecture need to be proposed to tackle this issue.

IEEE Conference Record #45982; IEEE Xplore ISBN: 978-1-7281-1261-9

f) Efficient of Data generated by IoTs: The data generated from IoTs devices (connected through internet) will be in present in different volume, variety and formation. So big data/ IoTs generated data specific design should be invented to handle these types of data.

B. Issues in Internet of Things

IoT system includes large number of nodes which should be identified uniquely in the network configuration. Since the IPv4 numbered addresses are about to exhaust, so we have to find a new addressing scheme like IPv6 to configure all IoTs devices. Further, different devices use different protocols to handle hardware/ software compatibility, this is also a major issue with IoTs. Hence, the lack of standardised tools for security, communication and identification need to be developed to make the IoT ecosystem efficient, accurate and safe (privacy preserved). In summary, information security and data privacy protection are two major concerns in IoT. Having highly complex, deployment, mobility and heterogeneous in nature, IoT always faces severe security and privacy threats. From [4] and above discussion, we conclude that "privacy protection in IoT environment is more vulnerable than in traditional Information and Communications Technology (ICT) network due to the large number of presences of attack vectors on IoT entities". A popular example can be discussed as: "IoT based health care monitoring system will collect patient's data (e.g., heart rate, pulse, body temperature, respiration, etc.) and later on send this information directly to the doctor's office or hospital via network (Internet)". As the time of data transfer over the network, if patient's data is stolen or misplaced serious risk may arise which can cause even death to the user. In such situation, it is noticed that most of the architectures do not include privacy, and security aspects into the respective concept which is drawback that needs to be clarified. Hence, as we have discussed in above sections that Data is collected or produced in raw form, i.e., consist non-relevant handouts. And this generated data is too helpful in decision making in several applications. The value of this collected/ generated data is only possible after analysis/ filtering process. So efficient and modern tools to analysis this collected data needs to developed. Also a commonly accepted service description language (which is compactable with different communication and implementation) must be identified to make the development process easier.

Hence, this section discusses several challenges in internet of things like heterogeneity, lack of unified infrastructure, lack of unified standards, huge data base, huge consumption of energy, etc. Some more work towards IoTs devices has been discussed in Table 1 (in appendix A). Hence, these issues, challenges can be considered as future work in near future from/ by respective interested researchers/ research community. Now, next section will conclude this work in brief (with some future scope of this work for future).

VIII. Conclusion and Future Scope

Today's internet of things are being used everywhere, i.e., in many applications (like smart home, smart transportation, smart farming, etc.) to make human life easier. Even some countries are insisting their citizens to use these devices, for example, in India, Amravati (new capital of Andhra Pradesh state) will be first smart city. Similarly, Dubai will work completely on smart things, i.e., as a smart city before 2022. So, as uses of these devices are increasing, attacks will also be increased in near future. This work provides a detail description of internet connected things. It also discusses some serious concerns and challenges in IoTs in near future. These investigated issues, challenges need to be overcome or require attention from research community. Also, major limitations of IoTs like Battery life extension and Lightweight Computation are also needed to be improved (for providing efficient, smart, and secure services for a longer-time). Hence, security at the device level, protecting the master-device, encrypting information/ communication links are critical to perform secure operations (among IoTs). In summary, we should improve existing methods to secure IoTs/ IoT ecosystem instead of searching for a new method. As future work, we should focus on delivering the current state-of-the-art security controls, and optimise the new and complex embedded applications to drive the further adoption of IoT (because integration of IoTs in several applications and in many counties is growing exponentially).

Appendix - A

Table 1: Challenges, Issues and Cyber-Attacks including Solutions in Internet of Things

S.No	Challenges	Issues	Cyber Attacks	Overcoming Solutions
1.	Security	As the IoT connected devices increases it will also increases the opportunity to exploit security vulnerabilities for an attacker	-	A collaborative approach to security will be needed to resolve this issue
2.	Privacy	The collection of this information exposes legal and regulatory challenges facing data protection and privacy law.	-	Strategies will need to be developed to respect individual privacy choices across a broad spectrum of expectations, while still fostering innovation in new technologies and services.
3.	Standards	Absence of the standards can enable stupid behaviour by IoT devices.	-	It requires a thoughtful design and standardization of configuration tools, methods, and interfaces, coupled with the adoption of IPv6, will be essential in the future.
4.	Home Invasions	IP address can be easily exposed easily, later location of residential address also can be leaked.	Hackers sold this information to the underground websites, to use this information for their business	-
5.	Remote Vehicle access	Car Hijack can be done easily	-	-
6.	Easy exposure	IoT devices are not resilient to third-party exposure — they either lay open or easily accessible to anyone.	This means that an intruder can either easily steal the device, connect the device to another device containing harmful data, or try to extract cryptographic secrets, modifying the programming or even replacing those devices with malicious ones in which the intruder has complete control.	-
7	Infrastructure	It requires large number of address schemes. Addressing schemes are used to identify with respect to identify sender's identification/ location, to provide security to devices.	-	-
8.	Data and Information	To handle and anlayze the data generated by the devices	-	Analytic tools is required
9.	Security and Privacy	Privacy related to personal data, and data sharing	-	-
10.	Ecosystem	It stimulate innovation and growth in areas such as components, devices, wireless connectivity, system integration and decision-support tools	-	-

A Performance analysis of Medical Image Transmission Based on Compression and Parallelism

Abstract:

In the period of creating advanced imaging system, it for the most part centres to improve demonstrative translation and computerized picture the executives. The advanced picture the executives include different handling steps: picture obtaining, picture preparing, and image storage and picture transmission. In the human services condition, computerized picture securing modalities particularly processed tomography and attractive reverberation imaging system produces complex experiences as far as picture stockpiling and picture transmission. This examination paper tends to these issues by proposing a picture pressure procedure alongside parallel transmission control convention which sets up relationship between two application elements.

An objective single compression ratio may not be suitable for CT and MRI datasets because of their different mode of image generation and bit depth and contrast resolution. From the results, it can observed that experiments over Local Area Network (LAN) and Wide Area Network (WAN) using parallel connection, transmission time is improved linearly to the maximum value and decreases to some extend and it reaches flat. The transmission time is highly influenced by use of type of networks. In this research, it can be concluded that for 10 parallel WAN connections achieves maximum speedup compared to LAN for the four datasets.

Keywords: Image storage, image transmission, transmission time, Compression ratio and parallelism

Research Background

Telemedicine is an interactive communication tool which is widely used by doctors to remotely monitor the health status of the patients. Today, almost all healthcare providers depend on high-quality digital images from digital image acquisition modalities for diagnostic interpretation. The image acquired from the computed tomography (CT) and magnetic resonance imaging (MRI) frameworks are digitized and transmitted to advanced PCs for picture preparing. The consequences of the prepared pictures are exhibited to the radiologists for screening and indicative translation [1, 2].

In a multispecialty emergency clinic,a standard Brain CT and Chest CT may create around 250 to 350 pictures and a normal Brain MRI and Spine MRI may likewise deliver 300 to 400 pictures. To store a CT or MRI picture, it requires a high extra room as far as Mega Bytes (MB). So as to store and spare every one of these pictures, it requires monstrous extra room which isn't monetarily plausible. In this manner, it is important to pack the picture so as to lessen the limit of capacity and diminishing the transmission time. Further, Computer systems have been broadly used to convey the computerized pictures to remote spots [3]. In a multispecialty emergency clinic, a normal brain CT and Chest CT may create roughly 250 to 350 pictures and a standard Brain MRI and Spine MRI may likewise deliver 300 to 400 pictures. To store a CT or MRI picture, it requires a high extra room as far as Mega Bytes (MB). So as to store and spare every one of these pictures, it requires tremendous extra room which isn't monetarily attainable. Thusly, it is important to pack the picture so as to diminish the limit of capacity and diminishing the transmission time.Further, Computer systems have been broadly used to convey the computerized pictures to remote spots [3]. In Image processing, there are two types of image data compression: a) Lossless or reversible, b) lossy or irreversible

compression. In lossless compression method, to provide the compressed image involves image transformation and encoding. In lossy compression method, to provide compressed image involves image transformation, quantization and encoding [4, 5]. Ramakrishan et al. [6] presented an approach to improve the speed of data transmission between DICOM application entities using progressive transmission. In this paper, a wavelet based set partitioning in hierarchical trees coder has been used which consumes minimum bandwidth than variants of JPEG. Standard compression techniques that were used for clinical is Joint Photographic Experts Group which was developed based on irreversible compression technique. Each compression techniques performance depends on mode of image generation and contrast resolution [7]. Kalyanpur et al. [8] determined that for a lossy 10:1 compression was most suitable for CT image transmission. The author has not estimated compression ratio for MRI images.

Maani et al. [9] proposed parallel connection between two DICOM application entities. Two interfaces were used for parallel data transmission. The results indicate that transmission time is accelerated to 14 times for WAN. The author has not concentrated to decide the ideal number of parallel associations and picture pressure systems. Maani et al. [10]

This research paper addresses these issues by proposing an image compression technique along with parallel transmission control protocol which establishes association between two application entities. Further to determine the optimum number of parallel connections over the LAN and WAN for the BREBIX and CARCINOMIX datasets.

This paper has been classified into four segments, first introduction, second discusses about the proposed method in this paper, third about experimental setup and results, and finally the work is concluded with future work.

DICOM PROTOCOL

The Digital Imaging and Communications in Medicine (DICOM) Standard specifies a non-proprietary data interchange protocol, digital image management format, and file structure for biomedical images. It defines the form and flow of the electronic messages that convey biomedical images and related information between two computers [11]

Fig. 1 DICOM as an application layer protocol

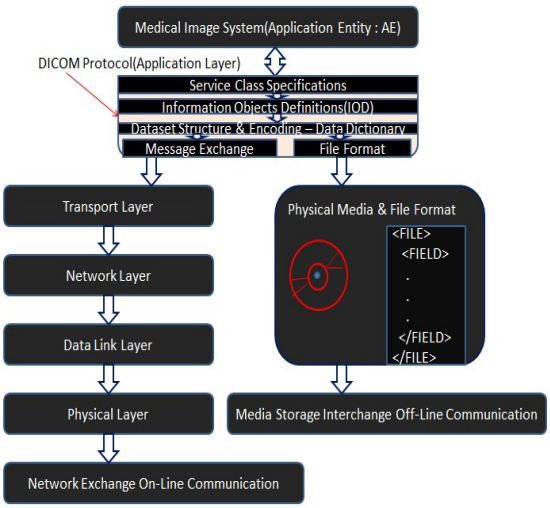

Fig 1

DICOM is an application layer convention and it's been related with TCP/IP convention suite that can be effectively utilized over the web is appeared in the figure 1.AE (application substance) is the application utilizing with the help of DICOM, AE can ask for or give administration rely upon the situation, SCU(serviceclassuser) means AE requesting services ,SCP(service class Provider) implies AE giving administrations to other applications. For

occurrences if DICOM application needs to discover picture in DICOM server. DICOM Application become SCU,DICOM server become SCP and DICOM FIND administration is the administration class.

The item occurrence by and large alluded data object definition(IOD) (e.g., a CT picture). The capacity or administration for the article (e.g., capacity) is called DICOM message administration component (DIMSE). Since each administration class called as an administration combined with an item, that is alluded as a Service–Object Pair(SOP).Sometimes two AE willing to begin imparting, that must be built up session. By and large session alluded as affiliation. After setup of affiliation the SCU sends solicitation to SOPs from the SCP. Once the SOP solicitation finished the affiliation is ended consequently.

PACS (Picture Archiving and Communication Systems) are restorative systems comprising of essential equipment and programming structured and used to run computerized therapeutic imaging. They contain computerized picture obtaining gadgets (modalities –, for example, figured tomography (CT) scanners, or ultrasound), advanced picture documents (where the gained pictures are put away), and workstations (where radiologists see the pictures). When you play with your advanced camera (methodology), store the pictures on your PC (document), and send them to your companions (analysts), you utilize precisely the same model. Obviously, PACS take the model to a significantly more mind boggling level as appeared in the figure. 2Fig 2 PACS Architecture

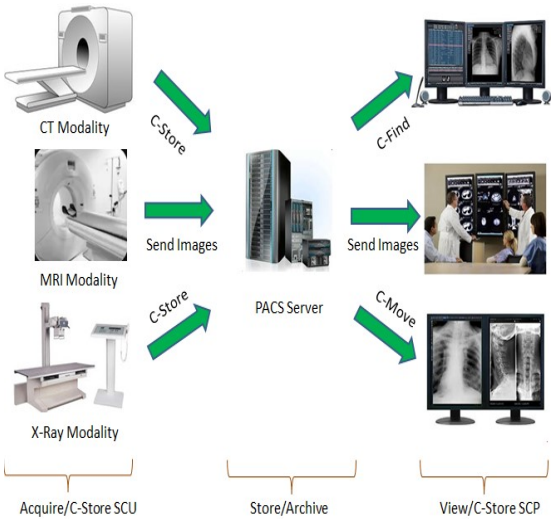

Fig 2

Data Image Compression

Because of their large volume of CT and MRI images, efficient compression techniques are necessary to reduce storage and bandwidth costs of medical systems. In this research, we modified the work of Zixiang Xiong et al. [2003]. In their exploration, proposed 3-D whole number wavelet change structure pursued by legitimate movements which accomplishes best execution as far as lossy and lossless pressure. In our examination we utilized blend of Integer wavelet change and 3-D set parceling in various leveled trees. To expand the coding effectiveness of 3-D SPIHT, every hub in the spatial-fleeting direction tree speaks to a gathering of wavelet coefficients. For a fixed picture measure, expanding the deterioration levels improves the pressure execution with wavelet change and 3-D SPIHT coding. The proposed pressure calculation of half breed blend of 3-D whole number wavelet change and 3 D SPIHT coding has connected to four diverse datasets; two distinctive CT pictures and two diverse MRI images[13-15]

Dataset Description:

In this research, we used four standard datasets for the evaluation of the proposed compression algorithm and image transmission. The description of the dataset is shown in the Table 1. In the

Table 1, it consists of four datasets namely, BREBIX,CARCINOMIX, MR BODY and MR BRAIN. The datasets BREBIX and CARCINOMIX consists of 1075 CT images and 539 MB uncompressed image data.

Table 1 Description of the experimental dataset

S. No	Name of the dataset	Type of Modality	Total number of images	Total volume of uncompressed data (MB)
1	BREBIX	CT	638	320
2	CARCINOMIX	CT	437	219
3	MR BODY	MRI	218	34
4	MR BRAIN	MRI	140	61

Table 1

Similarly, the datasets MR BODY and MR BRAIN consists of 358 MRI images and 95 MB volume uncompressed data images. The total dataset consist of 1433 images and 634 MB volume of uncompressed data images.

Data transmission using parallelism:

System Description

In this exploratory setup, LAN and WAN has been utilized to investigate the presentation of the system. So as to decide the ideal number of parallel associations, aggregate of 50 associations were consolidated in the examination. To find the mean speedup time, the experiments were repeated for 50 times on LAN and WAN. A sender system arranged with Pentium Quad center CPU and 8 GB of RAM running Linux Ubuntu. The recipient framework designed with a 4 Quad center CPU and 8 GB of smash running on Ubuntu OS.

Two interfaces are using for parallelize data transmission; each interface is located exactly where AE is located. Storage device carried out by interfaces; moreover only single connection existing between the AE and the interface. This method allows maintaining single association between the interface and AE that gives freedom to parallelize connection without increasing associations. The computer has both AE and interface and two interfaces are working using parallelism method, this can make use of available network bandwidth effectively, so we can easily increase the data transmission speed.

In many cases two interfaces using only one DICOM connection until otherwise AE sends storage SOP request. Here AEs plays either SCU or SCP at a time, but interface plays SCP or SCU based on sending or receiving data. For example AE1 request a MR image from interface1.AE1 is a SCU and Interface 1 is a SCP consequently interface 1 transfer the request to interface 2.Now interface 1 is SCU and interface2 is a SCP.Finally particular request is transferred to AE2 from interface 2.Here interface 2 is a SCU and AE2 is SCP.

In this paper Interfaces are implementing by using java language. Dcm4che is an open-source, which is used to implement DICOM protocol. The thread pool which is used to make TCP connections, but user must identify the size of the pool,(i.e.,)whenever an interface receives a message from the sender,type of sender must be checked. Generally interface has five main components receiver, sender to AE, and sender to interface, message interpreter, and thread pool**.**

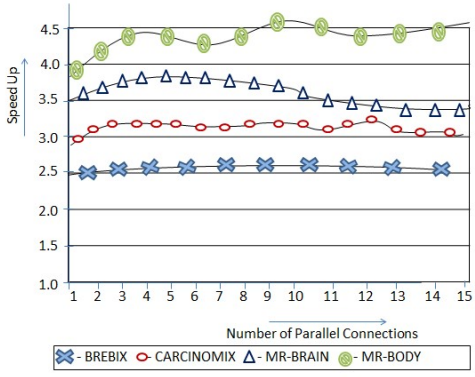
Experiments on LAN and WAN

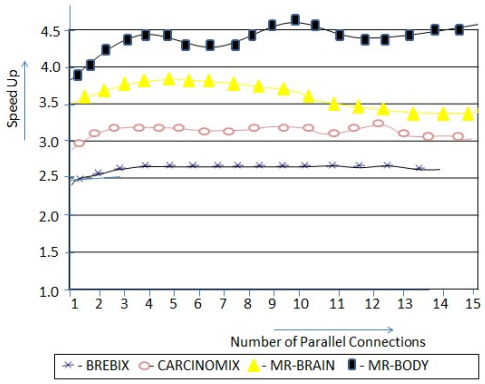
For the BREBIX dataset, this consists of only CT images, by adding six parallel connections to LAN, the transmission time has been improved for about 2.5 times. For the CARCINOMIX dataset, this consists of only CT images, by adding eight parallel connections to LAN, the transmission time has been improved for about 3 times. For the MR BRAIN dataset, this consists of only MRI

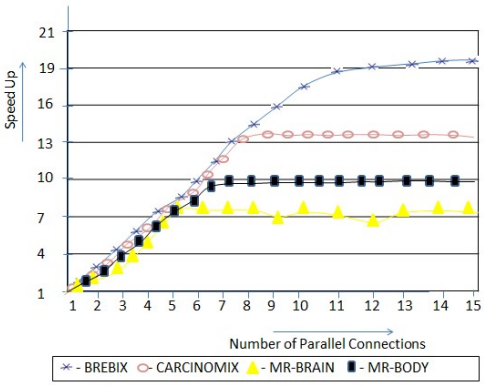
images, by adding four parallel connections to LAN, the transmission time has been improved for about 3.5 times. For the MR-BODY dataset, this consists of only MRI images, by adding ten parallel connections to LAN, the transmission time has been improved for about 4.5 times. By varying the parallel connections using trial and error method, it can be fixed optimum level of 6 parallel connections for LAN which reports mean transmission time about 2.5 times.

For the BREBIX dataset, this consists of only CT images, by adding fifteen parallel connections to WAN, the transmission time has been improved for about 19 times. For the CARCINOMIX dataset, this consists of only CT images, by adding 13 parallel connections to WAN, the transmission time has been improved for about 16 times. For the MR BRAIN dataset, this consists of only MRI images, by adding twelve parallel connections to WAN, the transmission time has been improved for about 8 times. For the MR-BODY dataset, this consists of only MRI images, by adding eighteen parallel connections to WAN, the transmission time has been improved for about 9.5 times. By varying the parallel connections using trial and error method, it can be fixed optimum level of twelve parallel connections for WAN which reports mean transmission time about 10 times.

Draw graph here







Results and Discussion

From the test results, it tends to be exhibited that straightly expanding the quantity of parallel associations, the speedup factor does not directly increments. In the wake of achieving an immersion level, speedup achieves level.When the number of parallel connections reaches almost constant and does not support to increase the speedup time, optimum use of parallel connections can be determined. Further, by increasing the number of parallel connections, both LAN and WAN adds overhead and reaches saturation and tends to decreases the speedup. From the results, it can be observed that compare with LAN, WAN uses relatively large number of parallel connections. It can also be observed that WAN performs better in terms of speedup. Maani et al [9] revealed the exhibition of the strategy for the long separation association on WAN was amazing and quickened the transmission time to around multiple times for the given dataset.

Further, Maani et al [10], reported the higher speed up for about LAN using parallel connection.

In this research work, we proposed an image compression technique along with parallel transmission control protocol which establishes association between two application entities. By using the combination of parallelism and compression, there is a relatively large improvement in the transmission speed up. By employing hybrid compression algorithm, it reduces storage space and network transmission time in both LAN and WAN.

Conclusion

In this exploration work, proposed a half and half pressure calculation alongside parallelism to improve transmission time of CT and MRI information picture. Structure the outcomes, it was shown that mix of half and half pressure calculation alongside parallelism improves moderately transmission time over both LAN and WAN. The speedup was about 2.5 for CT picture datasets and was around 10 for the two MRI picture datasets. From results, it demonstrates that there is a deviation of speedup in view of the CT pictures and MRI pictures. It can likewise be confirm that the methodology type assumes basic job in by and large speedup.

***Abstract*- Advanced driver-assisting systems (ADAS) performs a crucial role for the safety and ease of transportation. Finding of lane markings is an essential step of ADAS. For the protection of automated vehicles, the precise results of lane detection are compulsory. In this study, we present an innovative approach based on structural analysis of lane and Computer Vision Technique such as Hough Transform (HT) for the detection of lane markers. Firstly, a stage of preprocessing is applied to remove the pavement area that develops the lane markings background. Next, an edge detection technique is applied to generate the map of the edge and masking is performed to obtain edges in our region of interest (ROI). Then, using HT to find lanes, important lines are analyzed in the area of interest. In end, the concept of vanishing point used to predict lane has been explained. Experimental result states that the proposed system can find boundaries of the lane and exact lane departure alert in the existence of several image artefacts, such as light change, bad lane mark. The proposed technique displays more efficiency.**

Keywords- Advanced driver-assisting system, lane-finding, image preprocessing, ROI making, Hough transform.

I. INTRODUCTION

As per the report of World Health Organization [1], approximately 1.32 millions people die in traffic accident each year i.e., on average 3,288 deaths in a day [2]. Additionally 21-50 millions are disabled or injured. In India, at least 201,050 peoples dies every year as an outcome of vehicle accidents on the road acc. to the WHO [1]. Valued efforts should be build-up to promote the adoption of deed for road safety enhancement. The advanced driver-assisting system (ADAS) has caught the attention of several security/safety divisions and related researches nowadays. Using different variety of detectors install on vehicles to gain relevant facts from the inner and outer of vehicle. These facts are used to perform tracking, identification of dynamic object and various processing jobs. These systems permits driver to find out the probable danger so quickly, thereby increasing the safe driving. The precise detection of road lanes is a critical problem. Lane boundaries empower vehicles to remain into the right lane and to avert crashes or collisions.

A. Lane Detection

Lane detection, one of the most important areas of Computer Vision, finds its applications in driver support systems and autonomous vehicles. The lane marker is a traffic signal that looks for the car's primary driving specifications. A lane has well-defined geometry and when the road becomes clear, then detection of the lane can be trivial. However, lane marks in the natural environment are not always obvious. The factors that affect the clarity in lane detection include environmental and human factors like shadow of trees, poor weather conditions, bad road conditions or even poorly painted lane markings. Identifying road routes is a daunting action, especially in the existence of poor light situation. The lane finding plays a crucial role in both current unmanned driving and traditional assistant driving. To reduce the issue of detecting poor lane mark, robust lane finding and lane departure techniques should be used. The system of lane finding must be able to detect all type of markings from disorganized roadways and these markers should be filtered to produce reliable estimation of vehicle trajectory and position with respect to the lane.

B. Advanced Driver-Assisting Systems (ADAS)

Advanced driver-assisting systems (ADAS) are system that assist the driver in avoiding collisions and unwanted accidents by providing alerts and/or warnings whenever required, which enhance the well-being of vehicles. The development of autonomous or self-driving vehicles depends on the development of ADAS. ADAS has caught the attention of several security/safety divisions and related researches nowadays. Using different variety of detectors install on vehicles to gain relevant facts from the inner and outer of vehicle. These facts are used to perform tracking, identification of dynamic object and various processing jobs. These systems permits driver to find out the probable danger so quickly, thereby increasing the safe driving.

In this study, we present an innovative approach based on structural analysis of lane and Computer Vision Technique such as HT for the detection of lane markers. Firstly, a stage of preprocessing is applied to remove the pavement area that develops the lane markings background. Next, an edge

detection technique is applied to generate map of an edge and ROI masking is performed to obtain edges only in our region of interest. Then, using HT to find lanes, important lines are analyzed in the area of interest. In the end, the concept of vanishing pt. used to predict lane has been explained.

This paper is organized as follows. In Section II, we presents the related work. In Section III, we describe the proposed work. In Section IV, we present the simulation of proposed system and its results. Finally, in Section IV we presents the conclusion and future scope of the paper.

II. Related Work

Identifying road routes is a daunting task, the lane marker is a traffic signal that looks for the car's primary driving specifications. In the existence of diverse environmental and light conditions, strong lane finding and the lane departure technics should be applied to diminish the issue of detecting bad lane marks. Lane markers are shiny from the surface of the road, using this feature [5] propose the technique of finding lanes on the basis of horizontal {black, white and black} arrangement. Chiu and Lin [6] used colour-based partition to find out the edges that offer strong performance in the existence of noise, which disrupts the lane notation by the preceding vehicle. Depending on the angle information of the lane, the Lane Departure Identification (LDI) does not give less false warning ratio. In such a situation, different noise aspects [9] can affect its performance. Lane markings visibility is influenced by endangered. Lee et al. [10] introduced a lane boundary pixel extractor approach that maximize the durability of lane identification, that finding pixels to increases the LDI which are potentially component of the lane limitation. However, the optical center of the installed camera on a vehicle coincide with the centre of lane, which is an important condition. The main drawback of this approach occurs when the vehicles are presents infront of the camera that results more false output signals.

Many researchers suggest different image preprocessing techniques that are used to improve the accuracy of identifying lanes. These techniques are the examples of morphological processing to reduce noise; and to modify an image for the hue-saturation-value [12]. Canny edge detection technique [3] is used for histogram equalization [14], to produce single pixel wide edges [13], grayscale conversion and the application of a Gaussian low-pass filter to remove noise [16], filtering [8], clustering and polyline extraction [15], splitting, and smoothing of an image [17].

Parajuli et al. [21] using good local shield features and obtained good results. But, in the shadow this approach attains poor performance and generate less correct warnings. To recognize any arbitrary shape, HT is used which results strong performance in the various situation [18]. In this paper, HT is applied to find the lane lines derived from binary images [11]. The computation complexity of HT is optimal. Chi-Feng et al. [20] suggest the lane departure technology based on the angular relationship of lane boundaries, but it suffer from failure of proper identification and therefore, results less accurate. C. Mu et al. [22] propose lane identification technique on the basis of piecewise fitting and object segmentation. There is a problem of detecting false lanes in their study. In our methodology, HT technics is used for finding lane marker of road. While Euclidean's distance is applied to evaluate the parameters respective to the lane. On basis of those parameters lane departure recognition is gone through it.

III. Proposed Work

Most of lane markers are basically straight on the road, and there are some sharp tilt in the turn of the road. Therefore, in locating and tracking the lane, HT technique is employed for detecting the line and depict the lane's estimated position. Basically, there are 5 parts in our proposed method: Image Preprocessing, Edge Detection, ROI masking, Lane Detection, and Lane Departure Recognizer.

A. Block Layout

The block layout of our proposed methodology is described below in Fig.3.1.

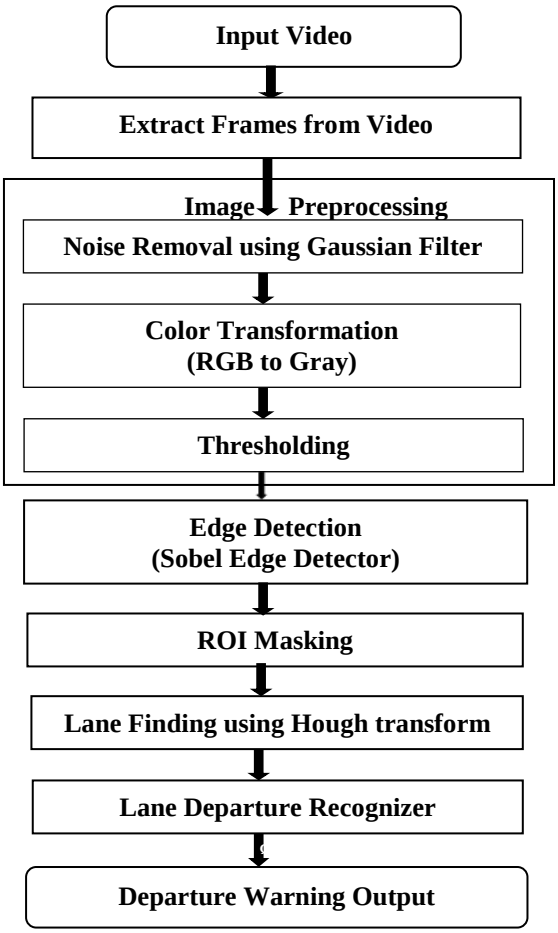

Fig. 3.1: Block Layout of Proposed method

B. Image Preprocessing

Pre-processing of the image is primarily to suppress the interference and to gain the meaningful information of image. In order to preprocess the image taken by the camera in actual time, primarily to remove the different noise of the image, color transformation technique like RGB to Gray, etc. includes.

1) Noise Removal using the Gaussian Filter

Firstly, the smoothing of input image is to be performed to diminish noise in the image. Image de-noising ensures that that in the image, noise does not interfere in any image processing in the future. To convert the input video frame to a filtered RGB image, use of the standard Gaussian filter in MATLAB having function imgaussfilt3() has done with the default sigma value of 0.5.
Here, comparison of before and after filtering shown below.

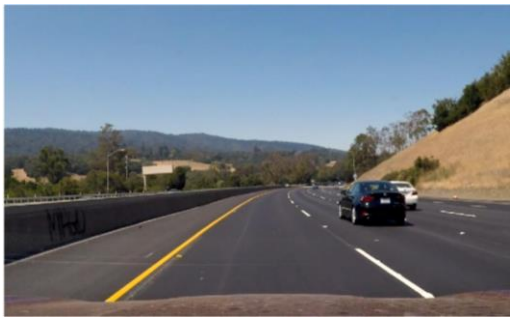

Fig. 3.2: Image before filtering

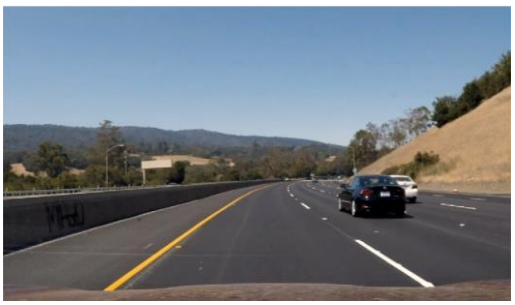

Fig. 3.3: Image after filtering

2) Color Transformation

Since the lane markers are tinted with yellow or white colour on the black road surface, it can easily be distinguished by the contrast between the border and the surface of the road. Therefore, while locating the lane marker, only Gray level components is to be considered. To transform the filtered RGB image into grayscale image, RGB to GRAY colour transformation function is employed. It alters the values of RGB image into grayscale by performing the weighted sum of R, G and B components is given by:

$$Y = (0.299 * R) + (0.588 * G) + (0.114 * B) \quad (1)$$

In addition, it must be taken into account that a mapping function has been configured essentially for grayscale images from RGB. Color component is more sensitive as compared to the Human vision system and the impaired critical information of visually is expressed by the luminance component(Y). The gray balance step on filtered RGB image as shown below:

Fig. 3.4: Grayscale Image

3) Thresholding

Once the grayscale image has been acquired, we do thresholding to create a binary image that improves the accuracy and speed of the lane finding system. This is done because the edge detector needs to have an input intensity image or binary image. We set any value higher than the pixel intensity of 180 (value obtained from test and error) to 0 (white). Thresholding helps in sections of the road made especially with concrete.

Fig. 3.5: Image after Thresholding

C. Edge Detection

The boundaries of the lane are marked with the edge. So, the edge detection is a fundamental step of lane finding system. In this step, output of the initial image processing is taken as an input in the edge detection technique. Now, we are ready to discover the edges in our image. There are many strong edge detectors namely sobel edge detector, canny edge detector, etc. available for detecting the edge. In this paper, use of Sobel Edge Detector to obtain map of the edges. The advantage of using the Sobel Operator, apart from the fact that it is computationally expensive, is that it can seek edges in the particular direction. This is more helpful for us because our lanes are vertically oriented in the image. Fig. 3.6 demonstrate the image obtain from the Sobel Edge Detector appears as an outline of the threshold image.

Fig. 3.6: Sobel Edge Detector Output

D. ROI masking

Applying edge detection on the entire image results in several extraneous edges which may hamper the lane detection when we later apply the Hough Transform. To deal with this we select a polygonal region right in front of the car as that's the region which we are interested in. We create a mask such that all the values within this are set to 0 and all values outside it are set to 1.

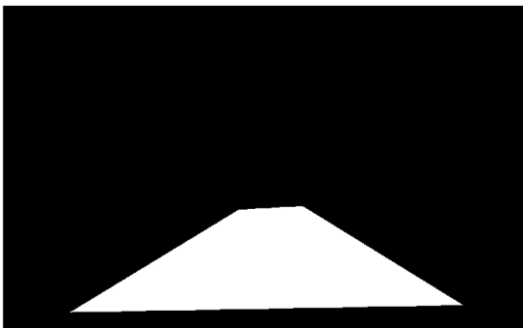

Fig. 3.7: Selected ROI mask

Now we apply this mask on our edge detection output to obtain edges only in our region of interest. Following, this we obtain edges only in our region of interest.

Fig. 3.8: Image after ROI masking

E. Lane Detection

Once we have our edges in the region of interest we can go ahead and find lines in that area using the Hough Transform. We used the Hough transform (HT) to find the lane because this technique is tolerant towards the interval in the feature boundary (such as partial blockage) and image noise. HT technique is applied to find the parameters of lane marking, which best fits to a set of pixels obtains from the detection of an edge [7]. Implementation of HT is given by [19]:

$$d = x_i \cos\theta + y_i \sin\theta \quad (2)$$

Where, θ = Angle between the normal line and the x-axis. And the range of theta is between 0° and 90°.

(x_i, y_i) = coordinate position of the i^{th} pixel.

d = Distance of the fitted line from the x-axis.

Hough transform is applied to a set of edge points (x_i, y_i) results in a 2-D function P(d, θ) which represents the number of edge points satisfying the (2) [19]. Whenever, equation (2) is computed for e, the value associated with the cell of the accumulator array determined by θ and resulting d are added by 1. The local maxima of P(d, θ) can be used to detect straight line segments passing through edge pixels. The below Figure 3.9 shows that detection of lane line and highlighting lane on the road using Hough Transform technique.

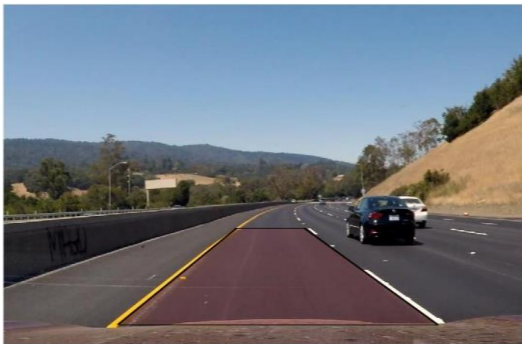

Fig. 3.9: Detection of Line and highlighting lane on the road

F. Lane Departure Identification Recognizer

1) Calculate Vanishing Point

We utilize the concept of vanishing point to predict if the lane is curving towards right or left, or going straight as shown in figure 3.10. We calculate the vanishing pt. by finding the point of intersection of our two lanes. Note that we only need the x coordinate of the vanishing point. This is done again by using simple geometry. By finding the equations of lines in point-slope form and equating them to obtain x. Our strategy will be to analyse the location of vanishingPoint of the image. If the vanishingPoint is close to centre of the image then the road ahead is straight, if it is on the left half on the image, then the road is curving right and if it is in the right-half of an image, then the road is curved on the left side. There's of course some thresholding to be applied as the car might not always be traveling at the centre of the road.

After trial and error, the following scheme was developed:

```
if vanishingPoint > 530
lanePrediction = "Right Curve Ahead"
else if vanishingPoint < 515
lanePrediction = "Left Curve Ahead"
else
lanePrediction = "Straight Ahead"
end.
```

Fig. 3.10: Lane Departure Identification Image of Input frame

2) Buffer of Vanishing Points

Simply using the vanishing point calculated at each frame to do lane prediction may not always give desirable results as there may be some frames where the lane prediction is a little tilted which hampers the calculation of vanishing point. To do this, a circular buffer was implemented which stores the vanishing points of the last 25 frames and calculates their average. This average value of vanishing points is then used to predict the direction of the lane. However, lane prediction on the patch where the road is not dark takes a hit.

IV. SIMULATION AND RESULTS

The simulation of our proposed methodology has been done using MATLAB R2017a environment. MATLAB stands for Matrix Laboratory and it is a very effective tool used by several researchers for simulation purposes. We simulated the basic lane finding system can find/detect boundaries of lane in the presence of various image artefacts, such as bad lane mark, light change and shadow of trees, and it demonstrate the exact departure alert for lane in small intervals. The comparison will be done based on higher detection and lower false alarm rates. The proposed system of working demonstrate higher efficiency percentage with almost all original input videos and produces higher detection and lower false alarm rates.

A. Simulation Parameters

The proposed methodology is implemented on the Intel based Core-i5 processor with CPU M3230 and 2.60GHz processing rate. Acquisition of data is being taken out using an input video sample and stable images in the real time scenario to examine the proposed system. Simulator platform specification details are given in the Table 4.1.

Table 4.1 Platform Information

Processor	Intel(R) Core(TM)-i5 CPU 3230M @ 2.60GHz
Processor cores	2
Memory	4 GB DDR III RAM
Compiler	Borland C++ Builder 6.0
Software tool	MATLAB
Resolution	1280 pixels × 720 pixels
Operating System	Windows 8
System Type	64 bit operating system
Frame Rate	30

There were a total of 1250 frames in the input video, whose resolution was 1280px × 720px and the speed of frame was 30frames / second. The size of the video input sample was 24.0 MB with the data rate of 4037kbps. This video contains several type of straight and curved lane regions.

B. Simulation Results

We simulated lane finding using lane structural analysis and Hough transformation technique in MATLAB simulation environment according to the parameters listed above in the table 4.1. The results are shown with the help of snapshots taken after simulation.

1) Input Frame Images

Figure 4.1 shows a set of original frame of video passed as input images of different types.

Fig. 4.1: A set of original frame of video passed as input images of different types.

2) Colour Transformation Result

Figure 4.2 shows the colour transformation result of filtered RGB images into grayscale images.

Fig.4.2: Colour change result of filtered RGB images in grayscale images

3) Thresholding Output

Figure 4.3 shows a set of images after applying thresholding operation on grayscale images.

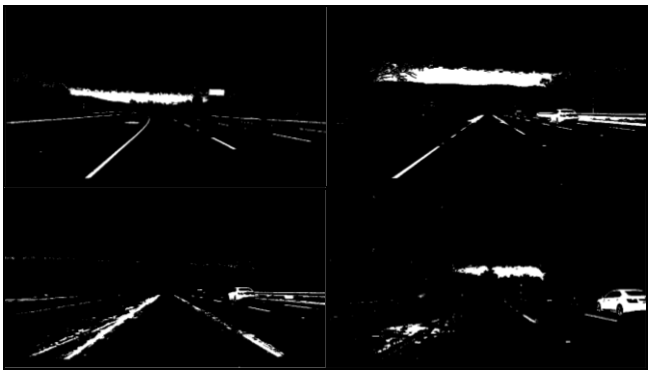

Fig. 4.3: Set of images after applying thresholding operation on grayscale images.

4) Deployment of Sobel Edge Detector

Images obtained from the Sobel Edge Detector are shown in Figure 4.4 which appear as the outlines of threshold images.

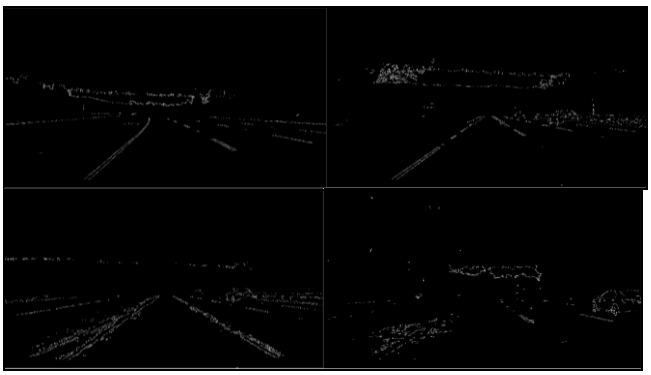

Fig. 4.4: Output images obtained from the Sobel Edge Detector

5) Masking with Selected ROI mask

Figure 4.5 shows a set of images after applying ROI masking on the output images of our Sobel Edge detector.

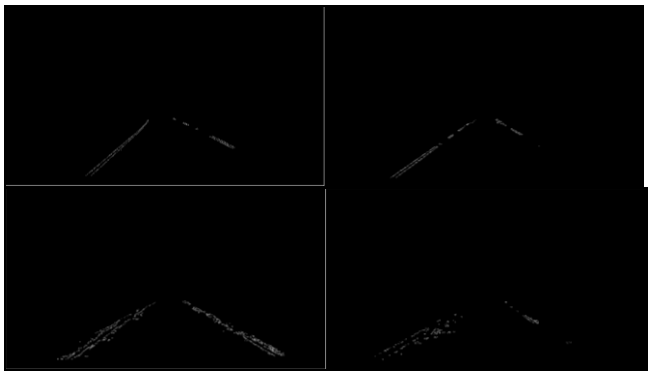

Fig. 4.5: A set of images after applying ROI masking

6) Lane Detection Output

Figure 4.6 shows a set of final outputs with lane finding and departure identification of original video frames passed as input images of different types.

Fig. 4.6: A set of final outputs with lane finding and departure identification of original frame

It has been shown that the proposed system identifies the lane signs correctly and in various cases issuing lane departure alert to the driver. Table 4.2 illustrates the false-alarm rate and lane detection rate by the proposed system for various input video.

Table 4.2 Experimental result of proposed system

Parameters		***Case 1***	***Case 2***	***Case 3***
Input Frame Resolution		1280 x 760	1280 x 760	1280 x 760
No. of Output frames		212	526	1250
No Departure		0	131	353
Left Departure		212	405	501
Right Departure		0	0	396
Lane detection	***True***	212	524	1024
	False	0	2	26
False Warning		0	35	103
True Warning		100%	93.35%	91.76%

The given system is compared to the lane departure identification (LDI) technique presented by Gaikwad and Lokhande [11]. According to the Euclidean distance based departure, LDI is introduced. Table 4.3 shows the comparison of these two techniques on the basis of average lane detection rate and false warning rate for day-time, night-time.

Table 4.3 Comparison of LDW technique presented by [11] with the proposed system.

	Proposed System		***LDW by [11]***	
	Day-time	***Night-time***	***Day-time***	***Night-time***
True Lane Detection	97.92%	99.97%	87.9%	94.1%
False Lane Detection	2.08%	0.03%	12.1%	5.9%
True Warning	94.9%	97.8%	90.4%	96.4%
False Warning	5.1%	2.2%	9.6%	3.6%

From the above Table 4.3, it is concluded that we can attains false-warning ratio is low and true lane detection is high with the proposed system.

V. CONCLUSION AND FUTURE SCOPE

This paper describes an innovative lane departure alert model based on the Sobel Edge Detector and Computer Vision Technique such as Hough Transform. Hough line recognition technique is simple as well as accurate; with this after adding the tracking algorithm the curve can be detected. To enlarge the contrast of input frame, Histogram equalizer method is applied in this proposed method. In Hough transform (HT) technics, there is an independent extraction of lane marking on the left and right side of the ROI subdivision. This will minimizes the time of computation needed to recognize the lane.

Practical outcomes show that the submitted lane-finding system provides the lane identification rate is high, 97.92 percent and the rate of false warning is low, approximately 5.1 percent. The whole system performs superb under various environmental situations such as night time, bad weather, and shade from trees or vehicles, however its functioning is mostly depends upon the road-lane markers visibility. When the vehicle direction gets distracted from its disappearing pt., then the driver is reminisce to take appropriate actions to receive the lane departure alert that can effectively prevent the happening of the accident. The biggest disadvantage is that the demonstration of lane identification is affected by the vehicle or other objects obstructing the lane markers in front of the vehicle and may be suffer from several interference. That's why, the identification of lane lines should be adaptable to different conditions.

In the future, more research is requisite to select the region of interest's (ROI). To detect the turns, we can also try to enhance the identification capability of the different curves by adding fitting technique. So, further research work on this should be done to build a more accurate lane finding system.

Abstract*— The minimum spanning tree is a fundamental problem in distributed networks. We wish to extend this problem into cognitive radio networks. In general, a tree spanner is minimum spanning tree T which has a real-weight with n vertex (or secondary user (SU)) and m edges. It approximately preserves distances to multiple stretch factor σ in graph G. A tree spanner with good stretch factor may be useful to find the applications in distributed system, communication network, and network design. However, to find valuable tree spanner in CRN is very tough computational task. If we face an edge failure due to randomly appearance of primary user (PU) in cognitive radio network (may be minimum spanning tree), the effort must be afforded to reconstruct a new minimum spanning tree can be excessive. To avoid this drawback, we propose an efficient algorithm in CRN. The method aims to lists all finest feasible edge and applies swapping of edges in order to find MST in CRN. Moreover, the article acquainted and resolved issues related to all finest swap edges of MST in a cognitive radio network.

Keywords*— MST, SU, PU, Cognitive Radio Network (CRN).

I. INTRODUCTION

Cognitive radio network (CRN) is a rising area of research in the wireless network. A cognitive radio is a creative communication system that senses it around and accommodate its internal seats for the statistical change within incoming radio frequencies signals by building comparable changes in a conversed operating parameter in a real time. The nodes present in a cognitive radio network are classified into two components: licensed user or primary user or PU and unlicensed users (secondary users or SU). The primary user node holds a license of a spectrum. The secondary users always cooperate the environment while came in influence on other using a white hole or free spectrum of primary user(s). The networks formed by SU nodes are temporarily available. The minimum spanning tree (MST) is a classic problem for efficient data communication in all the networks types. In CRN, the minimum spanning tree is maintained by SU nodes. In this, if some link fails then it may destroy tree, so we have to find the alternate link(s) to update or maintain the MST. A problem for evaluating the best swap edge for minimum spanning tree in cognitive radio network had a rich algorithm culture. Let suppose, $G = (V, E, w)$ represent a MST having n vertices and m edges (links between SU nodes) and a 2-way edge connected graph which is undirected and having a positive real number as edge weight. The problem is about computing a swap edge for every edge belongs to minimum spanning tree in a cognitive radio network. The edge e belongs to MST and f belongs to CRN (not belongs to MST). We intend to accomplish the edge swap between edge e with edge f in T throughout all the possible swap trees. In this context, the basic principles of all the best solutions based on switching edge are as follows. The edge swap operation is usually performed (possibly optimal) when a spanning tree for each time an edge failure occurs and hence a corresponding optimal switching edge is inserted. The approach may help us to reestablish the connection in minimum spanning tree in faster way.

The article is focuses on the elusive spanning tree structure that have all the best swap edge problem with the tree spanner. The purpose of building a tree spanner is to maintain the distance from each node to all other nodes in CRN. In fact, the stretch factor of a MST T in a cognitive radio network is define as $dT(u, v)/dG(u, v)$, where, u and v are SU nodes and dT and dG denoting the distance in T and G, respectively. Thus, a tree spanner which is optimal will show the smallest stretch factor for every spanning tree in CRN. However, finding best tree spanner is a typical task. Thus, if a given solution experience a temporary edge failure, recalculating from best solution is not easy.

Therefore, swapping edges in minimum spanning tree is more interesting and appealing, in general, and absolutely the all best swap edges-TS problem. The author derived two solution for the weighted and unweighted graph that are executing in $O(m^2 \log n)$ and $O(n^3)$ time, $O(m)$ and $O(n^2)$ space complexity, respectively. We presents to explore a latest algorithm that solves ABSE-TS (all best swap edges - tree spanner) problem in $O(n^2 \log^4 n)$,$O(n^2 + m\log^2 n)$ time and space respectively. The solution given by the authors improves time complexity of both the algorithm given [3] for weighted and unweighted graph whenever as $m = (n \log^3 n)$. The most important for the dense graph which is weighted, improvement is about quadratic in n. Moreover, the extensive analysis of cost has been focused in the literature [10]. For example, in CRN, if a given edge e fails, a single switching edge f results O (m) evaluation time cost in each pairs of CRN. The collection of tree edge can be used for the swapping purposes. In addition, one of the important advantages of edges f is that it elongates the availability of vertices and increases stretch width. Hence, both the previous approaches take (m^2) time.

To avoid cost related bottlenecks, the total number of vertices' optimal replacement edge may be greatly reduced by

the number of critical edge, if used. More specifically, for every *n*-1 edges in *T*, *O*(nlogn) is successfully reduce to the number of optimal swap edges candidate, and for each of them O ($\log^2 n$) check the possible critical. The main factors to achieve this goal are:

The centroid decomposition of spanning tree *T* consist of a logarithmic decomposition of all vertex of *T*. Using the decomposition, carefully, we combined with the series of preprocessing steps to accomplish all information with the all the nodes of tree. It helps to reduce the corresponding best swap critical edge candidate.

From the literature view, we noticed that the best use of decomposition to solve best swap link (edges) problem for a MST in CRN useful like in other environments. The stretch factor function is associated with an edge which are not belongs to MST. If an edge fails, the stretch factor activates the any other one from non-tree edges. The resultant edge is optimal that is used for edge swapping. A simple illustration of the centroid decomposition of a tree *T* corresponding to the first vertex of *T* are shown in figure 1. Thus, when we find the critical edges, candidate optimally rectified edge *f*, we must evaluate the maximum value of all functions in *f*. The given below figure 1 explains geometric view. We maintain the upper bound envelope of the series of function. Furthermore, for consistency, the series of functions need to be correctly grouped give to basic centroid decomposition. All these groups are dynamic, and they are completely interdependent. At the end of the tree decomposition, the networks find MST in CRN.

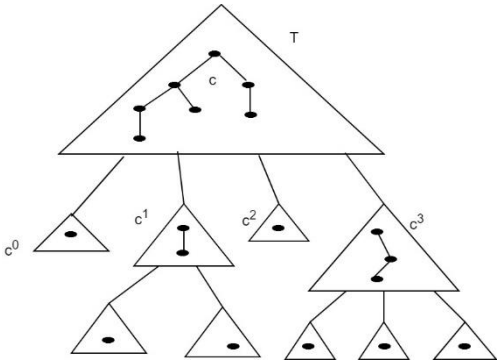

Fig 1. Centroid Decomposition of tree T

II. RELATED WORK

The explorations on these tree spanners are appropriately operative and strongly linked to extensive literature on spanner, where the distance of CRNs is largely conserved by some sparse spanning trees. As indicated earlier, finding the best tree spanner is very difficult problem. More accurately, if CRN does not tolerate tree 1-spanners on the weighting graph (i.e., if spanning tree having stretch factor = 1 must be built in polynomial time [9]). It is not approximated good than $\sigma = 2$ unless P = NP [16]. We propose a new algorithm for solving the Best_Swap_edges-TS problem in O ($n^2 \log^4 n$), O ($n^2 + m \log^2 n$) time and space respectively.

Thus, when $m = \Omega (n \log^3 n)$, our algorithm improves the execution of the two algorithms on time complexity explained in [3] applicable for both weighted and unweighted graphs. In order to focus on our results, observed in [10], evaluation of the expansion of exchange tree caused by a single exchange edge f is G in principle will need to be evaluated. An extension of the node pair associated with *O*(m), that is, all non-tree edge endpoints that can be used as replacement edges of e except f. Data structures that show effective solutions to all optimal exchange edge problems include Power Heap [6], Top Tree [3], Mergeable Heap [18], and many other issues. In fact, the Best_Swap_Edge-TS problem is analyzed in [10], and the authors used O ($m^2 \log n$) and O to design two solutions, weighted and unweighted uses the space of O(m) and O(n^2) respectively. For approximations there is no significant upper bound other than the O (n) coefficients returned by the G.

If CRN is not weighted, stuffs will get better. High accurately, in this area the problem approximately an *O*(log n) and problem is inaccessible with the addition of O(n) unless P = NP [11]. Furthermore, the determination of whether CRN tolerates the corresponding tree spanner and stretch factor tree decision problems is NP complete for each fixed stretch factor greater than 4 or equal to 2 may be resolve in polynomial time [9], and for stretch factor 3, problem is open till now. Decisively it is well known observe about constant stretch tree spanner that is found for some different categories of graphs (unweighted), such as strong strings, spacings, displacement maps, etc. ([7] and See the references in). With regard to the exchange problem in the exchange tree, this is drawing great attention from the algorithm community. In fact, there are series of papers that solve the swap edge problem from various types of spanning trees in CRN. In addition to MST we remember MDST (minimum diameter spanning tree), MCSRT (minimum routing costs spanning tree), and a single source SPT (shortest path tree) to name a few for MDST the best exchange is to minimize the end of the diameter of replacement tree [13] and [17], and the bests solution is to perform in $O(m \log \alpha (m,n))$ time [6]. For MRCST, the good exchange is absolutely an advantage to minimize the cost of switch tree [23] and a good solution to solve this type of problem in [5].

The authors propose two new standards to replace the SPT associated with this paper which minimize, maximum and average the stretch factors from roots for which they are valid in O($mn + n^2 \log n$) and O($mn \log \alpha(m),n)$) time solutions. In last, for well-being of completeness, reference is made to the notion of mean tree sigma spanner focusing on mean tree stretch. It is shown that each graph allows the mean tree O (1) spanner [1].

III. SYSTEM MODEL

We are assuming a cognitive radio network (considered graph G) having *V* nodes, *E* edges and weight w, which is 2 edges connected, weighted and undirected with a given cost belongs to real positive numbers. If edge *e* belongs to *E*, then we may stand for by $G - e$ achieved from *G* by eliminating the same edge. Alike, if vertex *v* belongs to *V* (*G*) then we may denote by $G - v$ achieved from *G* by eliminating the same vertex and its incident edges. With edge *e* belongs to *E*(*T*) we are assuming *S*(*e*) is the set of all the swap edge for *e* having

endpoint substitute in two distinct components (connected) of $T - e$. Let $T_{e/f}$ stand for *swap tree* obtained from T by exchanging edge e to edge f. Let node i, j belongs to V so distance between node i and j in CRN is represented by $dG(i, j)$. We are defining the *stretch factor* of pair (i, j) with respect to graph G and minimum spanning tree T as $\sigma_G(T, i, j) = dT(i,j)/dG(i,j)$. Where σ represent stretch factor and dG(i,j) represent distance between node a and b.

Notation	Detail
V and E	Set of vertices and edges respectively
S(e)	Swap edges of e
$T_{e/f}$	Tree after exchanging edge e by f
σ	Stretch Factor
ϕ	Objective function
T	Subtree of graph G
U_e	Containing all vertices of T-e including root of T
D_e	Containing all vertices of T-e excluding root of T
¬	NULL

IV. ALGORITHM DESCRIPTION

We consider minimum spanning tree T a rooted at any vertex which is useful and assuming that tree T is binary. Absolutely, if spanning tree T is not a binary it may be possible by using standard techniques to convert G and spanning tree T into its equal graph Q' and corresponding spanning tree S' (binary tree) with vertices and edges in Q' are n and m respectively such that a best swap edges for some edge of given spanning tree T is associated with best swap edge for a corresponding edge of corresponding T'. According to preprocessing steps we are computing a *centroid* of spanning tree T. A centroid of tree (n vertices tree) is a vertex by deletion of this vertex tree divided into subtrees of a size maximum $n/2$. In $O(n\log n)$ time centroid decomposition of T may be computed and it should be defined by tree T with height $O(\log n)$ whose vertices are indeed subtree. The root of T is T.

Algorithm: Best_Swap_Edges-TS(G,T)

1. $T \leftarrow$ Centroid of T;
2. foreach edge e belongs to E(T) **do**
3. $U_e \leftarrow$ all vertices of T – e;
4. $f^* \leftarrow$ random edge;
5. foreach v belongs to U_e **do**
6. compute v-Best_Swap_edges f for e;
7. if $\sigma_{G\text{-}e}(T_{e/f}) < \sigma_{G\text{-}e}(T_{e/f^*})$ then $f^* \leftarrow$ f;
8. return f^* as the best swap edge for e and continue.

Let $\mathcal{T}$ is a simple node of minimum spanning tree T (subtree of T) so that $\mathcal{T}$ contain higher in compare to single vertex and we are assuming c be the centroid of subtree $\mathcal{T}$. After-all T is binary and forest $\mathcal{T} - c$ contains not more than 3 tree that we may call T^1_c, T^2_c, and T^3_c (if $T - c$ generate not more than 3 subtrees then we may allow some T^i_c empty tree). Furthermore, assuming T^0_c is the subtree of T that contains a vertex c. Then, $\mathcal{T}$ will be in tree T a child for every subtree T^2_c, $i = 0$ to 3. In linear we can found the centroid of n vertex tree then the complete procedure desire $O(n\log n)$ complexity and looks simple to analyze tree height is $O(\log n)$. In this paper, solution (observe algorithm all best swap edges-TS) work in $n - 1$ phase for every tree edges considered in preorder with respect to T and at last of each phase return a best swap edge for the same edge. Let edge e belongs to $E(T)$ is recently considered edge. Our authors crack down each and every of the phase into $O(n)$ extra sub phase: where edge e is in the condition of failing, we favor all vertices that belongs to T-e tree, and for every vertex v. Edge f belongs to set of vertices form T-e and having the minimum stretch where stretch factor is $\sigma_{G-e}(T_{e/f})$.To resolve this approach of special cases any time we conclude that f is a random edge and stretch factor is infinite(+ve). As in the remaining part of this paper, basis of our algorithm is applicable for the evaluation of v-Best_Swap_Edges and for the stretch factor also. That is completely through an adept selection of the set of *candidates* v-Best_Swap_Edges as we should discuss in brief description in the next. Formerly all v-Best_Swap_Edges for edge e are computing some best swap edges that can observed as one that minimize a associated stretch factor. A best swap edge for e (v-best cut edge) is an edge f minimizing $\max g \in s(e) \phi(f,g)$.

Procedure: Find_v-Best_Swap_edges(x) // x is a subtree of T

1. If |V(x)| = 0 then return (¬,¬);
2. C← the Centroid of x;
3. if C belongs to U_e then;
4. $\mathcal{T} \leftarrow$ *distinct child of* x in T that consists all vertex common in x and D_e;
5. return Find_v-Best_Swap_edges($\mathcal{T}$);
6. else
7. f = minimize $w(f) + d_T(u,c)$; //c belongs to D_e;
8. g1 = evaluate a critical edge function for f;
9. $\mathcal{T} \leftarrow$ NULL or it is a child x in T;
10. $(f', g_2) \leftarrow$ Find_v-Best_Swap_edges(subtree x);

if $\phi(f,g_1) <= \phi(f',g_2)$ return $\phi(f,g_1)$; else return $\phi(f',g_2)$;

Now, we will resolve critical edge function in $O(\log^2 n)$ which find the critical edge for a given edge. If vertices in a subtree is only one, then the only vertex invokes critical candidate function which return a critical edge. If vertex is greater than one, then we differentiate two instances depending upon the centroid position of subtree x. if centroid of subtree x is belonging to D_e then it is noticed that critical edge for f should be incident to any of these tree (T^1_c, T^2_c, and T^3_c). Let j be a index selected from 0 to 3 and not belongs to i in (T^i_c) then critical candidate function return a critical edge g1 otherwise invoke the algorithm recursively and return critical edge for f.

V. CONCLUSION

The all best swap edges approach has been used to develop MST in CRN. The proposed algorithm allows minimum spanning tree to find all the replacement of links that may fails and maintain minimum-cost spanning trees in cognitive radio network. An effective solution for link failure issue runs in $O(n^2 \log^4 n)$ time which impacts definitely while swapping the failure edges in a minimum spanning tree. Moreover, the complete transmission structure of algorithm is relatively straight-forward. An attractive problem is open to find out whether it is possible to improve the space complexity of this algorithm.

***Abstract*—Memory is a component, playing a significant role in electronic systems. The use of static random access memories (SRAMs) is increasing in multimedia and system on chip applications. The key challenge faced by SRAMs is soft errors induced by the radiation that cause the change of values in memory cells. Error correction codes (ECCs) are used to face this challenge. As the technology is scaling down the chances of multiple bit upsets(MBUs) is increasing. So ECCs with higher correction ability are needed. Many ECCs have been proposed to face the challenge of MBUs. Some of them are SEC-DED codes, QAEC codes, FUEC-QUAEC codes. In this paper, we are presenting ECCs that has same redundancy as recently proposed FUEC-QUAEC codes [1] and can correct all the errors till 5-bit adjacent error. The procedure for encoding and decoding of proposed codes is presented. The encoder and decoder have been implemented using 45nm library and compared with QAEC codes, showing that proposed codes have better error correction capability with moderate delay over head and low power consumption than QAEC codes.**

***Keywords*—Static random access memory (SRAM), Error correction codes (ECCs), Multiple bit upsets (MBUs), 5-bit adjacent error**

I. INTRODUCTION

In reliability of memories, Soft errors plays the most prominent role. Soft error don't cause any harm to hardware, but instead they will corrupt the data which is being streamed. Soft errors are detected and corrected by using ECCs. Computer memories are very delicate to the soft errors, which reduces system reliability. Cells in memory may be corrupted by alpha particles projected from IC package material or high-energy neutron from terrestrial atmosphere [2].

When memories are continuously concatenated with electronic systems or even when CMOS technology scales down, the occurrence rate of soft errors in memory cells is abruptly increasing, mainly with the memories that operate in space applications [3] [4] and are caused from ionizing effects of atmospheric neutron [5], cosmic rays [6] and alpha-particle [7]. More importantly, SRAM memory failures are significantly increasing, which is leading to exposure of major reliability concern for most of the applications. Single bit upset(SBU) and multiple bit upsets (MBUs) both have became major reliability concern in memory based applications [8]. Therefore, error correction codes (ECCs) are used in improving the memory protection to make memory fault free.

Many methods are available to secure memory from soft errors. To keep away soft errors of single bit, Single Error Correction (SEC) codes are usually used. Moreover, as technology scales down, a single particle hit have the chance of changing multiple memory cells that are adjacent more commonly. This phenomenon leads to Multiple Bit Upset.

Based on this, we can say that adjacent bit corruption are most common error patterns in the set of multiple bit errors. So, the adjacent bit correction has become more popular in the memory based designs. Different codes have been presented, that have calibre of correcting adjacent bits errors like double bit adjacent error correction (DAEC), triple bit adjacent error correction (TAEC), 3-bit random error-correction, Quadruple adjacent error correction (QAEC) codes.

For example, codes designed for SEC-DAEC and 3-bit BEC are presented in [9] [10] and codes designed for QAEC are presented in [11]. Codes that are more advanced in terms of correction ability are required. So, extension of the ECCs to correct all errors till 5-bit adjacent errors is of interest. It can be done by adding two parity bits to the codes presented in [11] and with same redundancy to the codes presented in [1]. As we concentrate on increasing error correction capability, there will be trade-off between performance parameters [12].

In this paper, we present codes that can correct all errors till 5 bit burst error by making changes in the QAEC codes [11]. The conditions used for the construction of the parity check matrix and the algorithm used for the construction of the parity check matrix are specified. The codes are presented for data size of 16, 32 and 64. Encoding and decoding simulations are done in Verilog HDL and the synthesis is done in Cadence 45nm library. The proposed codes are compared with respect to area overhead, delay overhead and power overhead with QAEC codes [11] to show that the proposed codes have error correction ability for more number of bits with less power consumption and slightly high delay .
This paper is split into the VII sections. In sections II, linear binary block code is introduced. In section III, design rules for the proposed error correction codes are discussed. Algorithm used to construct the H-matrix is shown in section IV. In section V, proposed codes are presented for 16, 32, 64 bit data, encoding and decoding procedure is also discussed. In section VI, the proposed codes are compared with QAEC codes [11] with respect to area ,power ,delay overheads. In section VII, the conclusion and scope are presented.

II. DESCRIPTION OF LINEAR BINARY BLOCK CODES

In linear binary block codes there are two types- systematic and non systematic. The only thing differentiating them is that there will be an unit matrix at the beginning or the ending of the generator matrix in systematic linear binary block codes but there is no identity matrix in non systematic codes.

In a linear binary block code of size (n,k) there will be r redundant bits (r=n-k). Here n and k represents number of bits in the codeword and number of bits in the data respectively.

To convert data to codeword we use the generator matrix

$$G = [P, I_{k\times k}]_{k\times n} \tag{1}$$

Where I is unit matrix and P is some binary matrix of size kx(n-k). If D represents data and C represents codeword then

$$C = D_{1\times k}.G_{k\times n} \tag{2}$$

To convert the received codeword(R) to data we find syndrome using a parity check matrix H.

$$H = [I_{n-k\times n-k}, P^T]_{n-k\times n} \tag{3}$$

$$S^T = H.R^T \tag{4}$$

Where S represents syndrome and er is error vector.

$$R = C + er \tag{5}$$

$$S^T = H.(C + er)^T$$

$$S^T = H.er^T \quad (H.C^T = 0) \tag{6}$$

So by finding syndrome we will be able to find the error positions and correct the received codeword.

III. BASE FOR THE PROPOSED CODES

In this section we are going to discuss about syndromes.To correct errors, how many syndromes are required and what should be the characteristics to correct required errors.

A. Syndromes required:

Let us assume a codeword of size n in which data size is k and r is no of redundant bits-

$$n = k + r \tag{7}$$

In a code word of length n there will be n possible SBUs(—1—), (n-1) adjacent double bit errors(—11—), (n-2) adjacent triple bit errors(—111—), (n-2) 3 bit almost adjacent errors(—101—) and so on. similarly for a error of window size q there will be (n-q+1) possibilities of that type of errors in that code word.

In the proposed codes we are correcting all the errors till window size four and five bit burst errors. One type of error of window size 1, one type of errors of window size 2, two types of errors of window size 3, four types of errors of window size 4 and a five bit burst error fall into the above mentioned categories. To find each error we need one syndrome. So total no of syndromes required is

n+(n-1)+2.(n-2)+4.(n-3)+(n-4)

$$\text{total syndromes required} = 9(n) - 21 \tag{8}$$

TABLE I: CHECK BITS AND SYNDROMES NEEDED FOR PROPOSED CODES

Data Bits	Check Bits	Total Bits	Syndrome needed
16	9	25	204
32	10	42	357
64	11	75	654

B. Characteristics of syndromes:

In order to differentiate one error from another all the syndromes should be unique. Another important thing about syndromes is that, no syndrome representing an error that need to be corrected, should not be equal to zero. Because no error condition will give a syndrome equal to zero. This can be understood by getting the idea on how syndromes in the syndrome set are generated.

The syndromes are generated by XOR operation of the columns corresponding to the error positions. Let S(a) represents syndrome for an error at position a in the codeword, S(a,a+1) represent errors at position a and a+1, S(a,a+1,a+2) represent errors at position a, a+1 and a+2. The syndrome equations that are used in this paper are

$$S(a) = H(a) \tag{9}$$

$$S(a, a+1) = H(a) \oplus H(a+1) \tag{10}$$

$$S(a, a+1, a+2) = H(a) \oplus H(a+1) \oplus H(a+2) \tag{11}$$

$$S(a, a+2) = H(a) \oplus H(a+2) \tag{12}$$

$$S(a, a+1, a+2, a+3) = H(a) \oplus H(a+1) \oplus H(a+2) \oplus H(a+3) \tag{13}$$

$$S(a, a+3) = H(a) \oplus H(a+3) \tag{14}$$

$$S(a, a+1, a+3) = H(a) \oplus H(a+1) \oplus H(a+3) \tag{15}$$

$$S(a, a+2, a+3) = H(a) \oplus H(a+2) \oplus H(a+3) \tag{16}$$

$$S(a, a+1, a+2, a+3, a+4) = H(a) \oplus H(a+1) \oplus H(a+2) \oplus H(a+3) \oplus H(a+4) \tag{17}$$

The conditions for the syndromes are-

$$S(a) \neq S(a, a+1) \neq S(a, a+1, a+2) \neq S(a, a+2) \ldots. \neq S(a, a+1, a+2, a+3, a+4) \tag{18}$$

$$S(a) \neq S(b) \tag{19}$$

$$S(a, a+1) \neq S(b, b+1) \tag{20}$$

$$S(a, a+1, a+2) \neq S(b, b+1, b+2) \tag{21}$$

.....

$$S(a, a+1, a+2, a+3, a+4) \neq S(b, b+1, b+2, b+3, b+4) \quad (22)$$

where a$\neq b \forall a, b \in [1, n]$

IV. CONSTRUCTION OF PARITY CHECK MATRIX FOR THE PROPOSED CODES

Parity check matrix, H matrix is a matrix which describes the linear relations to find the elements of a codeword. In order to construct H matrix for (n,k) systematic linear binary block code, initially we need to consider an unit matrix of size (n-k) as the H-matrix. So, there will be $((2)^{n-k})$ possible column vectors. Since we have already used (n-k) column vectors of weight one in construction of the initial columns of the H-matrix and cannot use zero column vector in the construction of the H-matrix. So, finally there will be $((2)^{n-k}$-(n-k)-1) column vectors remaining to choose other k column of the matrix. In order to reduce the complexity of the code, we need to reduce the number of ones in H matrix. So to do that, while selecting a column, we start checking whether that column vector is suitable or not from lower weight column vectors. We start checking vectors with weight two and once all the column vectors with weight two are checked, we move to weight three and once all them are checked and then we increment weight by one. This process happens at the selection of each column for the H-matrix. In order to verify whether a column vector is suitable for that position or not, we need to find the syndromes that will be generated for the corresponding column vector at that position and compare the resultant syndromes with the syndrome set. If none of the resultant syndromes generated by adding column to H-matrix are not present in the syndrome set, then that resultant syndromes will be added to the syndrome set and fix the position of the corresponding column in the H-matrix and move to find the next column of the H-matrix. While search for a^{th} column of H-matrix, if all the column vectors are failing to satisfy the satisfiability condition then we remove the $(a-1)^{th}$ column of the H-matrix and all the syndromes corresponding to $(a-1)^{th}$ column will be removed from the syndrome set and Again searching for the $(a-1)^{th}$ column starting from column weight two.

The search process here will be similar to other column vector search except that it doesn't consider the previously used column vector at that position. once it finds a column

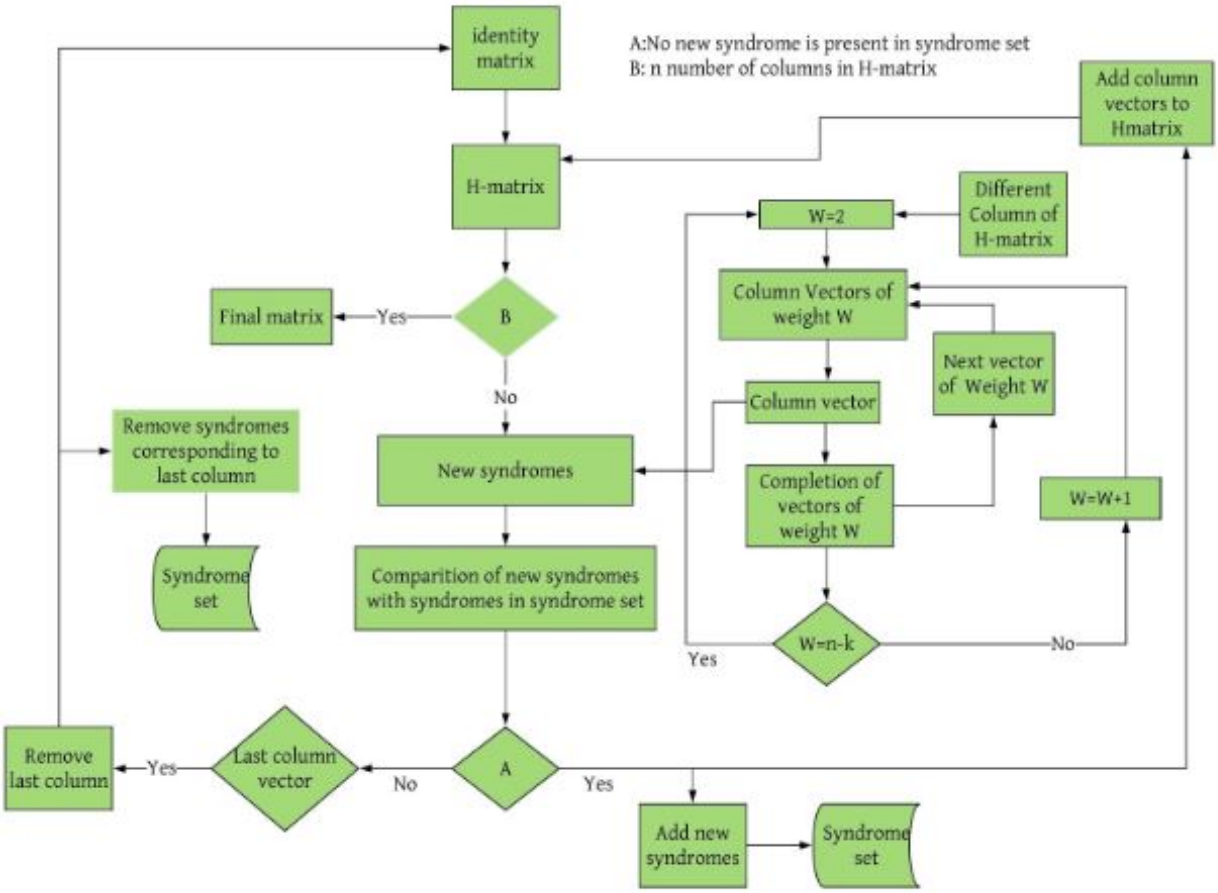

Fig. 1: Flow chart for generation of H-matrix

TABLE II: PERFORMANCE OF PROPOSED CODES W.R.T TOTAL NO OF ONES AND HEAVIEST ROW

Code	(n,k)	Total no of ones	Heaviest row
Proposed codes	(25,16)	51	8
QAEC Codes [11]	(23,16)	54	9
Proposed Codes	(42,32)	91	12
QAEC Codes [11]	(40,32)	96	14
Proposed Codes	(75,64)	178	25
QAEC Codes [11]	(73,64)	186	22

vector and adds its syndromes to the set then it moves to the a^{th} column and continue this process until H-matrix has n columns. The flow chart of this process is shown in Fig.1

The total ones in a parity check matix gives how complex the circuit used for encoding and decoding are, the heaviest row indicates the highest time taken to find a checkbit.

From the above TABLE II, We notice that the proposed codes have less no of total ones than the QAEC codes and the size of the heaviest row of proposed codes are also less compared to the QAEC codes except for the 64 bit data. So the circuit of the proposed codes is less complex when compared with QAEC codes.

V. ENCODING AND DECODING FOR THE PROPOSED CODES

By using the procedure mentioned in section IV, we have found codes that can correct single bit (..,1,..), double adjacent (...,11,...), triple adjacent (...,111,...), 3-bit almost adjacent (...,101,...), four bit adjacent (...,1111,...) and other 3 patterns with window size 4 [(...,1001,...), (...,1011,...), (...,1101,...)] and 5-bit adjacent (...,11111,...) error patterns for 16, 32, 64 bit data.These patterns represent a stream of data, where 1 represents the error of the data at that position. The H matrix for (25,16), (42,32) and (75,64) codes are given in Fig.2, Fig.3, Fig.4 respectively.

$$H = \begin{bmatrix}

\end{bmatrix}$$

Fig. 3: Best parity check matrix for (42,32)

To explain how encoding and decoding works, Let us consider a data $D(D_1\ D_2...D_{15}\ D_{16})$ of size 16. First we need to find check bits for the given data D.

From the H-matrix shown in Fig.2, we get the following equations to find the check bits for 16 bit data

$$C_1 = D_5 \oplus D_9 \oplus D_{13} \tag{23}$$

$$C_2 = D_1 \oplus D_6 \oplus D_{10} \oplus D_{16} \tag{24}$$

$$H = \begin{bmatrix}
100000000000000000000100001000001000100000001000000000001000000100010001001\\

\end{bmatrix}$$

Fig. 4: Best parity check matrix for (75,64)

TABLE III: COMPARISON OF PROPOSED CODES TO QAEC CODES

		Encoder			Decoder		
Data Size	Code	Area(nm^2)	Delay(ps)	Power(mW)	Area(nm^2)	Delay(ps)	Power(mW)
16	Proposed Codes	127	689	0.011	1171	4899	0.081
16	QAEC Codes [11]	123	1124	0.013	797	4184	0.089
32	Proposed Codes	252	1091	0.026	2243	5440	0.174
32	QAEC Codes [11]	269	1316	0.032	1695	5030	0.181
64	Proposed Codes	521	1761	0.069	4314	6002	0.371
64	QAEC Codes [11]	522	1373	0.077	2850	5808	0.366

$$C_3 = D_2 \oplus D_7 \oplus D_{11} \oplus D_{12} \oplus D_{15} \quad (25)$$

$$C_4 = D_3 \oplus D_{12} \oplus D_{14} \quad (26)$$

$$C_5 = D_4 \oplus D_8 \oplus D_{12} \oplus D_6 \quad (27)$$

$$C_6 = D_1 \oplus D_9 \oplus D_{11} \oplus D_{15} \oplus D_{16} \quad (28)$$

$$C_7 = D_2 \oplus D_6 \oplus D_{10} \oplus D_{11} \oplus D_{14} \quad (29)$$

$$C_8 = D_3 \oplus D_7 \oplus D_8 \oplus D_{13} \oplus D_{14} \oplus D_{15} \oplus D_{16} \quad (30)$$

$$C_9 = D_4 \oplus D_5 \oplus D_8 \oplus D_{10} \oplus D_{12} \oplus D_{16} \quad (31)$$

By using the above equations we find the check bits and add them in the front part of the data to form a codeword $C(C_1\ C_2...C_9\ D_1\ D_2...D_{15}\ D_{16})$ and the code word will be stored in the memory.

When a alpha particle hits the memory, the content of some bits will get flipped [13]. Let us assume that the data is flipped at positions 8, 9, 10, 11 and 12 in codeword. When we are retrieving data from the memory cell, we receive the codeword as $R(C_1\ C_2...C_7\ C_8^{'}\ C_9^{'}\ D_1^{'}\ D_2^{'}\ D_3^{'}\ D_4...D_{15}\ D_{16})$

Next we find syndrome $S(S_1\ S_2...S_8\ S_9)$

$$S_1 = C_1 \oplus D_5 \oplus D_9 \oplus D_{13} \quad (32)$$

$$S_2 = C_2 \oplus D_1^{'} \oplus D_6 \oplus D_{10} \oplus D_{16} \quad (33)$$

$$S_3 = C_3 \oplus D_2^{'} \oplus D_7 \oplus D_{11} \oplus D_{12} \oplus D_{15} \quad (34)$$

$$S_4 = C_4 \oplus D_3^{'} \oplus D_{12} \oplus D_{14} \quad (35)$$

$$S_5 = C_5 \oplus D_4 \oplus D_8 \oplus D_{12} \oplus D_{16} \quad (36)$$

$$S_6 = C_6 \oplus D1^{'} \oplus D_9 \oplus D_{11} \oplus D_{15} \oplus D_{16} \quad (37)$$

$$S_7 = C_7 \oplus D_2^{'} \oplus D_6 \oplus D_{10} \oplus D_{11} \oplus D_{14} \quad (38)$$

$$S_8 = C_8^{'} \oplus D_3^{'} \oplus D_7 \oplus D_8 \oplus D_{13} \oplus D_{14} \oplus D_{15} \oplus D_{16} \quad (39)$$

$$S_9 = C_9^{'} \oplus D_4 \oplus D_5 \oplus D_8 \oplus D_{10} \oplus D_{12} \oplus D_{16} \quad (40)$$

Syndrome generated : $S_1\ S_2\ S_3\ S_4\ S_5\ S_6\ S_7\ S_8\ S_9$.
Now the syndrome will be compared with XOR operation of different combinations of columns of H matrix and when they match, it takes the position of the columns that gave XOR operation equal to syndrome, as the error position in the given codeword and flip the bits at the position and take last 16 bits of codeword as data. Received codeword after decoding is $R(C_1\ C_2...C_7\ C_8\ C_9\ D_1\ D_2\ D_3\ D_4...D_{15}\ D_{16})$. so data is $D(D_1\ D_2...D_{15}\ D_{16})$.

VI. EVALUATION AND COMPARISON

The proposed codes are compared with QAEC codes presented in [11] and the potential benefits of the proposed codes are discussed in this section. The modeling of encoder and decoder is done in Verilog and synthesized in Cadence 45nm library.

The comparison of the codes is done on the basis of redundancy and complexity, area, delay and power overhead. The TABLE III shows the comparisons on area, delay, power overhead.

In terms of redundancy the proposed codes has redundancy greater than QAEC codes [11] by 2 but the complexity of the proposed codes is less than the QAEC codes [11]. Which can be seen from the total no of ones and heaviest row in H matrix in TABLE II.The proposed codes can detect and correct all the errors till window size of 4 and 5 bit adjacent errors but the QAEC codes given in paper [11] can only detect and correct all the errors till window size of 3 and 4 bit adjacent errors.

With respect to other performance parameters For 16 bit data the area on the encoder side is increased by 3.25% and decreased by 6.31% and 0.19% in 32 and 64 bit data respectively. While the area on decoder side have increased by large percentage for the proposed codes by 46.924%, 32.3%, 51.36% for 16, 32, 64 bit data respectively. On the encoder side the delay of the proposed codes have decreased by 38.7% and 17.09% for 16,32 bit data respectively but increased by 28.25% for 64 bit data and on decoder side the delays have been increased by 17.08%, 8.15%, 3.34% for 16, 32, 64 bit data respectively. The power consumption of the proposed codes is decreased by 15.38%, 18.75%, 10.38% for 16, 32, 64 bit data respectively on encoder side and decreased by 8.9% and 3.864% on decoder side for 16, 32 bit data respectively but increased by 1.36% for 64 bit data. The above percentage changes are with respect to QAEC codes [11].

As summary, the codes with advanced correction ability presented in this paper comes at the cost of increased redundancy but the complexity on the encoder and decoder side is decreased as the total number of ones in the parity check matrix of proposed codes is less than that in the QAEC codes [11]. And as for area, it has increased but since the Area of ECC is much small when compared with total memory, the increase of ECC area is not much significant. From the percentages comparisons made in the above paragraph we

can clearly see that overall delay of proposed is slightly higher and the power consumption of proposed codes is less when compared with QAEC codes [11].So the proposed codes correct more errors and consume less power with moderate increase in delay when compared with QAEC codes [11].

VII. CONCLUSION AND SCOPE

This paper proposes new error correction codes that can correct all errors till 5 bit adjacent error by which reliability is increased. The proposed codes have a redundancy greater than the QAEC codes by two. The codes for the 16,32,64 data bits have been presented.The proposed codes are enforced in Verilog and synthesized in Cadence for 45nm library. The addition of ECCs means introducing delay, power and area overheads. The area overhead of proposed codes is almost same as that of the QAEC codes [11] on the encoder side but they have increased on the decoder side. While the delay overhead of the proposed code is much less on encoder side but it has slightly increased on the decoder side when compared to the QAEC codes [11]. The power consumption of the proposed codes is less than the QAEC codes [11]. Therefore the propounded codes can be used to correct MBUs in application where the power consumption, reliability and delay are the major factors. The proposed scheme can be extended to correct more conditions in 5 bit errors patterns without increasing the redundancy.

Abstract: Moving data and computation to the cloud is a promising technology in recent years. As the device density increases in the connected world, proper storage in the traditional cloud without security threats is a cumbersome task. Modification and leakage of data is the major threat in adopting cloud computing. Intelligent technologies are needed to safeguard against cyber-attacks. Fog paradigm enables users for data storage, management and network functions closer to them. Fog server introduced as a middle layer between user devices and the cloud to provide more security for uploaded data. It collects and transfers the encrypted data from the user, and apply reed Solomon code for error detection and MD5 hashing for malicious message detection to ensure more security and integrity. This data will be stored in different cloud servers and respective user's fog devices. Thus the combination of cloud with fog computing will ensure integrity, availability and confidentiality of users data.

Keywords: Fog computing, Cloud computing, Security, Encryption, Cyber-attacks.

I. INTRODUCTION

The cloud provides immense data storage and computation facility at low cost. Due to its on demand nature with low cost and zero maintenance cost features, organizations move their data and computation facilities to it. It consists of several servers and storage facility which are installed at huge data centers located at different places. It offers IT resources like storage, processing power, networking solutions, software, etc. It have many advantages like on demand, pay per use, rapid elasticity etc. While we are adopting cloud, the data is stored not in the local disk, but in the remote cloud datacenters.

However, day by day number of connected devices is increasing and they are using cloud computing for storing and managing their data. When technology and devices of internet of things are more occupied in peoples' life, present cloud technology cannot satisfy their needs like mobility support, low latency, intermittent network connectivity etc. It is also noted that cyber threats also increasing day by day. To fulfil these requirements, we need more intelligent distributed architecture like fog. It is an embryonic distributed architecture and it brings functions for computing, control, storage and networking closer to the end user devices. It chucks out the delay between the cloud and end devices connected to it. Usually fog computing is happening very near to the devices deployed. Data from these devices first pass to fog node and then to the cloud. The fog acts as a middle layer between things and the cloud. The system with fog nodes is considered as a three layer architecture as shown in the Fig. 1. Bottom layer consists of end devices and the things. Middle layer consists of fog nodes and cloud is considered as the top most layer.

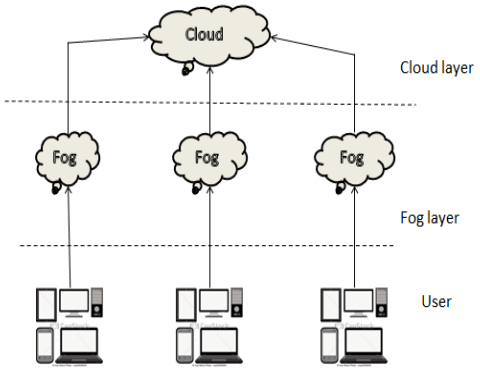

Fig.1. Three layer fog architecture

The fog [4][8][12]concept is a computing paradigm similar to cloud. A fog node can handle a large volume of data along with computing and management functions. Like cloud fog deals with heterogeneous services with different requirements. Hence, data can be store and processed at fog to avoid delay in computation. The data, device or application control functions for end user systems like control manufacturing systems, vehicles etc., can be handled by a fog node. Thus a fog node can act as an alternative of cloud nearest to the user rather than a remote cloud.

The cloud users are more concern about the data they stored at remote location. Fog can be used to enhance the security of data which is stored under cloud. It can also perform integrity checking when a user downloads the data from the cloud. In this paper a hybrid cloud-fog model is implemented to enhance the data security. It also enhances the number of data block handled at time to the cloud, since the computation is done at the fog node. The rest of this paper is organized as follows. Related works in this area is discussed in section II. Detailed system design is given section III and implementation details are given section IV. Analysis and conclusion are given section V and VI respectively.

II. RELATED WORKS

The vide adoption of cloud computing raises several new problems in this area. Data security is the most important issue in adopting a cloud platform for the end users. In this section, we will introduce these researches and analyses the advantages and weaknesses of them. Various security problems in adopting the cloud are discussed in [2]. There are several encryption methods available for data security in cloud, especially Advanced Encryption Standard (AES) [18]. Fog can apply to many fields like smart grids, connected vehicles, Internet of Things (IoT) and software defined networks. Fog forensics doesn't have a problem with bandwidth which is present in cloud forensics. The problems related to fog computing is mentioned in [5]. In order to simulate resource management scenarios and scheduling policies in fog computing various tools were invented like ifogSim [9]. Characteristics, applications, and security issues of fog computing are also discussed in paper [13][14].

The paper [3] proposes a third party auditing method to check the integrity of data. The users have to send a request to the third party auditor. The auditor is responsible for checking the integrity of data and he will prepare a detailed report and send to the user. But sometimes third party auditor may act as malicious. Another method discussed in [4] uses a trusted authentication, authorization, data encryption, hashing and key management technique. It makes use of both symmetric and asymmetric algorithms and One Time Password (OTP). But the problem is that OTP is not confidential at all. The paper [19] discusses a method to secure the data shared among social networks based on the cloud. User will encrypt and decrypt data using private and public keys. Then data first send to a proxy server. It will re-encrypt data using AES algorithm. Before send to another user it pre-decrypt data. Here group key manager is used to provide the public key, private key and symmetric key to the users and proxy server. Several authentication schemes for private cloud environments based on time stamp, one time secret password and nonce based approach are presented in [20]

A fog security mechanism in the healthcare system is tested with a decoy system [15]. In this a decoy medical big data is created at the fog layer to make attackers believe that it is the original data. But the original data is stored in cloud layer which can be only accessed by authenticated users after user profiling. Fog security mechanism is successfully used in IoT systems [16]. In this method fog layer is used to reduce latency. An authentication mechanism for fog-IoT computing using block chain technology is introduced in paper [17]. Here block chain is used for the authentication between fog and end users and also between fog nodes.

III. SYSTEM DESIGN

The proposed design is three-tier architecture as shown the figure 2. The bottom layer is device or things layer which consists of end devices and users. The data generated from this layer is transferred to middle layer. Middle layer consists of many fog nodes.

A. System Design

The problems with centralized cloud are data security and the transmission delay [1][11][18]. To tackle these problems, we propose a system which includes fog computing which have a several fog nodes between things and the centralized cloud. Here the data from the sensors are transferred to fog nodes. At fog nodes, there will be a series of security mechanisms to ensure the privacy and integrity of data. Fig. 2 shows the system design of the proposed approach. First, fog node accepts the data generated from the devices. At fog, the user data undergoes encryption. Here the AES [6][10] algorithm is used which is shown in Fig. 3.

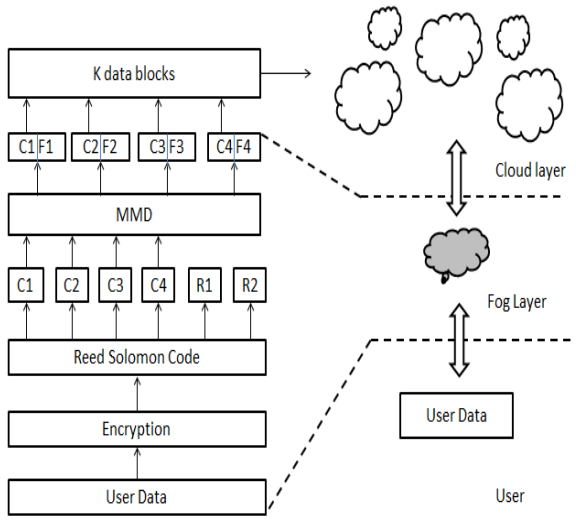

Fig. 2. System Design

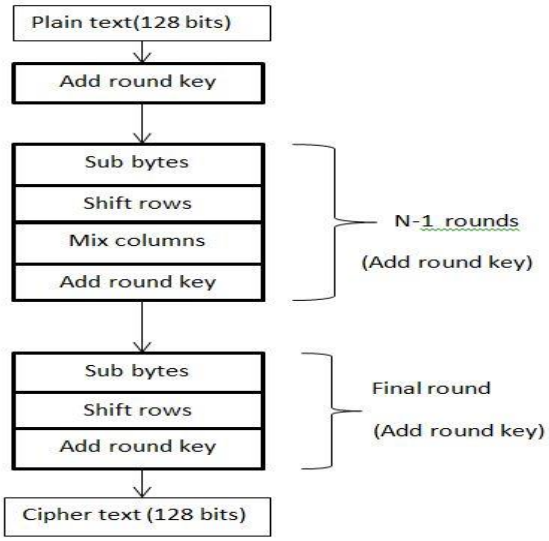

Fig. 3. AES encryption

Step 1	Generate an encoding matrix which have identity and vandermonde matrix.
Step 2	Multiply the user data with the encoding matrix. It generates $k+m$ data blocks.
Step 3	Upload or transfer data to the receiver.
Step 4	At the time of downloading, check whether it contains full data. If yes then exit,else go to step 5.
Step 5	To recover the full data, find the encoding matrix of remaining pieces of data. Let it be matrix X.
Step 6	Find the inverse of matrix X.
Step 7	Multiply the inverse of matrix X with remaining pieces of data to reconstruct the original data.

Fig. 4. Steps for reed Solomon code

After encryption, reed Solomon code [8] mechanism is applied to generate different data blocks. In this process, it generates $k+m$ data blocks, k is number of data blocks and m is the redundant data blocks. The steps are reed Solomon code is given Fig. 4. For experimental purpose, we have chosen k as 4 and m as 2. To this k data blocks, message digest 5 (MD5) [7] is applied to generate fingerprints to ensure the integrity of data. Redundant data blocks and fingerprints are then uploaded to fog and the remaining data blocks into different cloud servers. Usually, user's data is stored in only in one cloud location. But when that cloud service provider is under threat, entire data stored in it is also under threat. To avoid this problem this paper used a fog-cloud combination to store parts of data in a reasonable proportion. One of the advantages of this scheme is that, it can reduce the transmission delay. Because, fog situates very near to the end users. Cloud can't be used for the applications which need latency less than some milliseconds. This problem can be tackled with fog computing, since the transfer rate between fog computing layer and other layers is faster than the rate directly between cloud layer and the bottom layer.

Sometimes, attacker can modify the user's data. User and cloud service provider will be unaware of it. To address this issue we have used MD 5.

B. Uploading

If a user wants to upload files, the fog node takes it as an input and encrypts it using AES algorithm. After encryption, reed Solomon code mechanism is applied. It generates $k+m$ data blocks where k is the real data blocks and m is redundant data blocks. Then MD5 algorithm is applied on each data blocks to generate fingerprint. It is used for integrity checking of data. These fingerprints and redundant data are stored on fog and remaining data into different data blocks. The uploading process is shown in Fig. 5.

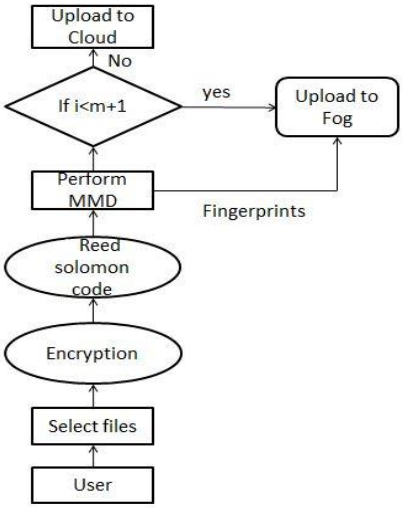

Fig. 5. Uploading

C. Downloading

When downloading a file, to ensure that there is no data change is happened, MD5 is applied for modification detection. Then a fingerprint is generated based on the downloaded data. This fingerprint and the already stored fingerprint at the time of uploading are compared with each other. If any change is found, we can recover the lost data through inverse reed Solomon code mechanisms. But as a worst case scenario, sometimes the amount of errors may be greater than the limit of error that can be recovered. In this case, the only way is to delete the data and give negative feedback about the cloud service provider. With this scheme,

we can improve the performance and the competition between cloud service providers. Fig. 6 shows the process of downloading.

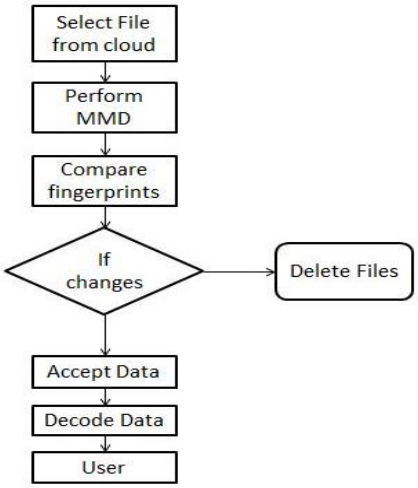

Fig. 6. Downloading

IV. IMPLEMENTATION

The proposed method is implemented using laptop as fog nodes and mobile phones as IoT devices. These devices are connected through Wi-Fi and Bluetooth. The data from a user reaches to the specific location of the laptop which can act as memory of fog Node. In this node security mechanisms like encryption, error detection and correction and integrity checking are carried out. Here Google drive is used as cloud and *k-1* data blocks uploaded to it and remaining redundant data blocks and data blocks stored in fog itself. At time of uploading, an identification number (ID) is generated for each data blocks. These ID and message digest of each data blocks are stored in the database for further checking. Encryption is applied to this file and this file will undergo reed Solomon code and generate 6 files, i.e., 4 data files and 2 redundant files. Output of the uploading process is shown in figure 7. From figure 6, we can see that file is divided into 6 parts and for each data block, MD5 checksum is generated and inserted the file name and its checksum in to the database. At the time of uploading, an ID is generated and this is also stored in the database. Here 3 blocks are uploaded with unique ID.

Next process is downloading of data stored in cloud. First we need to download these files into fog with the ID generated at the time of uploading which is stored in the database. From fog, the data undergo integrity checking with MD5 hash. After that, if there is no error, then data undergoes reed Solomon and AES decryption to decode and decrypt data. The change in data can be happen in two ways, one is from inside the cloud. Second one is at the time of transfer of data from cloud to fog. The change of data can be data loss or data modification. If data loss is happening at inside the cloud, data cannot be downloaded with the id generated at the time of uploading. Malicious modification also gives the same situation. In the next scenario, if the data lost at the time of transfer, lost data can be recovered with the reed Solomon code. Otherwise, if data is maliciously modified, it can be detected with MD5 comparison. Modified data is deleted and whole data is recovered with reed Solomon code. Figure 8 shows downloaded files from cloud and its MD5 hash also compared. New MD5 hash is generated for downloaded data. This hash is compared with the previously stored message digest of the corresponding data blocks which is stored in database.

V. ANALYSIS

Experimental evaluation and analysis consists of different parameters. First one is the performance of uploading and downloading, when the number of data blocks (*k*) increases.

Second one is the traffic analysis. It shows the amount of data needs to send to cloud with fog and without fog. Last one is the delay and it shows the time need to complete the process with fog and without fog.

A. Performance

Performance of the system is tested by varying the value data blocks (*k*). Time taken to upload and download is recorded. Here number of redundant data blocks fixed as 2. Table 1 show that, when number of data blocks increases, time taken to upload and download is also increases. In case of uploading, for bigger the value of *k*, time to upload is also increased. This is due to increased complexity of the security matrix. When the value of *k* increases, the complexity of encoding matrix is also increases. Thus, the security of data increases. In case of downloading, for larger value of *k*, the downloading time is high.

TABLE 1. PERFORMANCE

k	Upload time (ms)	Download time (ms)
4	16684	7846
5	17364	9348
6	18170	9516
7	19904	10549
8	23480	10874
9	23672	12480
10	27794	12984

B. Traffic Analysis

Table 2 compare the traffic to cloud with and without fog. For the experimental purpose the data blocks *(k*) is taken as 4 and redundant data block size (*m*) as 2. A fog node have substantial amount of data storage capacity. In this system, redundant data blocks remains in the fog and only *k-1* data blocks are uploaded to the cloud. Without fog entire data need to send to the cloud. For our experiments were conducted with small amount of data. But in real time, amount of data will be huge. It is also noted that in years, with the intervention of IoT, the data transmitted from end devices will increase drastically. At that time, cloud cannot afford this big data and it causes delay. Fog reduces the amount of data to be sent to the cloud which reduces traffic.

TABLE 2. TRAFFIC ANALYSIS

Data Size (KB)	With Fog (byte)	Without Fog(byte)
8	8192	6159
10	10240	7695
12	12288	9231
14	14336	10767
16	16384	12303
18	18432	13839
20	20480	15375

C. Delay

The table 3 and 4 shows that time taken to upload and download takes more time when fog is present but it is not much significant. This is justifiable due to the enhanced security mechanisms implemented at fog nodes. In this proposed work, data first pass to fog then only to the cloud. The fog takes a little time to process data i.e., to apply the proposed security mechanisms to data. The time taken at fog node is not much significant. Even though upload and download time is less for without fog implementation, but data traffic is more, which is to be further investigated.

TABLE 3. UPLOAD TIME - WITH AND WITHOUT FOG

Data Size (KB)	With Fog (ms)	Without Fog (ms)
8	16871	14955
10	16746	14223
12	16035	14854
14	17206	15833
16	16479	15900
18	16873	15472
20	16138	14011

TABLE 4. DOWNLOAD TIME - WITH AND WITHOUT FOG

Data Size (KB)	With fog (ms)	With fog (ms)
8	9657	8601
10	9340	8904
12	9204	8897
14	9851	9016
16	10218	9735
18	9695	8492
20	10735	9612

VI. CONCLUSION

Cloud computing is distributed and scalable architecture with massive storage capacity at low cost. But data loss and modifications are serious issue in adopting cloud as computation platform. The fog computing offers distributed computing, that officers control, data storage, and networking functions closer to end user devices. The proposed method provides security through cloud-fog integration with reed Solomon code and MD5.This enhanced method improves the security in cloud data storage. Here the Reed-Solomon code used to correct errors original data. It generates different data blocks and redundant data blocks. For each data blocks, MD5 is applied, which is used to generate fingerprints. These fingerprints and redundant data blocks are stored in fog and remaining data blocks are stored in to different cloud. With this cloud-fog hybrid storage technology, we can avoid cyber threats like data loss and malicious modification. By this way, the proposed technique can ensure the integrity, availability and confidentiality of data. As future scope, we can develop

more secured data encryption and error detection algorithms based on block chain technology to use in fog.

Abstract: **This thesis presents a development and implementation of a remote controlled car (RC) for surveillance purpose and the whole system is controlled from anyplace from the world by Smartphone accelerometer. The work was led by establishing Wi-Fi communication between RC car and Smartphone. After setting up the network connection between RC vehicle and Smartphone, the vehicle can be controlled by just tilting the Smartphone by using remote IMU application that is installed in android phone. This application uses accelerometer, gyrometer and magnetometer for linear and rotational movement of car. The values from this application are sent to the Raspberry Pi through UDP protocol. For the surveillance purpose and to navigate the area while controlling the car remotely we used pi camera that is joined to the vehicle. The test was carried on the RC vehicle with four directions. Directions are 1) Left 2) Right 3) Forward 4) Backward.**

Keyword: IMU, Accelerometer, RC car, Surveillance, Smartphone.

I. Introduction:

Research on mechanical autonomy has continued for a very long while. In spite of unique presence, robots offer a typical mechanical and movable structure. A robot utilizes sensors to see nature. Buyer robots will in general have microcontrollers along with restricted computational power and little measures of memory. Sensors for customer robots are additionally very expensive. In expansion, it takes micro controller assets to deal with these mounted sensors. With the progress of modern day Smartphone innovation, many regular sensors are officially implanted in a Smartphone [1]. The best preferred standpoint of utilizing a Smartphone is that it allows user to drive their vehicle away from their true location. Now days there are various accessible articles concentrating the advancement of correspondence models between a Smartphone and a machine. A modern Smartphone has numerous advantage (for example computerized compass, accelerometer, sound, mouthpiece and camera) and numerous helpful communication interfaces (for example Wifi, Bluetooth, etc.). There is no uncertainty that smartphone phone processors have higher processing power and large memory than the basic miniaturized scale controllers. This propels us to include a Smartphone into remote control vehicle in request to handle complicated tasks and progress the general execution. In this examination, we actualized a different directing agenda with Smartphone movement control. The general implementation of the proposed framework is assessed by activities that we planned. Our proposed work can be utilized in Surveillance purpose.

In light of the situations portrayed above, we present a versatile surveillance system that runs on raspberry pi. Raspberry pi drive the vehicle which is remotely connected with the client by means of the android application. A control board is additionally given through the remote IMU application introduced in the Smartphone that uses accelerometer and gyroscope to drive the car wirelessly by just tilting the Smartphone in the desired direction. Accelerometer are made up of multiple axes, two to determine most two dimensional movement with option of 3D positioning [2]. Most Smartphone typically make use of three axis model. We measures the values of 3 axes based on the phone movement. Figure1 shows the X, Y and

Z axis of Smartphone. X, Y and Z axis orientation relative to the device remain constant.

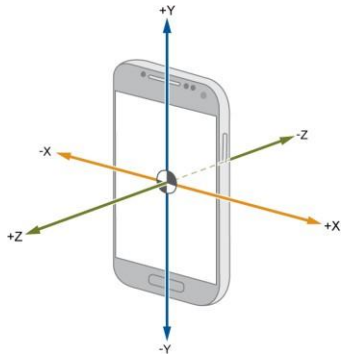

Figure1:Smartphone Accelerometer Axis

For rotation of car we use gyroscope. Rotation measured in rad/sec around the the X, Y, and Z axis of the gyroscope relative to the android device. For any positive axis on the device, clockwise rotation output negative value and vice versa. For example if we place the device up on table and spin it clockwise, then the block output is negative value for the z axis. Figure 2 shows the gyroscope axis orientation. Based on the sensed value of accelerometer and gyroscope movement of the vehicle is determined.

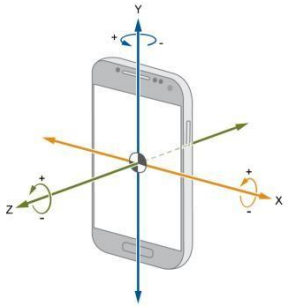

Figure 2: Gyroscope Axis Orientation

.

This paper proposed a prototype of remote controlled car which gets control of movement from Smartphone tilting position with greater control of car, while navigating the car from remote location. Steering of car using web interface key is not able to gives proper control of car, especially when one wants to slow down the speed or want to take slight turn of car they are not able to do. So our aim is to find proper solution to this context. The rest of this thesis is arranged as follows. Segment II describes the several work regarding the design and development of remote controlled car. Segment III describes the architecture of proposed work. Segment IV describes the working mechanism of the proposed work. Segment V talks about the result and segment VI presents the summary of this work.

II. Similar Work

There are various work has been done related to the remote controlled car for the various purposes. Paper [3-5] developed remote controlled car that is controlled by computer via a parallel port and controlling command is voice and facial expression. Computer convert this voice command/face image to the digital signal and then converted to radio signal and accordingly car takes decision for their movement . The Yuxinzing presents RC car using Arduino and Android communication for search mission. This system named AndroRC that require two separate Arduino Board (Mega and Uno) for RC unit. Due to the use of servo motors for turning, the speed is constrained for four directions [6]. A vision based obstacle avoidance algorithm for a low cost and off-the-shelf electronics has been implemented, where this algorithm is fast and works with very low resolution image. Ultrasonic sensor is widely used in mobile applications for measuring distance, which helps in detecting obstacles. A system was implemented using ultrasonic sensor and infrared sensor intended to help the elderly and people with vision impairment [7]. Another system proposed by R. Manduchi is a system based on stereo range measurements, for obstacle avoidance [8-10]. K. Dumbre presents a robotic vehicle for surveillance purpose that is embed with automatic arm that can be utilized to catch and shift things wherever required and it is controlled via keyboard [11]. G.Pavani and V. Kadiam presents Smartphone operated RC car using Raspberry Pi [12].

III. System Structural Design

In this work hardware that we used are connected as figure 1. These figure include Raspberry pi, picamera, L293D Dual H- bridge IC and RC car structure.

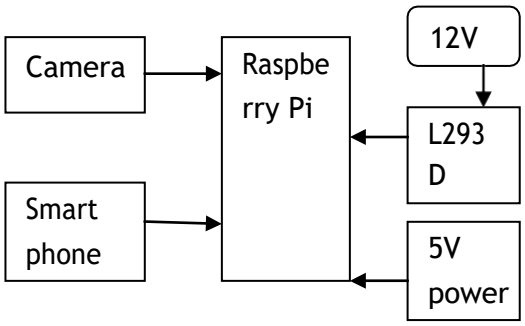

Figure 3: Block Diagram

A. Raspberry Pi B3

Raspberry pi is the heart of this system. Raspberry pi is used in this work because of its low cost, small size, compatible for most of the high language programming and that can be plug in to computer or TV. It is capable of doing many things like it acts as desktop computer, browsing the internet, game, word processing etc [13].

B. Motor control

Here we used L293d motor driver IC to control motor of rc car. Normal DC geared motor require current greater than 250 – 300 mA. ATMEGA16 microcontroller gets damage because they cannot supply this amount of current, so we need circuit that acts as a bridge between motor and microcontroller. Hence L293D IC acts as bridge between microcontroller and motor of RC car[14].

L293D IC is a dual H- bridge motor driver IC. Using this we can manage the direction of rotation of motor in both clockwise and anti-clockwise direction. Figure 2 shows the connection with DC motor.

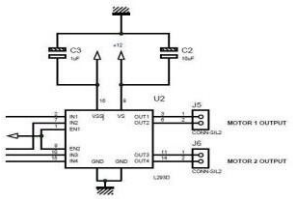

Fig 2: Circuit diagram of L293D and Motor connection

C. Drive Algorithm

RC car gets direction of movement according to the phone position with respect to the accelerometer axis. Accelerometer gives two outputs one for horizontal direction means left or right direction and other for vertical direction means forward and backward movement. Hence to drive the car according to the accelerometer value we need to set some range of rotation of phone with respect to accelerometer axis, for movement of car in these four directions. So for our work we set these values for x and y. Table 1 show the value of x and y relative to the position of phone.

Table1: X and Y coordinate Relative to accelerometer axis

Direction of movement	X – axis	Y – axis
Forward	X >= 3	-3 <Y< 3
Backward	X <= 3	-3 <Y< 3
Left	Y >= 3	-3 <X< 3
Right	Y <= -3	-3 <X< 3

Each output of accelerometer ranges from 1v to 2v. An ADC within the pi converts the outputs to digital signal and transmitted to the motor driver, there it decide direction of movement of car and accordingly car moves.

IV. Working Mechanism

This section describes how the work has been implemented. Whole work is divided into various phase.

A. Hardware Assembly

We connect Raspberry Pi with four geared motor using L293D module. For powering up the Raspberry pi we used power bank and to power geared motor we used 12v rechargeable battery. After assembling of wheels and geared motor into the chassis structure look like the figure I.

Figure I: RC car

L293D IC is used to drive the dc motor in any direction. It works on the principle of H-Bridge, that allows voltage to be flowing in any direction. It has four input which is trigged by raspberry pi. Connection of motor IC as below

GPIO7 – IN1

GPIO11 – IN2

GPIO13 – IN3

GPIO15 - IN4

GND Raspberry Pi – GND L293D

12 v of Raspberry pi - Enable pin

To make the car run forward pin 7 and pin 13 must be ON and other two pins are OFF, similarly to run backward pin 11 and pin 15 must be ON and other two are OFF. Now to run the car in left direction pin 13 is ON and other are OFF. To run the motor in right direction pin 7 is ON and other pins are OFF. For live video streaming we connect Pi camera to raspberry pi.

B. Setting Up the Raspberry Pi

To install the Raspberry pi several things are needed for proper functioning of Pi. Table 2 shows the needed device for the first time booting of Pi.

Devices	Details
SD Card: It is recommended to use at least 8GB class as the card will be installed with the Raspbian Image.	
HDMI/DV input : Work as a display for the pi.	
HDMI input will be the best result .	
Keyboard and Mouse: Any standard keyboard and mouse will work perfectly	
Power Supply: Pi is powered using USB micro power supply that gives at least 2A at 5v. Lower current like 700mA will work for basic usage. However pi will reboot if the power is drawing too much	

Table 2: Device needed for first time boot of Raspberry pi

First phase in setting up the Pi by placing the SD card with Raspbian(via NOOBS) into the micro SD card slot of the Raspberry Pi. Now plugged the keyboard and mouse into the USB port, and then turned on the monitor or TV. After that, plugged the HDMI wire to the monitor/TV, and then hooked the other end of the cable into the Raspberry Pi. Now it's time to give power supply to the raspberry pi, it turned on and boot up raspberry pi. A power indicator light now began to shine. Now downloaded and install the Raspbian operating system on the raspberry pi. When the warning window pops up, clicked yes to confirm. Once the installation process is finished, raspbian automatically began to reboot. Under the menu bar that is on the top left corner of screen, pick the preferences in the dropdown menu, then pick the raspberry pi configuration and in the configuration tab sat the location, time zone and keyboard language. Then again reboot the pi [15-16].

C. Wi-Fi Arrangement

Pi was configured to communicate automatically with the chosen network [17]. Two file that are network interface and wi-fi protected access (WPA) were edited using script editor to enable Wi-Fi. In this we have used a nano script editor which is easy to use. Pi has its own IP address. This prototype provides distinctive feature, where controller is allowed to control the vehicle by a remote controller that is placed at a distant far away from the vehicle location but remote controller should be connected with the network as the Pi connected. There are some techniques that can be use to activate this special feature. One of the techniques known as port forwarding can be used to access raspberry pi at a distant place from pi.

Port forwarding is a method that allows us to access a server or a device from anywhere. It can be initialize by setting up router as all incoming packets from the internet to the port of the specific local ip address of pi. Port forwarding has one drawback that it allows any device to connect with forwarded port, hence make slightly insecure so it must be handle cautiously.

D. Remote Control

For controlling the car we use accelerometer for linear movement and for rotational movement we used gyroscope. Accelerometer and gyroscope is inbuilt feature of android phone. To use this feature we use inertial measurement unit(IMU app) that was installed from google play. Now we established UDP connection between android phone and pi, then we create socket using python program for receiving the data from android app[18]. Python program wait for input from android app and process the data for movement of RC car. Now pi decodes the received data and sent command to the motor driver circuit. Direction of car depends upon the movement of android phone. After running the code and setting the IMU app with raspberry pi IP and port address we can tilt phone in that direction to which we want to drive the car. Figure 2 shows the IMU setup page where we filled ip address and port , then start the app. After running this app this app start to send output of accelerometer and gyroscope according to the phone position and accordingly RC car start to move.

Figure3: IMU setup page

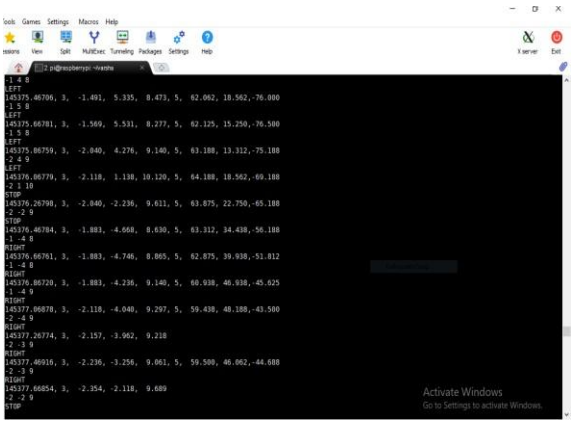

Figure 4: Navigation output

1. Live Video Streaming

Pi Camera is used as an eye of remote controller[19-20]. Following are the command to configure camera.

1. Run the " sudo apt – get update"
2. "sudo apt – get upgrade"
3. " sudo rasp – config"

After running this command, some option will pop up, among them, camera option is to select and enable it. Once all configurations have been established, write the script for video publishing. For this we created a new file called rpi_camera.py and saved it here. Under this write the code that is available in official picamera package documentation. After writing code, run this code, then go to web page and type the raspberry pi IP along with port 8080, now live video is streaming. Fig4 shows the live video streaming.

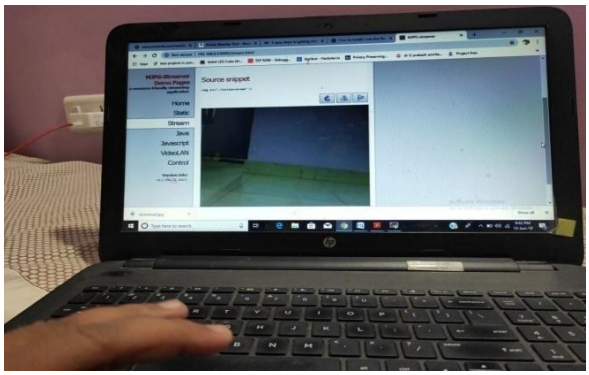

Figure 5: Live video streaming

V. Result and Discussion

The proposed work has been designed to run an RC car, and it gets direction of movement according to Smartphone tilt position and broadcasting network node was build for live video publishing that helps to navigate the area for controlling the car movement remotely. Raspberry pi drive the RC car and it has a Wi-Fi connection to communicate with Smartphone. For power supply pi is connected to 5v power bank and RC car is powered by 12v rechargeable battery. Figure 6 shows the fully functional prototype of this work.

For local access authentication, one can control RC car only by connecting both pi and Smartphone with the same Wi-Fi network as well as if pi is powered on.

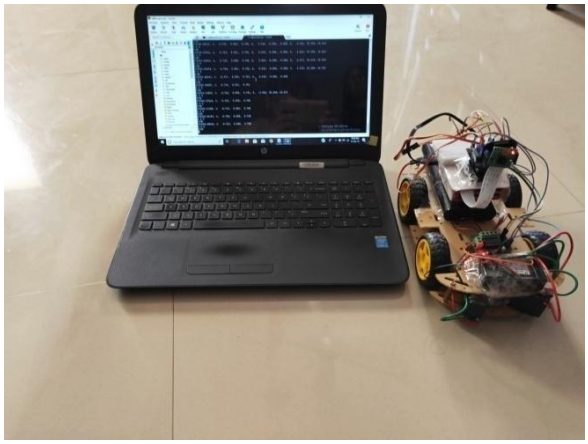

Figure 6: RC car and its control output

VI. Summary

This work prompts the prototype of Remote controlled car with the help of Smartphone Accelerometer. By means of a completely well-designed prototype this vehicle can be useful for surveillance purpose in dangerous area, industrial buildings, border and many more such areas with greater control of vehicle than the existing switch controlling mechanism. Several improvements are possible like one can use solar panel to give power of the motor so that charging problem of batteries will short out.

Abstract- In recent times the growth of population has been increased very much, when compared to last 10 years. so there is a need to implement an effective traffic system to avoid congestion. In the present traffic situation the emergency vehicle is getting blocked in middle of traffic and not able to reach the destination in correct time. In this paper we suggested a centralized system for emergency vehicle passing with authentication where the driver he himself can control the traffic and can pass through from that signal with the use of authorized control system and the authorized control system will control all the traffic signals and only certified people can access the control system.

Keywords- Traffic Light, NRF, GSM, IOT, Emergency Vehicles, RTC.

I. INTRODUCTION

Transportation system is the prime service to provide peaceful life to the people. It is used to achieve the target of different audiences [7][8]. Main problem in the transportation system is the traffic congestion [1]. Traffic congestion is the problem which arises due to more number of vehicles than the road facility. Providing service without congestion demands huge investment. This problem is common among the different countries. Accident is occurred around the world due to poor management of traffic system [5]. Traffic congestion can be controlled by monitoring the traffic and makes a wise decision based on the situation[4]. But it is the toughest work to achieve. Mainly, in emergency condition, the ambulance and government vehicles should reach the desired location within the minimum time. So that human life can be saved as quickly. It involves data interpretation, authentication and also manpower. The above requirement can be satisfied with the help of recent technology. Data interpretation is the difficult task because it changes time to time and day to day. Sensors are placed in the vehicles. System can able to interpret the information about vehicles by reading sensor output[10]. Interpreted information can be analyzed with the help of suitable software tools, system can able to adjust the signal traffic time. Thus avoids long waiting of vehicles in queue [9]. Current system is failed to achieve the proposed outcome. It introduces delay and also it may be a reason for the loss of lives [2]. Recent survey says that death rate increases with poor traffic management system[6]. Researchers are proposing different ideas for solving the issues. One of the methods is the use of adaptive system based on various conditions. It uses internet of things and embedded technologies [8]. Other technology is in use was implemented the first based on RFID networking. Its main goals are minimizing travel time, improving safety and public transport service. Such improvements are beneficial to health and the environment, Traffic control system by using RFID technique. Compose of different RFID tags and other hardware peripheral components. Tags control the condition of real time. It can change the set times automatically. Sensors are used in the driver circuit to know the traffic jams [9]. The output can be demonstrated by LEDs. These are old techniques and also some of the technique are presently in use in different countries [4] [7] [9] and goal is to counteract the traffic control management system. This paper has three sections. Section II has the detail about the proposed system; Section III explains the result and its detail output. Conclusion and Future work is given in section IV. They are Control section, Traffic section, and Ambulance unit.

II. PROPOSED SYSTEM

Proposed consists of three sections. They are Control section, Traffic section, and Ambulance unit. In our work when the ambulance wants to go in a traffic area that ambulance driver should send a message to the control unit in which signal traffic he wants to clear. Message is sent through the GSM board. Then the control unit receives the message

using a GSM board. It sends the control message to the concerned traffic unit to change into green light using NRF. Power supply unit is available to provide the supply to the entire control unit. Arduino Uno board is used as central processor to control the various operations.LCD display is displaying the movement of the particular vehicle through GPS installed in the ambulance unit. IoT module is used for sharing the details globally. In traffic section receive this data using NRF. In this section it stops the normal loop of the traffic signal and the signal is switch on the green light. Using LCD and traffic signal it shows that the emergency vehicle is passing so that the people who are passing through that signal can understand the problem. Here using RTC it calculates the time duration. After some duration the traffic signal changed into normal loop. Then the next signal moved into green. This process will happen up to the destination of the ambulance. Finally, the ambulance sends the successfully reached message to the control unit. Here we are using an authorized control unit which will control all the traffic signals and only certified people can access the control system. And all the details will be updated in the web server for analysis purpose. LCD is used to display that emergency vehicle is passing. In this, we are using GSM where we can establish a wide range of network of more than a kilometer range.

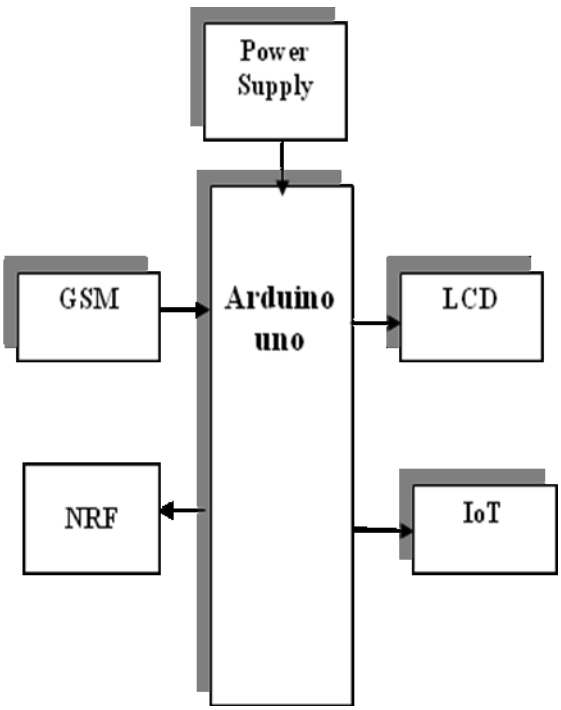

Figure 1. Control Unit

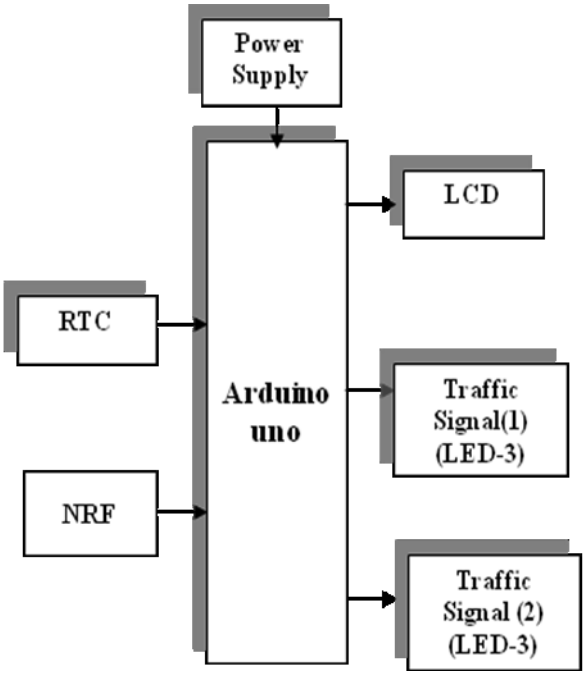

Figure 2. Traffic Unit

Figure 3. Ambulance Unit

In this project, we are using the following components like Arduino UNO, GSM modem, LCD, IOT, NRF, RTC, and LED. Here Arduino is an open-source microcontroller board based on ATmega328p and it has 14 digital input/output pins, 6 analog inputs, a USB connection, power jack, header and reset button. GSM is a wireless modem that works under GSM wireless network and it behaves like a dial-up modem that receives and sends data through radio waves. LCD is a liquid crystal display screen, it is an electronic display module with a wide range of applications. It has a 16*2 LCD display which is used in various devices and circuits. LCD has no limitations and it is

economical and easy to program. NRF is a highly integrated and ultra-low-power RF transceiver IC. It has advanced power management with a 1.9 to 3.6v supply range. The NRF24L01 has UPL solution which gives months to years of battery life to coin cell. The internet of things is a physical device network used in vehicles, buildings, electronics which uses the embedded system and it is the network connectivity that which enable these objects to collect and exchange the data. IOT sense the object and controls remotely across the existing network infrastructure. RTC is a real-time clock, it is low power and full binary coded decimal clock. The address and data are transferred serially. It is a timekeeping operation that works under time. LED is a light emitting diode(LED) is a semiconductor device that emits visible light when an electric current pass through it. LED's will have different colors in our project we are using 3 different colors like red, green and orange. At first, the Arduino board will take the coding and runs the circuit as per the code is given, then the message which was received in GSM modem will be sent to the LCD. There authenticates and verifies whether the message is sent by the certified user and the entry of the message will be stored in the IOT. From the control unit to traffic unit message will be sent through NRF. From there the traffic unit will change the red signal into the green signal by using RTC. After some time it will change to red and this process repeats whenever an emergency vehicle passes and all the data will be uploaded in IOT cloud.

III. RESULT AND DISCUSSION

Information will be received to centralized unit whenever accident happens. Centralized unit identify the nearest ambulance unit closer to the accident spot. Ambulance driver sends an acknowledgement signal to the centralized server once it ready. Movement of the ambulance vehicle can be monitored in the centralized section through GPS placed in the ambulance unit. After reaching the spot, ambulance unit sends an request message to centralized server to clear the traffic. Centralized unit verify the number and if it is authenticated then control message send to traffic unit. At first, the Arduino board will take the coding and runs the circuit as per the code is given, if a message is received in control unit by any emergency vehicle it will check whether the number is matching or not with the numbers given in the coding. If the number is matching then GSM modem will send message to LCD. There it will display that message received and number is matching message on LCD and the entry of the message will be stored in the IOT cloud. All this message will be stored for the authentication purpose and also to check that control unit is working according to the code given. From the control unit to traffic unit the message will be sent through NRF. Where NRF is a transceiver IC which can be used as short range signal transmitter and it acts as a communication device in between control unit and traffic unit . All the process and arrangement of components has shown in Figure 5.

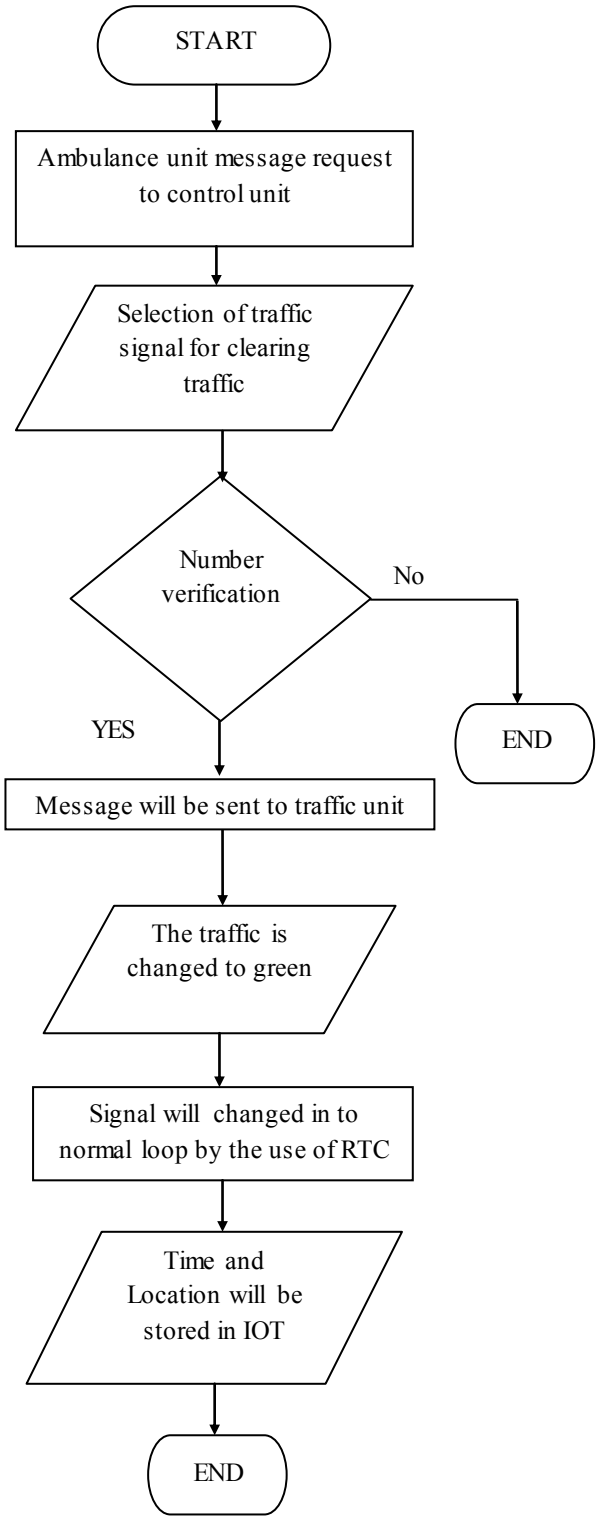

Figure 4. Flow Chart

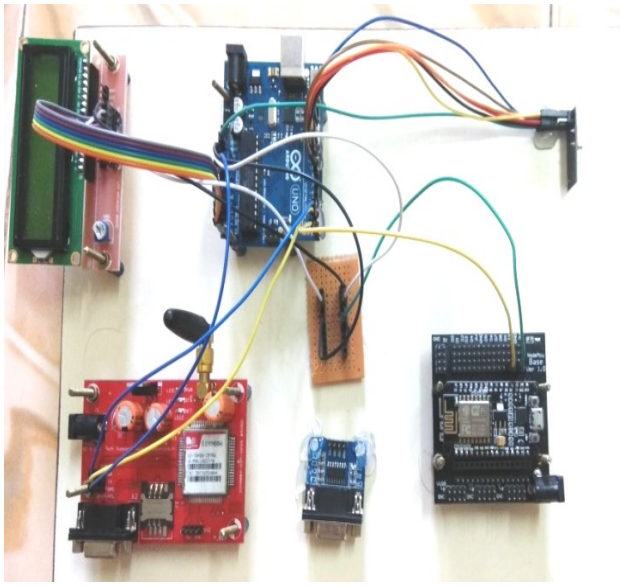

Figure 5. Control Unit

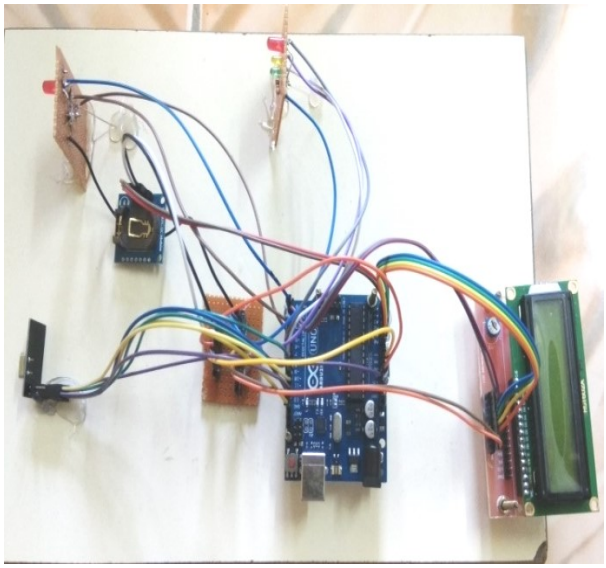

Figure 6. Traffic Unit

After receiving a message from the control unit the message will be sent to Arduino, as from there it will be transmitted to LCD there it will display the emergency vehicle is passing and the LED will change its color from red to green so that the driver can get a clear way to pass through from the traffic jam. Here we are using RTC, which acts as a clock. From the RTC after a period of time, it will change to red and this process repeats whenever an emergency vehicle passes and all the data will be uploaded in IOT cloud. It is the next unit, after receiving message from control unit as shown in Figure 6.

IOT web server will have all the access details of all the emergency vehicles which have been passed through the signal. Along with the time and the area of the traffic signal will be updated in the IOT cloud. It is shown in Table 1. And we can check all the details through this web-link:

IV. CONCLUSION

We have designed a centralized system for the emergency vehicle passing with authentication where the driver he himself can control the traffic and can pass through from that signal with the use of authorized control system and it will control all the traffic signals and only certified people can access the control system. Request is given by a person who is in the location to the central station. Station assigns the jobs to the emergency vehicle based on their position to the spot. Emergency vehicle driver communicated to central office and central office send the control signals to the traffic signals which are available on the way. Centralized system can able to track the movement of vehicle. Based on the traffic it generates control signals and reduces the time delay .Thus the proposed system

can able to control the traffic effectively as well as saves people lives. In future the above system can expand by adding the identity number with the vehicle. Vehicle should have the capability to send information by own whenever accident happens. So that centralized system can able to receive the request about accident spot without receiving request from human.

V. ACKNOWLEDGMENT

Abstract-In India, the agricultural economic loss is mainly due to insects and pests. Therefore, pesticides are widely used by farmers to control weeds, insects and plant diseases. Excess usage of pesticides is not only an adverse for the environment but also for human and economy of the nation. In this paper, we proposed a pest control system that makes use of IOT (Internet of Things) and image processing technologies to control pests, thereby reducing the use of pesticides. The proposed system uses infrared sensor (PIR) to detect the presence of insect by the heat radiated by their body. Image processing is used to capture images of the pest to confirm their presence in the field. After confirming the presence of insect by Image processing and PIR sensor, the ultrasonic generator is used to generate ultrasonic waves which are intolerable to insects and pests, drive them away from the agricultural field. The proposed system helps the farmers to improve the agricultural production and management in an eco friendly way.

I.INTRODUCTION

Pesticides are a major problem for Indian farmers compared to pests. There is always a bit of poison in the food we consume. Pesticides are agents used to destroy pests, which are detrimental to humans or human concerns like agriculture. Almost 30,000crores worthy of crops are destroyed by pests and insects in India every year, which make farmers to use pesticides. Experts believe that chronic low level pesticide exposure is associated with a broad range of nervous system symptoms such as headache, tension, dizziness, depression, anger.Agriculture scientists worldwide are working on biological alternatives to chemical pesticides with increasing consumer pressure on both farmers and supermarkets to minimise the use of chemical pesticides.

With the growth of organic market, people are taking much more interest on what farmers use to control pests. Nowadays farmers are encouraged for practicing organic farming. Organic farming produce good quality food but production costs are very higher, needed more workers and they cannot produce enough food that the world population need to survive. Both the approaches have their pros and cons. As Prevention is better than cure, the better solution for this problem could be preventing usage of pesticides rather than treating for its side effects.

One of the major problem in agriculture that limits the yield of crops is pest diseases which caused by pests including rodents. Farmer in spite of competing with pests for years, the Crop loss caused by pests has been increasing which threaten all around the world. It has been estimated that 70% of crops could be lost due to pests. These pests are controlled by applying either physical measures such as trapping or chemical measures such as usage of pesticides. Although pesticides benefits the crops and is most effective, it makes the crops toxic. In this paper, we provide an innovative solution to control pests by repelling it from the field instead of using pesticides. This is done by generating ultrasonic waves using ultrasonic sound generator.

The term ultrasonic or ultrasound refers to the sound with frequencies above 20,000 Hz or audible sound. The Ultrasonic sound generator uses various methods including piezoelectric method, magneto striction method to produce sound waves above 20,000 Hz. The demand for more food is increasing. Smart agriculture through use of IOT technologies will help the farmers to reduce generated wastes and enhance productivity. IOT helps the farmers to capture real time data regarding crops using sensors and to analyze the status of crop to make decisions earlier which increases the quality of production. It enables better monitoring of crops and avoids crop losses due to diseases or adverse weather.

In this paper, we proposed a pest controlling system which confirms the presence of pests in the field through PIR sensor and image processing technique and generates

ultrasound which is intolerable to rodents and insects. By doing this, we can prevent the pests feeding on the plants which results in the increase of crop's health and production thus increasing the economic level of farmers.In section II, the literature survey is discussed, in section III, the pest controlling system based on IOT is proposed and the implementation is described, in section IV, we conclude the whole work.

II. RELATED WORK

Dileep Kumar Tiwari, etal, [1] have proposed an electronic pest repellent that is capable of producing ultrasonic sound waves to repel rodents, insects and pests. The proposed system mainly aims to prevent pest in an eco-friendly and environment–friendly way. The proposed device can be used in both small and large scale. The system is alternative to chemical pesticides and repeller which have an adverse effect on human health.

Ibrahim, etal, [2] have discussed on the use of electronic pest control device, other measures, advantages and drawbacks of the device. Electronic pest control is an electronic device used for repelling pests. The advantage of this device is that, they are cheap, eco-friendly and not harmful to human beings. This device differs from other devices by targeting the hearing range of pest and work based on it. Thus this device is more efficient.

J.Mahalakshmi, etal,[3] has proposed an image processing algorithm for crop inspection and pest control. This work mainly focus on recognization of paddy plant diseases. Using this technique various paddy diseases are identified .

Johnny L. Miranda, etal, [4] has proposed a system that makes use of image processing techniques to detect pest in rice fields. Using the system the farmers can make monitoring process easier. The proposed system is simple and efficient and fully automated The experiment results shown by the prototype is reliable. As future work, neural network can be used to improve performance of the proposed system.

KanishkSisodiya and MandeepSingh ,[5] have designed a ultrasonic insect detector system that uses ultrasonic sensor and infrared sensor to detect the presence of insect and pest in the field. The system also makes use of GSM module to inform the farmers about the presence of pest in the field. This system is designed especially for oilseed crop. This prototype helps the farmers to increase agricultural management and production. In the future, some of the other sensors can be interfaced with the prototype system for more accurate results and image processing can also be used to take real time images of the pest.

KhapareNilima Kailas, etal ,[6] have proposed a system that uses electronic devices such as ultrasonic sound wave to repel the pest from the agricultural land. The drawbacks of chemical method, the use of bio-pesticides are also discussed in this paper. The main aim of the system is to control pest in an eco-friendly way.

Murali Krishnan, etal, [7]have proposed an image processing based, automatic pest control algorithm. This proposed algorithm aims to prevent coffee berry from insect and diseases. Rapid detection of insects can be achieved through this system.

Navin, etal, [8] have proposed a pest control system using wireless sensor network that uses acoustic device wireless sensor to detect the noise level of the pest and indicate farmers about the presence of pest through alarm. The proposed system is very low energy consuming and can cover maximum field area. The main focus of the system is to control and monitor pest for sugarcanes using wireless sensor network technology.

Nicholas Aflitto and Tom DeGomez ,[9] have discussed on sonic pest repellents which are devices that emit sound to repel insects, pests and rodents from the agricultural land. They briefly discussed on their working, advantages and drawbacks. The allure of sound for prevention of insects will be a successful approach in the future and will be safer for humans.

RichardW.Mankin, etal, [10] have discussed the structure of acoustic system for insect detection in plant stems, by attaching an accelerometer to the plant stem. The accelerometer system is used for detecting movement of insects.

Saeed Azfar, etal, [11] have discussed on a wireless sensor network for pest control and agricultural monitoring. Various pest control methods have been discussed in this paper. Agricultural areas will be using WSN technology in the future for beneficiary output. The designed system can be improved in the future to check the pest at early stage and convey the information to the farmers, thus reducing the manual burden of monitoring the field.

Simeon, etal, [12] have discussed on the performance of an electronic pest repeller. The main aim of the prototype is to emit ultrasonic energy of varied frequency. The experimental results show that the proposed system has the potential to repel rodents. The performance of the device is also more reliable. The prototype can be improved by using microcontroller and ultrasonic sensor. The proposed system is an alternative to chemical methods to repel pest.

III. PROPOSED SYSTEM AND RESULT

In India, the crops that require high usage of pesticides are paddy (17%), wheat (10%) and cotton (45%). So our proposed system mainly focuses on these crops. There are numerous pests such as beetles, bugs, moth and rodents including rats, squirrels, mouse, rabbits that feed on crops which causes a massive destruction to the yield of crops. In our proposal, these pests in the field are repelled by generating ultrasound instead of using pesticides. The proposed system comprises of

1. Passive Infrared(PIR) sensor
2. Image processing

3. Acoustic sensor
4. Microcontroller
5. Ultrasonic generator.

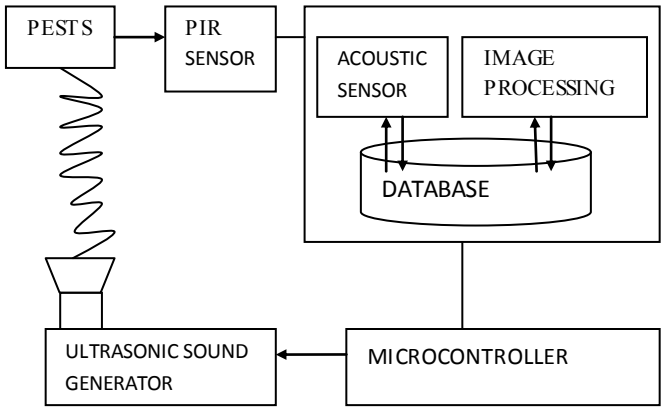

Figure1.The proposed system

1.Passive Infrared(PIR) sensor:

PIR sensor is used to detect the motion of pests around particular environment. All objects with temperature above absolute zero emit heat energy in the form of radiation. PIR sensor detects the motion by measuring the changes in the infrared levels emitted by the object, such as pests in the environment.PIR sensor covers a distance of up to 20 feet (6 m). They are small, inexpensive and easy to use.

2.Image processing:

Image processing is used to extract some useful information from images captured by performing some operations on it. It isused to detect the presence of pests in field by capturing images of pests and comparing it with stored images. The image processing includes the following steps:

- Capturing image and send it to the microcontroller.
- Processing the image to detect the object in microcontroller.

Image processing is classified into two types, analog and digital image processing. It enables to acquire a visual record of moving object.

3. Acoustic sensor:

Acoustic wave sensor is used to detect the noise level of the pests in the field. It also detects the invasion of pests on crops in early stage. Acoustic sensor detects sound by using microphone.

4. Microcontroller:

Microcontroller is an integrated circuit consisting of processor, memory and input/output peripherals to control actuators. It is used to process the data collected by the sensors and control the ultrasound generator to generate ultrasound of high frequency.

5. Ultrasonic Generator:

Ultrasonic sound refers to the sound with frequency greater than the 20,000 Hz or audible sound. Ultrasonic can be produced by different methods which includes mechanical method, piezoelectric method, magnetostriction method. In piezoelectric method, the ultrasonic waves are generated by a transducer which converts electric current to sound waves. In magnetostriction, iron or nickel is magnetised to produce ultrasound.

6. Working:

The proposed system shown in Figure1 produces a discomfort but not harmful, high frequency sound waves which is not audible to human beings. Every pest has sensory structures to produce and detect ultrasound. For example, cockroaches have sensory hairs, spiders, beetles, flies have tympanic membrane to sense ultrasound. The ultrasound sensors are present in the antennae or genetalia of the pests. Bats and rodents communicate through ultrasonic frequency. The ultrasonic sound being generated by the system will create a stress on the nervous system of the pests and jam their own ultrasound frequency. As a result, the pests get confused, scared and try to escape from the source of ultrasonic sound. Every pest has its own bearable decibel. Rodents respond to ultrasound with a frequency 60K Hz while fleas, mosquitoes, beetles respond to ultrasound with frequency 38-44K Hz.

In our proposed system, the presence of the pests is detected using PIR motion sensors which are deployed in the fields. The PIR sensor detects the pests by monitoring the changes in the amount of infrared radiation (heat) emitted by the pests. Heat is radiated from any object with temperature above absolute zero. The PIR sensor can cover a distance of 20 feet(6 m). Once the presence of pest is detected, the images of the pests are captured through the cameras in the field and then compared with the images of the pests in the database. An efficient image processing algorithm is used for the identification of the pests. The main aim of the image processing is to observe the pests that are not visible to human eyes. For more accuracy, in parallel, the sounds waves emanating by the pests during feeding, laying eggs are collected with the help of acoustic sensor and is analysed with the sounds in the database with which it is ensured that the eco-friendly pests will not get affected. This is done by using microphones which detects the sound signals and converts them into electrical signals. The outcome from both the process is combined to identify the pest type and their unbearable sound level is given as an input to the microcontroller. All these actions are done in microseconds.

Finally, the microcontroller automates the ultrasonic sound generator which is adjustable to produce powerful ultrasonic waves of different frequency. The output is coupled to the tweeter which repels away the pest in the

field. The Ultrasonic waves ranges up to 15 feet. The ultrasonic waves above 20K Hz is inaudible to humans and it also stimulates the plant growth. Therefore entire system will not cause any problem to the human beings as well as eco-friendly pests and crops. The beneficiary of the system is that it is automated so that there is no human intervention thus reducing labour and man power.

The purpose of the project is to design an ultrasonic pest repellent. Such a device can be very useful to counter the various problems caused by ants, insects, pests, rodents to the crops. This system is proposed aiming the target beneficial for farmers, consumers, crops and land. The farmers are benefited as it increases the possibility to have enhanced healthy plants and reduce the cost of input spent on buying fertilizers and pesticides. This promotes sound structure and healthy poison free plants for human consumption. The system aiming to reduce the environmental risks associated with pest management by encouraging the adoption of ecological practice.

The main goal of the proposal is to reduce the potential of air and ground water contamination and increase the yield. This can do a great positive effect on environment through decreasing the use of pesticide. The long term goal is helping the farmers to reduce the labours involved in pest management programs and also to eliminate pest residue issues. The qualitative outcome of this idea in is expected to encourage farmers as cultivators adopt and encourage non toxic pesticides farming. The inculcation of IOT in pest management supports for device to device communication without human intervention and reduce manpower and labour.

The proposed system has been tested within the bounds of pastureland and the outcomes are analysed. The presumed results are acquired with an accuracy of 87%.

IV.CONCLUSION AND FUTURE WORK

Agriculture is considered to be a backbone of India. Therefore, the development of villages mainly depends on the increase agricultural production and food security. The main objective of the system is, to aware the farmers about the pests and condition of the agricultural field. In the proposed system, for more accuracy image processing technology has been used and acoustic, PIR sensors are interfaced. The proposed system is a best alternative to chemical pesticides and can able to reduce the manual labour of monitoring the agricultural field. Therefore this proposal would help the farmers to increase their crop production by automated pest management at low costs and ensures a healthy food. Our proposed system mainly focuses on three crops (paddy, wheat and cotton). Hence our focus in future is to extend the implementation of system, which will be admissible to diversity of crops with varying heights and pest attacks. Our future goal is to provide the farmers an efficient pest control system with affordable cost to get rid of pests and thus increase their crop productivity.

***Abstract*—This paper compares the performance of Affine projection sign algorithm and Maximum Correntropy criteria based adaptive algorithm used for double talk scenario. The performance metric involves the speed of convergence, mean square error under steady state and complexity. Simulations were also performed to identify the best performing algorithm under different environmental conditions for double talk scenario. Finally it is concluded that Maximum Correntropy criteria based adaptive algorithm outperform the family of Affine projection sign algorithm under both sparse and non-sparse conditions.**

Keywords— Affine projection sign algorithm; Maximum Correntropy criteria ;convergence;mean square error;complexity.

I. INTRODUCTION

In all telecommunication systems, whether it is wireless or wired, the predominant problem is the presence of noise, which includes thermal noise, co-channel interference, echo signal etc. An echo signal is said to have delay and attenuation compared to the original signal with several reflections. It usually occurs in a room, mountain, under the sea or inside a cave. From [1], it is found that the effect of these echo signals is not considered when their delay is very small or the magnitude is below the threshold value. An acoustic echo is a type of echo signal that is generated whenever loudspeaker and the microphone are placed in a closed room such as teleconferencing system. These echoes are generated due to the reflections of acoustic signal between loudspeaker and microphone as well as from the walls, or through other objects present within the room etc.,

Under this condition, there is acoustic coupling between loudspeaker and microphone which is made up of direct path and echo paths which is not desirable. Hence echo cancellers are required to improve the quality of speech in telecommunication system. Therefore an adaptive filter that is capable of adjusting the filter coefficients according to the change of signal properties is required for Acoustic Echo Cancellation (AEC) application as the signal statistics are not known priory or it is time varying. The development of adaptive algorithms for AEC application is based the two scenarios that occur namely single talk and double talk. Under single talk scenario, the far end speech is assumed to be absent. If the far end signal is also present along with the near end signal, then the scenario is double talk. Hence the problem under consideration is an unknown system identification problem with impulsive noise along with background noise.

Traditionally Least Mean Square (LMS) adaptive filters and their variants have been used throughout because of its simple nature and easy implementation [2]. The main function of these algorithms is to estimate the echo in such a way that the Mean Square Error (MSE) is minimized. Since the echo path is said to be time varying and it requires a long length adaptive filter with hundreds of filter coefficients and a constant step-size parameter is used in the update recursion, there is performance trade-off and they perform poorly for speech signals. Affine Projection algorithm (APA) is better for echo cancellation application as it works faster convergence with lower steady state MSE especially for colored inputs, such as speech signal with the increase in computational complexity [3,4].Firstly variable step-size strategy have been developed. The next strategy is to exploit the sparse nature to improve the performance and hence sparsity aware adaptive filters have become very popular [5,6]. In the recent years, combinational approach has become very popular due its capability in obtaining better performance than the single filter approach but they are said to be more complex than the single filter approach [7].

Information theory criterion based adaptive filters and sign algorithms were the popular algorithms used for double talk scenario due to their robustness against impulse noise. Different variants were proposed under each category to improve the overall performance .Even though they serve the same purpose of robustness under impulsive noise, there is no previous study to the best of our knowledge that compares the performance of these two family of adaptive filters. Thus this paper focuses on the comparison of the family of APSA and MCC based adaptive filters. Convergence rate, MSE and complexity were used to identify the best performance algorithm suitable for double talk scenario.

The further sections are distributed as follows: Section 2 describes the problem formulation where the system under consideration is describes along with the notations. Section 3 and 4 are devoted to the review, description and comparison of the famous variants of APSA family and MCC family of adaptive filters respectively. The performance comparison among them is made in Section 5 in terms of speed, error and computational complexity and conclusions are drawn in Section 6.

II. PROBLEM FORMULATION

In order to formulate the problem, let us consider Fig 1 in which the Loudspeaker Enclosed Microphone (LEM) system is assumed to be an unknown, linear system with optimal filter weights w_o given by

$$\boldsymbol{w}_o = [w_o, w_1, w_2, \dots, w_{N-1}]^T \quad (1)$$

Let x(n) be the input to the system given by

$$\boldsymbol{x}(n) = [x(n), x(n-1), .., x(n-N+1)]^T \quad (2)$$

where n is discrete time and N is the input length and as well as weights. The desired response d(n),modeled as a linear regression model is as follows.

$$d(n) = w_o^T x(n) + v(n) + u(n) \quad (3)$$

where v(n) is the Gaussian background noise signal with variance σ_v^2 and u(n) be the interference signal which is the far end speech ($S_{Far\ end}$). Let w(n) be the estimated weights given by

$$\mathrm{w(n)} = [\mathrm{w(n)}, \mathrm{w(n-1)}, \dots., \mathrm{w(n-N+1)}]^{\mathrm{T}}. \quad (4)$$

The error signal $e(n)$ is given by

$$e(n) = d(n) - \boldsymbol{w}^T(n)\boldsymbol{x}(n) \quad (5)$$

Thus the aim is to update the filter coefficients such that error is minimized with increase in convergence speed with reduced complexity.

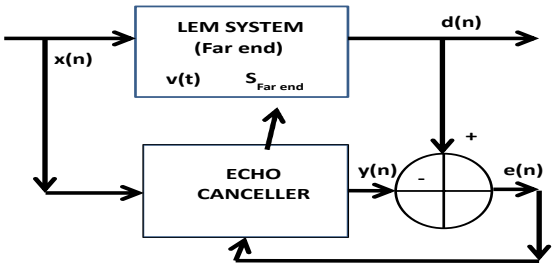

Fig 1. LEM system with echo canceller

III. .FAMILY OF AFFINE PROJECTION SIGN ALGORITHM

An Affine Projection Sign Algorithm is the combination of best feature of SA and APA [8] by providing robustness against impulse interference with lower computational complexity. The convergence and steady state MSE were considerably poor than APA. In [9], a general theoretical transient analysis of error non linearity adaptive filter using energy conservation relation is made. The validity of a priori error as Gaussian signal assumption is proved through simulations.

Two proportionate APSA was proposed by for AEC application [10]. Here proportionate type and APSA are combined to obtain Real Proportionate (RP-APSA) and Real Improved Proportionate APSA (RIP-APSA). Experiments were done to prove the performance improvement. Memory improved proportionate APSA in order to further improve the performance of proportionate APSA is proposed [11]. This is done by taking the past values of the input projection matrix. Thus improvement in steady state MSE is obtained at the cost of increase in memory requirement. A variable step size APSA is proposed to eliminate the performance tradeoff [12]. The ZA-APSA is proposed [13] by combining l_1 norm penalty and APSA. Improved performance is obtained under sparse environment. The update recursion of the general APSA [14] is

$$\boldsymbol{w}(n+1) = \boldsymbol{w}(n) - \frac{A(n)sgn(\boldsymbol{e}_p(n))}{\|A(n)sgn(\boldsymbol{e}_p(n))\|_2} \quad (6)$$

If l_1 norm is included, then ZA-APSA can be written as

$$\boldsymbol{w}(n+1) = \boldsymbol{w}(n) + \mu\frac{A(n)sgn(\boldsymbol{e}_p(n))}{\|A(n)sgn(\boldsymbol{e}_p(n))\|_2} - \rho sgn(\boldsymbol{w}(n+1)) \quad (7)$$

The update recursion of the proportionate family is given by

$$\boldsymbol{w}(n+1) = \boldsymbol{w}(n) + \mu\frac{A(n)sgn(\boldsymbol{e}_p(n))}{\|A(n)sgn(\boldsymbol{e}_p(n))\|_2} - proportionate\ term\ ) \quad (8)$$

Here μ is the step size. The strength of attraction of the zero coefficients is given by ρ called as the zero attractor controller which provides improved convergence when the system is sparse.

IV. INFORMATION THEORY CRITERION BASED ADAPTIVE FILTERS

The local similarity measure between two random variables based on the kernel width is called Correntropy [16]. If gradient descent approach along with Gaussian kernel for correntropy is used, the resulting algorithm is called MCC algorithm. Thus MCC has the advantages of robustness to outliers with appreciable performance for non-Gaussian data which is similar to MEE algorithm. Also the computational complexity involved in MCC is the same as that of the well-known LMS algorithm.

The steady state MSE of MCC algorithm and the tracking analysis has been made by [16,17] which indicates that MCC based algorithm is more suitable for non-Gaussian impulsive noises. Variable step size approach has been successfully used in LMS adaptive filters to remove the tradeoff. Therefore variable step size approach based on the instantaneous MSE for MCC adaptive filter is proposed [18]. The MCC adaptive filter with weights $W(n)$ and input $X(n)$ is defined as

$$W(n+1) = W(n) + \mu\, exp\left(\frac{-e^2(n)}{2\sigma^2}\right) e(n)X(n) \quad (9)$$

It should be noted that as kernel size tends to ∞ , the algorithm reduces to Stochastic Gradient LMS algorithm. A variable step size MCC algorithm update equation is given by

$$W(n+1) = W(n) + \mu(n) exp\left(\frac{-e^2(n)}{2\sigma^2}\right) e(n)X(n) \quad (10)$$

V. Performance Comparison

The different performance measures that are normally used by adaptive algorithm are discussed in this section.

A. Convergence Rate

One of the desirable characteristics of adaptive filter is faster convergence. It measures the rate at which the algorithm reaches to the final state. It is a dependent performance characteristic where, there is always a tradeoff in other performance criteria such as steady state MSE.

B. Mean Square Error

The Mean Square Error (MSE) is a second order statistical term that indicates the difference between ideal and actual values A small MSE is the desired one.

C. Computational Complexity

Computational complexity includes the number of arithmetic operations required to complete one full iteration of the algorithm, the amount of space required for data storage and the hardware requirement to implement the algorithm in real time applications. Therefore a less complex algorithm is the desirable feature because highly complex algorithm results in increase in cost, size, time , etc.

D. Robustness

Robustness is a measures the ability of the system to resist to noise . The robustness has a direct relationship with the estimated error. The disturbance can be either external or internal to the filter.

E. Misalignment

The Misalignment is another quantitative parameter measure which indicates the amount by which the final MSE differs from the minimum MSE produced by the Wiener filter.

VI. Results and Discussion

This section is devoted to the comparison of the recently proposed ZA-APSA along with recently proposed VSS-MCC algorithms with the list of algorithms designed for double talk scenario is made. The competing algorithms are APSA, RP-APSA, RIP-APSA,MIP-APSA, MCC and the traditional APA. The algorithms are evaluated through parameters namely a. MSE, b. Normalized Misalignment, c. Computational Complexity d. Convergence speed. In order to compare the two proposed algorithm for double talk scenario, a system with 512 unknown system coefficients are taken and two experiments were conducted. The first experiment consists of sparse system with sparseness level of 0.9375 and the second experiment is said to be dispersive with sparseness level of 0.0625.The experiments are conducted by considering the adaptive filter with the same length as the unknown system coefficient which is initialized as zero.

The first order system with pole at 0.8 is taken. The noise with variance σ_v^2 and zero mean is taken such that it has a particular signal to noise ratio (SNR). The interference signal u(n) is a Bernoulli-Gaussian (BG) signal with a particular signal to interference ratio (SIR). Here probability of success is represented as Pr. The results of simulations are obtained as follows: All the algorithms are made to run with 10,000 samples . An ensemble average is taken to obtain the figure of merit. The results in steady state are obtained by taking average of the last 2000 samples and averaged over 10 independent runs. All the algorithms are made to operate with a parameter selected in such a way that they has uniform convergence in the initial stage.

The Figures 3-11 depicts the MSE and Normalized Misalignment of the above mentioned algorithms for a SNR of 30dB and 20dB ,SIR of -10 dB and -20 dB and pr as 0.001 and the results are tabulated in Tables 1-4. Table 1-3 summarizes the results obtained for different filter lengths, level of sparsity , SNR, pr values.

From the tabulated and simulation results shown in Tables 1-6, the following conclusions are obtained. Among the family of APSA ,the proposed ZA-APSA has the fastest convergence and lowest steady state MSE when the system is sparse and is the worst when the system changes to non sparse As far as ZA-APSA is considered,there is no matrix inversion and thus the computational complexity is lesser than ZA-APA and APA. When the number of multiplications is considered, we find that ZA-APSA requires only extra N multiplications more than APSA which is independent of M. Thus we find that the proposed ZA-APSA approach has lesser computational complexity when compared to the conventional APSA or the proportionate family of algorithms. The proposed VSS-MCC algorithm has the lowest value of steady state values of MSE and Normalized Misalignment thus it removes the steady state error and convergence tradeoff when compared to ZA-APSA under all conditions.

VII. CONCLUSIONS

A detailed performance comparison of APSA and MCC based adaptive filters is made. Both of them outperform their traditional counterparts. When compared among them, it is found that MCC based variable step size algorithm is found to be superior than ZA-APSA not only in convergence speed and steady state MSE but also in the computational complexity. Thus it can be concluded that variable step size MCC algorithm is a suitable candidate for double talk scenario. The future work is to find methods to choose the kernel width as it plays a key role in the final steady state mean square error.

***Abstract*---This paper design a power monitoring system for household's plug-in loads which consumers use on a daily basis. This project once deployed in the field will sense the electrical quantities and upload it on the web server so that it will be accessible through the website as and when required. The output will show the graphical analysis of the analog electrical quantities which are easily analyzed by the non-technical person in the household. This system will help the user to have an analysis of power usage. On that basis, a detailed survey on power quality usage can be done by further developments and help us to have energy cut downs wherever necessary to save energy on industrial sites and distribution areas.**

Keywords—Analog voltage current sensing, Database, raspberry-pi, ADC.

I. INTRODUCTION

This system can be referred to as an Energy Management System (EMS). The main motive of the system is to reduce the power consumption by recording, monitoring, analyzing and comparing the load parameters. The system will draw energy consumption trends on a daily/weekly/monthly/yearly basis, so this will improve the energy budget corresponding to user requirement and it will also diagnose the specific area of wasted energy. In conventional energy meters, inaccuracies due to manual limitation and maintenance of log are quite tedious and time-consuming so the proposed system stores data at the server and can share the real-time data with electricity board and the user.

The paper presents the theoretical as well as experimental aspects related to the implementation of the power monitoring system. In the first section of the paper, the designed hardware is discussed with all the schematics and the waveform. After that, sensing and conversion of the sensed values using ADC are explained. The proposed method helps us to keep the database localize in order to be secure and reliable. The UI output of the monitoring system is also presented by running the prototype.

II. LITERATURE REVIEW

Nowadays on a global level, the main aim is to use electrical energy efficiently and to develop the usage system more profitably with less power consumption. Due to industrial growth and urbanization energy is the basic need of our life. Any vulnerability about its supply of energy can undermine the working of the whole economy. The production of electricity from utilities has increased from 11,67,584GWh during 2015-16 to 12,35,358 GWh during 2016-17, registering an annual growth rate of about 5.80%. Of the total consumption of electricity in 2016-17, industry sector accounted for the largest share (40.01%), followed by domestic (24.32%), agriculture (18.33%) and commercial sectors (9.22%) [1].

III. VOLTAGE AND CURRENT SENSING

A. Voltage Sensing

The voltage at the source needs to be sensed to be analyzed. The first step is using a Potential Transformer (PT) to reduce the AC mains voltage to a lower value in order to feed it to the low potential operating circuits. PT stepdown the 230 VAC voltage to 5 VAC. This voltage is then given to terminal IN_VLT1 and IN_VLT2. A reference voltage of 1.75V is fed to this signal which is generated by using a Precision Reference Generator. This is required so that the magnitude of the AC signal can be sampled by the ADC.

This project has deployed galvanic isolation for voltage sensing. The two main reasons for introducing isolation in the system [2].

1. To prevent passing high voltage to lower potential circuits such as Raspberry-pi and ADS1115 (ADC).
2. To break the ground loop, when there is more than one ground connection path between two pieces of equipment. The duplicate ground paths act as an equivalent loop antenna which easily picks up interference currents. Lead resistance transforms these currents into voltage fluctuations. As a consequence of a ground-loop induced voltages, the ground reference in the system is no longer a stable potential, so signals overlap and results as noise. This can cause interference in the ADC sampled values and can reduce the tolerance of the system conversion.

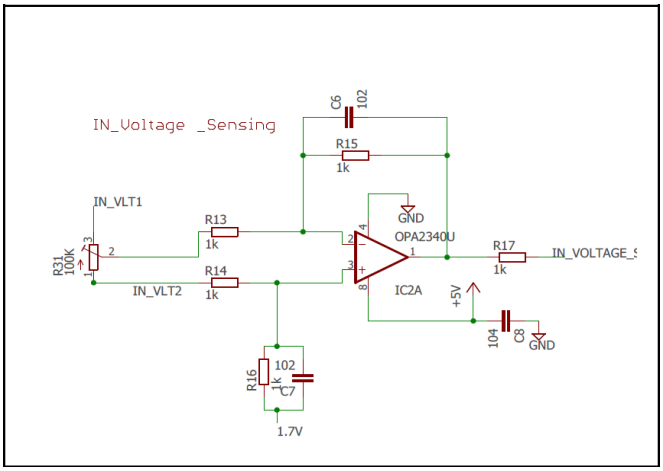

Fig. 1. AC voltage sensing circuit

B. Current Sensing

Normally current shunts were used for measuring the current flowing in the circuits. The shunt produces a voltage of 75mV per 10A of current. This voltage is sensed according to the requirement. A shunt resistor is frequency independent element (1>MHz) and it does not change the phase of the current with respect to voltage. The main drawback of the shunt resistor is that it does not provide galvanic isolation. This can cause damage to the lower potential sensing circuit during a fault condition [3]. To provide galvanic isolation with a direct method of measuring current ACS712 Hall sensor is used. The current flowing through the hall's crystal creates asymmetry in its internal structure that is reflected by the voltage potential. ACS712 provide electrical isolation up to 12.1kVrms and signal bandwidth of 80MHz. It is not appropriate to apply the ACS712 Module's analog output to ADC as input directly because the signal cannot be interpreted by the ADC, therefore, the supplementary circuit is shown in Fig. 2. that should be implemented for the purpose of signal conditioning.

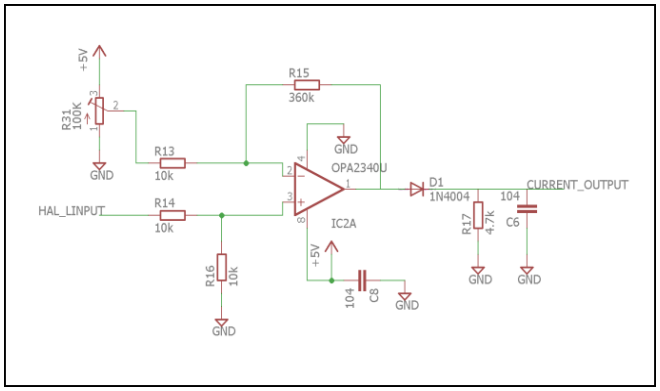

Fig. 2. AC Current Sensing Circuit for ACS712

Fig. 3. shows the resultant output waveform of the voltage and current sensing circuit. The yellow waveform shows the waveform that signifies the AC voltage across the load, and the cyan waveform signifies the current flowing through the load. There is a small lag between voltage and current waveform because the nature of the load is inductive. The output is tested on the load side using a digital signal oscilloscope (DSO) to check whether any spike or noise is present. The Fig. 3 shows the output of the analog voltage and current sensing circuits.

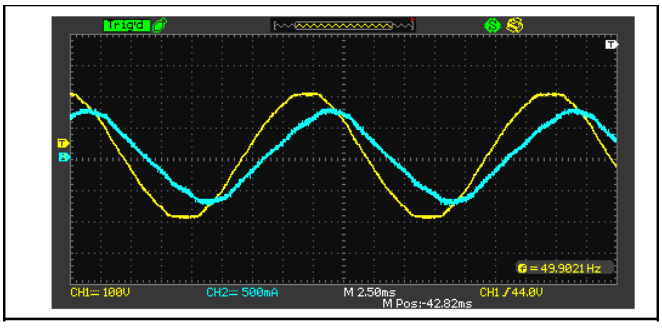

Fig. 3. Voltage and current output waveform on DSO

C. Reference Voltage Generator

Whenever the system encounters an AC signal, the negative magnitude is considered and is sampled by the ADC. The ADC will not be able to read values below the 0V level and hence this negative magnitude cannot be sampled. So we need to clamp this AC signal to a certain DC level. A simple Capacitor-Diode Clamper cannot be used because it does not have a fixed potential and varies according to the charging current of the capacitor that the input supplies. There is a need to generate a precise voltage at which the ADC signal can be clamped and the negative magnitude can be read as well. This is implemented by using a TL431 precision regulator which is operating at 2.5V as its reference voltage. Now, to clamp the signal we need to reduce it by a factor of 2/3rd which becomes 1.75V that is exactly Vdd/2 of the ADC (ADC works on 3.3V). This clamp voltage is buffered and fed wherever required. At the same time, it is sensed so that any deviation in the reference can be captured in real time.

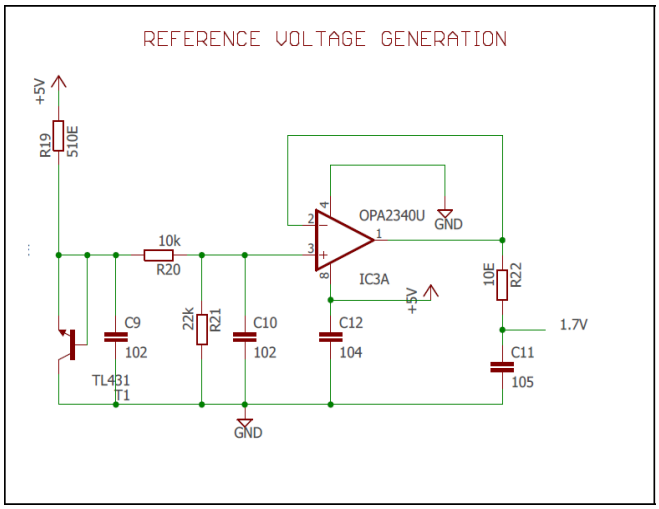

Fig. 4. Reference Voltage Generation

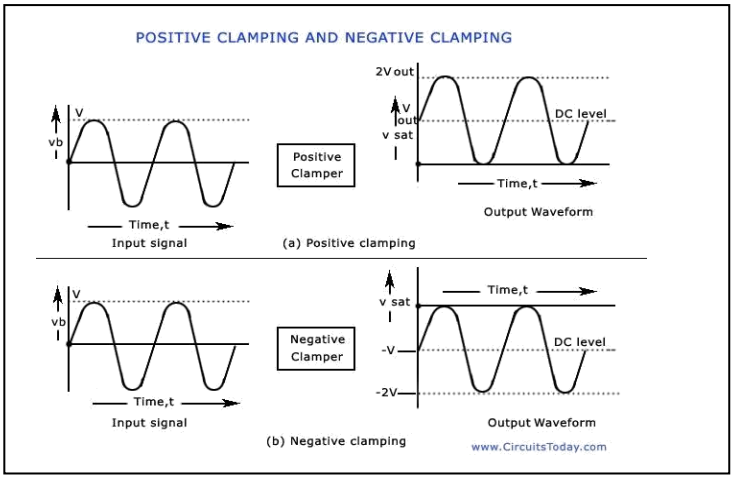

Fig. 5. Level sifted output

IV. ADC SAMPLING

A. *Analog to Digital conversion*

Now the analog values have been sensed by the above integration of circuits but at the output, there are analog values. The digital processing is simpler than analog sampling as the processing unit understands the digital samples. The digital values are generally in the binary format of 1's and 0's. The analog to digital conversion is necessary in order to have digital values. These discrete values are called as digital samples of analog quantity. This samples are further processed by the microprocessor and converted into the original analog values for reading purpose. The ease of processing is obtained because of ADC and the data transfer rate from ADC to the microprocessor depends upon the sampling rate and clock frequency of the microprocessor. The pre-processing of analog sinusoidal values takes place in this section. This is necessary in order to forward it to the Broadcom Processor which doesn't have onboard ADC.

B. *ADS1115 as ADC*

The ADS1115 is used for analog to digital conversion of the sensed values. ADS1115 devices (ADS111x) are precision, low-power, 16-bit, I2C-compatible, analog-to-digital converters (ADCs) offered in an ultra-small, leadless, X2QFN-10 package, and a VSSOP-10 package. The ADS111x devices incorporate a low-drift voltage reference and an oscillator. The ADS1115 also incorporate a Programmable Gain Amplifier (PGA) and a digital comparator [4]. The ADS1115 provides 16-bit precision at 860 samples/second over I2C. The Full-Scale Range of any analog quantity is been divided into 32676 discrete values. There are 4 different channels on ADC which can sense 4 analog quantities simultaneously or two differential inputs. The comparator is present inside the ADS1115 for those differential inputs. The data is transferred to the processor through SDA and SCL bus lines which are serial data and serial clock inputs to the processor.

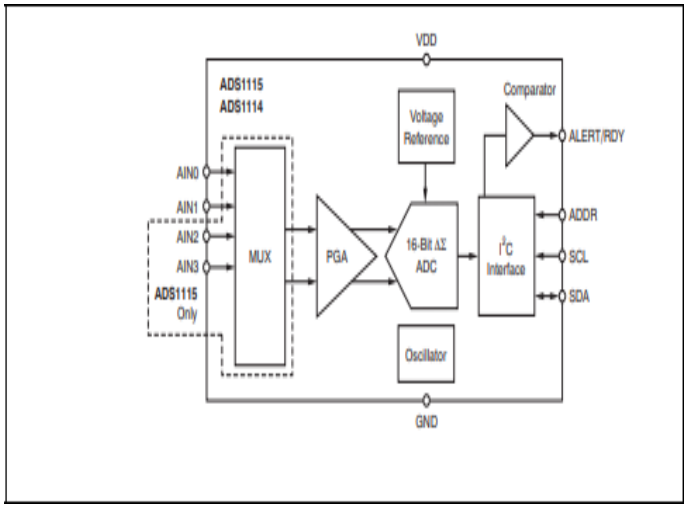

Fig.no 6. Internal block diagram of ADC ADS1115

C. *Digitizing the Analog values.*

Once the values are converted into digital samples the main task is to display them on the server but the user cannot decode this digital sample as the analog quantity. This is done by the Raspberry Pi's Broadcom processor. The block diagram for the ADC is as follows: Analog voltage and current are sensed and each of them is converted into digital values using two channels of ADC. This gives us a different set of digital values at the output. Hence, it is processed separately for voltage and current.

D. *Calculating the Analog values from processed digital values.*

The values for the analog voltage, current active power and reactive power are calculated using the digital values which are converted by ADC and is processed by Broadcom processor in Raspberry-pi. The ADC sampling rate is set at 860 SPS. It is better to maintain it at highest as to collect as many as samples in a second in order to get the accurate sinusoidal wave. Once we get the accurate sine wave, we can calculate its RMS value for voltage and current as well. We process the 860 samples each of voltage and current first to get the sinusoidal values and then processing it further to get the RMS values of each. The formula is as follows.

The threading method is used to calculate the RMS values of voltage and the current. Multithreading is a method of improving the execution performance of a process by the use of concurrency, that is allowing more than one thread to run independently of each other within that program. Since each thread could run on a different core at the same time, it is hoped that multithreading does not only improve the efficiency of both single and multi-core processors, but it could also increase the battery life of mobile systems [5]. Overall three threads are formed wherein first 2 are used for voltage and current samples calculation. The third thread is evolved to calculate the power using the earlier two. This way we process the accurate values of the voltage and current at the same instant and using those values in the third thread we calculate the active power. Now we need to find out the phase difference between the current and the voltage waveform to find the reactive power. Hence we have used zero-crossing detector code in python on Raspberry Pi to find the phase difference by calculating the difference between the two points at which the voltage and the current waveforms cross the time axis. Thus with that value, we calculate the phase difference and further the reactive power consumed. With the help of active and reactive power, we can calculate the real power consumed.

RMS Voltage:

$$V_{RMS} = K_v \sqrt{\frac{\sum_{n=1}^{Sample\ count} v^2(n)}{Sample\ count}} \quad (1)$$

RMS Current:

$$I_{RMS} = K_v \sqrt{\frac{\sum_{n=1}^{Sample\ count} i^2(n)}{Sample\ count}} \quad (2)$$

Active Power:

$$P_{ACT} = K_p \sqrt{\frac{\sum_{n=1}^{Sample\ count} v(n)*i(n)}{Sample\ count}} \quad (3)$$

Reactive Power:

$$P_{REACT} = K_p \sqrt{\frac{\sum_{n=1}^{Sample\ count} v_{90}(n)*i(n)}{Sample\ count}} \quad (4)$$

v(n)= Voltage sample at a sample instant 'n' i(n)= Current sample at a sample instant 'n' Sample count= Number of samples in 1 second K_v = Scaling factor for voltage K_I = Scaling factor for current
$v_{90}(n)$ = Voltage sample at a sample instant 'n' shifted by 90° K_p = Scaling factor for power

The quantity sensed and converted to the digital output can be plotted to sinusoidal by using the above calculations [6].

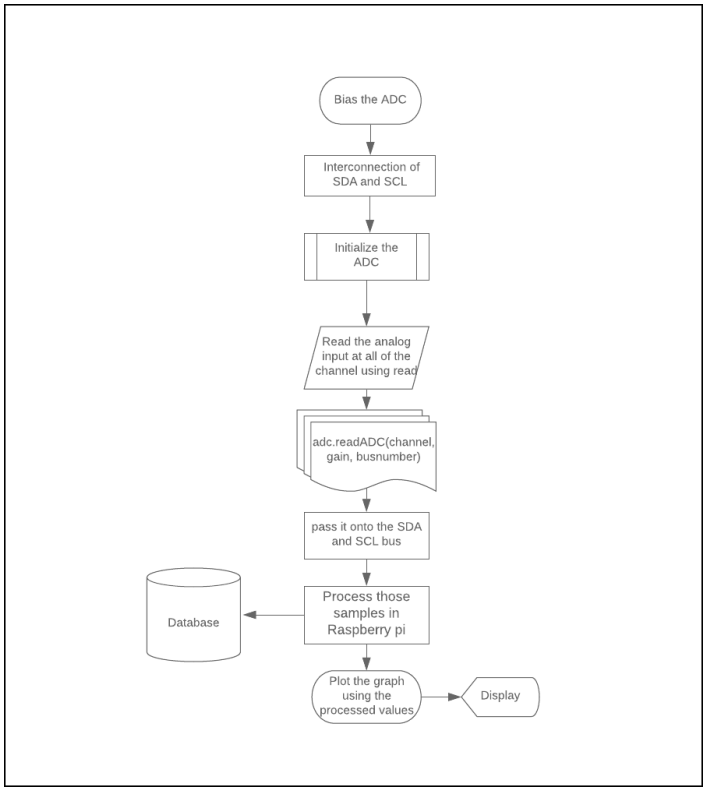

Fig. 7. Flowchart of ADC with the processor's operation

V. DATABASE CREATION AND HANDLING

HTTP is a set of protocols designed to enable communication between clients and servers. It works as a request-response protocol between a client and a server. The database is created so it can be accessed at anytime anywhere in the world and it should be well managed and the output should be directed to HTTP so that user can have an application layer over it to have a user interface.

A. Python Request library

Request is a Python HTTP library, released under the Apache2 License. The goal of the project is to make HTTP request simpler and more human- friendly. So user can direct all the outputs of power, voltage and current through the processor to the localhost server (standalone PC) which will record all the calculated output values and then plot them on the website with the help of PHP. It can customize as user want to have an interface. Here are some of the outputs which have been recorded while testing the system. here only active power is calculated as the load is resistive (200Watt) but the system can also calculate the reactive power if the load is inductive. The request library allows us not to have load on the Raspberry-Pi's Broadcom processor and thus all the load comes on the standalone computer. This method saves the power consumption of the processor as well as the memory bank. It has limitless advantage on the amount of information to be stored and the type of data to store in the database. The processor now acts as the bypass to the internet with the help of a local server.

VI. PROTOTYPE SYSTEM

The final prototype incorporates the onboard processor with the PCB of voltage and current sensing combined with the ADC along with voltage reference circuit and also onboard plugs and terminal. The final outlook of the system is shown in Fig.8.a. We just have to connect the load in between the plugs and connect the 230V power supply (line voltage) which will be sensed by the circuit. The Fig.8.b shows the connection of the Active load with the server setup. The Fig.10 is the final output on the website. Table I outlines the results obtained displaying the power, input voltage and the input current at the instant of time.

13:05:30	715.71	172.63	4.15	800
13:05:35	724.29	169.96	4.26	800
13:07:03	719.72	168.81	4.26	800
13:08:11	751.09	168.81	4.45	800

Fig. no.9 shown below is the terminal screen of the local host (RPI), thus getting the real-time data on the backend. This data is then transferred, using the python script in which the python request library is called, through the local network.

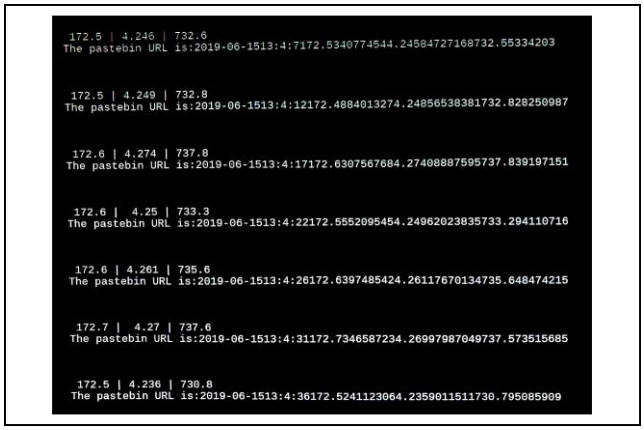

Fig. 9. The terminal screen of localhost

This data is then segregated on the server side and stored on the local database. Using PHP the graph is plotted and the website can be designed [7]. Rather than going into the complexity of designing the aim was to transfer data accurately and with minimum discrepancies. From the table that has been derived based on the calculations, we can calculate the efficiency by using (5).

$$Efficiency = \eta = ((output)/input) * 100\% \quad (5)$$

By measuring the maximum deviation of the output power from the actual load applied, the efficiency is calculated which comes nearly to 80%.Thus in order to increase the efficiency it needs to process more samples per unit time and bring the observed value close to the real value.

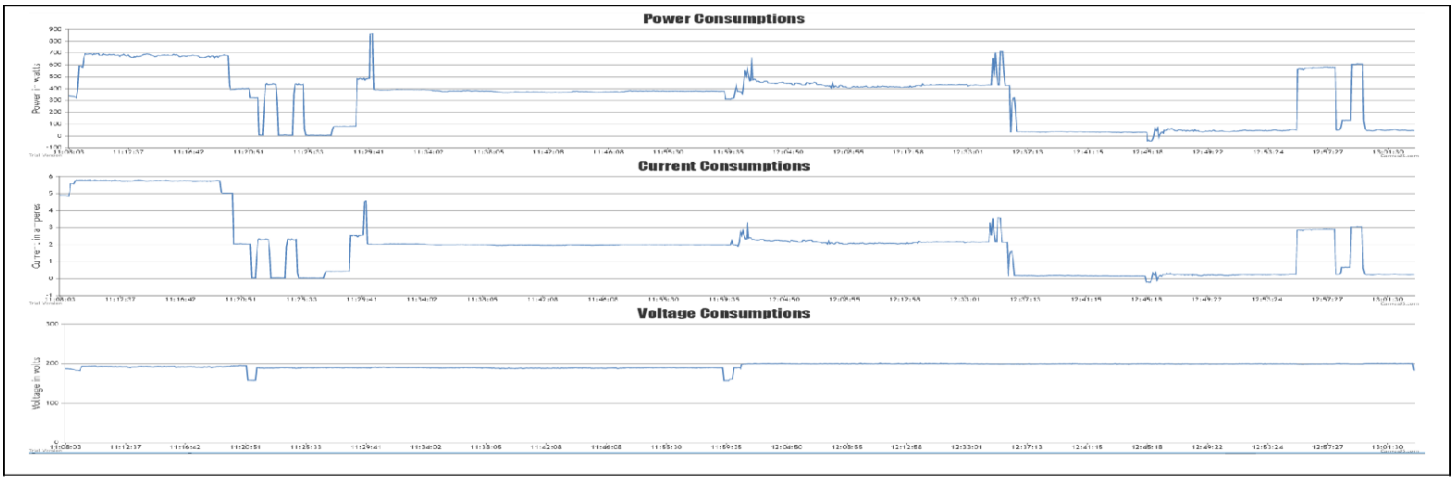

Fig. 9. Graphical output of voltage current and power

A. LIMITATIONS

1. The load cannot be increased beyond 2.1kW because of maximum isolation tolerance of Current sensor (ACS 712) is 2.1kW; this can be overcome by changing the higher rating current sensor.
2. The voltage across load cannot go beyond 240VAC because the potential transformer is customized to convert 230VAC to 5VAC.
3. Present setup is designed to monitor up to two household appliances. It can be increased by increasing the number of PTs and Current sensors.

B. FUTURE SCOPE

1. This system can be further developed for three phase supply and can be associated with industrial loads for their analysis.
2. The analysis can be brought to the app by designing it particularly for targeting the on-go customer.
3. The fault detection system can be implemented using the sensing system at a particular point of contact.
4. There can be a separate database for power calculations and fault detection storage so it will be better future analysis.
5. We can add solar PV system in order to reduce the grid consumption and we can analyse its power even. The environmental conditions can also be logged on to database for a solar system for detail analysis of it.

VII. CONCLUSION

As this system helps out to plot the data in real-time it is better to analyze the system malfunction and the usage of the electrical power. Power Quality is the major factor in the industry as well as in house plug-in loads performance. The power factor calculation aims at maximizing real power accuracy [8]. The calculations required for the cost of power consumed can be further added to the backend server so the bill is auto-generated. This can be a new method to calculate electricity expenses instead of currently available manual intervention method. By having a detailed analysis of the database, the points where more power is consumed unnecessarily can be detected and have a fault analysis, which directly helps to have energy cut downs in order to make the system consumption more efficient. The threading method involved will increase tolerance for errors in the output.

***Abstract*:-This article introduces "A high voltage gain non - isolated DC DC converter based on inductors for Microgrid application." This converter presents high voltage gain without penalty of high duty ratio. The presented converter employs two single inductors, both are charging in parallel and discharging in series. The steady state analysis of proposed converter is shown in section IV. The simulation of proposed converter 17V/182V is developed in MATLAB Simulink to check the feasibility and performance of the converter.**

Keywords— DC DC converter, *microgrid, high voltage gain, two single inductors* .

I. INTRODUCTION

Demand for clean and sustainable energy sources has increased rapidly in past few years. DC microgrid is come forward with increase utilization in green energy. As DC power generator produces low output voltage hence it require high gain converter to meet the load conditions. [1-2]. Photovoltaic cell, batteries, fuel cells are commonly used as green energy sources for integration purpose.

A particular high gain converter is used for the individual solar panel. These converters are used for individual solar panel. These converters boost lower level input voltage to desirable higher output voltage[3]. Large duty ratio, compact size and high efficiency are main advantages of this system [4]. Large duty ratio contributes extended conduction losses, also it affects the operation of the switches as voltage stress increased on them.to overcome this the high rated switches are used[5]. Upcoming converters are consists of coupled inductor, switched mode capacitor, multiplier cell to get desired gain[6]. For getting high voltage gain and improved efficiency more converters have been invented by researchers.[7-9].

Various isolated and non isolated converters are invented by researchers in recent past years. The main goal for them is to get high voltage gain. In isolated converter main disadvantage is saturation of transformer core. Due to this researchers are moves towards non isolated type of converters such as cascaded boost[10], the quadratic boost[11], voltage lift[12-14] etc. the disadvantage of these are number of stages for capacitor and inductor. This increases complexity as well as cost of converter.

Some coupled inductor based converter system delivered high gain and considerable low stress on switche[15-17]. The elected duty ratio and turns ratio of inductors will produce high input ripple. So in addition eith converter filter circuit is implemented.[18]

In this paper, the solar PV panel with MPPT block is used as input source for the proposed topology. The converter is designed with three power switches which operate on 2 different duty ratios. Other than this following are some advantages of the proposed system.

1. Incremental conductance and integral regulator technique is used for maximum power point tracking algorithm.
2. The inductor is supplied with source directly without any additional coupling circuit. This stored energy is independent of other clamping circuits.
3. High voltage gain is the main advantage of proposed system.
4. The proposed system is independent of voltage multiplier cell[VMC] and switched capacitor technology.

The block diagram of the system is shown in figure (1).The proposed converter have solar panel as a input source. MPPT block is used to track maximum output for that particular time duration. This input source converts solar energy into electrical energy irrespective of irradiation and temperature. The maximum power for that particular time will be taken with the help of incremental conductance and integral regulator technique (MPPT). Due to maintenance batteries are removed from the circuit. The effective handling is the main concern. By economical point of view it is also advantageous to remove battery from input side..

Upcoming sections gives circuit details with parameters and steady state analysis. The next section gives simulation results for the both open loop as well as closed loop configuration of the proposed system.

The fig(1) shows block diagram of the proposed converter system. Solar PV panel is used as the input source for given system. The main converter block is used to convert lower level input voltage to desired higher level. To connect this system with MPPT some voltage and current sensing is required. This sense the voltage and current from the system

and passed to MPPT block where this sensed input is converter into required duty ratio of the operating switch. The PWM converter converts it into pulses and then it provided to the gate terminal of the operating switches.

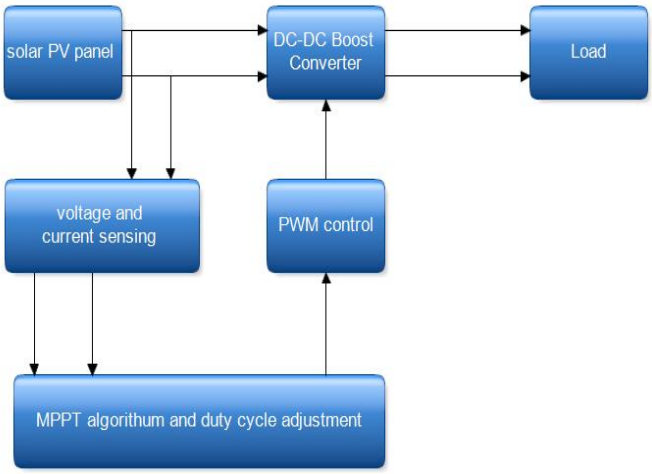

Fig.(1).Block diagram of DC-DC Boost converter.

II. CIRCUIT DETAILS:

Figure 2 shows the proposed system. It includes three switches P_1,P_2 ,P_3. It also consist of two inductor, 2 diode and one capacitor. The converter is operated in a Continuous Conduction mode. The duty ratio for P_1,and P_2 is D_1 and For P_3. It is D_2.

In steady state operation of the converter some assumption must be considered.

1) All the components should be in ideal condition.

2) Value of capacitor is considerably large so as to manitain constant output voltage.

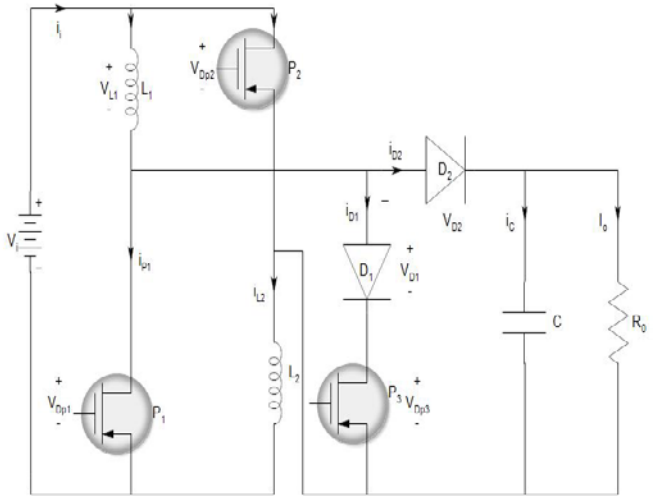

Fig.(2). Circuit Diagram for the proposed converter.

III. MAXIMUM POWER POINT TRACKING SYSTEM

Generally PV cell generates energy with respect of solar irradiation and temperature. The MPPT block is used to define a duty cycle for solar PV operation. In this incremental conductance methodology, dI/dV to work out the magnitude relation of dP/dV. Once dI/dV is equal and opposite to of I/V(where dP/dV=0) the concept is aware of that the maximum power point is reached and therefore it stop the loop and come back to the reference value of operational voltage. In this method rapidly changing irradiance sense exactly than P&O method. The basic working of the MPPT algorithm is as shown in fig (1)

IV. STEADY STATE OPERATION

In this section Continuous Conduction Mode is discussed. The proposed system is worked on three different modes of operation.[19]

Consider , the number of turns are same for both the inductors.

$$L_1 = L_2 = L \tag{1}$$

Voltage across inductors be,

$$V_{L1} = \mathrm{L}_1 \frac{di_{L1}}{dt} = \mathrm{L} \frac{di_{L1}}{dt} \tag{2}$$

$$V_{L2} = \mathrm{L}_2 \frac{di_{L2}}{dt} = \mathrm{L} \frac{di_{L2}}{dt} \tag{3}$$

Where $i_{L1}$and i_{l2} are current through L_1 And L_2.

As discussed earlier three modes of operation for the converter these are as follows.

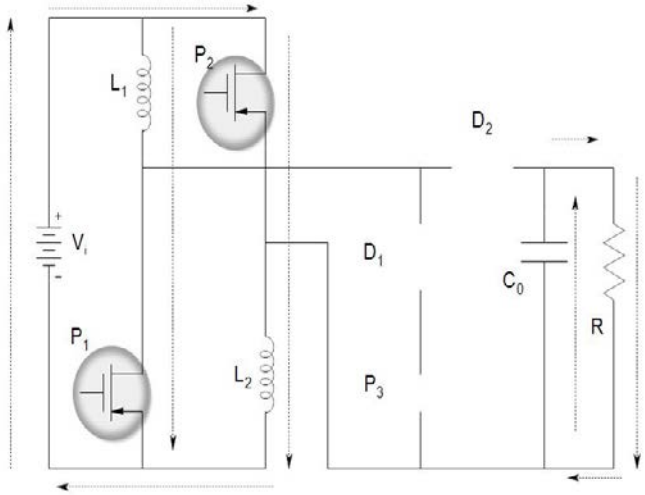

Fig.(3a). Mode I of operation.

CCM Mode- I

In this mode of operation Switch P_1 and P_2 are turned ON and P_3 is turned OFF. The flow of current is shown fig (3a) the current is pass through L_1,L_2 . Capacitor start discharging through the load as both diodes are in reverse biased. Due to this Inductors are parallel to the souse hence

input voltage will be equal to voltage across inductors, hence ,

$$V_{L1} = V_{L2} = V_i \quad (4)$$

Put equation 2 and 3 in equation 4

$$L\frac{di_{L1}}{dt} = L\frac{di_{L2}}{dt} = L\frac{di_L}{dt} = V_i, \quad t_0 \le t \le t_1 \quad (5)$$

$$\frac{di_{L1}}{dt} = \frac{di_{L2}}{dt} = \frac{di_L}{dt} = \frac{V_i}{L} \quad (6)$$

CCM Mode-II

In this mode P_1 and P_2 turned OFF and P_3 is turned ON. Due to this both inductor and source supply to load, And capacitor starts charging. This make diode D_2 forward biased. The direction of flow of current is as shown in fig (3b). Respective current and voltage equations are as follows,

$$i_{L1} = i_{L2} = i_L \quad (7)$$

$$V_{L1} + V_{L2} = V_i \quad (8)$$

Now substituting equation 2 and 3 in equation 8 we get,

$$\frac{di_L}{dt} = \frac{V_i}{2L}$$

$$t_1 \le t \le\le t_2 \quad (9)$$

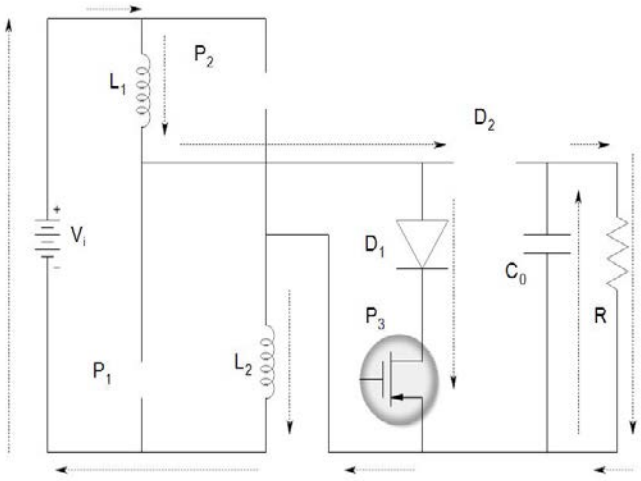

Fig.(3b). Mode II of operation.

CCM Mode-III

In this mode of operation aall the three switches turned OFF. Hence current will flow from L_1, D_2 ,C , load ,L_2 and back to the supply. Here D_2 is in forward biased while D_1 in reverse biased condition. As inductors are in series to the the average of input voltage is applied across the switches. The flow of current for this mode of operation is shown in fig (3c). the equations for voltage and current in this mode is as follows,

$$i_{L1} = i_{L2} = i_L \quad (10)$$

$$V_{L1} + V_{L2} = V_i - V_0 \quad (11)$$

Rearranging the above equation with equation 2 and equation 3 we get,

$$\frac{di_L}{dt} = \frac{V_i - V_o}{2L} \qquad t_2 \le t \le t_1 \quad (12)$$

Applying state space averaging method we get,

$$\int_0^{D_1 T_s} \left(\frac{di_L}{dt}\right)^I dt + \int_0^{D_2 T_s} \left(\frac{di_L}{dt}\right)^{II} dt + \int_0^{(1-D_1-D_2)T_s} \left(\frac{di_L}{dt}\right)^{III} dt = 0 \quad (13)$$

Where I, II, III, show mode of operation. Simplifying this equation (13) we get, final equation as follows,

$$\frac{V_o}{V_i} = \frac{(1+D_1)}{(1-D_1-D_2)} \quad (14)$$

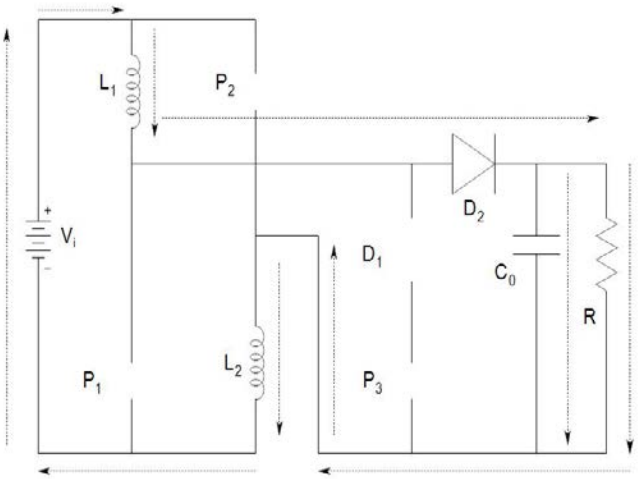

Fig.(3c). Mode III of operation.

V. SIMULATION RESULTS

To authenticate the performance of planed high gain boost converter is simulated in MATLAB Simulink software. The output voltage of planed converter is near about 182V. The input of the planed converter that is output voltage of the solar panel is around 17V.The duty cycle is set by MPPT algorithm with respect to irradiation and temperature of solar panel. After this the duty cycle is around '0.6' and '0.2' respectively to reduce conduction losses. The fig (04) shows the Simulink Model of the proposed converter and fig (05) shows the both values duty cycle. Output Voltage of the

converter is shown in fig.(06), PV Array Voltage fig (07), pulses of the both power switches is shown in fig (08). The table. I. shows all the feature details of the proposed system.

TABLE. I. FEATURES OF PROPOSED SYSTEM

Element	Parametric Quantity
P_{max}	100 W
V_{input}	17 V
V_{out}	182 V
Switching Hz	50 KHz
Duty Ratio	0.6, 0.2

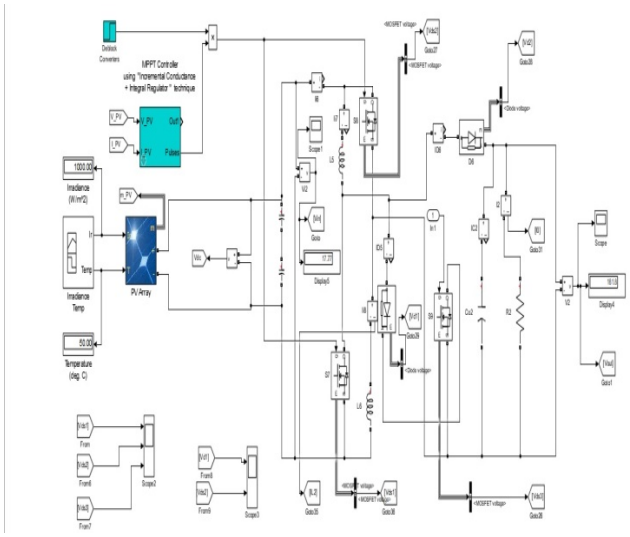

Fig.(04). MATLAB Model of proposed converter

Fig.(06). Output voltage of the converter

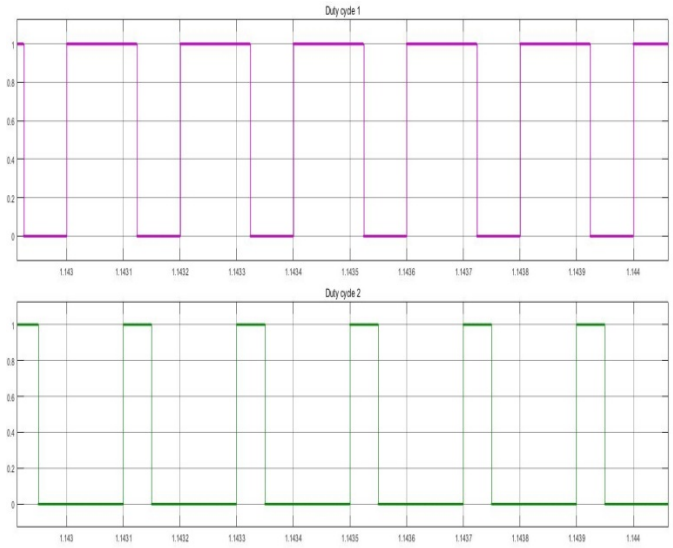

Fig.(08). Pulses for power switches

VI. CONCLUSION

In this paper new improved high gain DC-DC boost converter topology is discussed. The system deals with three switches with two different duty ratios results in higher efficiency and desirable high output voltage. Rather than this voltage gain of about 10 is achieved. Elimination of battery is also one of the advantages of this article. MPPT based solar panel sets autonomous duty ratio of DC-DC converter, which helps in providing constant output voltage even though fluctuating input voltage of the solar panel. This converter may be integrate with AC microgrid by developing the appropriate inverter circuit. By implementing ZVS and ZCS technique switching losses of converter will be reduced which may enhance efficiency of converter.

Abstract -- In the field of image processing application such as medical diagnosis, crime prevention, publishing or advertising, historical research a common image retrieval technique is used. Simple browsing can easily identify images in a small collection of images but for large and different collection of images identification of image becomes critical issue. In this paper for image retrieval four different features are extracted using DDBTC technique. The first two features such as Color Co-occurrence Features (CCF) and Color Histogram Features (CHF) are obtained using color quantizers, Bit Pattern Feature (BPF) and Bit Histogram Feature (BHF) are obtained using Bitmap image. In order to remove the false counter problem and blocking effect different error diffusion kernels are employed. The results shows better accuracy.

Keywords— Average Recall Rate Average Precision Rate, Bit pattern feature, color co-occurrence feature color histogram feature, Dot diffused block truncation coding.

I. INTRODUCTION

Content based Image Retrieval application of computer vision technique to minimize the problem of image retrieval.In annotated based method we have to annote every image based on information of metadata or keywords. In this process the system is not able to capture the exact keywords to represent The images and it becomes time consuming. In CBIR system search of images is based on visual contents rather than metadata. Here "content" is information of texture, shape, or color obtained from images. In 1979 [1] Mitchell and Delp introduces first Block Truncation Coding (BTC). Udpikar and Raina [2] describe the overhead statistical information using source encoding of a block truncation coding. (BTC). Author uses the vector quantization which reduces the bit up to 1.5 bit/ pixel. Yiyan Wu [3] derives Blo for image retrieval. BTC generates the vector quantized bitmap which are then decomposed into a set of vectors. It achieves the compression ratio up to 10:1. G. Qiu [4] uses BTC technique for feature extraction. N. Jhanwara [5] uses motif co-occurrence matrix (MCM) for content based image retrieval. The MCM is similar to the color co-occurrence matrix (CCM), but MCM performs the retrieval task better than the CCM. Experiment shows the MCM improves the retrieval performance as compared to CCM. In [7-10] author uses dot diffusion block truncation coding for image retrieval. To measure the performance of image retrieval various distance metrics are employed.

I.SYSTEM DESIGN

System design flow is mentioned in fig.1

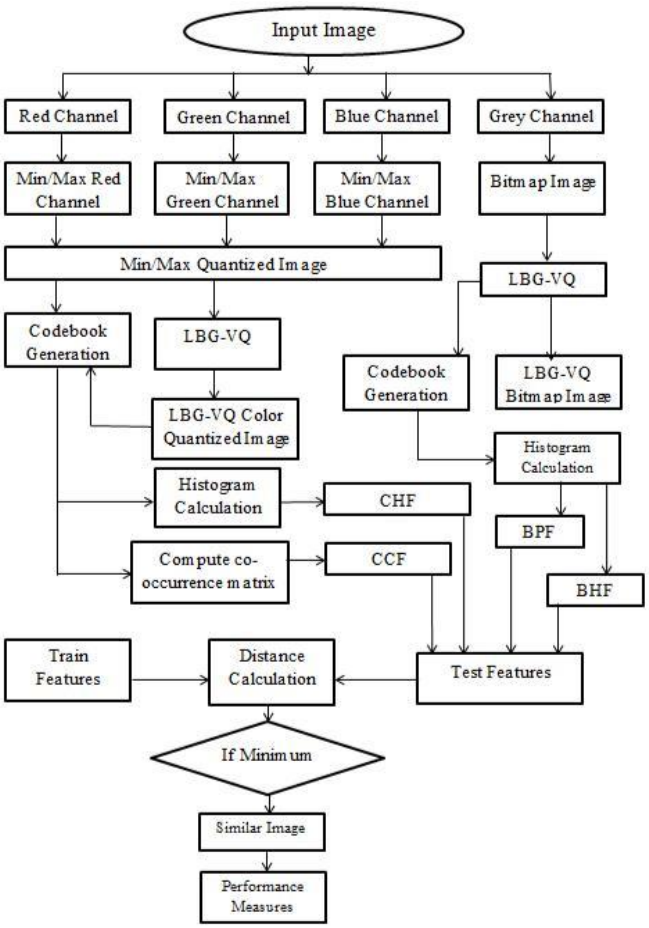

Fig. 1. System Design

A. *Dot Diffused Block Truncation Coding :*

A sample image is used to derive the minimum and maximum quantizers. In this assume at position (i, j) an f (i, j) be the image block. The color images are in RGB color space.

$$Q_{min} = \{\min f_R(x, y), \min f_G(x, y), \min f_B(x, y)\} \quad (1)$$

$$Q_{max} = \{\max f_R(x,y), \max f_G(x,y), \max f_B(x,y)\} \quad (2)$$

In this Red, Green and blue color are represented by R, G and B. The color image is converted into grey image using:

$$f\hat{}(x,y)=1/3[f_R(x,y)+f_G(x,y)+f_B(x,y)] \quad (3)$$

The Bitmap image is also computed using:

$$b_m=1; \text{ if, } f\hat{}(x, y) \ f(i, j) \quad (4)$$

$$0; \text{ if } f\hat{}(x, y) < f(i, j)$$

II.FEATURE EXTRACTION

1.Color Histogram Feature (CHF) :

The Process of CHF is shown in Fig 2.

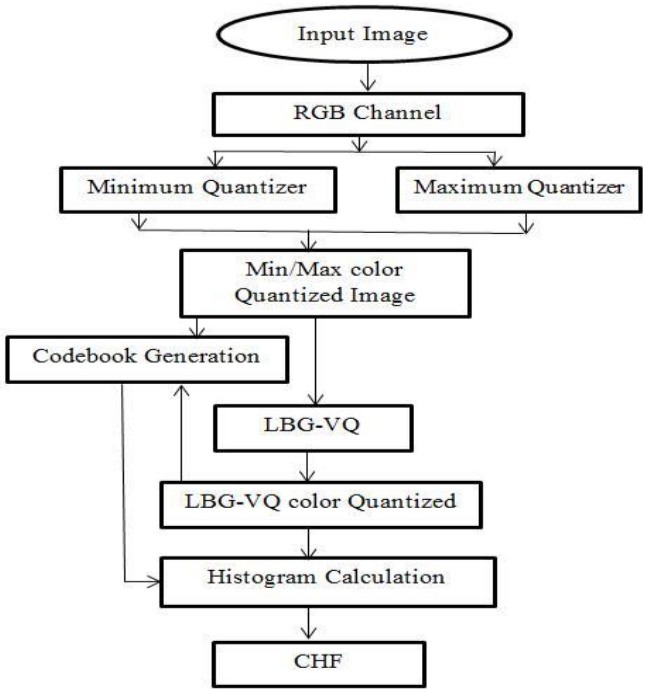

Fig. 2. Design flow of CHF

2. Color Co Occurrence Feature (CCF):

The Process of CCF is shown in Fig 3.

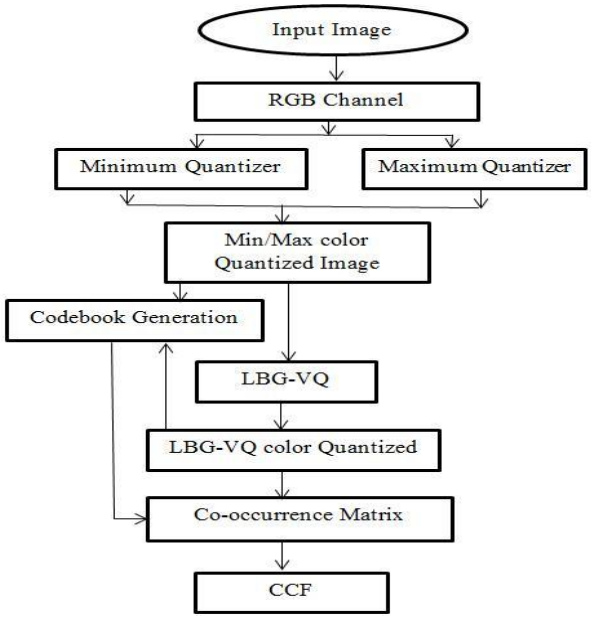

Fig. 3. Design flow of CCF

3. Bitmap Pattern Feature (BPF):

The Process of BPF is shown in Fig 4.

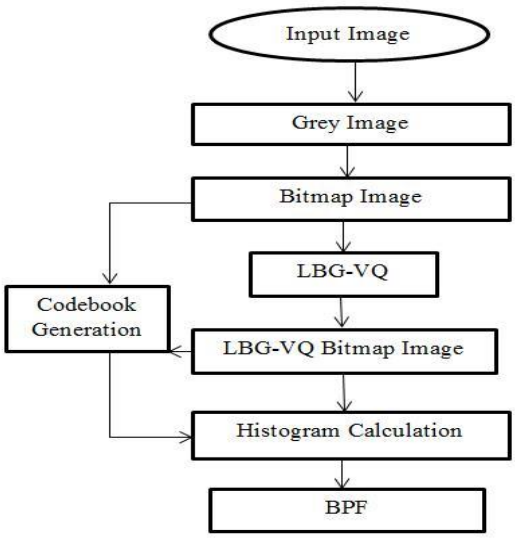

Fig. 4. Design flow of BPF

4. Bit Histogram Feature (BHF):

The Process of BHF is shown in Fig 5.

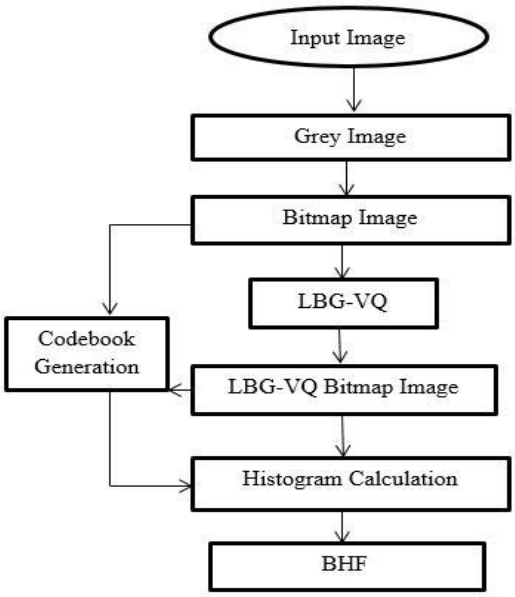

Fig. 5. Design flow of BHF

B. Distance Metrics :

The different distance metrics are given by:

1.L_1 distance

$$\delta(query, target) = a_1 \sum_{k=1}^{Nmin} | CHF_{min}^{query}(k) - CHF_{min}^{target}(k)| + a_2 \sum_{k=1}^{Nmax} | CHF_{min}^{query}(k)\, CHF_{min}^{target}(k)| + a_3 \sum_{k=1}^{Nb} | BPF^{query}(k) - BPF^{target}(k)| \quad (5)$$

2.L_2 distance

$$\delta(query, target) = [\, a_1 \sum_{k=1}^{Nmin} (CHF_{min}^{query}(k) - CHF_{min}^{target}(k))^2 + a_2 \sum_{k=1}^{Nmax} (CHF_{min}^{query}(k) - CHF_{min}^{target}(k))^2 + a_3 \sum_{k=1}^{Nb} (BPF^{query}(k) - BPF^{target}(k))^2]^{1/2} \quad (6)$$

3.x^2 Distance

$$\delta(query, target) = \alpha_1 \sum_{k=1}^{N_{min}} \left(\frac{CHF_{min}^{query}(k) - CHF_{min}^{target}(k)}{CHF_{min}^{query}(k) + CHF_{min}^{target}(k) + \varepsilon} \right)^2 + \alpha_2 \sum_{k=1}^{N_{max}} \left(\frac{CHF_{max}^{query}(k) - CHF_{max}^{target}(k)}{CHF_{max}^{query}(k) + CHF_{max}^{target}(k) + \varepsilon} \right)^2 + \alpha_3 \sum_{k=1}^{N_b} \left(\frac{BPF^{query}(k) - BPF^{target}(k)}{BPF^{query}(k) + BPF^{target}(k) + \varepsilon} \right)^2$$

4. Fu Distance:

$$\delta(query, target) = \frac{L_2 distance}{|CHF_{min}| + |CHF_{max}| + |BPF|}$$

5. Modified Canberra distance

$$\delta(query, target) = a_1 \sum_{k=1}^{Nmin} \frac{|CHF_{min}^{query}(k) - CHF_{min}^{target}(k)|}{CHF_{min}^{query}(k) + CHF_{min}^{target}(k) + \varepsilon} + a_2 \sum_{k=1}^{Nmax} \frac{|CHF_{max}^{query}(k) - CHF_{max}^{target}(k)|}{CHF_{max}^{query}(k) + CHF_{max}^{target}(k) + \varepsilon} + a_3 \sum_{k=1}^{Nb} \frac{|BPF^{query}(k) - BPF^{target}(k)|}{BPF^{query}(k) + BPF^{target}(k) + \varepsilon} \quad (7)$$

C. System Performance:

System performance determined using:

$$APR = \frac{1}{Nt\,L} \sum_{q=1}^{Nt} Nq(L) \quad (8)$$

$$ARR = \frac{1}{Nt\,Nr} \sum_{q=1}^{Nt} Nq(Nr) \quad (9)$$

D. Error Diffusion Kernels:

Here we can mention various Error Diffusion kernels in order to generate the Bitmap images. The advantage of Error diffusion kernels is that it can achieves better image quality as compared to Block Truncation Coding technique. The image compression using BTC and EDBTC and BTC also used in [3, 4, 6]. Here we mention the six different error diffusion kernels.

$$\left(\frac{1}{16}\right)\begin{bmatrix} & * & 7 \\ 3 & 5 & 1 \end{bmatrix} \quad \left(\frac{1}{42}\right)\begin{bmatrix} & & * & 8 & 4 \\ 2 & 4 & 8 & 4 & 2 \\ 1 & 2 & 4 & 2 & 1 \end{bmatrix} \quad \left(\frac{1}{32}\right)\begin{bmatrix} & & * & 5 & 3 \\ 2 & 4 & 5 & 4 & 2 \\ 0 & 2 & 3 & 2 & 0 \end{bmatrix}$$

(a) (b) (c)

$$\left(\frac{1}{32}\right)\begin{bmatrix} & & * & 8 & 4 \\ 2 & 4 & 8 & 4 & 2 \end{bmatrix} \quad \left(\frac{1}{48}\right)\begin{bmatrix} & & * & 7 & 5 \\ 3 & 5 & 7 & 5 & 3 \\ 1 & 3 & 5 & 3 & 1 \end{bmatrix} \quad \left(\frac{1}{200}\right)\begin{bmatrix} & & & * & & 32 & \\ 12 & & 26 & & 30 & & 16 \\ & 12 & & 26 & & 12 & \\ 5 & & 12 & & 12 & & 5 \end{bmatrix}$$

(d) (e) (f)

Error diffusion kernel: (a) Floyd-Steinberg (b) Stucki [62], (c) Sierra (d) Burkers (e) Jarvis and (f) Stevenson filter

Generally while using BTC technique many problems are occurred such as blocking effect and false counter problems. Due to this the image quality can be degraded. In order to overcome such problems various error diffusion kernels are employed

III. EXPERIMENTAL RESULTS

E. Experimental Setup:

Fig.6. Corel Image Dataset

The Fig.6.shows sample images from Corel 1000 Dataset. The Corel 1000 dataset having 10 different Classes. For our image retrieval task we can select 20 images from each class, so that the dataset.

Fig.7. Input color image

Input color image is selected as shown in Fig.7.The Fig.8. is obtained using quantization process From Gray color image Bitmap image obtained as shown in fig.9.

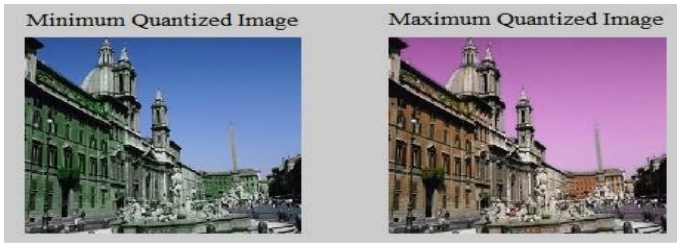

Fig. 8. Min. and Max. Quantized Image

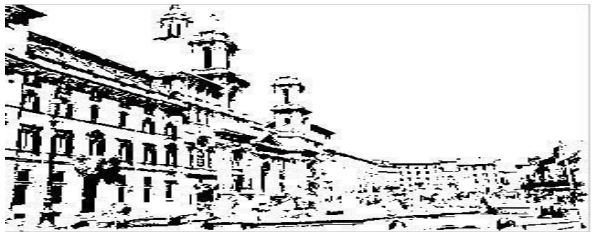

Fig.9. Bitmap Image

The fig.10 and fig. 11 are obtained Using color co-occurrence matrix the image can arrange with vertical, horizontal centered points and diagonally ordered centered points.

Fig.10.Ordered Matrix with centered Points

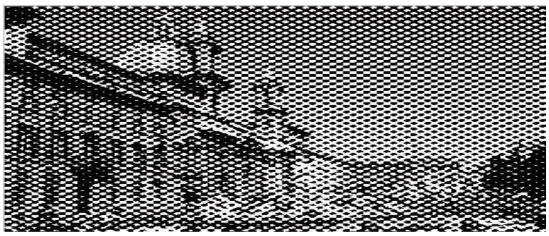

Fig.11.Diagonal Ordered Matrix with Balanced Centered Point

Fig.12.shows the Retrieved images using modified Canberra distance.

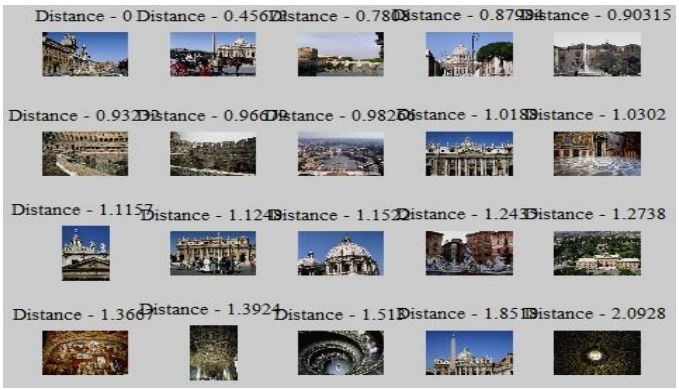

Fig.12. Retrieved Images

The image retrieval task can be performed by using five different distance metrics. The simulated results of L1 and L2 distance listed in Table I and X2 and Fu distance results are listed in Table II.The modified Canberra distance shows the better accuracy listed in Table. III.

Performance Image Retrieval is graphicallyshown in Fig.13. And Fig.14.

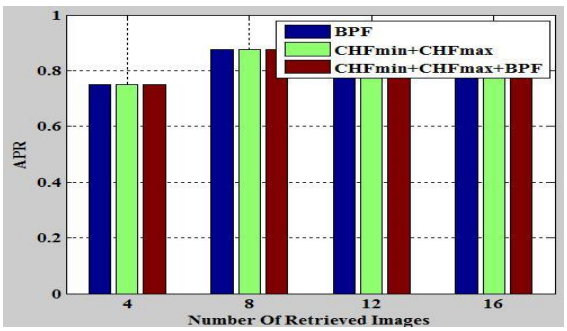

Fig.13. Performance Graph of APR

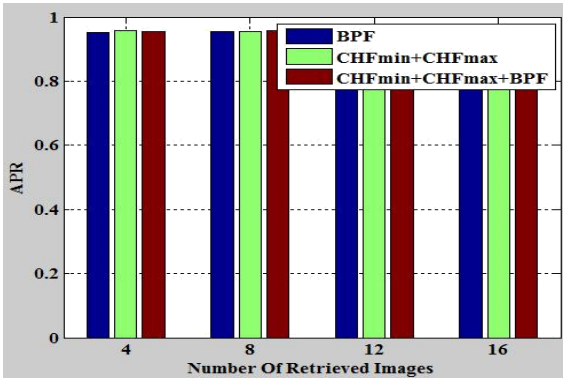

Fig.14.Performance Graph of ARR

COMPARISION OF RESULT WITH OTHER METHODS

In this experiment we measure performance of system and compare with the other retrieval methods.It shows that the proposed system shows the better retrieval accuracy. The Author N.Jhanwar in [4] uses modif co-occurance matrix for image retrieval which achieves 0.5268 accuracy.In our method the average precision rate is 0.9125.Table IV. Shows the comparison of APR with other techniques.

Table IV

In paper [2] author uses the Error Diffusion Block Truncation Coding and derives the two features which achieves the Precision Rate as 0.797 under Corel 1000.

CONCLUSION

To perform the Experiment DDBTC method and four number of image features are used. The bit pattern feature (BPF) and Bit Histogram Feature (BPH) recognize the contents of image. The color co-occurrence feature (CCF) and color histogram feature (CHF) represents color distribution and image brightness. The simulated results shows better average recall rate and average precision rate. The Error diffusion kernels are employed to minimize the problem of blocking effect and false contour problem. The Modified Canberra distance shows better accuracy as compared to other similarity distance. In the future work, we can increase the size of dataset and computational time for image retrieval can also reduce.

Abstract*—Cyber security is a most important trepidation in the widespread adoption of internet technologies in the everyday activities of human being. Even though more sophisticated technologies emerged on the Internet, but different kinds of attacks and threats are also increasing day by day. Cyber attacks causes loss of customer confidence in adopting internet based applications. Phishing attack is one of the common vulnerabilities in the cyber space. Most of the anti-phishing solutions proposed so are focused only on a single issue and needs improvement. For malicious web page detection and prevention, an intelligent multi agent solution is proposed in this paper with the help of machine learning methods. The proposed approach detects both phishing sites and websites with malicious content. This multi-agent system contains four autonomous intelligent agents, which communicate with each other using the Extensible Messaging and Presence Protocol (XMPP) for decision-making. The first is a monitoring agent, second and third is for decision-making (using the machine-learning classifiers) and the fourth is for action-performing. The first agent is responsible for extracting URLs. It passes the extracted URLs to the second agent for feature extraction and classification. If any phishing is detected, the second agent communicates with the fourth agent and the site is blocked. Otherwise, the second agent communicates with the third agent for malicious script detection. If any malicious script is detected then the fourth agent blocks the entire web page. We have tested the performance and accuracy of the proposed method and obtained results ensures its efficiency.

Keywords*—Phishing attack, machine learning, classifiers, intelligent agents, support vector machine.

I. INTRODUCTION

Cyber security is critical in adopting online services in today's world. Both academia and industry had given much attention in this field due to high threat rate. As the network becomes a more pervasive, all the cyber attacks have become a serious threat to the network users. Internet security is crucial, since most of the human business and social and financial activities occur through it. Even though more sophisticated technologies emerged for the internet, more focused attacks are also happening. Financial and personal information loss is the major hazard for a customer, while loss of trust and reputation is the resultant effect to the business owners due to security issues. Ultimately security threats will create lack of confidence in customers to adopt online services. The weak internet security, huge and quick economic benefit attracts criminals to this area. Since online services have become more popular, security risks on the internet is also grown exponentially. The attackers are more intelligent and they make newer and adaptable attacks that bypass existing security measures. Some of the attacks are DDOS, Man-in-Middle, Phishing, SQL injection, Cross-site scripting, etc.

One of the most common type of attack in cyber space is phishing. In phishing, a forged website is created by an attacker to mimic the original website so as to steal sensitive information or credentials of a user. In some cases, attackers may inject malicious scripts to the legitimate websites. The intruders adopt several methods to steal the information from the user. So it is difficult to provide security to the emerging new kind of attacks [3]. Phishing attack can be done in several forms. URL obfuscation, based on hyperlink and email are some of the common attacks. Many research proposals are offered to protect websites from this type of attack but the phishers are much smart, so that they try new methods to overcome the protection measures.

Recently phishing attacks became one of the serious issues due to the use of smart strategies for the creation of phishing websites. Phishing sites are actually a forged website created by an attacker that mimics the real website. Using these fake sites all the sensitive information are taken away by the attacker. First of all, an attacker creates phishing emails and sends it to the victim. For the receiver this email seems to be from an authentic person and request victim to update or validate their sensitive information related to bank account,

other personal information etc., by using the hyperlink provided in the email. This link will leads to a phishing website and when the user enters the details to this site all their confidential information or credentials will be captured by the hacker. To prevent these types of attacks anti phishing techniques are available [3], but still these attacks are evolving and bypassing all the countermeasures and most of these solutions are imprecise because of false positive rates. There are some existing machine learning technique for the detection of phishing attacks [8][9] and more, but it focus on single objective. To overcome, this paper presents a machine learning based method. For improving the accuracy and efficiency here we have incorporated another detection mechanism known as the Link Guard algorithm [6].

The objective of this work is the detection and prevention of phishing and malicious script attack using machine learning classifier and agent based intelligent system. The rest of this paper is organized as follows. Section 2 describes about the various literatures in this field. The detailed description of the proposed method is given in the section 3. Experimental setup and performance analysis of the proposed method is given in section 4. Finally this paper concludes in section 5.

II. RELATED WORKS

There are several methods adopted for ensuring phishing attack free website operations. These methods can be classified according to the mechanisms adopted in each one. Blacklisting, heuristic methods, visual similarity assessment methods and machine learning based methods. In the following paragraphs we have analyzed these methods.

Blacklist Methods

Blacklist is actually a database that stores all the previously detected phishing URLs or IP addresses. The paper [2] is an enhanced blacklist method that detects phishing by extracting the key features from source code. In this method already existing or the imitation of phishing websites or its variations are identified. Using the features these website are identified with a unique fingerprint. The unique fingerprint generation is based on the Simhash algorithm. The key features used are filename in the request URLs, path name and attribute values of tags used in the scripting language. Now a large number of toolkits are available for creating phishing websites. So detecting phishing using blacklist method like [16] has become inefficient. The white-listing method proposed in [17] that automatically updates a list of all familiar original websites.

Heuristic Methods

Blacklisted methods detect phishing sites, but still it has certain disadvantages such as new phishing attacks remain undetected. In order to address this issue heuristic methods are introduced. These are experience based techniques for solving a problem. These methods produce near optimal solutions. It finds solutions by learning the situation and then the discovery of solution to the problem under consideration. The solution obtained using these methods are not guaranteed to be optimal. The methods mentioned in [4][11] are heuristic approaches for phishing detection. The method in [10] called CANTINA is based on the term frequency and inverse document frequency of a word in the query.

Visual Similarity Based Methods

Another technique used by the phishers is visual similarity method. They create visually similar websites to the original ones. This similarity usually confuses the users and sometimes they think or feel that the mimicked website as original. Some research works are based on this similarity identification [5] [18]. The method proposed in [18] considers content and format of text in the website. It also considers images, tags, style sheets, etc., to detect the phishing. [5] is based on the image level, which matches the suspicious Web page snapshot image with the legitimate Web page snapshot image, and therefore can deal with the non-text tricks that make similar Web pages with various HTML contents. [5] uses local and global features of the snapshot images which can be used for phishing detection together.

Machine Learning Methods

Artificial Neural Network (ANN) is another method used to detect phishing attack [8]. The main aim of this machine learning based method is to model neural network to classify websites as legitimate or phishing. They have used one hidden layer for their experiments. They trained the neural network by changing the values of momentum and learning rate until a lower error rate is acquired. The papers [9][20] are also deals with machine learning methods for phishing detection. In [20] a wrapper-based features selection method was introduced. This method aid in the selection of most significant features. This selected features are subsequently used for the accurate phishing website prediction. But wrapper-based features selection method spends more time and need additional computational overhead than other methods.

The support vector machine achieved notable classification accuracy because it uses a labelled dataset. Web page source code characteristics can also be used for phishing detection [9]. There are certain features that differentiate phishing websites from original. Based on these characteristics, it finds the severity percentage. It considered characteristics like logos, suspicious URLs, short-lived, HTTPS, pop up window script, iframe and domain.

The paper [7] introduced multi-agents for phishing detection. In this paper, they try to detect a new type of phishing attack known as tab napping. They have used image retrieval method for detecting the website layout changes and

other reloads. Considering the above facts, an intelligent agent based method is proposed in this paper.

III. PROPOSED METHOD

In the proposed method, effective phishing detection and prevention mechanism using agent-based intelligent system is introduced. Here an agent-based intelligent system is used for the detection and prevention of phishing attacks. It also detects malicious scripts present in non-phishing sites. Agent technology is used to solve the critical problems with some sort of intelligence. Most of the existing methods used are based on single issue or agent. As the internet technology advances to horizon, new problem arises, so there is need for multi-agent based approach to prevent phishing attacks.

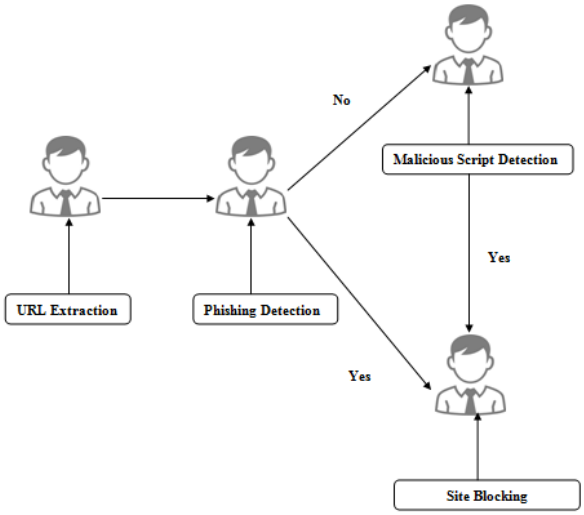

Fig.1. Overview of the Proposed Method

The overview of the proposed method is given in Fig. 1. The aim of this method is to use different intelligent agents for phishing detection. This multi-agent modular approach will increase the performance. The decomposition allows the agent to use the most appropriate technique for solving the problems. The multiple agents cooperate and coordinate with each other to solve the phishing issue continuously. These heterogeneous agents work autonomously. These agents communicate to each other using message passing mechanism.

Proposed system contains three tier software layers with four agents. These layers are named as lowest, middle and upper most layers. The first two layers contain one agent each while third layer contains two agents. The function of lowest layer is the extraction of URLs. The classification of phishing attacks are done at layer 2. The upper most layer contains two agents. One agent for blocking the phishing URLs and other for unauthorized malicious script detection. The proposed layered architecture is shown in the Fig. 2.

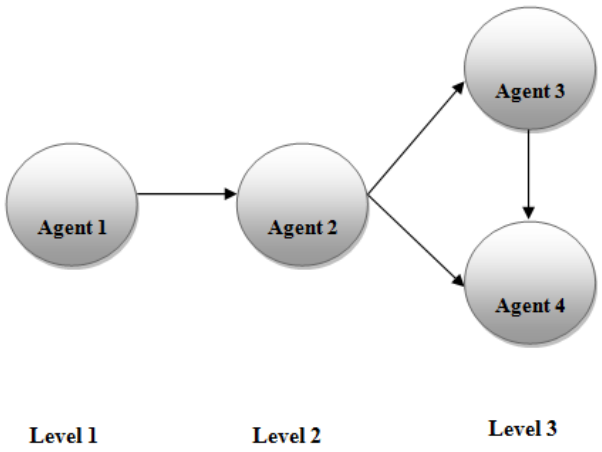

Fig.2. Layered Agent Architecture

In the proposed layered method the autonomous agents with high intelligence are distributed and they can cooperate each other. Here the task and responsibilities of each agent in the different layers are well defined. Each agent knows how to overcome a situation independently or collectively with the help of other agents. Thus, this multi-agent system has high learning capacity and it can easily adapt with the news changes in the system.

In the proposed architecture, the level 1 agent acts as a sensor module. It extracts the URL of web pages from email, browser or any other source. The results or the extracted URL information at this level is passed to agent at the next level i.e. level 2 in the hierarchy of the classification process. The detection of phishing is done at layer 2 with the help of agent at this level. Here webpage is classified as whether it is phishing or not. This is done using machine learning classifiers. In this level, we have used ANN and SVM for classification. At level 3 there are two agents. One agent for blocking the malicious website and another for script detection. After the script detection phase, if the URL is free from phishing attacks and scripts then it is marked allowable website. If any malicious script or phishing is detected then the URL is passed to blocking agent at this level and the webpage is finally blocked.

IV. EXPERIMENTAL SETUP AND RESULT ANALYSIS

The proposed method is experimented using data set from [12][13][14]. In order to confirm whether the data used is a phishing dataset, we have tested it with link guard algorithm. This algorithm is to analyze the difference between actual and visual links. The algorithm first extracts the DNS names. If the extracted names are not identical then it can be considered as a phishing. Next it checks is there is any dotted decimal IP address is directly used in the DNS. This is also considered as a phishing. Sometimes, actual and visual links are to be checked. For this encoded visual links are decoded and compare with the original link. If the method unable to obtain the destination information from this provided visual DNS

then it analyze the actual DNS. While analyzing the DNS the method checks whether actual DNS is present in black-list or white-list. If it is not present in any of the list then go for pattern matching. The pattern matching is invoked mainly to find unknown attacks. In pattern matching process, it checks whether the actual DNS name is different from the sender's DNS name. If it is similar then invoke similarity and calculate the minimal number of changes. If it is similar then the method concludes that two strings are identical. In the similarity check if number of changes are little, then there is high similarity rate. If two DNS names are similar but not exactly identical then they are also considered as phishing.

The proposed methodology is implemented using the Smart Python Agent Development Environment (SPADE) software framework [1]. The distributed multi-agents can communicate and cooperate with each other. For the agent communication the method used Extensible Messaging and Presence Protocol (XMPP). The XMPP is a protocol for streaming XML elements over a network in order to exchange messages. This protocol is mostly used in instant messaging applications. The agents are deployed at different levels to reduce the bad effect of a phishing attack and malicious scripts to a webpage.

Phishing and the malicious script are detected using a machine learning classifier. In the case of phishing detection, first system considers certain features from the URL. The features considered given in the Table 1. After feature extraction, the binary data is passed to the proposed model. This multi-layer multi-agent model first learns from the data set given. After that, we tests whether the model has learned properly or not. After the learning phase of the model, then a new URL are classified as phishing or non-phishing. In malicious script detection, a dataset is given to the model converted to vectors before learning and testing phase. Then the system classifies the inputs as malicious or not.

TABLE 1. FEATURES FOR PHISHING ATTACK DETECTION [12]

Features	Description
URL Length	Length of URL. Sometimes long URL names are used to hide the doubtful part in the phishing site.
IP Address	IP address is a substitute of URL names.
Shortening Service	Short URL can also be used direct to the requested webpage.
@ symbol	Ignore the rest of a URL after this @ symbol.
Double Slash Redirecting	The "//" symbol in a URL also used as redirection to another location.
Prefix or Suffix	Adding some prefix or suffix terms especially separated by (-) to the domain name is a phishing method.
Subdomain	If a URL have more than two dots (.), i.e., subdomains high chance of phishing.
Website Traffic	Websites can be classified according to traffic into it. Phishing website or suspicious websites has less traffic.
Favicon	Loading favicon from a domain is considered as phishing.
Port	Port opening is crucial. Anybody can access the data or attack through an open port.
HTTPS Token	Sometimes https token is used for phishing.
Request URL	Usually the all the contents such as images, videos, etc., are embedded in the page itself and shares same domain.
URL of Anchor	This is same as previous Request URL.
Links of Tags	Link tags are to be connected to the same domain.
Submitting to Email	Proper use of mail() and mailto() functions.
Abnormal or Nonstandard URLs	In this type URL doesn't contain the original host name.
iframe	Use of "iframe" tag and make it as invisible from the users.
Age of Domain	Phishing websites exists temporarily
DNSRecord	Entry in the DNSRecord is an attribute to find whether a website is original or not.
On Mouseover	Usually onMouseover() command is disabled in a phishing website. This is to prevent users from knowing the correct address shown in the address bar.
Right Click	Phishers also disable right click function. Since right click facility allows user to view and the page source code.
Pop up Window	An original website doesn't use any popup window to submit personal information.
Page Rank	Phishing website does not have a page rank.
Google Index	Usually Google index is created for each webpage. A Phishing site doesn't have any index.
Links Pointing to Page	Most of the phishing websites does not have hyperlinks points to them due to its volatile nature.

Performance Analysis

For the performance analysis and comparison, two different classifiers with five types of dataset are used to test the efficiency of the proposed technique. The proposed model uses support vector machine for classification and artificial neural network for the comparison. For the evaluation, the confusion matrix is considered. From the confusion matrix accuracy, precision, recall and specificity can be calculated. Table 2 and Table 3 show the accuracy, precision, recall, specificity, false positive and false negative of the proposed ANN and SVM classifiers in five different datasets with different sizes respectively. Accuracy is that the whether the proposed method correctly labelled a website from all the phishing websites. We have used 80 percentage data in the data set for training purpose and 20 percentage data for testing phase.

TABLE 2. ANALYSIS OF PROPOSED ANN CLASSIFIER (VALUES IN PERCENTAGE)

No. of Data	Accur-acy	Prec-ision	Recall	Speci-ficity	False Positive	False Negative
779	91.2	81.5	93.9	90	6	100
2456	59.6	25.2	76.5	56.4	23.4	43.5
8550	89	84.4	96	81.7	3.9	18.2
10000	87.8	83.5	93.7	82.1	6.2	17.8
11055	89.3	82.7	97.1	81.6	2.8	18.3

From the tables it is clear that accuracy of the proposed SVM method is high compared to ANN based method. This is

also true in the case of precision analysis. As the data increases the SVM shows good rate than ANN, i.e. it is correctly labelled phishing sites. Similarly recall and specificity value is high for the proposed method. False positive is the rate of incorrectly classified positive values and false negative is the incorrectly classified negative values.

TABLE 3 ANALYSIS OF PROPOSED SVM CLASSIFIER (VALUES IN PERCENTAGE)

No. of Data	Accur-acy	Prec-ision	Recall	Speci-ficity	False Positive	False Negative
779	92.3	79.4	100	89	0	10.9
2456	92.5	91.6	91.6	93.2	8.3	6.7
8550	97.4	98	97.4	97.3	2.5	2.6
10000	96.8	97.5	97	96.6	3.3	2.9
11055	97.1	97.7	97.1	97	2.8	2.9

From the table 3 it is clear that while comparing SVM and ANN, SVM shows better results for the every evaluation.

Next we have evaluated the script detection efficiency of the proposed SVM method with existing method in paper [15]. The obtained values are given in the Table 4. The experimental results shows that the proposed SVM have higher efficiency that the existing method. The comparison of evaluation parameters such as precision, recall, F-score and negative predictive power are better for the proposed method.

TABLE 4 SCRIPT DETECTION EFFICIENCY

Classifier	Precision	Recall	F-score	Negative predictive Power
Proposed SVM	95	99	97.43	99
SVM [15]	92	74.2	76.4	99.7

In the existing system, the malicious script detection is done based only on few features and in the proposed method the malicious script detection is done by directly converting the scripts into vectors. If the detection is completely based on few features it may limit the detection accuracy and sometimes all types of the script may not be able to detect. If certain condition fails detection process also fails. This is the one of the advantage of the proposed method. In future the proposed mechanism can be extended to block only the malicious script execution without interrupting the whole website.

V. CONCLUSION

In this proposed method an attempt is made for implementing an agent-based architecture and machine learning classifier for resisting different types of phishing attacks. The existing phishing methods are single agent mechanism. In the distributed internet we need a system that works using multiple agents that communicate in a peer-to-peer fashion by message passing. This paper presented a layered multi-agent framework for detecting and rectifying web phishing attacks. The multi-agents are used for URL extraction, phishing detection, script detection, and blocking. The method is capable to recognize and learn according to the environmental changes. The experimental result indicates that the proposed system is capable of achieving the objective. The experiment results also show that the proposed SVM method is an effective mechanism to detect phishing attacks and malicious scripts. The phishing detection is done using machine learning classifier SVM and ANN. From the results, it is clear that many functions can be incorporated in one method using multiple agents and these multi-agents can be triggered to find a solution for different complex problems.

Abstract: Neural Networks And Deep Learning Currently Provide Best Sollutions To Many Problems In Image Recognition,Speech Recognition. Diabetic Is Diabetic Complication That Affects Eyes. Diabetic Can Easily Detect From Eye Image Of Person Optic Disk Detection And Segmentation Of Eye Is Very Difficult Due To Variation Of Size And Shape Of Optic Disk .In This Paper Deep Learning Network Applied To Train The Data .The Eye Images Collect From Public Database And Hospital . Train The Images By Using Neural Network. Store Features And Results From Trained Images. Then Upload Test Image To Get The Result Testing Image Procedure Include Preprocessing Feature Extraction, Then Random Forest Classifier Used To Extract Features And Classify The Image Based On Train Images Data Set .Accuracy Of The Model Is High.

Key Words: Deep Learning; Optic Disk Segmentation; Feature Extraction; Diabetic

Ⅰ.Introduction

Optic Disk Detection Is Key Step To Find Eye Diseases. In This Process, OD Detection Plays An Important Role [3] [2] Diabetic Retinopathy Can Be Detect In Different Ways, Like Eye Image, Blood Samples The Main Cause For Diabetic Is Sugar Level High In Blood Vessel. Increase In Sugar Mainly Damage Eye Vision .Main Symptoms Of Diabetic Retinopathy Blurred Or Double Vision, Difficult In Reading, Eye Pain, And And Eye Pressure. In The Eye Fundus Images OD Segmentation Can Be Categorized Into Three Categories [10] [11] Namely Template Based Methods, Deformable Model Based And Morphology Based Methods. Diabetic Disease Can Be Detects By Using Numerous Methods .Here Machine Learning And Deep Learning Methods Are Applied For Training And Classify Data. Preprocessing Of Eye Image And Feature Extraction [4] Optic Disk Segmentation Is Explained

New Method For Fast Optic Disc Segmentation In Retina Using Polar Transform. The Methodology Has Used Hierarchical Combination Of Morphological Operations And For The Optic Disc Localization. This Gives Better Results As Relying Only On The "Optic Disc As The Brightest Spot" Technique [6]

A Rule-Based Method Is Proposed To Segment Optic Disc. Firstly, We Apply Two Over-Segmentation Algorithms To Produce Super-Pixels. Taking Super-Pixels Instead Of Pixels As Basic Processing Units Greatly Improves The Efficiency But Still Defected Part Gives Inaccurate Segmentation [7]

Hybrid Approach Optic Disc Segmentation For Retinal Images. The Success Of The Hybrid Approach Was Evaluated According To Both Localization And Segmentation. Performance Of The Study Was Evaluated With 30 Images According To Dice And Jacquard Similarity. [8]Machine Learning Based Automatic Neovascularization Detection On Optic Disc Region Nv Particle Proves Indicator Proliferative Diabetic Retinopathy (Pdr) And It Is Featured By The Presence Of New Vessels In The Retina. The New Vessels Are Fragile And Pose A High Risk For Sudden Vision Loss [9]

Detection Of Diabetic By Using Multi Layer Perception Neural Network Classifier And Dct Transform Is Used To For Feature Extraction [10] Deep Learning Algorithm Method [11] Is Used To Detect Different Types Of Diabetics Like Type 1 Or 2. .Here Convolution Neural Network Method Is Using To Detect Automatic Detection Of Diabetic [12]

III. Proposed Method

There Are 2 Stages Shown In Figure 1

I Training Stage

2 Testing Stage.

Deep Learning Neural Network Applied To Train The Model .In Testing Stage First Performed Preprocessing Stage ,In Preprocessing Stage Following Procedures Are Done .Sharpening Image, To Remove Noise, Detect The Edges Of The Optic Disk, Calculating Gradient Magnitudes ..Here Dwt /Dct Feature Method Applied To Extract From Test Image. Extract Energy Contrast, Standard Deviation, Entropy By Using Random Forest Classifier Then Classify Based On The Trained Data Set. Drion Database There Are 110 Eye Images. In Hospital Database 125 Images Are There. We Use 125 Images For To Train The Model.110 Images For Testing .Deep Learning Network Gives High Accuracy,

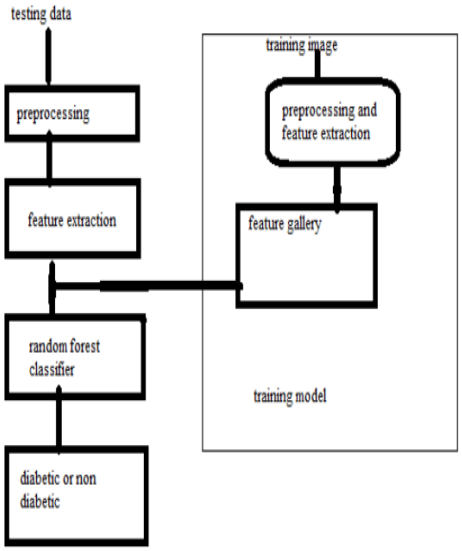

Fig 1.Shows Flow Diagram Of The Proposed System

IV .Implementation

Mat Lab Software Is Used To Implement The Proposed System. Mat Lab Is High Level Computing Language .Feasible And Easy To Work With Data. First Training Of The Image Is Done, After Completion Of Training, Upload The Test Image. Then Following Sections Are Performed

1 .Preprocessing Stage

First Crop The Eye Image To Get Optic Disk Portion. Then Detect The Optic Disk Of An Eye.[6][9] There Are Several Steps In Preprocessing Of Image .Like, Thresholding Circular, Hough Transform Finding Boundary Edges, Gradient Magnitude, Sharpening And Dct Of Image .Convert Color Image Into Gray Image. Gray Image Conversion Colors [7] [8] Displayed

On Retinal Images Are Usually Defined In Tri Colors As Red, Green And Blue Space Is Called As Rgb Color Space. There Are 2 Conversion Methods Are There

1, Average Method

2, Luminosity Method

Average Method Add All 3 Colors Of Image. Find Average 3 Colors.

Gray Scale Image = R+G+B/3

In Luminosity All Color Wavelength Is Change According To Intensity Of Wavelength, Grayscale Image Get From Below Equation

Gray Scale = ((0.3*R) + (0.59*G) + (0.11*B))

1.1 Canny Edge Detector

Canny Edge Detector Is Used To Detect Edges Of Optic Disk. It Contain Following Procedure. . Apply Gaussian Filter To Remove Noise .And Smoothening And Sharpening Of Image Find Intensity Of Gradient. Non Maximum Suppression Method. Apply Double Threshold To Get Edges .Upper And Lower Threshold. Then Track The Edges, Finally Get Boundary Of Optic Disk Haris Edge Detector Is Also Used To Get Perfect Boundary.[5] [14]

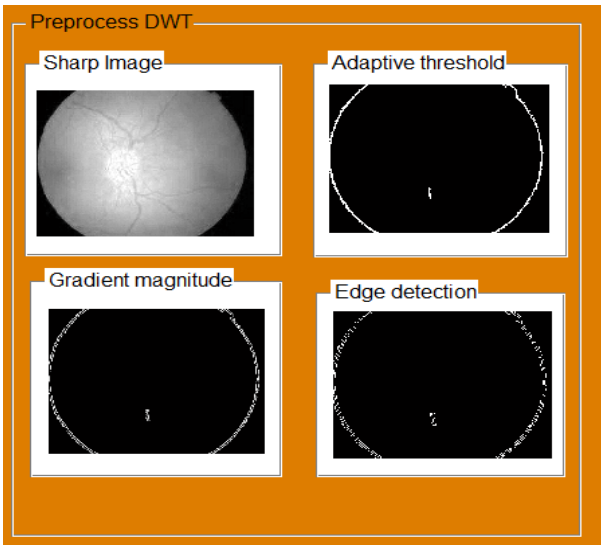

Fig 1.1 Shows Preprocessing Stage

1.2 Dct/Dwt Method For Feature Extraction

There Are Numerous Methods Are There To Extract Feature. In This Model Feature Extraction Is Done By Dct /Dwt Type. .Dct Decomposes The Signal Into Underlying Special Frequency. Allows Preprocessing Technique To Reduce Precision Of Dct Coefficients. Dct Coefficients Considered As Feature. And Ability To Represent Regularity, Complexity. Find Mean And Standard Deviation From Dct Coefficient Matrix .Dwt Generates Coefficient Matrix Horizontal, Vertical, Diagonal Components. For Example Dwt Generates 3 Horizontal, 3 Vertical, 3 Diagonal Matrix .Instead Of Using All Matrix Dwt Features Are Shown In Fig 1.2 And 1.3 Compute Mean And Standard Deviation Of Each Matrix. Store In Feature Vector .Dwt Is More Accurate And Efficient. Har Is Used As Mother Wavelet, By Comparing All Wavelet To, Mother Wavelet Finally Extract Dwt And Dct Features Segmented Images Are Shown In Figure 1.4 And 1.5

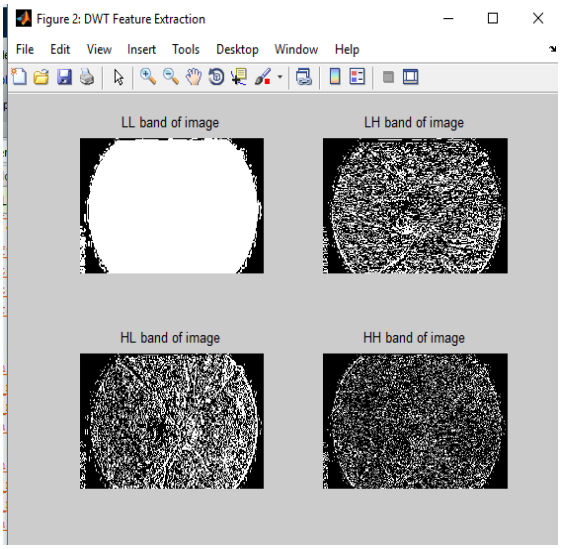

Fig 1.2 Shows Sub Bands of Dwt Features

Fig: 1.3shows segmented image

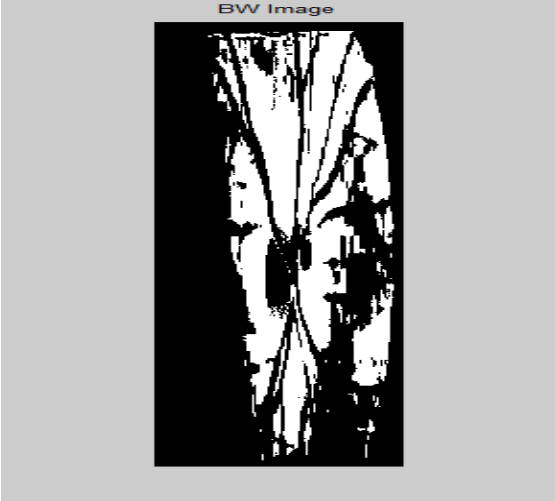

Fig 1.4 shows segmented BW image

1.3. Deep Learning

In Deep Learning Neural Network Play Important Role. Neural Network Have Multiple Hidden Layers Plus Mathematical Optimization .In Real Life Training Neural Network Is Not So Easy. Lot Of Procedure Must Be Done On Inputs To Make Them Learnable. Ann Work By Multiplying X Values (Weights) And Adding To Constant Called (Bias). Train The Model Until Model Learn Perfectly. Then Upload The Test Image. The Extracted Features Of Test Image Is Compared With Trained Image Data Set. Un Till Get Zero Error Or Best Result While Comparing With Trained Data Set, First Iteration Error Generated From The Model. Error Is Propagate Backward And Inputs Are Change Until Get The Correct Result, Or Zero Error. No Of Iteration Depends On Input Image [1] [8] That Zero Error Trained Eye Image Is Sent To Classifier .In This Model 125 Images Are Trained .In Dataset Diabetic Non Diabetic ,Mild ,Severe Type Diabetics Images Also There.[12] All The Images Are Well Trained Using Deep Learning Neural Network. And Results. Are Stored Trained Image Is Used As Target Image Neural Network Is Shown In Fig 2.1 And Neural Network Graphs Are Shown In Fig2.2 , 2.3 and 2.4

Random Forest Classifier Is Supervised Machine Learning Algorithm. .Decision Trees Are Generated Based On Nodes. This Algorithm Generates Forest With No Of Large Tress. More No Of Tress Give High Accuracy. In This Algorithm We Find Root Node And Splitting Feature Nodes Will Run Randomly. This Classifier Can Be Used For Both Classification And Regression Purpose [13] Test The Features Randomly Then Predict The Outcome. Again Start Predicts Until Get The Final Outcome. High Voted Predicted Target Is Final Outcome. By Using This Method Classification Is Too Easy No Missing Any Feature Or Value Over Fitting Problem Is Eliminated.

V.Experimental Result

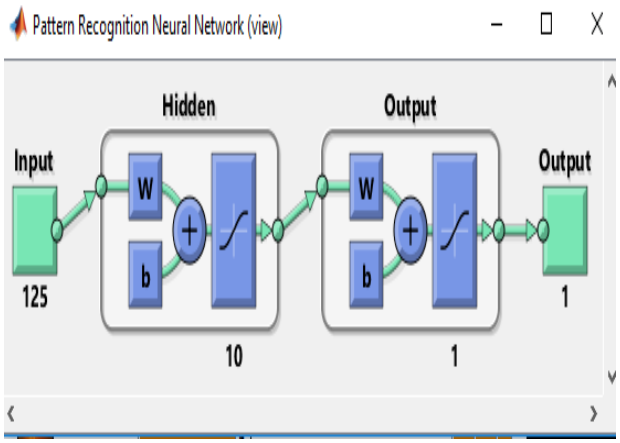

Fig2.1 .neural network

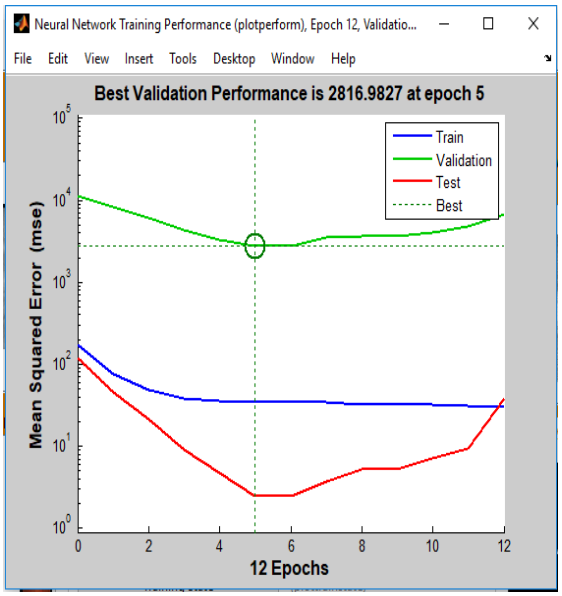

Fig 2.2 best validation performance

The Graph Shows Best Validation Occur At Epochs 6. For Given Test Image .The Plot Consist Three Lines In Fig 2, 2 Shows Trained, Test And Validation.

  310.3798

     2

Detected
```

The Result Is Appeared In Command View

Mat Lab Software Used For This Model. The Preprocessing And Dwt Features

Results Are Shown. The Neural Network Graphs For Training Data Is Also Shown. The Result Is Too Accurate, And Over Fitting Data Problem Is Eliminated By Using Random Forest Classifier .Duration Of Time For Training The Data Is Also Less Random Forest Classifier Gives Correct Result. There Is Minimize In False Result. Accuracy Of The Model Is 100%

VI. Future Scope& Conclusion

This Model Can Be Extend To Distinct Type 1, Type 2 Diabetic. And Also % Of The Disease. It Is Easy To Train The High Rate Data Using This Model. .Mode L Can Be Extended To Train Large Number Of Data. It Can Be Implementing To Find All Disease, Its Easy To Predict Diabetic In Early Stage From The Trained Model .It Can Be Easy To Find Patient Condition Earlier Like Mild Or Serious Or Critical Or Normal. By Using This Classifier We Can Classify All The Eye Diseases Glucoma, It Gives 100% Accuracy. And Easy To Implement.

***Abstract*—V2V, also known as Vehicle-to-Vehicle communication system comprises of wireless networks where, the automobiles communicate with each other by sending message (which may include direction of travel, speed, location or loss of stability). In this paper, we are implementing IEEE 802.11p in a V2V communication system with mesh networking topology and Hybrid wireless routing protocol using NS3 Simulator. The vehicles (which here we symbolise as nodes) are stationary. Further, the paper presents performance analysis of proposed system on the basis of various parameters like Packet Size, Data Rate, Packet Delivery Function and Throughput etc.**

***Index Terms*—V2V, DSRC, WAVE, HWMP, NS3**

I. Introduction

The era of wireless communication has enabled the exchange of data between vehicles (V2V). The IEEE802.11p amendment has enabled the vehicles to communicate with each other through Dedicated Short Range Communication (DSRC). The Dedicated Short Range Communication (DSRC) and Long-Term Evolution for V2V (LTE-V2X) are two prior technologies used for V2V communication [1]. The broadband Internet and phone services to the mobile phones and other devices are spared by the Long-Term Evolution (LTE) network, a type of wireless communication network compatible with GSM and HSPA network [2] . Wireless Access in Vehicular Environment (WAVE) was added to the IEEE 802.11p protocol is an approved amendment to the IEEE 802.11 standard [3]. The half-duplex communication exists in DSRC by transmitting the data at rate of 3 to 27 Mbps. The modulation technique elaborated in DSRC [4] having communication range of up to 1000 meters is Orthogonal Frequency Division Multiplex (OFDM). DSRC has 7 channels in which for safety communication, the first channel is used, for critical safety communication- the second channel is used and for high power safety communication- the third channel is used, while the rest of the channels are used for either non-safety or safety communication [5]. While establishing the link between the two vehicles or in V2V communication system, the physical layer and the MAC layer are considered in implementation of the IEEE 802.11p. The physical layer is composed of two sub layers namely, the Physical Layer Convergence Protocol (PLCP) which is responsible for communicating with the MAC layer and the Physical Medium Access (PMA) which is the interface to the physical transmission medium, its task is to manage data encoding and perform modulation [3]. On the other hand, MAC layer provides flow control and the multiplexing for the transmission medium. Frame delimiting and recognition, addressing of designation stations, protection against errors, and control access to the physical transmission are the major functions of the MAC layer. In this paper, we present a V2V communication system using the mesh topology and as routing protocol we have considered the Hybrid Wireless Mesh Protocol(HWMP). To simulate the V2V communication system, here we have used the NS3 simulator as it provides substantial support for simulation of TCP, routing and multitask protocol over wired and wireless networks. The paper is divided as follows: Section1: Introduction provides a brief description of the V2V communication system using IEEE 802.11p and the considered topology. Section 2: Defines the parameters that we have considered for the proposed model. Section 3 defines the proposed methodology with its materials and methods and section 4 and 5 provides the result, conclusion and future direction.

II. System Description

Vehicle-to-vehicle communications is a system consisting of an inbuilt wireless network infrastructure in which the convertibles can send messages to each and every vehicle about the information of the real-time. These data may include speed, location of the vehicle, capacity of the vehicle and stability loss of the vehicle. In carrying out any simulation process, one needs a workflow via which the whole process is carried out. Below Fig1 is the workflow of the considered model.

According to Fig. 1, the first step is the topology definition. Generally, topology definition is used in defining the interre-

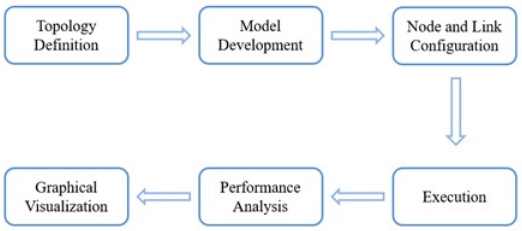

Fig. 1. Work Process

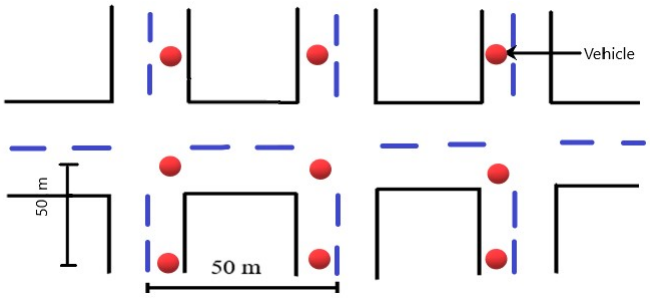

Fig. 2. V2V Communication Scenario

lationships and in providing easy creation of basic facilities. So, here we have considered the mesh topology to establish a link between the nodes. An extensible mesh networking framework has been defined to ensure a common standard that will synchronize all WLAN mesh network devices from all vendors.

In wireless mesh network, data packets travel over multi wireless hops [6]. The topology and routing information is shared by nodes in wireless mesh while communicating with other neighbouring nodes. The enlarged network capacity through various factors like spatial frequency reuse, shortened communication distance, automatic network configuration and better robustness has enabled high data transmission rate in WLAN mesh network [7]. Mesh stations are the devices that form mesh and forwards the frames wirelessly. The information about the mesh that helps other mesh stations to detect and join the mesh are carried by mesh station's beacon [6]. A single transceiver is used by mesh which operates in single frequency channel. If a larger channel precedence value is held by mesh station, it broadcasts its value and indicate different frequency channel [6]. Mesh network does not provide end-to end encryption as both mesh stations initiate together and both links are independently secured [6].

One of the benefits of mesh topology is its expanding nature as the new nodes can be added easily to self-adjusting network [7].The routing protocol that we have considered here is HWMP. It is a default routing protocol for wireless mesh network which is based on Ad hoc On-demand Distance Vector Routing (AODV). It has both reactive components and proactive components [8]. Proactive routing protocols periodically update its routing information and share the whole topology with other nodes. In reactive routing protocol, routing tables are constructed on the requirements of nodes, and the complete topology of the network is not shared with other nodes in a network [7]. In case of mesh networking these use MAC addresses for "routing", instead of IP addresses. Therefore, we call it as "path selection" instead of "routing". As per [8], HWMP has the lower average latency and the higher data transmission throughput .

As per Fig. 1 The next step is the model development which is shown in Fig. 2. In Fig. 2, we have considered the V2V communication model with 3 rows and 9 stationary nodes (3 in each row). All the adjacent nodes are 50m apart from each other. Here, a client-server type communication is considered. The server node can broadcast its information to other nodes (Client). The Client node can become the server node according to the need of the communication system. Again considering Fig. 1, the next process in the simulation workflow is the node and link configuration. To establish the node and link configuration we use the NS3 Simulator. NS3 is designed as a set of libraries that can be combined together. NS-3 is more modular as compared to other some simulation platforms. With NS3, one can easily use several external animators and data analysis and visualization tools. However, users should expect to work at the command line and with C++ and/or Python software development tools. NS3 has a work flow which needs to be followed while using the simulator.

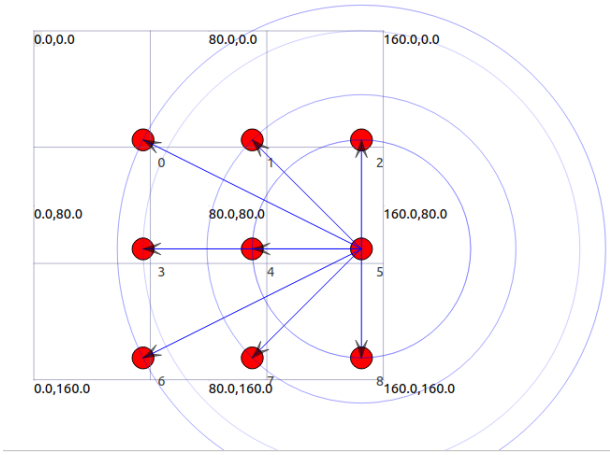

Fig. 3. Mesh Network Simulation

As per system description given in reference with Fig 2, the simulation is carried out in NS3 Simulator using NetAnim and the simulated result is shown in Fig. 3 and Fig. 4. Both the figures show a mesh network among the 9 nodes. All the adjacent nodes are placed at a constant distance of 50m. The total simulation time that is taken for simulation is 100s irrespective of the size of the packet.

III. Result and Discussions

The following results have been found from the extensive simulations from NS3 Simulator using Ne-

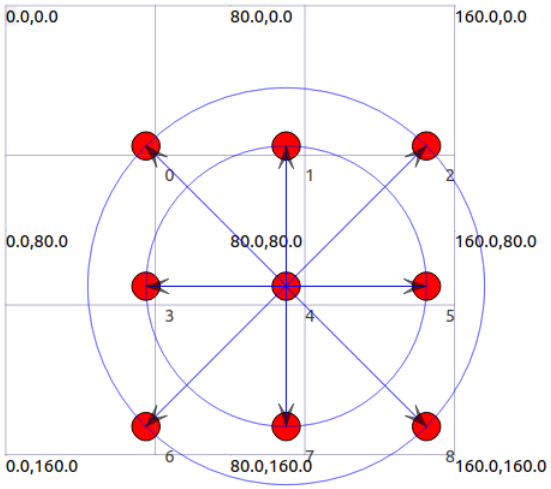

Fig. 4. Mesh Network Simulation

tAnim(Flowmonitor). In Fig. 5, a comparison is carried out

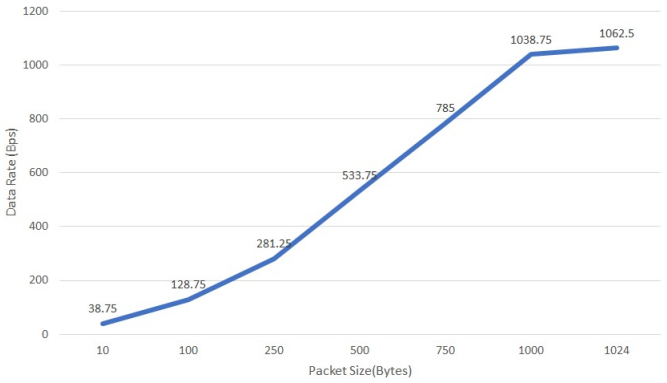

Fig. 5. Packet Size vs Data Rate

among Packet Size(kbits) and Data rate(kbits/sec). It is observed that, as we increase the amount of Packet size, the Data rate also increases. From the above observation, it is concluded that, the Packet Size is directly proportional to the Data Rate irrespective of the increase or decrease in the above two parameters.

PDF is defined as the ratio of the number of data packets delivered to the total number of packets. This gives the efficiency of data delivered to the destination.

In Fig. 6, a comparison is carried out among Packet Size and PDF. It is observed that, as we increase the amount of Packet size, the Packet Delivery Function(PDF) decreases. From the above observation, it is concluded that, the Packet Size is inversely proportional to the Packet Delivery Function.

In Fig. 7, a comparison is carried out among Packet Size and Throughput(bits/sec). It is observed that, as we increase the amount of Packet size, throughput also increases. From the above observation, it is concluded that, the Packet Size is directly proportional to the throughput, irrespective of the

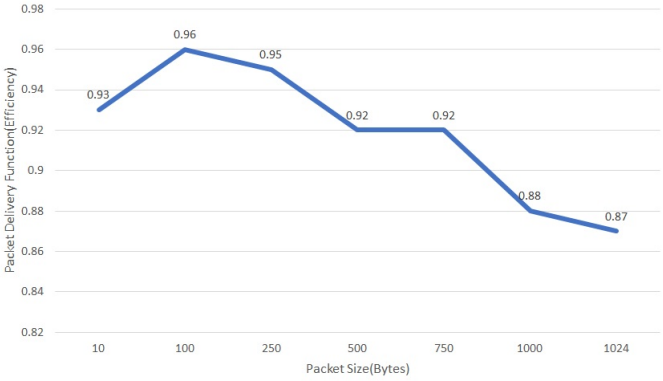

Fig. 6. Packet Size vs Packet Delivery Function(PDF)

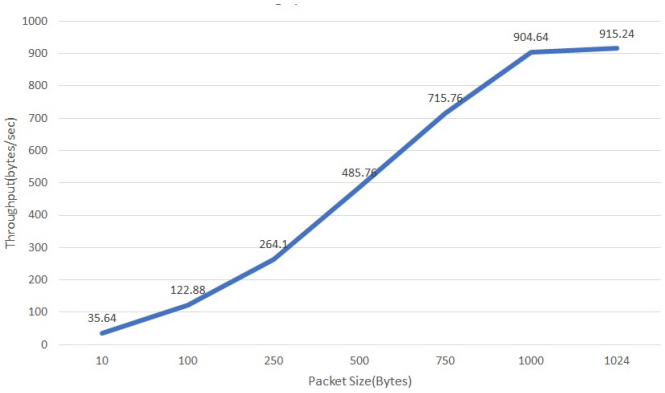

Fig. 7. Packet Size vs Throughput

increase or decrease in the above two parameters.

IV. Conclusion and Future Direction

The overall aim of this paper was to implement IEEE802.11p in V2V communication System for stationary vehicles using NS3 Simulator. In the beginning, we presented a brief description of the layers on which IEEE 802.11p is based upon and further discussed about DSRC. For establishing a link between the vehicles, mesh networking as the network topology and HWMP as the routing topology is considered. The results have been simulated using NS3 simulator and parameters are analysed based on the obtained result.

This paper consider stationary vehicle whereas in future mobility in vehicles can be added in comprehensive understanding of implementing IEEE802.11p in V2V communication system.

***Abstract* – The tightly coupled control plane and data plane in inbuilt hardware devices such as switches and routers are not suitable to meet the current needs of vehicular network requirements. The complexity to integrate moving devices with other high-speed moving devices and heterogeneous elements in the vehicular network is due to high-speed mobility where network topology changes dynamically and sometimes communication is also broken because of short network range of devices. The decentralized decisions of routing and switching in the traditional network architecture, where control plane and data plane are tightly coupled, demands an innovative approach for the routing and switching of network packets. Software-defined network (SDN) is a promising network architecture, which decouples the control plane from the inbuilt device. SDN can be a single or multiple controllers based network system. An SDN having multiple controllers with self-organization capability provides fault tolerance and handle heterogeneity and scalability with collaborative behaviour. In this paper, we propose to augment the traditional vehicular network architecture with SDN to embrace the required computational demand in networking with fault tolerance. The controller is a software program that can be programmed to address various issues of vehicular network intelligently by improving the performance of information exchange between the vehicles. OpenNet with POX controller is used to emulate the SDN on network topology and confirm its effectiveness.**

Keywords – Internet-of Vehicles, VANETs, SDN, IoV

I. Introduction

The Internet of the vehicle (IoV) is a vehicular ad hoc network in the wireless network environment and works on the concept of Mobile ad hoc network (MANETs). It supports creating the communication network spontaneously between vehicles with no pre-configured network infrastructure, which is unlike mobile ad hoc network [1]. The participating devices in the communication network rely on each other and are required to act as a router, to forward the network packets for all the devices including nodes that are not in range to keep connectivity. VANET creates an ad-hoc network spontaneously with communication capability for the high-speed moving devices and roadside units (RSUs). In VANETs, the moving devices communicate with no restrictions of energy unlike Mobile ad hoc Network (MANETs). The Internet of vehicles is engaging many researchers due to the potential it has to support connectivity with communication capable devices and provide network functionalities by improving safety and traffic such as Intelligent Transport System (ITS) [3]. ITS is not limited to road transport but includes all kind of transportation devices including inside vehicle, between the vehicles and also to rail, water and air transport. Therefore, ITS is a superset of the vehicular network [3].

The traditional network architecture is unable to meet the current trends in emerging communication technologies and innovation, this is due to the vendor-specific configuration where data plane and control plane are tightly coupled and prohibit the customization of routers and layer 3 switches as depicted in Fig.1. The current emerging computing technologies demands for the new communication network architecture, that is not vendor specific, open and flexible to adapt the recent changes in requirements [9]. SDN is a promising paradigm, implements the concept of decoupling of the control plane and data plane from tightly coupled devices in networking.

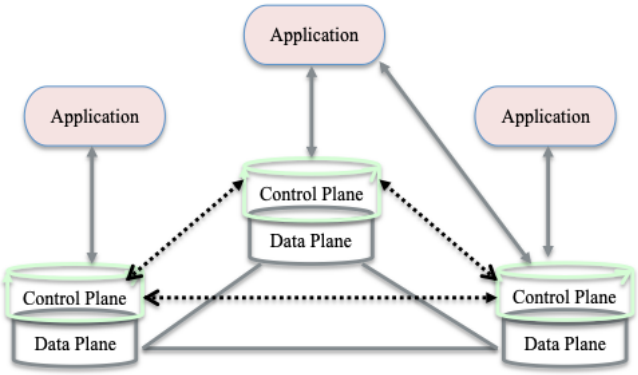

Fig.1. Distributed Control Plane

Software Defined Network (SDN) [3] envisioned and promotes innovation continuously by considering the vehicular network requirements, designed to work on the concept of flexible and customizable network configurations. SDN innovates continuously by providing an environment to program and customize according to the nature of change as in vehicular network [14]. It addresses the challenges of the vehicular network by increasing the efficiency of network services including resource management and network applications by the centralized SDN controller at the control plane. OpenFlow specification is developed to support the

programming interface (southbound interface) for the control plane to interact with data plane on the principle of communication technology [5, 6] protocol. The objective is to promote innovation by programmability, flexibility and simplify the network management operations for the network communication [4].

Augmenting vehicular network with a software-defined Internet of vehicles promotes innovation in communication network technology of vehicular network to meet the current computing demands. The separation mechanism of SDN decoupled the control plane from dedicated devices (refer to one or more switches) and leaves the switches to work only as a forwarding device. The OpenFlow foundation has developed the OpenFlow protocol to leverage the SDN principles using open source platforms. The protocol is developed based on the open architecture that can be programmed to modify the forwarding tables and used for the communication between the control plane and the data plane [3]. The main idea behind the SDN architecture is to decouple the control plane from the data plane. The control plane is used to manage and control the network traffic and the data plane is used for the data forwarding. The controller in the SDN is responsible to manage the flow control for the entire network. Fig.2 depicted the components of SDN.

The objectives of this research are to contribute in the area of software-defined Internet of vehicles by exploring the previous work and to augment the vehicular network with SDN for programmability and promote innovation [12]. There are following contributions made to increase the acceptance of an SDN approach into the existing vehicular network:

- Existing communication network architecture is reviewed and analyzed along with exploration on how SDN promotes innovation and programmability in the network and can be one of promising solution over the traditional approach.
- Simulate sample network topology on OpenNet with POX controller and evaluate its functions for common network operations.

The remaining work is organized as follows. In Section II, we discuss the related work on the architecture of the vehicular network and software-defined network. Section III presents the basic vehicular network model and its limitations. In Section IV, augmented software defined vehicular network is compared with existing network architecture. In section V, experiment and analysis of SDN on OpenNet with POX controller is discussed. In Section VI, conclusions and future work are discussed.

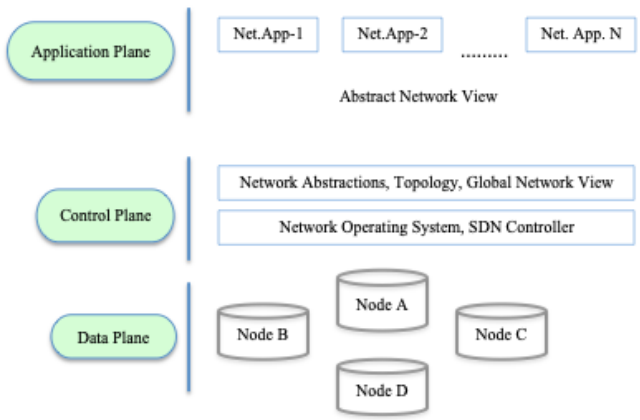

Fig.2. SDN Components

II. RELATED WORK

In this section, we reviewed the existing research work in vehicular network and adaptability of SDN for the network applications. Due to the emergence of network services in the vehicular network, the research organizations and industries are interested in improving on limitations of the traditional network, by proposing new network architecture in order to support services effectively.

I. Ku et al. [3] considered the services offered by VANETs as essential for the vehicles, which need to be improved, such as safety services, network management services and infotainment services. However, it lacks in flexibility and makes the deployment hard. They proposed software-defined based network architecture for the inter-vehicle ad-hoc communication in a vehicular network by introducing SDN controller in the network system. The simulated routing algorithms exploit the global view of the network and the results show its effectiveness. Jun Li [2] proposed an SDN controller based ARP for the network scalability that managed the network packets traffic effectively. Further, it considered some network application and fallback mechanism in vehicular network scenarios during the design of SDN for the deployment. The simulation and comparison of routing protocols in the traditional MANETs/VANETs were performed to highlight the benefits of using SDN in the network.

N.B Truong et al. [4] proposed the architecture of SDN with Fog computing in order to support the low latency services in network effectively. They considered the research in recent years on the offering of several network services by VANETs and the limitations during the deployment and management of traditional network, especially due to the poor connectivity, non-scalability, and less flexibility. The SDN based network architecture provides programmability in the network and makes the network to be more flexible, scalable and intelligent by the features of SDN controller, whereas the Fog computing managed to offer delay sensitive and location-based services to meet the demands of the future vehicular network. Further, they studied use cases of the data streaming

and lane change assistance with illustration benefits of the proposed architecture.

S. Wang et al. [7] proposed a novel architecture based on SDN to address the limitations by leveraging the decoupled mechanism of network control logic from the tightly coupled control plane and data plane in dedicated devices (refer to one or more switches). The proposed architecture provides a uniform way to configure heterogeneous switches. The tightly coupled devices in traditional networking are complex to configure and change, as it requires a lot of manual effort and physical presence for the network management activities. Further, it is observed that the network infrastructure cost is high to maintain. This novel architecture for Internet-of vehicles has the limitation on the size of flow tables and it impacts during the flow rule installation, hence it is required to build compact flow tables for OpenFlow enabled switches for the scalability of IoV [11].

III. Basic Vehicular Network Model

In this section, we describe the basic vehicular network components and communication model based on traditional network architecture.

The vehicular network comprises of high-speed moving devices that is vehicles, access points as roadside units (RSUs), mobile broadband (4G/LTE), and wireless broadband (WiFi/WiMax) to provide the network related application services. Vehicle-to vehicles communication performed by establishing a spontaneous communication network via RSUs and vehicles-to Internet communication by network broadband services. The interconnected network components and method for the communication in the traditional approach are depicted in Fig. 3 [3]. The network application related services in the VANETs includes safety of the vehicles, safety on the road, traffic management and infotainment-related services within vehicles. The vehicle and road safety services help in reducing accidents and loss of life of travellers. Traffic services network applications support in regulating the regular traffic on road by coordinating between vehicles and provides information from the local map. The infotainment-related services within vehicles include surrounding information on the road, music and multimedia by global Internet access.

The control plane and data plane are tightly coupled in inbuilt network devices such as switches and routers in the communication model of the traditional vehicular network, which is less flexible, less scalable, and less intelligent. To forward network packets from source to destination, there is a need to pre-configure the network communication elements that cannot be changed at the later stage of the communication. This method of communication prohibits supporting emerging networking technology in the communication network. The basic model of communication is depicted in Fig.1 in which switch's ports are pre-configured to accept and forward the packets in the connected network between source and destination. All the applications are required to be loaded with information about a pre-configured network and in case of any change in the network configuration, the inbuilt devices need to be reconfigured again, which is time-consuming and so is not practically feasible.

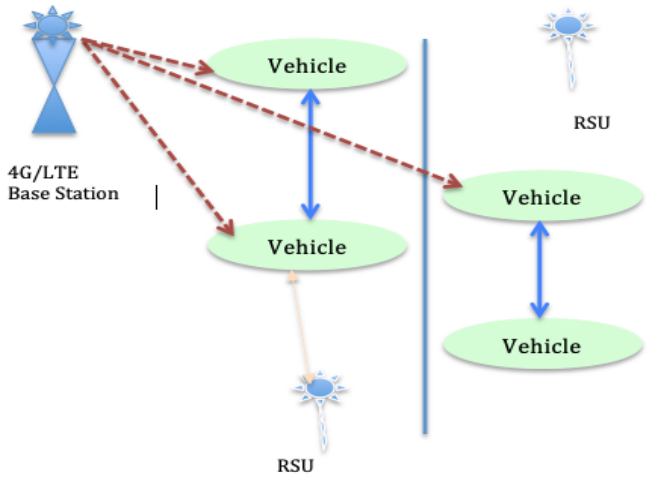

Fig.3 Vehicular Network Communication and Its Components

IV. Software Defined Vehicular Network

There have been several attempts made to resolve various issues of the traditional vehicular network in the era of the Internet-of vehicle, in which there are heterogeneous devices connected to work together in a collaborative and coordinative way for a common goal. These attempts are made mainly to meet the current network computing trends and improve the productivity of each network elements along with minimizing of various applications silos.

The proposed architecture embraces the dynamic nature of the vehicular network, i.e. it is a paradigm shift from traditional networking to software-defined networking, which enables programmability and intelligence in the network. Due to the centralized networking, SDN directly impacts the various issues in traditional IP networking such as improved resource utilization, better network management, avoiding redundant flow entries and collision. The software-defined network (SDN) is an emerging and promising paradigm shift in communication technology. It decouples the control plan from the tightly coupled devices and makes it work as a forwarding device only. The forwarding device works based on the instructions from the controller. The SDN controller is capable to monitor and control the entire network centrally with a global view [9].

The vehicular network architecture extends with SDN as it will be operated in wireless vehicular network environments that are expected in future VANETs and enable innovations [14]. According to the proposed architecture, different communication technology can be used in the control plane and data plane as depicted in Fig. 4, i.e. for control plane LTE/4G and for data plane WiFi/WiMax. There is a known problem in the vehicular network, that is all the network access points are not reachable via roadside units due to the network range and design of network infrastructure. The augmented software defined vehicular network with SDN

controller is depicted in Fig. 4 that includes the various access points and components of communication in the network. In this architecture, the inter-vehicle and intra-vehicle communications are efficient in data flow management, where the vehicles and roadside units are working as open flow enabled switches, and OpenFlow protocol is used for the communication between the control plane and the data plane.

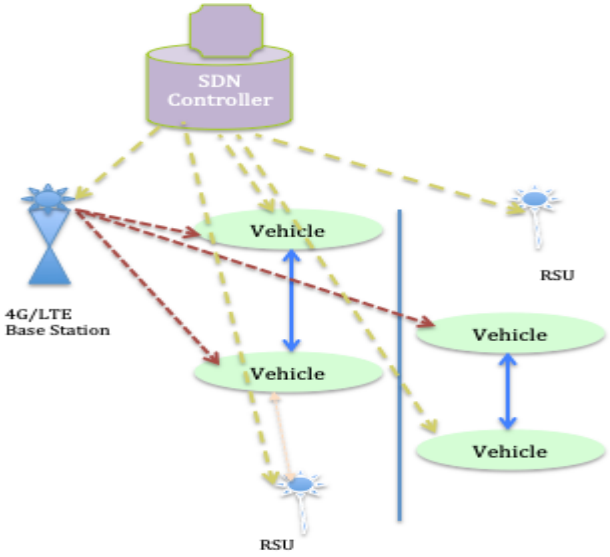

Fig.4 Software Defined Vehicular Network

The main idea behind augmenting the vehicular network with software-defined Internet-of vehicles paradigm is to bring flexibility, scalability and intelligence into the vehicular network. It is to meet the current computing demands in communication technology, where evolving requirements of user impacts the performance of the network badly. The existing communication system prohibits innovation due to tightly coupled control logic on inbuilt device and decision for a request is decentralized. This is to change the way the current vehicular network is adopting the changes in network technology. In this paper, we researched the functioning of the traditional vehicular network and analyzed how SDN can embrace the dynamic nature of vehicular network to meet the current developments in the communication network.

SDN promotes programmability and flexibility support in resolving the limitations of the vehicular network by providing a centralized control mechanism for the entire network. The centralized approach has the limitation to scale the network but can be addressed using the method of controller placement by placing multiple controllers in a network. Table-1 depicts the comparative benefits of the software-defined network over traditional networking.

TABLE-1 SDN ARCHITECTURE VS. TRADITIONAL NETWORK ARCHITECTURE

No.	*Parameters*	*Software Defined Network*	*Existing Network*
1	Network controlling and Monitoring	Control plane decoupled and function independently and make it easier	Complex due to the tightly coupled control plane in inbuilt device
2	The global view of Network	Centralized view due to SDN controller and an entire knowledge of network	Distributed view and limited knowledge of network
3	Maintenance cost	Lessor	Higher
4	Required time to update/error or resolve issues	Easy	Difficult and depends. Sometimes takes a month
5	The controller (s) utilization	Important	Not relevant
6	Network Consistency and Integrity	Important	Not Important
7	Network State and Forwarding tables	Important	Important
8	The capacity of the controller (s)	Important	Not relevant
9	Network resource utilization	High	Less

V. EXPERIMENT AND ANALYSIS OF SDN ON OPENNET

An emulator for SDN is OpenNet, which integrate MiniNet and NS3 to emulate the software-defined network [8][10]. It creates a virtual network environment in which network topology can be emulated as a real network. As shown in Fig. 5, it depicts an example of tree network topology with 7 open flow enabled switches, 1 SDN controller and 8 hosts. We simulated the two hosts h1 and h8, connected with switch s1 and s4 respectively to check the network connectivity. The OpenFlow enabled switches and SDN controllers are design to support the OpenFlow specification, the OpenFlow v.1.0 has been considered during this simulation. There are 7 OpenFlow enables switches in the tree topology depicted in Fig. 5, are interconnected to form the network and all switches are connected with an SDN controller (c0). When a packet arrives at OpenFlow enables switch, the switch has been programmed to connect with SDN controller using secure channel TCP connections and forwarding the packets based on the routing decisions and instructions installed into the forwarding table by the controller (c0). The programmed OpenFlow devices (s1-s7)

maintain a forwarding table, which SDN controller modifies by inserting or updating the flow rules as the installation process of the controller [8][10].

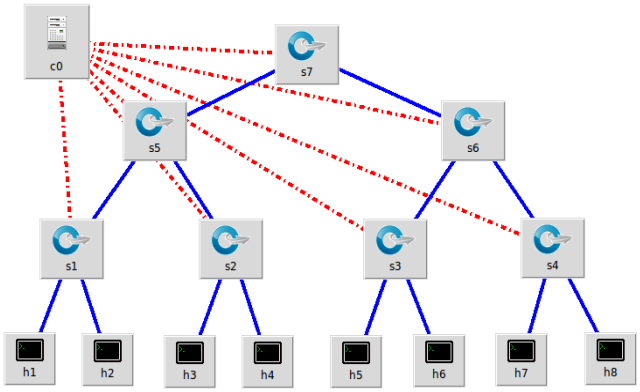

Fig.5 Network Tree Topology with 8 Hosts

MiniEdit along with POX controller is used to create the tree topology and simulate an instance of SDN. POX-controller supports OpenFlow protocol and installs the rules on the number of switches connected in the network. The controller is instantiated by running the python script of POX and is connected using port number 6633 as shown in Fig.6. An experiment has been performed to confirm the impact of the controller on the network i.e. when the POX controller is not instantiated, the network does not function and connected hosts are unreachable. It has confirmed that the SDN controller should be instantiated and functional for the network to function. The SDN controller has the control logic of the entire network, which is designed and programmed to initialize and modify the flow table contents of an OpenFlow enabled switch. Each entry of flow table consists of the field to match, request priority, required action, timeout, cookie and instructions. For an example, when a request of 64 bytes packet arrives on OpenFlow switch s1 then switch searches for the matching field in the table as per the programmed, on successful match the packet gets processed otherwise a table-miss occurs.

Fig.6 SDN Remote Controller C0 with 8 Hosts (Dump Information)

The created virtual hosts h1 to h8 on MiniEdit are connected in the network of 7 OpenFlow enabled switches s1 to s7 using Ethernet virtual links s1-eth1 through s7-eth2. For simulating the tree network topology and checking the consistency in connectivity in SDN, we measure the round trip time (RTTs) by ping operation between host h1 and h8 as it is on one of the longest path [13], as shown in Fig.7. When the ping command starts executing from h1 to h8, it first requests 64 bytes from h8. The connected switch s1 sends the request to SDN controller (c0), the controller then installs the required open flow rules after taking routing decision for packets into the forwarding table of switch s1 [12][13].

```
opennet> h1 ping h8
PING 10.0.0.8 (10.0.0.8) 56(84) bytes of data.
64 bytes from 10.0.0.8: icmp_seq=1 ttl=64 time=0.219 ms

64 bytes from 10.0.0.8: icmp_seq=6 ttl=64 time=0.118 ms
64 bytes from 10.0.0.8: icmp_seq=7 ttl=64 time=0.116 ms
64 bytes from 10.0.0.8: icmp_seq=8 ttl=64 time=0.103 ms
64 bytes from 10.0.0.8: icmp_seq=9 ttl=64 time=0.198 ms
```

Fig.7 Ping Command On Tree Topology from H1 to H8

The SDN network test has been conducted using ping and iperf command for 30 and 15 iterations respectively to check the reliability and consistency of the produced result on tree topology network on OpenNet. We recorded the results and plotted the trends for minimum, average and maximum RTTs along with TCP bandwidth in Fig. 8 and Fig.9 respectively. Where round trip time (RTTs) is an important metric to determine the health of connection and TCP bandwidth is to measure the quality of connection in a network. There are 10 packets of size 64 bytes used in the iteration of experiment and RTTs are recorded for the analysis. The minimum, average and maximum RTTs of the first request is higher as compared with rest of the RTTs, this is because OpenFlow switches (s1, s5, s7, s6, s4) are needs to initialize the forwarding tables in communication with SDN controller (c0).

SDN controller installs the forwarding rules in flow table considering the routing path in the network. In the measure of TCP bandwidth, the iperf command is executed 15 times to check the consistency (h1, h8) in performance of the network and recorded for the evaluation as trend depicted in Fig.9.

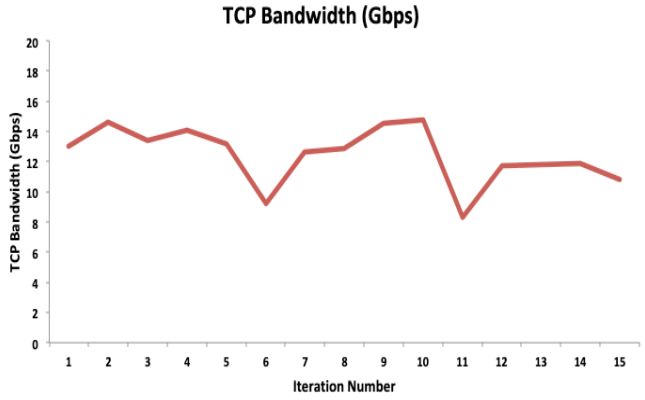

Fig. 9 TCP bandwidth between h1 and h8

VI. Conclusion and Future Work

The main idea to augment the vehicular network is to meet the current emerging computing technology's demands in communication. The augmented vehicular network with SDN can change the way of communication in a traditional network, this research work concluded that SDN could embrace the dynamic nature of the vehicular network and can be one of the promising solutions to suppress the limitations of a traditional network. We conducted an experiment on OpenNet with POX controller to emulate a sample tree topology, to confirm the effectiveness of SDN in the network. The augmented vehicular networks with SDN paradigm transform the traditional approach of communication and dynamically control the network packets flow by controlling the vehicles applications intelligently.

Most of the existing research work in the architecture of the vehicular network has considered the application in offline mode with global knowledge and centralized approach but there are cases where online approach is essential to consider such as works related to finding the route for a destination are required to consider the local knowledge and decentralized approach in online mode. The future work would consider the simulation of advanced network scenarios to validate the effectiveness of SDN in the vehicular network such as SDN connectivity strength or loss of connectivity with SDN controller, where isolated nodes are required to form the cluster network and connect with SDN controller.

manjushanairm@gmail.com

***Abstract*— Coordination in neural activity is thought to be a key element in propagation of information. Coordinated spiking in neurons in an effective signaling mechanism and helps in self-organization of the network over time. Using computational techniques, this study investigates the parameters affecting the coordinated activity of a population of granular layer neurons of the cerebellum. This study investigates the spike train coordination using two basic measures: spike correlations and spike synchrony. The values were quantified from modeled granule neurons of the cerebellum under various excitatory and inhibitory synaptic balances and under induced plasticity states. Increased excitation from mossy fibers (MFs) increased the output correlation of granule neurons while increased inhibition from Golgi neuron reduced the output correlations. Synchronous firing of granular layer population under *in-vivo* like inputs was increased with the increase in excitation and inhibition. Synchrony was also estimated under different induced plasticity states of the modeled neurons. The firing was more synchronous under the long-term potentiation (LTP) state compared to control state and was more asynchronous under long-term depression (LTD) state compared to control. Since plasticity signifies the learning activity in the neurons and is affected by temporal coordination in spiking, these results have greater relevance in understanding the nature of neural code.**

I. INTRODUCTION

A nerve cell (neuron) in the brain carries electrical impulses and fire signals to communicate with each other through the tiny gaps between them called synapses[1]. Depending on the nature of the neuron receptor present in the postsynaptic side, the postsynaptic membrane either becomes more electrically positive (excitatory) or become more electrically negative (inhibitory) and produce postsynaptic potentials (PSP) called Excitatory Postsynaptic Potential (EPSP) or Inhibitory Postsynaptic Potential (IPSP). PSPs thus formed are nonlinearly integrated across time (signals from the same pre synaptic neuron, one after the other) and space (signals from various presynaptic neurons, received at the same time) in the axon hillock and result in producing a signal called action potential.

Even though there are minor variations in the amplitude or shape of different such signals, these variations are assumed to be irrelevant. Neurons are assumed to use stereotyped and pulsed variants of such action potentials or spikes to communicate over long distances. A sequence of spikes from a neuron is represented as a spike train, consisting of a sequence of their spike times. Each spike typically lasts for 1-3 milliseconds approximately and are separated from other spikes by a few milliseconds[2]. These spike trains can be modeled as random processes since the same neuron produces a wide range of responses for the multiple invocation of identical stimuli. Neurophysiologists use multi electrode arrays to record simultaneous activity of several neurons within a particular brain region. Simultaneously recorded data from multiple neurons represent multidimensional point process time series.

Various coding schemes are used to study the transformation of information from one processing stage to another in a neural circuit. Rate coding assumes that the firing frequency of the neuron carries information. Since the shape of the action potential is not assumed to be significant in carrying information, the time of arrival of the action potential is used in many studies to measure the information content of the signal[3]. Hence time code considers the temporal patterns as information carriers. Inter spike interval based and first spike latency-based coding schemes also exist[4]. In frequency coding, neurons act as an analog to frequency converter while in latency code[5], neurons act as an analog to delay converter[6]. All these above-mentioned coding schemes study the neuron from a single neuron perspective and fail to represent the emergent properties of the joint activities of a group of neurons. Population level coding schemes are used to estimate the relationship between groups of neurons. For e.g., correlation coding studies suggest that correlations or synchrony between neurons could convey information in neuronal population level which is not contained in other coding schemes.

Correlation coding schemes are in practice from early 1960's [7] and several studies demonstrated the functional correlates of this measure with a multitude of parameters such as shared inputs, shared presynaptic partners, distance between neurons and receptive fields, intrinsic properties such as synaptic time constants etc.[8] It has been suggested that the neural responses are influenced not only by the firing rate of the inputs that it receives but also by the input correlations [9]. Spike train distance-based estimates also exist to measure the synchrony in neural firing[10].

This study investigates the correlation and synchrony between specific types of tiny neurons in the cerebellum, called granule neurons. The granular layer of the cerebellum, has more than 50% of the total number of the neurons in the brain. Granule neurons are present in the input layer of the cerebellum and receive inputs from various brain regions through long axons called mossy fibers. These mossy fiber inputs are excitatory in nature while the input connection that the granule neuron receive from another type of neurons called Golgi neurons, is inhibitory in nature. Each granule neuron, on an average receive one to four excitatory and inhibitory connections. Using computational models, this study investigates the coincident activity of multiple granule neurons under different synaptic conditions. The functional significance of these very tiny and densest neurons in the brain has greater relevance in computational modeling studies.

II. METHODS

A. Computational Modeling of Neurons

In computational modeling studies a neuron is abstracted as an RC circuit describing the electrical properties of the neuron [11].The RC circuit equivalent model is used to mathematically model the current flow in the circuit. In simulation studies, this mathematical framework is converted into a computational model. The biophysics of a single neuron is often abstracted as resistance-capacitance (RC) circuit with low-pass filtering properties wherein the lipid bi-layer of the neuronal membrane is modeled as capacitance (C), the voltage-gated ion channels in the membrane as electrical conductance (g) and the electrical gradient across the membrane as reversal potentials. Ohm's and Kirchhoff's laws are used to calculate the total current flowing and the voltage generated across the membrane of the neuron. The lipid bi-layer of the membrane acts as a capacitor by accumulating charges over its surface. The intracellular and extracellular solutions of the membrane act as the conducting plates separated by the non-conducting membrane. Total current flowing across the membrane is the sum of the capacitive and ionic currents:

$$I_{Total} = I_c + I_{ion} \quad (1)$$

When the capacitor is further charged with the input current I_{ext} which is applied into the cell, the current leaks through the membrane. Open membrane pores or channels in the membrane gives rise to more resistance components in parallel. Conductance of the channel increases with the increase in number of open ion channels in the membrane. Ionic current flow through a neuron with Sodium, Potassium and Leak channels can thus be modeled as,

[redacted] (2)

B. Multi compartmental modeling of granule neurons of the cerebellum

In multi-compartmental neuron modeling, each neuron is abstracted as a cylinder which is divided into different RC compartments. Each compartment is modeled with voltage gated ion channels and synaptic channels. The equations model close correspondence with the biophysical properties of neurons, ion channels and synapses. They also consider the propagation of membrane voltage change over axons and dendrites. Cable theory is used to model the variation of voltage across the axon. Every compartment is assumed to be iso-potential i.e., the voltage within each compartment is assumed to be constant and is modeled as an RC circuit. Multi-compartmental model of granule neuron used in this study contain 52 compartments[12] : N_A –No. of axonal compartments, N_D –No. of dendritic compartments, N_S –No. of somatic compartments, N_H –No. of hillock compartments (Figure 1: A). The membrane voltage V_m is estimated separately for each of the compartments separately.

$$\frac{dV}{dt} = \frac{1}{\tau_m}\left(\frac{\sum_i g_i(V-V_i)+\sum_{syn} g_{syn}(V-V_{syn})+\sum_{br} g_{br}(V-V_{br})}{g_{tot}}\right) \quad (3)$$

where the conductance of ion channel i is modeled as g , syn (synaptic dynamics), br representing the neighboring attached branch and $gtot$ (total) is the total conductance. The time constant is represented as $\tau_m = R_m C_m$ R_m is the membrane resistance and C_m is the membrane capacitance. The multi compartmental GrC model used included stochastic synapses where each synapse was constituted by few releasing sites comprising of pre-synaptic dynamics and release mechanisms. The granule cell model includes 1-4 excitatory and 1-4 inhibitory connections. Excitatory post-synaptic mechanisms were shown as AMPA and NMDA receptor components as seen in granule neurons [13]. AMPA receptor dynamics was modeled using a three-state scheme that was activated by a direct component of glutamate, modeled as pulse, and an indirect component representing the spillover of glutamate from nearby synapses in the glomerulus. Similarly, the NMDA receptors were modeled as five-state kinetic scheme, activated by the same direct and indirect glutamate components, and magnesium block was modeled by a Boltzmann equation [12]. The $GoC - GrC$ inhibitory synapses were modeled as in [13]. The granule neuron model was provided with 1-5 input spikes through each of the four MFs (Figure 1: B) and the simulations were performed in the presence and absence of inhibitory inputs to the neurons.

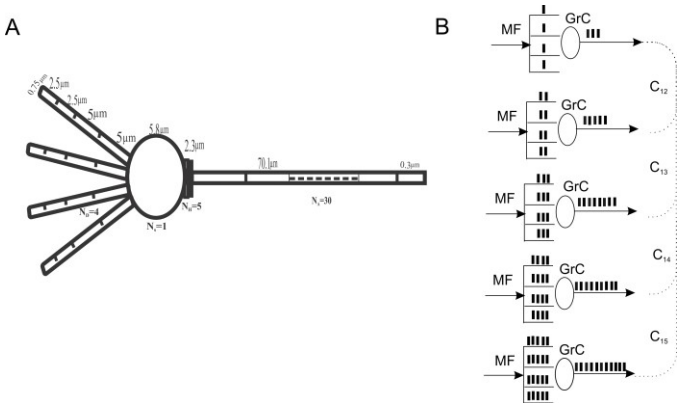

Figure 1: Computational modeling of neuron. A) The granule neuron model

used in this study included 52 compartments: 1 for the soma, 4 each for the four dendrites, 5 hillock compartments and 30 compartments for the axon. B) Input of varying spike rate was applied to the granule neuron model (GrC) through mossy fibers (MF). Cross correlation coefficients between paired neurons (C_{12}, C_{13}, C_{14}, C_{15}) was estimated as shown.

Plasticity states were also introduced in the neuron model. LTP and LTD were introduced by modifying the intrinsic excitability of the cell and also by modifying the release probability of the synapses[14].

C. Modeling the neural responses

Individual responses to the same stimulus are highly variable in the neurons. The process of action potential generation is a stochastic process. Poisson point processes on real line are used to model these spiking responses of neurons which are random spiking events in time. Point processes describe random events whose occurrence are timed. A Poisson point process is defined as a collection of random elements located on some mathematical space which can be used as mathematical models of some phenomena. The inter spike interval (ISI) of spike trains follows exponential distribution (Poisson distribution).

$$P(x) = \lambda e^{-\lambda t} \tag{4}$$

where λ is the inter-spike interval. Refractory periods modify this Poisson process to form Gamma distributions. Simultaneously recorded spike trains from multiple neurons are considered in our study as stochastic- dynamic multi-dimensional point process time series whose properties probabilistically change over time. Standard signal processing techniques used to analyze continuous valued data is not suitable to analyze such discrete datasets. The following sections describe the different techniques used in this study for spike train data analysis (Figure 2).

D. Measures of Spike Coordination

1) Cross correlation

Paired association between neurons (say a reference neuron and a target neuron) is tested traditionally using cross correlation measures. It shows the dependence of firing events of two neurons. The degree of correlation between neurons is quantified generally using various correlation measures. This study uses standard measures of correlation.

Given two time series,

$X = \{X_1, X_2, X_3 \ldots, X_n\}$ *and* $Y = \{Y_1, Y_2, Y_3, \ldots Y_n\}$

the correlation coefficient r measures the linear "similarity" between them.

$$r = \frac{\sum_{i-1}^{n}((X_i - \bar{X})(Y_i - \bar{Y}))}{\sqrt{\sum_{i-1}^{n}((X_i - \bar{X})^2}\sqrt{\sum_{i-1}^{n}((Y_i - \bar{Y})^2}} \tag{5}$$

Cross correlation measures the degree of similarity between spike trains as a function of its time shift. The values range between 0 and 1 where a 1 represents increased correlation strength.

2) Spike Train Synchrony

Since the standard measures of correlations work on a rate-based framework, neural coordination is also estimated by measuring relative timing in spiking events of two neurons.

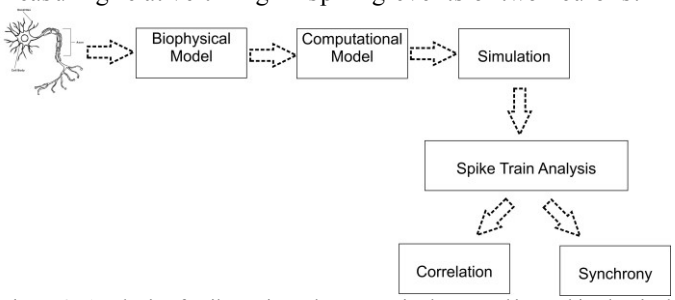

Figure 2: Analysis of spike trains. The neuron is abstracted into a biophysical model and is converted into computational model. The spike train responses of neural simulations are then used to quantify the coordination between neurons using the estimates of correlation and synchrony.

This study used a spike pattern distance measure called Victor-Purpura distance to estimate the synchrony in the neural responses [10][15].

Consider p and q as two spike trains with spike times $p_1, p_2 .. p_n$ and $q_1 q_2 .. q_n,$, . A measure of spike train synchrony maps the pair to a positive real number. A high value corresponds to two closely related spike trains and is expressed as $s(p,q)$ and a low value corresponds to very similar spike trains .In the case of dissimilarity measures expressed as the distance between spike trains $d(p,q)$, a measure of dissimilarity is a metric , so that $d(p,q) = 0$ implies $p = q$.

The Victor-Purpura distance measure

It is a measure of the amount of change required to transform one spike train into the other [15]. It uses a cost-based metric, measured while changing one spike train into another using three basic operations: spike insertion, spike deletion and spike shift. Spikes can be added or deleted at a cost of one for each operation, and spikes can be moved at a cost of $q|\delta t|$ for a cost per time unit q and a temporal distance δt.

Population measures were calculated in two ways in this study: those which measure the similarity (or dissimilarity) between a pair of responses and those that measure the over-all similarity of a set of responses and are calculated by averaging single-neuron measures.

III. RESULTS AND DISCUSSION

A. Neural correlation affected by synaptic excitation and inhibition

In order to estimate the effect of excitation and inhibition on coordination between neurons, two modeled neurons with differing synaptic balances were chosen and the paired correlation coefficient was estimated. In order to change the effect of input firing rate on correlation, MF inputs with 1 to 5 spikes through the four synapses was applied (Figure 1:B). Cross- correlograms were generated for paired spike trains.

It has been observed that cross-correlation was reduced as the neurons more differed in their firing frequency. The number of mossy fiber inputs were also changed from 2 to 4 and found that the correlation increased with the increase in mossy fiber inputs to the neuron (Figure 3: A). The granule neuron responses were also recorded in the presence of Golgi neuron inhibitory inputs and found that the correlation was high in the absence of inhibition and reduced with the introduction of more and more inhibition into the neurons (Figure 4: A). These correlation estimates suggested that the paired association between neurons is increased with more excitation and reduced with more inhibition into the neurons.

Correlation for time lags of ± 25 ms, centered on the first spike train was calculated and the peaks in the correlogram indicated the highest value of correlation between the spike trains. The correlation measures are the maximum values from the cross-correlograms of the spikes. Peaks in the cross correlograms represent the simultaneous firing events of target and reference neurons. The width of the correlogram increased with increase in excitation and the correlation peaks were more shifted towards the left (Figure 3: B, C, D). The width of correlogram was reduced with increase in inhibition and the correlation peaks were more shifted towards the center (Figure 4: B, C, D).

B. *Neural synchrony affected by synaptic excitation and inhibition*

The synchronous firing of granule neurons under different synaptic conditions were estimated using a spike distance measure. MF input spikes of 1 to 5 were applied to a granule neuron population and the multi-neuronal responses were recorded. Average spike distance between all pairs of responses (D_{Mean}) in the response set was estimated (Figure 5: A). This measure was observed to be decreased with the increase in MF excitatory inputs to the neuron, suggesting the increased synchronous firing with increased excitation.

D_{Mean} was also estimated with and without inhibition into the neurons in the population (Figure 5: B). Reduced distance measure with the increase in inhibition suggested the increased synchrony between firing responses.

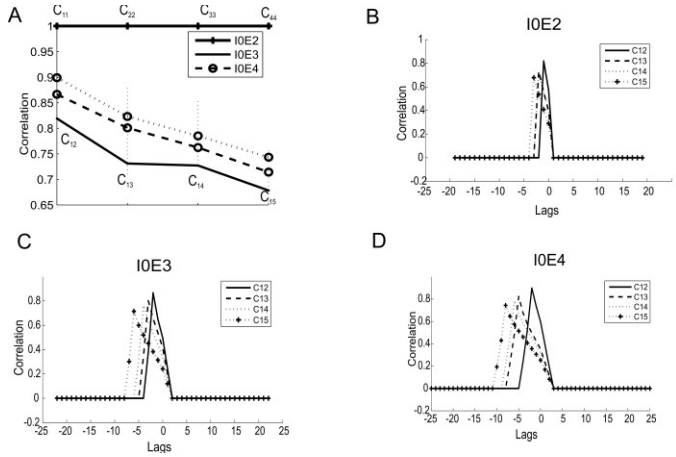

Figure 3: MF excitation and granule neuron response correlation. A) Cross correlation reduced with the increase in firing rate and increased with the increase in mossy fiber inputs. B, C, D) Cross correlograms plotted for three different synaptic conditions: I0E2 – Inhibition 0 excitation 2, I0E3 – Inhibition 0 excitation 3, I0E4 – Inhibition 0 excitation 4.

C. *Firing synchrony during induced plasticity states*

Simulations were performed under induced plasticity states of the neurons[16] .Long term potentiation (LTP) was introduced by increasing the intrinsic excitability of the neuron and by increasing the release probability of MF synapses above 0.41. Long term depression (LTD) was induced by reducing the
intrinsic excitability of the neuron and by decreasing the release probability of the MF synapses below 0.41. D_{Mean} was estimated for LTP, control and LTD conditions of the neuron and it was observed that D_{Mean} was decreased during LTP from control while D_{Mean} was increased during LTD from control (Figure 5:C). These results suggested that the neurons fired more synchronously in their LTP state compared to the control state and the firing was more asynchronous during LTD state compared to control state.

CONCLUSION

The observation from the study suggested how the inhibitory and excitatory synaptic balance modulates the post synaptic responses of a neuron. Also we propose that, coordinated activity is controlled in the neuronal level using such balances. Enhanced firing synchrony during plasticity conditions also reflect its influence on functional connectivity between neurons.

Due to the high dimensionality of the multi neuronal data, population coding studies are less advanced compared to studies on information coding in single neurons[17] . Even though cross correlation represents relationships that exist between the spiking activities of two neurons, this method assumes that the spike trains are stationary. The time varying adaptation of the spike trains in the time course of the stimulus, is not addressed in the method and it is assumed that the statistics of the spike trains are constant over time.

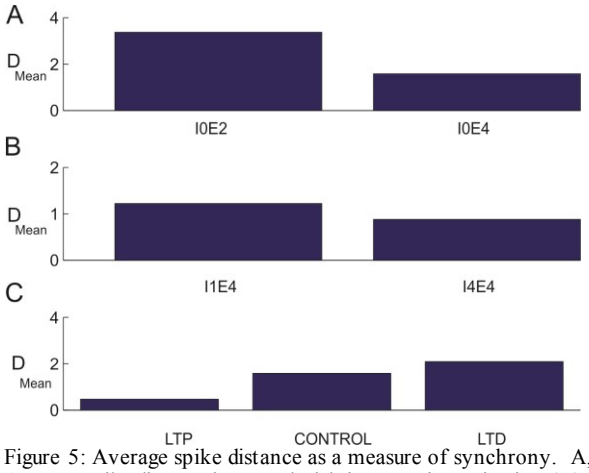

Figure 5: Average spike distance as a measure of synchrony. A, B) Average spike distance increased with increase in excitation (A) and inhibition (B). C) Average spike distance was decreased in LTP compared to control and increased in LTD compared to control.

Spike distance-based measures are able to capture the temporal structure and synchrony in the responses and is a powerful tool in mutual information-based studies[18] . Spike correlations and spike synchrony may function as an additional information transfer mechanism in neurons and further work is required in this direction to study the effect of such coordinated activities in the information encoding properties of the neurons.

ACKNOWLEDGMENT

This work derives direction and ideas from the Chancellor of Amrita University, Sri Mata Amritanandamayi Devi. The authors of this work also acknowledge the support received from Computational Neuroscience Lab, School of Biotechnology, Amrita Vishwa Vidyapeetham.

***Abstract*—In this paper,real time Facial expression recognition on a raspberry pi using K Nearest Neighbors (KNN) classifier is proposed. Global shape features are extracted with Histogram Of Gradients (HOG) and Local texture features are extracted using Grid of Local Binary Patterns (GoLBP) and both the vectors are combined. Various block sizes for GoLBP feature vector extraction are evaluated. Genetic Algorithm is used for feature selection and optimisation, Change in efficiency of classification with number of iterations (Generations) is studied. The proposed method is tested using Japanese Female Facial Expression Database, Taiwanese Facial Expression Database and Cohn-Kanade Expression Database. The proposed technique is compared with some state of the art techniques. The proposed technique is trained with locally developed Indian facial expression dataset and deployed on raspberry pi Single Board Computer(SBC).**

Keywords: HOG, GoLBP, Genetic Algorithm, KNN.

I. Introduction

Facial Expression recognition is essential for human computer interaction and to build smarter systems. Today smart appliances and home automation work on the basis of interaction between the smart system and humans. According to Albert Mehrabian, a professor of psychology, In communication just 7% information is transmitted via verbal communication and 93% information is transmitted through non-verbal means [1]. These non-verbal modes range from Facial Expressions to body language and the tone of speech. Similar words said with different facial expressions often convey different emotions and give different meaning to the same message. Facial expressions are universal and dont vary over nationalities. Facial Expressions can be classified into seven categories, Happy, Surprise, Disgust, Unhappy, Fear, Anger and Neutral.

The above facial expression can be broadly classified into two emotional states. The facial expressions of Disgust, Unhappiness, Fear and Anger representing a persons negative emotional state. The facial expressions of Happy and Surprise representing and positive mood and a Positive state of mind. Classification of emotion is a binary classification problem, whereas facial expression classification is a multi-class classification problem. Apart from human computer interaction there are a lot of application areas where detection negative emotions can be applied. Few Such application areas are Crime-scene investigation from CCTV footage, Criminal Interrogation, It can be also applied to surveillance and preventing crimes. Other applications of Facial Expressions include medical sciences , E-learning and market research.

Genetic Algorithm is an algorithm which tries to mimic the process of natural evolution put forth by Charles Darwin. Genetic Algorithm is capable of extracting features from a given pool of features, which helps in reducing the total number of features and at the same time increase the accuracy of classification. Genetic Algorithm achieves this by selecting the fittest features from a pool of features. Our work is validated with help of widely used standard databases such as Japanese Female Facial Expression (JFED) [13] , Taiwanese Facial Expression Image Database (TFED) [12] and Cohn-Kanade Facial Expression Database(CKFED) [14].

II. Related Work

Viola and Jones proposed haar feature based face detection technique which used adaboost training and cascaded classifiers [3]. Zhe Sun et al. in [10] proposed a discriminative learning scheme for facial expression recognition. V-2DLDA was used to aid in classification tasks. The algorithm achieved accuracy of 91.87% on ck+ dataset, 82.24% on kdef dataset. Stefanos Eleftheriadis et al in [6] proposed a multi-view and view invariant classification of expressions using DS-GPLVM. The method achieved accuracy of 93.55% on Multi-pie database. Shojaeilangari et al in [7] proposed a model that can jointly learn dictionary and non-linear classification model. A spatio-temporal distinctive and pose invariant descriptor was proposed, the method also works on video data. The technique is computationally slow. Evangelos Sariyanidi et al. in [8] represented facial expression variation as localised basis functions. The technique utilizes svm for classification. Mengyi Liu et al. in [9] proposed method for video data. The technique extracts SIFT and HOG features. Universal Manifold model is learnt from low level features. S L Happy and Aurobinda Routray in [11] proposed method for low resolution images using SVM classifier. They proposed a novel framework by using appearance features of selected active facial patches. Khorsheed and Yurtkan in [16] used LBP for

feature extraction, a novel classifier was proposed, which used chi square distance metric. The technique has accuracy of 82%. The above methods have limitations such as illumination variations leading to misclassification, lack of global or local features

III. Facial Expression Recognition System

Facial expression recognition system comprises of 2 phases. The 1st stage is the training phase where the system is trained to recognize various facial expressions. In the training stage image samples for each facial expression are applied as input. The system learns from this input data. The input images to the system are first pre-processed. In pre-processing stage a face is extracted from the image. From the detected faces feature vectors are extracted. Best features are extracted from the feature vector in feature selection stage. The selected features are applied as input to learn a classification model. In testing face an unknown image is given to the system. The system pre-processes the image, extracts the features and then predicts the facial expression.

Face detection is the process of capturing a face of a person from an image frame. There are various methods for detecting faces, such as viola jones method [3] and various deep-learning based detectors. Due to better performance of deep learning techniques in real-time applications, in this proposed work deep learning based technique has been utilized. Andrew G. Howard et. al. proposed efficient convolutional neural network called MobileNet for mobile phones and embedded applications in [4]. Wei Liu et al. proposed a multi-box detector for detecting objects in images using single deep neural network in [5]. Googles tensorflow api provides an api which is combination of both the above works. The api is called ssdlite-mobilenet, and was designed for implementation on mobile-phones, embedded devices and single board computers such as raspberry pi. In the proposed work, tensor-flow object detection api is installed on the raspberry pi device. Tensorflows, ssdlite mobilenet model is transfer trained to detect faces in an image. The model is trained using 1200 images with different facial orientations and inclinations.

The tensor-flow model gives detection boxes, detection scores and detection classes as outputs. If the detection score is greater than 50%, it is assumed that the detected object is a human face. The detected face image is then pre-processed to make it robust for further processing. The face image is histogram equalized. Histogram equalization makes the face image invariant to illumination variations. To reduce the computation time, the image is converted to gray scale and resized.

Feature Extraction module is the most vital component of the entire system. The features extracted from each image provide vital information in identifying expressions. To extract features, a combination of Grid of Local Binary Pattern and Histogram of Gradients is used and a single feature vector is obtained. Feature extraction reduces dimensionality to a single dimension. The extracted features undergo feature selection, where the best features are selected from the pool of available features. After feature selection a feature vector of reduced length is obtained. The reduced features are used for further classification. A feature can be categorized either as a global or a local feature. Global features such as HOG try to capture the shape of structures in the image by capturing gradient information. In contrast Local descriptors such as LBP give information about textures in parts of the image. By applying feature extraction, the aim is to convert large quantity of pixel data into computationally efficient feature vector. The accuracy of classifications is directly impacted by the choice of feature descriptors.

The next step in Facial Expression Recognition System is Feature Selection. Feature selection has impact on both, the computational time required and the accuracy of classification. Feature Selection takes the feature vector as an input and selects the features which contribute most to describing an emotion. In doing so, redundant features are discarded and the length of feature vector is reduced. Reduction in feature vector length results in less computational time and also greater accuracy. Genetic Algorithm is used for feature selection. Genetic Algorithm is an Evolutionary Algorithm which follows the process of natural selection. Genetic Algorithm is ruled by the law of survival of the fittest.

The Final step in Facial Expression Recognition System is classifying the extracted features into predefined classes. Those classes are: Happy, Unhappy, Surprise, Disgust, Fear and Anger. Machine Learning is utilized for classification of these expressions. K- Nearest Neighbors (KNN) is a supervised learning Algorithm. KNN estimates output directly from the test data and training data, based on the classes of training data points surrounding the test data point. The entire system is deployed on raspberry pi for real time emotion classification.

A. Grid of Local Binary Pattern

Local Binary Patterns(LBP) are local texture descriptors proposed by Ojala et al [18]. LBP are simple yet powerful and robust features. LBP have been widely used for detection and recognition applications. LBPs illumination invariance make them highly suitable for face recognition and facial expression recognition applications. Ngoc introduced a modified version of LBP know as Grid of LBP (GoLBP) [19]. GoLBP provides better texture description as compared to original LBP [18]. LBP and its versions are applied on gray scale images. But it has also been extended to Colour images, videos and other volumetric data.

Fig 1 represents the GoLBP structure and the manner in which different pixel values are to be compared. Equation (1), shows that all the 8 neighbouring pixels contribute to the calculation of the GoLBP value. In calculating GoLBP, the difference between pixels according to GoLBP structure is calculated. If the difference between the numbers is non-negative, then 1 is assigned. If the difference between the pixels is negative than 0 is assigned.

$$A = d_{0,c} + d_{2,c}2^1 + d_{3,c}2^2 + d_{5,c}2^3 + d_{1,4}2^4 + d_{1,6}2^5 + d_{7,2}2^6 + d_{7,4}2^7 \quad (1)$$

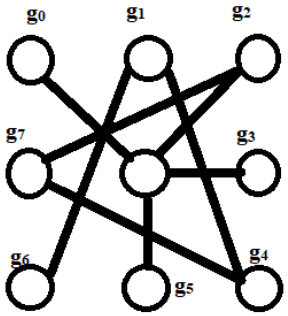

Fig. 1. GoLBP Structure [19]

$$d_{x,y} = s(x,y) = \begin{cases} 1, & \text{if } g_x \geq g_y. \\ 0, & \text{otherwise.} \end{cases} \quad (2)$$

If Fig 2 is the input image block, than by applying the grid structure and equation (1), the GoLBP code obtained is 111100012 . The decimal code equivalent is 241. Therefore a single decimal value is obtained for the entire block. The process is repeated over all the blocks in an image and an image feature vector is obtained. The biggest advantage of GoLBP and other LBP codes is that, it is invariant to illumination variation, as even after change in lightning conditions the difference between the pixels remain the same. Due to this GoLBP and other LBP variants are highly suitable for real time applications.

65	79	41

77	42	53

Fig. 2. Input Image Block

B. Histogram Of Gradients

Histogram of Gradients(HOG) are global features introduced by Dalal et. al. [17]. The aim of HOG is to extract shape information in an image. The shape information is obtained by extracting gradient and edge information. To calculate HOG, first gradients in x direction G_x and gradient in y direction G_y are computed. From the gradient information, the gradient magnitude and orientation are calculated.

$$M(x,y) = \sqrt{G_x(x,y)^2 + G_y(x,y)^2} \quad (3)$$

$$\theta(x,y) = \frac{G_x(x,y)}{G_y(x,y)} \quad (4)$$

The HOG features are extracted as follows: In a gray-scale or Colour image the gradients are calculated in horizontal and vertical direction. From horizontal and vertical gradients the magnitude is calculated according to equation(3) and orientations are calculated according to equation (4). The gradient histogram is divided into 9 bins from 0 to 180 degree. According to magnitude, each pixel is voted for its orientation.

C. Genetic Algorithm

K.F. Man et. al. proposed genetic algorithm as an evolutionary algorithm [20]. Genetic algorithm attempts to mimic the process of natural evolution. The algorithm is based on principle of survival of fittest, where the fittest features are selected to produce a next generation of features. The next generation inherits characteristics from parent features and are supposed to be fitter features. There are five phases in Genetic Algorithm:

- Obtaining Initial Population
- Evaluating Fitness using a fitness function.
- Feature Selection
- Cross-over
- Mutation

The Algorithm begins with a set of features called a population. Each point in a feature vector is called a gene. Each feature vector is called a chromosome. In genetic algorithm, the set of genes is represented as binary values. Thus chromosome is represented as a vector of 1s and 0s. Initially a random population is selected from the available features. Fitness score is calculated for each individual using a fitness function. Fitness function can be the classification score of a classifier. The individuals with higher fitness score are selected for further operation. Then the selected individuals will be used to create a new generation. A cross over point is selected and the genes of the two individuals are exchanged. The new generation created, inherits the fitness from both its parents. The new generation is now subjected to Mutation, where some genes are flipped from 0 to 1 or 1 to 0. After this again the fitness of new population is computed and the procedure of cross-over and mutation repeated.

Fig. 3. Population, Chromosomes, Genes

Fig 3 shows how each feature vector is represented as a chromosome, and each element of the vector is represented as a gene. In genetic algorithm the genes are represented as one and zeroes and during the crossover operation, according to crossover, certain number of genes of a chromosome

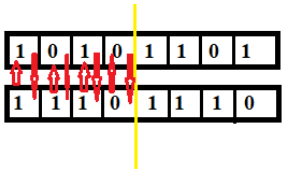

Fig. 4. Cross-Over Operation

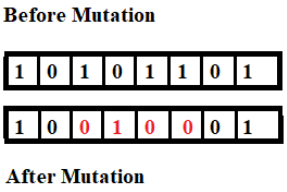

Fig. 5. Mutation Operation

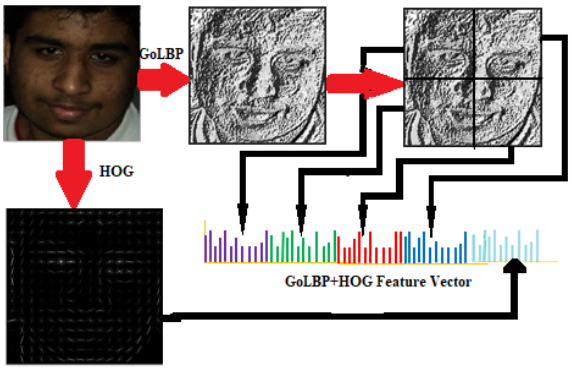

Fig. 6. Decomposition of Face Image into Feature Vector

TABLE I
OVERVIEW OF EXPERIMENTS PERFORMED WITHOUT GENETIC ALGORITHM

Block Size of GoLBP (Vector Length)	JFED	TFED	CKFED
256x256 (2020)	88.57	88.23	90.59
128x128(2788)	88.57	88.23	92.30
64x64 (5860)	92.85	90.19	93.16
32x32 (18148)	67.14	89.22	74.36

represented in binary form is exchanged with same number of genes of another chromosome as shown in fig 4. In mutation operation the genes are flipped as displayed in figure 5.

For application in image processing, a single feature vector will be considered as a chromosome and individual data points in the vector are genes. Initially fitness is calculated for all chromosomes and all the genes are considered. Then randomly for every chromosome some of the genes are neglected in computation. This genes can be represented by zero. The genes considered for evaluation are represented by 1. Fitness score is evaluated with this reduced number of genes. If greater fitness is obtained the cross-over and mutation operations are performed else a new population is generated.

IV. PROPOSED ALGORITHM

The proposed algorithm was developed to perform real time facial expression recognition on raspberry pi. In the proposed algorithm pyramid approach is used for feature extraction, the detected pre-processed face image is resized to 256x256 image. In pyramid approach a set of features are extracted and then image is resized to half its size and another set of features is extracted. The GoLBP image is calculated for 256x256 image. The image is then resized to 128x128 and HOG of the image is calculated. The GoLBP image is divided into blocks of equal size and histogram of each block is obtained as shown in fig 6. Histograms from various blocks are concatenated and at the end HOG vector is concatenated. The concatenated vector is the feature vector. Feature vectors from different images are obtained.

In the training phase, the genetic algorithm is applied to the extracted features. From the training images, 20 % images in the training set are used as validation images for the genetic algorithms fitness function. In the proposed work K-Nearest Neighbour(KNN) classifier is used as a fitness function. Higher KNN classification accuracy corresponds to higher fitness. Genetic Algorithm computes a solution which takes into account which element of the vector contributes how much information to the classification process. The best feature elements are selected, in doing so the length of feature vector is also reduced. The final result of genetic algorithm is a long integer number, which when represented in binary form, provides information about which Feature elements to be considered and which feature elements are redundant to the classification problem. With help of training set, and the validation set, a solution to genetic algorithm is obtained. This solution is used for feature selection in the test dataset and for real time execution on the raspberry pi.

V. EXPERIMENTATION AND RESULT ANALYSIS

The FER algorithm is developed to detect the basic emotions such as Happiness, Disgust, Fear, Surprise, Anger, Unhappy and Neutral. Different sets of images were used for training and testing the system. The Algorithm iteratively loads images from the datasets and features vector is calculated using combination of GoLBP and HOG. The image is divided into different block sizes and Histograms from different GoLBP image blocks and HOG are concatenated together to obtain the feature vector. KNN classifier then classifies the test images into one of the emotion depending on the trained image dataset.

Table I summarizes recognition rates at various block sizes leading to varying lengths of features vectors. It is observed that highest accuracy is obtained when the GoLBP image is divided into 16, 64x64 blocks. The histograms from the 16 blocks are concatenated into 4096 length vector. The HOG vector of length 1,764 obtained by resizing image to 128x128, using cell size of 16x16 and block size of 2x2 is concatenated at the end of the 4096 length vector. The HOG configuration is selected as it provides good balance between

HOG feature length and the amount of information captured. The confusion matrix for high accuracy recognition cases are tabulated further.

TABLE II
FER WITH GENETIC ALGORITHM ON COHN KANADE DATASET.

	Neutral	Happy	Surprise	Disgust	Unhappy	Fear	Angry	Accuracy
Neutral	21	1	0	0	1	1	0	87.5
Happy	0	21	0	0	0	0	0	100
Surprise	0	0	29	0	0	0	0	100
Disgust	0	0	0	8	0	0	0	100
Unhappy	1	0	0	0	7	1	0	77
Fear	0	0	0	0	0	10	0	100
Angry	0	0	0	0	0	0	16	100

Overall Accuracy (Test Set):95.72%

To optimize features using genetic algorithm, images from train set were used as validation set and optimized solution representing the features to select and features to discard was obtained. The solution is applied to test data set and optimized features are obtained from test data set too. This process was repeated for Cohn Kanade, Japanse Female and Taiwanese Facial Expression Datasets. Cohn Kanade train Dataset had 296 images out of which 60 images were included in validation set to calculate genetic algorithm solution. Using that solution, feature selection for test dataset is accomplished. Table II represents confusion matrix for Cohn Kanade dataset, where test set had 117 images and accuracy of 95.72% was obtained. Thus Genetic Algorithm increased accuracy from 93.16 to 95.72%.

TABLE III
FER WITH GENETIC ALGORITHM ON JFED.

	Neutral	Happy	Surprise	Disgust	Unhappy	Fear	Angry	Accuracy
Neutral	20	0	0	0	0	1	0	95
Happy	0	20	0	0	0	0	0	100
Surprise	0	0	14	0	0	0	0	100
Disgust	0	0	0	16	0	0	0	100
Unhappy	3	0	0	0	10	1	0	77
Fear	0	0	0	0	0	13	0	100
Angry	0	0	0	0	0	0	13	100

Overall Accuracy (Test Set):96.36%

Japanese Female train Dataset had 254 images out of which 60 images were included in validation set to calculate genetic algorithm solution. Using that solution, feature selection for test dataset is accomplished. Table III represents confusion matrix for Japanese Female dataset, where test set had 110 images and accuracy of 96.36% was obtained. Thus Genetic Algorithm increased accuracy from 92.85 to 96.36%.

Taiwanese train Dataset had 245 images out of which 60 images were included in validation set to calculate genetic algorithm solution. Using that solution, feature selection for test dataset is accomplished. Table IV represents confusion matrix for Taiwanese dataset, where test set had 102 images

TABLE IV
FER WITH GENETIC ALGORITHM ON TFED.

	Neutral	Happy	Surprise	Disgust	Contempt	Unhappy	Fear	Angry	Accuracy
Neutral	18	0	0	0	0	0	0	0	100
Happy	0	15	0	0	0	0	0	0	100
Surprise	0	0	11	0	0	0	0	0	100
Disgust	0	0	0	8	0	0	0	0	100
Contempt	1	0	0	0	23	0	0	0	96
Unhappy	2	0	0	0	0	7	0	0	78
Fear	0	0	0	0	0	0	8	0	100
Angry	1	0	0	0	0	0	0	7	78

Overall Accuracy (Test Set):95.09%

TABLE V
PERFORMANCE COMPARISON OF VARIOUS STATE OF THE ART TECHNIQUES WITH PROPOSED WORK

Database	SVM+ Bi-directional LBP [21]	SVM+ LBP + LDA +AFP [11]	BPN [22]	RBF [22]	LBP + GRNN [23]	Proposed work
JFED	96.91	92.22	69.82	85.71	95.48	96.36
TFED	94.66	-	83.85	92.85	94.25	95.09
CKFED	-	94.09	-	-	94.91	95.72

and accuracy of 95.09% was obtained. Thus Genetic Algorithm increased accuracy from 90.19 to 95.09%.

Fig 7 represents the number of generations Genetic algorithm is allowed to run for, and the accuracy corresponding to the number of generations. It can be seen that accuracy keeps on increasing to a certain point, after which the accuracy remains same, despite the number of generations the Genetic Algorithm runs.It is also seen that, genetic algorithm leads to 50% reduction in size of feature vector. On an average the feature vector length, for 64x64 GoLBP block was reduced to an average of 3000 from 5860. The Accuracy also varies with change in the size of initial population that is initiated, In our experiments, optimum results were obtained by considering an initial population of 50.

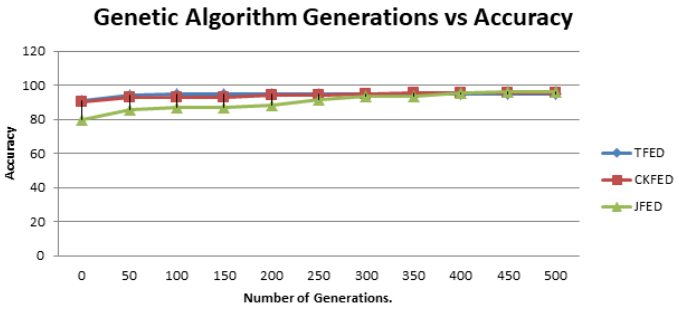

Fig. 7. Genetic Algorithm Training Generations vs Accuracy

It can be seen in table V, that the proposed work gives comparable results to state of the art techniques while at the same time providing optimized features.

For real-time implementation, a local database of Indian facial expression images was constructed and fed to the algorithm to be learnt. The dataset consisted of 78 images of angry expression, 126 images of disgust expression, 92 images of fear expression, 78 images of happy expression, 119 images of surprise expression and 151 images of unhappy facial expression. A validation set of 28 angry images, 26 disgust, 26 fear, 25 happy, 25 surprise and 25 unhappy images is constructed and Genetic Algorithm solution is evaluated. The solution is used for feature selection on the real time faces detected via tensor-flow model.

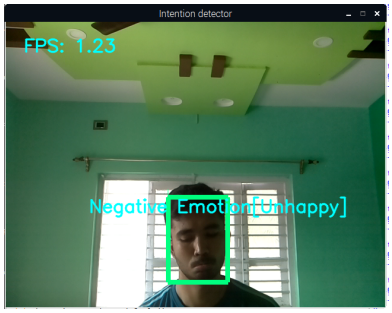

Fig. 9. Real time unhappy Emotion detection

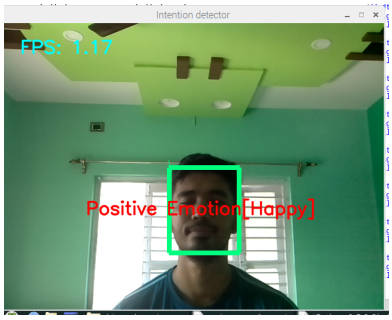

Fig. 10. Real time happy Emotion detection

Fig 8,9 and 10 show the real time detection results. The face is detected by raspberry pi using tensorflow model and marked with a green box. The face region is passed to the proposed algorithm to predict the facial expression. In fig 8, Unhappy emotion is predicted, in fig 9 anger is detected and in fig 10 Happy is detected. The FPS, in the figure represents the time required for entire process from, frame capture, face detection feature extraction and emotion prediction to complete. A FPS of greater than 1 represents computation time of less than 1 second, which is good enough for real time applications on a raspberry pi board.

VI. Conclusions

A new approach based on combination of global and local features has been proposed to encode shape and texture information. Genetic Algorithm is proposed for feature selection and optimization. The optimum block size for GoLBP image which generates a feature vector that gives highest accuracy, has been evaluated. The increase in accuracy with number of generations of Genetic Algorithm has been studied, It is seen that population of 50 and running the Algorithm for 300 generations gives the best optimized solution. The proposed work is tested on standard datasets, and the results are comparable to state of the art techniques. The algorithm operates at frame rate of more than 1fps, which is because of the light weight feature extraction algorithm, which still provides good accuracy. The future scope of the study can include applying Genetic Algorithm to other feature extraction techniques. Experimenting with Genetic Algorithm to use different mutation techniques and selection techniques such as roulette wheel, tournament and others. Creating a more robust dataset, for training the algorithm for real world application.

To deploy the system, for real time applications in real world scenarios, the system needs to be trained with a much robust dataset, where in the faces are inclined at certain angles or rotated in some direction.

***Abstract*— In this work, the design guidelines for conformal reflector backed printed dipole antenna for directional UAV applications is presented. Firstly, the concept of reflector backed printed dipole antenna for directional radiation is presented. Secondly, the concept of conforming the printed dipole antenna to the shape of a typical wing leading edge is studied by embedding the printed dipole antenna inside a Glass Fiber Reinforced Polymer (GFRP) structure for radiation transparency, backed with low dielectric constant foam with a thickness of λ/4 ending with a Carbon Fiber Reinforced Polymer (CFRP) ground plane to essentially produce directional radiation normal to the antenna plane. The conformal antenna is fabricated and tested for performance giving a gain of 5.22dB across a 1.66% measured bandwidth from 3.580 GHz to 3.638GHz. The 3dB beamwidth in the H-plane is around 70^0 and E-plane beamwidth is around 90^0. This idea readily satisfies the UAV conformal antenna requirements for high throughput directional communications.**

Keywords—printed dipole; conformal load bearing antenna structure; wing leading edge; unmanned aerial vehicles (UAVs)

I. INTRODUCTION

The recent advances in Unmanned Aerial Vehicle (UAV) technologies has led to an increasing demand for small, lightweight, directional and high gain antennas to be used for communication systems. UAVs are widely used in military, scientific and exploration missions. They are used routinely to collect data and send information back to a ground station that provides real-time information on the covered area. Through wireless links the data transmission from UAVs is done [1-2]. For transfer of data through RF link we require antennas. There are many antennas available in literature to meet these requirements with limited feasibility to use in case of UAVs. To meet these requirements for UAVs, the printed antenna is chosen as the candidate antenna to be embedded as it can meet the minimum gain required over ± 45^0angle [3-6].

In this paper, firstly, a bi-faced printed dipole antenna which is fed with a coaxial feed presented for low profile, conformal requirements of UAV applications [7-8]. The antenna radiates Omni directionally by nature. To have the directional radiation, secondly, the antenna is backed with a reflector spaced with a space of λ/4 in order to produce in phase reflected signal. The design optimization is carried out using FEKO's EM tool. Thirdly, the reflector backed dipole antenna is conformed to the wing leading edge of typical UAV, fabricated and tested for its performance.

II. DESIGN AND DEVELOPMENT OF REFLECTOR BACKED PRINTED DIPOLE ANTENNA

The configuration of the proposed printed dipole antenna (PDA) is shown in Fig. l. The physical parameters of the antenna are calculated by using formulae available in the literature [3-6] [9-11]. The antenna consists of two arms printed on both sides of the substrate in alternate configuration (each arm onto opposite sides).

First, the conventional printed dipole antenna (Antenna 1) is designed for 3.70GHz with FR4 dielectric substrate material of relative permittivity (εr) 4.4 and dielectric loss tangent (tanδ) 0.03036 with thickness of 0.2 mm. Secondly, the conventional antenna is backed by finite perfect electric conducting (PEC) ground plane (Antenna 2) with approximately quarter wavelength of gap (g). Thirdly, the aperture in the PEC ground plane exactly below the feed point with an aperture radius of 10mm is named as Antenna 3. The aperture is to accommodate the cable connection. The method of coaxial feed is used for 50Ω impedance. An impedance transformer is used for matching the input impedance to the feed impedance. All the physical dimensions are tabulated in Table 1. Altair's FEKO 17.1 EM Simulation tool is used for the modelling, simulation and optimization of doubled sided printed dipole antennas [12].

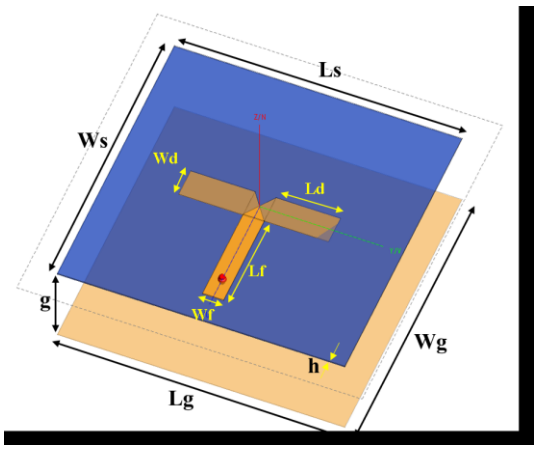

Fig. 1. Geometry of printed dipole antenna with ground

TABLE I. FINAL OPTIMAL PHYSICAL DIMENSIONS OF PROPOSED PRINTED DIPOLE ANTENNA

Sl. No.	Parameters	Value(mm)
1	Length of one arm of the dipole (Ld)	11.18
2	Width of the dipole (Wd)	5.13
3	Length of the feed (Lf)	17.33
4	Width of the feed (Wf)	3.68
5	Length of the substrate (Ls)	50
6	Width of the Substrate (Ws)	50
7	Length of the ground (Lg)	50
8	Width of the ground (Wg)	50
9	Gap between the patch and ground (g)	15
10	Thickness of the substrate (h)	0.2

III. DEVELOPMENT OF CONFORMAL LOAD-BEARING ANTENNA STRUCTURE (CLAS)

When the antenna has to be conformal to the surface of the UAV, it is required to have essential structural strength to endure the aerodynamic forces and still perform as an antenna with desired characteristics. The material design for embedding the dipole antenna at the leading edge of a typical UAV airframe for the development of Conformal Load-bearing Antenna Structure (CLAS) involved innovative employment of GFRP and CFRP composites and their foam sandwiches using combination of co-curing and co-bonding processes. The multi stage development process initially involved vacuum thermoforming (to conform to leading edge) of high performance rigid polymeric foam, which had dual (electrical and mechanical) functionalities in CLAS, viz., creating the necessary dielectric spacing (15mm) between the antenna and the conducting back plane / reflector as well as imparting the structural rigidity through the sandwich construction. The said dielectric spacer, carbon-epoxy back-plane and the glass-epoxy leading edge structure were then co-cured by out-of-autoclave processing of prepregs and the antenna was then conformed and bonded to the same on the dielectric spacer foam surface after creating necessary opening to pass the connector of the antenna to form an integral multi-functional structure. The process was completed after finally covering the mentioned structure with 0.5mm glass-epoxy skin acting as thin wall radome on the frontal foam side matching to the profile of the leading edge by co-bonding process. The schematic representation of the CLAS is given in the below Fig.2. The developed CLAS is shown in Fig. 8 (a) and (b).

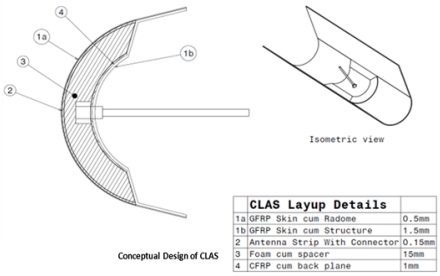

Fig. 2. Schematic representation of CLAS

IV. RESULTS AND DISCUSSION

A. Simulation studies

Fig. 3 shows the comparison of simulated VSWR versus frequency of Antennas. From the figure we can observe that the antenna with ground plane is tuning at lower side with 113MHz when compared to without ground plane.

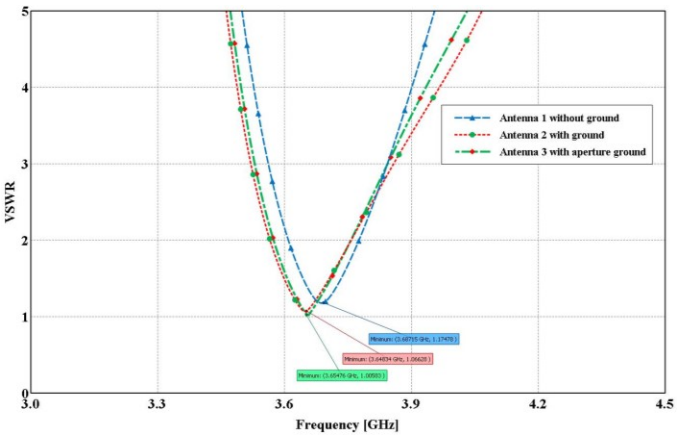

Fig. 3. Simulated VSWR versus frequency of Antenna 1, Antenna 2 and Antenna 3

Fig. 4(a) - (c) shows the simulated radiation patterns of antennas without ground and with ground plane. From these figures it is clear that the antenna with ground plane giving peak gain of 6.29 dBi with directional 3dB beamwidth of $\pm 67.75^0$ in H-plane and $\pm$ 92.59^0 in E-plane. But, the Antenna 3 with aperture giving peak gain of 4.84dBi with directional 3dB beamwidth of $\pm$ 70.80^0 in H-plane and $\pm$ 126.75^0 dBi in E-plane at its respective resonating frequency. This variation in pattern is due to the aperture in the ground pane.

Fig. 5(a)-(c) shows the simulated 3D far field radiation patterns of antennas without ground, with ground and with aperture in the ground plane respectively. Fig. 6 shows the simulated gain versus frequency of Antenna1, Antenna 2 and Antenna 3 from 3GHz to 4.5GHz.

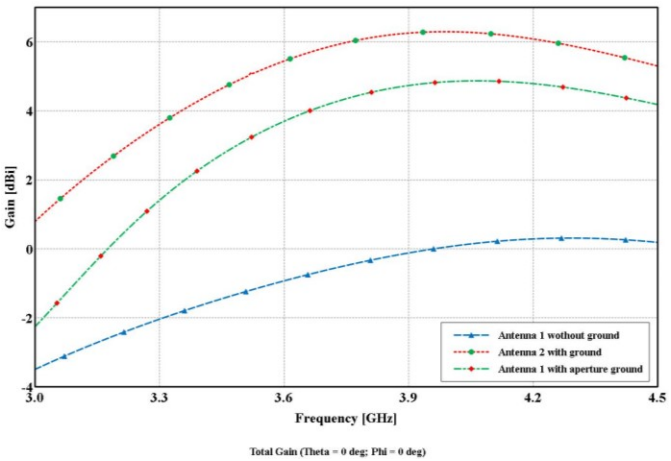

Fig. 6. Simulated gain versus frequency of Antenna1, Antenna 2 and Antenna 3

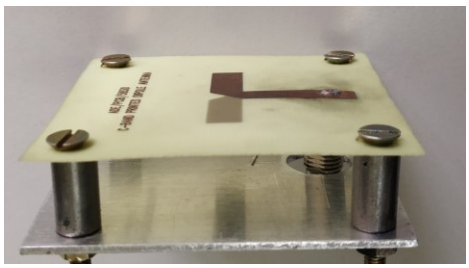
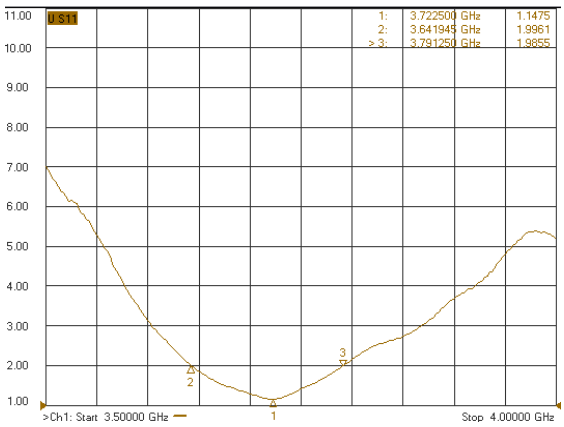
B. Measurement studies

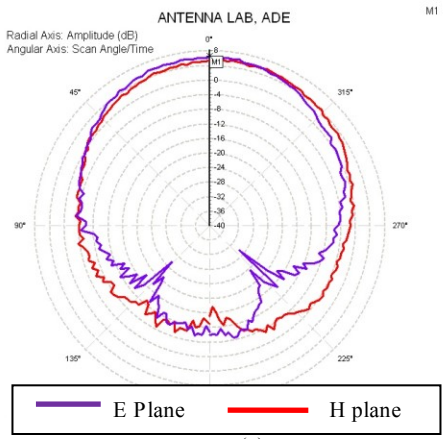
In order to verify the validity of design method, the proposed fabricated antenna parameters are measured. A vector network analyzer is used to measure VSWR of the antenna and radiation pattern measurements are carried out in microwave anechoic chamber. Fig. 7 (a) shows the photograph of the fabricated reflector backed printed dipole antenna and corresponding measured VSWR versus frequency plot is shown in Fig. 7(b). The Measured Radiation characteristics of Antenna 3 is shown in Fig 7(c). Table 2 shows the comparison of results of simulated and measured results of printed dipole antenna without and with aperture in the ground plane.



(a)



(b)



(c)

Fig 7. (a) Photograph of the fabricated reflector backed printed dipole antenna (Antenna 3), (b) Measured VSWR and (c) Measured Radiation characteristics

TABLE II. COMPARISON RESULTS OF SIMULATED AND MEASURED PRINTED DIPOLE ANTENNAS

Antenna	Resonating Frequency (GHz)		Bandwidth (MHz)		VSWR		Gain(dBi)	
	Sim	*Meas*	*Sim*	*Meas*	*Sim*	*Meas*	*Sim*	*Meas*
Antenna 1 (Without Ground)	3.68	3.75	156	143	1.17	1.12	0.06	0.68
Antenna 3 (With aperture Ground)	3.64	3.72	180	147	1.06	1.14	4.84	5.22

In next step, the measurements of fabricated reflector backed printed dipole antenna embedded in the leading edge of a typical UAV airframe is carried out (refer Fig. 2 for details). Fig. 8 (a) and (b) shows the photographs of CLAS – view 1 and CLAS – view 2 of the developed CLAS. Fig. 9(a) shows the measured VSWR versus frequency of Antenna 3 loaded inside wing. The frequency range in which VSWR is less than 2 is from 3.580 to 3.640GHz with a bandwidth of 60MHz, which is less than that of simulated antenna without loading inside the wing. This variation in result is due the 0.5mm glass-epoxy layer in front of the antenna.

Fig. 9(b) shows the measured radiation pattern of Antenna 3 i.e., printed dipole antenna embedded inside the typical wing leading edge of UAV. From the figure we observe that the perturbed radiation pattern is due to loading inside the wing and a peak gain of 5.22dB when normalised with respect to standard gain horn antenna. The asymmetry of about 4dB is observed in the H-plane is attributed to the asymmetric lossy wing surrounding the right hand side (RHS) of the antenna.

Fig. 10 shows the photograph of anechoic chamber setup for radiation pattern measurements.

(b)

Fig. 9. (a) Measured VSWR and (b) radiation pattern of Antenna 3 embeded inside leading edge of a typical UAV airframe.

Fig. 10. Photograph of radiation pattern measurement setup in anechoic chamber

IV. CONCLUSION

The design and implementation of conformal reflector backed printed dipole antenna as a load bearing structure of a typical wing leading edge of a UAV is demonstrated and tested in anechoic chamber. The simulation and measurement results of the VSWR, radiation and gain patterns of antenna loaded wing structure are presented and compared to be in good agreement. The proposed concept will enable directional, high throughput communication link while occupying small space and volume. Such features will also reduce the power requirements of a transmitter to meet the given range compared to using on-board Omni directional antennas. Further study will be carried out to study the feasibility of such multi-functional CLAS with respect to the actual scale of UAV.

Abstract: **Analysis of microarray data for disease prediction is an arduous machine learning job. Due to its high proportions and low samples, the computational risk is high. To increase the efficiency of the classifier a Signal-to-Noise Ratio algorithm can be used to get the most relevant genes. Then to these selected gene datasets, an ensemble-based classification algorithm is applied to get an efficient classifier for future prediction. The ensemble-based algorithm is an optimal combination of a set of learner algorithms. Our research focuses on 3 main classification algorithms namely SVM, KNN and Decision Tree which increases the performance and give confidence to the result. The ensemble is done using majority voting method which outperforms the base classifier.**

Keywords—gene expression, SNR feature selection, SVM, KNN, Decision Tree.

I. INTRODUCTION

All organisms in the world excluding viruses consist of cells. Yeast has only a single cell, whereas human beings have trillions of cells. Humans have trillions of cells in them and each cell consists of a membrane, cytoplasm, and nucleus which provide structure for specialized functions. Nuclei contain most of the cell's genetic material organized as DNA molecules. Gene expression profiling has been proved to be a valuable resource for the classification of complex diseases such as cancer. By using feature selection methods on a large microarray Gene Expression data we can get the most probable cancer-associated genes. We use DNA microarray which consists of a collection of microscopic DNA. Proteins in genes are generated in two steps. First, DNA is converted to mRNA and the second, mRNA is translated into proteins. Gene expression can be defined as a protein which is the result of activations in genes and these proteins can be defined as the blueprints for the characteristics of each and every living organisms. A microarray is a particular arrangement of dots of DNA, proteins, or tissues aligned in an array for easy diagnosis. DNA microarray is a soul of the gene expression profiling that plays a vital role in classification purposes. Materials like glass, plastic or silicon chip are received as an end product of this process. Identification of genetic individuality, diagnosis of genetic and infectious diseases are the applications of the microarray.

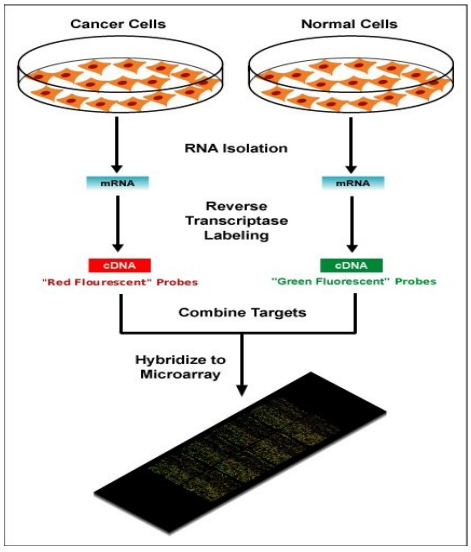

Fig 1: Conversion of cells to microarray

In general, abnormalities in the genetic material of the converted cell is referred to as being subjected to cancer. Cancer is known to be as a deadly disease, so there is a high scope for the research on these topics. We can predict the output of the data by using machine learning techniques like feature selection and classification.

The objective of the present work is to attain an enhanced classification accuracy by gene profile data comprising of a number of genes and samples of patients. These data are then used for cancer classification and prediction that if a person has colon tumor or not. For that, we are using feature selection methods to get the most probable and precise cancer-associated genes or features from large microarray gene expression profile, for that we use feature selection algorithms like SNR, Top Scoring and T-Statistics algorithms. Once we apply the feature selection methods we go for feature classification techniques like Decision Tree Induction, K-Nearest Neighbor (k-NN), Support Vector Machine (SVM), etc.

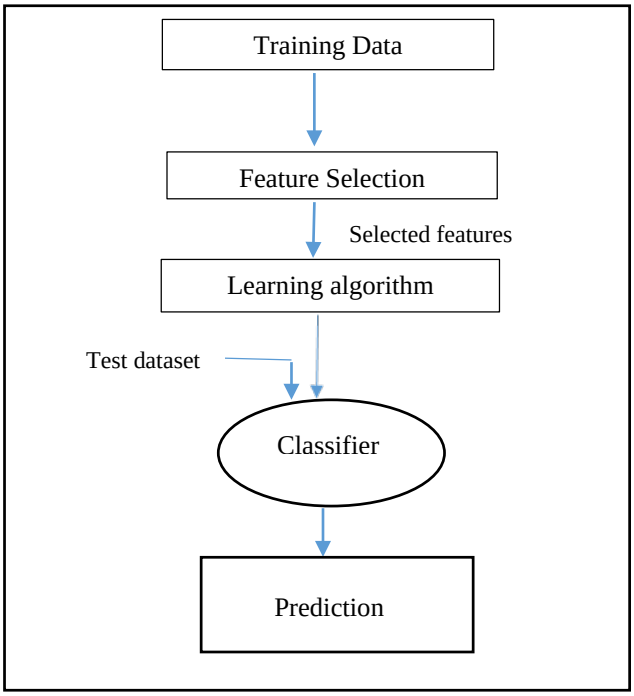

Fig 2: Feature Selection and Classification

The pinnacle of our paper is to make the study of gene expressions easier. That is techniques that can be used for finding the patterns or by doing the feature selection using SNR ranking and we apply a modification to the SNR by normalizing the equation and then applying the feature classification algorithm to analyze the result. The way in which we are going to normalize our data is by removing all the null values, remove all the space and making all the values unique. Then we can use this result to know which classification algorithm gives significant meaning to classify the genes using the SNR feature selection algorithm.

II. RELATED WORKS

Debahuti Mishra and Barnali Sahu. Feature Selection for Cancer Classification: A Signal-to-noise Ratio Approach, presents a comparative analysis of the SNR ranking applied with KNN before clustering and SNR ranking applied after clustering. We get all the top scored features from each of the clusters which will give as more accurate value as compared to that of the gene profile data without clustering i.e.; randomly selected features. In the second case, we are getting redundant features or unwanted noisy features with the same score and hence there is no chance of having any relevant information about our data and hence it will affect the performance of learning algorithm.

In Gene-Expression-Based Cancer Classification Through feature selection with KNN and SVM Classifiers by Sara Haddou Bouazza [6] presented a way of using filter approach of predicting the accuracy of the supervised classification in the field of medicine as a part of feature selection methods. In this, a comparative understanding of various feature selection algorithms like Fisher, T-Statistics, and SNR are applied out between different gene expression profiles and using two classifiers KNN and SVM intermediately. The pinpoint of the paper was to differentiate the entered data as Acute Lymphoblastic Leukemia or Acute Myeloid Leukemia.

In Feature Gene Selection and Classification with SVM for Microarray Data of Lung Tissue by Si-Hao [7] states that microarray analysis can be a widely used tool for detecting the diseases. They started the work by using SVM but as there continued they find it difficult for them to make use of SVM as the classifier so they go for finding an advanced version of SVM. It is better to classify the gene after epsilon-SVR analysis. This paper also says that SVM gives as the highest prediction with less number of original genes. And hence, writers say that it is better to use SVM as the classifier.

Jun Chin Ang, Andri Mirzal, Habibollah Haron and Haza Nuzly Abdul Hamed Supervised, Unsupervised and Semi-Supervised Feature Selection: A Review on Gene Selection", proposed the classification of the entire dataset to a set of three groups: supervised, unsupervised and semi-supervised. In this, they have done a comparative study between the top 5 gene expression and it shows that the accuracy of semi-supervised and unsupervised feature selection results is good enough as compared to that of the supervised feature selection algorithm result. As we have the output in supervised learning and we are training our dataset on the basis of this. So if we give new input to the supervised learning it will predict the output only on the basis of the data that we have trained but it is not in the case of the unsupervised or semi-supervised dataset.

Johannes Mohr [9] Automated Microarray Classification Based on P-SVM Gene Selection, presented a newly microarray gene selection and classification algorithm called P-SVM-GS. The method makes use of the P-SVM for getting the small subset of genes and a ν-SVM will give as a result which we can use as a classifier. It is said that the experiment conducted on two datasets gives the proof that a sparse set of the gene will give as a good prediction performance.

III. PROPOSED WORK

This part describes the proposed system. The modules are described here,

A. Feature Selection

The algorithm which can be used to reduce the overall features available in our gene expression profile. There are certain algorithms that can be considered as feature selection algorithms. Some of them are:

a. SNR (Normalized)
b. T-Score
c. Top Scoring

a. Signal to Noise Ratio

The collection of microarray data is known as a microarray gene expression profile. Here we have a microarray gene profile of colon tumor cancer which is given to modified SNR feature selection methods. In this method, we will find out all the mean and standard deviations of the class labels available. The means in this dataset refers to signal and the standard deviation refers to the noise. Then we apply mean and standard deviations to all the class labels for getting the ranks of each sample.

$$snr = (\mu 1 + /\mu 2)\ (\sigma 1 + \sigma 2)$$

Where μ denote the mean of the gene expression data and σ denotes the standard deviations of the entries in each class labels.

These ranks of the samples can be used to find out the number of columns to be taken for feature classification. Since the SNR we applied is good enough it is necessary for us to normalize it, so that we can increase the accuracy of the algorithm.

b. Normalized SNR

Data normalization means converting all the variables in the data to a specific range and its main purpose is to minimize the redundancy and remove null values, blank spaces. Data redundancy happens when the same data is held in two separate places. In order to reduce redundancy, we use a hash set. It contains unique elements only. The algorithm is normalized by removing a null value, removing blank space and also it stores unique details by using this hash set. By applying this our algorithm became more accurate and it gives most affected genes as the output thus feature selection become more efficient.

From the dataset we take the data and store it to an array list of an array, to store a dynamic collection of elements, then we convert that ArrayList to two-dimensional arrays. Finally, we will find mean (μ) value, standard deviation (σ) of each column of two-dimensional arrays then find the normalized SNR value.

Step 1: mean (μ) = $\sum X / n$
Step 2: standard deviation (σ) = $\sqrt{\sum (X-\mu)^2 / n-1}$
Step 3: to find the snr value
snr = μ / σ

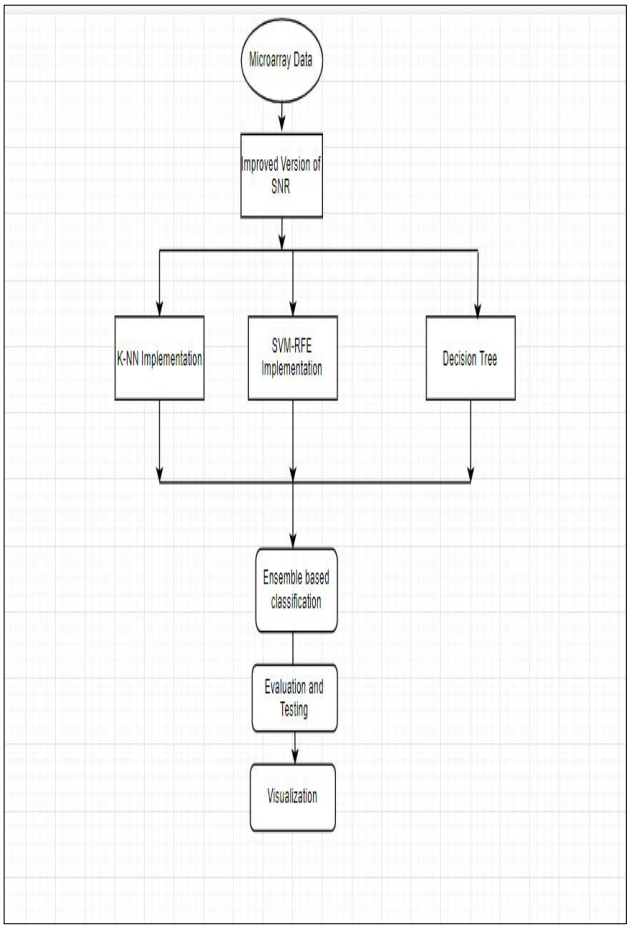

Fig 3: System Architecture

In parallel to this, we are going to apply SNR to the different feature classification algorithms like K-NN, SVM, and Decision Tree to get the comparative study of finding out which SNR is best suited with which of the above algorithms. We are then giving the result to an ensemble based classifier to group it into one. Then we are evaluating and testing our results to get a final output and this final output will be shown in the form of a graph.

B. K-Nearest Neighbor (K-NN)

In KNN for each training dataset values, we will be calculating the K nearest values of training data sets and then taking the most regularly occurring classes in the dataset and then assigning that class values to the test data. Therefore, K means the number of training data sets values falling in close to the test dataset point value which we are going to use for finding the class labels. If we don't have a separate testing dataset we can use the same training dataset as the testing dataset values.

Algorithm 2: K- Nearest Neighbor (KNN) [1]

Input: {r1,r2,r3,..,r_n} where r is each *row of a dataset.*
Output: the threshold of the features to remove
Output: The k nearest value of each row will be returned

1. Load testing and training dataset.
2. Pick a random the value for k.
3. For any data in the testing dataset:
   a. Find the Euclidean distance to all the training dataset.
   $$D = \sqrt{\sum_{i=1}^{k}(xi - yi)^2}$$
   b. Store these results in a list and sort it
   c. And then select the first k point
4. Return *the K nearest value.*

C. Support Vector Machine (SVM)

In machine learning, supervised learning models such as SVM is mainly implemented for pattern recognition and data analysis. SVM mainly is mainly known for classification and regression analysis. Its theory is mainly based on the structural risk minimization and is one of the best classification techniques which can best split the given data and discriminate between objects that belongs to one of the two categories(+ve or –ve). The distance between the support vectors (points) and the hyperplanes (lines) are as far as possible. SVM uses large margin and kernel function as a key concept to discriminate the data. The important factor in SVM is to select the appropriate kernel function as it is very important for higher dimensions. SVM is used in classification due to its high accuracy, ability to deal with high dimensions (gene expression) and its flexible technique in modeling the data. SVM technique is a very promising supervised learning tool in dealing with microarray gene expression data.
We are using Linear SVM for our data.

D. Decision Tree

Decision tree is one of the most successful classifications and decision tool that uses branching method to classify the example and each branch represents outcomes of the test.

In our work, we have used the J48 algorithm from Weka1, which is a library having a large number of machine learning methods. Weka J48 is a Java implementation of the well-known algorithm C4.5.

a. Apply decision tree on the input dataset
b. We have used the same dataset for both train and testing purposes.
c. Evaluate dataset and find correct and Incorrectly classified instances
d. Give the output for Ensembling.
e. Visualize the tree using a visualize function

IV. EXPERIMENTS AND RESULTS

The experiments and testing are conducted on two public available dataset Colon with 2000 genes and Leukemia with 3572 genes.

The initial experiment is conducted in order to decrease the dimensionality of the dataset by SNR based feature selection algorithm. The number of selected features after SNR is shown in the below table.

TABLE 1: AFTER APPLYING SNR BASED FEATURE SELECTION

Dataset	Total Number of genes	Number of Features Selected
Leukemia	3571	1534
Colon	2000	865

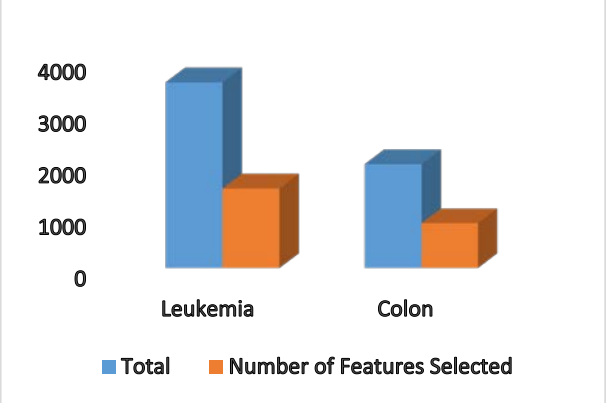

Fig 4: Number of genes after applying SNR algorithm

For evaluation purpose, we are initially ensemble all the feature classification algorithm that we have implemented. So, we go for a majority voting algorithm. Since each

algorithm makes a prediction that is voted for each instance of test and the final result is the prediction that receives votes more than half of its total votes. If any of the algorithms don't get any of the votes more than it's total votes, we can say that the particular algorithm doesn't have a consistent (stable) prediction for the particular instance. So the majority voting algorithm is mainly based on the majority of the voting, even if an instance doesn't have a majority of voting we go for the votes that have more number of prediction. This is also known as "plurality voting".

If we were using the nearest neighbor algorithm for evaluation purpose then the result will we the 100% accurate as we are using the same set of data, that is a dataset, for training and testing purposes. In general for evaluating any data mining algorithms with a testing dataset which is a subset of the training dataset results in the optimistic value generation which is not good. So in order to improve the evaluation pattern more accurate we use another algorithm which uses all the data of the dataset more efficiently and does the same process in an iterative manner and we can take the final value from the average of the resultant values from each iteration.

For the evaluation purpose, we are using a k-fold cross-validation method in which we are dividing the entire dataset to k packets each of which is having a set of values. We are taking the value of k as 10 hence we can say that we are using 10-fold cross-validation. In this we are dividing the entire dataset into 10 packets from which we are taking the first 9 datasets as the training dataset and the rest 1 dataset as the testing dataset in one iteration and in the next iteration the 9 testing dataset will change and as a result of this, the corresponding training dataset also changes. This will continue until the 10th iteration. The resulting value is added up to form the final result.

TABLE 2: EVALUATION OF EMBEDDED BASED CLASSIFIER

Dataset	Total Features	Accuracy	Error Rate
Lukemia	3572	98%	2%
Colon	2000	97%	3%

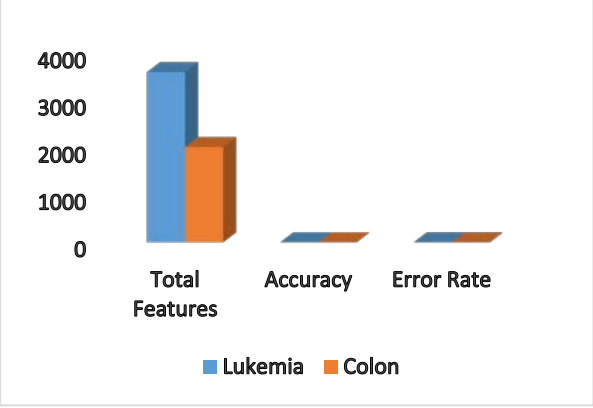

Fig 5: Accuracy and Error Rate of the Embedded Classifier

We can say that the 10-fold cross validation is an excellent choice because we are almost training 90% of the data. For example, if we have 2000 entries, we will train our classifier in 1999 of them and then test on 1 and repeat this process for 2000 times. We can increase the accuracy of our classifier by using the maximum amount of data that we possibly have for testing.

CONCLUSION

In our work we initially had a large dataset which is reduced to minimal size with all the necessary features that we want, for that purpose we used the Signal-to-Noise Ratio algorithm. Then to this reduced dataset, we apply feature classification algorithms like Support Vector Machine, K-Nearest Neighbor and Decision Tree. If we do these feature selection algorithm independently it will have more error rate and less accuracy as compared to that of the accuracy we get from an ensemble based system which has a combined effect of the above three algorithms. For ensemble, we have used the majority voting algorithm which is used to get the majority of the three algorithms. And finally, to this ensemble system apply 10-fold cross-validation to evaluate and test the dataset we get relatively high accuracy ie;98% for Leukaemia dataset and low error rate ie;2% for the same dataset. This work can be extended to include multiclass gene expression.

***Abstract*—in the recent years, Internet of Things basically applied into smart city applications only, nowadays Internet of Things playing a vital role in changing the manual controlling and monitoring in agriculture towards automated and remotely controlled and monitored operations. Recent improvements to the Internet of Things help to increase efficiency in precision agriculture. Use of the Internet of Things is remodeling agriculture environment. By making farmers capable to face problems related to precision and sustainable agriculture. Internet of Things technology helps in remotely collecting information from various sensors placed in the field. Sensors are like soil pH, Moisture level, Humidity, temperature, the fertility of the soil, level of water, insect population, pest detection, crop growth. Farmers are remotely connected with his farm using IoT and Smartphones. By using wireless sensor network nodes collects crop and environmental related data from the field. Then transfer information through the ZigBee network to the server node. The main node performs processing on collected data. Microcontrollers are used to automatically monitor and control the processes on the farm. For visualizing farm conditions cameras are placed into fields. The use of smartphones keeps farmers updated regarding the changing condition in his farm automatically at anywhere and anytime. Due to the use of the Internet of Things in agriculture, it reduces farmer efforts, enhances productivity, save the cost and time and provides automated controlling and monitors agriculture remotely. Automated irrigation system, pest controlling, monitoring plant growth, analysis of pesticides, controlling the insect population, etc. are implemented through the Internet of Things which converts traditional farming into automated farming.**

Keywords—automated irrigation, pest control, crop productivity, precision agriculture

I. INTRODUCTION

Things on the earth connected to each other with the help Internet of Things for communicating with each other. Internet of Thing connects thing to thing, the thing to human and human to things for sharing information. The Main goal of the Internet of Things is to bring out the large network be connected. Combining and connecting various types of device to each other forms a large network. Cost saving, automation in everything and communication are major pillars of the Internet of Things. It allows users to remotely monitor and control routine activities. Using the internet and handheld devices like smartphones and IoT makes framers' life easy. It ultimately increases productivity and saves the cost and time of farmers. Remotely enables objects to be sensed and actuated with in-network using the Internet of Things.

Internet of Things plays a vital role in automated irrigation, smart farming, monitoring greenhouse, crop monitoring, crop growth monitoring, pest controlling and monitoring, insect population controlling and monitoring, etc. Collects real-time data from various sensors placed into the farms. The node contains sensors like temperature sensor, soil moisture, humidity sensor, ultrasonic sound, light intensity, atmospheric pressure sensor, and leaf wetness sensors. Cameras are used for capturing the images and videos of the farm. Zigbee protocol [16] takes care of all data collected from all sensor nodes. Also handles operations based on threshold values. ZigBee low powered device which helps in energy saving. Solar panels may be used for saving energy at wireless sensor network nodes. All information collected from sensors transferred to the main server (microcontroller/ Raspberry Pi, Arduino) node through the internet or local network for further analysis. Using moisture level and temperature sensor data converts manual irrigation system into automated irrigation [3] [5] system. Switching motor on/off sprinkling system results in the optimum use of water. With the help soil pH values and environmental conditions, soil condition is measured. According to results, required pesticides list is generated. Align with environmental conditions suitable solution is generated. The solution is provided to the farmers which result in over usage of pesticides into the farm. Also saves cost and time and increases the productivity of the crop. It's proved by science music helps to increase the growth ratio of crop and increases crop productivity. The major issue in the agricultural field is pest control [23]. Farmers make use of chemical for controlling pest in the farm. This harms crop growth as well as farmers health. An appropriate list of chemicals aligns with environment suggested to the farmers. Significantly proved, with various frequency ranges pets get affected. Various sound frequencies effects on pest brain and nerves system. This also effects on reproduction system of pets. Use of sound emitter will result in pets controlling. Making use of ultrasonic sound emitter into the fields helps in pest control. Generating various frequency farmers can control pest and saves cost. Also, it will increase the growth of the crop. Capturing real-time images from fields with insect [26] affected area and an environmental condition. Processing/server station informs farmers regarding the density of insect population through notification as SMS. Real-time data and historical data considered for monitoring and controlling the insect population in farms.

Using the latest low energy protocols like LoRaWAN, LoRa, ZigBee saves power consumption. Also secured data transfer from nodes to the main server [1] [2]. Challenges consider while a designing system using the Internet of things are security, key management, authentication and authorization, access control, routing protocol and data aggregation [8]. Farmers are notified regarding monitoring and controlling information via smartphones. With the help of the appropriate use of ICT [7] and various visualization tools. which result in ease of using. Farmers are remotely connected with their fields. Farmers can control and monitor their own

field operations through smartphones using GSM/ Cellular module [1] [2]. Making use of Internet of things enabled drones/ Agrobots get used in pesticide spraying. This will result in decreasing the death ratio of farmers.

II. LITERATURE SURVEY

The survey is based on the following points

a. Smart automation in irrigation.

b. Smart agriculture.

c. Plant/Crop growth monitoring and controlling.

d. Pest control.

e. Insect population controlling.

f. Use of latest technology, issues, and challenges in IoT based agriculture system.

A. Smart Automation in Irrigation

Vijay Kumar [1], Lin Zhang [2] work on automated water sprinkler irrigation system. Provide information regarding water usage, soil pH values using wireless sensor technology. WSN nodes formed with sensors like moisture sensor, temperature sensor, soil pH, atmospheric pressure sensor and leaf wetness sensor. All information collected from nodes and according to the soil moisture level sprinklers are controlled automatically and stopped when an adequate level of water is sprinkled. All information regarding water level and soil pH send to the farmer's mobile through the GSM module. Using this information farmer plans for fertilizers.

Joseph Haule [3] designed a system using a wireless sensor network for automation in irrigation. Based on moisture levels of soil optimum use of water distribution managed through automatic communication using wireless sensor technology in irrigation. A designed process which set parameters like time for water and the frequency of watering for proper water management and produce a high-quality crop. Build system using wireless sensor technology with making use Zigbee for battery life. The overall system is controlled with devices based on inputs received from various sensors with efficient manner.

G. Nisha [4] designed a system for automated irrigation using WSN and disease monitoring using Image processing technique. Images captured from the camera mounted in the field and send through WSN nodes for processing and inform to the farmers using GSM modules. An automated irrigation system designed for the adequate use of water in farming in dry areas using distributed nodes consisting of sensors like moisture, temperature, etc placed in the field. Automated irrigation system builds using WSN, Zigbee protocol, microcontroller, solar panels, and cellular network. Desired threshold values set for the proper functioning of the automated irrigation system.

R. Balamurali, K. kathiravan [5], Yunseop Kim [6] proposed a system considering parameters low power consumption, appropriate network topology, protocols with high reliability. Research major focuses on automatic irrigation monitoring and controlling. Using a wireless sensor network with network capabilities and sensor nodes deployed as Adhoc for monitoring and controlling the irrigation system. Operates based on data collected from sensor nodes which collect data from water level and motor movement. A system contains base stations place near to the residence which process all data and reduced farmers efforts, save the cost, minimal training required for installation of the system.

Manish Bhimarao Giri, Ravi Singh Pippal [43] designed system for smart irrigation system using Wireless Sensor Network and Linear Interpolation Programming. A system based on three parameters temperature, soil moisture, and light intensity. Based on readings timings are formulated for controlling water distribution using drip.

B. Smart Agriculture

K. A. Patil, N. R. Kale [7] designed a model for smart agriculture with the help of the Internet of Things and ICT. The system provides a real-time monitoring system for soil pH value, temperature, moisture and provides the advisory system for paste and diseases control and disease identification through SMS alerts system to the farmers. Also provides the facility to control various operations remotely with the help of smartphones.

Liu Dan, Cao Xin, Huang Chongwai, Ji Liang [8] experimented using Zig Bee technology on the greenhouse monitoring system. A system designed with low cost and minimizes human efforts and converted from wired technology to wireless technology. Provide good controlling and monitoring of greenhouse. The main motive behind research to provide an efficient system to manage the greenhouse environment and reduce farming cost with low energy. Make use of IoT technology with B-S structure and cc2530 as processing chip for coordinating wireless sensor nodes within the Linux environment.

Sivasankari S. Gandhimathi [9], Alan Main-Waring [10] reviewed a study of real-world agriculture operating through wireless sensor technology. Considered the set of design requirements and developed system with the help of Wireless sensor technology, accessing data remotely, processing at center places and monitoring based on data processing results. According to the above details implemented prototype which is tested at James San Jacinto Mountains in California reserved forest.

Zulhani Rasin [11], Wang Weighing, Cao Shuntian [12] presented a system based on Remote intelligent Monitoring System based on Zigbee and Wireless Sensor Network technology. A system designed using wireless mesh topology instead of wired connections.

K. Satish Kannan, G. Thilagavathi [13], Nguyen Tang Kha Duy [14] focuses on industrial household's shrimp farming. A designed system which provides a versatile solution to improving the accuracy monitoring environmental conditions and reducing human efforts. The proposed system is capable of collecting data, analyzing data and generating the graphical representation of data. A system designed in such a way that which reduces human efforts as well as electricity usage and result in helping small/medium scale farming.

Nelson Sales [15] making use of wireless sensor technology and cloud computing designed build system for monitoring and controlling agriculture. Smart objects interact with each and share environmental information and send to the main node for processing and analysis. Cloud computing provides high storage and processing capability for rapid processing and data analysis which defiantly make changes in agriculture computations.

C. Plant/Crop Growth Monitoring and Controlling

Arvind G. Athira, V. G. Haripriya, Akshaya Rani, Arvind S. [16] designed a system with advanced irrigation, paste control and seed germination with the help of Internet of Things, Artificial Intelligence and machine learning. With the help of moisture, humidity and temperature sensor data collected and send to the remote processing unit using an Arduino microcontroller and send via Zigbee to the database. Irrigation system gets controlled and monitored by the analysis performed on stored data during the lifecycle of the crop. Paste control is a major issue in agriculture. Basically, every farmer makes use of chemicals for controlling the population of paste. Researchers designed a system for paste control using ultrasonic sound emitters by placing emitters in the field. Which effect on pests brain and nerve a system. Research also focuses on plant growth by using sound emitters placing into the field. Scientifically it is proved that plan growth rate increased due to musical sounds.

Fu Bing [17], V. Sandeep, K. Lalith Gopal, S Naveen, A. Amudhan, L. S. Kumar [18] designed system in China making the transition from precision agriculture to modern agriculture. Research focuses on fruits production and controlling the quality of fruits. An experiment carried out on organic melons and fruit production and quality control. The system makes use of IoT and RFID and a sensor which results in to reduce farmers' efforts also reduce production cost by increasing fruit quality. Internet of Things plays a vital role in the transition to modern agriculture.

Sonal Verma [19], A. Sivasankari, S. Gandhimathi [9], Chen Xion Yi, Yang Xiong, Jin Zhi Gang[20] discussed the approach for crop growth monitoring using inexpensive camera system called crop phonology recording system. While estimating biophysical parameters camera based vegetation index helps. The design explores recorded header region of EXIF formatted JPEG files with RGB and proposed with vegetation indices like ev-NDVI, ev-SR and ev-CLgreen calculated using cDN and daytime exposure. With results en-VAR, I worked best for the maize and ev-CLgreen for soybean.

Meng Ji-Hua [21] designed a system for crop growth monitoring which satisfies the need for global crop growth monitoring. Research carried out on variations in growth trends of crop, status and crop seedlings. Design methods for crop real-time growing methods and crop growing status time by time through remote sensing techniques. Consider real-time data as well as historical data for processing information their result is prepared to show variations in crop growing levels with respect to the conditions. Used three scales based on geographical orientation like state level, country level and continent level for global crop growth and status of crop growing process.

So Yahata, Tetsu Onishi, Kanta Yamaguchi, Seiichi Ozawa, Jun Kitazono, Takenao Ohkhawa [22] research focuses on decision making for good yield for various agriculture condition. This paper focuses on soybean growth monitoring and controlling in real fields. Using image sensing methods observation are captured automatically of soybean flowers and seedpods. Appropriate cultivation of soybeans achieved through available bigdata on the growth status of agriculture and environment conditions. Research focus on flower detection and counting, Flower counting and seedpot detection which results in growth management of soybeans.

Santosh Warpe, Ravi Singh Pippal [44] research focuses on the appropriate distribution of fertilizers to increase the growth of corp and plants to increase yield. Soil with less amount of nutrients is nitrogen, phosphorus, and potassium. These nutrients should be applied to proper preparation to increase the crop yield. With the help of wireless sensor network, authors proposed a system for fertilizers distribution with proper proportion.

D. Pest Controlling

Archana Chougule, Vijay Kumar Jha, Debajyoti Mukhopadhyay [23] designed system using the Internet of Things for paste management with the use of algorithm ontology. The system works by considering data from Integrated Pest management generates ontology based on the text then performance relationship extraction, apply the pest description ranking algorithm and with help weather IPM appropriate conditions for calculated for applying pesticides.

Balaji Banu [24] designed system managing sensor node failures and energy efficiency. The system observes the conditions of the farming and increasing the crop yield and quality using a wireless sensor network. A system designed using various sensors like humidity, temperature, water level, etc. processor ATMEGA8535 and IC-S8817BS, analog to digital conversion, Zig bee protocol, and wireless sensor nodes.

Hemantkumar Wani, Nilima Ashtankar [25] research focuses on the prediction of pest/diseases of various crops using machine learning algorithms. Yield per hector is lesser in India than international standards. The main cause of lesser yield is planted diseases. Diseases are increased because of pest. Improper water management, the fewer number of soil nutrition which leads to increasing the pest. Using the Navie Bayes Kernel algorithm used to find out the patterns which control the flow of plant disease and flow of pest control.

E. Insect Population Controlling

N. A. Bhorgese, P. Tirelli [26] designed a system with visualizing insect population graph for predicting regions and monitoring and controlling insect populations with weekly span. Insect population affects crop production. The system captures images of insect population from different locations and forwarded to the main unit which will perform severity analysis and generate alarms to inform farmer regarding the insect intensity. Client nodes are mounted into fields which captures images and send to the master nodes for further processing which will generate graphs based on the insect population. A system based on wireless sensor network technology in a distributed manner which automatically captures images and performs the analysis.

Nikesh Gondchawar et al., [27] research based on smart agriculture using the Internet of Things. Designed and developed a robot for performing operations like spraying, weeding, and sensing. Spraying harms farmer's health. Spraying is done using robot will save farmer's life as well as proper spraying of pesticides. Systems designed with sensors, robot, ZigBee, microcontrollers, and raspberry pi. Provides information field condition. Irrigation issues detected and handled using remote based robots.

Tanmay Baranwal et. al., [28] this research proposed system on protection for field grains from various insects. PIR sensor used to identify heat and starts URD sensor and camera to

detect insects. Which provides security and protection of agricultural products from rodents and various insects.

G. Naveen Balaji et. Al., [29] proposed system provides a solution to protect the crop from animals using image processing techniques. Image processing using video surveillance detects animal intrusion into the agriculture land. Based on movement detection animal images will compare with stored data and animal is detected. Once the animal is detected will be identified and informed in the form if text message to the farmer through the GSM module.

F. Use of Latest Technology, Issues and Challenges

Danco Davcev, Kosta Mitreski, Nikola Koteli [30] designed a system for agriculture with the help of the Internet of Things with LoRaWAN and cloud computing. LoRaWAN network basically used to transfer data from nodes to backend cloud services.

Soumil Heble, Ajay Kumar, U. B. Desai [31] proposed system smart agriculture with the help of low power IoT network. Introduce solar-powered features sensors and nodes. For covering large agricultural area LoRA based gateways are used to solve line power problems. In future scope planning for drone-based remote controlling and monitoring precision agriculture.

Chen XianYi, Yang Xiong, JinZhi Gang [20], Rwan Mahmoud [32] research focuses on challenges and security issues in the Internet of Things. Focus on wide applications using IoT facing security issues. Paper starting with the basic architecture of IoT, Layered architecture of IoT and security issues and provides solutions to those issues. Discuss focuses on security, key management, routing protocol, access control and authentication with data fusion technology.

Fiona Edwards Murphy [33] research deals with monitoring honeybee colony and surrounding area using a wireless sensor network. Make use of a Wireless sensor network, Internet of things, cloud computing designed smart hive system. Cloud used to monitor data from a different colony collected from various sensor nodes with low power consumption. The system consists of smart hive communication, data aggregation, and visualization tools. Making system intelligent machine learning techniques adapted for extracting meaningful information for supervising and additional deployments of the system without the intervention of human efforts.

Ling-Ling [34], research major focus on software and hardware used for developing a system using Wireless Sensor Network nodes, topology, network, and Zigbee platform. The experimental result shows appropriate data capturing from various sensor nodes through network nodes from various sensors mounted into greenhouse like humidity, temperature, moisture, etc. system makes complex greenhouse monitoring automated and controlled inefficient manner. Provide good network stability to the system.

R. Balamurli [5], Chen XianYi, Yang Xiong, Jin Zi Gang [820, Narut Soontranon, Panwadee Tangpattarnakul, Panu Srestasatheirn [35] major focus on analyzing routing protocols like integrated MAC, DSR, AODV, AOMDV and routing protocols used in precision agriculture using wireless sensor network. For precision agriculture using wireless sensor network Integrated MAC and routing algorithm is suitable for multi-hop routing. Discussed regarding real-time precision agriculture based on soil pH sensor, moisture, humidity, etc. sends recorded data to the remote server for analysis and take appropriate action based on collected data.

Lei Xiao [36], Meng Ji-Hua, Wu Ning-fang, Li Qiang-is [21] designed system based on wireless sensor network which monitors agriculture conditions using real-time data collected from sensors like humidity, temperature, etc. Experimental setup handles all challenges regarding protocols, network topology, and data processing. Experimented on data collection and transmission ultimately improves production efficiency agriculture. The system builds with the appropriate framework, lightweight, good performance, and appropriate operations.

Elias Yaacoub [37], K. Satish Kannan, G. Thilagavathi [13] discussed system which monitors and analyze air quality in Doha based on wireless sensor technology. Using R programming performs analysis on stored data in a different form as per end user requirement.

Giuseppe Anastasi [38] designed a system for monitoring and controlling productivity in high-quality wine and deployed at Silicon winery. A system designed based on wireless sensor technology. Sensor nodes are placed in grapes fields as well as in the factory where wine is produced. A system designed with proper planning infield and in preservation workshops. WSN based Infrastructure controls distributed production chain nodes. All data collected the main unit which process information and monitors and controls the quality of graphs in the field and aging of produced wine in the workshop. Ensure good quality production of grapes and wine.

Dragos Mihai Ofrin [39], Zulhani Rasin, Shahrieel Mohd areas, Hizzi Hamzah Mohd [11] based on parameters like performance, efficiency, and flexibility designed system for controlling and monitoring environmental conditions. Parameters like accuracy, resolution, energy consumption and data acquisition system considered while designing. Low power Zigbee protocol is used in the system. The major disadvantage of the system is power consumption. The author predicts alternative for power consumptions, energy resources, traffic, alternative resources, etc. to monitor and control operations over long distance make use of Wi-Fi or GSM connectivity.

Duan Yan-e [40] enhancing agriculture production and utilizing all resources researcher explained Agriculture Information Technology used in every part of agriculture. Agriculture production efficiency gets affected by agriculture information management. MIS is designed with detailed agricultural data.

Rachel Cardell-Oliver [41] research more focuses on environmental drastically changing condition. Based on such conditions reactive event-driven network should build for controlling and monitoring environmental conditions. Reactive means as soon as condition changes system should predict and control. More focus is on dynamic responses and limits the useless data gathering as well as network lifetime and robustness. The researcher demonstrated on reactive sensor network gathering data in rainy and dry seasons based on soil moisture levels. Future scope provides improvement regarding the network, packet delivery, and event interest. The implemented system monitors the environment effectively based on moisture levels in the reactive driven model.

Mohanraj et. Al., [42] research uses ICT to provide help to farmers regarding agriculture yield. As farmers required guidance at different stages of plant/crop growth at the right time. Farmers facing various problems like weather condition, market analysis, irrigation planner, crop profit /loss analysis and water utilization. Using ICT authors connecting farmers to huge knowledge dataset which will increase productivity and yields by providing accurate information.

III. Discussion

With the above survey, we can provide a complete solution for smart farming using Wireless Sensor Network and Internet of Things. Smart Irrigation, Smart Agriculture - greenhouse monitoring, crop growth monitoring and controlling, pest controlling using various techniques mentioned above with the help Wireless Sensor Network and Internet of Things. With the help of Smartphones will make farmers life easy by maintaining and controlling of all agricultural activities on a single click.

Table I

Survey – Problem faced by farmers and their IoT based solutions

Reference Papers	Survey Parameters	Problem Faced by Farmers	IoT based Solution to the problems
1, 2, 3, 4, 5, 6, 43	Smart Irrigation	Adequate water levels, Improper usage of water Water distribution according to various plants	Proper utilization of water with the help WSN systems based on parameter like temperature, soil moisture, and leaf wetness sensors. Drip irrigation
7, 8, 9, 10, 11, 12, 13, 14, 15	Smart Agriculture	Facing problems in Greenhouse Management	Auto controlled greenhouse management
9 16, 17, 18, 19, 20, 21, 22, 44	Plant/Crop Growth and Monitoring	Selection of pesticides for different plant/crop The ratio of pesticides according to plant and environmental conditions Real-time monitoring of large scale farming Accuracy monitoring of environmental conditions Fertilizers distribution with the proportion Growth trends and growth methods of various crops according to geographical conditions	Fertilizer distribution with proportion to the available neutrinos with the help of soil testing. Easy to monitor large scale farming with the help WSN systems. Equal distribution of fertilizers and pesticides using remote control robots. With the help ICT tools, farmers get all information on their smartphones which leads to increased yield.
23, 24, 25	Pest Control	Controlling pest and Insect population without using pesticides Seed germination and Pest management Detection of various plant and crop diseases	Using Machine Learning techniques plant crop disease are predicted and appropriate solutions provided to farmers. Alternative options to control pest population using ultrasonic sound & save the life of farmers.
26, 27, 28, 29	Insect population Controlling	Controlling Insect population Protection of field storage grains and crop from animals	With the help of image processing density of insect population is calculated and informed to farmers. With the help video, surveillance technique plants and grains are protected from animals.
5, 13, 11, 21, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42	Used of Technology	Lack of technology usage	With the help ICT tools, farmers get all information on their smartphones which leads to increased yield.

IV. Conclusion

With the help of survey smart irrigation, smart agriculture, pest controlling, insect population controlling as well as plant growth management is improved with the help of Internet of Things. Death ration of farmers is minimized with such systems. Yield is increased with the help of technology. Using Wireless Sensor Networks technology nodes with various types of sensors placed into the farm. Node collects information regarding real-time environmental changes,

insect population, pest and crop conditions, etc. Then this information is processed and analyzed. Then the information is transmitted using the GSM network through smartphones. Actuators are controlling devices with corrective actions. Internet of Things profits the farmers by enabling manual operating into automated operating. Also makes crop monitoring easy. Pest monitoring and controlling and enhance crop productivity. Use of Internet of Things connects farmers remotely to their fields at any time. Predicting future conditions by using analytics on uncontrolled conditions like rainfall and drought enhance water usage and use of pesticides. Making use of cloud computing, Machine learning, Image processing makes smart farming much easier.

***Abstract*— the paper focuses on a Simulink based model and design of the different control mechanisms of a DC motor powered via fuel cell. At first, fuel cell is used as the prime power source of the DC motor and a differential controller is used to achieve a uniform output. Then, the differential controller is replaced with Proportional Integral (PI) controller, Proportional Integral Differential (PID) controller and Fuzzy Logic Controller (FLC) subsequently to compare and demonstrate the variations that occur in the different characteristic curves with the change in various parameters. If Photovoltaic cell is used instead of fuel cell, the output operation of the DC motor may vary. So, in addition, a comparative performance analysis of both methods of power with regards to DC motor control is also presented.**

Keywords— DC motor; Fuel Cell; PI & PID controller; FLC controller; Simulink.

I. INTRODUCTION

Currently, there are finite source of conventional energy resources. Therefore, the only feasible solution for the future is to move towards the proper utilization of sustainable power sources. A Fuel cell derives energy from the reaction of two atoms of hydrogen with a molecule of oxygen producing water as by-product, hence converting chemical energy into electrical energy. It is considered a renewable source as it does not diminish with time. Fuel cells are used in applications such as in transportation systems and portable power backup systems. There are many different types of fuel cells like PEM (Polymer Electrolyte Membrane), AFC (Alkaline Fuel Cell), SAFC (Solid Acid Fuel Cell) and PAFC (Phosphoric acid fuel cell) [1]. On the other hand, the applications of DC motors are countless where optimization and fine-tuning is most desired. In order to calibrate DC motors at a proper level, controllers are necessary. Therefore, the prime objective of this paper is to design a DC motor control system which will be powered by PEM fuel cell and produce calibrated outputs with maximum performance targeting both efficiency and sustainability. A buck-boost DC to DC converter has been used for the purpose of switching the DC motor properly. It operates in discontinuous conduction mode and the duty cycles have been supplied to the converter using controllers which calculate and find the optimized performance factor of the DC motor.

II. LITERATURE REVIEW

There are many kinds of fuel cells currently available on market. PEM fuel cells need a common electrolyte called perfluorosulfonic acid. The operating temperature is below 120°, typical stack size is below 1 KW-100KW and electrical efficiency is around 60%. It is the most used fuel cell which has many advantages like how the solid electrolyte reduces corrosion, it works at low temperatures and it has quick start-up and load following. The only disadvantage of this cell is that it needs expensive catalysts and is sensitive to fuel impurities [2]. It has been observed that with increase rate of air flow, the maximum current increases in PEM fuel cell because of the decrease of the level of concentration polarization losses and also the voltage regulation for load increases. Maximum power generation in a PEM fuel cell is a logarithm function of rates of air flow [7]. Nevertheless, the Simulink model of fuel cell that is used in this paper is a generic model which represents most popular types of fuel cells operated with oxygen and hydrogen [3]. The simplified model represents a particular fuel cell stack operating at nominal conditions of temperature and pressure [2]. PEM fuel cells are the leading fuel cell technology which is used in material handling applications such as forklifts and for transportation applications [10]. Electric vehicle's main focus is DC motor. Robotic manipulators, guided vehicles, steel mills and electric traction are driven by DC motor which is highly controllable electrical drive [12]. Since our main focus is achieving optimized DC motoring outputs, this model was selected. For optimizing speed of DC motor, three different controllers have been used in this paper. Buck boost converter has the expertise to generate both step up and step down

output voltage [8]. Inductor's reluctance to allow rapid change in current is used to best understand the operation of a buck boost converter [9]. Proportional Integral controller is mainly used to eliminate the steady state error emerged from only proportional controller. The proportional parameter controls the reaction to the current error, the integral parameter controls the reaction established on the sum of previous errors and the derivative parameter controls the reaction based on the rate of changing error i.e. future error [11].

III. Methodology

Fig. 1 exhibits the basic block diagram of the Simulink model. A fuel cell with 48 Volt DC rating specially designed to meet the demands of a 10 HP DC motor has been used. The fuel cell supplies the Dc motor via a controller and a Buck-boost converter. The controller controls the duty cycle of the converter which in turn enhances the performance of the motor. A feedback loop consisting of a voltage sensor and a voltage feedback used to render reference voltage to the controller.

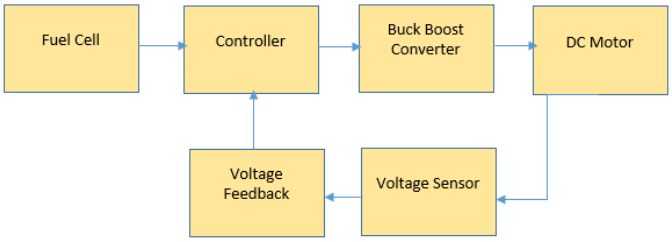

Fig. 1. Block Diagram of the Controlling System

IV. Modelling of Proposed System

Fig. 2 shows the overall Simulink model of the proposed system including Fuel cell, Converter and DC motor. Each component used are described below.

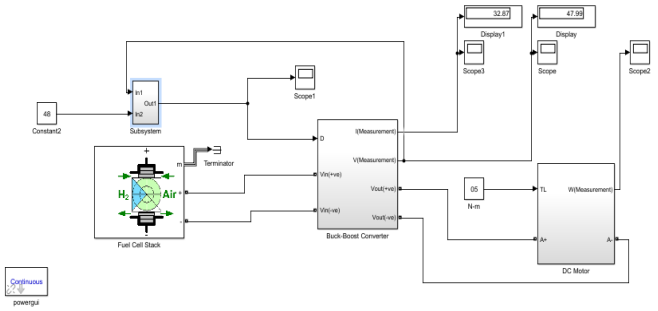

Fig. 2. Simulink Model of the System

A. Fuel Cell

The design utilizes a generic hydrogen fuel cell, a renewable source, of model PEM 50 KW 635V DC. Fig. 3 shows the VI (Voltage and Current) & PI (Power and Current) characteristics which is an inbuilt characteristics of the selected fuel cell. This is a simplified model appropriate for the system.

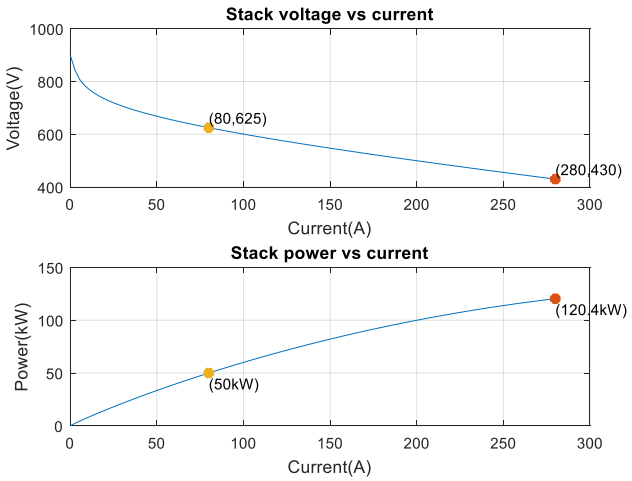

Fig. 3. VI & PI Characteristic Curve of Fuel Cell

B. Controller

Different types of controllers have been used in system for analysis. First, a differential controller was used and the outputs examined. Secondly, PI controller replaces the differential controller and the outputs are monitored again. Lastly, PID controller was used and the process is repeated and all of the observations are compared. All the converters are used in the discrete time domain.

1) Differential Controller

Fig. 4 illustrates the Simulink model of the differential controller with input 1 being the output voltage of the buck boost converter. Similarly, input 2 is the reference voltage of 48 V. The saturation and repeating sequence block used helps to generate proper duty cycles for the converter.

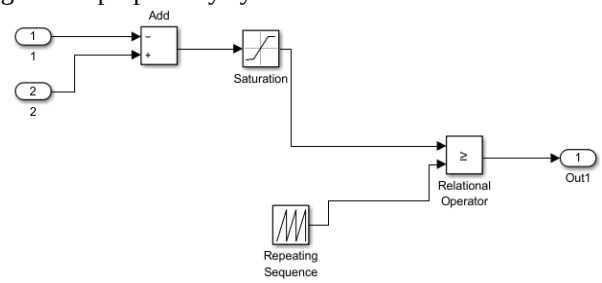

Fig. 4. Simulink Model of Differential Controller

2) PI Controller

Fig. 5 presents the Simulink model of the PI (Proportional Integral) controller situated between the rational operator and saturation block. It refines the system and provides improved outputs.

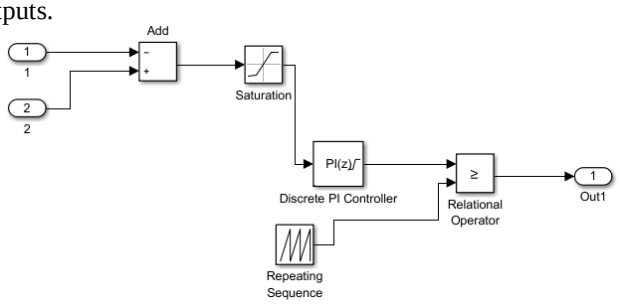

Fig. 5. Simulink Model of Proportional Integral (PI) Controller

3) PID Controller

Fig. 6 shows the Simulink model of PID (Proportional Integral Differential) controller. It further upgrades the design and provides smoother outputs.

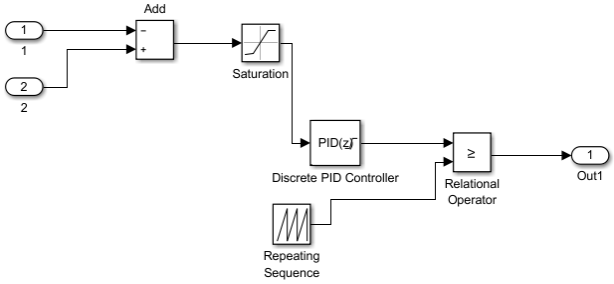

Fig. 6. Simulink Model of PID Controller

4) FLC Controller

A fuzzy controller with empirical rules are very useful in operator controlled plants [13]. Fig. **7** shows inclusion of Fuzzy logic controller between saturation and regional operator block. Fig. 8 shows fuzzy logic designer where input is taken from adder/comparator and output is going to out1 which is basically duty cycle for buck boost converter. In fuzzy logic designer, three membership function is taken which corresponds with three output functions. In fig. 9, the input rules have been arranged with the output functions. Input is taken from range 0 to 0.5 while output range is 0 to 1. For three MF(membership function), three parameters have been selected, first one is 0 to 0.1, second one is 0 to 0.5 and third one is 0.3 to 0.5. The output is taken corresponding to three input rules.

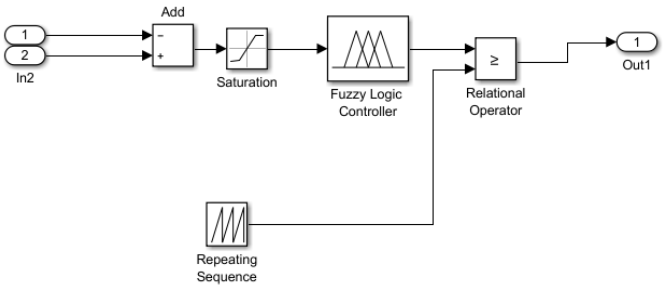

Fig. 7. Simulink model of FLC controller

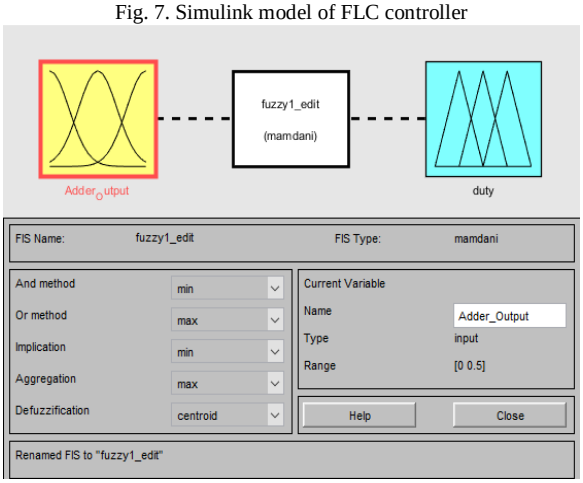

Fig. 8. Fuzzy Logic Designer

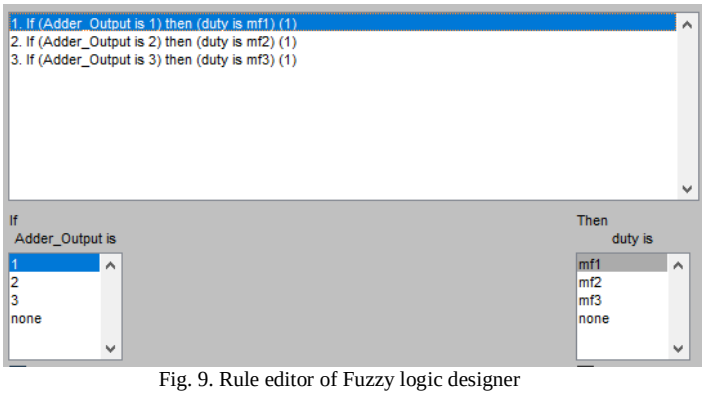

Fig. 9. Rule editor of Fuzzy logic designer

C. Buck Boost Converter

A DC to DC MOSFET switched buck-boost converter is used in the system as shown in Fig. 10. The inputs of the converter, V_{in} (+ve) and V_{in} (-ve), are outputs of the fuel cell. Port number 1 of the MOSFET serves the duty cycles supplied by the controller. Scopes have been used to obtain the curves of the switching elements. The outputs are connected to DC motor via ports. The inductor and capacitor values are chosen 4.5 mF and 15mH respectively for minimizing ripple effect of voltage and current.

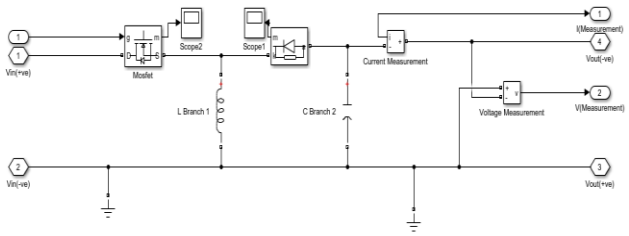

Fig. 10. Simulink Model of Buck Boost Converter

D. DC Motor

A PMDC motor is used in this system [4] as shown in Fig. 11 with ports 2(A+) and 1(A-) connected to V_{out} (+ve) and V_{out} (-ve) of buck boost converter. Port 1(TL) is connected to a constant torque of 5 N-m considering load torque. The given parameters are stated below [4]:

Power = 7776W
Voltage = 48 V
Full load current = 162 A
Break down torque = 21N-m
Constant torque = 0.13N-m
Motor speed = 367 rad/s

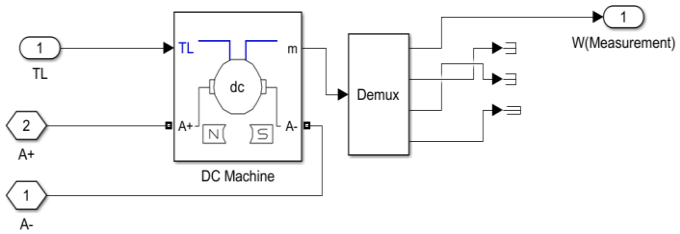

Fig. 11. Simulink model of the DC motor

V. Result Analysis of Output vs. Step Time Curve

A comparative analysis of the output characteristic curves of the DC motor and converter which varies with the use of different controllers has been conducted in this section. In some characteristics curve, spikes are generated because of turning on and off power or by increasing and decreasing the flow of power. It is caused by using buck-boost converter which operates on pre-determined duty cycle. Speed reference load torque and drive inertia are the quantities that can influence performance of a speed controller [12].

A. Differential Controller

From Fig. 12, it can be seen that the output voltage of the buck boost converter is 35.84 V and current is 1.7mA. A simulation step time of 20 is considered and varying voltage and current curves are generated as shown in Fig. 13 and Fig. 14 where small spikes are generated in range step 2 to step 3.5. At step 3.25, the spikes have high frequency and abruptly drop before reaching step 3.5. Voltage and current spikes are created due to improper generation of duty cycle which causes inefficient operation of buck boost converter.

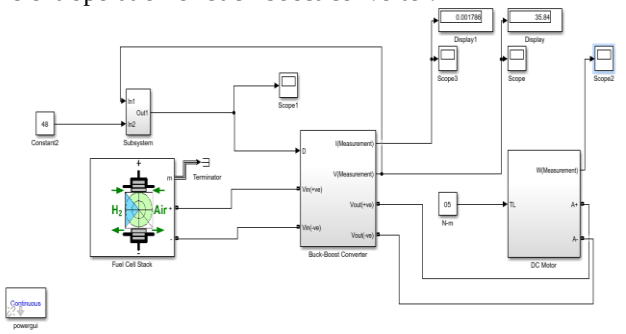

Fig. 12. Output obtained using Differential Controller

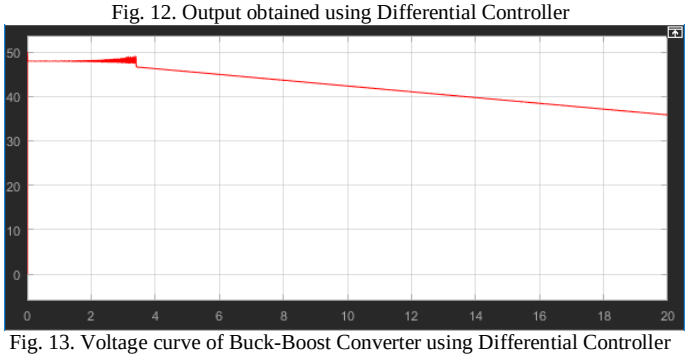

Fig. 13. Voltage curve of Buck-Boost Converter using Differential Controller

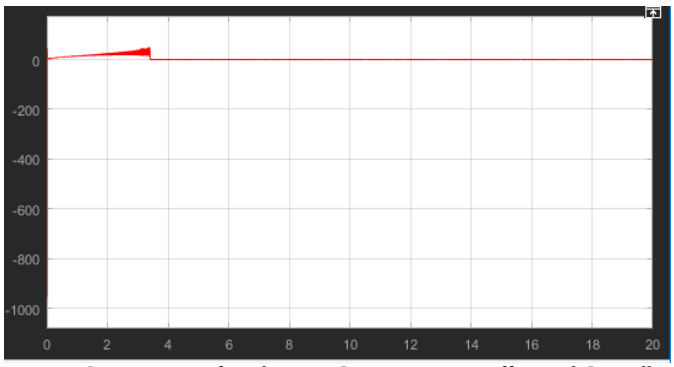

Fig. 14. Current curve of Buck-Boost Converter using Differential Controller

Fig. 15 shows the output speed curve of the DC motor. It can be seen that there is a change in gradient at point (3.45, 358) and the speed of the motor drastically decreases with steps number.

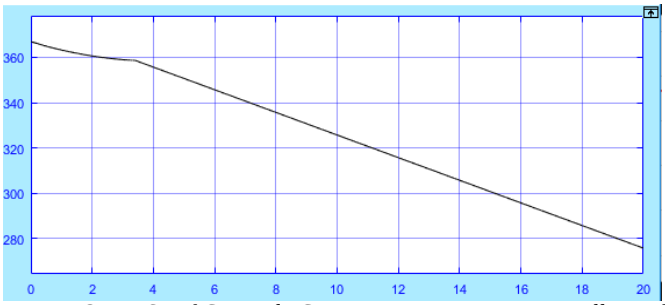

Fig. 15. Output Speed Curve of DC motor at 5 N-m torque using Differential Controller

B. PI Controller

In order to obtain smoother outputs, a PI controller is used the second time. From Fig. 16, it can be seen that the output voltage of the buck boost converter is 47.99 V and current is 32.87 A. A simulation step time of 20 is considered and varying voltage and current curves are generated as shown in Fig. 17 and Fig. 18 where there are small spikes at some intervals of curves. The curves are not completely smooth but compared to Fig. 10 and 12, they are improved and yield better results.

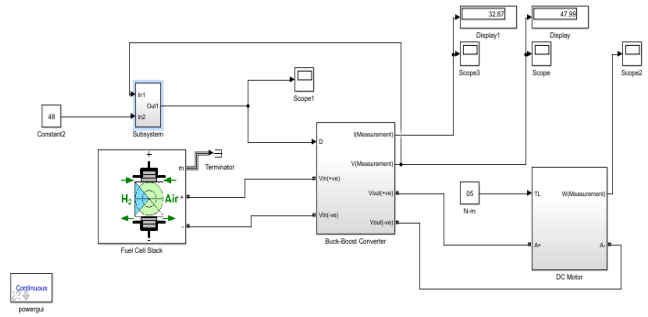

Fig. 16. Output Obtained using PI controller

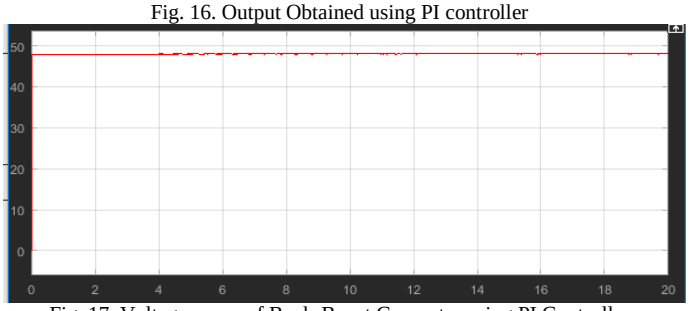

Fig. 17. Voltage curve of Buck-Boost Converter using PI Controller

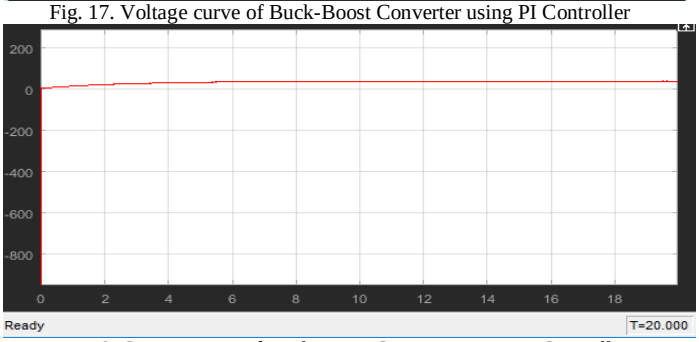

Fig. 18. Current curve of Buck-Boost Converter using PI Controller

Fig. 19 shows the output speed curve of the DC motor using PI controller. The speed curve is smoother compared to the one using differential controller shown in Fig. 13. This curve also contains small spikes from approximately step 4 to 14.

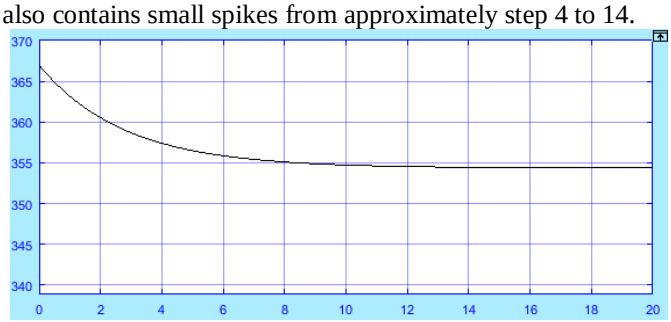

Fig. 19. Output Speed Curve of DC motor using PI Controller

C. PID Controller

A PID controller is used to further obtain smoother and stable characteristic curves. From Fig. 20, it can be seen that the output voltage and current of the buck boost converter is 48V and 38.66 A. A simulation step time of 20 is considered and varying voltage and current curves are generated as shown in Fig. 21 and Fig. 22 where there are no spikes and the curve is completely smooth and stable, yielding the most desirable and efficient results of the three controllers used.

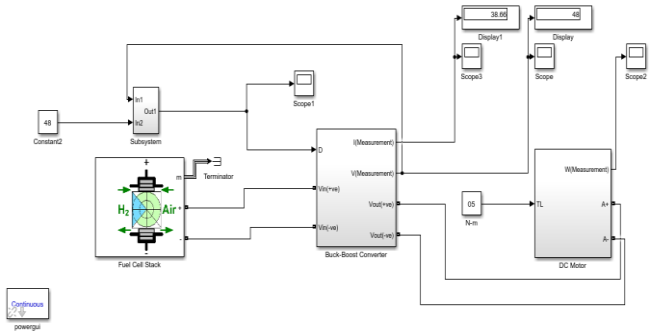

Fig. 20. Output Obtained using PID controller

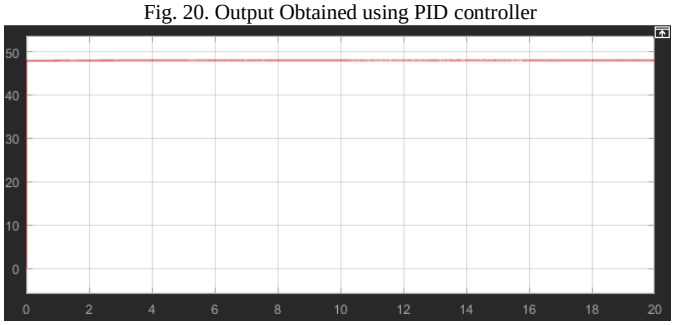

Fig. 21. Voltage curve of Buck-Boost Converter using PID controller

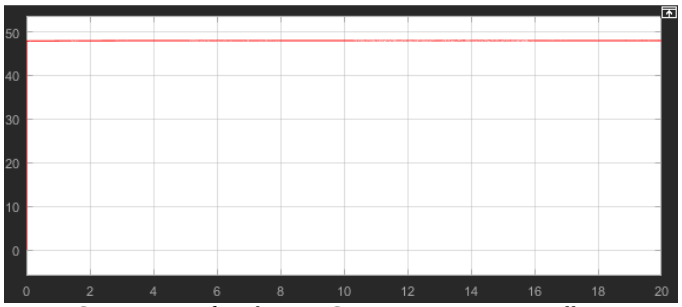

Fig. 22. Current curve of Buck-Boost Converter using PID controller

Fig. 23 shows the output speed curve of the DC motor using PID controller which is completely smooth with no spikes. The value of current is also better due to the stability and uniformity of the curve. Table. 1 presents a summary of the results obtained using all three controllers.

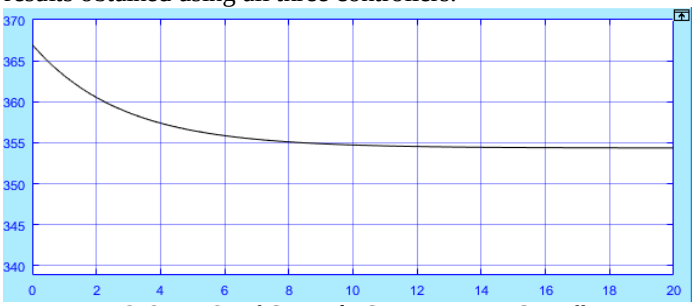

Fig. 23. Output Speed Curve of DC motor using PI Controller

D. Fuzzy Logic Controller

Finally, an FLC controller is used to obtain voltage and current output from buck boost converter. From Fig. 24, it can be seen that the output voltage and current of the buck boost converter is 48.53V and 45.78 A. A simulation step time of 20 is considered and varying voltage and current curves are generated as shown in Fig. 25 and Fig. 26. Small spikes are generated in current and voltage curves.

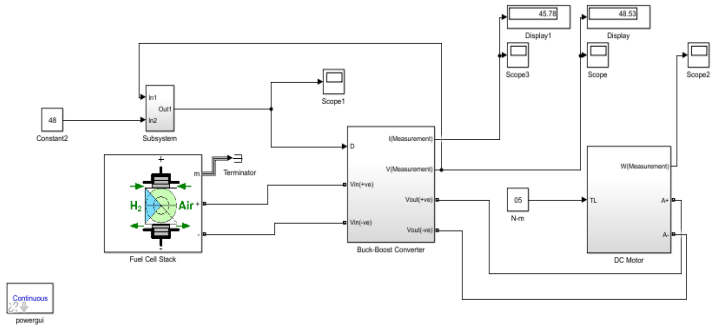

Fig. 24. Output obtained by using FLC

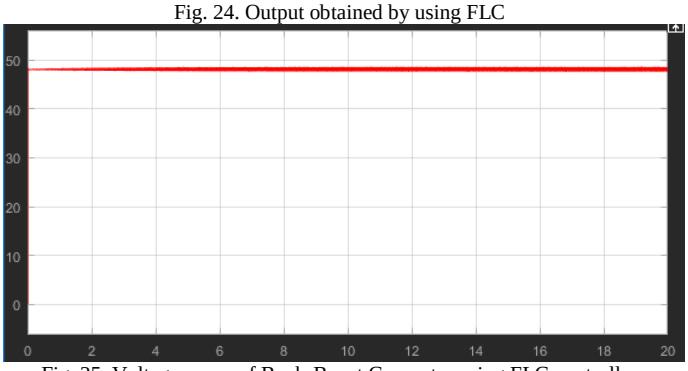

Fig. 25. Voltage curve of Buck-Boost Converter using FLC controller

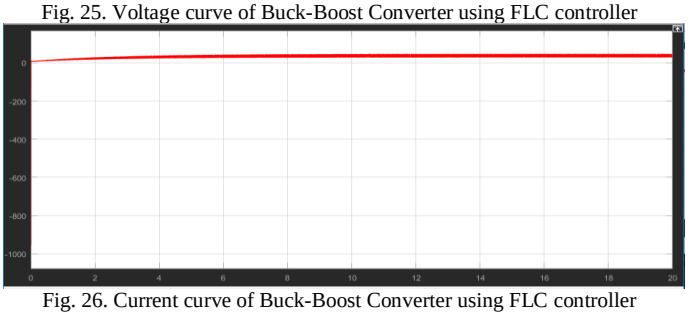

Fig. 26. Current curve of Buck-Boost Converter using FLC controller

Fig. 27 shows the output speed curve of the DC motor using FLC controller which is completely smooth with no spikes.

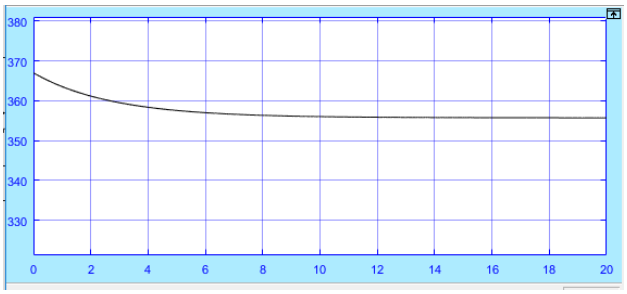

Fig. 27. Output Speed Curve of DC motor using FLC Controller

VI. Comparative Performance Analysis of DC Motored Powered by Fuel Cell and Solar PV

If solar PV is used instead of fuel cell, the performance of DC motor will be reduced to some extent. This can be observed by comparing the speed characteristic curves of both designs using PID controller. The output curves using solar PV power are shown in Fig. 28 and Fig. 29. It can be observed that the output of motor's speed is stable due to the use of PID controller but there are still a few spikes at. Hence, it is concluded that the motor will have steadier operation when powered using fuel cell compared PV cell.

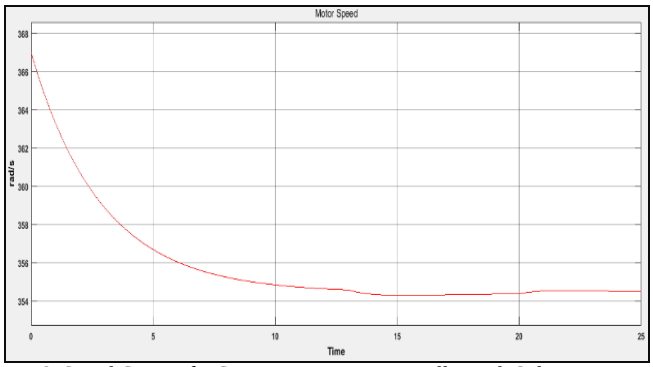

Fig. 28. Speed Curve of DC motor using PID controller with Solar PV as Power Source (System response of variable irradiance) [4]

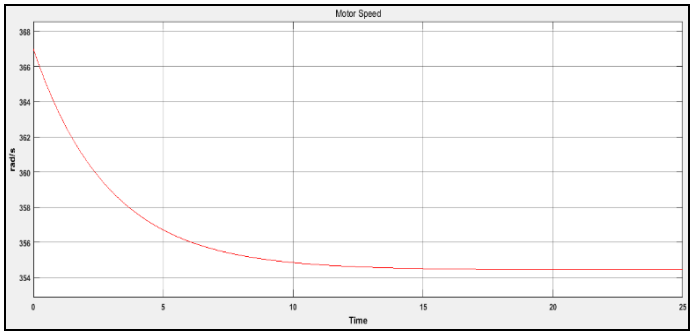

Fig. 29. Speed Curve of DC motor using PID controller with Solar PV as Power Source (System response of variable temperature) [4]

VII. Summary

In this paper, fuel cell powered DC motor system has been designed. For efficient output, converters and controllers have been used. Different controllers were used to compare and obtain the best result. It is finally observed that using PID controller yields the best output curves. PID always provides better results than FLC in such cases where uncertainty of characteristics (Current & Voltage) is bounded. Lastly, a comparison of using two different renewable sources is presented. It is concluded that fuel cell powered DC motors are more preferable in terms of efficiency and performance. Table. 1 presents a summary of the results obtained using all four controllers.

TABLE I. Summary of Output Range for Four Controller

Controller	Voltage (volts)	Current (Amps)	Speed(rad/s)
Differential	48-35.84	0-1.7*10^{-3}	275-367
PI	47-48	0-40	355-367
PID	48	0-40	354.5-367
FLC	48.53	0-45.78	357-367

VIII. Future Scope

In the proposed model, some changes can be brought for better performance. An ideal speed characteristics curve of DC motor can be obtained by continuously tuning different controllers. Adaptive neuro fuzzy inference system or fuzzy-PID can be used instead of PID or fuzzy logic controller for future research. Instead of buck boost converter, CUK converter or H-bridge buck boost converter can be used for swifter switching. Moreover, instead of DC motor, servo motor can be implemented.

IX. Conclusion

Fuel cells are increasingly becoming involved in vehicular, portable and stationary power generation systems [5]. Operating fuel cells in optimized conditions is very important in order to achieve optimum efficiency. In the design presented in this paper, a DC motor is provided power via a fuel cell. Optimizing the power efficiency is the main concern intention. By utilizing different converters, different optimization results have been analysed. PID controllers yielded the best output among all the controllers. The output of DC motor by using PID controller powered by solar PV is extracted from another research paper and compared with the outputs obtained in this paper using fuel cell. A DC motor is a machine with many applications therefore it is crucial to design systems of operation that are both sustainable and efficient and this paper presents exactly that. Overall, using a fuel cell has proven to be advantageous in terms of performance and sustainability. Future applications of this design in the field of electric vehicle which gained wide popularity because of the problem of increases in prices of fossil fuels in addition to lessening of this fuel [6]. The only

constraint is the expense of such systems but with the vast ongoing research in this field, this may be overcome as well.

***Abstract*— The volume of data entering into cloud is rapidly increasing; therefore, on-demand cloud services should be provided to clients at any time, whereas providers must be able to preserve system availability as well as process a large volume of data. It is obligatory for cloud service providers to lessen large volumes of data; thereby they can reduce costs for maintaining large storage systems. Infrastructure level performance is an important problem which directly affects the overall working of cloud computing environment. The objective of our framework is enhancing the performance of cloud infrastructure. Our approach demonstrates high effective in cloud performance enhancement, as it displays enhancement in both the service providers as well as for cloud users.**

Keywords— Resource allocation; Cloud Computing; Fuzzy Scheduling; Hadoop

I. INTRODUCTION

Security issues and privacy are the main threats that threatens the field of cloud computing. This is due to the nature of multi-tenancy and the subcontracting infrastructures that are the reasons for the cloud computing challenges. Cloud computing are widely accepted in many fields, which includes several education institution, business organization and many other enterprise organization. Security is the main concern in the field of cloud services for the reliable and secured connection that helps the vendor with their computational needs and their business needs. Several malicious activities such as unusual software and application from the illegal users where they try to have an access with the confidential data that are typically used by the cloud handlers. Virtual environment is promoted in the cloud computing field. Important technologies that deal with the virtualization, networks, memory management, transaction management, load balancing, resource scheduling, operating system and finally the concurrency control face the security issues. These capacities deal with the security and hence special attention is required. Cyber-attacks are possible when necessary security frameworks and measures are not taken. A single malware could provide a pathway to several other attacks. Replication of confidential information could be done by these cyber-attacks. These challenges should necessarily be taken care in the industries and the academia. The storage enterprise that promotes the cloud services could be anonymous and several confidential data could be connected with the identical data that could lack in trust of an organization. Several linking attacks and identity theft could be overcome with the identity information technique known as the Anonymization. Further, the problem that arises due to the identity information and authentication should be necessarily addresses. Effective resource management can also benefit from authentication at least at its conceptual level. In cloud the amount of information is stored in the form of storage and computation.

II. CLOUD METRICS

In order to enhance cloud services, metrics must be taken into account since a metric delivers information about features of a cloud property by its parameters namely, unit, rules and expression and the values emerging from the observation of the property. For example, to estimate a particular response time property from one client to another, we can consider the customer response time metric employed in a cloud email service search feature. By considering the customer response time metric, we can drive indispensable information which can employed for verification of observations as well as analyzing the results.

Metrics for cloud computing services can be described employing the Cloud Service Metric model which states higher level perceptions about the abstract metric definitions employed for a precise cloud service property which maybe a service uptime. Definitions for abstract metrics contain parameters and rules to direct a formal understanding the property of interest. The CSM model entails concrete metric definitions that are based on abstract metric definitions.

Nevertheless cloud metrology has to be understood in a proper way. Frequent terminologies namely, definition of measurement, metric or groups of measurement artifacts, consists of have numerous definitions, these myriad terminologies becomes tedious for the cloud service customer to associate services or depend on third party tools to observe the health of the service. And cloud provider should be to analyze service whether it's operating correctly or to permit its service to arrive into an intricate cloud service federation. International organizations should construct a group of metrics which should be reliable, shareable and trustworthy .By defining the metrics; it not only increases the support of the decision-making process but enhances different phases of the cloud service lifecycle.

Cloud computing is regarded as a competent data management [15] which employs k-median clustering for managing data. Even though cloud computing entails high profitable technology for business value, it lacks certain security features. Hence it is obligatory to ensure that data and infrastructural resources in cloud are scheduled and data deduplication is carried out in an efficient way. Current frameworks have limitations and may not be resolving certain drawbacks encountered in cloud [16].

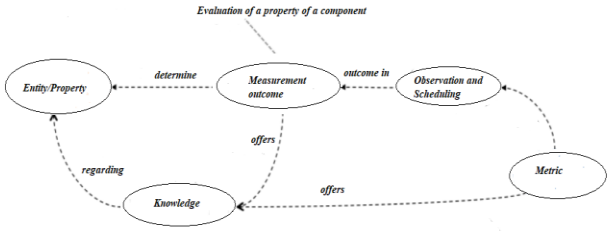

Fig. 1. Cloud Metrics

The volume of data entering into cloud is rapidly increasing; therefore, on-demand cloud services should be provided to clients at any time, whereas providers must be able to preserve system availability as well as process a large volume of data. It is obligatory for cloud service providers to lessen large volumes of data; thereby they can reduce costs for maintaining large storage systems. Cloud storage employs data deduplication technique to enhance performance of cloud storage. The technique of data deduplication employed for enhancement of efficiency in storage. In a normal deduplication system, duplicated data recognize as well as collect a single copy of data in storage. Generations of logical pointers are employed for supplementary replicas as a replacement for storing redundant data. The main advantage of employing deduplication is that it reduces storage space and network bandwidth. The drawback of employing this technique is that it will take a toll on system tolerance since files denote to the identical chunk of data, if it turns out to be unobtainable due to failure which will in turn lessen reliability. The static scheme is said to be a drawback that cannot grasp with the user's changing behavior and duplication of storage in the cloud services, which sufficiently requires a dynamic scheme that adapts several access patterns and the changing behavior.

A. Dependability Issues

In order to lessen storage space in cloud, we can employ data deduplication technique. This can be done by employing hash functions i.e. values to associate chunks of data with redundant data, thereby saving single copy and logical pointers to additional copies are created [17]. By employing deduplication technique, the following advantages are achieved:

- Amount of data residing in disk space is reduced
- Energy consumed by storage systems will be reduced.
- In cloud disaster recovery, deduplication plays a vital role by replicating data speeding up replication time and bandwidth cost savings.
- Data deduplication reduces physical capacity and network traffic which acts as a backup storage in clouds.

Important performance metrics which is obligatory to follow: overall data transmitted, service downtime and total migration time. Deduplication can overcome extensive downtime which leads to service failure. In virtual machines images, deduplication is employed to lessen storage of dynamic data. Balancing the trade-offs between storage space and performance plays an important factor in deduplication technique. Data chunks are required in groups while performing deduplication. Data chunks are assigned in the form of group of various files. Redundancy of data chunks are not required by the conventional deduplication methods. This reduces the reliability by eliminating certain data chunks from the storage system resulting in the loss of important files.

III. PROPOSED FRAMEWORK

Infrastructure level performance is an important problem which directly affects the overall working of cloud computing environment. The objective of our framework is enhancing the performance of cloud infrastructure. The cloud infrastructure deals with several nodes which eventually lead to queueing of systems, where huge amount of servers displays inconsistency in terms of processing arrival and service time. Considering the potentially high number of servers in a cloud system, we propose a fuzzy scheduling algorithm which is efficient and easy-to-implement solution. The proposed framework is integration of a fuzzy scheduling scheme to enhance infrastructure performance of cloud. Our approach demonstrates high effective in cloud performance enhancement, as it displays enhancement in both the service providers as well as for cloud users. By distributing resources as per business strategies and availability will benefit cloud service providers, at the same time enhancing services for cloud users. In nutshell, our proposed framework consists of following stages: Monitoring the data usage pattern and then cloud service provider allocating priority by cloud service provider according to our proposed fuzzy scheduling algorithm which in turn enhances infrastructure performance.

A. Fuzzy scheduling algorithm

The selection of parameters plays a vital role in providing effective scheduling. Considering real time tasks, three main scheduling parameters; computation time, arrival time, deadline and single output where the single output computes the order of task execution. In fuzzy scheduling system, these scheduling parameters are included with real-time tasks. The computation time is determined in terms of response time and utilization. S is said to be the fuzzy set of defined membership function on the universe of discourse P that is represented as a curve, which acts on every point of element of D in the space of input is diagrammed to a membership value amongst 0 and 1. The universe of disclosure is denoted as,

$$\mu_S: D \rightarrow [0, 1] \qquad (1)$$

Where value μ_S, denotes the membership that defines the membership grade of the element D in fuzzy set S. The various types of memberships are trapezoidal MF, Gaussian MF. We employ triangular MF because it is widely used in real-time implementations and effective computation.

$$\mu_D(d) = \begin{cases} 0, & d \leq n \\ \frac{d-n}{w-n}, & n < d \leq w \\ \frac{q-d}{q-w}, & w < d < q \\ 0, & d \geq q \end{cases} \quad (2)$$

Here, these three parameters {n, w, q} where n<w<q defines the triangle membership. The d coordinates of the underlying triangular MF in figure 2 were determined by n, w and q. In Fig. 2, the y axis signifies degrees of membership in the [0, 1] interval while x axis signifies the universe of discourse.

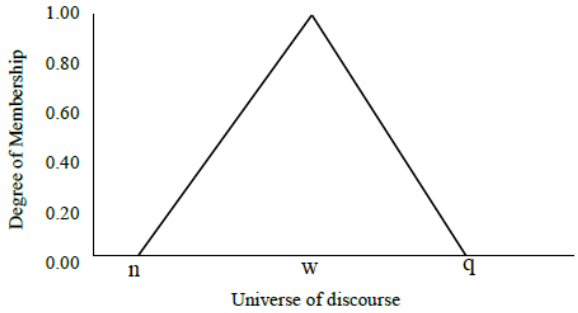

Fig. 2. Fuzzy inference model

Fig. 2 presents fuzzy inference model which consists of three main scheduling parameters, namely, computation time, arrival time, deadline and single output.

B. *Defining the Inputs/Output Membership Function*

The input parameters of the fuzzy along with their linguistic groups, namely, medium, long and short employed for arrival time, computation time and limit of the real-time tasks. Each and every task is allocated with the linguistic category for each parameter. The membership function distributions signifying the linguistic notion for fuzzy inputs and runtime priority were distinct. The fuzzy input parameters were defined by employing triangular membership functions as described as:

1) Arrival time:

TABLE I. REPRESENTS LINGUISTIC CATEGORIES DEFINED FOR THE ARRIVAL TIME OF ALL TASKS

Fuzzy Categories	Crisp input range
Early	0-5
Intermediate	0-10
Late	5-10

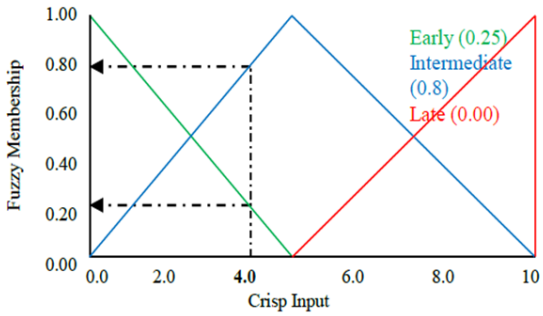

Fig. 3. Membership Function for Arrival Time

2) Computation Time:

TABLE II. REPRESENTS LINGUISTIC CATEGORIES DEFINED FOR THE COMPUTATION TIME OF ALL TASKS

Fuzzy Categories	Crisp input range
Short	1-10
Medium	1-20
Long	10-20

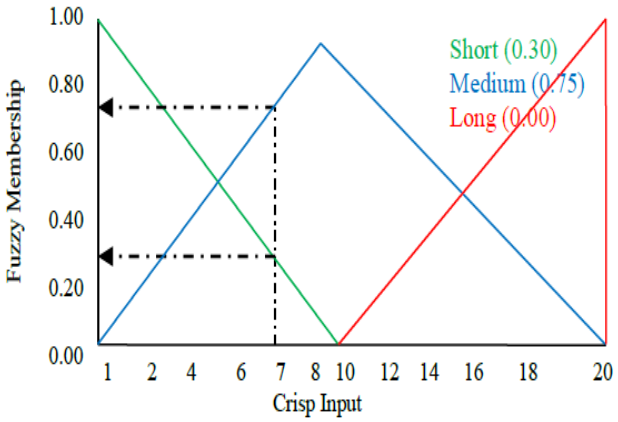

Fig. 4. Membership Function for Computation Time

3) Deadline:

TABLE III. REPRESENTS LINGUISTIC CATEGORIES DEFINED FOR THE DEADLINE OF ALL TASKS

Fuzzy Categories	Crisp input range
Critical	1-25
Normal	1-50
Sufficient	25-50

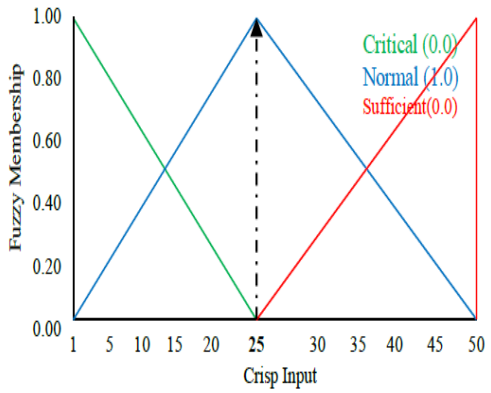

Fig. 5. Membership function for deadline of all tasks

4) Set-up Fuzzy Rule Base:

The set-up a fuzzy rule base on the foundation of the number of linguistic categories defined for each of the input parameter. Let q, w, n represent the number of linguistic categories defined for computation time, arrival time and deadline, then the fuzzy rule base will have 27 rules i.e. (3 × 3 × 3) rules of fuzzy logic.

TABLE IV: FUZZY RULES

S.No.	Arrival Time	Computation Time	Deadline
i.	Early	Short	Critical
ii.	Intermediate	Short	Sufficient
iii.	Late	Short	Critical
iv.	Early	Medium	Critical
v.	Late	Long	Sufficient

These fuzzy rules which have been created are attached with a standard fuzzy union in order to cumulate the membership functions of the three parameters attached with each task. Hence, we obtain 29 a crisp output value for each task. The crisp output value acts as a runtime priority for task allocation by virtual machines. When we apply these inputs with the membership function, we obtain the following values:

i. The crisp input for arrival time = 5.0,

The corresponding fuzzy outputs with membership values are; Early: 0.45 Intermediate: 0.56 Late: 0.78

ii. The crisp input Computation time =7.0,

The corresponding fuzzy outputs with membership values are;

Short: 0.30

Medium: 0.75

Long: 0.00

iii. When crisp input Deadline =25.0,

The corresponding fuzzy outputs with membership values are;

Critical: 0.00

Normal: 1.00

Sufficient: 0.00

The results generated only four from these rules:

i. If Arrival time is Early (5.0) AND Computation time is Short (0.45) AND Deadline is Normal (78.00), THEN Runtime priority is High.

ii. If Arrival time is Early (0.25) AND Computation time is Medium (0.75) AND Deadline is Normal (1.00), THEN Runtime priority is Normal.

iii. If Arrival time is Intermediate (0.8) AND Computation time is Short (0.30) AND Deadline is Normal (1.00), THEN Runtime priority is High.

iv. If Arrival time is Intermediate (0.80) AND Computation time is Medium (0.75) AND Deadline is Normal (1.00), THEN Runtime priority is Normal.

IV. EXPERIMENTAL RESULTS

We employed Java based toolkits, namely, CloudSim and HDFS Simulator that has the difference purposes for simulation. We employed CloudSim for testing the proposed allocation algorithm and simulating of cloud computing environments and infrastructure while HDFS simulator employed for replication. The evaluation of the proposed framework takes place through simulating cloud in terms of a performance and availability. The following components were created:

- The Namenode acts as metadata server.
- Datanodes which acts as file servers in XML format residing in the Namenode which stores instances of copies.

Various sizes of files employed are: 100 KB, 150 KB, 200 KB, 300 KB, 500 KB, 800, 1 MB, 2 MB, 250KB. Ten file are uploaded employing single data dedupilcators. We were able to reduce to 85.75% and 94.20% of the processing time taken by one data deduplicator. As the number of files increases, we created four deduplicators which lessen the processing time.

TABLE V : REPRESENTS LINGUISTIC CATEGORIES DEFINED FOR THE ARRIVAL TIME OF ALL TASKS

Fuzzy Categories	Five (upload)	Ten (upload)	Five (update)	Ten (update)
10	86.75	91.87	43.78	76.13
100	93.20	96.65	63.79	75.34
1000	91.30	95.58	64.78	83.90
10000	60.10	80.71	76.25	96.17

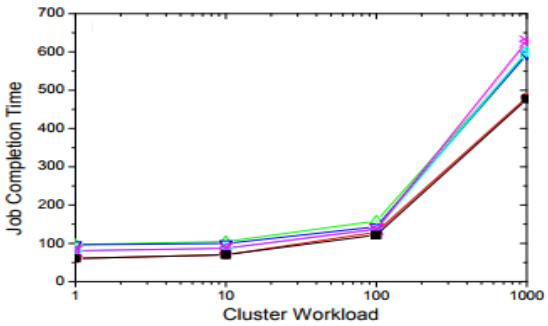

Fig. 6. Evaluation based on job completion time, where brown line signifies that the proposed algorithm completes faster

In order to evaluate the proposed algorithm, we compared with four task scheduling algorithms, namely, MaxCover-BalAssign(MB), Hadoop Default Scheduler(HDS), Delay Scheduling(DS). It is evident that the proposed scheduling has faster job completion time. It was detected that the response time varies when the system load, this proved that the proposed algorithm have better performance at higher system load..

V. CONCLUSION AND FUTURE WORK

The cloud infrastructure deals with several nodes which eventually lead to queueing of systems, where huge amount of servers displays inconsistency in terms of processing arrival and service time. Considering the potentially high number of servers in a cloud system, we propose a fuzzy scheduling algorithm which is efficient and easy-to-implement solution. The proposed framework is integration of a fuzzy scheduling scheme technique to enhance infrastructure performance of cloud. The technique of data deduplication employed for enhancement of efficiency in storage will be conferred in future work.

Secondary User As An Opportunistic Relay Based Path Selection Network Using Fuzzy Logic In Cognitive Radio Network

Vasundhara, Avtar singh buttar- vasundharamimit@gmail.com, danshavtar@rediffmail.com

***Abstract*- Wireless spectrum is not properly utilized so for efficient usuage of the spectrum band and for mitigating the issue of spectrum scarcity cognitive radio network came into existence.For boosting the cooperative communication among the users cooperative relay network come into the picture.In that direct ,opportunistic relay based and partial relay based communication came into the picture.Here secondary user act as a relay for forwarding the information from source to destination.Two paths are taken one is direct path and the other one is indirect path .on the basis of some parameters like Throughput,distance between the nodes,degree of competence,power allocation best path should be choosen among the different paths.This all done through a fuzzy logic design and relay based algorithm is also usedfor taking the fuzzy decision**

Keywords—Cognitive radio network(CRN),relay based algorithm,parametrs based decision using fuzzy inference system(FIS).

I. INTRODUCTION

A smart wireless communication system which is well aware about its environment is none other than cognitive radio .According to the environment ,it changes its parameter like frequency range,modulation mode,and power at the transmitter etc.There are 4 functions of Cognitive radio

1.Spectrum sensing
2.Spectrum decision
3.Spectrum sharing
4.Spectrum mobility

Proper spectrum utilization is always a major concern in the wireless field .So for enhancing the spectrum utilization ,cooperative communication is now a days a hot topic for the wireless researchers .In earlier works of cooperative communication includes cooperative diversity on maximum ratio combining technique ,no. of cooperative protocols used at relay node like Amplitude &forward(AF) ,Decode and forward(DF) etc [1].To remove the noise at the intermediate stages DF protocol used .Cooperative communication used through the no. of relay node and we have to choose the best relay node out of them based on some parameters like throughput ,distance ,power and channel allocation [2].so by implementing the cooperative communication enhancing the SNR and also increase the efficiency of the system comparing the previous systems.study of basically three channels as Relay channel ,Direct channel ,Dual hop channel .when the spectrum range is present at all the cooperative nodes which are basically the relay nodes then the channel is called as a relay channel because it provides end to end communication also.if spectrum range is present at the source and destination node but absent at the relay then is known as a direct channel as here directly acheived end to end communication.if one spectrum range is present at the source and relay and one at the relay and destination node then it is known as a dual hop channel.

II. RELATED WORKS

Formulation of different power distribution schemes with the help of both Direct and relayed transmissions for the cognitive radio network [3]. Analysis of BER under Decode and Forward cognitive radio networks in the case of underlay. Cooperative relay channel are used to facilitate the end to end throughput in terms of Bandwidth and power parameters [4]. Using outdated channel state information(CSI),we visualize the secondary systems performance based upon a regression model.Consideration of the hybrid underlay and overlay model so that throughput of the primary users (PU's) increase by the use of idle Secondary users (SU's) as a relays. Here focusing that using relay selection scheme,cooperative network performance should be increased .from that point ,interest towards relay is going to a higher extent[5].

III.SYSTEM MODEL AND PROBLEM FORMULATION

Consider a base network having a primary transmitter and a primary receiver and a direct link is formed between a primary transmitter and a primary receiver and a no. of secondary users which behaves as a relay node for forwarding a signal data from the primary transmitter to primary receiver[6].From all the relay node ,choose the best relay node based on distance ,throughput etc.Various relay/cooperative protocols used in it like AF and DF[7].Considering the parameter of distance from transmitter to relay and from relay to receiver like in the diagram.

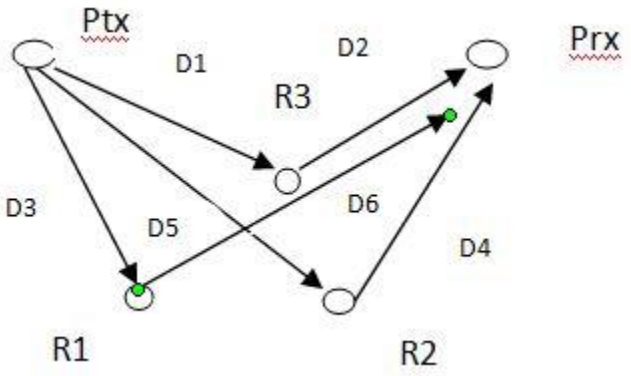

Fig1.Relay Model

Three distance path is considered
1.D1 D2[Ptx-R3-Prx]
2.D3 D6[Ptx-R1-Prx]
3.D5 D6[Ptx-R2-Prx]

Based on the reliable distance values from the receiver link that distance values would be considered using one of the fuzzy input .first of all a base network is designed in which all the three secondary users are shown which act as a relay .Three relays are there ,based on some parameters relay worked. Different distance are taken from Source to destination via relay. Decision are made based upon the different values of distance[8].

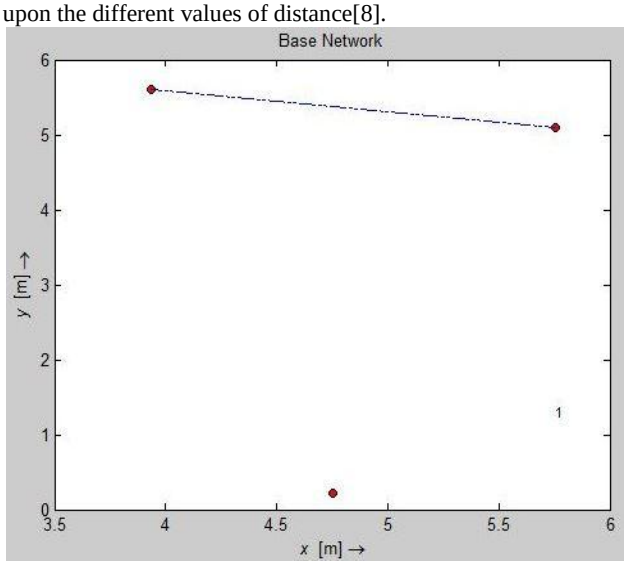

Fig2 is the base network consisting of the nodes location

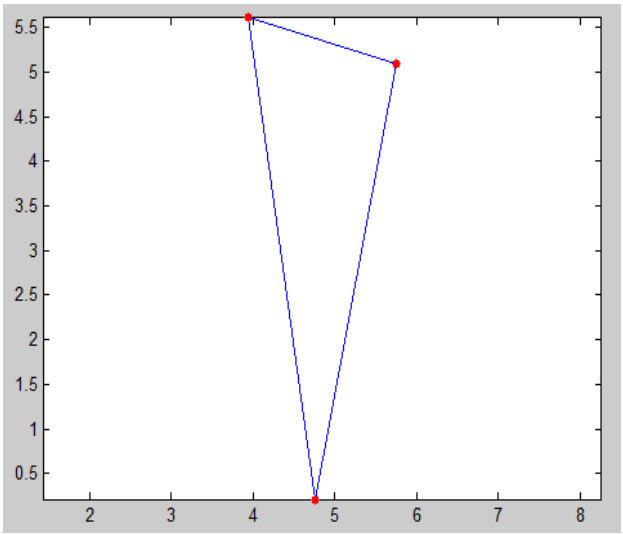

Fig3 is calculating the distance between the nodes

F ig2 shows the three secondary nodes ,it is the base network and fig3 shows the distance from the secondary nodes to each other[12].Now this distance parameter and degree of relevance which actually defines the strength of each rule are the two inputs in the fuzzy through fuzzy inference system(FIS) as shown below.

1. **SNR for direct path transmission as** [16]

$$\alpha_{s\text{-}D} = \frac{|h_{s\text{-}D}|}{N_D} \quad (1)$$

SNR for Ist hop for jth relay $SNR_{s\text{-}rj}$ and is

$$\alpha_{s\text{-}rj} = \frac{|h_{s\text{-}rj}|}{N_{rj}} \quad (2)$$

The decoded message /signal is forwarded to destination in 2nd hop.SNR at 2nd hop for jth relay is

$$\alpha_{rj\text{-}d} = \frac{\beta |h_{s\text{-}rj}|^2 |h_{rj\text{-}D}|^2}{N_{rj}(\beta^2 |h_{s\text{-}rj}|^2 + 1)} \quad (3)$$

SNR for Direct path is calculated that is from the source to the destination.Direct path SNR is then compared with the relayed path SNR value and on the basis of that best relay is selected.

β is the container of the decoded message .For ultimate relay selection ,the minimum SNR out of the two hop is used.

$$\alpha_i = \min(SNR_{s\text{-}rj}, SNR_{rj\text{-}d}) \quad (4)$$

2. **Relay selection with channel allocation** :As the cognitive radio source (CRS) don't have an initial knowledge that which relay is best one so depending on the channel allocation $CRR_{j(1\ N)}$-CRD links the best CRR(cognitive radio relay) is choosen .

$$R_{max}^{best\ CRR} = \max_{1 \le m \le N} |h_{rm}^{b}\, d|^2 \quad (5)$$

Where $R_{max}^{best\ CRR}$ designated as index of the selected best CRR.best CRRis selected from N relay (CRR's) and channel allocation is performed with this best CRR.basically there are 4 mode for channel allocation as:

Mode 1: Direct transmission from the source to the destination.

Mode 2: Dual-hop transmission from the source to the relay.

Mode3:Dual-hop transmission from the relay to the destination.

Mode 4: Relay diversity transmission by using all threelinks with cooperative relay protocols

3. **Power allocation:**Estimate which secondary node acquire more power allocated .Suppose ,a Node A having power

P1,and a Node B having power P2,so maximum power is formulated as

$$\max_{P1,P2} P_a(P1,P2) \qquad (6)$$

4.Interference power constraint :Interference power threshold is used with the objective to minimize the power consumption and channel estimation load. It is defined as interference temperature also denoted by T_c.

$$T_c = \frac{P_i(f_c,b_c)}{k * b_c} \qquad (7)$$

where k is the boltzman constant $=1.38*10^{-23}$ m^2 kg $s^{-2}k^{-1}$

In the next section consisting these 4 parameters as fuzzy parameters based on fuzzy logic design.

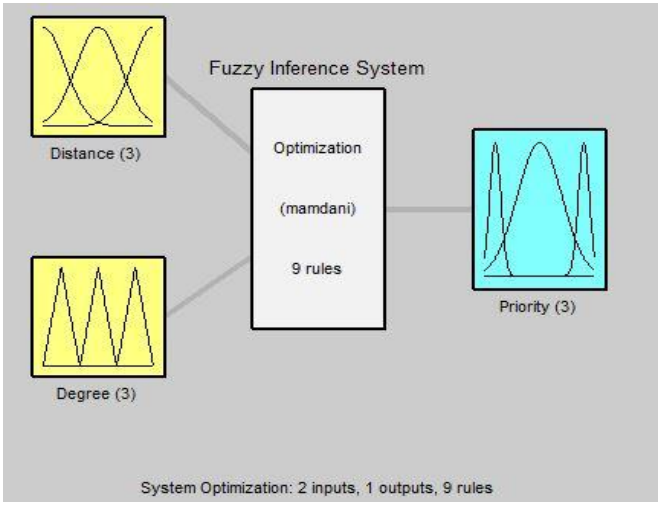

Fig4. Distance and Degree of Relevance as the two inputs in the fuzzy

Through this figure ,distance is being one of the parameter for depicting the priority at different values of distance through Fuzzy logic[13].So based on the values of distance,membership functions is designed of input 1.We formulated a Degree of Membership functions of input distance directing from low value to high ,by giving priority to the low value then to the medium value at last to the high values.

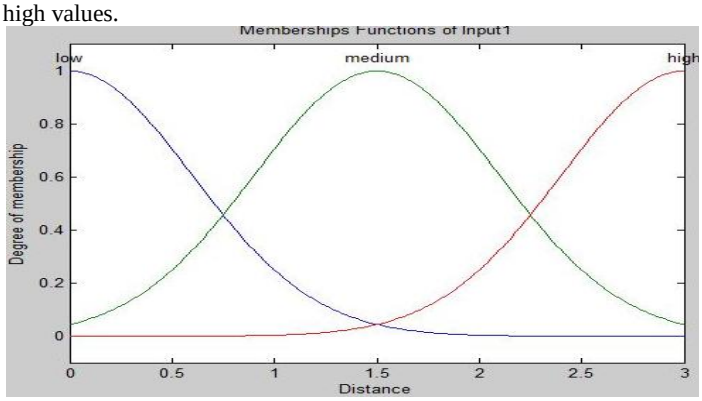

Fig5 Degree of Membership Function of Input 1

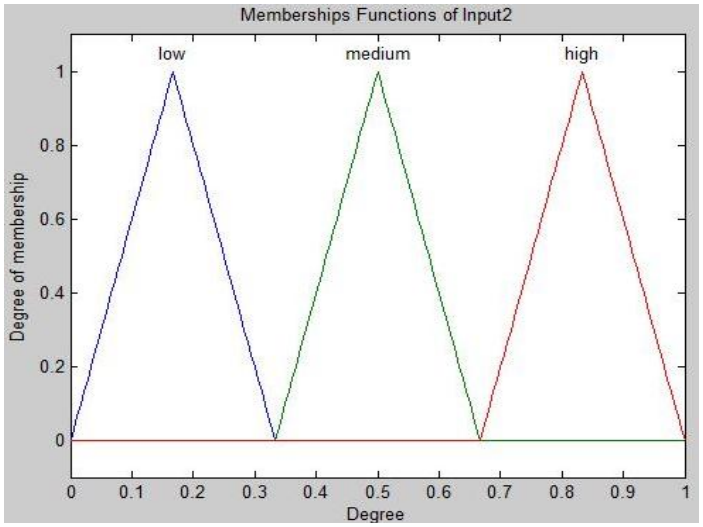

Fig6 Degree of membership function of input 2

This figure below shows the Degree of membership function basically defines a priority for the different inputs.

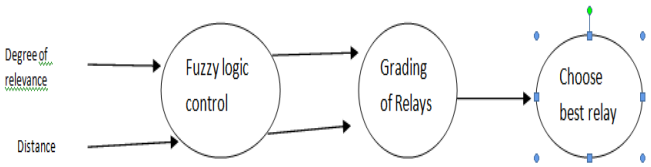

Fig7. Relay Grading Model using Fuzzy

On the basis of Fuzzy Logic Design selection of best relay is to be selected[9]. Degree of relevance and distance are the input parameter in the fuzzy logic controller on the basis of these two parameters Ranking /grading is provided to the relays and out of which best relay is selected,for this we have to use the algorithm also as stated below.

Step1.Start with k=0
Step2.Increment k=k+1
Step3.Design fuzzy parameter for the kth relay
Step4.Degree of relevance should be considered
Step5.If k=N then go to step 6 else go to step 2
Step6. Compare degree of relevance and select it having good degree of relevance.

IV.SIMULATION RESULTS

Random Deployment of nodes occur in which one is act as a source while the other one is act as a destination and rest of the nodes are the relay nodes [10].

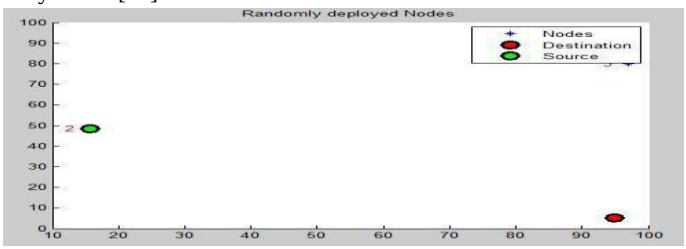

Fig 8.Random Deployment of nodes

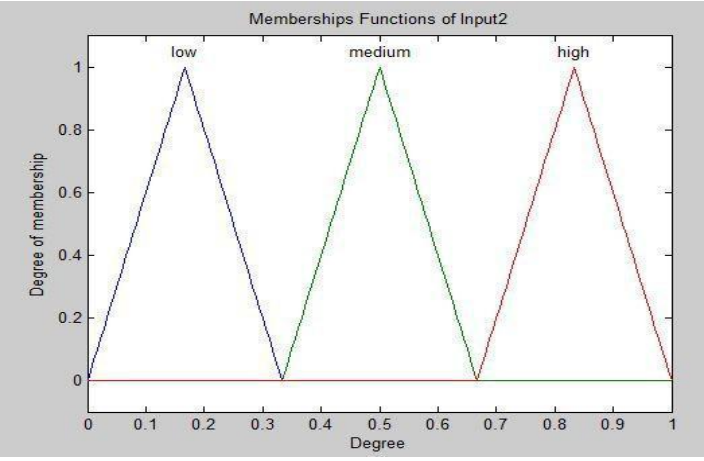

Fig 9. Degree of Membership Function of X2

This above figure shows that the Throughput is increasing with the power level by using Fuzzy logic design. This is what the end to end throughput from the source to a destination via relay. Rho is defined as the power spectral efficiency .It basically defined the spectrum efficiency of the nodes.

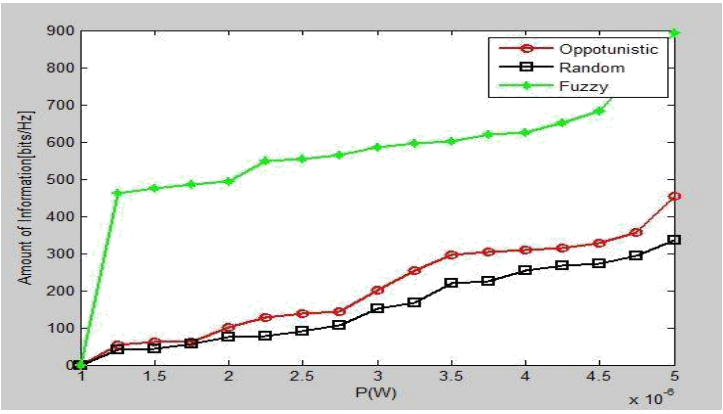

Fig 10 Amount of information bits verses power

Above figure shows that how the amount of information bits increase with power in case of fuzzy[11].Above figure shows that how the throughput is increasing with the increase of the power in case of fuzzy logic design as compared to opportunistic and random deployment of nodes. Green color line shows the amount of information bits is increasing means capacity of the relay nodes are increasing with the increase in the power level in case of using Fuzzy logic design.

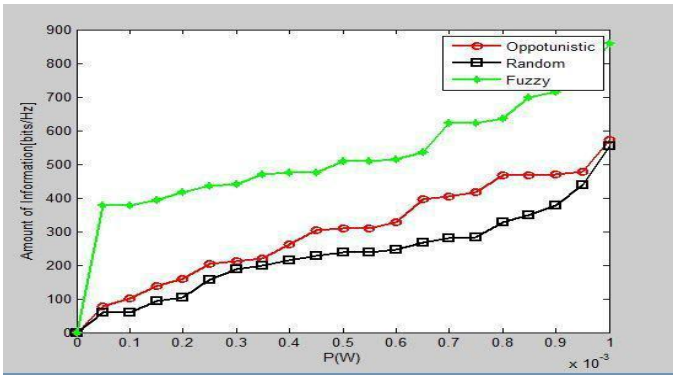

Fig 11 Steep Curve of amount of information varied with the power

This Figure depicts the Amount of information variation with the power .With the increase of power ,capacity of channel also varies linearly with the power variation.

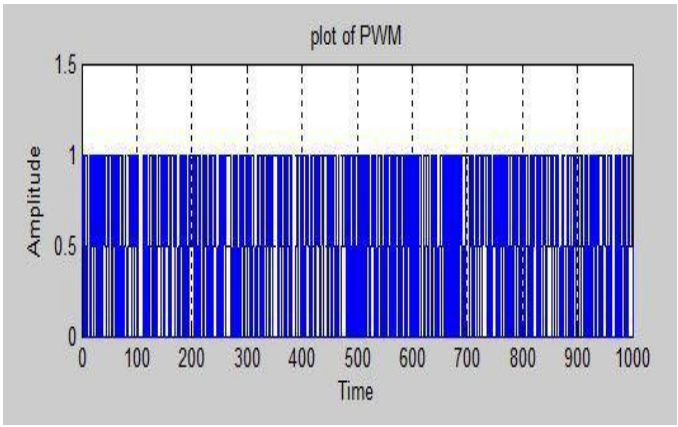

Fig 12 PWM output

This above figure depicts the PWM wave generation. This PWM wave generation basically tells about the switching mode of the application that when the relay is on and when it is off.

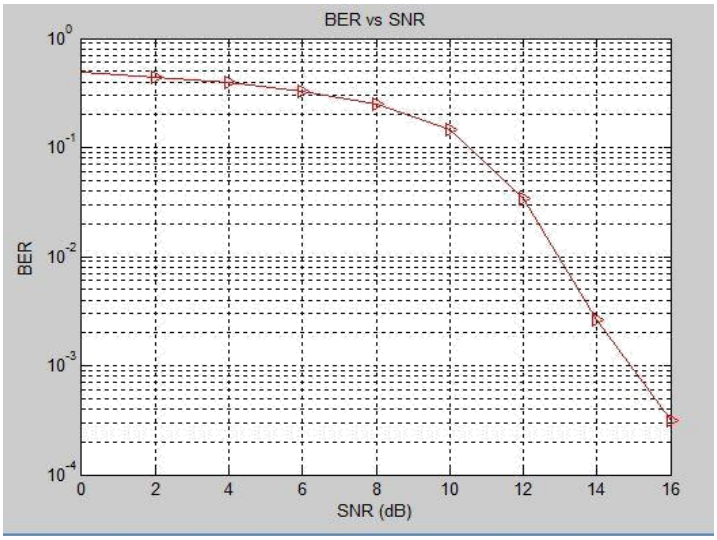

Fig 13 BER vs SNR

This figure depicts the BER verses SNR(dB).With increase in the SNR there is a decrease in the BER .Error probability decreases with the improvement in the SNR.

TABLE I. SIMULATION PARAMETERS

Parameters	Values
Source Transmit Power	1w
Relay Transmit Power	1w
Amplification Factor	Fixed
Modulation Scheme	B-PSK
Receiver Diversity	MRC
Number of Relays	5
Relaying Protocol	Amplify-and-Forward
Number of Bits	10^6
Receiver Noise	AWGN
Channel Model	Rayleigh, Nakagami, Rician

V. CONCLUSION AND FUTURE SCOPE

Simulation results that contain the Fuzzy logic based decision takes place based on some parameters Like Throughput, Amount of information bits ,Distance ,Power etc.On the basis of these parameters decision should be takes place and best relay path should be choosen among the N relay users. Meanwhile we compare the opportunistic, random and fuzzy distribution and analyze how the throughput ,amount of information bits varies in all the 3 cases. We generalize then BER vs SNR .we calculated the distance among the users. In fuzzy we built Rule set of X1 and X2 inputs and according to that labels have been assigned to the Y output. We generalize the 3D view also by analyzing the surface view structure .This surface view helps in giving the 3 D view when more than two inputs are given in the picture. For all this to occur we have taken the OFDM QPSK signal in the original and PWM (Pulse Width Modulation) signal as the input signal. We also analyze the network lifetime(LN) of the nodes which specify the increment in the nodes lifetime with the increase in power in case of random deployment of nodes[14].
In future, this work can be extended by determining the secrecy constraints parameters in proposed relay selection schemes.While Multihop with Multi user Cooperation with additional cooperation may enhance the performance of the system and Code rate is also expected to be increase[16].We can also make the secondary user as a relay in reconfigurable mode.We can also enhance the network by using multiple nodes as a relay in the network.Different channel models should be combined or collaborated in the fashion to increase the efficiency of the network.We can also implement threshold constraint on throughput parameter also[15].

***Abstract*— With rapid industrial development and flourishing population, power demand is increasing rapidly. UHV power line is one of the ways to meet this increasing demand. 1200kv UHV transmission line, is India's forthcoming project to tackle this situation. Right Of Way (ROW) is one of the major concerns with transmission lines. An electric field is one parameter to define ROW. In this paper, electric field of three configurations of the 1200kv line is calculated by the Finite Element Method. FEM is used to solve partial differential equations. Calculations have been done by taking a case with the minimum ground distance of conductors of lines. Plotted results are compared with ICNIRP standards and safety limits defined. Biological effects of electric field on people, animals, and plants are also discussed.**

Keywords—Biological Effects, Electric field, Finite Element Method (FEM), International commission on non-ionizing radiation protection (ICNIRP), Right Of Way (ROW).

I. INTRODUCTION

To limit the Right Of Way with bulk amount of power transfer over long distances, countries need to incite the ultra-high voltage transmission system. Russia has 1200kv transmission line which operates at 1150kv up to few years since then it is operating at 500kv level. China has initiated the project of commissioning of 1000kv UHVAC transmission line [1].

In India major power transmission systems operates in 220kv and 400kv voltage level. To meet increasing power demand, India adopted 1200kv UHVAC transmission network which is under implementation. 1200kv test station is established at Bina, Madhya Pradesh. The first 1200kv test line is installed between Wardha to Aurangabad having length of 382km [2].

Many parameters need to be taken care with higher voltage level as its affects human beings. One of them is an electric field. ICNIRP is one of the standards which specify a limit of the electric field for occupational and general public, which helps to define ROW [3] [4].

In this paper, electric field produced due to the 1200kv transmission line is evaluated by Finite Element Method. An electric field is calculated at ground surface and above ground surface up to several meters of height. From these results right of way is defined for transmission line. Biological Effects of excess electric field on living beings, animals and plants also discussed [4] [6].

II. LINE PARAMETERS

A design specification of 1200kv transmission lines is given in table.1. In this paper, three configurations of a line have been discussed, which are single circuit horizontal configuration, single circuit delta configuration, and double circuit vertical configuration [5]. In table 1, R represents radius of bundle conductors. For evaluation of electric field bundle conductor can be represent as in single conductor with equivalent radius as given in (1).

TABLE I. LINE PARAMETERS

Description	Notation	Value	Units
Number of sub-conductors in a bundle	N	8	Nos.
Bundle Radius	R	0.60	m
Sub conductor spacing	B	0.46	m
Diameter of sub-conductor	d	4.63	cm
Conductor height above ground at a tower	H	37	m
Conductor height above ground at mid span	Hm	24.3	m
Phase spacing	S	27	m
Bundle conductor type	Bersimis/moose		

$$r_{eq} = R\left(\frac{Nr}{R}\right)^{\frac{1}{N}} = 0.518 \text{ m} \quad (1)$$

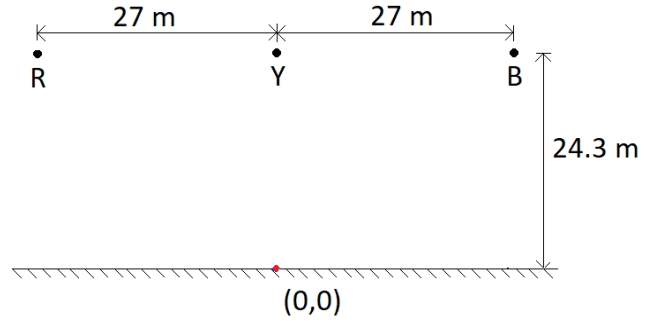

Fig.1. S/C horizontal configuration

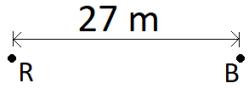

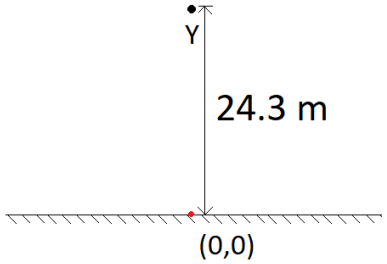

Fig.2. S/C delta configuration

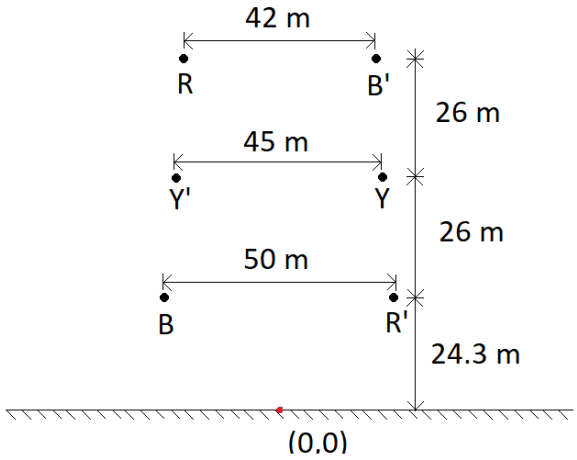

Fig.3. D/C vertical configuration

III. ELECTRIC FIELD CALCULATION

The Finite Element Method is used to calculate electric field distribution at the ground surface and above the ground surface up to 10-meter height [6]. In this study, one assumption is made that ground surface is flat. As per Gauss law relation between electric field and voltage is given as in (2) [7]-[8].

$$E = -\nabla V \tag{1}$$

Electric flux density correlates with charge density and electric flux density correlate with the electric field as given in (2) and (3) respectively.

$$\nabla \cdot D = Q \tag{2}$$

$$D = \varepsilon E \tag{3}$$

By substituting (1) and (2) in (3) final relation between voltage and charge density given as (4).

$$-\frac{\partial}{\partial x}\left(\varepsilon \frac{\partial V}{\partial x}\right) - \frac{\partial}{\partial y}\left(\varepsilon \frac{\partial V}{\partial y}\right) = Q \tag{4}$$

Here, E stands for Electric field intensity V/m
V stands for voltage Volt
D stands for electric flux density C/m^2
ε stands for permittivity of medium F/m
Q stands for volume charge density C/m^3

Overall procedure of Finite Element Analysis can be explained in four steps.

A. Domain Discretization

The first step of FEA is to divide the domain into a number of two-dimensional elements. In this problem, domain is divided into triangular elements with a quadratic shape. So each element has six nodes. A triangular element is shown in the fig.4 [7]-[8].

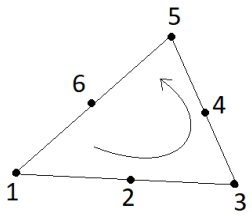

Fig.4. Quadratic type triangular element

Each node is associated with two label numbers, one local number which represents its location within that element and second number is called the global number to represent the location of a node in a domain. Voltage equation at a node can be given as in (5).

$$A_{(x_1,y_1)} = a + bx_1 + cy_1 + dx_1^2 + ex_1y_1 + fy_1^2 \tag{5}$$

In (5) a, b, c, d, e and f are unknown constants. Voltage at all six nodes can represent in same manner. One common

equation in matrix form can be represent. By simple matrix inversion, six constants can be representing in form of voltage and location point of node terms. Final equation for voltage at any (x, y) point in a particular element can be formed as (6).

$$V = \sum_{i=1}^{6} N_{i(x,y)} V_i \tag{6}$$

B. Formulation of a system of equations

Ritz method is used to formulate functional equations. Functional equations for eth element can be written as (7). It is a simple surface integration within the area of an element. V stands for voltage at nodes in an eth element. Q represents charge density in an eth element. Here, omega sign represents two dimensional problem [7]-[8].

$$\mathrm{F}^{\mathrm{e}}(V^e) = \frac{1}{2}\iint \left[\varepsilon \left(\frac{\partial V^e}{\partial x} \right)^2 + \varepsilon \left(\frac{\partial V^e}{\partial y} \right)^2 - 2QV^e \right] d\Omega \tag{7}$$

In (7) voltage is differentiating w.r.t. x and y. substituting (6) into (7), functional equation for eth element can be transformed into matrix form where the voltage at six nodes are used. Differentiation of functional equation w.r.t. a voltage at any node equals to zero. Expanding this differentiation with all node voltages. An expanded equation can be written as in (8). In (8) M is representing total numbers of nodes in domain of the system.

$$\frac{\partial F(V)}{\partial V_i} = \sum_{j=1}^{M} \iint \varepsilon \left(\left[\left(\frac{\partial N_i}{\partial x} \right) \left(\frac{\partial N_j}{\partial x} \right) + \left(\frac{\partial N_i}{\partial y} \right) \left(\frac{\partial N_j}{\partial y} \right) \right] V_j - QN_i \right) d\Omega = 0 \tag{8}$$

In a simplified manner, these equations can be represented in matrix form as in (9) [9].

$$[K]_{(M\times M)}[V]_{(M\times 1)} = [B]_{(M\times 1)} \tag{9}$$

Where K and B terms of matrices stand for,

$$K_{ij} = \iint \varepsilon \left[\left(\frac{\partial N_i}{\partial x} \right) \left(\frac{\partial N_j}{\partial x} \right) + \left(\frac{\partial N_i}{\partial y} \right) \left(\frac{\partial N_j}{\partial y} \right) \right] dxdy \tag{10}$$

$$B_i = \iint QN_i dxdy \tag{11}$$

In (9) terms of matrix V are unknown which can be found by matrices K and B.

C. Incorporation of boundary condition

Two types of boundary conditions have been used. One is Dirichlet condition and second is Neumann condition. At ground and conductor surfaces, Dirichlet condition is applied. Neumann condition is applied at an exterior boundary to bound air medium [7]-[8].

Dirichlet conditions:

$$V_g = 0V \tag{12}$$

$$V_r = 692.820323kV \tag{13}$$

$$V_y = 692.820323e^{-j\frac{2\pi}{3}}kV \tag{14}$$

$$V_b = 692.820323e^{j\frac{2\pi}{3}}kV \tag{15}$$

Neumann condition:

$$\left[\varepsilon \left(\frac{\partial V}{\partial x} \right) \hat{x} + \varepsilon \left(\frac{\partial V}{\partial y} \right) \hat{y} \right] \cdot \hat{n} = 0 \tag{16}$$

D. Continuity conditions

In the domain of 1200kv power line conductors and air medium have different permittivity value, so at conductor surface two different types of material are interfaced which produces discontinuity. So at boundary interface some continuity conditions needs to be satisfied [7]-[8].

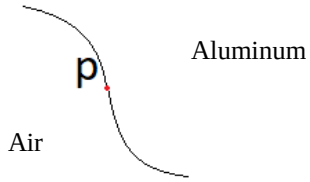

Fig.5. Two boundary interface

Fig.5 shows interface boundary interface of aluminum and air medium. So continuity conditions at interface given as in (19) and (20).

$$\left[\varepsilon_{air} \left(\frac{\partial V}{\partial x} \right) \hat{x} + \varepsilon_{air} \left(\frac{\partial V}{\partial y} \right) \hat{y} \right] \cdot \hat{n} = \left[\varepsilon_{con} \left(\frac{\partial V}{\partial x} \right) \hat{x} + \varepsilon_{con} \left(\frac{\partial V}{\partial y} \right) \hat{y} \right] \cdot \hat{n} \tag{16}$$

$$V_+^p = V_-^p \tag{17}$$

IV. IMPLEMENTATION IN COMSOL MULTIPHYSICS

For Analysis COMSOL Multiphysics software is used. First rectangle is drawn with 300 meter height and 600 meter width to represent air medium. Reason behind take that much long dimensions are to generate more practical case as in real case air medium cannot be bound in any dimension. In air medium three circles are drawn with radius of 0.518 meter, each circle is distanced with 27 meters. Three circles are representing R, Y and B phase cross sectional conductors respectively [10].

Electric field is to be calculated at ground surface and above ground surface with height 2m, 4m, 6m, 8m and 10m. For that 5 lines are drawn with 2 meter vertical distances. Final geometry in COMSOL Multiphysics is shown in fig.6. Aluminum material property is assign to three conductors and air medium property is assign to whole rectangular area except three conductors.

Ground surface representing as in red line in fig.6, has been applied Dirichlet condition as in (15). Conductor surfaces of R, Y and B phase also have been applied Dirichlet conditions as in (16), (17) and (18) respectively. At blue line boundaries representing in fig.6, Neumann condition is applied as in (19). Neumann condition represents that zero change in electric flux density in normal vector direction of boundary.

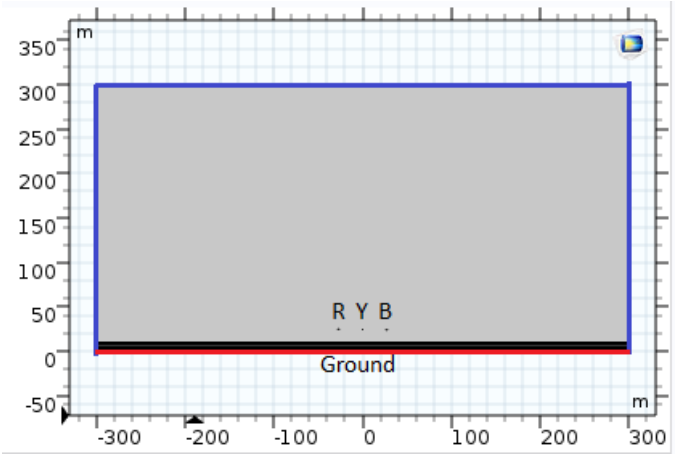

Fig.6. Geometry of S/C horizontal configuration 1200kV transmission line

COMSOL provides feature to decide element size as your analysis area to get higher accuracy with lesser computation time and less RAM of device The results are need to be obtained at ground surface and some meters above from ground surface up to 10 meters. Here, results are evaluated at six equidistance lines from ground surface to height of 10 meters from ground surface, so small sized elements are constructed with 1 meter maximum element size as shown in fig.7, element size within conductors is 20 mm and in remaining area coarser type elements are formed.

Final geometry with construction of elements in whole domain is called as mesh domain. Mesh domain of S/C horizontal configuration of 1200kV line is shown in fig.8. Similarly model of S/C delta configuration and D/C vertical configuration of 1200kV UHV transmission line can be implementing in COMSOL Multiphysics [10].

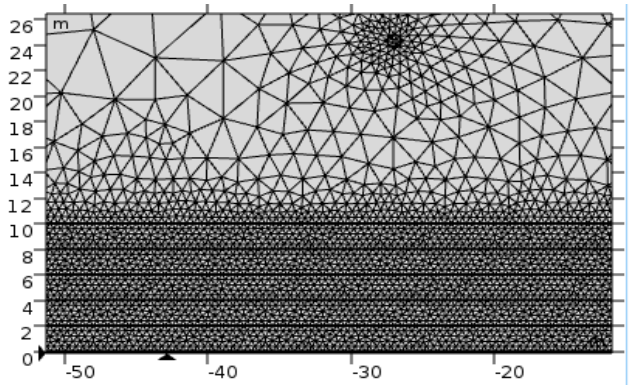

Fig. 7. Discretization of domain with different element sizes.

V. RESULTS

An electric field is calculated and plotted for three configurations of a 1200kV transmission line; electric field plot is carried out for up to some distance from reference point on ground surface. It is repeated for various heights from the ground, ground surface and 2m, 4m, 6m, 8m and 10m above from the ground surface. The analysis is performed by considering the minimum height of conductors in a span.

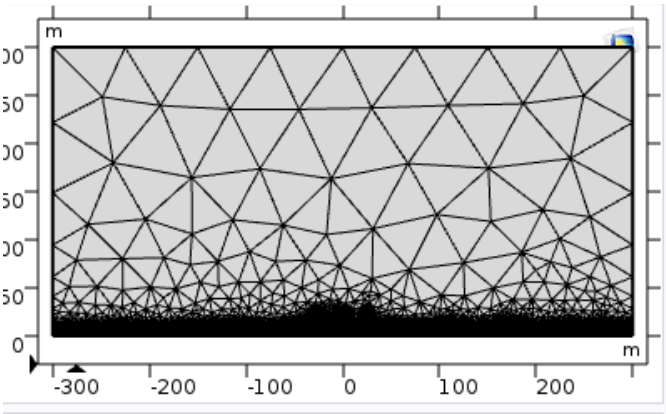

Fig.8. Mesh domain of S/C horizontal configuration

In fig.8. S/C horizontal configuration domain is discriminated into triangular elements. Similarly, fig.10. and

fig.12. shows mesh domain of D/C horizontal configuration and S/C delta configuration respectively. In fig.9. electric field is plotted for 70 meters from reference point in both directions. Maximum electric field for at 10 meter height above ground surface is 13,370 V/m at 27 meters from reference point. Within 52.25 meters from reference point electric field above 5000 V/m. So, ROW for S/C horizontal configuration is 104.5 meters.

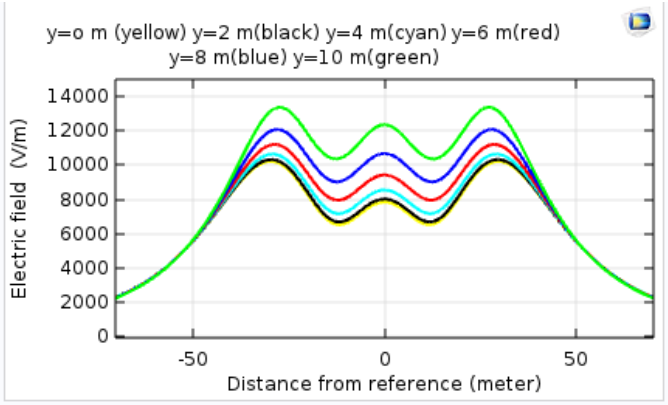

Fig.9. Electric field distribution for S/C horizontal configuration

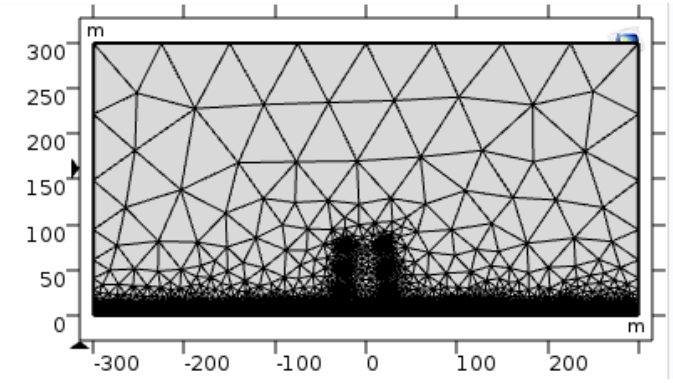

Fig.10. Mesh domain of D/C horizontal configuration

In fig.11. electric field is plotted for 50 meters from reference point in both directions. Maximum electric field for at 10 meter height above ground surface is 12,810.65 V/m at 25 meters from reference point. Within 46.04 meters from reference point electric field above 5000 V/m. So, ROW for S/C horizontal configuration is 92.1 meters. In fig.13. electric field is plotted for 50 meters from reference point in both directions. Maximum electric field for at 10 meter height above ground surface is 12,218.23 V/m at reference point. Within 19.45 meters from reference point electric field above 5000 V/m. So, ROW for S/C horizontal configuration is 39 meters. From fig.9. and fig. 11 it can show that, there is a dip in electric field at reference point due to partial cancellation of 3 phase fields [11].

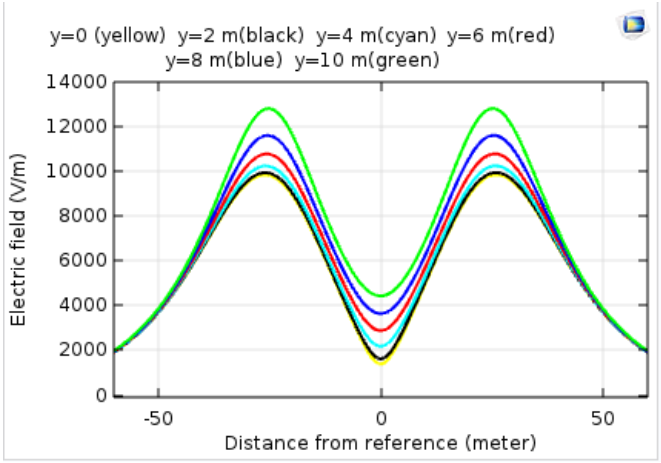

Fig.11. Electric field distribution for D/C vertical configuration

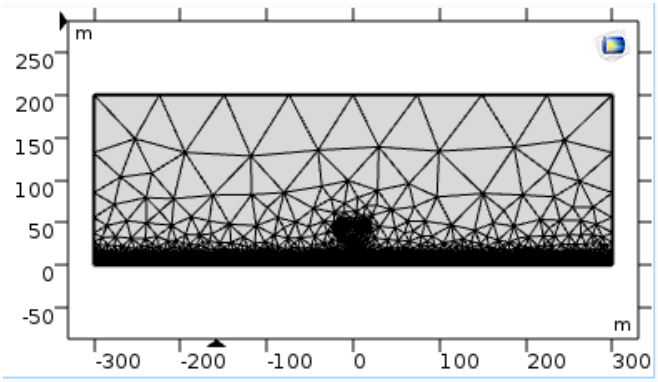

Fig.12. Mesh domain of S/C delta configuration

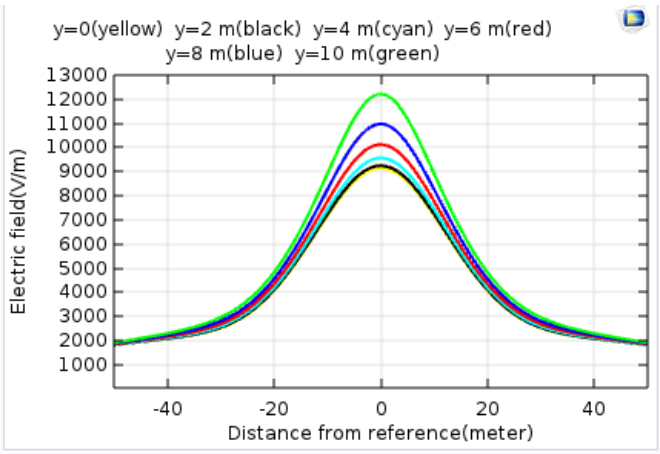

Fig.13. Electric field distribution for S/C delta configuration

VI. IMPORTANCE WITH ICNIRP GUIDELINES

International Commission on non-ionizing radiation protection had approved the exposure limit of 50Hz based on electric field is shown as in table 2 [4]-[12].

TABLE 2. ICNIRP GUIDELINES

Exposure type	**ICNIRP-2010**
Occupational	10kV/m
General public	5kV/m

From the results of three configurations, a region can be defined where electric field is excessing the safety limits. Due to excess electric field exposure many adverse effects may happens like cardiovascular disorders and neurodegenerative disorders [4].

VII. CONCLUSION

Application of Finite Element Method to evaluate an electric field of 1200kv transmission line is explained. From electric field of 1200kv transmission line, Right of way of line is defined. Here three configurations have been taken for analysis; results of lines are compared with international standards for safe limits of electric field for public. Calculation is taken at ground surface and several meters of height from ground surface like 2m, 4m 6m, 8m, and 10m. This paper highlights the application of FEM and COMSOL Multiphysics in analysis of electrical field.

***Abstract*—This study presents comparison between two different control techniques for PFC converters with less total harmonic distortion (THD). The PR current controller provides the gain at resonant frequency & eliminates steady state error. On other hand, PI controller has less disturbance rejection capability in high frequency range. Hence PR controllers can be applied to PFC converters to obtain extended DC-link voltage with enhanced power quality at input. Here, Cuk converter is introduced for power quality improvement and it's operation is described in three modes with corresponding waveforms. The simulation study of Cuk converter with PI controller & PR controller is carried out and comparative analysis of these two techniques is presented.**

***Index Terms*—power-factor correction, THD, power quality, PR controller, Cuk converter.**

I. Introduction

The rapid changes in world energy scenario encouraged design, development & control of power electronic converters with enhanced power factor. The PFC converters are often employed to obtain enhanced power factor and these can generate balanced DC-link voltage. The combination of buck & boost converters is selected, as operation in both modes can be obtained. The buck-boost converters is a combination of diode bridge rectifier with DC-DC converter [1], [2]. The Cuk converter is implemented here which is a single switch based converter & results in decreased torque & current ripple, approximately UPF and low harmonic distortion at AC mains.

Due to increased applications of AC-DC converters, they are evolved in single-stage with lower number of components & high efficiency to improve power quality & also considered as better option for flexible operation of system. The operation of PFC converters is studied in two modes, that is, continuous conduction mode (CCM) & discontinuous conduction mode (DCM). As switch suffers hard switching because of continuous inductor current, CCM is nominated for medium & high power applications while restricts DCM for low power applications. On control part, three sensors are required to operate in CCM while a DCM only requires single voltage sensor [3].

The selection of control scheme includes appropriate consideration between cost, complexity & waveform quality required to meet standards of power quality in low voltage applications. The simple proportional integral controllers have some limitations such as presence of steady-state error in stationary frame even though they are easy to implement [4]–[6]. Overcoming the drawbacks of PI controller & achieving equivalent frequency response characteristics as synchronous frame PI controller, PR controller is introduced to track reference current in stationary frame. This paper evaluates performance of PI controller, identifies limitation & presents PR controller as best selection to overcome the drawbacks of conventional PI controller [7]. The current controller put remarkable effect on quality of source current of converter & hence it has more importance to the fact that controller should provide best quality sinusoidal input source current with less distortion to neglect harmonics [8], [9].

To avoid adverse effect on power quality, several standards are made for THD and it is limited under permissible value by IEC 61000-3-2 standards. [10].

II. Overview of Operation of Cuk Converter

Cuk converter is a special type of DC-DC converter or it is a cascaded combination of boost converter followed by buck converter with capacitive energy transfer.

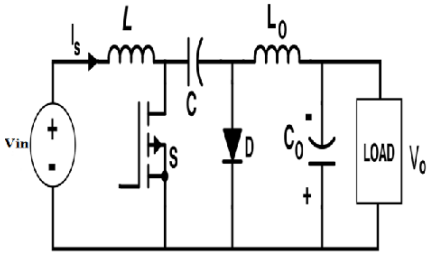

Fig. 1. Equivalent circuit diagram for Cuk converter

The Cuk converter works in both buck & boost mode. The operation of Cuk converter in DCM is studied in this section [11], [12].

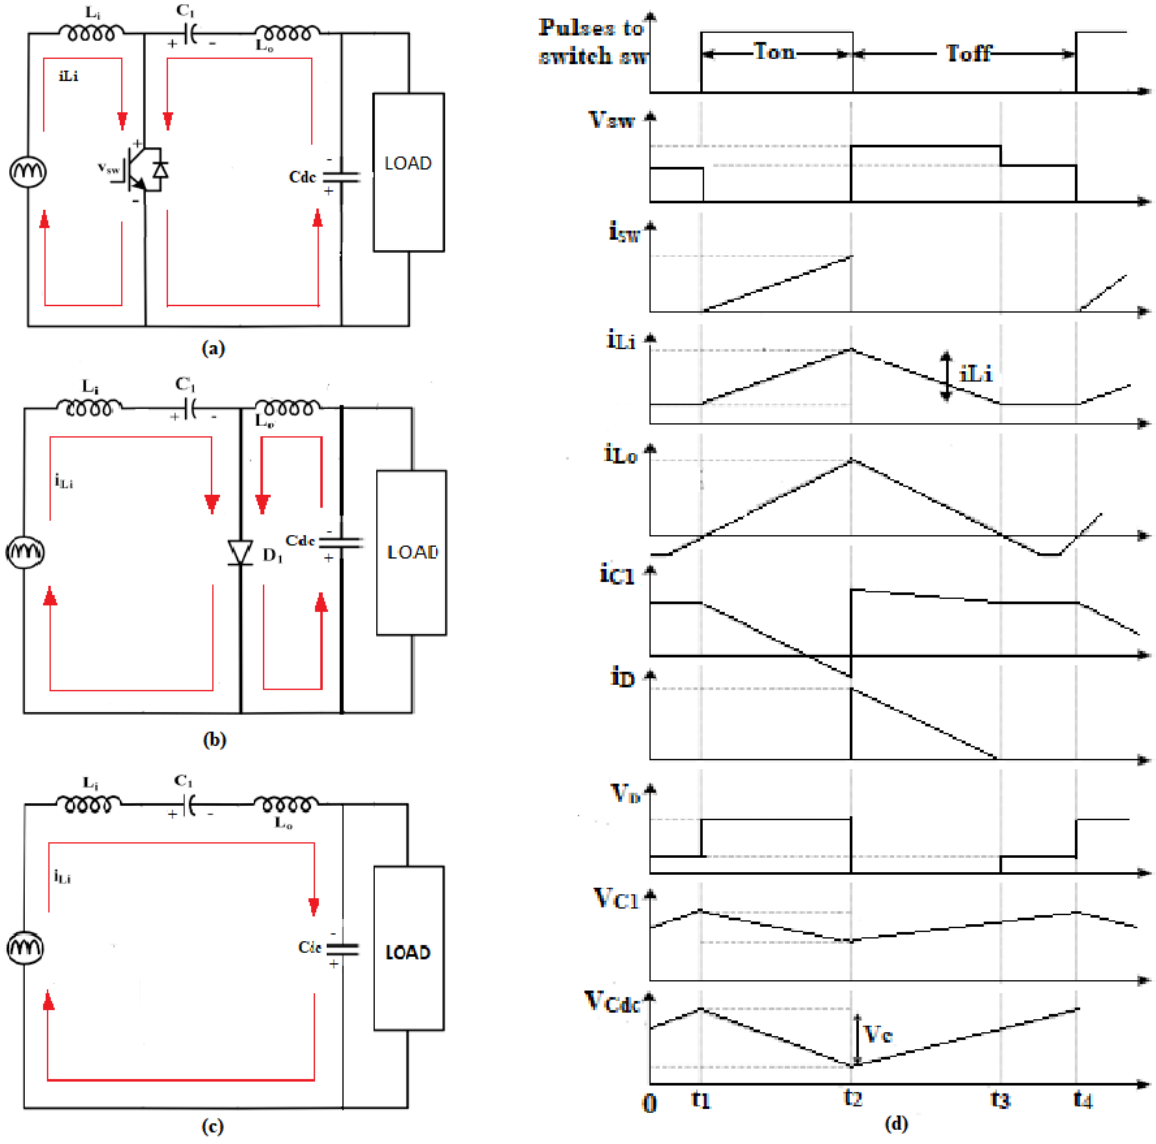

Fig. 2. Operation of Cuk converter when (a) Switch is on, (b) Switch is off, (c) Freewheeling period, (d) Related voltage & current waveforms

Fig. 1 shows equivalent Cuk converter which provides enhanced power quality at input side & precisely regulated DC output. It is known as ideal current shaper as input current shaping is inherent & DC output voltage controller decides duty cycle.

The complete switching cycle of converter is described in three different modes given in fig. 2 [13].

A. *Mode I* $(t_1 - t_2)$:

In this, switch is on (fig. 2a) in which energy from source (v_s) is transferred to input side inductor. The capacitor (C_1) discharges & energy is transferred to output side inductor (L_o). The input side inductor is used for continuous current conduction & short-circuit path is provided for capacitor current.

B. *Mode II* $(t_2 - t_3)$:

Fig. 2b shows second mode in which switch is turned-off & diode starts conducting. The intermediate capacitor absorbs the energy stored in input inductor (L_i) & output side inductor transfers it to output capacitor. The zero output inductor current is takes place at end of this mode.

C. *Mode III* $(t_3 - t_4)$:

The switch remains off in third mode as shown in fig. 2c and small current freewheels through output side inductor.

III. CONTROL IMPLEMENTATION

The closed-loop control of DC-DC converters is essential to maintain power quality at AC mains during transient in addition with steady-state operation. Here, two control schemes

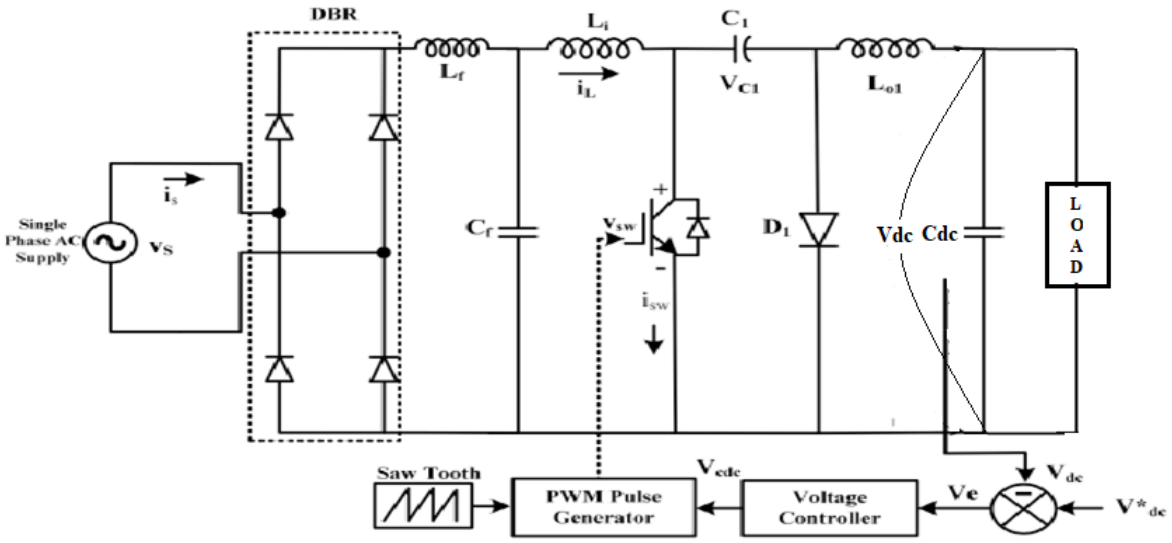

Fig. 3. Circuit diagram of PFC Cuk converter with conventional control scheme

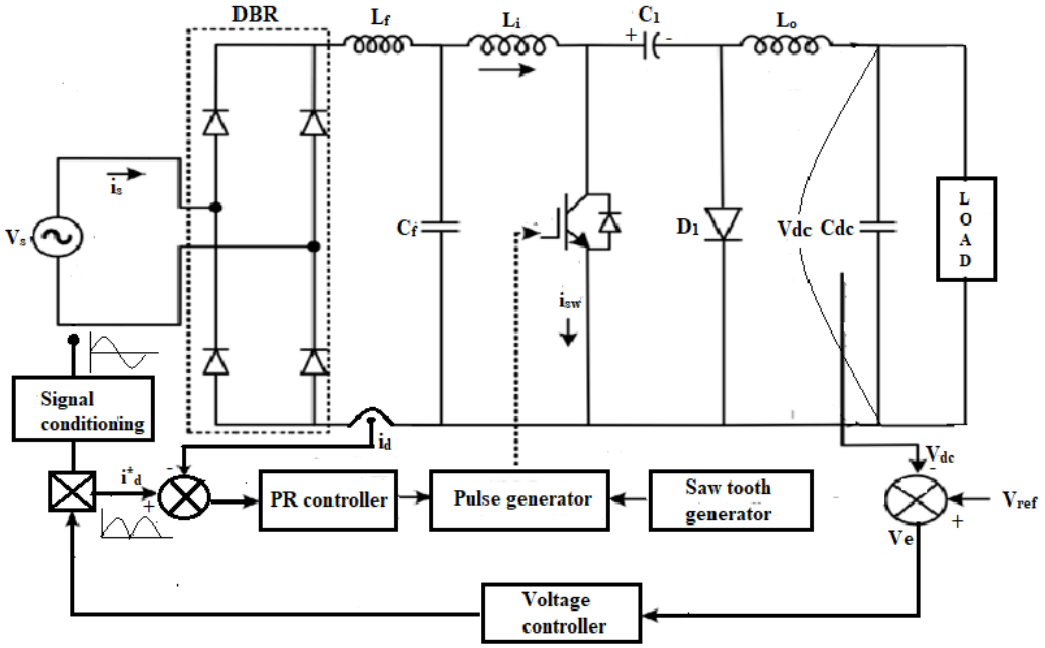

Fig. 4. Proposed control scheme for PFC Cuk converter

are reported to meet this requirement [14]. The proportional controller is chosen as inner loop controller to make system response faster. The implementation of conventional PI controller & proposed PR controller are discussed in this section. The PI controller does not track reference current in absence of steady-state error, hence proportional resonant controller is employed which introduces gain at resonant frequency & null gain at other frequencies.

A. PI implementation for Cuk converter

The Cuk converter with conventional PI implementation is as in fig. 3 in which DBR is used to provide rectified DC output as input to LC filter [15]. It keeps switching harmonics under control and puts limit on it from entering to system. The switching signal is generated by sinusoidal PWM method where DC-link output voltage is compared with reference voltage & obtained error signal provided to proportinal integral controller. The saw tooth carrier frequency of 20kHz is compared with PI controller output which generates PWM

signal. Both the signals are compared in PWM pulse generator to get switching pulses. This is most commonly used control method.

B. PR implementation for Cuk converter

Fig. 4 shows proposed control scheme of Cuk converter with PR controller. The principle of PR controller depends upon second order generalized integrator concept. The internal model control is applied to derive TF of PR controller, given as (1) for ideal PR controller in fundamental frequency. To avoid stability issues associated with this, the non-ideal PR controller is implemented as (2) by adding damping, where ω_c can be extended to control bandwidth. A value of ω_c is between 5-15 rad/s. The K_p is proportional gain to determine dynamics of system and tuned in conventional way while K_i is integral gain. The higher value of K_i is selected for the higher capability of PR controller to track the current reference [16].

$$G_{PR}(s) = K_p + \frac{2K_i s}{S^2 + \omega^2} \tag{1}$$

$$G_{PR}(s) = K_p + \frac{2K_i \omega_c s}{s^2 + 2\omega_c s + \omega^2} \tag{2}$$

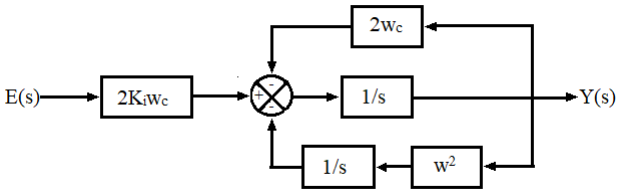

Fig. 5. PR controller implementation

The implementation of proportional resonant controller is shown in fig.5 where upper feedback path can be removed to obtain (2). Also, the system stability has great significance to make sure that controller is working within its stability region. The major part in stability analysis of controller having importance are gain margin & phase margin. The unstable point for gain margin is at 0dB while that for phase margin is at -180^0 [17].

The frequency response of (2) with Kp = 15, Ki = 400 and cut-off resonant frequency, ω_c = 10rad/s is given in fig. 6, where resonant peak has finite gain of 50 dB. The resonant term itself in proportional resonant controller exhibits an infinite gain at AC frequency & no phase shift for remaining frequencies. The study demonstrates that, higher the gain & phase margin better is the stability of system. The infinite gain margin means, the system at no time becomes unstable in future, even for the continuous increase in gain. This resonant peak can eliminate the voltage tracking error. The frequency response changes as the values of Kp, Ki or ω_c changes [18].

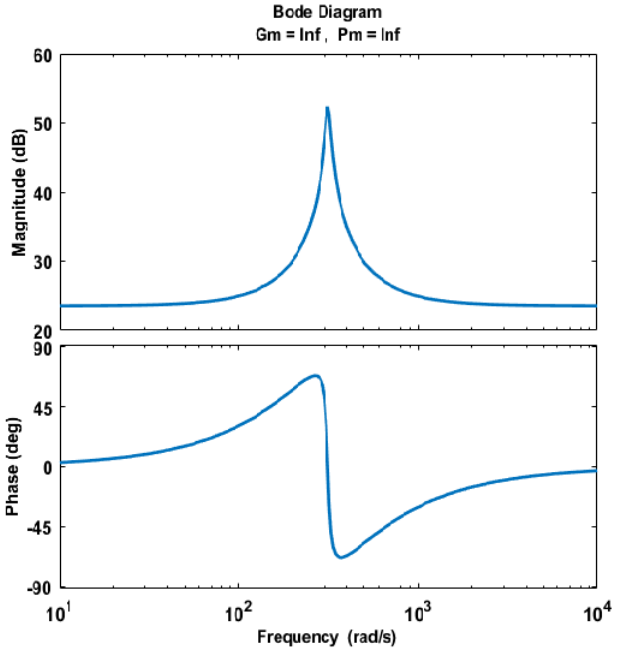

Fig. 6. Frequency response of non-ideal PR controller

IV. Simulation Results

The behaviour of both control schemes are investigated using MATLAB/Simulink with various system parameters. The selection of components for this converter is necessary to obtain enhanced power quality & DC output. The simulations are performed with 220 Volts, 50 Hz supply voltage having 100 ohm resistive load. The converter circuit & controller parameters are listed in Table-I.

TABLE I
SYSTEM PARAMETERS

Sr. No.	Symbol	Parameter	Value
1	v_s	Supply voltage	220V
2	L_f	Filter inductance	4mH
3	C_f	Filter capacitance	330nF
4	f_s	Switching frequency	20kHz
5	L_i	Input inductor	5mH
6	C_1	Inter-mediate capacitor	660nF
7	L_o	Output inductor	400μH
8	C_{d3}	DC-link capacitor	2200μF

The converter has been studied with both the controllers viz., PI controller & PR controller and results are presented in fig. 7 & fig. 8 for DC output voltage. It can be illustrated from fig. 7 that output voltage have some oscillations for some time for PI controller but it comes out to be smooth curve as in fig. 8 using PR controller. It is very clear from the above results that PR controller gives ripple free output voltage.

As per above discussion for power quality improvement, the THD should be under permissible limit given in IEC 61300-3-2 standards. Fig. 9 & fig. 10 shows, FFT analysis for source current THD of converter for both control implementation. The total harmonic distortion of converter source current is

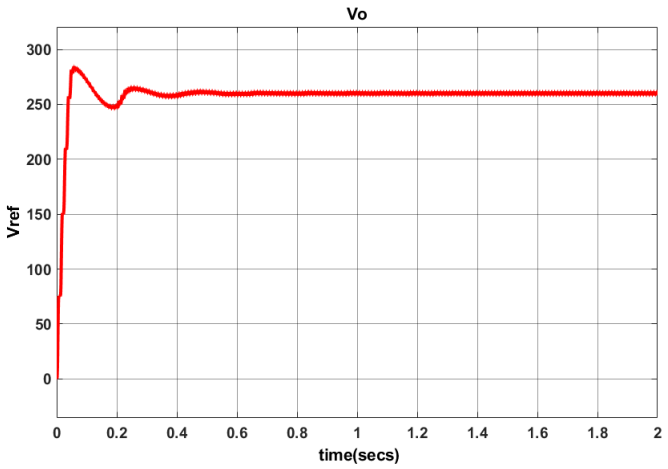

Fig. 7. Output voltage of controller with PI controller

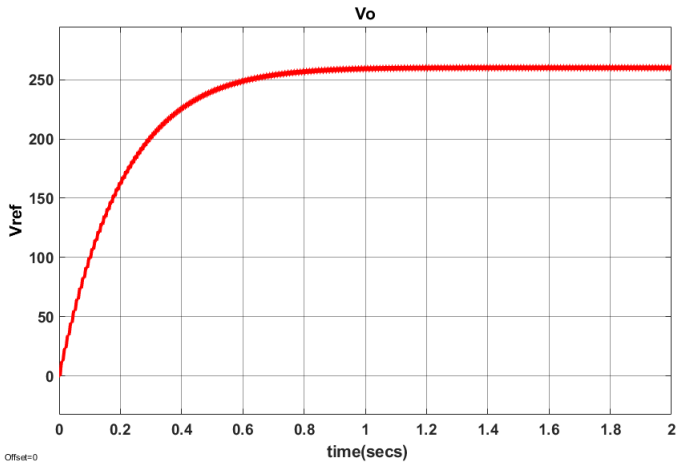

Fig. 8. Output voltage of controller with PR controller

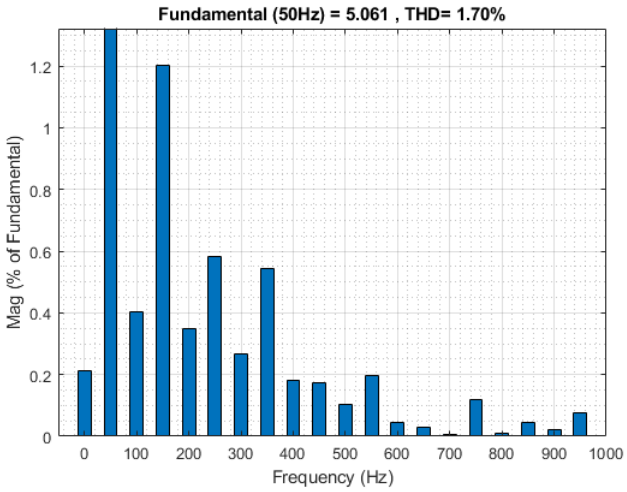

Fig. 9. FFT analysis of source current with PI controller

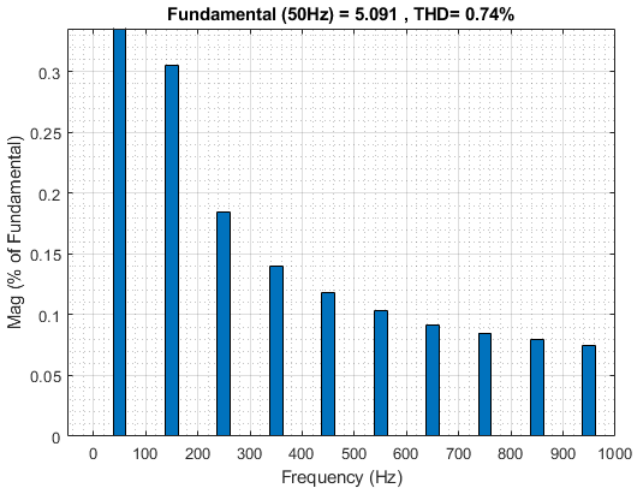

Fig. 10. FFT analysis of source current with PR controller

1.73% with conventional PI controller while it is 0.74% with PR controller. The results are graphically presented in fig. 11, PI controller curve shows that THD goes on decreasing upto the point where input voltage becomes equal to the reference voltage while for PR controller it decreases gradually for increasing reference voltage. Hence use of PR controller offers best power quality as compare to PI controller for Cuk converter.

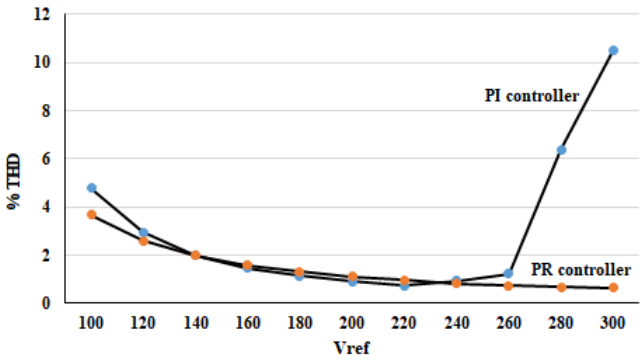

Fig. 11. Comparison for THD simulation results of Cuk converter with PI controller & PR controller

V. CONCLUSION

The suitability of PR controller for closed loop control of Cuk converter is discussed in this paper. The converter can be considered as suitable topology for many applications. The simplicity in implementing the current controller is advanced by use of PR controller and also current tracking capability is ensured. The theoretical analysis shows that proportional resonant controller has advantages as compared to proportional integral controller & it enables control system to adopt higher performance. It also shows that PR controller gives good transient response. The source current THD is less for PR controller as compared to PI controller.

***Abstract*—This paper proposes an efficient and novel approach for non-invasive diagnosis of Chronic Kidney Disease (CKD). A novel sensing module for CKD diagnosis is designed and developed in the proposed work. The concentration of urea in the saliva sample is measured for detecting the disease. A Convolutional Neural Network-Support Vector Machine (CNN-SVM) hybrid deep learning model is implemented for making predictions by extracting and classifying the features from the sensor response. Experiments are conducted to test the proposed model with real-time samples and to compare its performance with conventional CNN. The experimental results indicate that the proposed model outperforms traditional data classification techniques. The proposed hybrid model achieved a prediction accuracy of 96.59%.**

***Index Terms*—Ammonia sensor, Chronic kidney disease, Convolutional neural network, Deep learning, Support vector machine.**

I. INTRODUCTION

Commonly, the blood test is used for the diagnosis of kidney disease. A blood test for CKD diagnosis will measure the urea or creatinine levels in the serum [1], [2]. Urea and creatinine levels in the serum will be elevated when the kidneys are not functioning adequately. Since blood extraction is an invasive technique, it will obviously cause pain and discomfort to the patients. Non-invasive and minimally invasive disease detection methods are gaining importance nowadays. Saliva is gaining popularity as an effective bio-fluid in the diagnosis of diseases. Recent studies have shown a positive correlation between urea and creatinine values in the saliva and serum [3], [4]. The results of these studies show that it is possible to detect CKD by monitoring the salivary urea or creatinine levels [5]. Saliva-based disease diagnosis is advantageous as it is easily available, and it can be collected non-invasively, using simple equipment.

In our pilot study, salivary urea is monitored to detect kidney disease. There are several methods available to measure salivary urea concentration clinically. However, for an end-to-end real-time detection application, the clinical detection techniques wont be suitable. In this work, we describe a novel method to monitor salivary urea levels. We have followed the enzymatic reaction which transforms the urea in saliva into ammonia gas. A sensing module is developed for carrying out this enzymatic reaction, and to measure the ammonia gas. The amount of ammonia gas produced will be proportional to the urea concentration.

Furthermore, in this work, we present a novel CNN-SVM hybrid network algorithm for automatically analyzing the sensor response to make predictions. The CNN network is commonly used in image and video recognition, language processing and in recommender systems [6]–[8]. The reason for choosing CNN network is because of its ability to extract the target features from the sensor response automatically. As SVM is more accurate in classifying the samples, it is used along with the CNN network in the proposed network [9], [10]. Although CNN is designed to process pixel data, it can also be used to process signals in 1-dimension (1-D). More recent works have attempted to use CNN for analyzing 1-D signals [11]–[14]. The 1-D CNN version of the CNN algorithm was first introduced for analyzing ECG signals by Kiranyaz et al. [11]. They have employed the CNN network for real-time classification of ECG signals. Recently Lekha et al. [12] developed a novel 1-D CNN architecture for detecting and classifying diabetes non-invasively. Ince et al. [13] have employed the 1-D CNN algorithm for detecting faults in the motors. Further, a study conducted by Acharya et al. [14] demonstrated the use of 1-D CNN for automated detection and classification of seizure using EEG signals. These papers in the literature suggest that the CNN network can be modified and applied for analyzing 1-D signals. As the sensor response in our study is a 1-D signal, the proposed hybrid model is designed to analyze 1-D signals.

The rest of this paper is structured as follows: Section II gives an overview of the proposed hybrid model. The methodology of the work is explained in section III. The experimental results and performance of the proposed approach is presented in section IV. Finally, the conclusion of the study is reported in section V.

II. CNN-SVM DEEP LEARNING MODEL

CNN network is a class of deep artificial neural network. The artificial neural network is derived from the design of the biological neural network. The key part of the artificial neural network is the artificial neurons. The neuron model involves multiplication, summation and activation functions. All inputs will be multiplied with the corresponding weight. The summation function sums up all the weighted input and bias, and the added inputs will be passed through an activation function to produce the output. A CNN deep learning network

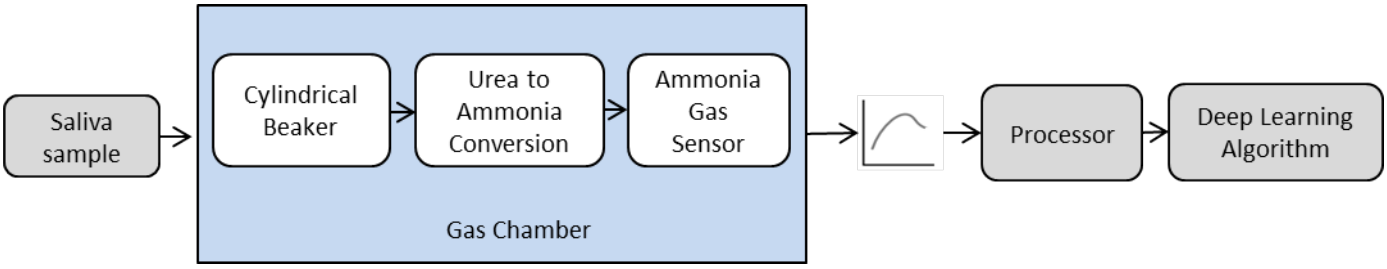

Fig. 1: Block representation of the overall system

consists of convolution layers and fully connected layers as in the multilayer neural network [15], [16]. The fully connected layer makes the final predictions.

The convolution layer performs convolution and subsampling operations. First, it convolves the kernel and the input signal. Then, it performs subsampling operation to reduce the signal dimension. These two operations are repeated for getting the reduced feature map from the signal. The convolution operation can be mathematically represented as:

$$F(n) = z(n) * k(n) \tag{1}$$

$$F_i(n) = z(n)k(1) + z(n-1)k(2) + ... + z(0)k(n) \tag{2}$$

where z and k represents the input signal and kernel filter.

After the convolution operation, a subsampling operation is performed on the convoluted signal. This will reduce the dimension of the feature set. A max-pooling subsampling operation is applied in the proposed work [17]. The max-pooling technique will divide the feature maps into multiple segments and will extract the maximum value from each segment. The maximum value is obtained as:

$$F_i = Max(F_i^*) \tag{3}$$

where F_i is the subsampled feature set.

The conventional CNN is incorporated with fully connected Multilayer Perceptron (MLP), which performs the classification task [18], [19]. In the proposed network, a more efficient SVM classifier is used instead of MLP. SVM is a better classifier compared to MLP, and it can provide better classification accuracy. The SVM classification function is given by:

$$F(x) = z_i w - b_i \tag{4}$$

where z_i represents the input to the classifier, w is the weight vector and b_i is the bias.

The input data is classified with respect to the defined maximum-margin hyper-plane based on the conditions:

$$z_i w + b_i > 0, C_i = 1 \tag{5}$$

$$z_i w + b_i < 0, C_i = -1 \tag{6}$$

where C_i represents the class label.

The margin is represented as:

$$margin = \frac{1}{\parallel w \parallel} \tag{7}$$

The training issue in the SVM classifier is considered as an optimization problem. For classifier optimization, the hyper-plane is estimated by reducing $\|\mathrm{w}\|$. Minimizing the value of $\|\mathrm{w}\|$ will increase the margin. For solving the optimization problem, the Lagrange multiplier is adopted. This is defined as:

$$L(w, b_i, \alpha) = \frac{w^2}{2} - \sum_{i=1}^{n} \alpha_i C_i z_i w + b_i \sum_{i=1}^{n} \alpha_i C_i + \sum_{i=1}^{n} \alpha_i \tag{8}$$

where α symbolizes the Lagrange multiplier.

Once the optimum Lagrange multiplier α_i^* is obtained, the optimal weight vector can be computed by:

$$w^* = \sum_{i=1}^{n} \alpha_i^* C_i z_i \tag{9}$$

The bias is updated as:

$$b^* = 1 - w^* z_i \tag{10}$$

The hyper-plane classification function in SVM classifier is:

$$F(x) = \sum_{i=1}^{n} \alpha_i C_i (z_i, z) - b_i \tag{11}$$

When the training data is not linearly separable, then the optimization problem will not have a solution. In this case, the slack variables are introduced which identifies the misclassification rate. The optimization problem, in this case, is defined as:

$$minimize\ Q(w, b_i, \xi) = \frac{1}{2} \parallel w \parallel^2 + C \sum_{i=1}^{n} \xi \tag{12}$$

Here C symbolizes the regularization parameter which decides the balance between the training error and the margin size. For classifying complex data set, appropriate kernel functions are applied for transforming the data set. The classification function with kernel function will be:

$$F(x) = \sum_{i=1}^{n} \alpha_i C_i K(z_i, z) + b_i \tag{13}$$

where K represents the kernel function.

III. MATERIALS AND METHODS

A. Saliva Collection and Testing

For experimentation, we have collected saliva samples from 98 participants. This includes 48 CKD patients with Glomerular filtration rate (GFR) less than 90 mL/min, and 50 healthy

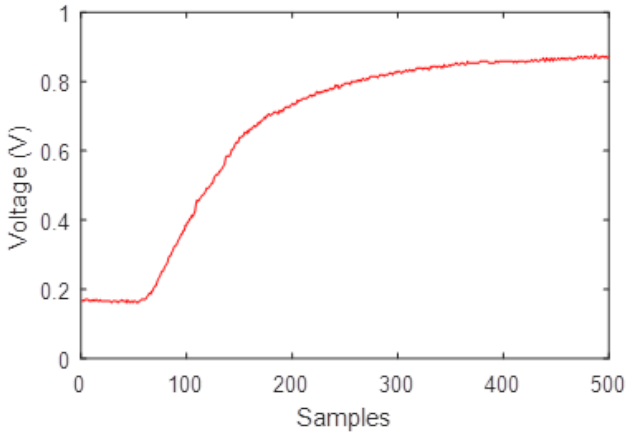

Fig. 2: Analog voltage response of the gas sensor for a test sample

individuals with GFR more than 90 mL/min [20]. We have collected 2ml of the sample in a sterile graduated test tube. The experimental analysis is carried out in accordance with the ethical guidelines of the Declaration of Helsinki.

The experimental testing is done with a novel detection method. The block representation of the overall system is illustrated in Fig. 1. The block diagram consists of a gas sensing apparatus chamber, an Arduino controller processor board and an MQ-137 ammonia gas sensor which is placed inside the gas chamber. Urea in the saliva sample is first transformed to ammonia using the traditional urea hydrolysis process [21], [22]. This conversion process involves urease enzyme which is responsible for urea conversion. Urease enzyme is placed inside the apparatus chamber in a small beaker. The saliva sample is dropped to this urease enzyme breaker through the inlet valve of the chamber. This enzymatic reaction produces ammonia gas. The MQ series ammonia sensor then measures the produced ammonia gas [23], [24]. The ammonia gas generated will be proportional to the urea concentration in the sample. In this conversion process, some amount of ammonia will be converted to ammonium ions as the testing sample here is a liquid. These ammonium ions can be converted to ammonia gas by increasing the pH of the solution. This can be done by adding a small amount of NaOH to the mixture. Output response from the gas sensor is received using the Arduino controller board. Sensor programming of the analysis is written in Matlab. The sensor reading is collected and recorded for 500 samples. Fig. 2 shows the analog voltage response of the gas sensor for a test sample in Matlab software. The snapshot of the sensing module is shown in Fig. 3.

B. Feature Extraction and Classification

The features are extracted and classified using the proposed CNN-SVM hybrid network. CNN performs the feature extraction operation and SVM performs the classification task. The analog voltage signal from the sensor is first convoluted with the kernel. A Gaussian kernel is used in our analysis [12]. The

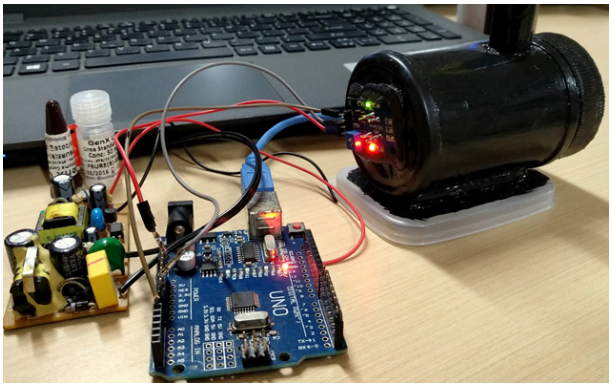

Fig. 3: Photograph of the sensing module

TABLE I: PERFORMANCE COMPARISON TABLE

Performance Parameters	Conventional CNN	Proposed Model
Accuracy (in %)	94.97	96.59
Sensitivity (in %)	93.33	94.59
Specificity (in %)	96.15	98.03
Precision	0.945	0.972
False Positive Rate (FPR)	0.038	0.019
False Negative Rate (FNR)	0.066	0.054
Negative Predictive Value (NPV)	0.952	0.961
False Discovery Rate (FDR)	0.054	0.027
F1 Score	0.939	0.958
Matthews Correlation Coefficient (MCC)	0.896	0.93

convolution of input and kernel will produce the convoluted signal:

$$F_i(n) = \sum_{i=-x}^{x} z(i+1)k(y-i+1) \tag{14}$$

where x represents the length of the input signal z and y represents the length of the kernel k.

The convolution operation is followed by max-pooling subsampling operation which reduces the size of the feature map. The proposed deep learning network has six convolution and sub-sampling layers. After repeating these two operations for six times, the reduced feature set is obtained.

The CNN network will extract the best features from the sensor signal. Further, these features are classified for predicting the output. For classification, we have employed an SVM classifier. We have implemented SVM with a Radial Basis Function (RBF) kernel [25]. The SVM classifier with RBF kernel has the classification function:

$$F(x) = \sum_{i=1}^{N} \alpha_i C_i \; exp \frac{(- \parallel z_i - z \parallel^2)}{2\sigma^2} + b_i \tag{15}$$

where σ is kernel width.

IV. RESULTS

Kidney disease is considered as a dangerous disease because once it is affected, it is impossible to overhaul the damage caused to the kidney. People die of CKD mainly due to limited medical facilities. In the proposed work, we have introduced an efficient method to detect CKD using simple hardware sensing module and deep learning technique.

In kidney patients, the urea concentration levels will be more. When the kidneys are affected, they fail to remove the urea levels out of the body. We have analyzed the sensor response by taking the samples from patients under different stages of kidney disease. In our analysis, we have observed higher voltage output values in CKD samples. This is because of the elevated urea levels in the CKD samples. As urea concentration is more in CKD samples, the ammonia gas produced inside the gas chamber will be high. This leads to a higher voltage output. We have observed a voltage level of 0.93V and above for CKD samples. The voltage values were below 0.93V for healthy samples.

A. *Performance Evaluation of the Hybrid Learning Model*

The output voltage signal from the sensing module is applied to the proposed hybrid learning algorithm for automatically predicting the output. The simulation results show that the proposed 1-D CNN-SVM hybrid algorithm can successfully classify the samples. The CNN network extracted the optimal features from the sensor output signal. These are then classified using SVM. For validation, a 10-fold validation approach is employed [26]. In this work, we have further implemented a conventional CNN network for comparing the performance of our proposed CNN-SVM hybrid network. The proposed CNN-SVM hybrid model and the conventional CNN network is analyzed with the same sensing module to detect kidney disease. The performance values obtained for both these networks are shown in Table I. The proposed CNN-SVM hybrid model achieved a prediction accuracy of 96.59%, which is more than the accuracy achieved by conventional CNN. The introduction of SVM classifier significantly improved the overall performance of the proposed network.

We have also evaluated the computational speed of the two algorithms. The total computational time includes the time consumption for extracting features and feature classification. Fig. 4 illustrates the computational time of the algorithms. The programming and simulations are carried out in an Intel Core i5-7200U 2.5 GHz base processor laptop with 4GB DDR4-2400 RAM. Conventional CNN has taken 1.196s for overall computation, whereas the proposed model has taken only 1.178s. The time consumed for feature extraction is almost the same for both the algorithms. However, the proposed hybrid model outperformed convention CNN in terms of classification speed. For feature classification, the conventional CNN algorithm has taken 0.783s, whereas the proposed algorithm has taken only 0.767s. The feature extraction speed is 0.4135s and 0.4113s for conventional CNN and proposed CNN-SVM deep learning algorithm respectively.

The performance of the model is also analyzed by evaluating the Area Under the Curve (AUC) value, which is obtained by plotting the Receiver Operating Characteristic (ROC) curve [27]. The ROC curve is the plot of sensitivity against 1-specificity, for different possible cutoff test values. The AUC value shows the ability of the model to classify the samples as 'healthy' or 'diseased'. The ROC plot is shown in Fig. 5. We have obtained the AUC values of 0.947 and 0.931 for the healthy and CKD samples.

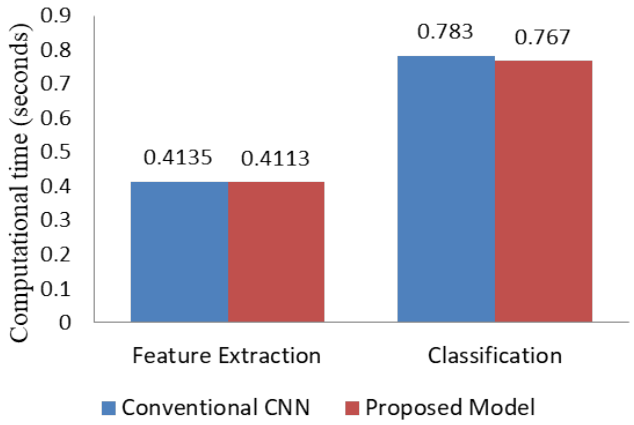

Fig. 4: Computational time comparison

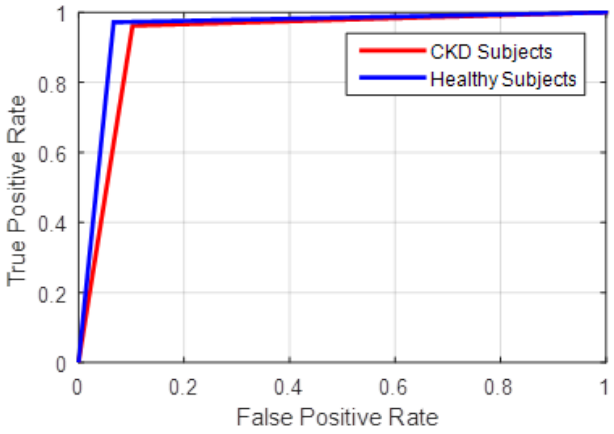

Fig. 5: ROC curve for the proposed model

B. *Clinical Validation*

The proposed sensing approach classified 45 samples as CKD patients and 53 samples as healthy subjects. To verify the results, we have carried out the clinical test to determine the GFR values of the participants. The GFR test is the gold standard used to identify kidney patients in clinical practice. The proposed model misclassified only three samples. The test results are validated by the medical professionals.

V. CONCLUSION

This paper proposes a novel approach for automated detection of CKD from saliva samples. A CNN-SVM hybrid deep learning network algorithm is developed for implementing the proposed sensing model. This network algorithm is computationally fast and efficient as the features are extracted automatically from the signal. The proposed model achieved remarkable results with a prediction accuracy of 96.59%. As the sensing approach we used in this work in new, we have validated and compared the output results with traditional clinical CKD detection method. The validation result and our experimental results are well correlated. This shows that the proposed approach can be used for monitoring and detecting CKD more effectively. In this study, we have focused on

enhancing the performance of the traditional CNN network by modifying the classification layer. We look forward to upgrading the performance of the proposed architecture by improving the feature selection and pooling part in the future. The proposed approach can be applied to further domains, by using appropriate sensors.

***Abstract*-Wireless Sensor network has enhanced in extensive applications like sensing environment, area monitoring, threat detection. At the point when the node communicates with its neighboring nodes, it influences the system lifetime hence developed into huge utilization of energy. Data aggregation strategies have been used mainly to diminish the consumption of energy by curtailing the quantity of messages where it is migrated from the source node to the sink node. Since applications of wireless sensor network is increasing in a rapid speed it is essential to consider the security of the network. In a hostile environment, wireless sensor network is deployed the sensor nodes would be susceptible to security issues thus it would become critical. The data aggregation approach is used mainly used to protect the data, this is done by using like asymmetric protocol like RSA encryption. By using the various security issues has been preserved in data aggregation. Hence the proposed scheme secures and aggregates data in wireless sensor network there by improving the energy efficiency and communication overhead.**

Keywords: Data Aggregation, RSA, WSN,Energy Consumption

I. INTRODUCTION

Wireless Sensor Network is an extensive technology incorporated of immense quantity of sensor nodes which also includes the base station. The aspect of sensor node is to retrieve the information from the physical surroundings and accumulates and impart it to the base station. The applications in WSN which include hospital monitory, military surveillance which supervise the environmental conditions[1]. Because of the establishment of sensor nodes in an invulnerable circumstance, it is not easy for restore and compensating the batteries. The priority of WSN is to make the network lifetime to be enlarged[2].

The sensor network usually contains two types of nodes i.e. parent node and sensor node. Therefore can infuse inquiries in the network and also accumulate the outcome in the sink node, this should be possibly done in the event that anybody needs the data from the network. Data gathering is the process of assembling the recognized data from various sensor nodes that are dispersed to the main station for further handling. Hence, it is inadequate for the sensor network to impart the information straightforwardly to main hub due to these motes are resource constraint. In comprehensive network, the data created is commonly enormous for the base station. However, it is essential to consolidate and compress the information at the aggregator nodes which in the long run discard the abundance data that is sent to the main hub bringing about utilizing energy. This is adequately knowledgeable by Data aggregation. It is the coarse of collecting information from the network to remove the undesirable conveyance thus give grade data to the main hub.

WSNs are characterized into two kinds in terms of secure aggregation i.e End to End and Hop by Hop encryption. In former base station can only have the privilege to access the data and also privacy assures only in the sink node[3]. But the aggregator nodes does not have the privilege to gain proficiency with the keys that are shared among children and aggregator nodes (source and sink nodes).The type of encryption used in the proposed system is hop by hop encryption is utilized when all the sensor hubs are in the faith. Here the key imparting to the parent node arouse the complexity in the key management. It constitutes a model of data security than the former one[4].

II. RELATED WORKS

There are wide range of diverse techniques which makes to sure the preservation of the network. There are different techniques that has referenced in survey mostly used to secure protection of the source data.

PDKP [5] primarily depends on the data and key security in WSN. By utilizing this method it doesn't disclose the key and information to different nodes in the system. The aggregation function used is Sum which is also known as additive aggregation function. This Framework apply homomorphic encryption where it mainly accomplish confidentiality of data. The disclosure of data is less in this method. In proposed system time taken to process the data packets is less than compared to PDKP method.

PEPPDA[6] is an aggregation method which accomplishes non conceded data accumulation . Hence sensor nodes in the network attack recurrence would get decreased.The sink node obtain the result from its children nodes thereby diminishing the communication overhead. The principle aim is to provide a reserved data aggregation thereby guarantees security, validness and novelty of identified data and furthermore confidentiality of the gathered data by not showing a tremendous overhead. It uses slicing and mixing operation to ensure good accuracy, robust key and aggregating the data securely. The final aggregated result of integrity checking mechanism is missing in this scheme.

SEEDA[7] which is mainly used to curtail the messages that is transmitted to base station inorder to advance the network lifetime In order to achieve the data security it employs end to end type of encryption. It permits the aggregation on the ciphertext by employing homomorphic encryption. Thereby lessening the data packet that are transmitted because it does not include the data about the non acknowleged nodes. This scheme employs significant overhead where as in the proposed system the significant overhead is less.

H.S Annapurna et.al[8], it recommended a method called Fault Tolerance for systems that offers end to end privacy also adaptation to non-critical failure during data aggregation. Here the network is suffering from faults that may arise because of various motives along with communique communication failure, non functioning of hardware and software resources. It would result in a lessen the network lifetime and also hazardous effects in critical utility contexts. It proposes to apply shared cryptography to verify message correspondence. One of the most important codemn restoration method is the misuse of redundancy.

SDAP [9] employs hop by hop encryption and each group have one aggregate.It is primarily stationed by the concepts of divide-and-conquer and commit-and-attest. By using the latter method, aggregation is divided into association. The aggregates is confirmable by the main hub using commit and attest principle. The proposed method doesn't depend on the number of shares hence packet processing time is faster than SDAP.

III. BACKGROUND

Data aggregation which uses the consolidated information from various sensor nodes and its children nodes disseminate the gathered data to base station. Fig.1 shows the data aggregation process and its architecture. By using data aggregation algorithm such as centralized approach such as LEACH, TAG the aggregated data can be obtained. The type of data structure used in the proposed scheme is Tree based. This collected information is transmitted to the base station (sink node).

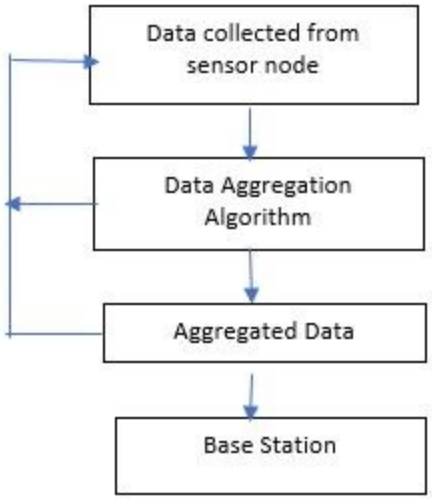

Figure 1 : Data Aggregation Process

There are different types of aggregation methods are employed,they are Centralised , In-Network aggregation, Tree Based Approach and Cluster Based Approach. In centralised approach.

In order to afford a secure communication in the sensor network it is necessary to satisfy few conditions. The necessities like availability, confidentiality, integrity and authentication. They provide guarantee to the data that is broadcasted in the network.

1) *Data Confidentiality*: When the data streams through many intermediate nodes the chances of data discharge is more. Hence it is necessary to implement data confidentiality when the encrypted content of data is utilized in such away that the data is decoded in different form.

2) *Data Integrity*: When the receiver receives the data for the first time it should not make attempt to alter the data. The assaulter changes the original content of the data mainly due to the physical environment conditions. At any point of time the assaulter can alter the data and send it to the receiver.

3) *Data Freshness*: When a message is broadcasted in the network each messages should be new and should not replay the old messages in the network. This is efficiently done by providing a time counter to each nodes to make sure that the data is new for each session.

4) *Data Availability:* Data Availability indicates even if there is assaults happens in the network, all the services should be available.

5) *Data Authentication:* It is the process in which the sink node should receive the correct data. Hence the

receiver node should do the verification process that it should receive the data from the authenticated node and should make sure should not receive the data from the malicious node.

IV. MODEL ARCHITECTURE

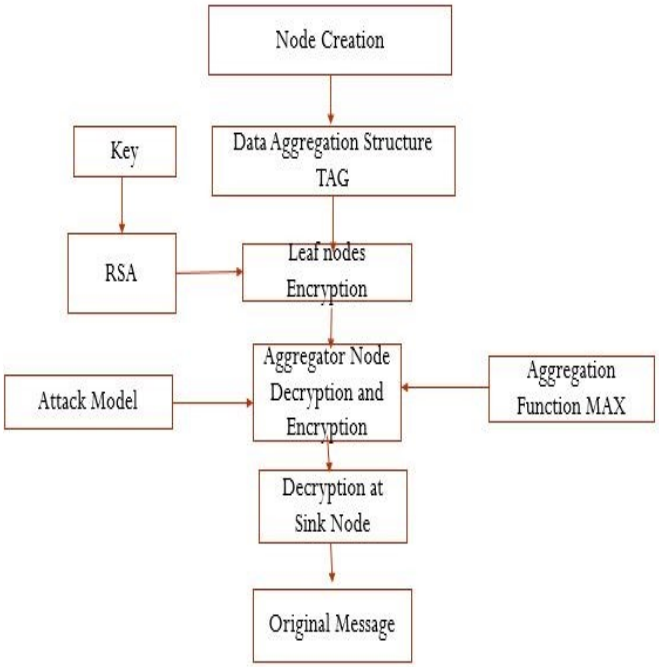

Figure 2 : System Architecture

The proposed system comprising of four modules which is shown in Fig.2 which is the proposed system architecture.

A. Network Module

The system comprises of countless compelled sensors, where as the base station is in a multi hop way. Three kinds of hubs are available in a WSNs; these are Base Station , Aggregator node and Sensor node. The children nodes is in charge of encoding the detected information and sending the aftermath to its intermediate node. Aggregator node is in charge of encoding the detected information and accumulating accepted information and forward its new outcome to its parent hub. Base Station receives the amassed outcome from various nodes.

B. Data Aggregation Structure

The data aggregation structure used is Tree Based approach[10]. This methodology characterizes from establishing the tree. Type of tree used is minimum traversing tree, central station grant as the root node and sensor hub grant as child nodes. The type of aggregation used is Tiny aggregation.

C. Secure Key Distribution and Encryption

The public key cryptography or asymmetric cryptography concocted an extreme difference in ideal models. Every sensor will figure its public/private key pair and communicate its public key to all hubs inside the system. In Key availability, the likelihood of one sensor hub finds a common key with its neighbor, is a significant factor to be considered in the key circulation plans. The type of encryption used is RSA strategy. In key generation, each node creates public key and its private key and provide two primes m and n and also prefer a integer k, gcd (k; Φ (n)) = 1. Thus node A public key is (n, k) and its private key is d. k and d are known as the encode operation and decode operation and n is modulus. For encryption B encrypts the A's message. It receive the node A's respective public key (n; k) and compute encryption and dispatch the result to A. For decoding it will get the plaintext by using the private key of the node A and does the decryption process.

D. Data Aggregation Approach

After the aggregation tree is constructed, the sink hub can spread keys to the hubs in the system. It comprises of various steps for aggregating the information, they are leaf hub encryption, encryption of intermediate node and sink node decryption. In request to aggregate the data, there are various sorts of data aggregation functions are used. The function used is max operation

E. Attack Module

Safeguarding considered as a basic worry of using the different utilizations in the network. The assailant will embrace different kinds of assault to crack the preservation of the information. The harm brought about by them fluctuates as indicated by the adversary model and system structure. There might be various potential assaults against a tree-based data aggregation protocol. One kind of assaults is behavior- based, in which the objective of an aggressor is to upset the ordinary task of the sensor organize. For instance, when a sensor hub in the tree is compromised, it can assault the fundamental routing convention, drop other hubs' readings deliberately, or cause refusal of message assaults to deny different hubs from getting communicate messages of the BS. The sort of assault that is utilized here is Blackhole assault which is executed in the aggregator hubs. An assault brought about by an outside foe on a subset of sensor hubs in a system is known as a black hole attack. The nodes are caught and re-customized by the adversary with the end goal that they don't transmit the data packets.

V. PROPOSED SYSTEM

The proposed framework utilized RSA encryption strategy is an public cryptosystem where the information are exchanged through powerful dynamic directing by time to time key esteem change securely and attack model is executed to check whether the data exchanged is verified or not.

A. Tree Construction

The type of structure used is Tiny aggregation which is a tree based structure. It is an information driven protocol, depends on a tree structure and explicitly intended for observing applications. The Fig.3 appeared above demonstrates that all motes are conveyed in the network. The base station send its id and level to the sensor motes as showed up in the figure. Right, when a center point D gets an impart notice first time from main hub S then F designates its level to be level of S plus one and allot its parent S. Then node F sends its level and id to all of its independent motes. Thus the path from children nodes to parent nodes have been constructed. This procedure is rehashed until every one of the motes have gotten the directive. The sink nodes sends question which it determines the amounts that it need to gather, and how there must be aggregated. After the tree development, the sink hub disperse the keys to every one of the hubs in the system.

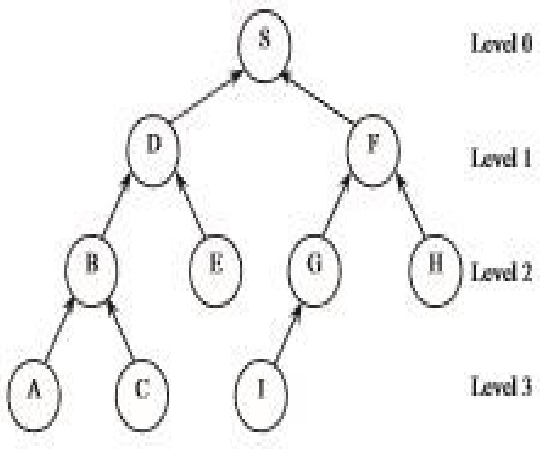

Figure 3: Structure of Tree using TAG

B. Encryption at Children nodes

The type of encryption used is RSA. Here the leaf node does only the encryption process. The children nodes broadcast the encode information to its intermediate mote even without gathering. When node A sends data to node B, the packet contains Identity of sensor node A and encryption process of node A.

$$c = m^e \bmod n$$

C. Aggregation at Aggregator node

The encrypted data in the leaf notes can be decoded uniquely by the central station. Aggregator node gets encoded information from children nodes which then decrypts and selects the max value by using aggregation function and send it to next aggregator node. This procedure proceeds for every one of the level in the tree till level 1.

D. Base Station Decryption

Base station gets the aggregated data which includes IDs of all the nodes. Committed sensor node is been identified by the base station.. To get original data it subtracts all nodes key in the system. The RSA decryption;

$$m = c^d \bmod n$$

IV. SIMULATION FRAMEWORK

It is carried out by employing Network Simulator-2 (NS-2). Ubuntu 16.04 is the Operating System. The framework where it is actualized is a 64 bit framework with Intel Pentium CPU and GB. The proposed technique has been implemented using different evaluation metrics like communication overhead and energy efficiency. The maximum packet size of the system is 100 bytes.

TABLE.1 SIMULATION PARAMETERS

Total Nodes	50
Total Frame Size	500 x 500 square meter
Transmission Range	200m
Time taken for Simulation	50 sec
Initial Energy	50J
Transmission Power	0.920J
Receiving Power	0.592J

V. PERFORMANCE ANALYSIS

A. Communication Overhead

Correspondence overhead is the quantity of information produced in the sensor network. The quantity of information expands corresponding to the quantity of motes in the network. Here one information in a sensor hub is encrypted and send to aggregator node and this encoded information are collected and send to the base station node. Communication overhead is plotted as time interval versus the number of messages. In this the number of messages is reduced by transferring the packet from low level nodes to high level nodes in the aggregation tree.

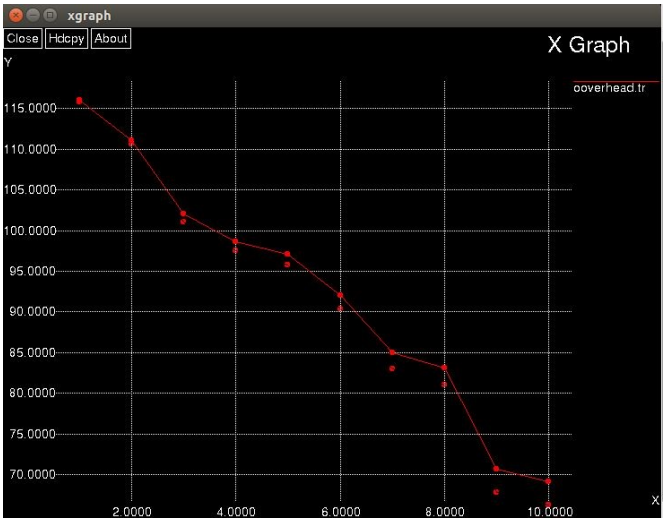

Figure 4 : Communication Overhead

B. Energy Efficiency

In this scheme the hop by hop encryption are employed. Here computational overload is less due to simple aggregation operations. The operation that is employed is Max operation. Here the information transmission and gathering requires more vitality of motes. Lessening the quantity of broadcasting fundamentally spare vitality of motes. From Fig. 5 energy efficiency of the motes increases after aggregation process.

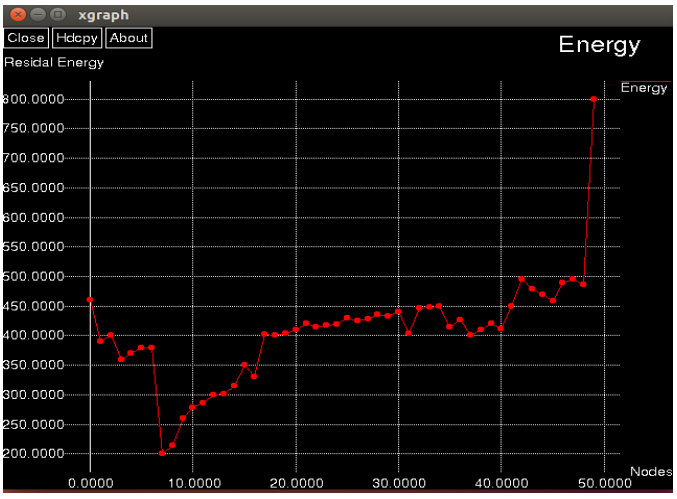

Figure 5: Energy Efficiency

C. Comparison Graph

The Fig.6 depicts the xgraph of data aggregation by using sum and max aggregation. From the pictorial representation it depicts that the time to process the data packets and complete the simulation is more in sum aggregation than max aggregation. Thus by using max processing time is efficient.

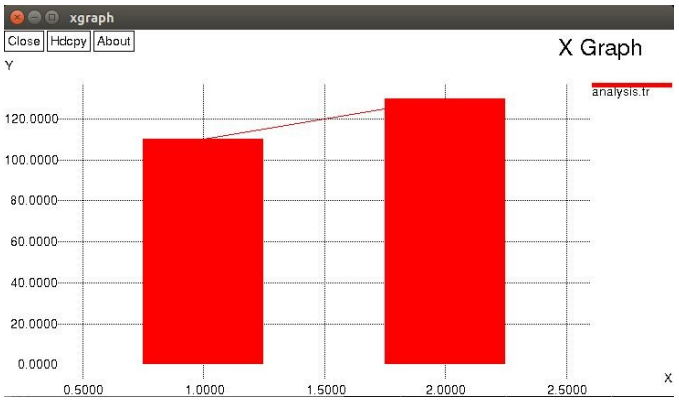

Figure 6: Comparison of MAX and SUM aggregation

VI.CONCLUSION

By utilizing data aggregation which brings about saving vitality and expands energy effectiveness, it additionally diminishes the quantity of transmissions in the system decreasing the data transfer capacity utilization and eliminating the superfluous energy utilization in the both transmissions and reception. Dependable and trustful information collection is required for every function in the network.

In this project, for securing the data there are key distribution and asymmetric encryption are employed. The kind of encryption utilized is RSA encryption. Hence time taken to process packets is less for max aggregation than sum aggregation. It additionally safeguards the different security issues, for example, data freshness, data trustworthiness, data secrecy in information total.

***Abstract*—The learning style can be referred to as the way a student prefers to acquire, process and retain information. The prominent learning style classification model is the VAK model. [1] According to this model visual, kinesthetic and auditory are the three major kinds of learning styles. Many research have shown that people prefer more than one way of learning, hence categorizing a person to just one of the above types as done in traditional methods is not accurate.[7] A method to identify our learning styles more accurately is required. Machine learning can be applied in this field to achieve our aim in the most efficient way. Once we have an accurate information about learning styles, we can use it to suggest career options. This research aims to predict the learning style combinations of students and suggest field of study using algorithms like k-means, SVM and decision tree.**

***Index Terms*—Machine Learning, auditory, visual, kinesthetic, Rule based system, k-means, SVM, Decision Tree**

I. Introduction

Choosing an appropriate field for higher studies is a complicated task. Most students require guidance in making the perfect choice. The domain of study of a student needs to suite not only the interest but also the learning style which will impart a way for career advancement. Even though there are many options that help in shortlisting career options, not many of them use learning style as one of the criteria for coming up with the choice.

Most of the traditional ways to identify the learning styles are predefined mathematical equations and patterns of questions that comes to a conclusion. It is not accurate because students prefer more than one mode of learning. The most widely accepted categories of learning styles are:

- Auditory
- Visual
- Kinesthetic

A student is said to be an auditory learner if he/she learns by listening. They tend to understand information in a better way when they hear it. These types of learners are comfortable with lectures, discussions and reading aloud. They get the idea after being told a couple of times since they are good listeners. They have a tendency to read aloud, this helps them in understanding the information in a better manner.

The main tool for a visual learner are their eyes, i.e they learn through vision. Visual learners benefit more from a live demonstration of how things are done. They require diagrams, flowcharts, presentations, etc for a better understanding of the information presented to them.

Kinesthetic learners are those who require hands-on experience to understand the concept. They like to be more involved in the processes that require their attention when compared to the other two types of learners. These learners require active learning methods like role-playing, hands-on workshops, practicals, etc for processing the information in a better manner.

Categorizing a student based on the above mentioned learning styles is not an easy task, because most students prefer more than one way of learning. For example, a visual learner might be interested in hands-on workshops. In such case a student can be considered as a kinesthetic learner too. In these type of situations, the traditional methods for identifying the learning style which are based on predefined equations and question patterns are less accurate. Thus it demands the possibility of the existence of combinations in learning styles. A student may exhibit more than one learning style. In order to find this combination of learning styles, we apply machine learning. We will be using the classification and the clustering to fit a learner into an appropriate class of learning style.

Clustering is an unsupervised machine learning technique. We used the k-Means clustering algorithm as it is an iterative algorithm, that tries to partition the dataset into k predefined distinct non overlapping subgroups where each data point belongs to only one group and inter cluster data points can be made. We do the classification which groups new data into known classes while clustering relies on underlying patterns to come up with the clusters. We have used two classification algorithms, Support vector machines (SVM) and Decision tree. We have used SVM to predict the individual learning style and decision tree to predict the learning style combination. All these algorithms were chosen in order to maximise the

accuracy and efficiency of our program.

Once we have acquired a student's learning style combination, we can compare it with the learning style combinations prevalent in existing field of study. Based on the degree of similarity we can suggest an area of study to that person. Career selection is a subjective process and depends on the interests of the individual too. With this work, we hope to suggest valid career options for prospective learners based on their learning style combination.

II. Background and related work

Much study was done in the field of identification or prediction of learning styles. For example, a survey was conducted in 2016 on 175 students studying MS programming in engineering. For this survey they have used the questions in Index of Learning Styles by Felder and Soloman [15]. According to this survey, there is a huge diversity in the learning styles among engineering students studying in different branches.[6]

A similar survey was conducted among medical students [3]. A questionnaire consisting thirty nine questions were used. Two-hundred and ninety students participated in the survey. Based on the results seventy three percent of the students who participated in the survey prefer only one learning style, twenty two percent prefer two learning styles and the rest prefer three learning styles. Most of the students who prefer single learning style prefer visual learning style followed by auditory and then kinesthetic. Among the students who prefer two learning style fifty four percent prefer visual and auditory, twenty six percent prefer visual and kinesthetic and the rest prefer auditory and kinesthetic.

An Indonesian translated version of Joy Reids (1984) Perceptual Learning Style Preference Questionnaire was used to conduct a survey among 3rd semester English Department students of Faculty of Cultural Studies at Universitas Brawijaya [2]. A total of hundred students participated in the survey, out of which sixty six were females and the rest were males. The study revealed that majority of the male students who took the survey prefers kinesthetic mode of learning while majority of female students preferred either kinesthetic or group study.

VARK questionnaire developed by Flemming and Miles (1992) was used to assess the learning style preferences of the engineering students at Atlm University [4]. The questionnaire was answered by 107 students out of which sixty one were from computer science, twenty two were from manufacturing engineering and twenty four were from mechatronics engineering. The study showed that around 25.2% of the students prefer more than one mode of learning style. 27.9% of the computer science students who took the survey prefers multiple modes of learning styles and among the students who prefer single learning style, the most preferred styles are auditory, kinesthetic and reading/writing. The most popular learning style among the manufacturing engineering students was found out to be auditory. 29.2% of mechatronics students prefer multiple learning style and among the rest of the students who prefer single learning style, the most preferred style was auditory.

One instance where machine learning was used to identify the learning style is the website 'First aid for you'. Here, machine learning was used to observe how the user interacts with the website and identify patterns in those interactions Those patters are then used to identify the best type of content for the next page. Here, they have used Felder & Solomon Index of Learning Style. Nave Bayes algorithm was used to identify the preferred learning style of the user and this information was used to customize the learning environment.[11]

In [5], the use of k-means in multi label classification is being discussed. The rule mining algorithm Apriori is a popular choice for rule generation, but when it comes to numerical data. With proper pre-processing, a lot of intricate rules can be derived form those numerical datasets. K-means algorithm can be used for this purpose. This helps in finding hidden patterns in huge numerical datasets.

A detailed study of the advantages and disadvantages of both traditional and modern techniques for learning style identification methods was done in [7]. Based on the result it was identified that most of the traditional methods which uses questionnaire and patters in questions lacks authenticity because they follow a general rule which cannot be applied in all individual cases. Modern techniques using machine learning are computationally expensive compared to the traditional ones but they tend to be more accurate.

Support vector machine (SVM) algorithm is widely used in classification and regression analysis. [8] does a detailed analysis on the implementation of SVM using both linear and Map-Reduce fashion. The performance of thus implemented algorithm is then compared.

A fuzzy inference system was used for predicting preferred learner style based on the features used for the VARK questionnaire. The system was tested on a group of students. The input data for the system was collected from a custom questionnaire that was designed specially to get the inputs for the fuzzy inference system. On comparing the output of the fuzzy system to that of the VARK system it was observed that 48% of the test cases were similarly classified.[10]

K-Means clustering encounters issues when it deals with text data. [12] focuses on eliminating this drawback by converting text data into a numerical value which results in more distinct clusters and accurate running times.

The use of tree augmented Bayes network was observed to have better classification accuracy when compared to naive Bayesian network. [13] Online learning environment was used as the platform for automatically detecting students learning style using tree augmented Bayesian network. The experimental results proved that the tree augmented naive Bayes network is capable of achieving higher detection accuracy when compared to the Bayesian network.

Decision trees are commonly used for representing data. In data mining, many different decision tree algorithms are used and each of those provide a unique decision tree from the input data. [14] focus on the comparison of different decision tree algorithms for data analysis.

A study was conducted among the dental students of King

Saud University to find their learning style pattern [16]. An arabic version of VARK questionnaire was used to conduct the survey. The results showed that most students (58.4%) preferred more than one learning style. Among the students who preferred single learning style, Kinesthetic and Auditory were the most prominent.

In [17] the authors have used supervised and unsupervised machine learning algorithms to predict the learners learning style. They have used the Felder and Silverman learning style model for categorizing learners. The unsupervised learning algorithm that they have used is K means and the supervised learning algorithm that they have used is Naive Bayes.

The learning style identification survey done among the architecture and interior design students reveal that there is no significant difference between the learning styles between students of architecture and interior design [18]. Here, the authors used Felder and Soloman's Index of Learning Styles questionnaire to conduct the survey.

III. Proposed Work

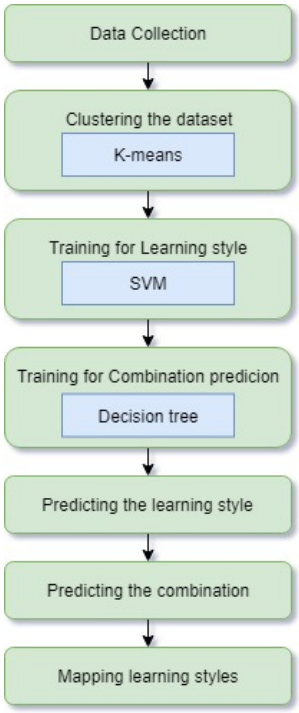

Fig. 1. Steps involved

A. Data Collection

A survey was conducted among the student community of Amrita Vishwa Vidyapeetam University. The survey consisted of fifteen questions. All the questions were multiple choice type and choices included "Strongly Disagree", "Disagree", "Neutral", "Agree" and "Strongly Agree". Each of the above value is mapped to a numerical value, with Strongly disagree as one and Strongly agree as five. The survey was conducted among people with age ranging from fifteen to twenty five. We were able to acquire one thousand one hundred and twenty three inputs. The obtained results was then stored in CSV format.

B. Data Clustering

Clustering of the data helps us to find underlying patterns and categorize them to different groups called clusters. Here we are using K-means clustering algorithm. k-means algorithm is computationally faster when compared to other clustering algorithms when the number of variables are more. According to this algorithm, the initial step is to assign k centroids randomly. Once we identify the centroids, Euclidean distance between each data point and the centroid is calculated. Each data points is then assigned to the centroid which is closest to it. The centroids are then re-positioned for optimization. These processes are iteratively repeated until the centroids doesn't change anymore i.e the centroids are at the center of the clusters that we wanted to create. Here, after applying the k-means algorithm we end up with fifty one clusters. Each and every data will have a cluster number associated with it. We add this cluster number as a feature in the dataset, so the total number of features will be sixteen after data clustering. Once the cluster number is also added to the dataset, we can divide the dataset into test set and train set. In this case we will be dividing the data set equally and one will be taken as test set and the other will be the train set.

C. Data Classification

Studies have shown that clustering the data before classification can increase the accuracy of the classification process. [9] Also the cluster number that we added after the clustering will play a vital role in classifying the data. Logistic regression is a simple and fast classification algorithm and we will be using it in our project. One of the simplest and highly preferred classification algorithm which produce significant accuracy with comparatively less computation power is the Support Vector Machines (SVM). Support Vector Machine is used for regression and classification. The objective of the support vector machine algorithm is to find a hyperplane in an N-dimensional space that distinctly classifies the data points. We apply this algorithm on the training set and trains the algorithm. Once the training is done we apply the same on the test set to predict the learning style. We compare the predicted value of learning style to the existing value and calculates the accuracy of our prediction. We obtained an accuracy of 92.87%.

D. Combination Prediction

We are at a stage where we could predict the learning style of a person but we are limited to a single learning style per person. Our next aim is then to find a combination of learning styles per person. For this we have used a statistical technique called Rand index. Rand index is used for finding the similarity between clusters. Combinations are obtained from clusters that are similar. If a data point that is in a cluster

that is predominantly auditory but if that cluster is similar to another cluster that is predominantly visual, we can trace that data point to visual learning style too, in such a way we find the combinations for all the data points present in training set.

Instead of calculating the combinations every time using adjusted rand index, we could use machine learning to predict the combinations. One of the most widely used predictive analytic algorithm is decision tree. Decision tree construct a tree of predictive decisions made based on actual values of attributes in the data. We create a training model using decision tree algorithm which takes the cluster value, the individual learning style and the combinations obtained using the rand index method as input. We pass the above said features of the training set as input to the training model. By doing so we are training the algorithm for prediction of combinations. Once we have trained the algorithm, we could pass the test set to the trained algorithm and obtain combinations as output.

E. Mapping

Now we are able to predict the learning style combination, in-order to suggest career options we require the information about the prevalent learning styles present in each career. The only way to acquire such information is through extensive survey. Once we have a database containing the most common career options and their prevalent learning style combinations, we could compare it with the learning style of a person and come up with valid suggestions. As of now, information in this regard is limited and based on some of the previous studies done in various parts of the world, we have acquired the following information:

- The prevalent learning styles present among **Computer Science** graduates are ***Auditory*** and ***Kinesthetic***.
- The prevalent learning style present among **Manufacturing Engineering** graduates is ***Auditory***.
- The prevalent learning style present among **Mechatronics Engineering** graduates is ***Auditory***.
- The prevalent learning style present among **Medical** graduates is ***Visual***.

Based on the learning style combination of a person we could suggest any one or more of the career options from the above list. We have used a rule based system for mapping the learning styles. The rules that we have created for the rule based system are as follows:

- ***Auditory***, ***Kinesthetic*** and ***Visual***: Computer Science, Manufacturing engineering, Mechatronics engineering and Medical
- ***Auditory*** and ***Kinesthetic***: Computer Science, Manufacturing engineering and Mechatronics engineering
- ***Kinesthetic*** and ***Visual***: Computer Science and Medical
- ***Auditory*** and ***Visual***: Computer Science, Manufacturing engineering, Mechatronics engineering and Medical
- ***Auditory***: Computer Science, Manufacturing engineering and Mechatronics engineering
- ***kinesthetic***: Computer Science
- ***Visual***: Medical

IV. RESULT

The initial distribution of learning styles in our database is as shown in Fig. 2.

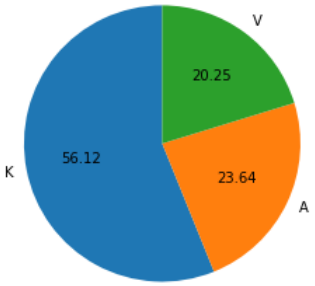

Fig. 2. Initial classification based on learning styles

Based on the rules that we have developed for mapping we can infer that fifty six percent of the students who took our survey can choose Computer Science related field as a career option and twenty three percent of the students can choose Computer science, Manufacturing engineering or Mechatronics engineering as a career option while the rest can choose medical field as their career choice. Using our proposed model we were able to efficiently predict the learning style combination of a student. After passing the same database to our program we obtained the result as depicted in Fig. 3.

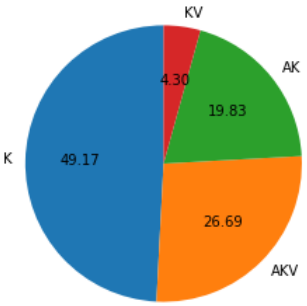

Fig. 3. classification based on learning styles after using our program

Here we observe the presence of combinations like Kinesthetic and Visual (KV), Auditory and Kinesthetic (AK) and Auditory, Kinesthetic and Visual (AKV) along with Kinesthetic. If we apply our mapping rules to the above result, we observe that around twenty six percent of the students who took our survey can choose any of the four career options, around twenty percent of the students can take Computer Science, Manufacturing engineering or Mechatronics engineering, nearly five percent of the students can take Computer Science or Medical as their choice while the rest can choose

Computer Science as their career option. Compared to the previous observation, learning style combinations have given us more accurate and specific results. Thus, identifying a student's learning style combination can help us in coming up with more precise and unique career suggestions.

V. Conclusion

We were able to learn in depth about student learning styles. Unlike the traditional methods, we are now able to predict the learning style combinations of a student using machine learning. The use of machine learning algorithms has provided a new perspective on the technique of finding learning styles. Using a rule-based system, we were able to map learning styles to certain fields of study and identifying the fields of study that suits a student's learning style can help the student in shortlisting career choices.

VI. Future Scope

As per the current implementation, we are able to suggest only four field of study. This is because of the lack of data regarding the prevalent learning styles in other fields of study. Much research can be done in this area and once we have enough information, we can suggest more and more options to students.

VII. Acknowledgement

We would like to express our sincere gratitude to the students of Amrita University who took part in our survey.

***Abstract*—Object recognition and classification are considered as major tasks in the field of computer vision. They are well suited for applications such as a real-time system for people counting, object recognition system for people with visual impairments, surveillance systems, etc. The deployment of computer vision, machine learning, and deep learning algorithms enable to recognize the objects from an image or video frame. This paper proposes a real-time system for indoor object recognition. Moreover, the proposed work mainly focuses on analyzing the performance of various texture features, machine learning classifiers and deep learning methodologies to recognize the objects in indoor areas. The proposed methodology is validated in a publically available indoor object dataset "MCindoor20000". The dataset consists of three categories of objects including doors, stairs, and sign. Our developed deep learning model using transfer learning approach yielded 100 % accuracy and texture features such as LPQ and BSIF have yielded an accuracy of more than 98% with SVM and KNN classifiers.**

Keywords—Indoor object recognition, LPQ, LBP, BSIF, Machine learning, SVM, KNN, NB, Transfer Learning

I. INTRODUCTION

Object recognition systems aid the user to classify the objects in indoor and outdoor areas into their respected categories. Object recognition is the important technology behind various systems such as driverless cars [1], robotic navigation systems [2], visual indoor navigation systems [3], etc. Indoor object recognition systems are developed to identify the objects commonly found in indoor areas such as door, tables, furniture, laptops, windows, food, medicines, etc. Indoor object recognition technology has various applications such as it can be extended to guide the people with visual impairments in complex buildings such as universities, shopping malls, museums. Moreover, indoor object recognition technology is leveraged in the development of robotic indoor navigation systems.

Considerable number of systems have been developed in the past decades to classify and recognize either indoor objects or outdoor objects or both indoor and outdoor objects. In addition, some of these systems are designed to recognize single objects while the rest of the systems can recognize multiple objects found in the single frame. In these systems, object recognition has been mostly performed by extracting various visual features of the images such as speeded up robust features (SURF) [4], color histograms [5], Histogram oriented gradients (HOG) descriptors [6] and utilizing machine learning methodologies such as SVM [7], artificial neural networks (ANN) [8] to do the classification task. Moreover artificial neural networks including deep convolutional neural networks [9] have been utilized in recent systems to recognize the objects.

Our work is mainly focused on the development of a fast and accurate system for the indoor object recognition task. The overview of the system is illustrated in figure 1. The main contribution of this work includes,

- Application of various image texture features such as LPQ [10], local binary pattern (LBP) [11] and BSIF [12] for indoor object recognition, where LPQ and BSIF have not been utilized for indoor object recognition in the past.
- Utilization of adequately large publically available indoor dataset for the validation experiments of proposed methods.
- Improving the recognition performance by utilizing the transfer learning approach with a pre-trained GoogleNet [13] model in the publically available indoor object dataset.

The rest of the paper is organized as follows. Section II reviews the related works briefly. The methodology of the proposed work is detailed in Section III. Section IV describes the details about the dataset. The evaluation results are provided in section V.Finally, in section VI we conclude the paper.

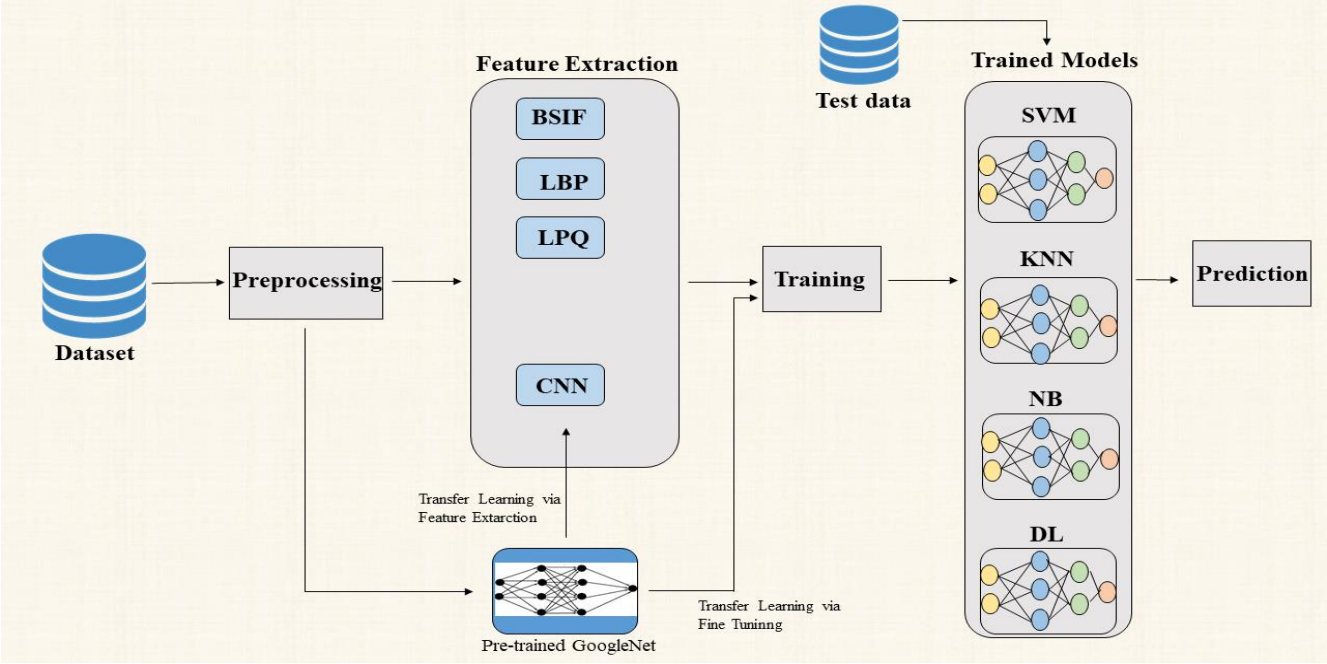

Fig. 1. System Overview

II. Related Works

Several indoor object recognition system has been proposed in the literature. Most of these systems are developed for a specific purpose such as to identify food [5] or currencies [14] or escalators [15] etc. There exist some systems developed especially for the people with visual impairments [16].In computer vision based systems, tag-based approaches are implemented in Badge3D [17], Shoptalk [18], Trinetra [19] to recognize objects. These systems make use of some visual tags or bar codes or visual marker embedded on the object to recognize them. A camera or smartphone will be available with the system to capture the tag and process it. In this section, we focused on the brief review of the systems which utilize handcrafted visual feature extraction techniques, machine learning algorithms and deep learning methodologies for the object recognition task.

Ramis et al. [20] proposed a SIFT features [21] based approach to recognize objects for mobile robots. The proposed method compares the sift keys of the query image with the sift keys of the images stored in the database. The nearest neighbor method using Euclidean distance metric was utilized for comparing the key points. Moreover, the Hough line transform is utilized to cluster the matching keys and thereby removing the outliers. The object recognition module of the LooKTel [22] utilized SIFT descriptor based bag - of- words features method to recognize the objects. The system is able to recognize packed goods, currencies, etc. To improve the recognition performance a tag-based approach was also combined with the SIFT feature based recognition system. Chincha et al. [23] proposed a system for people with visual impairments to recognize commonly found objects such as keys, wallets, mobile phones, etc. The proposed system utilized SURF feature descriptors of the query image and stored images to recognize the objects. Winlock et al. [24] proposed a system for the recognition of objects such as packaged items and other common objects found in grocery. The proposed system was specially designed for blinds. The system utilized SURF feature descriptor along with color histograms to recognize the objects.

Food cam [5] is designed for real-time food recognition using smartphones. The proposed system utilizes two machine learning models to fulfill the recognition task. The first model is an SVM classifier trained with color histogram and SURF features of the images. The second model is another SVM model trained with HOG patch and color descriptor. Lameira et al. [7] proposed an object recognition system using smartphones. The proposed system utilizes a trained SVM classifier model to recognize the objects in the captured images. The center-symmetric LBP features were extracted from the images to create the feature vectors for training the SVM classifier. Parkhi et al. [8] proposed a system to recognize objects such as coffee mugs, bags, laptops, containers, etc. An ANN trained with color and shape features of the objects is used for object recognition. The back-propagation algorithm was utilized to train the ANN and Sobel edge detector was used to extract the features. A smartphone-based currency recognition system was proposed in [14]. The proposed system analyzed the performance of different visual features of images such as SIFT, SURF, and ORB-FREAK for currency recognition. Obtained results displayed that SIFT feature descriptor improved the currency recognition accuracy compared to the other two feature descriptors. Bashiri et al. [25] proposed a system to assist the

visually impaired people in the indoor environment. The proposed system is able to recognize objects such as door, stairs, and signs. A deep convolutional neural network model was implemented for recognizing the indoor objects. Transfer learning approach was adopted for building the deep learning model using a pre-trained Alex Net model. The proposed system yielded a recognition accuracy of more than 98 %.

In brief, considerable number of systems have been developed for indoor object recognition. Various image features such as SIFT, SURF, HOG, and LBP are used in these systems. Deep learning models based on transfer learning approach was also adopted for object recognition. So we considered the usage of texture features such as LPQ, BSIF with SVM, KNN, NB classifiers and transfer learning approach using pre-trained GoogleNet model in our system.

III. METHODOLOGY

A. Feature Extraction

Local Binary Pattern(LBP) is a texture feature descriptor developed by Ojala et al. [26].LBP is a specific instance of the texture spectrum model. The LBP computation for an image consists of five steps. Figure 2 illustrates the steps involved in the calculation of the LBP feature of an RGB image.

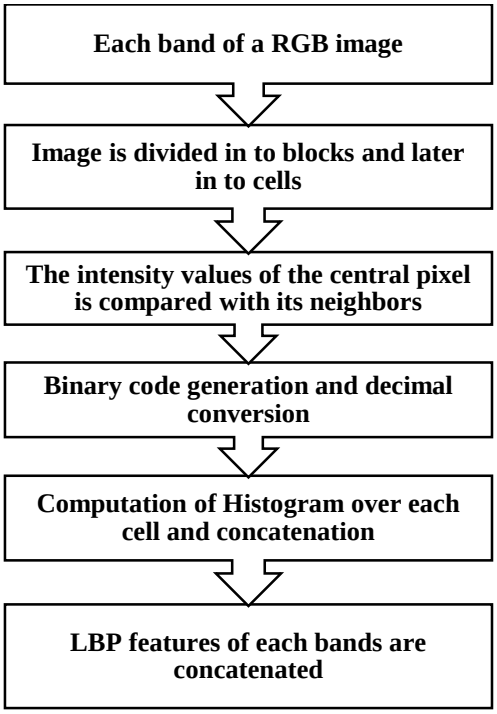

Fig. 2. LBP computation for a single RGB image

Binarized Statistical Image Features (BSIF) is similar to LPQ descriptor and LBP descriptor where pixel region or image patches are represented using binary strings. BSIF was proposed by Juho Kannala and Esa Rahtu [12]. Like LBP and LPQ, BSIF computation consists of two major steps; "Filtering the image with a set of linear filters" and "Quantization of filter responses". Instead of learning filters by utilizing hand-crafted or random filters, BSIF method utilizes the filters learned from natural images. In order to learn filter from natural images, a computational method namely independent component analysis is used to increase the statistical independence of the filter responses.

Consider an image patch P of size $l \times l$ pixels. F_i is the linear filter of size $l \times l$ pixels. Let R_i be the obtained filter response.

$$R_i = \sum_{x,y} F_i(x,y)P(x,y) = \mathrm{f}_i^{\mathrm{T}}\mathrm{p} \quad (1)$$

If there exist 'n' number of linear filters F_i, a matrix F is formed by stacking all F_i. Then all responses (R) are computed simultaneously.

$$\mathrm{R} = \mathrm{Wp} \quad (2)$$

For a random number of natural image patches, the filters F_i is determined in such a way that the elements R_i of R is maximum independent.

Let 'V' be the binary code string computed from the image patch P. Each element v_i of V is defined as;

$$v_i = \begin{cases} 1 & if\ R_i > 0 \\ 0 & otherwise \end{cases} \quad (3)$$

This method is repeated for each pixel to compute binary code and finally, the histogram is generated for image using pixels' binary code.

Local Phase Quantization (LPQ) is a texture descriptor proposed by Ojansivu and Heikkila [10]. This method depends on the quantized period of the discrete Fourier transform which is calculated in the local image window. The steps involved in the LPQ feature vector computation for a single RGB image is illustrated in figure 3.

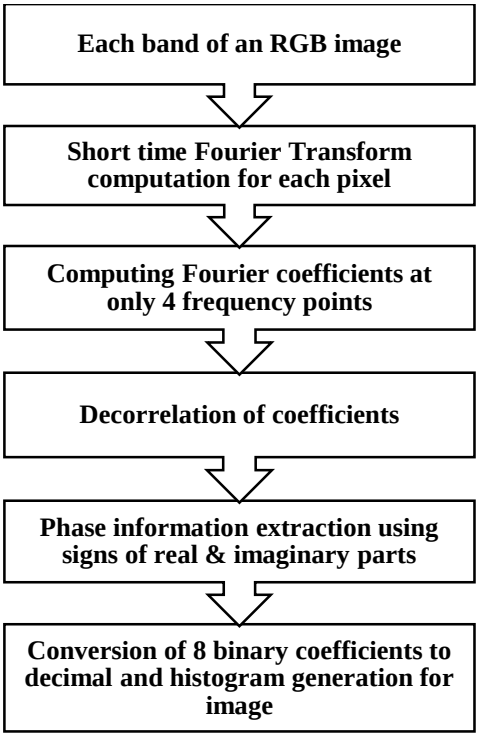

Fig. 3. LPQ computation for a single RGB image

B. Machine Learning Classifiers

After extracting the texture features (LBP, LBP, LPQ) from the images, the recognition performance was examined for three supervised learning algorithms: KNN, NB, and SVM. SVM algorithm was developed by Vladimir and Alexey in 1963.SVM is a classification and regression tool that utilizes machine learning methodology in order to improve the prediction results. SVM make use of one or more hyperplane to separate the classes on infinite dimensional space. To classify the new data (testing data), the SVM algorithm constructs an optimal hyperplane from the input labeled data [27].

KNN [28] is a non-parametric and simplest machine learning algorithm introduced by Fix and Hodges in 1951. The working principle of KNN is based on finding 'K'(k=1,2,3,4,….n) nearest neighbors in training samples from a specific query instance. In order to find the nearest neighbors, the distance between training samples and specific query instance are computed. KNN utilize different distance functions such as Euclidean distance, Manhattan distance, Minkowski distance and Hamming distance for distance calculation between data points.

NB [29] algorithm is a machine learning method based on Bayes' theorem. The prediction technique of NB classifier is based on the posterior probability calculation using Bayes' theorem. For a given query instance, the NB classifier computes the posterior probability for each class (training labels). The class which has the highest posterior probability is considered as the prediction result.

C. Transfer Learning

Transfer learning is a popular method in deep learning where a model created for a specific problem was reutilized for the development of the model for other related problems. In transfer learning, the pre-trained model is used as an initial point for training a new model with different input data. Usually, training a deep learning model from scratch requires a large amount of data. Transfer learning creates effective models even if the dataset is small. This is applicable only if the pre-trained model used in the transfer learning process was already trained with a large amount of data.

The transfer learning can be achieved in two ways: 1) Transfer learning via feature extraction and 2) Transfer learning via fine-tuning. In transfer. In the first approach, the existing pre-trained network is used as a feature extractor to obtain features from the input data. Later, the obtained features will be fed to supervised learning methods for training purpose. In fine-tuning approach, the pre-trained model will be used for training the new data. A small modification will be applied to the architecture of the existing pre-trained network.

GoogleNet is a well-accepted neural network model developed for image classification problem. The GoogleNet network is pre-trained in ImageNet [30] dataset. ImageNet is a large image dataset developed for object classification and recognition task. The images included in the ImageNet dataset fall under 1000 classes such as pen, pencil, laptop, various animals, etc. In this work, pre-trained GoogleNet model is used for transfer learning tasks.

IV. Dataset

The images used for the experiments are taken from MCindoor 20000 dataset [31]. The images of MCindoor 20000 dataset belongs to three classes: door, signs, and stairs. Figure 4 shows some sample images of the dataset. The dataset contains 2055 original images captured from indoor areas of Marshfield Clinic and different variations of the original images such as Gaussian noise models and Poisson noise models. The images were captured using a digital camera and a smartphone. We conducted the experiments using 2055 original images taken from this dataset.

Fig. 4. Sample images from Mcindoor20000 dataset

V. Evaluation and Results

All the evaluations were carried out in MATLAB. The libsvm toolbox is utilized to implement SVM classifier. Our SVM classifier is created using radial basis function kernel and a grid search method was utilized to compute the cost and gamma parameters. Statistics and Machine Learning Toolbox provided by MATLAB is used for KNN and NB implementation.

Accuracy is the major instinctive performance metric for image classification tasks and it is the ratio of correct prediction to the total observations. Accuracy can be considered as the best metric to rate the performance of a trained model only if the dataset is symmetric. In our case, the dataset is almost symmetric but not exact. However, we computed the precision, recall, and F1 scores along with the accuracy of the models to show the performance of our developed models.

The following equations are utilized to compute the above-mentioned performance metrics.

$$\text{Accuracy} = \frac{True\ Positive + True\ Negative}{True\ Positive + True\ Negative + False\ Positive + False\ Negative} \quad (4)$$

$$\text{Precision} = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (5)$$

$$\text{Recall} = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (6)$$

$$\text{F1 score} = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (7)$$

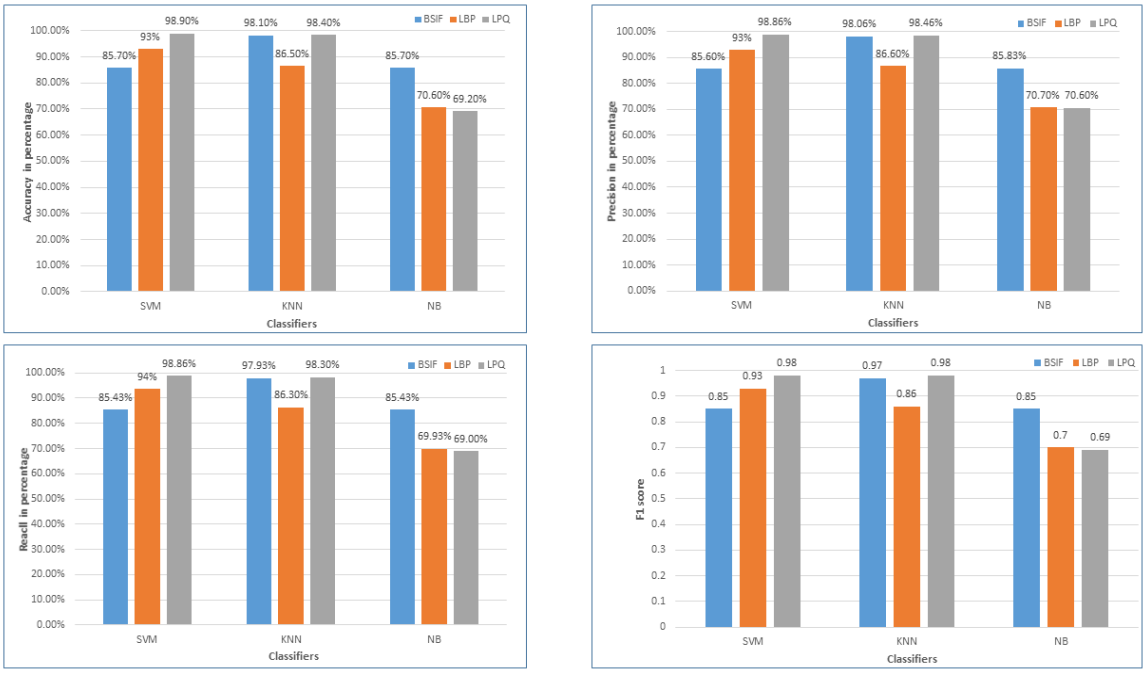

Fig. 5. Accuracy (Top left), Precision (Top right), Recall (Bottom left) and F1 score (Bottom right), of the developed object recognition models using texture features(BSIF, LPQ, LBP) with SVM, KNN and NB classifiers.

A. Texture Features with Machine Learning Classifiers

Many variants of LBP and LPQ features are available. We utilized uniform rotation invariant LBP with 8 neighborhood schema for extracting the LBP features. Rotation invariant LPQ with 8 neighborhood schema is used to extract LPQ features. A pre-computed filter is required for the LPQ feature extraction method. In our approach, we choose a filter with window size 7. In the case of BSIF features, we extracted the features in normalized histogram format. BSIF feature extraction method used a pre-learnt filter with size 7×7.

We partitioned the entire dataset into two portions. 70 % of the images are used for training the classifiers and 30 % for testing the performance of the trained classifiers. To extract LBP and LPQ features, the chosen image size is 640×480 pixels. The images are processed in RGB format itself and features were calculated for each band and later concatenated to form the final feature vector. In the case of BSIF implementation, during preprocessing the image was converted to grayscale, image size resized to 640×480 pixels.

The accuracy, precision, recall and F1 score of each trained model are displayed in figure 5.

The obtained results on the MCindoor 20000 dataset show superior performance of LPQ and BSIF for classifying indoor objects. While comparing with LBP features, LPQ and BSIF descriptors displayed substantial improvement in accuracy. LPQ features exhibited an accuracy of 98.9 % and 98.4 % with SVM and KNN classifiers respectively. BSIF features performed well with KNN classifier and provided an accuracy of 98.1%. Since the dataset is almost symmetric, the precision and recall values of each model are almost similar to their respective accuracy values. The precision and recall of the SVM classifier with LPQ feature are 98.86 % and 98.86 %. The KNN classifier with BSIF feature has 98.46 % precision and 98.30 % recall. The F1 score is the harmonic mean of precision and recall. The F1 score values of the SVM classifier with LPQ descriptor, KNN classifier with LPQ descriptor and KNN classifier with BSIF descriptor are 0.98, 0.98 and 0.97 respectively. The obtained F1 score values of above mentioned three models are almost near to 1, which shows the effectiveness of the developed model for classifying indoor objects such as doors, stairs, and signs. The performance results of the SVM classifier with LPQ descriptor, KNN classifier with LPQ descriptor and KNN classifier with BSIF descriptor were almost similar to the results obtained in [25] using transfer learning(pre-trained AlexNet model [32]) in the same dataset. This demonstrates the competitiveness of LPQ and BSIF features for indoor object recognition. SVM and KNN methods are well suited for classification tasks using texture features from images.

B. Transfer Learning

Deep learning toolbox provided by MATLAB is used to develop the deep learning model for indoor object recognition. The Deep learning toolbox contains various pre-trained model. We utilized the GoogleNet model trained in the ImageNet dataset as an initial point for training our model. The input images were resized to 224 × 224 pixels. In transfer learning via fine-tuning approach, the final two layers, 'loss3-classifier' and 'output', of the pre-trained model are replaced with new layers, according to the number of classes in our dataset. In order to speed up the training and prevent overfitting of data, the initial 10 layers of the pre-trained model were made frozen. In transfer learning via feature extraction approach, the activations on the fully connected layer ('loss3-classifier') were utilized to extract the features of the image. The extracted CNN features were utilized to train the SVM, KNN, NB classifiers.

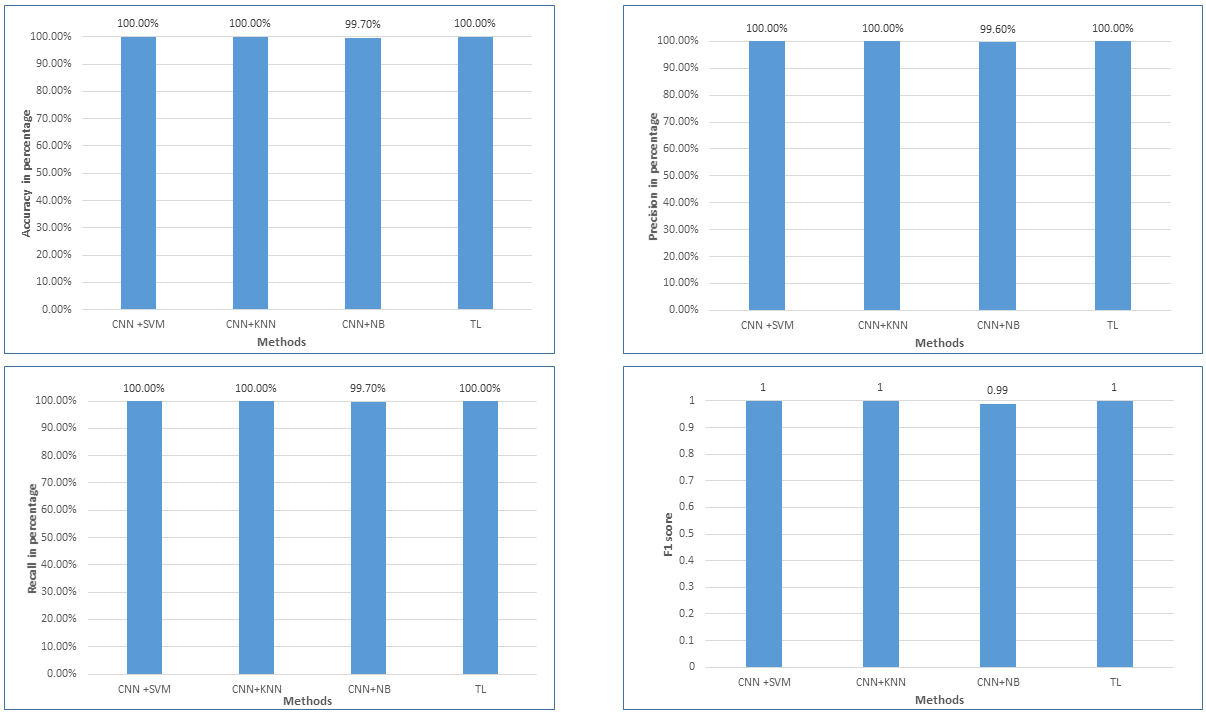

Fig. 6. Accuracy (Top left), Precision (Top right), Recall (Bottom left) and F1 score (Bottom right), of the developed object recognition models using Transfer learning(TL) approach, CNN features with SVM, KNN, and NB classifier.

The accuracy, precision, recall and F1 score of deep learning model, SVM, KNN, NB models trained with CNN features are displayed in figure 6.

The results displayed in figure 6 show the superior performance of our developed models using transfer learning approach. The four classification models including transfer learning (TL) model developed via fine-tuning and SVM, KNN and NB models trained with CNN features outperformed all other texture features in terms of accuracy, precision, recall, and F1 score.TL model, CNN features with SVM classifier, and CNN features with KNN classifier achieved a classification accuracy of 100 %. The CNN features with NB classifier showed 99.7 % accuracy. We extracted the CNN features from the final fully connected layer of the deep learning model. This approach gave us high-level features of the images to train the classifiers. Obviously, high-level features will perform better than low-level features with machine learning classifiers such as SVM, KNN, and NB. Since the dataset is almost symmetric, the precision, recall of the TL model, SVM, and KNN model are 100 %. The F1 score of the TL model, the SVM model, and KNN is model is 1 that is the maximum value a model can achieve.

In addition to accuracy, precision, recall, and F1 score we computed the average prediction time for each model to analyze its efficiency. The prediction time required by each developed model for a single image is shown in table 1.

We have already described the main applications of indoor scene recognition. During the implementation of a real-time system for object recognition, in addition to its accuracy and precision, the prediction time should be considered. Accuracy and precision of the developed models using TL, CNN with SVM, CNN with KNN, CNN with NB, LPQ with SVM, LPQ with KNN, BSIF with KNN are extremely good. But while considering the prediction time, LPQ with KNN and LPQ with SVM model takes more than 4 seconds for predicting the result for one image. The BSIF with KNN is very fast and took only 0.4 seconds which is similar to transfer learning models.

TABLE I. AVERAGE PREDICTION TIME FOR SINGLE IMAGE

Methods	Prediction time in seconds
BSIF+SVM	0.3276
BSIF+KNN	0.4569
BSIF+NB	0.6040
LBP+SVM	1.0204
LBP +KNN	1.0492
LBP +NB	1.1458
LPQ+SVM	4.6034
LPQ +KNN	4.8434
LPQ +NB	5.5722
CNN+SVM	0.4513
CNN+KNN	0.5906
CNN+NB	1.5038
TL	0.4908

[a.] TL means Transfer learning using pre-trained GoogleNet model

VI. Conclusion

In this work, we developed a computer vision-based system to recognize indoor objects. The proposed system was validated in a publically available dataset which contains images captured from indoor areas of a health clinic. SVM, KNN and NB classifiers were utilized to evaluate the performance of textures features such as BSIF, LPQ, and LBP. The indoor object recognition was very well performed with BSIF feature descriptor and LPQ feature descriptor.BSIF produced 98.1 % accuracy with KNN classifier. Moreover, LPQ yielded 98.9 % and 98.4 % accuracy with SVM and KNN classifiers respectively. Compared to NB classifier, SVM and KNN classifiers performed better with texture features. We performed the transfer learning via fine-tuning as well as feature extraction approaches. Our deep learning model developed using transfer learning approach yielded the highest accuracy of 100 % in the same dataset. The CNN features also delivered an accuracy of 100 % with SVM and KNN classifiers. Comparison with LPQ, BSIF feature descriptor, CNN features, and deep learning models took very less time for the prediction.

This work only considered the recognition of three indoor objects such as door, stairs, and sign. Recognition of multiple objects from a scene is not considered in this work. In the future, we will extend this system to recognize more common objects found in indoor areas including chairs, table, laptop, smartphone, etc. Moreover, we will consider the recognition of multiple objects found in a scene.

***Abstract*— now a days, the real time detection and tracking of face is very mandatory. This is mainly used for recognition of movement, safety purpose and surveillance systems. In this paper, we are using two algorithms that is Viola-Jones Detection (VLJ) algorithm and KLT algorithm. KLT algorithm is used along with Arduino packages available in MATLAB. In this paper, the total progression is divided into two categories, that is first one is the human faces are detected by VLJ algorithm and another algorithm is used to track the feature evidences in the live video surround. Using webcam and servo motors, the human faces are detected and tracked. The perfect intention of this paper is to progress a faster algorithm in detecting, tracking and recognizing a face, which serves as a useful process in several Real time applications like security systems, video surveillance, video coding and Advanced Robotics etc.**

Keywords*— KLT, VLJ, Face tracking, Arduino, MATLAB, Face Recognition.

I. INTRODUCTION

In so many computer vision applications, the detection and tracking of object are very important and also including recognition of activity, surveillance and motorized safety. A face tracking system is very simple and mostly used system and which is established by separating the tracking problem into three distinct problems: Face detection in the frame, Initial facial features, which is used for tracking and Face Tracking. Face detection in MATLAB can be through using various dissimilar existing algorithms. These algorithms use different mechanisms to identify the facial features. Some use edge detection methods while some use contrast separation. Generally, it is used in object detection applications but, due to its capability of detecting facial features using Haar based feature filters, is extremely easy to use for the face detection applications. The main reason overdue using MATLAB for image processing is due to its features with inbuilt tools and provision for good choice of hardware parts like that Arduino and Raspberry Pi. In this project, Arduino Uno was used due to its simplicity and compatibility with the MATLAB. Arduino hardware support package can be added to MATLAB via Add-Ons. The main significance of this paper is to accentuate the use of Viola Jones object detection frame work on human faces in real-time.

For training, they used latent SVM which considers a classification which notches every example x with a function $f_\omega(x)$ = max $z\epsilon Z(x)$ ω . $\psi(H, z)$ where the fixed $Z(x)$ describes all conceivable hidden values for an example x. A binary brand for this instance x can be acquired by thresholding the notch. The model parameters ω can be trained from labeled examples (x_1, y_1), … , (x_m, y_m) by minimizing the objective function:

$$L(\omega) = \frac{1}{2}\|\omega\|^2 + C\sum_{i=1}^{m}\max(0, 1 - y_i f_\omega(x_i))$$

For detection, the response of the i^{th} filter Fi in the l^{th} level of H is calculated by $R_{i,l}(x, y) = Fi$.$\varphi a(H, (x, y, l))$ in a sub-window of H with topmost leftward corner at (x, y) and its size is defined by the size of the root filter. The updated response of the i^{th} part filter in this optimum location $D_{i,l}$ and the corresponding optimal displacement $P_{i,l}$ are given respectively by:

$$D_{i,l}(x, y) = \max_{dx,dy}\ [R_{i,l}(x + dx, y + dy) - d_i \,.\varphi_d(dx, dy)]$$

$$P_{i,l}(x, y) = \operatorname{argmax}_{dx,dy}\ [R_{i,l}(x + dx, y + dy) - d_i \,.\varphi_d(dx, dy)]$$

II. METHODOLOGY

The proposed system used for detection of human face is designated under. This proposed system mainly categorized into four stages, they are briefly explained under.

A. Features of HAAR

Images are categorized primarily on feature constructed systems because in feature constructed systems the calculations essential is fewer. For face detection generally two rectangular dimensional features, three rectangular dimensional features and four rectangular dimensional features are used [2]. These features/structures are named as HAAR structures and are shown in below figure. The features are intended by simple adding and deduction operation. For any type of rectangular HAAR feature the features are intended in the above mentioned process. This process is frequent for dissimilar types of HAAR rectangular masks and also by fluctuating the dimension of the mask.

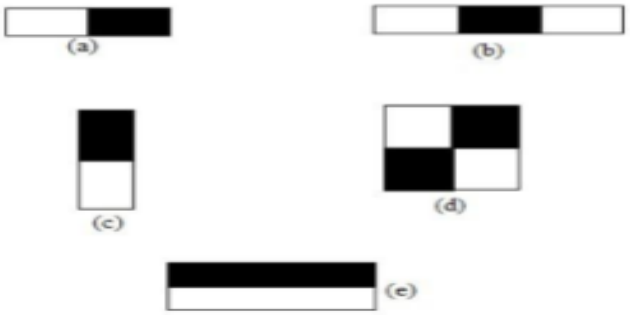

Fig 1: Features of HAAR

B. Image of Integral:

The image of integral is a rectangular structures of an image, which are greatly designated by its center. The equation calculation of integral form of an image is given by mathematically below and this can be described by captivating the below image [2].

$$qq(a,b) = \sum_{a' \le a, b' \le b} q(a', b')$$

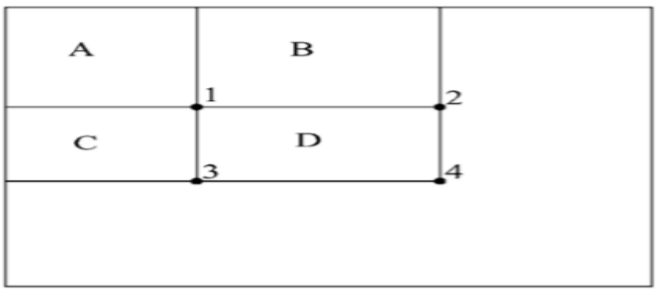

Fig 2: image of Integral

In the integral illustration, point1 designates the whole pixel sum which are existing in area A. the point2 indicates the area pixels sum. In the same way, point3 and point4 are area pixels sum (A, C) and (A, B, C, D) [3]. Where q(a,b) is an image of integral and q(a', b') is the original image.

$$P(a,b) = p(a,b-1) + q(a,b)$$
$$qq(a,b) = qq(a-1,b) + p(a,b)$$

C. AdaBoost Training (Adaptive Boost):

The integral image calculates a value at every pixel (A, B) that is the pixels sum values overhead and to the left side of (A, B) comprehensive [2]. The exercise set covers face and non-face examples with identical weight. For every round of boosting, it assesses every rectangular filter on every example and chooses the best threshold for every filter and then sets best threshold. After this, the weights are set again.

D. Cascading Classifiers:

After the exercise is completed, the integral images are coordinated with the filters and cascaded using the MATLAB objects. Using classifiers, the positive and negative portions of an image are separated, i.e., simple classifier. Weak classifiers are nothing but simple classifiers. Complex classifiers are sturdy classifiers in which it will yield the output from the preceding classifier and it will take as current input in which it may discard or accept that exact window.

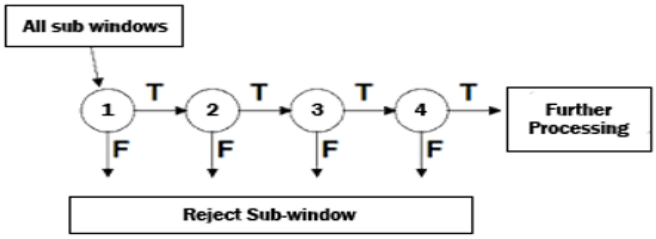

Fig 3: cascading

Cascade Objects in MATLAB:

- Cascading of the integral images is completed using the inherent cascade structures of MATLAB. vision.CascadeObjectDetector(); detects the distinct object from the video input.
- imaq.VideoDevice: This object allows MATLAB to interface camera to the system.
- vision.ShapeInserter: This object places the distinct outline at the position if recognized HAAR features.
- vision.VideoPlayer: This object shows the processing video with the recognized features.
- vision.HistogramBasedTracker: This object paths the actions in the HAAR features using the histogram information.

III. PROPOSED TECHNIQUE

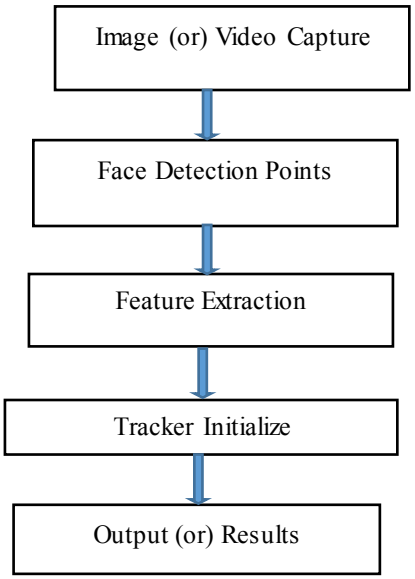

Fig 4: Proposed Model

The main purpose of the project work is to detect a human face in every frame of the video coming from a web camera and the captured image is processed using viola-jones algorithm using MATLAB and to detect the faces and send signals to the Arduino board to regulator the association of the camera using two servo motors. One of the servo motor is for horizontal variation and another servo motor is for vertical variation, face shall be tracked actively and maintained in the

frame. The MATLAB code may also include some of the built in functions for the effective face recognition and seamless tracking in real time environment [4]. Applications of this concept are wide spread from video coding to advanced robotics.

MATLAB Software: In this proposed method, MATLAB uses the built in vision objects to detect the faces from a live video feed [2]. For the first stage, a serial assembly to the Arduino hardware opens. Concurrently, the program recites the video feed from the webcam or external camera. For good efficiency, step is used for extracting frames from the continuous video feed. Using the Viola-Jones detection frame work, the frames extracted gets coordinated with the Haar features and faces are identified. Nose features gets matched after the faces. Then the boundary boxes will be placed at the identified face locations. Additional into the code, it computes the centroid of the boundary box and forms the portion of the frame it decreases in. As the frame of the video will be alienated into four quadrant, it computes the coldness from the center to the location of centroid of the bouncing box on both axes. These are fed to the Arduino serial input. MATLAB does this procedure constantly until the predetermined time after there is no face in the frame [4].

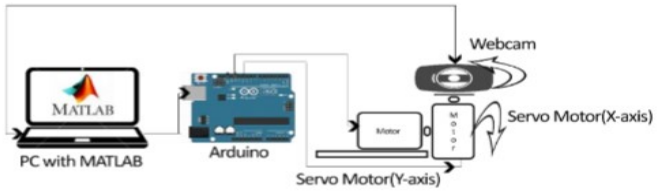

Fig 5: Block diagram

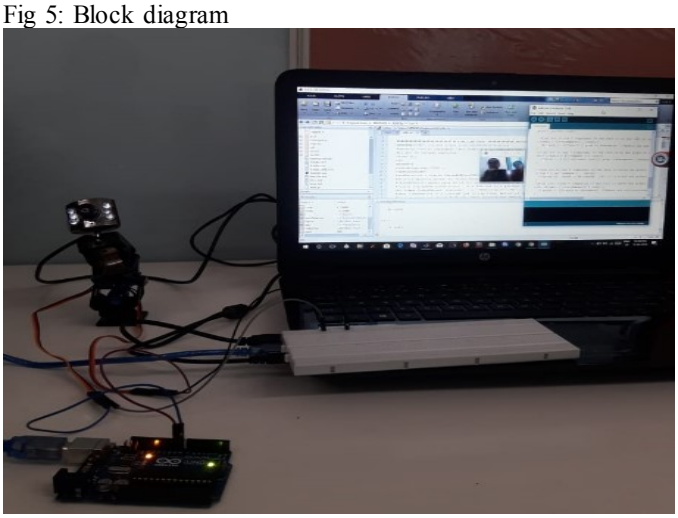

Fig 6: Hardware Setup.

Arduino IDE: In this paper, Arduino Uno is used which switch the tracking gesture for the camera on two servo motors (pan-motion & tilt-motion) [4]. We used Arduino platform for this model because of its simple interfacing and working with the MATLAB. Adding the hardware support package to the MATLAB through the add-ons is extremely convenient. As the procedure of face detection occurs, serial input at the Arduino obtains the detachments from the midpoint to that of the bounding box. With this input from the serial port, Arduino code is printed such that it associates the input co-ordinates to the conditions in the program and operates the servo motors accordingly.

Physical Connections: Components obligatory for this work comprises a web camera, Arduino Uno, a Computer with MATLAB (as well as Arduino hardware support packages) and Arduino IDE [4].

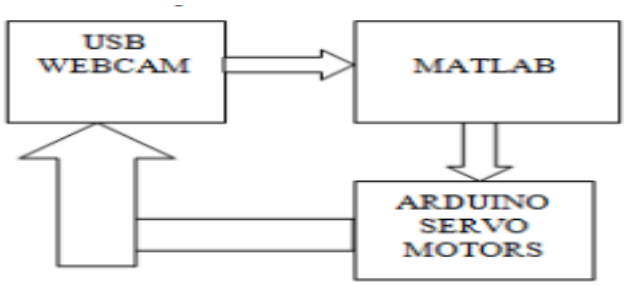

Fig 7: Connection between software and hardware

IV. SIMULATION AND RESULTS

In this paper, we are using Arduino Uno board, bread board, connecting wires and YUY2_160 x120 webcam. The below figures shows MATLAB section of the detection and tracking of the face.

Fig 8: Output for single face detection using Mat lab.

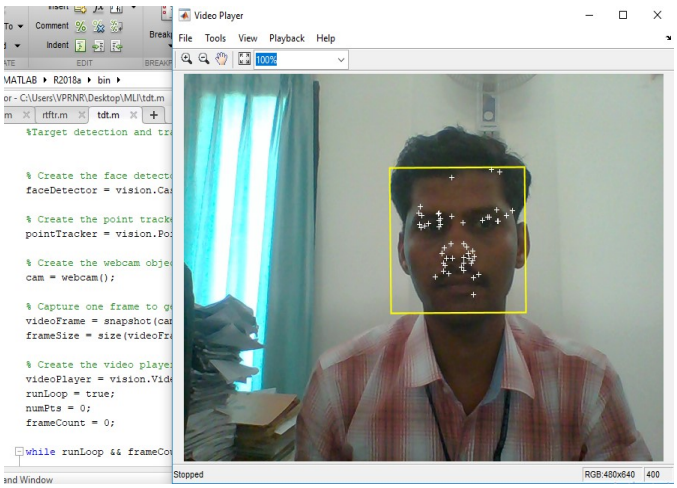

Fig 9: Output for single face detection using Mat lab.

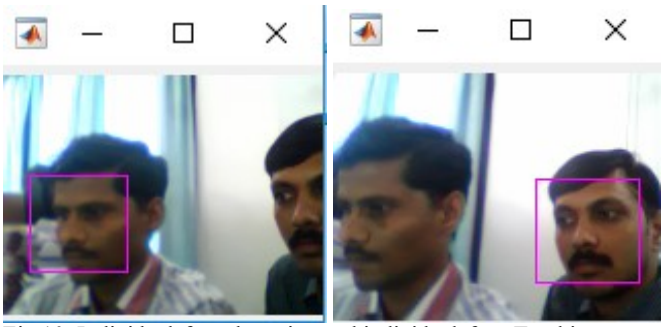

Fig 10: Individual face detection and individual face Tracking output.

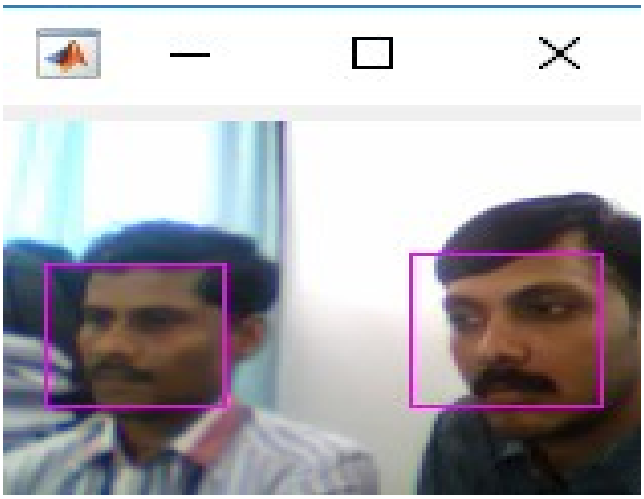

Fig 11: Output for Multiple face detection and Tracking.

The Individual face detection and individual face tracking output shown in figure 10 and multiple face detection and Tracking output as shown in figure 11. This output figures estimated from connection between MATLAB and Arduino setup. In this paper, C1, C2 represents centroid values, which are noted in below table.

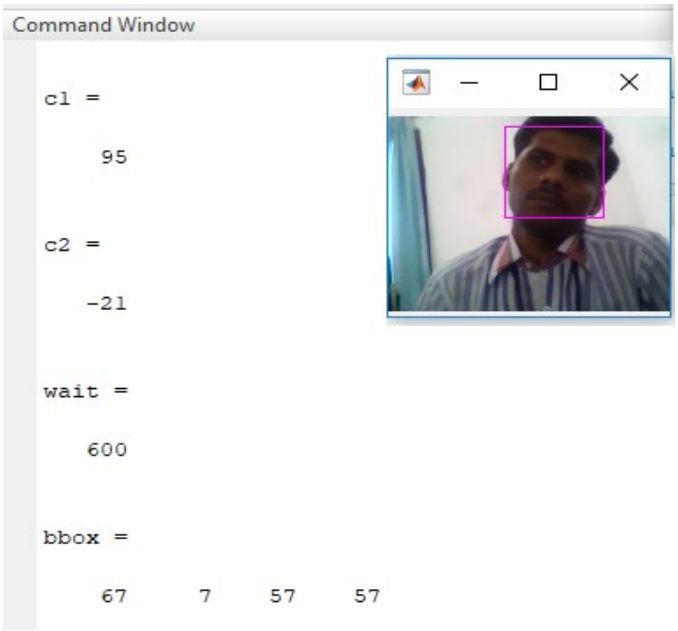

TABLE 1: Various wait time player's detection.

S. N	Wait time (in sec)	Output of video player	Calculation of centroid
1	287		C1 = 94 C2 = -25
2	320		C1 = 52 C2 = -6
3	600		C1 = 100 C2 = 4

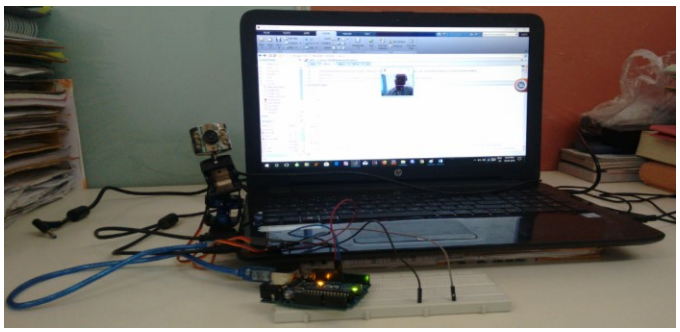

Fig 12: Hardware Setup

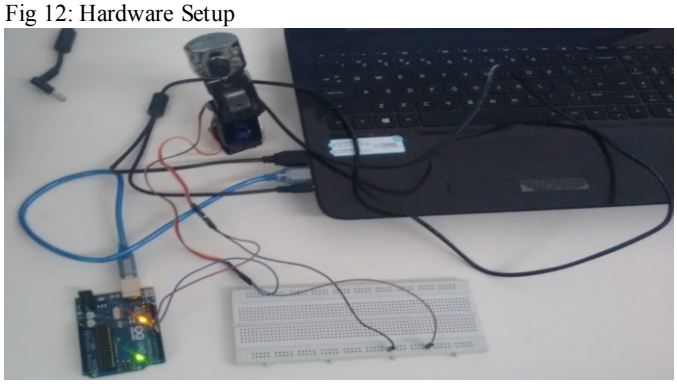

Fig 13: Servo Motor Setup

V. CONCLUSION

The planned system for tracking faces using Viola-Jones algorithm in MATLAB is better than the present methods. Usage of adaptive boosting for the algorithm helps in increasing the precision and efficiency of the proposed method. This kind of tracking can be used effectively in the surveillance field. Also, Computer Vision is the major field which holds a vast scope for robotics. It is an efficient and fast algorithm when compared to other algorithms. It is done by using MATLAB code, where Camera detects the face and tracking is done through the movement of camera using a Microcontroller called ARDUINO. We can implement this method in various places where security and video surveillance is highly essential. In this paper we are restricted with basic laboratory conditions where the application part can be done with high costs.

Abstract— **Modulation plays a significant role in the field of electrical communication where different techniques are employed to achieve better performance and focusing in meeting the standards of various parameters such as BER, SNR, and MSE etc. In this paper we have analyzed BER for passband digital communication techniques on AWGN channel and results are verified using MATLAB.**

***Keywords*— Binary Phase Shift Keying (BPSK); Quaternary Phase Shift Keying (QPSK); Quadrature Amplitude Modulation (QAM); Bit Error Rate (BER); Signal to Noise Ratio (SNR); Additive White Gaussian Noise (AWGN); Mean Square Error (MSE)**

I. INTRODUCTION

The history of communication focuses the development of civilization and the way it influenced its impact on modern societies. Communication stands in simple words as sending or receiving of messages from one person to another. When the receiver interprets the exact message deliver by the transmitter then only effective communication is going to happen.

The communication systems broadly classified into three categories based on the nature of the input signal as well as the behaviour of the system. The system may be unidirectional or bidirectional, whether it uses as analog or digital signal, which type of transmission technique the system is going to opt. The above discussed classification is also shown in figure 1.

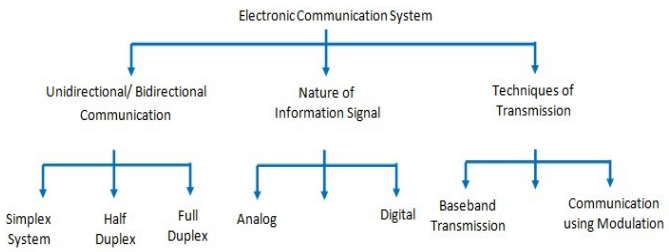

Figure 1 : Classification of Electronic Communication System

The current research majorly focusing on last category i.e. the techniques of transmission. We can also classify the transmission techniques in further two types namely baseband transmission and passband transmission (Communication systemusing modulation).

The message signals are directly transmitted in baseband transmission systems. The telephone networks are one of the common examples for these types of systems, where the input sound signal is going to convert into electrical signal and directly placed on the telephone lines and gets transmitted.

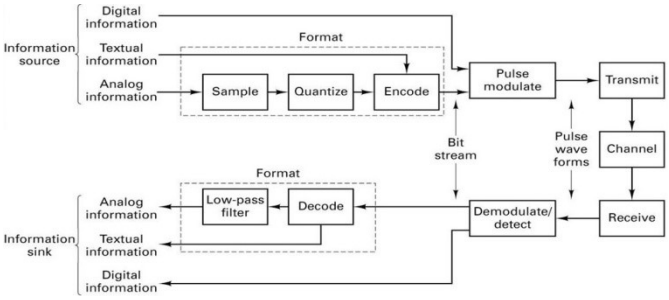

Figure 2 : Functional model of baseband data transmission system

The message signals are impresses onto a signal known as carrier in passband transmission systems. The space communications, terrestrial microwave communications and mobile communications are the areas which consider modulation where the modulated signal is shifted to an appropriate frequency band and then transmitted over large distance communication through antennas.

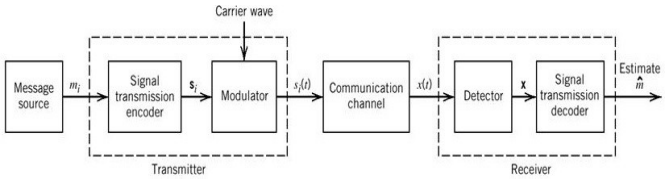

Figure 3 : Functional model of passband data transmission system

A. Literature Survey

Reference [1] presents different modulation schemes (BPSK, QPSK, and GMSK) and its performance evaluation in terms of BER in cellular mobile environment with GSM standard parameters. The main motive of this research is to identify the factors that go into consideration of the modulation schemes particularly in the wireless environment.

Reference [2] describes about BPSK, QPSK and QAM based OFDM system and performance comparison by employing different error correcting techniques (reed Solomon, convolution & concatenated coding) in wireless communication channel. The BER performance evaluated among each code and from these outcomes it is concluded that concatenated coding brings good results compare to other individual codes.

Reference [3] discusses the BER measurement for different modulation schemes over two different channel bandwidths of 1.25 MHz and 6 MHz respectively. The main objective of this research is to find out the best configuration between the modulation schemes and channel bandwidth, which helps to improve the system performance. The research has been performed by evaluation of BER and SNR for OFDM system models using MATLAB SIMULINK Tool.

Reference [4] analyses the BER, for different modulation techniques known to be BPSK, QPSK. After performing various simulations it is observed that performance can be enhance by selecting a proper modulation scheme and by employing suitable coding technique correspondingly. The performance is analyzed and compared by simulated results through Lab VIEW software.

B. Organization of the paper

The paper has been organized into six sections. Section I gives the brief introduction about the digital communication and some of the previous works related to this paper. Section II gives an idea about each scheme in digital communication. Section III focuses on details about the types of communication channel and its characteristics. Section IV is a more complex one deal with parameters to analyse various digital modulation techniques. Section V elaborates about the input signal specification. Section VI shown the simulated results in the form of graph and table. In section VII, based on the above observations, what can be inferred is described and conclusions drawn based on them.

II. DIGITAL TRANSMISSION SCHEMES

A. Introduction

The physical delivery of information (data) over a dedicated or distributed path (communication channel) is known as data transmission, digital transmission or digital communication. The digital transmission techniques basically classified into two types i.e. baseband transmission (Line Coding) and passband transmission (Digital Modulation)

B. Classification

The digital transmission is classified in into two major categories namely Baseband Transmission and Passband Transmission (communication using modulation). The layman classification of digital signals transmission is clearly depicted in below figure

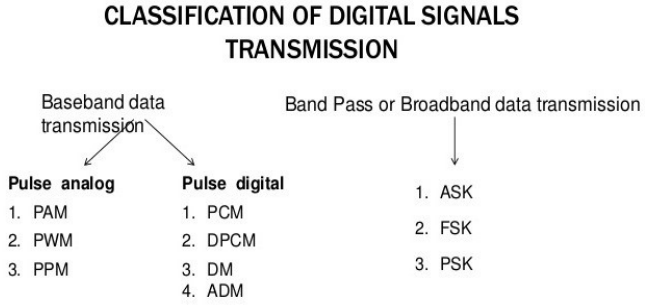

Figure 4 : Digital Modulation Classification Model

C. Passband digital modulation techniques

The main objective of passband digital modulation is to impresses the encoded digital information by varying the parameters of a sinusoidal waveform known as carrier signal, over an analog communication channel. There are 3 basic modulation techniques and based on parameters like amplitude, phase or frequency variations in the transmitted signals, the modulation is referred to as Amplitude Shift Keying (ASK), Frequency Shift Keying (FSK), and Phase Shift Keying (PSK).

D. Binary Phase Shift Keying (BPSK)

Binary Phase Shift Keying (BPSK) is also known by the name of Phase Reversal Keying (PRK) in some specific applications. In this modulation scheme two phases of the carrier signal represented either by 0° or by 180° depending on the sequence of binary message signal i.e. 0 or 1 accordingly.

The transmitted BPSK signal can also be represented mathematically shown in equation 1

$$s_n(t) = \sqrt{\frac{2E_b}{T_b}}\cos\big(2\pi f t + \pi(1-n)\big), \quad n = 0,1$$

Equation 1 : Transmitted Signal Expression for BPSK

The probability of error for BPSK under AWGN channel can be calculated from expression present in equation 2

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right) \quad or \quad P_e = \frac{1}{2}erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

Equation 2 : BER Expression for BPSK

The output waveform representation of BPSK modulation corresponding to the input binary sequence is depicted in figure 5.

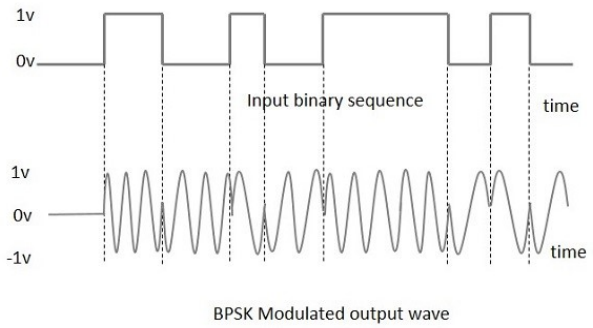

Figure 5 : Waveform Diagram of BPSK Modulation

E. Quaternary Phase Shift Keying (QPSK)

A four-level (4-ary) PSK is called Quaternary Phase Shift Keying (QPSK), and constellation points also chosen as four. As per the theoretical analysis, it is found that QPSK system and BPSK system having the same BER. The QPSK system can also be utilized to double the data rate compared with a BPSK system for some special applications.

The mathematical implementation of transmitted QPSK signal is clearly represented through equation 3

$$s_n(t) = \sqrt{\frac{2E_s}{T_s}}\cos\left(2\pi f_c t + (2n-1)\frac{\pi}{4}\right), n = 1to4$$

Equation 3 : Transmitted Signal Expression for QPSK

The QPSK using two independently modulated quadrature carriers known as in-phase component and quadrature-phase component. The BPSK is used on both carriers as they can be independently demodulated and therefore resulting BER for QPSK is like BPSK.

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right) \text{ or } P_e = \frac{1}{2}erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

Equation 4 : BER Expression for QPSK

The QPSK can transmit 2 bits/symbol and shifts the phase of the signal to one of four states as clearly mentioned in figure 6.

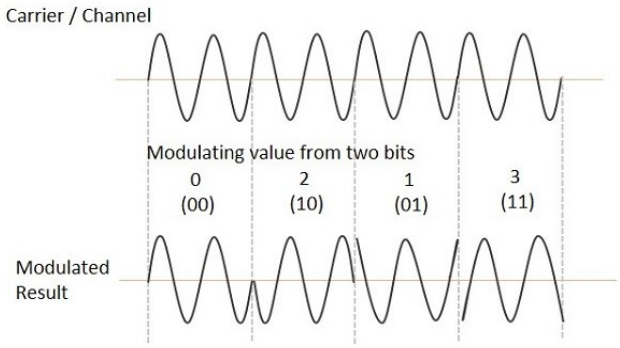

Figure 6 : Waveform Diagram of QPSK Modulation

F. Quadrature Amplitude Modulation (QAM)

QAM (Quadrature Amplitude Modulation) utilizes both amplitude and phase components of a carrier signal in order to achieve high levels of spectrum usage efficiency. This technique includes pulse amplitude modulation (PAM) in high speed data communication systems.

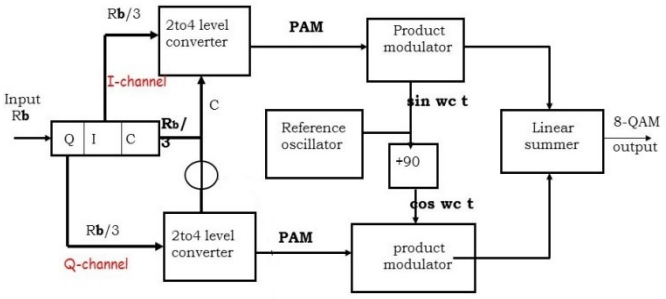

Figure 7 : Block Diagram of 8-QAM Modulator

M-QAM constellations involve two orthonormal basis functions and are two-dimensional. The transmitted QAM signal waveform can also be represented as

$$s_i(t) = \sqrt{E_i}\sqrt{\frac{2}{T_s}}\cos(2\pi f_c t - \theta_i)$$

$$where: E_i = \sqrt{A_{I,i}^2 + A_{Q,i}^2} \text{ and } \theta_i = \tan^{-1}\frac{A_{Q,i}}{A_{I,i}}$$

Equation 5 : Transmitted Signal Expression for M-QAM

M-QAM constellations involve two orthonormal basis functions and are two-dimensional. An important configuration of signal points is rectangular QAM, in each direction the signal points are spaced equally in amplitude and placed on a rectangular grid as clearly understood from the signal constellations diagram depicted in figure 8 for different values of M.

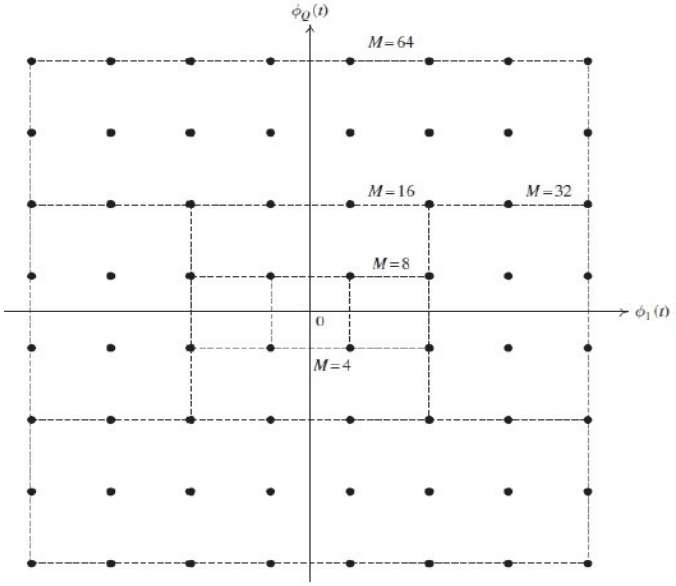

Figure 8 : Constellation Diagram of M-QAM Modulation

III. COMMUNICATION CHANNEL

Communication channels are basically of three types based on the classifications in terms of their characteristics as Noise model (AWGN), Radio frequency propagation model & Interference model. The detailed explanation about AWGN channel is given below based on the analysis.

A. Additive White Gaussian Noise Channel (AWGN)

The AWGN channel is mathematically represented by an output series *Yi* at different time index *i*. *Yi* is the summation of the input *Xi* and noise, *Zi*, where *Zi* is identically distributed and drawn independent from a zero-mean normal distribution with variance *N*.

$$Z_i \sim \mathcal{N}(0, N)$$
$$Y_i = X_i + Z_i$$

Equation 6 : Mathematical representation for AWGN Channel

The AWGN channel is often used for many satellite and deep space communication links. The major application of AWGN is to simulate background noise for channel under observation. This is not a good model for fading, frequency selectivity and does not account for terrain blocking, interference etc.

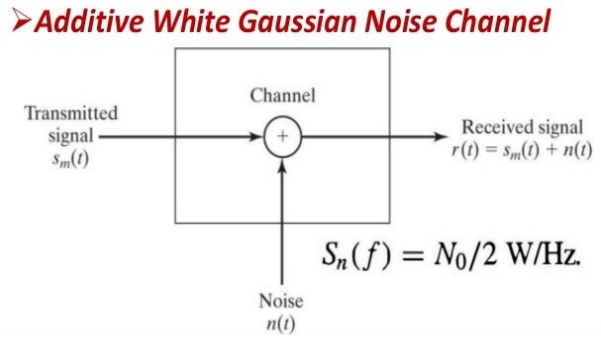

Figure 9 : AWGN Channel Model

IV. PERFORMANCE MEASURES

A. Bit Error Rate – BER

Bit errors are the number of bits corrupted or destroyed during the transmission of data from the source to destination. Bit error ratio is a unit less quantity and often measured in percentage.

$$BER = \frac{Number\ of\ bits\ in\ error\ (at\ receiver)}{Total\ number\ of\ bits\ (transmitted)}$$

Equation 7 : BER Formula

B. Signal To Noise Ratio - SNR

Signal-to-noise ratio is a measurement parameter that compares the level of signal power to a level of noise power and expressed its mathematical value in decibels. If the ratio is higher than 1:1, it shows that more signal than noise.

$$SNR = \frac{P_{Signal}}{P_{Noise}}$$

Equation 8 : SNR Formula

C. Mean Square Error – MSE

The mean squared deviation of an estimator measures the average squared difference between the estimated values and what is estimated. The MSE is the measure of quality of an estimator and the second moment of the error, therefore incorporates both bias and variance of an estimator.

$$MSE = \frac{1}{N}\sum_{i=0}^{N}(\hat{Y}_i - Y_i)^2$$

Equation 9 : MSE Formula

V. IMPLEMENTATION DETAILS

An input audio signal in .wav format having file size of 673 KB is fed as a common input to various modulation schemes and the same is analyzed by simulation through MATLAB. The resulted spectrum waveform of input audio is shown in Figure 10.

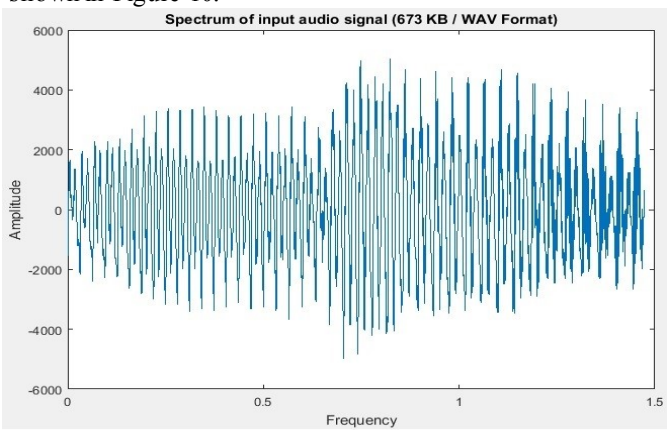

Figure 10 : Spectrum of input audio signal

Before processing to modulation, the real-time audio signal is converted to digital form and sampled at a rate of 44,100 Hz through MATLAB functions. In order to compare the digital modulation schemes performance, this digitize sequence is carrying through AWGN channel at different levels of SNR.

VI. EXPERIMENTAL EVALUATION

An audio signal whose spectrum as shown in figure 10 is fed as an input to obtain the results as mentioned below.

.

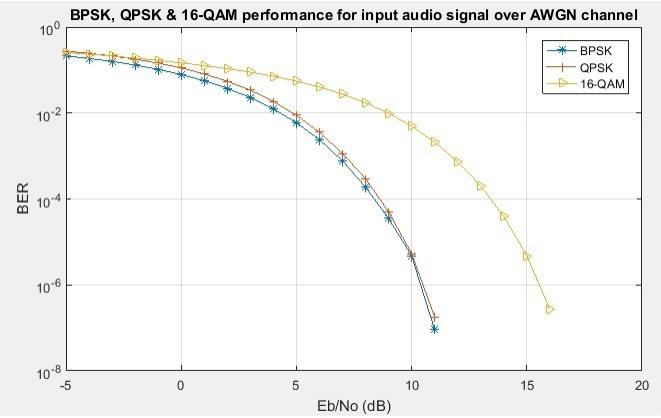

Figure 11 : BER curve for BPSK, QPSK & 16-QAM

From the obtained BER curve it is clear that the relation between SNR and BER quantities are inversely proportional. It is observed as SNR value increases the BER decreases.

In the table tabulated below, the observation made for different SNR levels on various techniques is mentioned.

MODULATION TECHNIQUES	BIT ERROR RATE
BPSK	0.0562
QPSK	0.1795
16-QAM	0.2557

Table 1 : BER value at SNR = 1dB

It is inferred that from the table 1 and table 2, at the lower SNR level say 1 dB the larger is amount of noise and at the medium SNR level say 5dB the amount of signal power is increased respectively.

MODULATION TECHNIQUES	BIT ERROR RATE
BPSK	0.0060
QPSK	0.0551
16-QAM	0.1678

Table 2 : BER value at SNR = 5dB

Considering the table 3 which says the SNR at 10dB there is a vast increase in the signal power and huge decrease in the BER values.

MODULATION TECHNIQUES	BIT ERROR RATE
BPSK	0.0000
QPSK	0.0012
16-QAM	0.0720

Table 3 : BER value at SNR = 10dB

From the above experimentation results we infer that when SNR is of high value the data rate techniques like 16-QAM shows better performance when compared to the lower data rate techniques.

VII. CONCLUSION

The respective conventional passband modulation schemes have been simulated in MATLAB software in terms of BER values as well as BER curve corresponding to different levels of SNR. The conclusion made from the above observation and discussions are as follows:

- Experimentally it is found that the minute difference of 1 dB (approx.) will occur among the BER curves of BPSK and QPSK as clearly shown in figure 11. Ideally the BER result of BPSK and QPSK are equal over AWGN channel.
- At low level SNR it is efficient to use low order modulation schemes such as BPSK or QPSK and at high level SNR it is better to use high order modulation schemes like 16-QAM as respective modulation schemes offer less amount of BER in respective levels of SNR.
- In future the research can also be proceed further while implementing these single carrier modulation schemes namely BPSK, QPSK & 16-QAM with multicarrier modulation schemes such as OFDM, FBMC, SEFDM etc in order to enhance the productivity of present communication system.

ACKNOWLEDGMENT

Our sincere thanks to all the associates & technical staff at Truba Institute of Engineering & Information Technology, Bhopal for rendering their valuable time & support in bringing this paper and also provided technical support for analyzing the results outcome. We would appreciate for more guidance and continuous support for all our future endeavours.

***Abstract*—Fuzzy clustering is a well-known data mining technique and it is used to solve some real world entity. In partitioned clustering, fuzzy c-means is one of the prominent techniques due to its straightforwardness and it produced least computational effort. Still, it falls into the problem of local optima. For solving this local optima problem, many swarms intelligent based optimization algorithm has been introduced and try to achieve a global optimum solution. Even though, some of the conventional optimization algorithms are failures to find global optimum because of premature convergence. In this research paper, a bacterial colony optimization algorithm is an integrated with fuzzy called fuzzy bacterial colony optimization has proposed and its purpose to solve both aforementioned shortcomings. The experimental outcomes are shows that the future new fuzzy clustering algorithm produced superior performance matched with previous fuzzy clustering methods.**

Keywords— Fuzzy Clustering Analysis; Fuzzy C-Means; Fuzzy Particle Swarm Optimization;Fuzzy Bacterial Colony Optimization

I. INTRODUCTION

The process of grouping a dataset based on their similar relationship is clustering. The low similar relationship data samples are handover to the one group and high similar relationship data samples are handover to other groups. The hard and fuzzy clustering are the two major types for solving the clustering problem. In both case, each data points are conveyed in different groups only in the hard clustering [1]. On the other hand, Fuzzy clustering techniques hosted a membership degree the dissimilar group of datasets [2].

The soft clustering is a famous data mining problem useful to solve many real world entities with effective manner. The fuzzy c-means is one of famous algorithm to solve the clustering problem[3]. But, it is falling into optima problems and could not achieve a global optimum. Several research works have been carried out in order to solve the shortcoming of conventional FCM. The problem of FCM noise sensitivity was excluded with the help of probabilistic Fuzzy c-Means [2]. Spatial information of the image can be effected the efficiency of the FCM and it does not completely used in FCM. Hence, a spatial functions is used with conventional FCM for extracting the spatial information of the images and it could be increased the accuracy of the image clustering [4]. However, the conventional and enhanced FCM has many weaknesses namely tend to local minima, arbitrary assignment of the cluster center values.

In the last decades, the clustering problem has been solved by using swarm intelligent based optimization techniques and it is more attention by the researchers. Such as ant colony optimization (ACO) based on the ants behavior [5], artificial bee colony optimization depends on bee performance (ABC) [6], particle swarm optimization (PSO) according to swarm activities [7], social spider optimization (SSO) [8], firefly algorithm (FA) [9] and bacterial foraging optimization algorithm(BFO)[10]. However, the traditional swarm intelligence based optimization clustering algorithms are failure due to lack of development aptitude that is simply to fall into premature convergence.

Hence, an advanced type of optimization algorithm is known as bacterial colony optimization (BCO) algorithm is combined with the fuzzy concept is referred as fuzzy bacterial colony optimization (FBCO) clustering proposed in this study work. The FBCO algorithm is scheduled through mimicking the behavior of bacterial colony and it has a positive evolutionary mechanism. It has given a modern implementation principle in swarm intelligence algorithms [11].

The robustness of the FBCO algorithm is applied to clustering problem and it compared with FCM and FPSO. The simulation effects are demonstrates that the proposed FBCO clustering algorithm produced significant classification accuracy. The document is structured as, a description of FCM is discussed in Section 2, FPSO is discussed in section 3, the behavior of BCO is discussed in Section 4, the proposed FBCO clustering algorithms is expressed in section 5, the experiment and outcome presented and discussed in Section 6. The conclusion of this research works conversed in the Section 7.

II. FUZZY C-MEANS (FCM)

In partition clustering, Bezdek et al developed FCM algorithm [3]. The iterative process of Fuuzy c-means is to discover meaningful patterns from obtained datasets and it apply the idea of soft membership as an alternative of conveying a pixel to a certain group, every pixel will include to dissimilar membership values on each group. In particular, unlabeled data set $O = \{O_1, O_2, \ldots\ldots O_n\}$ in R^d dimensional area, the Fuzzy c-Mean is to partitions the records into c ($1 < c < n$) fuzzy clusters with cluster centers $z = \{z_1, z_2, \ldots, z_n\}$ [12].

In fuzzy clustering, the data samples are expressed by a fuzzy matrix μ. It has with n rows and c columns. Where n is the number of data samples and the number of classes is denoted by c. The component μ_{ij} is in i^{th} row with j^{th} column. Them, μ specify the amount of association of the i^{th} data samples with the j^{th} cluster. The distinctiveness of μ is defined as follows:

$$\forall_i [0,\ 1]\ \forall_i = 1,\ 2 \ldots n\ \forall_j = 1,\ 2 \ldots c \quad (1)$$

$$\sum_{j=1}^{c} \mu_{ij} = 1\ \forall_{i=1,2,\ldots n} \quad (2)$$

$$o < \sum_{j=1}^{c} \mu_{ij} < n\ \forall_{j=1,2,\ldots,c} \quad (3)$$

The aim of minimization or maximization function is well-defined as follows,

$$J_m = \sum_{j=1}^{c} \sum_{i=1}^{n} \mu_{ij}^{m} d_{ij} \quad (4)$$

Where, $m(m > 1)$ is a values of scalar and is heavy exponents that regulating the fuzziness of the resultant clusters. Euclidian distance d_{ij} is denote the function from data point to the cluster center $z = \{z_1, z_2, \ldots, z_n\}$. The distance function d_{ij} is defined as follows,

$$d_{ij} = \left| o_i - z_j \right| \quad (5)$$

Where, the z_j centroids of the j^{th} cluster and i^{th} data objects which is defined by using below equation

$$z_j \frac{\sum_{i=1}^{n} \mu_{ij}^{m} o_i}{\sum_{i=1}^{n} \mu_{ij}^{m}} \quad (6)$$

If convergence criteria does not met after completing every iteration, then the membership values is updated as follows,

$$\mu_{ij} = \frac{1}{\sum_{k=1}^{c} \left(\frac{d_{ij}}{d_{ik}}\right)^{\frac{2}{m-1}}} \quad (7)$$

III. FUZZY PSO

The PSO algorithm is a well-known optimization techniques which are applied to solve clustering problem to obtained efficient clustering accuracy[13]. The PSO mimics the bird flying behavior and fish schooling behavior. The PSO clustering searching the optimum cluster center on their search space which is moving toward an optimum solution which is produced efficient clustering members based on their similarity[14].

H. Izakian et al has proposed FPSO for solving clustering problem in fuzzy [15]. In Fuzzy PSO, the particle position and velocity are defined as a fuzzy relation between groups and objects that is each particle are represented membership degree μ and it should satisfy the condition of equations(1) and (2). Then , the position and velocity updating done are given as,

$$V(t+1) = \omega \times V(t) + (c_1 r_1) \times (pbest(t) - X(t)) + (c_2 r_2) \times (gbest(t) - X(t) \quad (8)$$

$$X(t+1) = X(t) \otimes V(t) \quad (9)$$

Where, *pbest* is the personal best values achieved from current particle and gbest is a global best value achieved by all particle from $c \times n$. However, the process of searching ability in the conventional PSO is an inefficient due to the search process not carried out completely. In this situation, the PSO algorithm can disturbed by a problem of premature convergence[16].

IV. THE FUNDAMENTAL BEHAVIOUR OF BACTERIA COLONY OPTMIZATION

The BCO was developed by Niu and Wang in 2012 followed by the behavior of E.Coli bacterial colony[11]. The behavior of BCO algorithm is a combination of two bacterial foraging algorithms such as bacterial foraging optimization[17] and bacterial chemotaxis algorithm[18]. The conventional bacterial based algorithm is considered only entity behaviors instead of social behavior of swarm intelligence algorithms. The bacterial colony is an autonomously searching the food in the search space by their personal knowledge.

However, the conventional bacterial based algorithm is a problem due to their features and it takes more computation time. To solve above revealed limitations, a innovative fuzzy clustering algorithm is proposed such as fuzzy bacterial colony optimization (FBCO). There are five types of main steps presents in the BCO namely chemotaxis, communication, elimination, reproduction and migration process. The following subsection are briefly explained the behavior of the conventional BCO and its steps [11].

A. Chemotaxis and communication model

The communication is major activities of the bacterial colonies that are accompanied with two processes such as runs and tumbles. It has performed three kinds of information exchanges during the process of communication such as random direction, group information, and personal information. The bacterial colonies are used for an exchange the information and guide to them in the behaviors of movement and its guidelines. The process of the communication can be accomplished either run or tumble which is expressed as follows,

$$Position_i(T) = Position_i(T-1) + R_i.(Run_{\inf o}) + R\Delta(i) \quad (10)$$

$$Position_i(T) = Position_i(T-1) + R_i.(Tumb_{\inf o}) + R\Delta(i) \quad (11)$$

The relationship between the individual and the group of the bacterial colonies are considered by the position updating process. The information on the each bacterial colony is shared with the help of communication process.

B. Elimination and Reproduction method

Each bacterial colony is noticeable with a degree of energy level based on the ability of searching in the exploration. The level of energy of every bacterial colony is defined by its probability. The energy level of each bacterial colony is sorted and analyzed, then decide the qualification of bacterial colony used as a criterion. The assessment of the elimination and reproduction process can be defined as follows,

$$\begin{aligned} &if\ L_i > L_{given}\ and\ i \in healthy,\ then\ i \in Candidate_{repr} \\ &if\ L_i < L_{given}\ and\ i \in healthy,\ then\ i \in Candidate_{eli} \\ &if\ i \in unhealthy,\qquad then\ i \in Candidate_{eli} \end{aligned} \quad (12)$$

Where, L_i -is the energy level of i^{th} bacterial colony. All behavior of the bacterial colony was constrained surrounded by a reserved area. If bacterial colony moves left from reserving area, two schemes will be performed. Either, produce new entity to re-establish the outer one or modify the forward way to retains them effectively. In this stage, the boundary control is very important. The outer bacterial colony is considered as an unhealthy and it's ready to eliminate from the populations and then reproduce by the healthy bacterial colonies.

Algorithm 1 : Proposed FBCO clustering algorithms

Begin
- Step 1 : Initialize required parameters
- Step 2 : Each bacterial colony
- Step 3 : Chemotaxis and communication process in tumbling and swimming
- Step 4 : Calculate cluster center for each bacterial colony
- Step 4 : Performing an interactive exchange
  - Step 4.1 : If Individual Exchange
    - *if* Dynamic neighbor oriented
      - if found poorer fitness bacterial colony, then replace with random values
    - *else* Random oriented
      - Replace poorer colony after finding poor fitness value of bacterial colony from the given data chooses by randomly
  - Step 4.2 : Else if Group exchange
    - Replace the poorer after finding the best bacterial colony according to the fitness values
- Step 5 : Reproduction and elimination
  - Step 5.1 : Search the healthy bacterial colony using its fitness values
  - Step 5.2 : Perform the reproductions and elimination
- Step 7 : Migration process
- Step 8 : Update position for each bacterial colony
- Step 9: If terminating situation is not met, then go to step2.

End

C. Migration model

The migration is the process of constructing more nutrition and its performance is not followed by given probability. The bacterial colony would travel to a new random residence on the search space according to the given conditions satisfied. The BCO is performing the migration process in order to avoid the local minimum. It can be expressed as follows,

$$Position_i(T) = rand.(ub - lb) + lb \quad (13)$$

Where, lower and upper borders are lb and ub of the colony positions correspondingly. The random number generation is representing as *rand* that range between 0 and 1.

V. PROPOSED FUZZY BCO CLUSTERING ALGORITHM

The major purpose of the fuzzy clustering problem is to decrease the sum distance between samples which is defined as an objective function J_m as follows,

$$J_m = \sum_{j=1}^{c} \sum_{i=1}^{n} \mu_{ij}^{m} d_{ij} \quad (14)$$

Where, K is determine the number of clusters, D is the number of dimension in the data sets of x. The lowest values of J_m is considered as the best values. In the proposed FBCO, the fuzzy relation of the data sample X is defined as follows ,

$$X = \begin{bmatrix} \mu_{11} & \cdots & \mu_{1c} \\ \vdots & \ddots & \vdots \\ \mu_{n1} & \cdots & \mu_{nc} \end{bmatrix} \quad (15)$$

Where, μ_{ij} is the membership function value for i^{th} data samples and j^{th} cluster. It should be satisfied with the equation (1) and (2). Furthermore, the complete lives of the bacterial colonies are involved, two processes in the chemotaxis such as running and tumbling. Therefore, the updating the position of the each bacterial colony as follows,

$$\begin{aligned} Position_i(T) = {} & Position_i(T-1) + C(i) \\ & *[f_i.(G_{best} - Position_i(T-1)) + (1-f_i) \\ & *(P_{best_i} - Position_i(T-1)) + turb_i] \end{aligned} \quad (16)$$

$$\begin{aligned} Position_i(T) = {} & Position_i(T-1) + C(i) \\ & *[f_i.(G_{best} - Position_i(T-1)) + (1-f_i) \\ & *(P_{best_i} - Position_i(T-1))] \end{aligned} \quad (17)$$

$$C(i) = C_{\min} + \left(\frac{Iter_{\max} - Iter_j}{Iter_{\max}} \right).(C_{\max} - C_{\min}) \quad (18)$$

Where, $turb_i$ denotes the turbulent direction variance of the i^{th} bacterial colony, $C(i)$- is the chemotaxis step size of the i^{th} bacterial colony, $f_i \in (0,1)$, G_{best} is the global best and P_{best} is the personal best of the i^{th} bacterial colony. $Iter_{\max}$, $Iter_j$ are the maximum iteration and current iteration respectively. In proposing FBCO, the n number of bacterial colonies of the position is defined as *Position* and that is produced $D \times K$ cluster centroid. Hence, $n \times K$ position will be moved for achieving minimum distance that move to the global minimum.

VI. Experimental Resulrs and Discussions

In this research works, the strength of the proposed model is evaluated using six types of benchmark data sets and it obtained from the UCI repository [19].

A. Dataset descriptions

- Fisher's iris consists of three different species of the iris flower, one fifty samples and four features were collected in each species.
- Glass datasets have 214 data objects with 6 types of glasses and it has nine different features in each type
- Wisconsin breast cancer (WBC) data set has 683 data samples with two categories and it categorized by 9 features.
- In wine data sets, it contains of 178 data objects with 3 different types of class and categorized by 13 features.
- Contraceptive Method Choice (CMC) dataset has 1473 data points with 3 types and 9 features
- Vowel data set contains 871 Indian vowels with three features and six overlapping classes.

B. Results analysis and discussions

The FCM clustering algorithm is set 100 iterations as maximum iterations, optimization based clustering techniques such as FPSO and FBCO are set 10 iterations as a maximum iteration. Other parameters are set as mentioned in [11]. Table 1 summarized the efficiency of the clustering algorithms such as FCM, FPSO and proposed method BCO based clustering. The objective function is used to estimates the efficiency of the clustering methods which is defined in (4). The final result is an obtained the average values of 10 independent runs on all compared clustering methods.

Three types of values are considered in this research work as results such as best, average, and worst. The best value is considered as a better performance and it decides according to problem in an optimization process. Here, a low value is considered as best performance because the major goal of this research work concentrates to reduce the objective values (distance) between the data sample with the help of the proposed FBCO clustering algorithm. From the experimental results, the objective value of the proposed model produced enhanced results other then compared clustering algorithms.

VII. Conclusions

Fuzzy clustering is a complicated NP-Hard problem to solve with efficient manner. Hence, the fuzzy bacterial colony optimization clustering algorithm has proposed to solve clustering problem in order to obtain the higher accuracy. The evaluation of the proposed model has conducted on four of kind's benchmark datasets. The experiment results demonstrate that the proposed fuzzy bacterial colony optimization based clustering model produced higher clustering efficiency.

TABLE I. Performance comparisons of the proposed model

Abstract **- Microgrid (MCG) musters of distribution system and distributed energy resources concurrently storage units and adjustable loads. Operating conditions for these systems are sovereign (Islanding mode) or depending (Grid connected mode). Various technologies are using now a days for making easeful the local generation using very small sources and the extendable (in time phrase)sources which are available in bulk and in the nature like wind, biomass, geothermal, sun radiation on earth etc. the planned accomplishment of local microgrid going through the view of study which contains residential type load whose nature may be critical or non-critical, a governed battery, pv system power by solar radiation as RES, distribution network of any grid which integrate an islanding MCG into grid through a pole mounted transformer. Different load conditions are examined over a 24-hour time phrase and the variation results on battery POC (Phrase of Charge) examined on MATLAB2018a software and relative imposition is examined for the time limit at various parameters of load for planned groundwork purpose.**

Keywords-Microgrid, BESS, SPV, Phrase of Charge, Battery Governer

I. INTRODUCTION

Microgrid is an incorporated plan for distributed Generation (micro-generation), energy storages, governable loads determine in local distributed grid with main grid. Various definitions are available for MCG on the basis of govern strategies and classified sources known as renewable energy resources integrate with in MCG; It is called MCG whenever it has governed abilities with in it. Microgrid able to govern both mode normal (grid- connected) and emergency (islanding) [1], [11]. In depending mode (grid-connected) the energy shortage is fulfilled by the main grid whereas the excessive generation by MCG is equipped to the grid at the distribution level. In the sovereign mode (islanding), the MCG generates itself both active (P) and reactive power (Q) and poise the demand of the load side which includes

the energy transfer micro-sources to storages and vice-versa [2], [10]. With the solar energy availability, SPV fed the power to the charge of battery which supply to the load which is insufficient because the availability of solar energy is intermittent. POC of battery is governed by governer. The planned accomplishment of the system brought out for diverse instance horizon for diverse phrase of time over 24-hour loads differed to examine whether battery governs the POC and POC with the resultant output power of battery is differing whenever the load is getting change in demand.

II. MICROGRID PLAN ON MATLAB

A local Microgrid plan taken for examination point of view, with single phase AC of 200 V, generation by solar (maximum capacity 5 KW) which is taken as RES. Three power sources are taken in this plan main grid power, SPV, BESS (150 V, 30 ah). The battery governer governs the BESS. If there is any excessive power in MCG system this power is imbibe by the battery governler and fed to the BESS or it also gives power to the MCG system whenever the power shortage conditions occur. For load purpose two type of loads are considered as captious (C) or non-captious (NC) load. Three basic home are taken as NC while a hospital is taken as C (captious load). Tripping circuit is implemented for every load if it is needed. Portion of a plan is from MathWorks example and forward alteration is done as per need.

The pole mounted supports the system in connecting the main grid with the MCG. The overview Fig. of plan is in Fig. A. For the main grid account, a three-phase alternating current 33kv voltage source, is linked to a transformer (33kv/3.3kv). This planned network again linked to pole mounted transformer (3.3kv/200v, 50hz).

The SPV and Battery are DC power sources in the nature that's why before connecting with MCG, convert into single phase AC. For the governing plan of MCG, there is assumption that power requirement dependability of MCG is not onto the grid, and all the required power is catered by SPV and BESS. Statistics of BESS carries POC and FOC of the BESS which is governed by battery governer with the voltage rating and current rating available by the source authority.

This planned network is examined the overall battery capacity throughout the POC and FOD. The define networks are considered on the basis of discharge current and temperature. In planned network of this paper standard values are considered for accomplished aim.

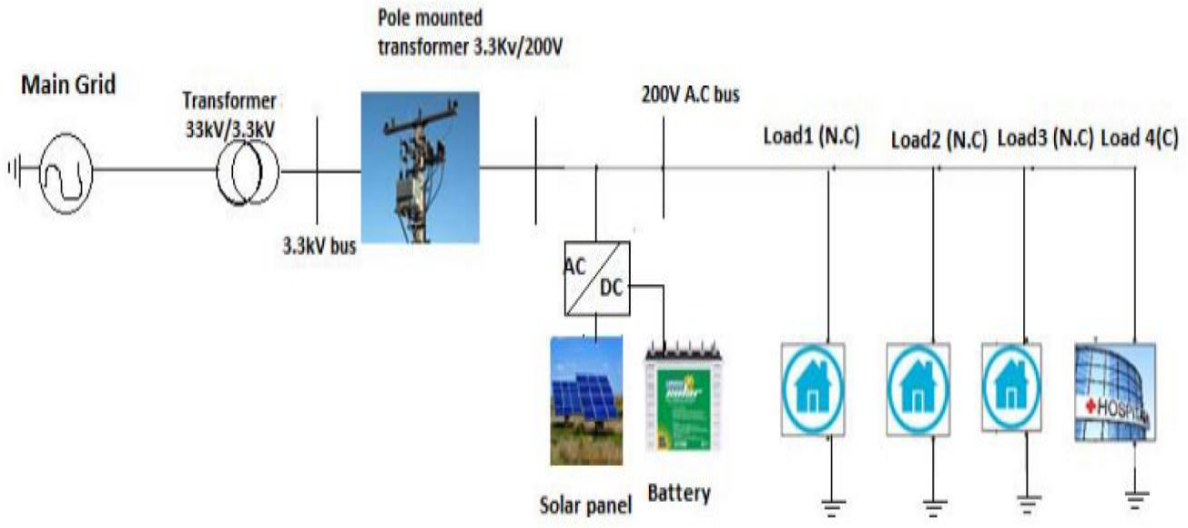

Fig. A. Planned MCG system musters with SPV, BESS, Four loads

III. POC PERFORMANCE DUE TO VARIATION IN LOAD VALUES

The fundamental for BESS strategies is totally turn up to the govern topologies which are implementing into charging or discharging mode of battery. For getting maximum output from the planned network on economy scale there is demand of accelerating the life cycle of BESS [3], [12]. Primary side current (I_{psc})/ voltage (V_{psc}) as it is secondary side current (I_{ssc})/ voltage (V_{ssc}) are two major measure aspects of primary and secondary side. I_{ssc} and V_{ssc} are account for the source as the authority for the SPV and battery at the battery end displayed on Fig. A. POC delineate as reference for the charge left with respect to the formal volume (capacity). In antecedent research FOD (Fall of discharging) defined the effect of POC on BESS life period, one cycle of battery [4], at this point cycle refers to the total process of battery including total charge and total discharge. The curve graph between FOD and life cycle shows in [5], resulting that at the lower FOD a raising many of formal cycles are demonstrating. In [6], [13] govern topologies for battery knowing FOD, the charging and discharge rate spans dealing with improvement into life of BESS. Optimal proportions and assigning methods are defining into [7] by economic analysis model that is given in the account for decrease the threat of energy import and export for BESS. Govern topologies applied for the keeping POC in the Range which are sets higher and lowering range for getting charged or discharged, defined in [8], [9], [14]. In this MCG plan, four cases accounts for check the result with the variation in the load. The Graph of time for all different arc is similar, displays in Fig. G, that is accounts for displays the POC in Fig. H, I and J. Time period is considered as 24-hour, one day for all the planning.

Case W: when all four loads are functioning

Fig. C. Power of Secondary side

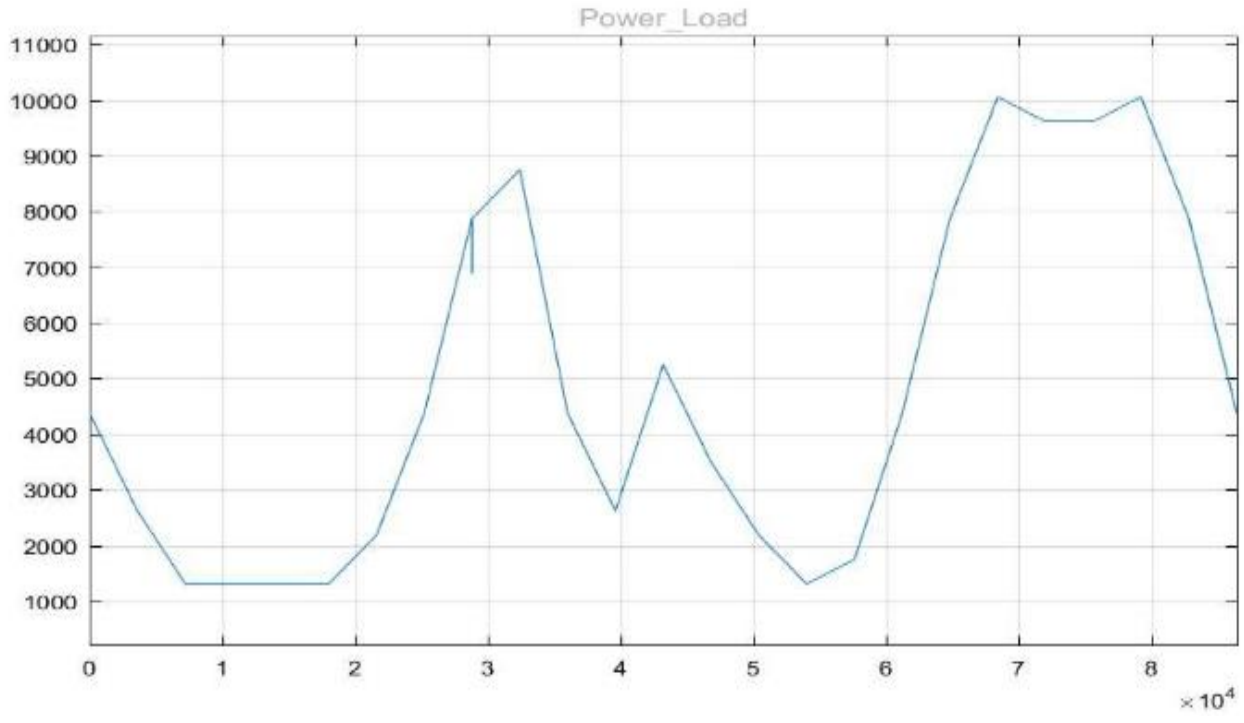

Fig. D. Power of Load side

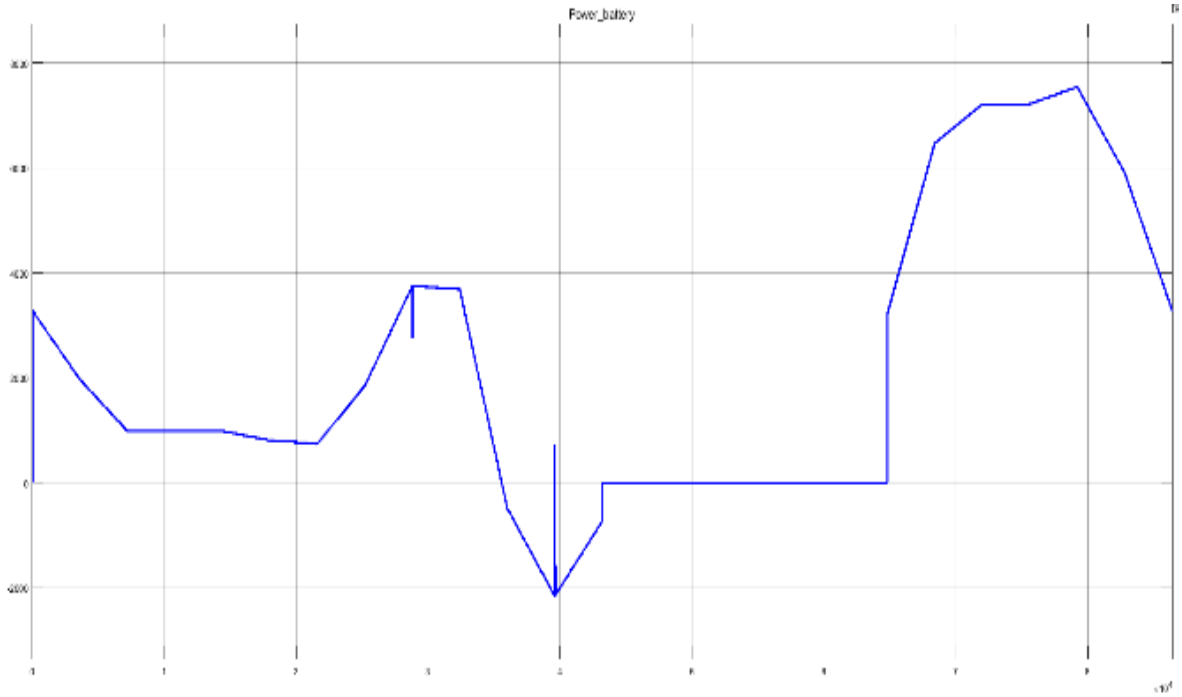

Fig. E. Power of Battery

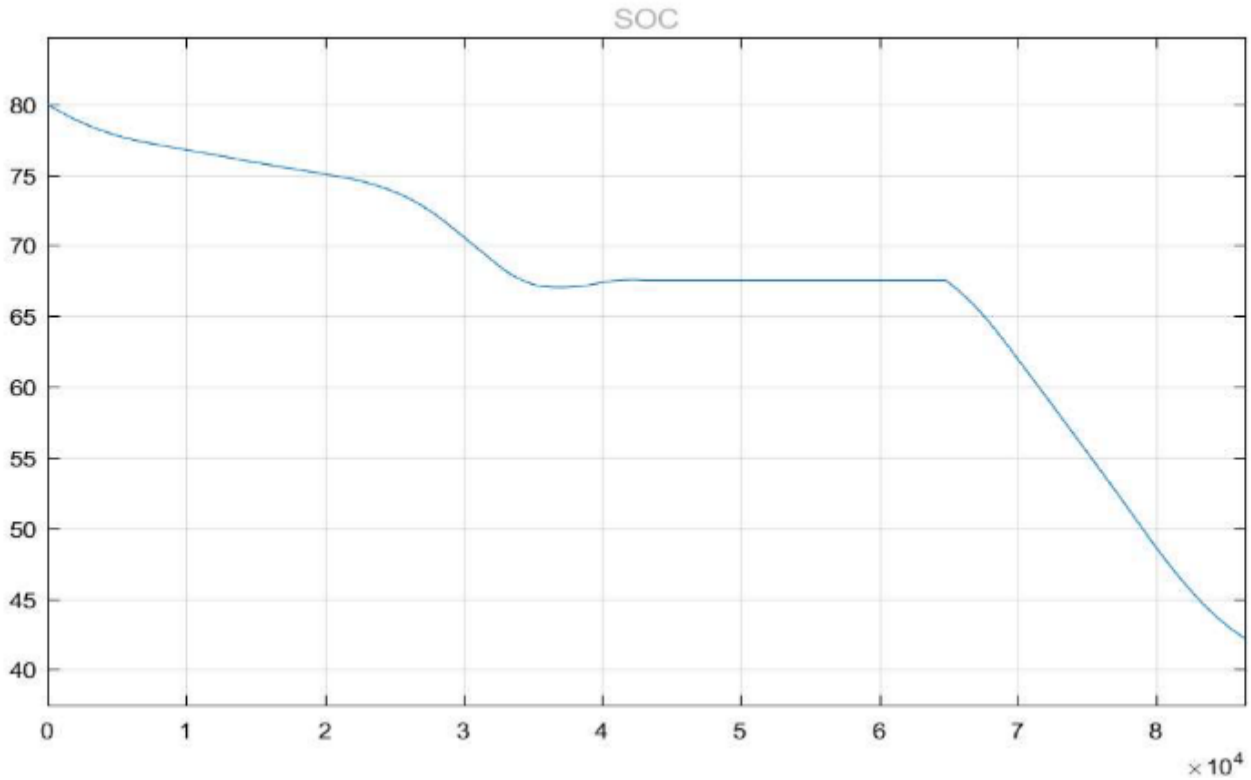

Fig. F. POC of BESS when all loads are functioning

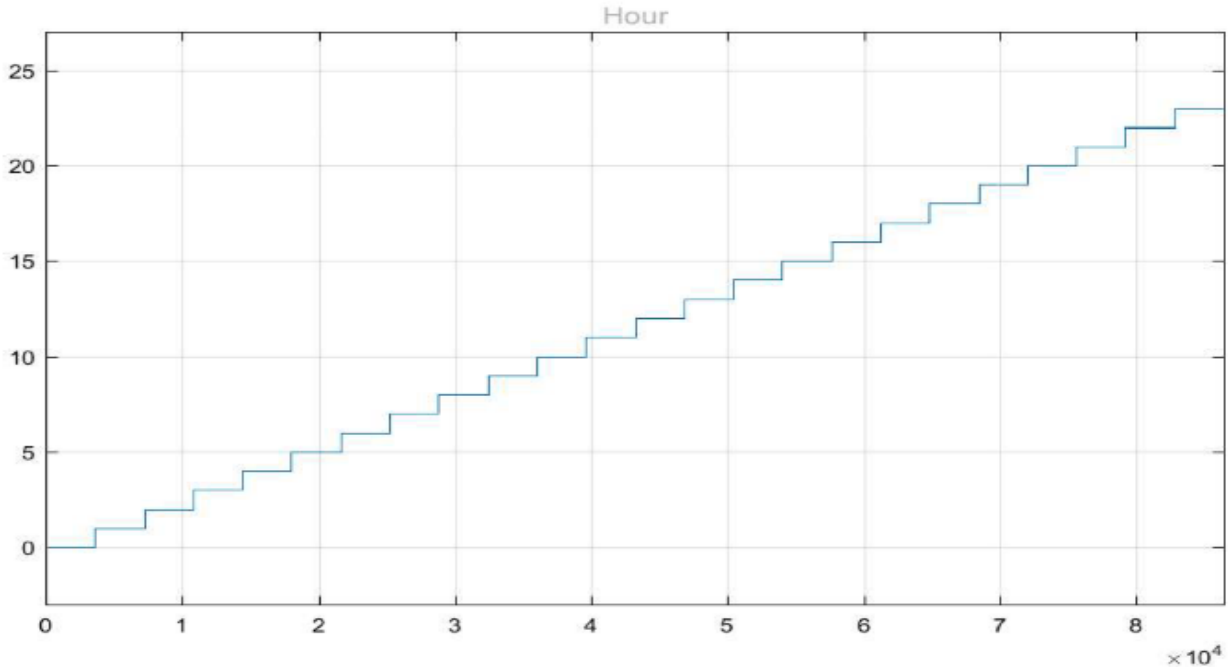

Fig. G. Days hour which are taken on various scale for calculation of planning.

Case X When all three loads are functioning.

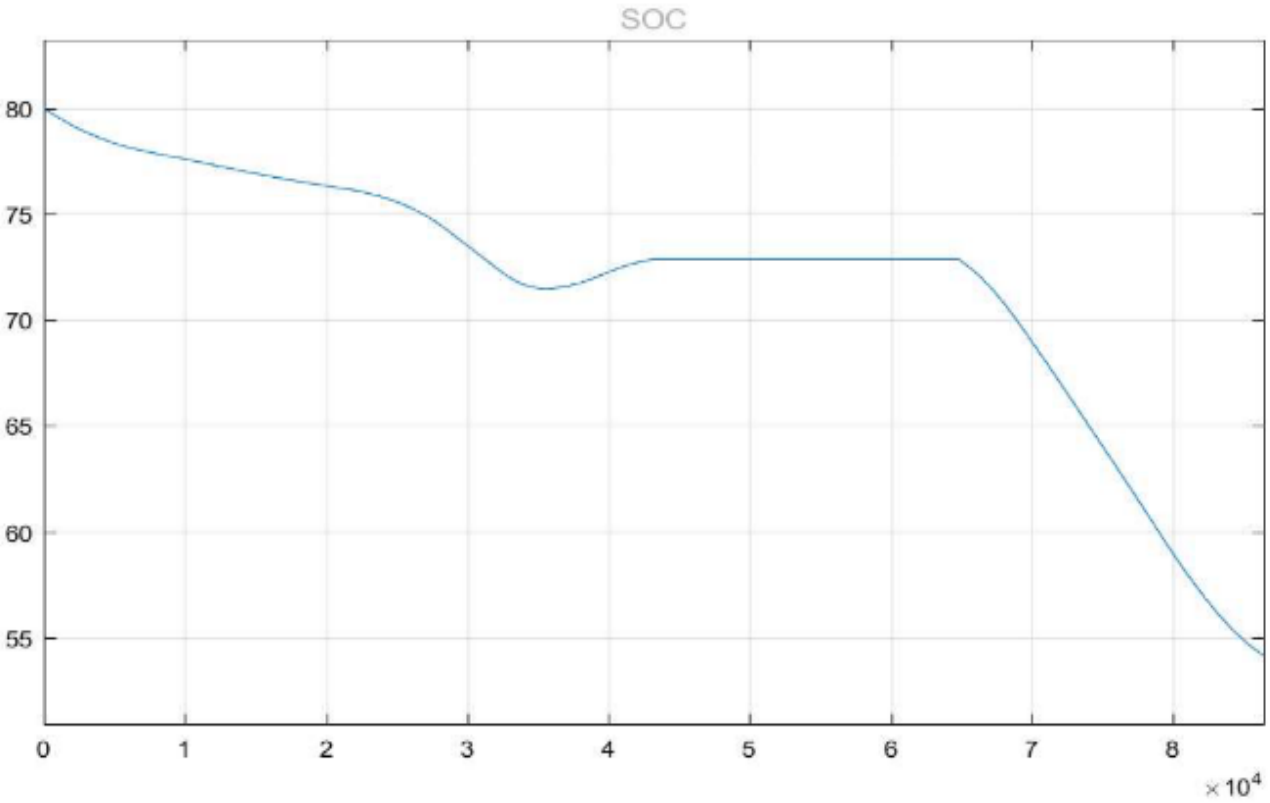

Fig. H. Battery POC for three load connecting network

Case Y: When two loads are functioning including critical one.

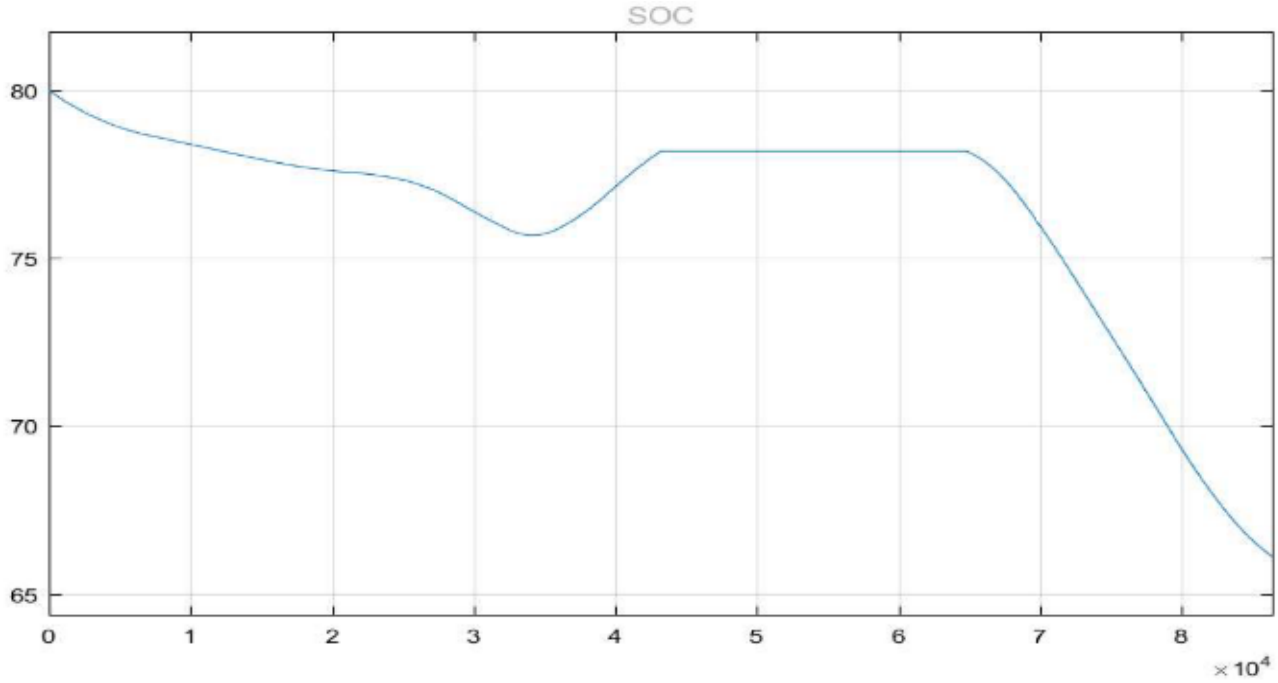

Fig. I. Battery POC for two load connecting network

Case Z: When only critical load is functioning.

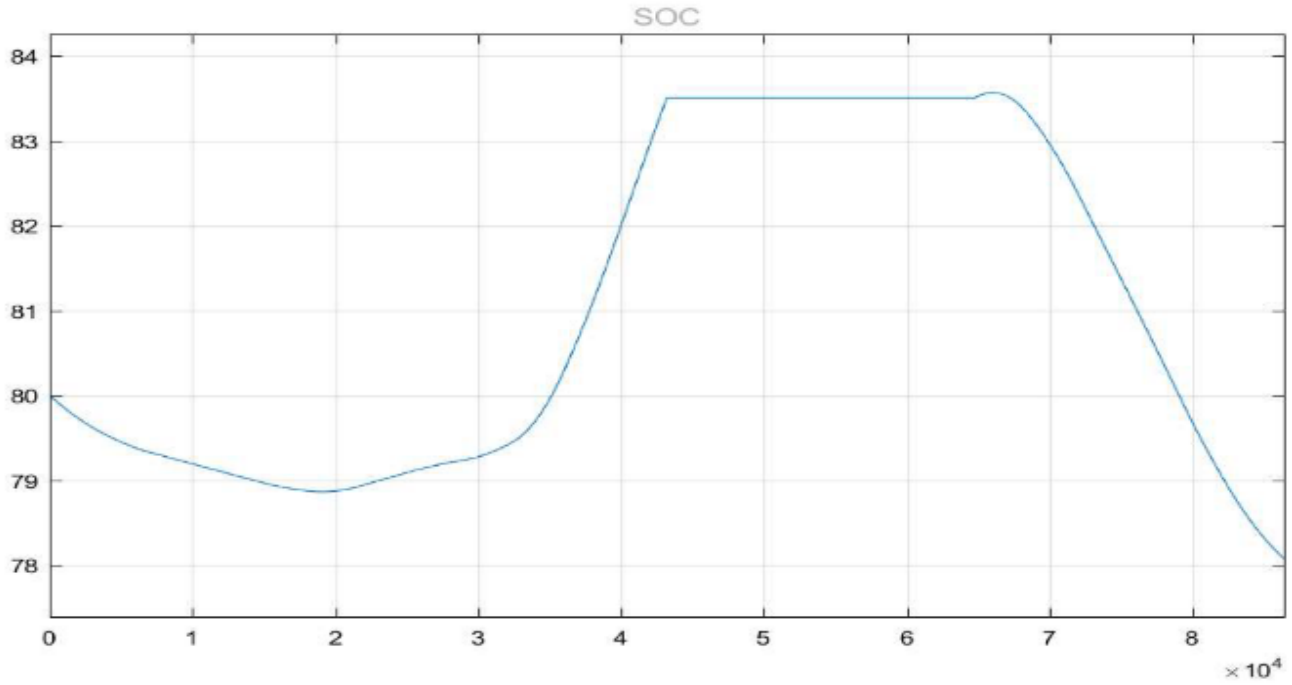

Fig. J. Battery POC for critical load

IV.RESULT ASSESMENT:

As shown cases i.e. case W, X, Y, Z, throughout the 20-hour to 4-hour, output of SPV is almost 0. A peak output (3 kW) is followed during 14 hour and 15 hour. Variation in nominal consumer load, the consumed power amount by load side get to the peak at 9 hour (2.1 kW), 19 hour and 22 hour (3.8 kW). The battery governer performs battery govern during 0 hour to 12 hour and 12 hour to 24 hour. govern of BESS contains the progressive tagging govern of the one of the parameters, current that's why true power flow towards the MCG, the power at MCG side of pole mounted transformer is fixed to zero. In case B three loads are working at a time which include one captious and other twos are non-captious, this decouple of one load accelerate the rate of POC with faster rate as compare to case- W. Hence in the planning of MCG load profile should be account for shaping aspects of overall network. Akin, in other two cases like case Y (Fig. I) and case D (Fig. J), a rapid variation in battery POC can be diagnose which displays the battery statistics and sizing of system. Battery ranges of POC governs by battery governer.

In case W, all loads are linked in system, power is fed by battery to the load, POC drop earlier. During 12h to 18h, no action performed by battery, load is directly supplied by system power. Later (after 18h) POC anew drop for the battery during the feeding of power to the load. Here SPV used as RES, it provides power for charging of battery during its maximum output hours and aid battery to conserve its POC. From case D, it is noticed that POC of battery is over 83% which is checked by battery governer.

V.CONCLUSION

It is observed that from the previous part of study that accomplishment of MCG is become more effective with size of BESS and POC which delivers a noticeable result that in the planning of MCG the battery type is the main consideration and also the govern topologies for battery govern.

It is suggested that for an intermittent load which vary with time i.e. works only for set of time and otherwise it is not active, in these conditions me must calculate the size of battery not the complete pv system. If load is not intermittent it works in uniform way then we must calculate PV system size not the size of battery. Plan for other MCG setups can also be executable with more RES or their fusion.

***Abstract*- In the fields of industry, communication, medical equipment and science that continuously emit electromagnetic radiation, the use of electronic and electrical equipment has risen dramatically over the past couple of decades. This electromagnetic radiation causes interference with other devices. To avoid the adverse effects of electromagnetic waves on equipment, the EMC compliance testing of electronic equipment is necessary. This paper introduces a Gigahertz Transverse Electromagnetic Mode Cell model for EMC testing over a DC to 1 GHz frequency range. The GTEM Cell is designed by adopting computer simulation technology (CST) microwave studio software. The performance of the cell has been examined. The measured results of the GTEM cell shows that the S11 is less than -10dB and VSWR is less than 1.7 during the 0.25 to 1 GHz of frequency band. The electric field uniformity and equipment testing volume below the septum is determined with the help of electric field probes which are placed at different heights.**

Keywords - Electromagnetic Compatibility (EMC), Gigahertz Transverse Electromagnetic Mode Cell (GTEM), EMC Compliance, Radio Frequency (RF) absorbers.

I. INTRODUCTION

In the modern age, technological development over the past years has been growing rapidly. The use of electrical and electronic devices is increased in day to day life. However, this equipment frequently generates electromagnetic signals. Consequently, these devices will act as a transmitter and receiver of electromagnetic energy. Therefore all electronics and electrical devices are tested with electromagnetic compatibility (EMC) test. The EMC test is classified in two types, emission and susceptibility (immunity). The emission is the generation of unwanted electromagnetic signals from the equipment under test (EUT) and susceptibility is the ability of electrical equipment to operate correctly in the presence of unwanted electromagnetic emission [1]. Different techniques are accessible for evaluating EMI / EMC readings. These depend on hypotheses like EUT size, frequency band, test limits, field types to be measured (electric or magnetic), field polarization, test signal electrical characteristics, etc.

Various EMC/EMI measuring techniques are used such as open area test sites, transverse electromagnetic cells, anechoic chamber and gigahertz transverse electromagnetic mode (GTEM) cell which depending on the size of the equipment. [2]. By considering all the above points a system designed with the help of CST MW software for EMC measurement equipment.

II. EMC MEASUREMENT METHODS

A. Open Area Test Sites (OATS)

One sort of EMC test technique is an open area test site. To perform the test in an open environment, some environmental conditions need to meet the standard requirements. For big systems such as railways, OATS is appropriate for performing both radiated emission and susceptibility tests. Most of the time all electronics and electrical equipment tested in shielded chamber. The shielded chamber could be transverse electromagnetic (TEM) cell, GTEM cell or anechoic chamber, etc. The only limitation in OATS is to establish a test without external interferences like radio frequency transmission from a civil communication system, satellites, radio transmitters, etc. [2, 3]

B. Anechoic Chamber

Anechoic chamber have been used for electromagnetic compatibility measurements in an electromagnetic isolated environment as per the international standards (e.g. IEC 61000-4-3). Anechoic chamber overcomes the restriction of the open area test site (OATS). It is often used to measure distinct EMC / EMI devices. The chamber is fully closed shielded room and the interior surfaces are covered with radiation absorbent material (RAM), i.e. RF absorbers and ferrite tiles. The most useful advantage of the anechoic chamber is that no external electromagnetic interference occurs, so EMC testing of equipment is more accurate. The limitations of this method are the high cost of a large amount of

RF absorbers and high input power required to establish the electric field [3, 4].

C. Transverse Electromagnetic Mode (TEM) Cell

The Transverse Electromagnetic Mode (TEM) cell, as shown in fig.1, was created in 1974. Its role is to produce normal electromagnetic (EM) fields in shielded environments over a frequency range of DC (0 Hz) to a few MHz [5]. The cell consists of a segment of rectangular coaxial transmission line tapered at each end to fit the normal coaxial connectors dimensionally. RF signal generator (input) linked to one end of the and 50Ω termination provided at the other end of the cell. In transverse electromagnetic mode, the EM waves produced in the cell propagate and therefore have the same features as plane waves. TEM cell's main limitation is that it cannot be used at a range of gigahertz. It is made up of three distinct components in shape. The length of the internal and outer conductors is distinct due to the bending of the transmission lines. Therefore, a wave traveling time along the outer conductor is longer. These field distortions result in higher mode propagation and thus affect the uniformity of the field inside the cell increasingly at higher frequencies. Another limitation is size of the cell, as the cell shows cavity effects, like resonances, at frequencies at which the dimensions of the cell are about half the wavelength. As the frequency of operation increases, its size decreases and the EUT size is restricted [6,7].

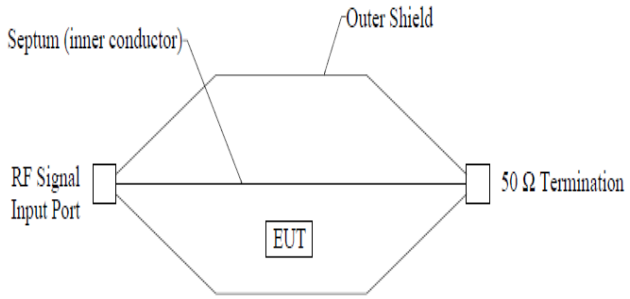

Fig. 1. Transverse Electromagnetic Mode (TEM) cell.

D. Gigahertz Transverse Electromagnetic Mode (GTEM) Cell

It is possible to use up to a gigahertz frequency range to overcome all of the above constraints by modifying the TEM cell, known as the GTEM cell. In 1987, D. Konigstein and D. Hansen launched the GTEM (Gigahertz Transverse Electromagnetic Mode) cell. It is the hybrid structure of TEM cell and anechoic chamber. Using a TEM cell strategy, the GTEM cell is a transmission line structure. Without the geometric distortion of the TEM wave, a spherical wave propagates from the RF source into a rectangular coaxial transmission line. Since the waveguide's opening angle is comparatively low, the undistorted spherical wave can be regarded as a plane wave. A tapered section of a rectangular transmission line is the structure of the GTEM cell. In the load termination section, RF absorbers utilize as absorbing material for EM wave termination and resistive load for current termination. The GTEM cell, therefore, needs less space and cost-effective relative to the anechoic chamber. Additionally, it is used for high frequency range. [8,9].

III. GTEM Cell Design and Construction

A. Design Guidelines

The Gigahertz Transverse Electromagnetic Chamber (GTEM) idea is focused on the transverse electromagnetic cell (TEM), which is essentially a coaxial rectangular transmission line operating in TEM mode. The necessary input power is obtained from the EUT position,

$$P = \frac{(E.h)^2}{Z} \quad (1)$$

And the field strength is given by,

$$E = \frac{\sqrt{P.Z}}{h} \quad (2)$$

From the equation (1) and (2) a small chamber of testing volume 10 cm^3 is defined. From equation (1) the intended intensity of electric field will be of 10 V/m, accounting for 0.2 W of input power within bottom of all and the septum. Accordingly, the exact location of the test volume is in the middle below the septum just in front of Radio Frequency (RF) absorbers. This is restricted to $\frac{1}{3}$ of height from the bottom to center conductor imposing the other restriction of boundary such as the height of absorbers i.e. 23 cm. A clearance about 5 cm is been considered to avoid the reflection on the body of chamber and the EUT. Thus, providing the cell length from the rule of thumb, the first estimate to the cell size is achieved as follows:

$$L = 3\ (T_V + D_{TA} + L_A) \quad (3)$$

Where,
T_V = testing volume
D_{TA}= safety distance between testing volume and absorbers
L_A= length of RF absorbers

The transition between N type connector and the cell body is very difficult for GTEM cell design. Design performs an significant part in determining the right size of an Apex.

GTEM cell output depends on the flared transmission line characteristic impedance. Therefore, for the construction of a cell, calculating the characteristic impedance is most essential. The electromagnetic wave is partially reflected back and high-order methods are stimulated due to the small volume and concentrated current in the transition part. To prevent these issues it is essential to match appropriate impedance [10].

The characteristic impedance of the lossless transmission line, according to the high frequency transmission line theory, is:

$$Z_0 = \sqrt{L/C} \quad (4)$$

Where, L and C are the inductance and capacitance of the transmission line per unit length, respectively. The speed of the electromagnetic wave in the lossless transmission line is determined by:

$$\upsilon = \frac{1}{\sqrt{\varepsilon_0 \mu_0}} = \frac{1}{\sqrt{LC}} = 3 \text{ X } 10^8 \text{ m/s} \quad (5)$$

Where,
ε_0 = permittivity of air or vacuum
μ_0 = magnetic permeability air or vacuum.

The equation (4) and (5) gives the characteristic impedance as follows,

$$Z_0 = \frac{1}{\upsilon C} \quad (6)$$

For standard transmission line, substitute $Z_0 = 50\ \Omega$ and $\upsilon = 3 \text{ X } 10^8$ m/sec in equation (6), per unit capacitance is found as C = 66.66pF. By adjusting the width of the septum for a given height to width ratio and height of septum above the center line (h) the desired capacitance and thus characteristic impedance can be achieved [11,12].

This paper introduces the structure of GTEM cells with a volume of 113 cm x 69 cm x 41.2 cm over a frequency range of DC to 1GHz by considering all of the above criteria. A test quantity of 10 cm x 10 cm x 10 cm is described because the chamber is supposed to operate only with small devices.

B. Simulation

GTEM cell evaluation designed by using the Finite Difference Time Domain (FDTD) method. The fig. 2 shows the simulated structure of GTEM Cell with load resistance and RF Absorbers for current termination and RF waves Absorption in CST MW.

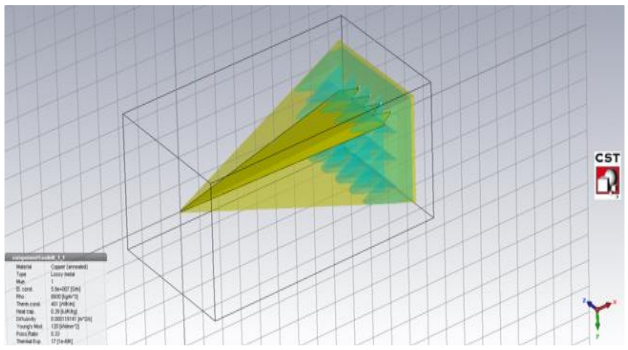

Fig. 2. A cross-Sectional view of GTEM Cell.

The fig. 3 and 4 show GTEM cell parameter S11 and VSWR. Over the frequency band, the results stated input reflection is below -15 dB. This implies impedance matching between source and load have been done very correct. The reflection loss for the frequency range 200 MHz to 400 MHz is below -20 dB and voltage standing wave ratio for GTEM Cell which is below 1.35.

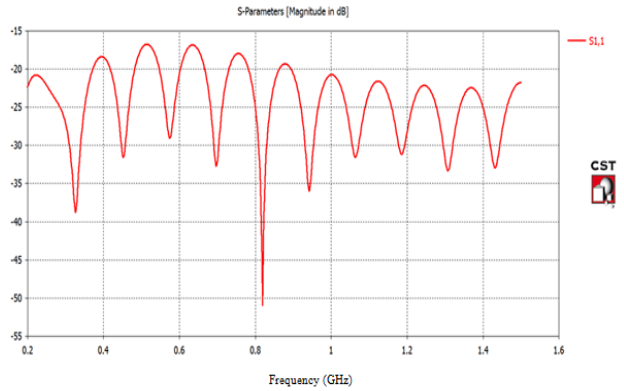

Fig. 3. Input Reflection vs. Frequency.

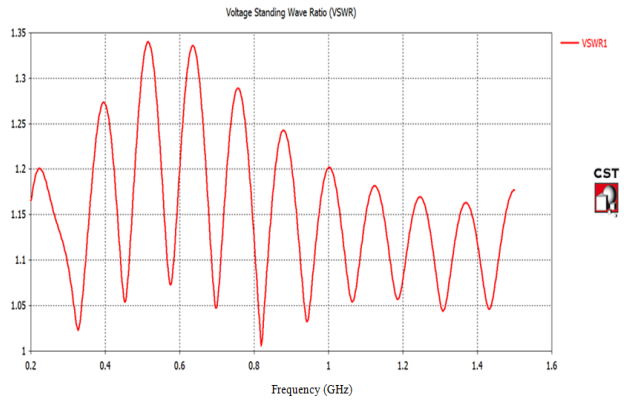

Fig. 4. VSWR vs. Frequency.

C. Fabrication

Aluminium 6082 sheet with 2 mm thickness used to fabricate GTEM cell. These sheets are joint together seam with the help of equal angles and aluminium rivet. All plates are assembled together with the help of nuts and bolts as shown in fig.5. For current termination 100 Ω carbon resistors are used. The combination of 2 X 100 Ω resistors in series connection mounted between the tip of septum and rear wall with the help of bolts as shown in fig.6. The pyramidal shape FUSU 9 RF absorbers of polyurethane material are used for RF wave absorption. The final fabricated GTEM cell with moving trolley is shown in fig.7.

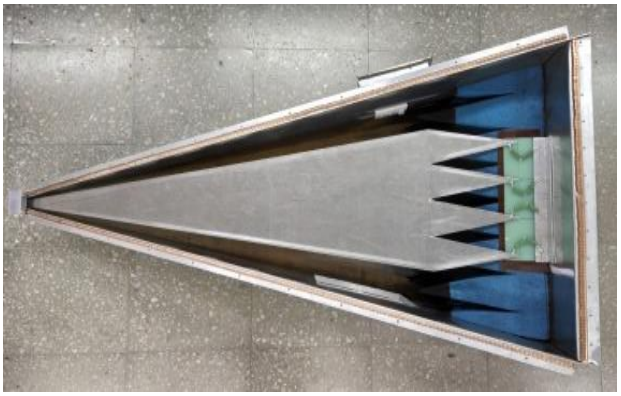

Fig. 5. Fabricated GTEM cell without top cover.

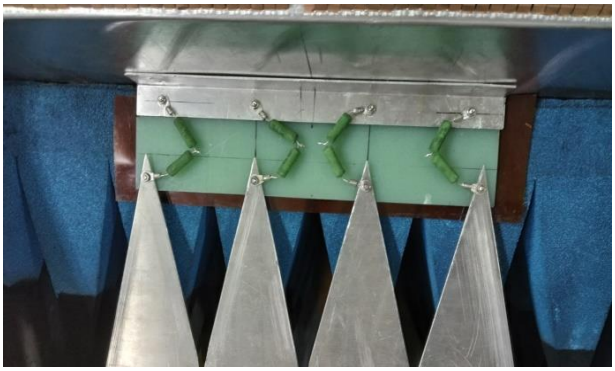

Fig. 6. Resistive load termination.

Fig. 7. Actual model of GTEM cell with trolley.

IV. MEASUREMENT AND TESTING

A. Input Reflection and VSWR

Following fig.8 and 9 show the input reflection and standing wave ratio of the GTEM Cell on vector network analyser respectively. Initially, frequency has set from 5 kHz to 2 GHz and fed radio frequency signals to the input (N type Connector) of GTEM Cell. The performance of the cell is observed from the graph of input reflection and frequency as well as standing wave ratio and frequency. The S11 and SWR parameter are measured at different frequency range by varying the marker position.

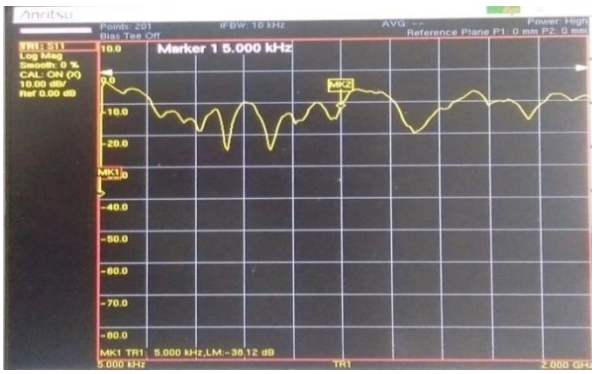

Fig. 8. Input Reflection vs Frequency.

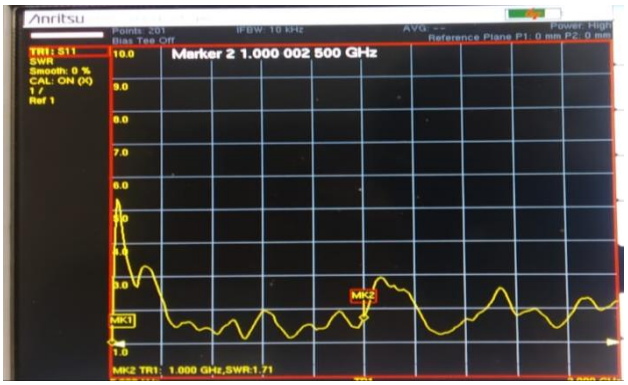

Fig. 9. Standing Wave Ratio vs Frequency.

The input reflection is found below – 10dB for the frequency range 250 MHz to 1 GHz. For frequency range 50 MHz to 250 MHz input reflection is below -8 dB. At frequency 600 MHz, it is -9.94 dB. Standing wave ratio is found to be 1.14 at the frequency of 700 MHz.

B. Electric Field Strength

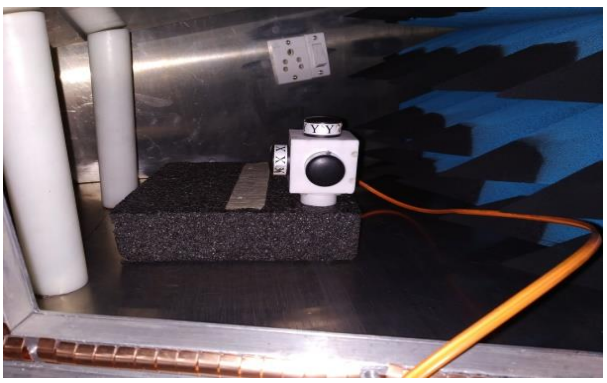

Fig. 10. Measured Electric field strength with isotropic field probe

The generated E-field below the septum is measured with the help of isotropic electric field probe, as shown in fig.10. It is found around 8 V/m at 4 cm height from bottom conductor. By changing the position of electric field probe the testing volume can be obtained below the center conductor. The maximum usable EUT height is recommended as 0.33h according to the IEC 61000-4-20 standard, with ' h ' being equal to the distance between the center conductor and the bottom conductor. By varying the position of E- Field probe, the obtained EUT size is 10 X 10 X 7 cm.

CONCLUSION

In this work a different EMC testing methods are discussed. It shows GTEM cell is one of the simple and easy techniques for EMC measurements. The Design and fabrication of GTEM cell are studied. The performance of the GTEM cell is observed with the help of vector network Analyzer. The maximum EUT size 10 X 10 X 7 cm is obtained below the septum. For the same electric field, it requires less input power as compared to anechoic chamber and open area test.

***Abstract*— with an ascent in the development of web-based business, the utilization of credit cards for internet shopping has expanded significantly. This, in turn, has brought about a great deal of credit card fakes. However, once in a while. Consequently, the execution of effective fraud detection frameworks has turned out to be fundamental for all banks to limit their misfortunes as far as credit card transactions are concerned. Numerous advanced systems have been created to monitor different credit card exchanges in literature. In this way, individuals have been attempting their best to identify the extortion in credit card exchanges as much as they can. Various machine learning techniques have been applied to predict whether a particular transaction is fraudulent or not. The biggest challenge with the techniques is the unavailability of the balanced dataset. Which is due to the nature of the transaction: the fraud transactions are too less when compared to genuine transactions. This work handles the challenge by balancing the dataset. Five machine learning techniques: Random forest, Naive Bayes, Support Vector Machine, K- Nearest Neighbor and Logistic regression were applied on the balanced dataset with different sampling techniques such as Oversampling, Undersampling, Both sampling, ROSE and SMOTE. The performance metric AUC – ROC suggests that logistic regression performs with an accuracy of 97.04% and precision of 99.99%.**

I. INTRODUCTION

Classification is the problem of identifying to which set of categories a new sample belongs on the basis of training samples whose class variable is known. It is a supervised approach as the class variables for the training samples are already known. This is a binary Classification problem as the class variables are either Benign or Malicious. Classification techniques have been used in various domain such as text classification and speech recognition [1], Multi-label logistic regression [2-3], collaborative filtering [4]

In general, the level of each class assumes a significant job in model precision and accuracy performance measure. The information by and large accessible in such cases is largely skewed in light of the fact that out of every atomic exchange only a few of them might be actually fraudulent. Subsequently, it forces an issue of highly imbalanced information. Due to this class imbalance issue, many generic machine learning algorithms such as decision trees, random forest, and naive Bayes tend to overperform in terms of accuracy measure. In reality, these algorithms were successful in predicting the non-fraudulent transactions correctly rather than the fraudulent ones. The minority class of fraudulent exchanges is ignored as exchanges that are noise. The work effectively handles this misclassification by altering the raw data provided to the classification algorithms to precisely predict the minority class, not the majority class.

The next subsection describes the dataset and exploratory data analysis.

A. Dataset Description

The Dataset[5] used for training the model consists of 284,807 records in total, of which only 492 of them are fraudulent cases i.e. 0.172% of fraud cases resulting in high-class imbalance. Features V1 to V28 are numerical values obtained from Principal Component Analysis (PCA). The attributes which are not changed by PCA are Time and Amount. Attribute 'time' contains the seconds gone by between each trade and the essential trade in the dataset. The component 'amount' is the total exchange Amount. Feature 'Class' is the response variable and it takes a value of 1 if there is an occurrence of fraud and 0 generally.

B. Exploratory Data Analysis

All indicators in the dataset have been anonymized, consequently, the non-anonymized indicators 'time' and 'amount' of the transaction for Exploratory Data Analysis were considered. The dataset contains 284,807 transactions with a mean estimation of all records being $88.35, while the biggest transaction recorded in this collection adds up to $25,691.16. Conclusively, the distribution of the amount value of all records is heavily right-skewed. By far most of the exchanges are moderately little and just a fraction of transactions come even near the greatest transaction in the dataset.

The time is recorded in the number of seconds since the main exchange in the dataset. Hence, it can be presumed that this data incorporates all transactions recorded through a span of two days as shown in fig1, with time on x-axis and transactions on the y-axis. In the case of distribution of 'amount' feature shown in fig2, it is bimodal with amount and transactions on x & y-axes respectively. This shows that roughly 28 hours after the main exchange there was a huge drop in the volume of transactions. While the time of the primary transaction isn't given, it is sensible to expect that the drop-in volume happened amid the night.

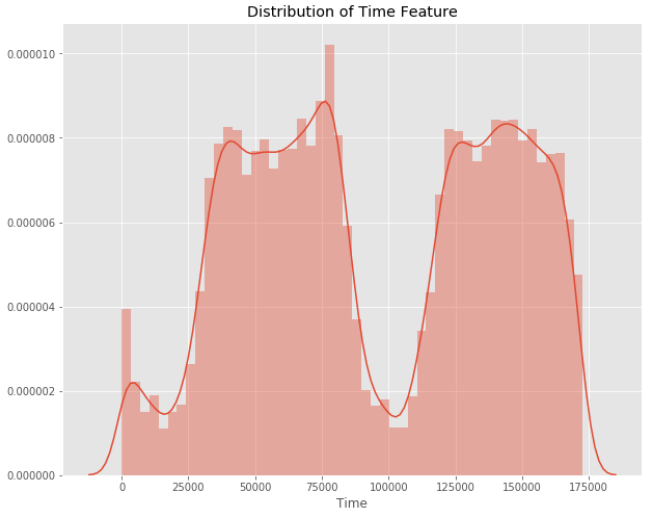

Fig. 1. Distribution of Time Feature

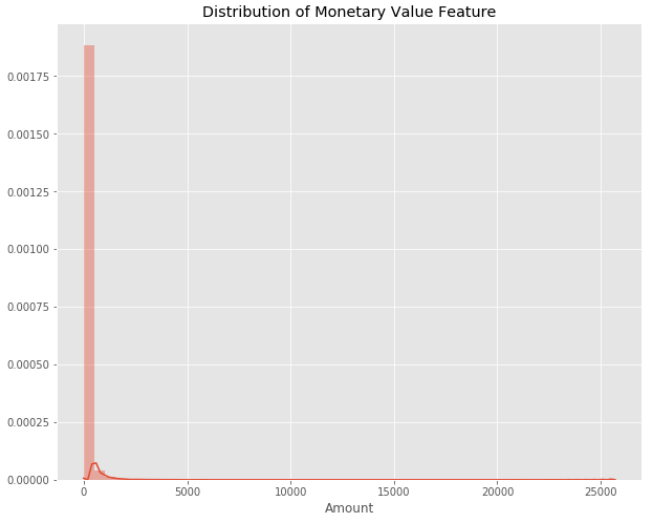

Fig. 2. Distribution of Monetary Value Feature

The remainder of this article is organized as follows: Section II speaks about the related work in the technology, Section III showcases the proposed system, Section IV describes the performance analysis of various classifications and sampling techniques, Section V showcases the experiment results; Section VI describes the conclusion and future work.

II. Literature Survey

A lot of work has been performed on classification techniques and handling class imbalance problem.

Samaneh Sorournejad et al. [6] work focuses on Statistical classification of occurrence of frauds in credit card, techniques for detection, difficulties which are majorly classified as fraud analysis (misuse detection) and user behavior analysis (anomaly detection) their work has also performed machine learning algorithms on many datasets of credit card transactions to detect the fraudulent transactions in that and figuring out the best one for overall credit card transactions.

The work by Lutao Zheng et al. [7] uses a method to construct behavior certificate. To begin with, they had modeled a lot of feature-based behavior highlights for every user from their card purchase records, and after that Behavior Certificate was built dependent on these highlights. Their work on fraud transaction detection is comprised of four characteristics: exchange type, hours of the transaction, sum, and area. After initial processing, they characterized a Behavior Feature Vector (BFV) utilizing 13 measurements to portray a card user's transaction conduct.

The work by V. Dheepa et .al [8] demonstrates the conduct of the client based on informational from the dataset, which are transaction amount, date, time, place, recurrence of procurement and charging Address. In this model, the Support Vector Machine (SVM) was used for classification. It will give great accuracy when fewer highlights are utilized. The other pressing issue is dealing with the class imbalance of information. To recuperate this issue viable component extraction technique is utilized, which is utilized for reducing the data. At that point, the model was trained with SVM classifier and they found the fraudulent transactions with lower error rates.

The work by Hien M. Nguyen et al. [9] presents an observational examination of over-sampling and under-sampling techniques. Test results demonstrate that under-sampling performs superior to over-sampling in the case of small datasets. All sampling techniques, be that as it may, are tantamount when the dataset size increases. All testing systems, be that as it may, are similar when the preparation set increases. This examination additionally proposes that a multiple random under-sampling (MRUS) method ought to be a decent decision for applications with imbalanced and spilling information on the grounds that MRUS is the best while as yet keeping a rapid accuracy.

The work by Arif syaripudin et al. [10] analyzes the strategies of handling imbalanced datasets with resampling and groups. From an alternate angle, this paper looks at how much impact the instances, number of traits, data types, the quantity of the objective class, and missing characteristic qualities influence the results with performance metric as f-measure. The test has come about that the criteria with respect to the number of characteristics, attribute information types, and the quantity of the objective class doesn't influence the order results. While the missing attributes with qualities have an influence on order result. For better high F-measure, the trial demonstrates that the best performing model is a blend of SMOTE 5000/0 and AdaBoostMl. The AdaBoostM1 method could be considered to address the imbalanced datasets. While in a couple of situations

SMOTE procedure can be used with duplication level of minority class (oversampling) of 500%. While in uncommon cases a blended procedure (a mix of SMOTE-500% and AdaBoostM1) has the best situation for dealing with imbalanced datasets. This is apparent from six of the sixteen datasets used to have high F-Measure esteem.

All of the above techniques try to either balance the dataset or apply different sampling methods. However, choosing the right sampling method and applying a valid classification technique plays an important role in credit card fraud detection. Therefore we propose a system that will compare different sampling methods such as over-sampling, under-sampling, Random Over-Sampling Examples (ROSE) and Synthetic Minority Over-sampling Technique (SMOTE), and apply the balanced data to the required classification algorithms, to obtain a high-performance model.

III. PROPOSED SYSTEM

The proposed framework for the model is shown below in figure 5. It clearly demonstrates the five important levels: Performing exploratory data analysis, Partitioning data, Building model on the training set, Applying sampling methods to balance dataset. The initial step of Exploratory data analysis consists of three sub-processing units: checking imbalance data, checking a number of transactions by the hour, checking mean using PCA variables.

EDA is done utilizing R to condense and envision huge qualities of the dataset. To discover the irregularity in the dependent variable, perform the accompanying, Gathering the information dependent on Class utilizing dplyr bundle containing "group by capacity", Use ggplot to demonstrate the level of class classification. To check the number of exchanges by day and hour, standardize the time by day and order them into four quarters as per the time. To discover anomalies, take mean of factors from V1 to V28 and check the variation.

In modeling, the information should be apportioned for preparing set (80% of records) and testing set (20% of records). Subsequent to apportioning the information, highlight scaling is connected to institutionalize the scope of free factors.

To build a model on the preparation set, perform the accompanying:

1) Apply model classifier on the preparation set.
2) Prediction of the test set.
3) Check the prediction yield on the imbalanced information.

Distinctive imbalance handling techniques are utilized to adjust the given information, apply the model on the balanced information, and check the quantity of good and extortion exchanges in the preparation set.

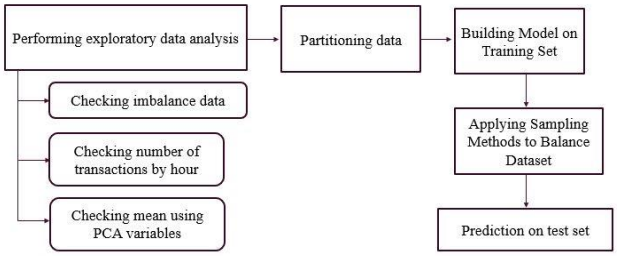

Fig. 5. Proposed System

IV. PERFORMANCES ANALYSIS OF VARIOUS CLASSIFICATION AND SAMPLING TECHNIQUES

The classification technique implemented in this work is explained below.

1) *Random Forest*: Random Forest is a managed supervised learning technique. It makes a collection of forests and makes it some way or another arbitrary [11]. The forest it constructs is an outfit of decision Trees, more often than not prepared with the "bagging" strategy. The general thought of the bagging strategy is a mix of learning models that expands the general outcome, it can be written as equation(1)

$$fi_i = \frac{\sum_{j:\, node\ j\ splits\ on\ feature\ i} ni_j}{\sum_{k \in\ all\ nodes} ni_k} \qquad (1)$$

where fi_i is the importance of feature i, ni_j is the importance of node j.

It is a supervised learning algorithm. It shapes different choice trees and consolidates them to show signs of improvement exactness and stable forecast. It has about the equivalent hyperparameters as a choice tree or a stowing classifier. Just an irregular subset of the highlights is thought about for part a hub. Trees can be made increasingly irregular, by also utilizing arbitrary limits for each component instead of looking for the most ideal edge.

2) *Naive Bayes:* Naive Bayes is a group of probabilistic calculations that exploit likelihood hypothesis and Bayes theorem to anticipate the tag of content [12]. They are probabilistic, which implies that they compute the likelihood of each tag for a given content and after that yield the tag with the most astounding one. The manner in which the model generates the probability is by utilizing Bayes theorem, which depicts the likelihood of a component, in view of earlier information of conditions that may be identified with that feature, as shown in equation(2)

$$p(A|B) = \frac{p(A)p(B|A)}{p(A)} \qquad (2)$$

3) *Support Vector Machines:* Support Vector Machines

is a model for classification and regression purposes [13]. In contrast to different models, it has an extraordinary choice limit and kernel components. The kernel is utilized to change the information vector into the ideal structure. kernels can utilize direct, nonlinear, polynomial, Radial Basis Function, and so forth. By utilizing kernels, Support Vector Machine at that point establishes the ideal limit which is called a choice limit that has the greatest separation from both the classes. Consequently, it in all respects viably characterizes the information as per limit.
Equations for SVM are shown below in equations(3-5)

Given some preparation vectors, i = 1,.....,n, in two classes and a vector, SVM classifier takes care of the accompanying base issue:

$$min\frac{1}{2}w^T + C\sum_{i=0}^{n}\zeta \quad (3)$$

subject to

$$yi\ (wT\varphi(xi)\ +\ b)\ \geq\ 1-\zeta i \quad (4)$$

$$yT\alpha\ =\ 0$$
$$0\ \ \leq\ \alpha i\ \leq\ C, i\ =\ 0,1,\ldots n \quad (5)$$

Figure 3 shows the hyperplane boundary created in SVM.

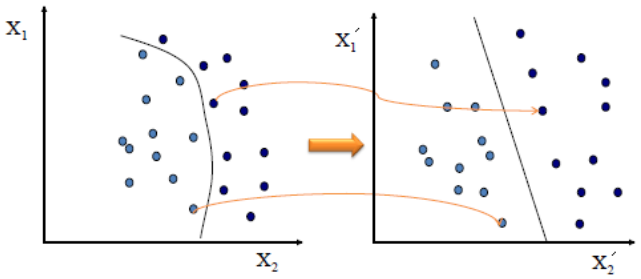

Fig. 3. Hyperplane in SVM

4) *K – Nearest Neighbors:* K nearest neighbors is a straightforward calculation that stores every single accessible case and characterizes new cases dependent on a closeness measure (e.g., remove capacities) [14]. KNN has been utilized in factual estimation and example acknowledgment as of now toward the start of the 1970s as a non-parametric system. A case is selected by a greater part vote of its neighbors, with the case being allocated to the class most regular among its K closest neighbors estimated by a separation work. On the off chance that K = 1, at that point the case is just allocated to the class of its closest neighbor. Various distance measures can be evaluated as explained in equation(6)

Euclidean Distance:

$$dist\big((x,y),(a,b)\big) = \sqrt{(x\ -\ a)^2} + (y\ -\ b)^2$$

Manhattan Distance:

$$dist\big((x,y),(a,b)\big) = |(x\ -\ a)\ +\ (y\ -\ b)\ | \quad (6)$$

Euclidean Distance:

$$dist((x,y),(a,b))\ =\ ((x\ -\ a)^{\mathrm{q}} + (y\ -\ b)^{\mathrm{q}})^{\frac{1}{q}}$$

5) *Logistic Regression*: Logistic regression is an arrangement calculation used to relegate perceptions to a discrete arrangement of classes [15]. Not at all like linear regression which yields nonstop number responses, logistic regression changes its yield utilizing the strategic sigmoid capacity value function to restore likelihood esteem which would then be able to be mapped to at least two discrete classes.

P ≥ 0.5, class=1
P < 0.5, class=0

The various sampling techniques implemented in this work are explained below:

6) *Oversampling*: This technique simply replicates the minority class records to perform class balancing. Firstly, the dataset has two lakh transaction records, this strategy is utilized to pattern replicate the minority class until it achieves balanced records. Finally, four lakh records are obtained. This can be achieved by setting up the strategy = "over".

7) *Undersampling:* These strategy capacities like the oversampling technique and is managed without substitution. In this technique, a non-fraudulent transaction is equivalent to fraudulent transactions. Henceforth, this method is not suitable for imbalance handling. This can be achieved by setting up the strategy = "under".

8) Both Sampling: Both samplings implements a blend of both oversampling and undersampling strategies. Utilizing this technique, the techniques simply undersampled the major class to half the size of the dataset and then increases the count of the minority class. This can be achieved by setting up the technique = "both".

9) Random Oversampling Examples (ROSE): 0ROSE is a class imbalance handling technique that generates data artificially, by providing a better estimate of original data.

10) Synthetic Minority Oversampling Technique (SMOTE): This strategy is utilized to prevent excess estimation while including careful copies of fraud transactions examples in principle dataset. For instance, a few fraud cases are taken. New manufactured comparable occurrences are made and added to the first dataset. One example of SMOTE instance shown in figure 4 shows how it synthetically maps the nearest rare case by assuming points on the path between them.

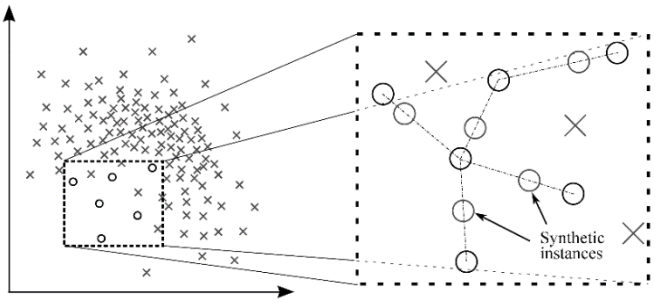

Fig. 4. SMOTE instances

V. EXPERIMENT

A. Experimental Setup

To abstain from building up a "naive" model, we should ensure the classes are generally adjusted. In this way, we will utilize a resampling (and, all the more correctly, oversampling) conspire called SMOTE. It works generally as pursues:
The calculation chooses at least 2 comparative examples of information.
It at that point irritates each example one component at any given moment by an irregular sum. This sum is inside the separation to the neighboring models.
The source code used is 'R' with required libraries such as mvtnorm, psych, pROC, ggplot, caTools and dplyr for data processing and various classification techniques.

B. Performance Evaluation Metric

AUC - ROC bend is estimation for the characterization issue at different limits settings. ROC is a likelihood bend and AUC speaks to the measure of dispersion. It compares whether the model is perfect for classification. A higher value of AUC indicates that the model is good at classification. By similarity, better the AUC score, better the model is at recognizing false and genuine.

The ROC is plotted with True Positive Rate against the False Positive Rate where the former is on the y-axis and the later on the x-axis.

Accuracy is the ratio is a ratio of correctly predicted observation to the total observations.

Precision is the ratio of correctly predicted positive observations of the total predicted positive observations.

The recall is the ratio of correctly predicted positive observations to all observations in actual class - yes.

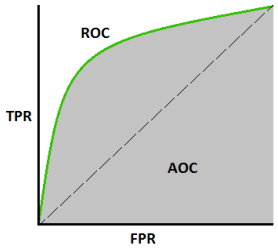

Fig. 5. ROC curve

VI. RESULTS

The results presented here are based on SMOTE as most astounding information exactness is acquired utilizing SMOTE strategy. The reason, SMOTE draws counterfeit examples by picking points that lie on hold interfacing the nearest neighbors to one of its closest neighbors in the component space. While different procedures produce better results that were inside and out unthinkable (negative Area sizes or rise).

Indisputably, logistic regression wins with an accuracy of **97.04%** and an amazing precision of **99.99%**. Logistic regression isn't actually a classifier. However, It is a likelihood/chance estimator. In contrast to different procedures, it takes into account and anticipates "near disasters". It will prompt an ideal solution since it doesn't attempt to trap the predictions into joining a utility capacity that is understood at whatever point the perceptions should be ordered. The objective of logistic regression is to utilize the most extreme probability estimation to give ideal appraisals of Probability.

	Accuracy	Precision	Recall	AUC
Naive Bayes	0.9693	0.0441	0.8163	0.9435
Random Forest	0.9871	0.1074	0.8877	0.9495
K-Nearest Neighbors	0.9689	0.0495	0.9387	0.9356
Support Vector Machines	0.9814	0.0750	0.8673	0.9257
Logistic regression	**0.9704**	**0.9999**	**0.9704**	**0.9704**

Table. 1. Performance results

The table displays the parameter results achieved. AUC-ROC values are displayed below.

AUC = **0.9495046**
False Positive Rate = **(1.000, 0.029, 0.000)**
True Positive Rate = **(1.00, 0.928, 0.000)**

VI. CONCLUSION AND FUTURE WORK

The proposed framework shows that balancing the dataset increases the chances of correctly classifying the fraudulent transactions. The SMOTE sampling performs

the best due to its method of synthetic sampling rather than the nearest values. Among the five techniques used, logistic regression performs well with an accuracy of **97.04%** and an amazing precision of **99.99%**. Therefore, SMOTE sampling along with logistic regression is suggested for credit card fraud detection

As future work, the framework is equipped for giving a large portion of the basic highlights required to avert fake and authentic exchanges. As innovation transforms, it winds up hard to follow the conduct and example of fake exchanges. Averting known and obscure extortion continuously isn't simple yet it is plausible. The proposed engineering is essentially intended to avoid credit card misrepresentation in online installments, and accentuation is made to give an extortion counteractive action framework to confirm an exchange as false or real.

***Abstract*—Load shedding refers to an intentional electrical power shutdown where electricity is cutoff for periods having not occupying parts of time over distinctdistribution region. This work aims at optimizing the power distribution during such cases using dynamic load shedding where the quantity of load shed is a defined variable based on the input signals. This process is programmed in the microcontroller and the circuits correspondingly switch the power to the prioritized plants and keep the system running. This is interfaced with an LCD to display the current status of production. The loads are implemented using Servos and LED. The rotation of load shedding is synchronized by real time clock (RTC). This circuit is powered with a transformer of 12V. The Load Shedding Module consists of microcontroller ATmega2560 which is used to control the overloading. Current Sensor is used to measure current reading from the load. Controlling is done with 'C' coding.**

Index Terms- Distributed generation, distributed control, optimum load shedding, system protection scheme.

I.INTRODUCTION

Load Shedding refers to instant removal of load from a grid to retain the remainder power as operational.Load shedding occurs when there is not enough electricity supply available to meet the demand.This works helps to optimize the power distribution during power outage, or low voltage cases. Using Arduino as microcontroller, a decision is taken whether to shed loads or not, based on the power drawn by the respective loads and consequently preventing sudden breakdown of the system and avoid blackouts.

This paper is organized as follows. Previously published related works are discussed in Section II. The proposed design of energy scrutinizing system is presented in section III.Section IV discusses the implementation of algorithm. Section V discusses the results of the work. In section VI work is concluded.

II. RELATED WORKS

Load Shedding is used when an imbalance of demand and supply due to weather occurs. In [1], the methods implemented for distributed under voltage load shedding are discussed. A new design is proposed based on load shedding against voltage instability. In [2], a new condensed, adaptive load shedding algorithm is proposed, the algorithm usesvoltage and frequency information provided by phasor measurement units (PMUs). The key contribution of this new method is the use of reactive power along with active power in the strategy of load shedding.Hence, this new method focuses the blending of voltage and frequency stability issue much better than in the independent approaches. In [3], the central contribution of the new method is the usage of reactive power together with active power in the load shedding strategy. In [4], the concept ofload shedding and Smart-direct load control (S-DLC) is proposed to reduce power outages in sudden grid load changes and to reduce the peak-to-average ratio. Forecasting and shedding method is used in the algorithm. To provide Real-time controlling of load this method also used stream analytics and Internet of Things (IoT). In [5],an uninterruptible-power-supply system powered using fuelcell is used. The grid interfacing inverter is connected by a fuel cell and a super capacitor through a 3-port bidirectional converter. The modes that a system can operate are stand-alone and grid connected mode.

III.PROPOSED DESIGN OF ENERGY SCRUTINIZING SYSTEM

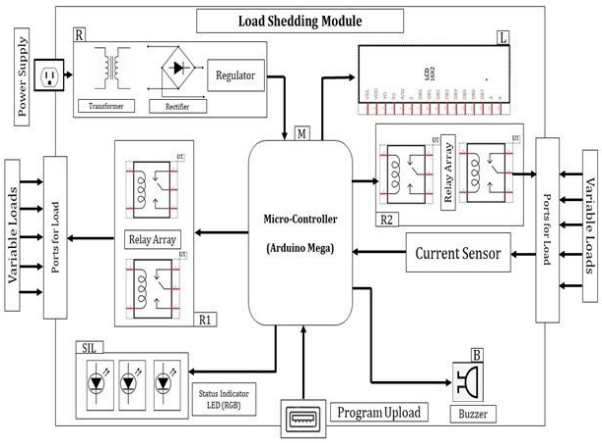

Fig.1. Block diagram of load shedding management module.

The block diagram consists of arduino microcontroller which is controller for the whole assembly as shown in Fig.1 and a rectifier unit to power the circuit. It has a current sensor to sense the current and based on those current values relay array switches off the non-prioritized load keeping only the prioritized loads on and it is displayed using an LCD[6-7].

A. Arduino Microcontroller (ATmega 2560)

Arduino Atmega2560 microcontroller is as shown in Fig.2.The Atmega2560 has 28 pins. It has 54 digital input-output pins, 16 analog inputs, some of the digital outputs acts as PWM outputs[8].

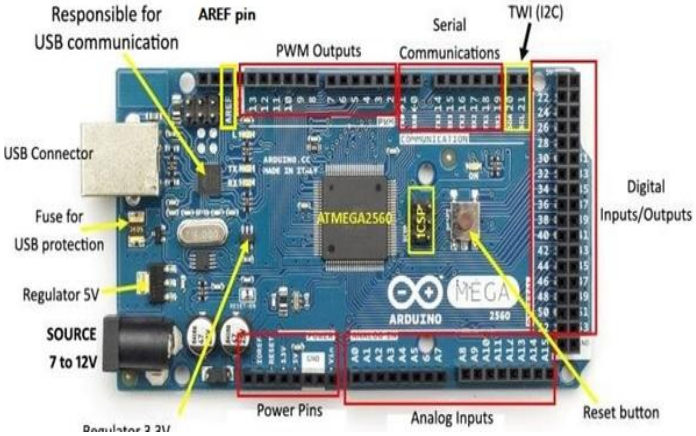

Fig.2. Architecture of Arduino Atmega2560 microcontroller.

B.LCD - Liquid Crystal Display

The picture of LCD is as shown in Fig. 3, which is used for displaying text, words and images having low information. Fig. 4 shows the interfacing of LCD with Atmega2560[9][10].

1. Pin VCC corresponds to +5Volts
2. Pin VEE is used for adjusting contrast
3. Pin VSS is Ground
4. The Pins from D0 – D7 corresponds to Data Lines
5. Pin R/W acts as Read when R/W is 1 and write when R/W is 0.
6. Pin RS is Register Select, acts as Instruction input when RS is 0 and Data input when RS is 1.
7. Pin EN corresponds to Enable Pin.

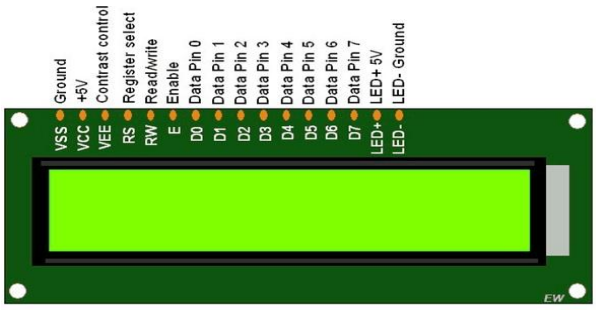

Fig. 3.

Fig.3. Liquid Control Display.

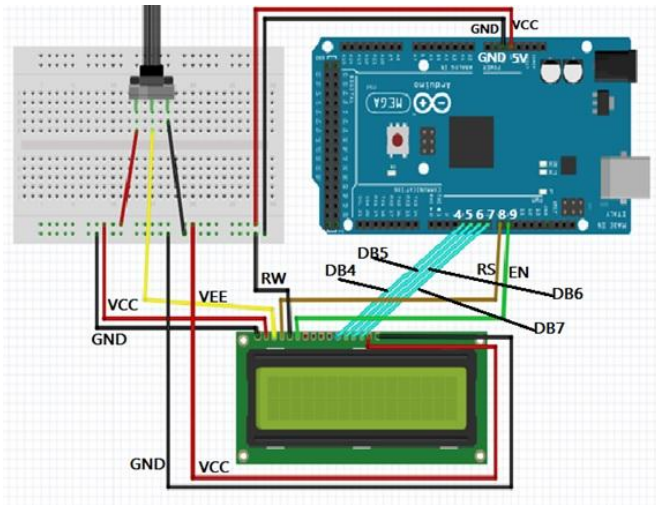

Fig.4.Interfacing LCD with atmega 2560.

C. Current Sensor

Fig. 5 shows the picture of Current Sensor ACS712 module. In Industries and communication systems where current sensing finds importance. ACS712 gives precise reading and solution for AC and DC currents. Customers finds easy because of its design package. Some of the applications like motor control, load detection and overcurrent fault protection use Current Sensor.

The basic principle of working of Current Sensor is Hall Effect. It says that when a current carrying conductor is placed in a magnetic field, a voltage will be generated perpendicular to the direction of the field and the flow of current[11].

Current passing through a semiconductor material causes potential difference and that potential difference will not be their ifzero magnetic field exists. The current flow is distorted when a perpendicular magnetic field exists. The potential difference across the output terminals will exists due to uneven distribution of electron density. The voltage due to this effect is called Hall Voltage. Hall voltage is directly proportional to the magnetic field's strength if input current is constant. Fig. 6 shows interfacing of ACS712 current sensor with ATmega 2560[12].

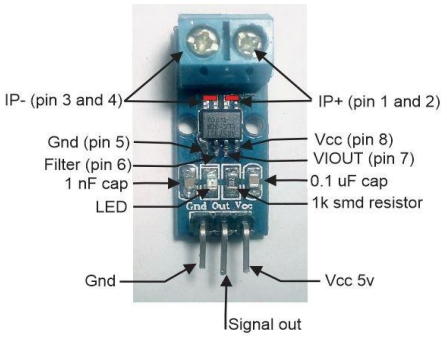

Fig.5. Current Sensor ACS712.

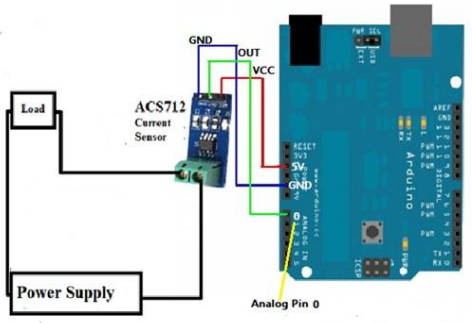

Fig.6. Interfacing current sensor with arduino.

D.Regulator Circuit

Regulator circuit consist of 12-0-12V transformer, rectifier and regulator is as shown in Fig. 7. The transformer lowers the voltage to the microcontroller working levels and the ac voltage is then rectified by using a bridge rectifier to get a pulsating dc which is then sent to a 7809 regulator which provides a constant 9V voltage to power up the arduino.

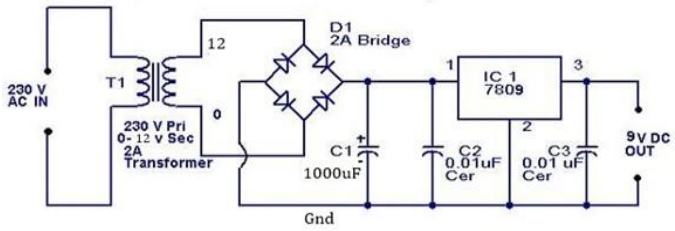

Fig.7. Rectifier Circuit.

E.Relay

A Relay is an electrical switch as shown in Fig. 8. Relay uses the concept of EM to act as switch and operating principle like solid-state relays are also used. They are used to control and switching of circuits when it is necessary. Nowadays Relays are found in most of the electrical circuits[13].

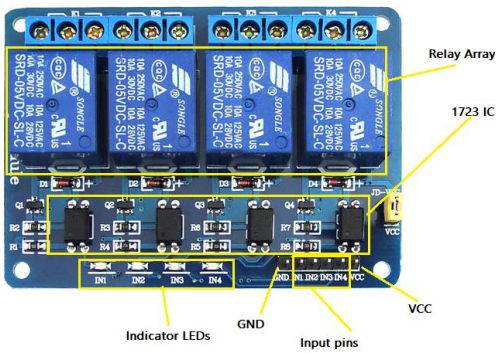

Fig. 8.5V Relay Array.

IV. IMPLEMENTATION OF ALGORITHM

The flow chart in Fig. 9 describes the control flow of the project model. The initial condition verified is the supply and demand imbalance. If the supply current is not able to satisfy the demand by loads then all the high power loads determined by the current sensor are shed. If power supply is able to provide current to additional loads after shedding then based on the priority the loads are reconnected. If an external supply like battery is available then cumulatively the power is supplied[14].

In the next conditional block the power capacity of the battery is monitored continuously along with the return of power in mains. If the battery capacity falls below 20% then the remaining loads are shed and only the basic necessities like light and fan that do not consume more power are retained. If power in the mains return, then all the loads are reset and the battery is connected for charging. Then the module starts checking for demand supply imbalance condition and this process goes on.

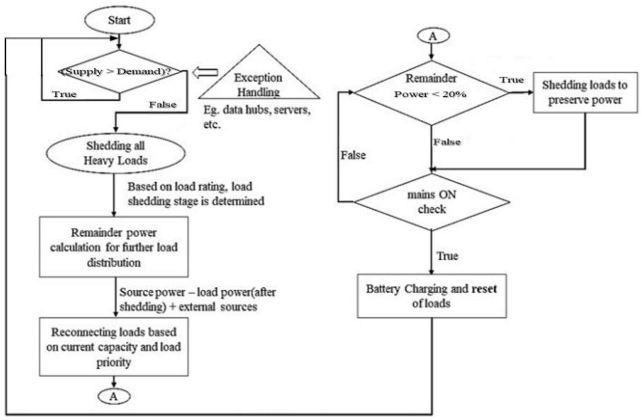

Fig.9. Flowchart of Energy Scrutinizing system.

V. RESULTS AND DISCUSSION

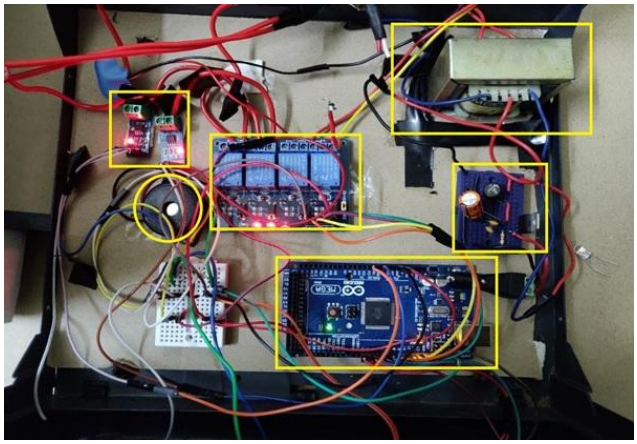

Fig.10.Model of the project with all connections.

Fig.11.Model with ports 1 and 2.

Fig.12. Output on LCD Displaying the Current reading values at Port 1 and 2.

Fig.13.Output at LCD display on overload.

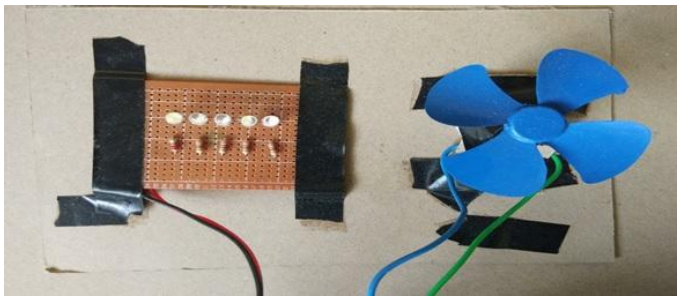

Fig.14.Loads at Port 3 and 4.

Fig. 10 shows the working model of the Load shedding system. At conditions where overload has not occurred, mains are kept ON and the loads at port 1 and 2 shown in Fig. 11are turned ON. Current readings from current sensor ACS712 connected at two ports monitor for current continuously. The LCD display in Fig. 12 displays the current values for user reference.

The microcontroller is programmed to detect current spikes above a defined threshold and take decisions accordingly. If the current in any of the connected ports exceed 1.4Amps, the microcontroller immediately disconnects that particular port and switches on the loads at ports 3 and 4 as in Fig. 14. These ports utilize power from the battery to run the loads. The port causing overload is displayed on the LCD screen as in Fig. 13 with the LED switching ON as an additional indicator.

VI. CONCLUSION

A microcontroller based energy scrutinizing system for dynamic load shedding management is designed and tested successfully. The loads which have high power rating tend to draw more current and cause overload condition and shuts down the whole grid. In such scenarios these modules detects such current spikes and based on a certain threshold, sheds all the high-power loads and reconnect prioritizedloads with low power consumption. In this way complete blackouts can be avoided and work can be continued even though at lower efficiency which is better than no work at all.

Abstract— **FIR filter is main and important block in the digital signal processing applications. Even though several approaches for FIR filter designs proposed, because of increasing waste usage of digital applications and rapid growing in the VLSI industry still need and scope for to design a power and area efficient filter. In this paper proposed a novel scheme for the design of an area and power efficient digital finite impulse response (FIR) filter for future multi standard communications. The presented parallel architecture model supports run time variation of filter order and filter coefficients. In the design process discussed every block in detail mainly for faster computation time of the design selected faster multiplier and adder. To get the less hardware area and fast in computation time Vedic multiplier is used for the multiplication block and carry save adder is used for addition in the design. The proposed design can handle the length of 16-tap and 8-tap is and implemented in Verilog HDL. Implemented Verilog code for the design is verified by using simulation results and checked synthesis of the design in Vivado Xilinx IDE. The synthesizable code is compiled in Synopsys Design Compiler (DC) for Power and area calculations using SAED 90nm CMOS technology. The ASIC results shows the improvement in power 18.89% and 18.30% for 16-tap and 8-tap FIR filter respectively than the conventional method.**

Keywords— Digital signal processing, Reconfigurable FIR filter, Software defined radio, Vedic multiplier, Adder tree

I. INTRODUCTION

A filter is a device which passes the required frequencies and preventing the other frequencies based upon the application. Filter is essential and important block in most of the signal processing applications. Digital Filter applications are widely used for band selection, noise elimination, signal computation, estimating and analyzing the signal, and in many signal processing applications [1]. Based on the impulse response type filters are mainly categorized into two types namely, infinite impulse response (IIR) and finite impulse response (FIR) in those FIR Filters are widely used compared to IIR because if its ease to attain linear phase and inherent stability [5]. Due to rapid increasing in the usage of digital signal processing-based applications like multimedia, mobile communications in day to day life which demands highly efficient hardware and ultra-low power operations [1]. Similarly, as the growing in communication technology which requires of support multiple communication standards in a single hardware for this instead of designing different filters with different filter orders needed a single filter hardware design which can handle different filter orders based on the requirement. To handle this type of multiple filter orders in a single design reconfigurable filters came into picture whose filter order and coefficients could change dynamically during the run time. In advanced communication applications like software define radio, multichannel filters and up and down digital converters the need of reconfigurable filter is high to get low power and efficient hardware [2].

The input and output relation of a fir filter is given by the equation

$$y[n] = \sum_{k=0}^{N-1} h_k a[n-k]$$

Where h_k, for $0 \leq K \leq N-1$, implies the filter coefficients while $a[n-k]$ for $0 \leq K \leq N-1$ means the N recent input samples, and $y[n]$ is the current output of the filter. Reconfigurable FIR filters whose filter coefficients [h_k] and filter order [k] change during run time plays key role in future multiple communication standard systems to get the low power and high throughput. In latest years, a good deal of studies has been carried out to introduce effective reconfigurable FIR filters. In this work reconfigurable FIR filter designed with Verilog code in such a way that it to get the efficient in its performance, low power and effective usage of hardware. The suggested architecture includes a Serial in Parallel out Shift Register (SIPO), a multiplier and an addition tree. Serial in parallel out Shift Register designed with D-flip flops as synchronous manner. In general multiplications operation is performed with shift and add logic. Multiplier is the one of the major design blocks in the design which occupies larg silicon region and needs more energy several study works has been performed for this purpose and compared many multipliers like booth multiplier, sequential multiplier, Vedic multiplier and many [9]. Finally, selected Vedic multiplier to get the efficient and faster computation time in the design. Vedic multiplier is ancient multiplication method which eliminates the unnecessary computations in its logic [6]. Similarly, in place of addition carry save adder is used for better results with less computing time and less complexity. A hybrid design has been proposed for implementing Adder tree with half adders and full adders and this adder tree also designed with carry save adders to get the low power, less area occupancy and for best performance. In the design clock gating concept is used to select the filer order and to deselect the unused gates to make the reduction in power consumption dynamically [7]. The rest of the paper discuss with

architecture of reconfigurable FIR filter with each block design in section II, analyzed performance of 8-tap and 16-tap reconfigurable FIR filter in both FPGA and ASIC with results and compared with conventional approach in section III, and finally conclusion and future scope in section IV.

II. DESIGN OF RECONFIGURABLE FIR FILTER

The proposed reconfigurable design derived from direct form of FIR filter in which Serial in Parallel out Shift Register is used to shift the samples for every clock pulse, Vedic multiplier is used to multiply the shifted samples with coefficients with synchronize with clock and Adder tree is used to add the samples.

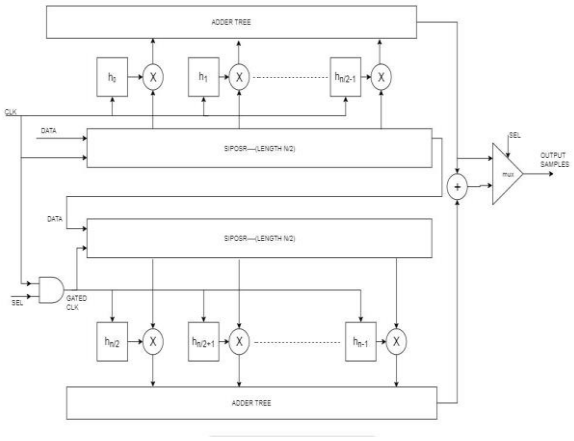

Fig.1.Archetecture Design of Reconfigurable FIR Filter

Here the Architecture contains two parts, depends upon the filter order the design works. During the function of the N/2 filter, the structure can decrease power consumption by using clock gating concept which disables the lower Serial in Parallel Out (SIPO) of length N/2. The registers used for storing the samples. The separation has been done with respect to clock the second part of the design contains gated clock derived from the main clock by using clock gating concept as represented in Fig.1. As shown in fig 1 architecture one clock is directly applied to registers, multiplier block and second clock is generated with AND gate logic and selection signal that's nothing but the gated clock signal. So, if the selection signal is logic high then only the elevated gated clock signal will trigger circuit. Generally, the notion of clock gating is used to decrease dynamic power dissipation and here in the design same clock gating concept is used to get the required length for filter order. The 2:1 MUX selects output of the upper adder tree if the selected filer length is N/2, the same MUX selects addition of upper adder tree and lower adder tree if the selected length of the filter is N. For MUX to produce the output based on the length of the filter SEL signal is used the signal which is used as input to produce the gated clock signal. By this if we need a filter in a single chip to work both for length N/2 and N in this case for filter order N the complete design is in on state and functionality is same but for N/2 length the half of the design is in on state and rest is in off state by using selection signal. For the length of N up to N/2 pulses, the half of the structure is in off state due to this unwanted switching power can decrease.

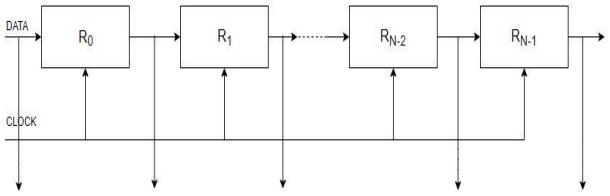

Fig.2.Serial in Parallel Out Shift Register (SIPO)of length N

The first block is serial-in-parallel-out (SIPO) shift register in which the samples are loaded with serial data as input one sample at a time and output is available in parallel form to the multiplier block. Multiplier block is designed with Vedic multiplier and the same clock which is applied for SIPO is applied for multiplier blocks also to get the maximum sync and to eliminate the timing checks between the coefficients and output of SIPO samples. Adder tree is designed with basic half and full adders as carry save adder type and this adder also in two separate parts for this designed one adder tree and is instantiated in two times for design. In the design based upon the filter length will get the sample output for this separation of adder tree output a multiplexer is used. with multiplexers by using selection line the output is procced and in case if the filter length is N/2 multiplexer selects direct first adder output as filter output in other case both adder trees output is added before procced as output. The detail information of multiplier and adder tree design is discussed as subsections.

A. Vedic Multiplier

Vedic multiplier is an ancient multiplication technique which is used mainly to reduce the complexity and unnecessary steps in the logic by this multiplication becomes faster and consumes less power compared to other multipliers.

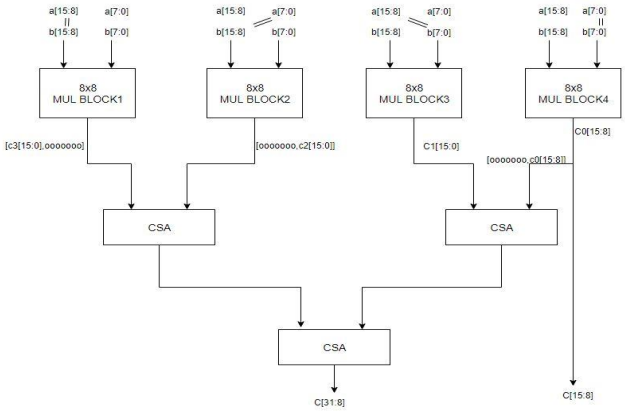

Fig.3.16-bit Vedic Multiplier

Vedic multiplier sutras and procedure in calculation is taken from research work from several papers. 16*16bit multiplier is needed in the present filter design and is designed by using bottom-up approach which is made up of by the 2*2bit, 4*4bit and 8*8bit multiplier. In every bit multiplier

partial product are added by using carry save adder. To get the equal weights before giving it to carry save adder padded extra zeros as mentioned in Vedic mathematics. At last least significant bits are directly produced from the multiplier block and remaining bits can produce by adding by using carry select adder.

C. Adder Tree

The output of multiplier block samples is addition, for this developed an adder tree with half adders and full adders with carry save addition. For this design first, full adder and half adder are implemented by instantiating the basic logic gates in the structure form. From half adder and full adder insanitation using for loop added single bit and result carry added by using carry save addition. As the maximum output of multiplier block is 32-bit number for this needed an adder tree which can add 32-bit number or less. Here in the design the eight outputs obtained from the multiplier block must add, for this designed eight samples adder tree and is instantiated in both lower and upper part of the design.

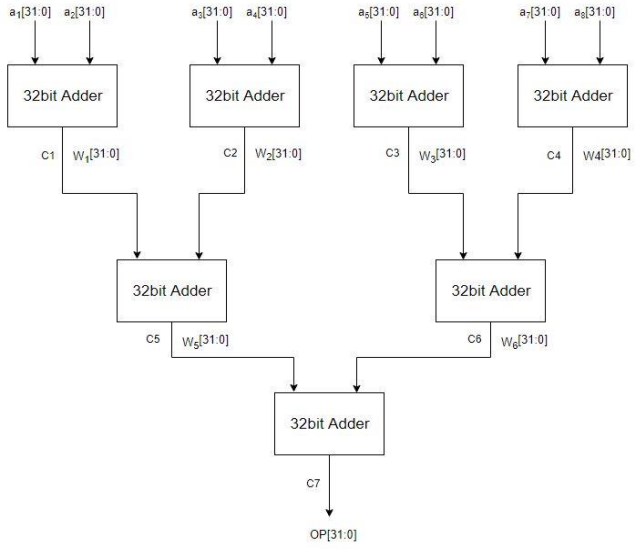

Fig.4. Adder Tree to add 32bit numbers

A 32-bit adder is required to add two 32-bit numbers. Here in the design eight 32-bit numbers must add for this designed an adder tree with four 32-bit adders at the stage-1 and the results are added in stage2 as same. In every 32bit adder output as 32bit number with carry. All the carry bits in every stage are added to get the MSB bits. For this full adder are used as represented in fig.5 by this full adder addition bit33, bit34, carry bit35. From Fig.4 and Fig.5 gives the complete adder tree to add eight 32bit numbers. By this adder tree to add eight 32bit numbers complete design is formed.

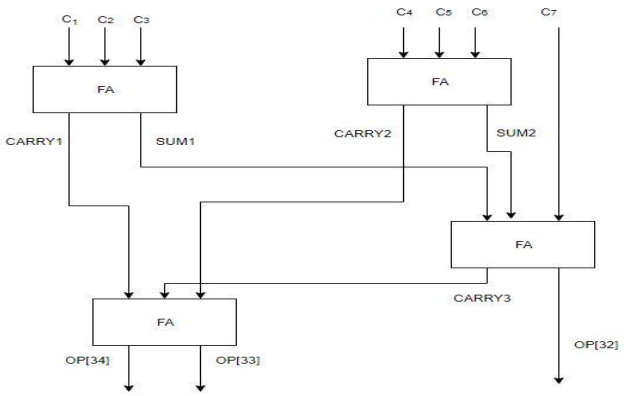

Fig.5.Adder Tree carry bits Addition for MSB bits

III. Results and Discussion

The proposed architecture design is implemented in Verilog HDL and simulated in Xilinx Vivado, the design is implemented with 16-tap reconfigurable FIR filter which also handle 8-tap with 16-bit as input. All the implementations are targeted FPGA is Artix-7. The coded Verilog module is successfully simulated and verified using Vivado. The simulations results are given in Fig.6 and Fig.7. Here gated clock used to reduce the switching times.

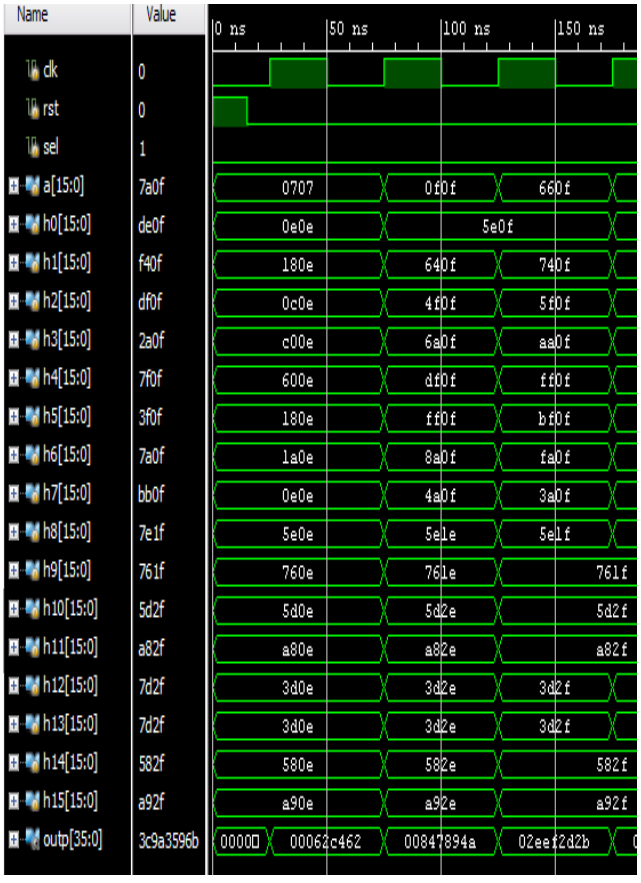

Fig.6.Reconfigrable 16-tap FIR Filter

For 16-tap, till the 8-clock pulses the lower part of the design is in off state as select signal is in logic-0 state by this switching power of lower registers and gates can abolish. This concept is same as clock gating which is used to reduce the dynamic power.

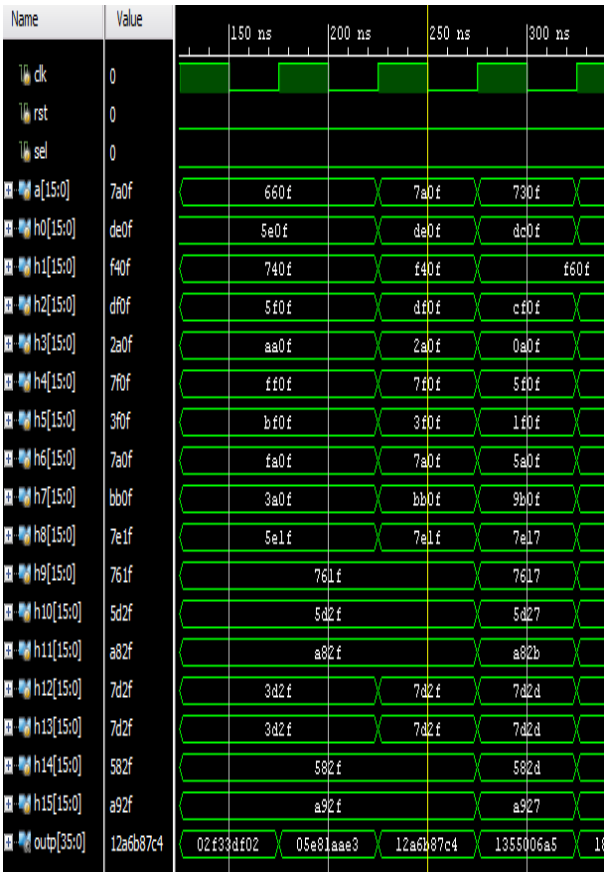

Fig.7.Reconfigrable 8-tap FIR Filter

For 8-tap FIR filter design has done in such a way that the lower shift registers completely in off state for this the selection signal always be in logic-0 state so that the gated clock is no more in active state. The same clock gating which is designed with selection signal is used to completely off the half of the design by which the 8-tap FIR filter is obtained in the same design of the chip.

Along with FPGA implementation, the proposed design Verilog code synthesized in 90nm CMOS technology using Synopsys Design Compiler (DC). In Fig,8, Fig.9 and Fig.10 represents comparison of power and area plots with proposed approach and conventional approach [2].

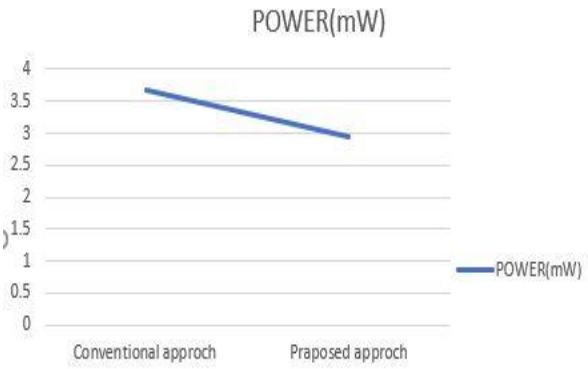

Fig.8. 16-tap FIR power comparison

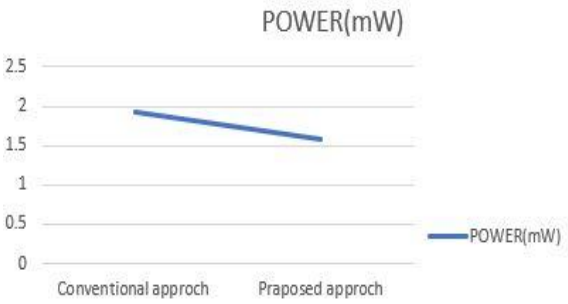

Fig.9. 8-tap FIR power comparison

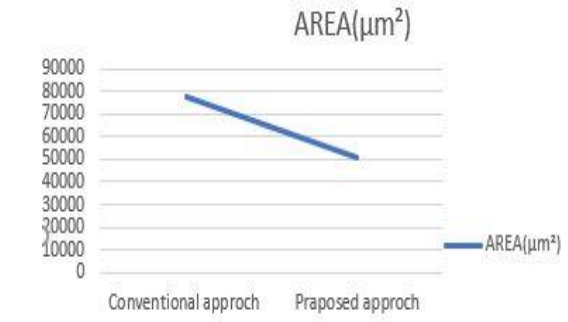

Fig.10. Area comparison

IV. CONCLUSION

The aim of this paper is to realize efficient digital FIR filter to work in multi-channel filter and for future communication systems. By using area and power graphs it is evident that the design meets improvement in power and occupancy of area. The proposed design achieves power reduction of 19.89% for 16-tap and 18.30% for 8-tap filter. Improvement also achieved in area from 77889 µm² to 50925 µm². Thus, proposed design of Reconfigurable FIR filter can be used in all type of DSP applications and advanced communication applications for improving the performance and speed.

In future, the work can be extended by using different types of gated clock designs and by using which the registers triggering to decrease the dynamic power and to select different filter orders in a single chip design.

***Abstract*—Brainy Grid (BG) is a coordination of conventional power network with advanced data and communication framework for bidirectional vitality stream among grid together with end clients. An enormous measure of data is being created by different smart gadgets sent in BG frameworks. Such a gigantic information generation from different smart gadgets in BG frameworks may prompt different difficulties for the systems administration foundation conveyed among end clients and network. Consequently, an effective information transmission system is required for giving wanted QoS to clients in this condition. The high dimensions of information may influence the execution of majority of the designed solutions in this condition. Maximum of the current plans announced to have complex operation for the information dimensionality decrease issue which may decrement the execution of any actualized answer for this issue. To address these troubles, in this paper, Sparse-based dimensionality decrease for huge information is intended for dimensionality reduction issue of colossal data made from various smart Gadgets. First the Singular Value Decomposition (SVD) is applied to high-order tensors (utilized for information portrayal) to limit the remaking mistake of the decreased tensors. Then VLCP (Software-defined networks(SDN) Controller) is used to broadcast the compressed data. The adequacy of the proposed plan has been assessed utilizing simulations completed on the information follows using Python and various libraries. The outcomes got portray the viability of the proposed plan concerning the parameters, for example, dimensionality reduction ratio and approximation accuracy.**

Keywords—Brainy Grid, VLCP, SVD, Sparse, QoS, SDN

I. INTRODUCTON

A Low rank sparse approximation-based data administration scheme is designed for representation and dimensionality reduction of data acquired from enormous smart gadgets in BG network. Due to sparse estimation reconstruction error is reduced. To propose sparse based dimensionality reduction issue in brainy grid. Brainy grid (BG) is an agile power grid which backing a Two-way power stream among users and grid. It improves client's demand, power generated, and network availability to provide reliability and productivity using automated controls, sensors, metering devices, and distributed energy sources. It consist of components such as brainy meters and sensing devices linked to one another applying communication infrastructure. The delivery of numerous benefits such as energy, voltage, and frequency regulations to the ultimate consumer lean on the steady and real-time report about the data flow between consumers and utility providers (grid). For this goal, a reliable transmission framework is needed to conduct the flow of input among sources of data propagation and smart meters.

In the wake of examining the previously mentioned recommendations, it is deduced that an enormous measure of huge information is being produced by different smart gadgets in the BG. Be that as it may; taking care of this huge information in an effective way is one of the greatest difficulties in BG condition.

Different systems have been examined concerning these issues in the present proposals. Be that as it may, none of the present recommendations have concentrated on tremendous information examination in BG structures for a productive QoS provisioning. Additionally, the present proposal has not investigated any unified model for information portrayal.

VLCP is a modern SDN controller ready to be incorporated with Open Stack, Docker and other virtualization conditions. It is intended to be

exceptionally adaptable, exceedingly accessible and have extremely low overhead for virtual systems administration. As of now it is prepared for creation, and has been checked, tried and being used in bunches with around 10 physical servers. Tests demonstrate that the controller remains stable for over seven days under high weight as: 1000 endpoints for every server; 16+ Gbps traffic; 200 endpoint changes (manifestations and cancellations) every moment per server.

In straight variable based math, the SVD is a factorization of a genuine or complex network. It is the speculation of the Eigen decomposition of a positive semi certain ordinary grid (for instance, a symmetric framework with positive Eigen values) to any M*N matrix by means of an augmentation of the polar decay. It has numerous valuable applications in sign handling and insights.

II. Related Work

In paper [1], a tensor-established SDN demonstrate for size degradation issue for huge information procured from different SG gadgets is planned. As this reason, a F-HOSVD calculation is structured. The motivation behind the suggested plan is to speak to the mass information produced by BG gadgets in a tensor structure. After tensor portrayal, the sub-tensors are consolidated to shape a brought together tensor.

In article [2], SDN-established edge-cloud exchange is exhibited to manage stream planning among edge and cloud gadgets. In such manner, a various-objective transformative calculation utilizing Tchebycheff deterioration is intended for stream planning in SDN. The proposed plan is assessed as for two streamlining issues: 1. Exchange off between vitality productivity and idleness 2. Exchange off between vitality effectiveness and transmission capacity.

A MCE [3] gives the establishment to satisfy the requirements of end customers, be that as it may in order to conduct the gigantic proportion of framework information traffic, and the hashing limit is service to enlist the grim rundown to install, look, and eradicate an entry in a show. Regardless, there may rise an occasion of accident when a hash record can be remade. Along these lines, in such a condition, twofold hashing limit is used to enroll another hash record to decide the effect likewise; gainful propelled data managing philosophy is required. SDN advancement is a united building that settles on shrewd decisions for ground-breaking framework the board. Framework hypervisors expect a crucial activity for making virtual SDN controllers so as to make various shrewd resources for expanding the fulfillment of the benefits. In article, journalists have dismembered the fittingness of a Bloom-channel based response for improved stream table organization.

Web of Things (IoT), [4] a bit of Future Internet, contains countless Internet related Objects (ICOs) or 'things' where things may identify, bestow, register and likely cause similarly as information, various-particular intersection, physical/virtual characters and aspects. The IoT vision has starting late offered rise to creating IoT tremendous information operations for instance splendid essentialness systems, syndromic bio reconnaissance, regular checking, emergency condition care, propelled cultivating, and wise collecting that are fit for conveying lots of data stream from geographically scattered information sources.

The paper [5] examines the contemporary state of collateral GIS concerning collateral GIS models, parallel taking care of systems, and appropriate subjects. We present the regular headway of the GIS structure which fuses principal two parallel GIS models reliant on world class figuring pack and Hadoop gathering. By then they shorten the present spatial information package procedures, key systems to recognize parallel GIS in the point of view on data rot and headway of the unprecedented parallel GIS computations. They use the collateral treatment of GRASS as a logical examination.

Despite the gigantic theories happening in the exchanges establishment, this outstanding parts a bottleneck for the use of specific supplications.

Paper [6] gives a technique for lossy information weight in splendid movement structures utilizing the singular regard breaking down framework. The proposed methodology can do out and out diminishing the volume of information to be broadcast through the exchanges organize and correctly reproducing the principal information. These characteristics are appeared by outcomes from tests finished using certified information assembled from metering tools at a wide scope of substations.

In [7], organization engineering Macro Serv exhibited that plays out the constant course proposition for the evacuees at the period of a fiasco. The proposed organization utilizes the live information removed from the ITS and the road side sensors to find out favored clearing ways that have most outrageous traffic stream limit, least blockage, and travel cost.

One of the key factors that will choose the accomplishment of splendid meters is clever meter data examination which oversees data getting, transmission, planning, and interpretation that pass on points of scrutiny to all accomplices.

Paper [8] presents an intensive diagram of adroit power meters and their use concentrating on solution pieces of metering process, the assorted accomplice concerns and developments used to assure accomplice interests. Concentrating on versatility, extensibility, synchronization, and power, a scattered data examination stage is proposed in paper [9] to process broad volume, rapid dataset. An arrangement of progressing and non-nonstop synchrophasor data examination applications are encouraged by this stage. The estimation burden is bestowed to alter by different center points of the examination gathering, and colossal data examination instruments, for instance, Apache Spark are grasped to regulate considerable volume data and to help the data getting ready speed.
In [10], a SDN-based correspondence structure for micro grid is shown to overhaul micro grid adaptability. This plan has two outstanding characteristics: First, the control layer is self-governing of the apparatus systems, which facilitates fast utilization of varying applications. Second, the SDN controller fills in as a screen managing the whole status of the framework switches similarly as a controller handling framework issues, for instance, data obstruct, port down, and transmission limit task. Thusly, the correspondence organize is fit for giving strong and revamp organization to micro grid.

III. Proposed System

Sparse-based information administration plan is presented to get raw information and reduce it to lower magnitude thereby optimizing the reconstruction error. The acquisition of huge information in BG atmosphere associates numerous problems such as-absent values, unpredictability, duplex also avoidable values etc. However, the suggested scheme handles these provocations in a productive manner. The motive of this paper is, in ruler area huge electricity is generated at power plants and in urban cities the utilization of that electricity takes place. So the information of electricity utilization in brainy grid need to reach at the power plant which is located at ruler area, distance between BG and Power plant is a lot. Transmission of electricity data will take more time and bandwidth by using traditional network but if the data sending takes place by compressing data then the time to reach the information from one destination to other will become less.

Hence in proposed scheme firstly the manipulation of data takes place by using python library called a Tensor Flow. From the dataset, electricity and year information is taken for the data manipulation by using Tensor Flow the data is being converted into Tensor form. In Fig (1). The first block shows the data acquisition through the smart devices means the data generated by Brainy grid, the dataset carrying this information from which we take electricity and year information for compression and transmission.

Second block of system architecture consist of data storing in tensor model means converting the given information in tensor form. Numpy Python library is used to support large multidimensional arrays and Pandas library is used for data manipulation and analysis.

Third block shows unified tensor means electricity data tensor and year data tensors are merging to form unified tensor.

Forth block is dimensionality reduction of unified tensor applying SVD. For factorization and decomposition SVD is applied. By using traditional network it will take more time to transfer the data from Brainy grids to the power plant. SDN comes in picture; using VLCP Controller establishment of SDN is taken placed. For Transmission and reception VLCP Controller is programmed. Graphic User Interface is used for security purpose when analysis is taken place.

Fifth block represents communication using SDN. Last block is BG applications. So this is the system architecture. Fig.1 shows the flow chart of the proposed system. If the data is in reduced form then the time required to transmit it from one destination to other is less than the time required to transmit the original data.

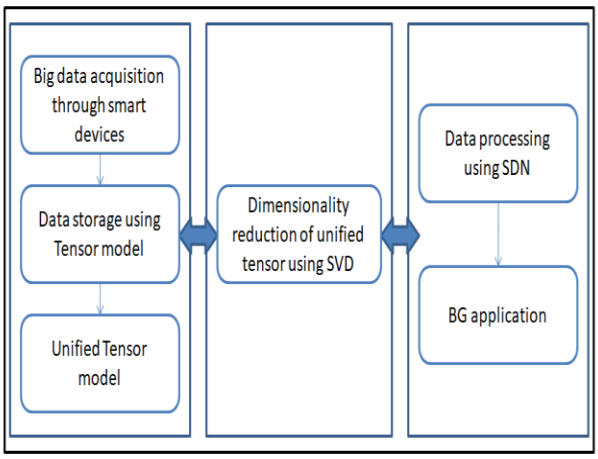

Fig 1.system architecture

IV. Result Analysis

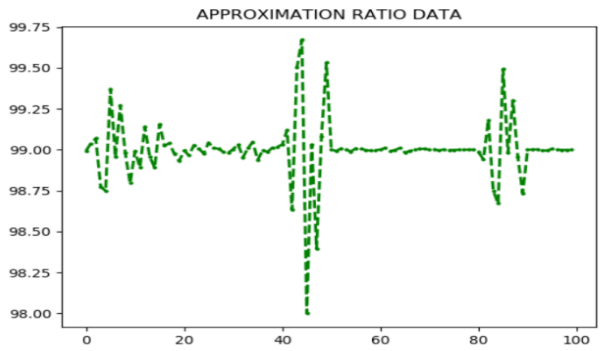

Fig 2.1 Approximation ratio of the data

The above graph is the outcome of the Subtraction of original data and reconstructed data. X axis indicates the 100 samples of the data and Y axis represents approximation ratio.

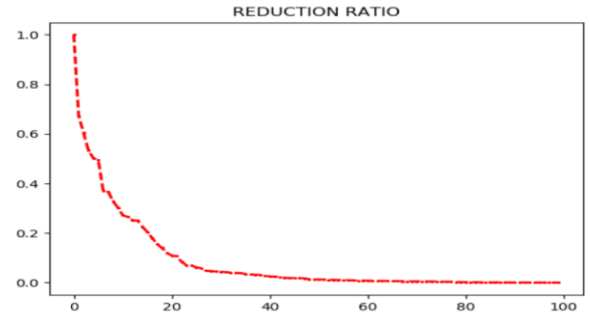

Fig (2.2). Reduction ratio

Above graph is obtained by subtracting reshaped data from reconstructed data. X axis indicates the 100 samples of data and Y axis indicates reduction ratio.

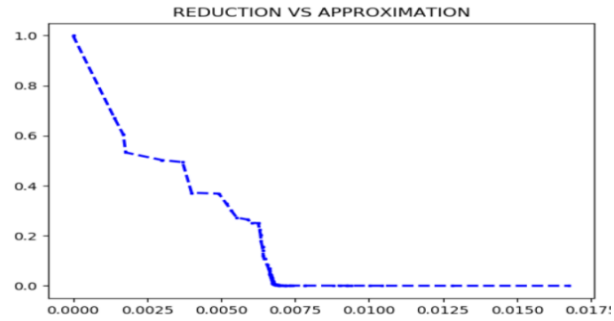

Fig (2.3). Reduction verses Approximation ratio

The graph present the comparison of reduction and approximation. The X axis is approximation ratio and Y axis is reduction ratio.

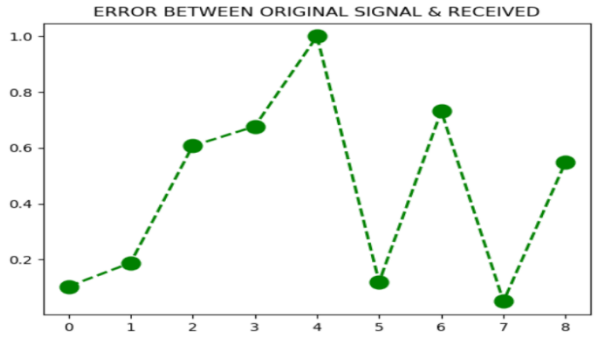

Fig (2.5). Error between Original Signal Verses Received signals

Above graph is a comparison of received data to the transmitted data to get to know the errors occurs between transmissions.

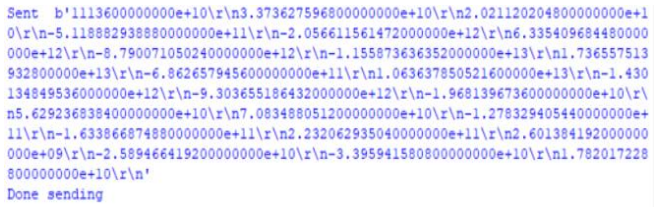

Fig (3). Sending of data to the Receiver

The manipulated data is sending it seems in this form because it's reconstructed data

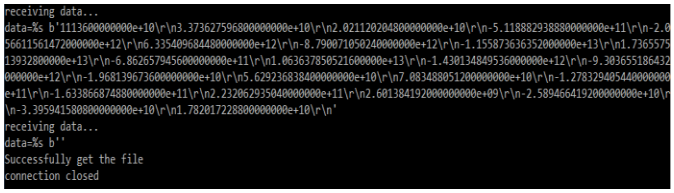

Fig (4). Reception of data.

The manipulated data is received to the port.

V. Conclusion

In this paper, Sparse based dimensionality reduction for big data is proposed. The purpose of proposed scheme is to reduce enormous data produced by the brainy grid. To manipulate data without losing the originality of the data is difficult task and finally to forward this data through the SDN network. Firstly to show the data in tensor form. Firstly enormous quantity of information is produced by smart devices

then by using TensorFlow in Python that data is converted into Tensor model. After that the data in the form of Sub Tensors, sub-tensors are adding together forming unified tensors then SVD is applied to unified tensors for decomposition of data. Analysis of the data is taken place and then using VLCP controller sending and reception of data taken place. VLCP controller is used as SDN controller. The outcomes show that dimensionality reduction in given data. Evaluation parameters in proposed scheme is approximation ratio means the differentiation of the actual data to the reconstructed data and reduction ratio means the amount of data reduced for the given samples, network performance and error between original data and received data means the error occurs in the send and received information, Sending of data to the receiver and reception of information is successfully done using VLCP controller. Hence, overall conclusion obtained from the suggested scheme is related to data administration and dimensionality contraction shows better performance.

***Abstract*—Vehicle and passenger safety is one of the key attributes in designing autonomous vehicles. Vehicles are equipped with several fast computing devices and sensors that will alert the driver in risk conditions, but there are events that cannot be identified by such sensors, such as road intersections. In such conditions, data collected from other devices or vehicles can help. Vehicular Networks ensure the safety of these by enabling the communication between the vehicles. The ideal scenario about Vehicular ad-hoc Network is, where the vehicles on the road are connected to each other and to RSU devices, details about their transit are transmitted to the manipulating devices. The objective of this work is to simulate such a condition via NS2 simulator and to implement the hardware prototype of such scenario to collect the data from various nodes and integrate it to the other nodes in the network. For Simulation, VANET environment is created with Vehicles and RSU units, shortest path routing algorithm is implemented for data communication between RSU units. The hardware prototype is created with two vehicles and one RSU unit, the data is collected from both the devices and emergency messages are transmitted to other vehicles. The setup is able to collect the data when collision occurs and this is transmitted to RSU for data processing.**

***Index Terms*—Autonomous vehicles, Navigation, computing device, collision avoidance, NS2, RSU range, data communication.**

I. Introduction

The next stage of vehicular safety is the evolution of unmanned vehicles or autonomous vehicles [1] , by far the development of these are started and taken the space in developed countries and are very soon visibly in the developing countries too. Autonomous vehicles brings us safety and also a doubt whether it can perform as theoretically mentioned or not. Figure 2 shows the overview of VANET system.

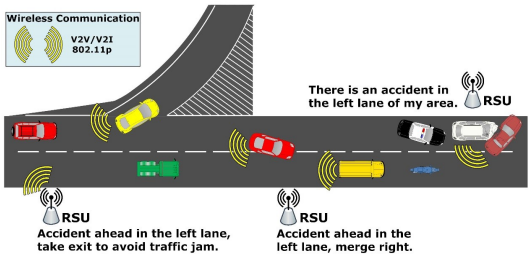

Fig. 1. Data Packet communication

In some cases only the data from sensors may not be sufficient to take a decision or it will lead to wrong decision making as in [2]. For example in a four way intersection road midpoint the sensors like camera cannot capture the obstacle on the other side of the road [3], in these cases the only solution is to collect information from the other vehicles that may cause as an obstacle.

Sensors are associated with special written algorithms [4] to process these data. Many states of these algorithms such as collision avoidance, stabilization of vehicle, lane tracking etc. are needed to be included in the system. Hence the controller prioritize these states according to the situation, such that the vehicle avoids big crash and provides smooth collision free navigation. Figure 2 shows the dependent of various sensors in a car.

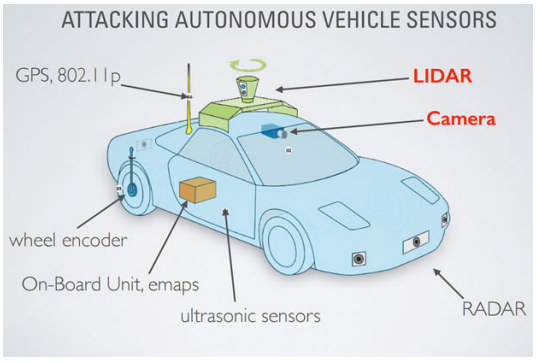

Fig. 2. Various Sensors in autonomous cars

Collision scenario can be understood earlier even before it is identified by the sensor, with the help of forming a network of vehicles known as Vehicular ad-hoc network.

Vehicular ad-hoc network is a kind of mobile ad-hoc network that forms network of vehicles based on the position of the vehicle. In VANET the vehicles are connected to each other and also connected to an infrastructure based computing device [5] called RSU (Road Side Units). These RSU's perform the possible manipulation of the data[6], the various RSU are interconnected to each other to share the details throughout the network. The vehicle in a network communicates with the RSU associated to it, and in some cases vehicle also

communicates to other vehicles in the network. RSU can also provide the details of the environment such as traffic status accidents in the route [7], speed limit, accident zone etc.

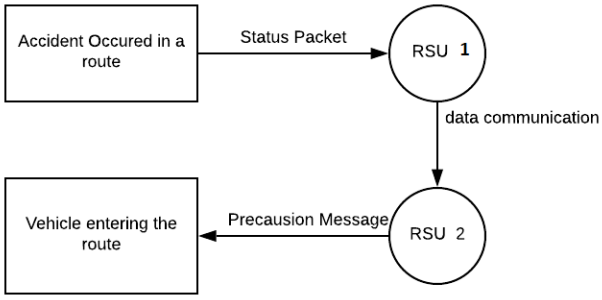

Fig. 3. Data Packet communication

The work proposes to develop a system as shown in Figure 3. The remainder of the paper is organised as follows: Section II speaks about the Literature Survey, Section III is about System Requirements,section IV discusses the proposed system and Section V showcase the Implementation and results.

II. Literature Survey

Various researches has been performed on VANET collision detection, collision avoidance and stabilization of autonomous vehicles.

A. Stabilization of autonomous vehicles

The authors J. Funke et al. in [8] discusses the need for stabilization in autonomous vehicles during certain emergency scenarios. The algorithm tries to stabilize the vehicle in some situations even though if it conflicts with collision avoidance. The control sequence is created by integrating vehicle stabilization, collision avoidance and path tracking. Model predictive controllers and feedback controllers are used to form the framework. In some scenarios collision avoidance is unavoidable therefore stabilization is performed. Prediction algorithm employs environment related parameters to predict the vehicles future dynamics.

B. QCP based Model Predictive Controller

Z. Wang et al. in [9] uses convex quadrature programming based MPC(model predictive controller) for navigation of Autonomous vehicles and collision avoidance, During trajectory generation the vehicle shape is considered as polygonal region. Cost function is created, that forms a model which navigates the vehicle through the environment, then the optimization of the cost function is performed for path planning. Simulations are done in MATLAB and CARSIM is used for better simulation of vehicle navigation. Model Predictive controller is formed in MATLAB.

C. Vehicle Risk Assessment

In [10] the work by H. Fahmy et al. perform simulations for different scenarios including the mechanical setup for controlling angle of trajectory. Vehicle risk is analysed by Vehicle communication and the optimal track is maintained by evaluation of cost of the various obstacle. The simulations are performed with a car and with different obstacle paths, obstacle avoidance and lane selection id for different scenarios. Several frameworks such as road model, driver model and vehicle mode are created by the numerical methods and are integrated to get the live vehicle model.

D. Vanet- Physical Model

In [11] D. Anadu et al. proposes the efficient algorithm for collision detection in a VANET environment. They address VANET security by implementing IFA(iterative filtering algorithm) that filters the wrong sensor reading. Various parameters of the vehicles such as position, speed and orientation are transmitted to the Vehicular network, from there the corresponding messages for the collision detection is created.

E. Numerical Methods

In [12], work by H. Fahmy et al. employ numerical methods to keep the track of the unmanned vehicles and prevent collision. The main theme of the work is that the road details are shared through Vehicular communication and hence the vehicles entering understand scenario well in advance, thereby preferring the exact lane, so that the obstacles are avoided in advance and necessary actions are taken as a prerequisite.

Various routing protocols [13], [14] for Vanet speaks about how quick the data packets can reach the destination with minimum hops required and with very less packet losses.

We summarize from the survey that collecting important data's and processing it plays vital role in collision detection/avoidance. Therefore we propose system that will collect data such as accidents occurence, traffic details and communicate this data to RSU through routing, which in turn makes decision for vehicles in its range.

III. System Requirements

The software and hardware used in the work is explained in this section

A. Software Requirements

For performing simulations, the following tools are used

1) NS2- Network Simulator 2
2) Arduino IDE

1) NS2: The network simulator 2 is used here to simulate network parameters. It is an open source simulator. The network simulation parameters includes routing protocol, topography, channel, link layer, MAC layer, initial energy, Antenna, etc. Scripts for simulating the network is written as TCL scripts.

OTCL is a scripting language that incorporates the object oriented properties of c++. The TCL script generates trace file that captures all the events that happen during the simulation

of the script. The algorithm for the project is written in AWK scripts, the awk script uses trace file to process the data. The output of the AWK script is written to another file, which is used in executing the NAM window in the TCL script.

2) Arduino IDE: It is a software which facilitates to write the code for Arduino and upload to the boards. The code for arduino boards are written in simple c language. This IDE also helps to serial monitor the arduino board.

B. Hardware Requirements

The hardware implementation of the system is done using the Arduino boards and nRF modules, for better understanding the system multiple nodes are created to imitate the real world like scenario. The components used in this project for prototyping the system are listed as below,

- Arduino uno boards- 3 units.
- nrf24L01 module- 3 units.
- LCD 16*2 module- 1 unit.
- GPS module- 1 unit.
- RC car- 3 units.
- joystick module- 2 units.
- IR sensor- 2 units.
- buzzer- 1 unit.
- lead acid battery- 2 units.

1) Arduino uno/ nano: Arduino Uno/nano is a microcontroller board containing ATmega328P as a Processor. It has 14 digital IO pins of which 6 pins can be used as PWM outputs, 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. In this work we used arduino boards with nrf modules to create network out of it.

2) NRF24L01 module: NRF24L01 module is multi transceiver that can communicate with six other modules directly, by using routing this module can be used to communicate with large number of nodes by forming a network between nodes. Figure 4 shows the pinout of NRF24L01 module.

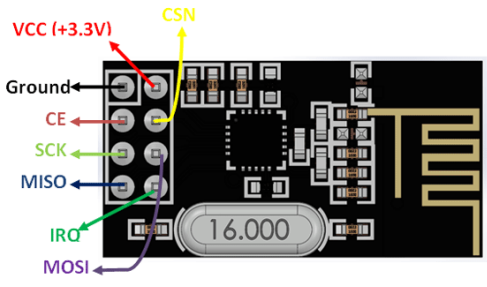

Fig. 4. nRF24L01 PINOUT

3) GPS module: Gps module is used to locate the vehicle with respect to the satellite positions, these data are then processed with arduino and the coordinates(x axis and y axis) are transmitted to the RSU unit.

4) Robot car: The robot car is developed with four geared motors and chassis, it is powered using 12v lead acid battery of capacity 1.3Ah. Some specifications of the robot car is mentioned below:

1) motors used: 12v geared DC motor.
2) Chassis: transparent plastic chassis.
3) battery: 12v 1.3 Ah Lead Acid battery.

IV. Proposed System

A. System Flow

A network is created with number of vehicle nodes and RSU nodes. When a vehicle enters in a range of RSU it gets connected to it. Vehicle shares its status and its destination to the RSU, whereas the RSU replies with the possible route and the status of this route. Shortest path routing algorithm (SPRA algorithm) is used to find the shortest path for data communication. The flow of the system is as shown in Figure 6.

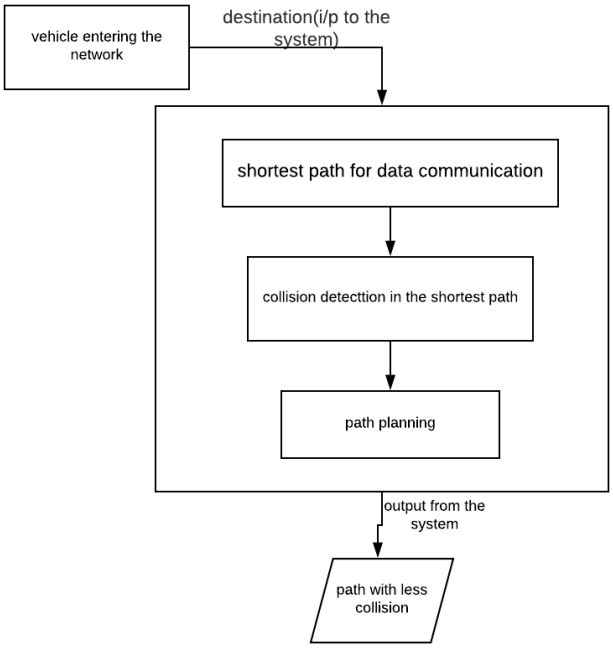

Fig. 5. System Flow Diagram

1) SPRA algorithm: The computing devices are placed apart with some distances to each other. When the vehicle triggers the system by giving a destination, the RSU with the vehicle's range compute the shortest path for which it can intimate the RSU near the destination. Shortest path routing algorithm based on Euclidean distance is employed to find the shortest path between source and destination. This path is used to share the data such as traffic status, accident occurrence in the route. Figure 7 shows the block diagram of SPRA algorithm.

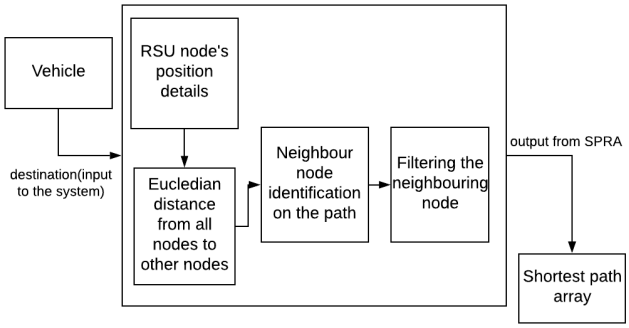

Fig. 6. SPRA block diagram

B. Hardware Prototype

To better understand the system a hardware prototype imitating the real world scenario of the system is implemented. A wireless network of three nodes are created with two vehicular node and 1 RSU node are created.

1) Vehicular node block diagram: Figure 8 shows the block diagram of the Vehicular node. GPS module is connected to the vehicles which records the GPS data and it is forwarded to the RSU in range to it.

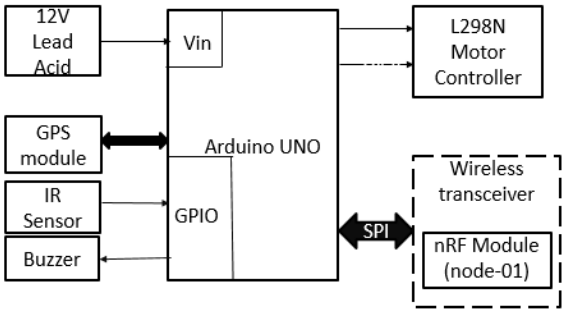

Fig. 7. Vehicular node block diagram

2) RSU node block diagram: Figure 9 shows the block diagram of the RSU node. It consist of Joystick module that imitates the control of vehicular node. The LCD module is used to display the messages received by the node from other nodes.

V. Implementation and Results Analysis

The prototype of the proposed system is implemented in NS2 simulator where vehicular ad-hoc network is created with various wireless nodes. To better understand the working, hardware implementation of the VANET is performed using microcontrollers, RC cars, NRF24L01 modules and other sensors.

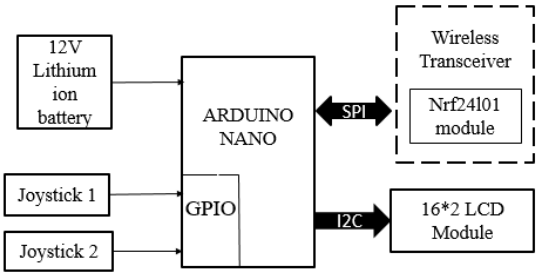

Fig. 8. RSU node block diagram

A. NS2 Simulation

For implementing the VANET in NS2, a network is created with number of wireless mobile nodes each having different functionality. The Figure 10 shows the created VANET environment in the Network Animator of the Network Simulator-2.

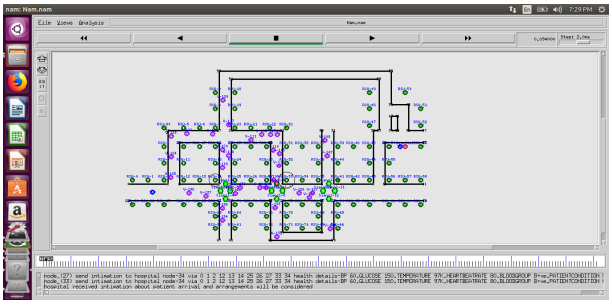

Fig. 9. Created Vanet Environment

B. Hardware Prototype

Physical Prototype consists of three nodes,

1) RSU node – which monitors the network and coordinates each of the vehicles within its range. Thereby it acts as server node.
2) Two vehicular node – which are the client nodes that perform some events based on the written code.

Figure 11 shows the server node that acts as RSU unit of the system, monitoring the network and sending crucial messages to the vehicles that enter the network. The two joystick is connected wirelessly to the two vehicles so that the vehicles are controlled for their forward and backward direction control.

Figure 12 shows the Vehicular node setup. The two wireless vehicles act as two clients for the server node of the network. These vehicles are controlled from the server node using the two joystick module. All the three nodes are wirelessly connected to each other by nRF24L01 wireless transceiver module.

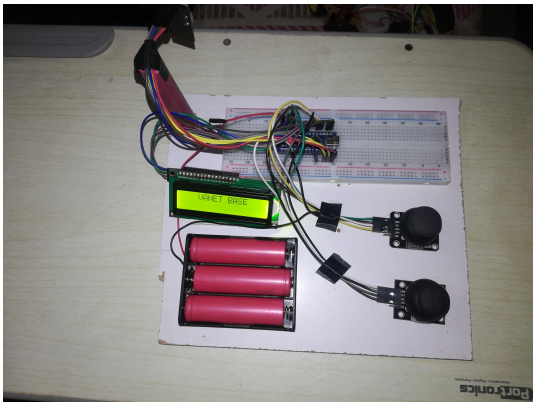

Fig. 10. RSU node setup

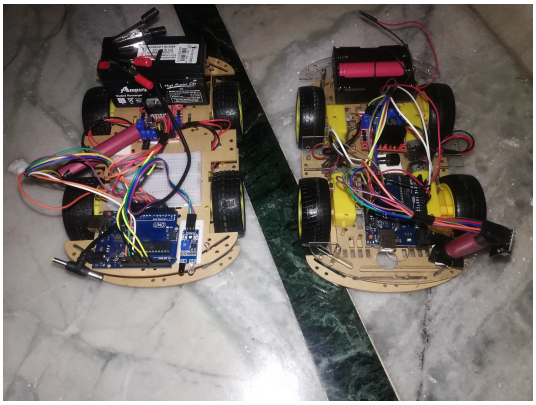

Fig. 11. Vehicular node setup

- 4 Wheel-Drive cars having four 12v BO geared motors are used, L298N motor driver is employed to control the motors via the arduino.
- One of the vehicles consist of IR sensor to detect any close obstacle within the vehicle, whenever this vehicle collapses with the obstacle the IR sensor creates a digital high which is transmitted to the network.
- Whenever this vehicles is guided to meet the obstacle the IR sensor present in it captures the event and transmits the data to the server node which acts as the coordinator of all the nodes in the network.
- The nRF24L01 module transmits the data to the node whose address is requested. Whenever this data is received in the server, the corresponding message is displayed in the LCD that is connected to the server node's Arduino via the I2C connector circuit.
- Then the server node transmits the data received to the vehicles that are entering in to the network (entering the range with the nRF24l01 module).

We tested the prototype by considering a vehicle in a route as an ambulance and another vehicle(v1) in the route. When vehicle v1 meets with collision in the route, the data is transmitted to the RSU, which identifies the entry of ambulance in the route and transmits the data to the ambulance. Thereby the ambulance is intimated with the incident.

VI. Conclusion and Future work

Vehicular ad-hoc networks in intelligent transport system help to improve the precision of decision making in autonomous vehicles by communication crucial data. In this work we simulated a system with VANET network created and SPRA algorithm implemented for data communication. The hardware prototype created by forming wireless network using sensors showed that the vehicle node can avoid accidents even before the sensor reads the scenario. Future work may include communication of parameters of the node like speed etc. so that other vehicle performs actions to avoid crashes.

***Abstract*—Hardware emulator is a special purpose device which mirrors the operation of a software or dynamic system. Such devices can be implemented using Programmable Logic Devices, Field Programmable Gate Array (FPGA) and Application Specific Integrated Circuit(ASIC). Field Programmable Gate Array (FPGA) is one of the popular solutions to design an emulator due to its high speed, reduced power consumption, reconfigurability and reduced cost. It is more flexible than a PLD and has less development time when compared to ASIC. In this paper, hardware realization of DC motor emulator using FPGA is presented. The continuous-time transfer function model of an armature controlled DC shunt motor is determined by conducting suitable experiments. The discrete-time model of the DC motor is the emulator and it is realized as a second order digital Impulse Infinite Response (IIR) filter. The hardware of this filter is designed with adders, multipliers and delays using Verilog and mapped on a Spartan 6 FPGA. Speed and load characteristics of this emulator is compared with the actual motor characteristics. This model can be used in place of DC motor for testing speed estimators and for verifying the performance of motors with different ratings without using the actual motors.**

***Keywords*—DC shunt motor, Armature control, FPGA, Emulator.**

I. Introduction

An FPGA based hardware emulator is used to replicate the behaviour of a real-time system. It is used for debugging and verifying the functions of the dynamic system under consideration.For example, in automation industries, an emulator is created to verify the functioning of automation system in real time. It can be linked with the controllers that are developed to control the real system. These devices target hardware debugging and can emulate any system with different sizes and structures, unlike prototyping which focuses on achieving the speed of the specific design. Developing such a multi-purpose device with several number of FPGAs connected together is useful to emulate complex hardware systems. It can achieve execution speed of few Kilohertz to Megahertz. They provide better hardware and software integration for most complex designs along with reducing the designing cost. There are two main categories which are classified as low level and high level emulators. Low level emulators reproduce the operation of system under design with high accuracy. High Level devices create an abstract of the system and used mainly for emulating a software. FPGA based hardware emulators are used in various fields such as automation, computer and storage, defense, Renewable energy technologies and product test and measurement. For example, wind generation using a DC machine [1] , photo voltaic emulator [2] to reproduce the characteristics of commercial Photo voltaic panels, state space controller [3] to control fast dynamic systems and FPGA based monitoring of wind and solar generators [4] are used in Renewable energy field. They are also used in Computer Science domain such as using an ARM processor [5] to mirror a Intel 8080 processor, Prototyping a Parameter Random Access Memory (PRAM) [6] using FPGA. Digital Wireless Channel Emulator [7] to reproduce RF environment in military networks and emulate an aircraft based satellite [8] to test an antenna array in space are a few defense based applications. To emulate a system in FPGA, is to initiate with implementing design using Hardware Description Languages such as Verilog and VHDL. It can be also achieved by using model-based methods such as Xilinx System Generator in Simulink. Fixed point algorithm is used to represent the decimals, due to the simplicity compared to the Floating point algorithm. In this paper, hardware emulator for an armature controlled DC shunt motor is proposed. Armature resistance, inductance, motor constants, inertia and friction are estimated by conducting experiments on a 220V, 2HP motor. Proposed model is determined by substituting the estimated values in standard DC motor model. This model is discretized and realised as an IIR filter. Direct form I filter is designed using A Hardware Descriptive Language and mapped on a FPGA. Armature voltage is given as input and the speed characteristics are analysed.

An overview of similar works carried out using emulator is summarized in Section II. The proposed mathematical model of a DC motor and IIR filter is explained in Section III. Section IV shows the simulation result of intended model and architecture of the hardware implementation. Emulator results are evaluated and compared with simulation and actual motor results in Section V. Conclusion of the proposed work is mentioned briefly in Section VI.

II. Related Work

The numerical issues connected with the discrete time induction motor implementation is discussed in [9]. To implement and verify the simulation of control algorithms to the emulator for the motors. The designing is started

with continuous time system and shift algorithm is used to discretize the model. A Direct Torque Control algorithm is verified using this emulator. Implementation of brush-less DC motor speed controller is discussed in [10]. The design is mapped on FPGA for testing the different validation and verification methods . It is designed using Xilinx system Generator blockset from Xilinx in Simulink. A PI controller is implemented in FPGA to verify the performance. The discretization methods of an induction motor for implementing a real time emulator is investigated in [11]. Shift operator method, Tustin and Delta operator method are discussed and the simulation results are carried out using simulink. A hardware emulator design of DC motor is projected in [12] for emulating the system when designing controllers.This emulator is developed without taking losses into consideration. It is realized using VHDL and synthesized to Virtex II FPGA. A torque input is given and the output is measured from emulator. It is then connected with the hardware or software controller.

III. Mathematical Modelling of Proposed Work

DC motor speed can be varied by changing the armature voltage while keeping the flux constant. The speed is measured by changing the series resistance with armature winding.

$$T = K_t \Phi I_a$$

Since Flux is constant,

$$T = K_t I_a \tag{1}$$

$$E_b = K_b \omega \tag{2}$$

where, T = Torque)
I_a = Armature Current
K_t = Motor constant
E_b = Back emf
K_b = Back EMF constant
ω = Angular Velocity
R_a = Resistance
L_a = Inductance

If voltage and resistance in armature are kept constant, speed will be proportional to current. Differential equation for DC motor based on Kirchhoff's Voltage Law is derived as

$$V_a = I_a R_a + L_a \frac{dI_a}{dt} + E_b \tag{3}$$

The torque equation based on Inertia (J_m) and damping (B_m) is derived as

$$J_m \frac{d\omega}{dt} + B_m \omega = T$$

From (1),

$$J_m \frac{d\omega}{dt} + B_m \omega = K_t I_a \tag{4}$$

Laplace Transform of (3) & (4)

$$V_a(s) = R_a I_a(s) + s L_a I_a(s) + E_b(s) \tag{5}$$

$$J_m s\omega(s) + B_m \omega(s) = K_t I_a(s) \tag{6}$$

Rewriting (5) with (2),

$$V_a(s) = R_a I_a(s) + s L_a I_a(s) + K_b \omega(s)$$

$$I_a(s) = \left(\frac{V_a(s) - K_b \omega(s)}{L_a s + R_a} \right) \tag{7}$$

From (6) & (7),

$$G(s) = \frac{\omega(s)}{V_a(s)} = \frac{K_t}{(L_a s + R_a).(J_m s + B_m)} \tag{8}$$

Closed loop transfer function the DC motor with H(s)=K_b is given by,

$$\frac{\omega(s)}{V_a(s)} = \frac{K_t}{(L_a s + R_a).(J_m s + B_m) + K_t K_b} \tag{9}$$

On conducting suitable experiments on a DC motor, the following values are obtained.
R_a=2.715Ω,
L_a=36mH,
K_t=1.032 N.m/A,
K_b=1.2633 V/rad/sec,
J_m=0.039 Kg. m^2
B_m= 0.0116 N.m.s

By substituting these values in (9), the continuous time model becomes,

$$H(s) = \frac{Y(s)}{X(s)} = \frac{1.032}{0.001326s^2 + 0.1063s + 1.202} \tag{10}$$

Eqn. (10) is discretized using MATLAB and the transfer function becomes,

$$\frac{Y(z)}{X(z)} = \frac{0.03007z^{-1} + 0.2303z^{-2}}{1 - 1.38z^{-1} + 0.4487z^{-2}} \tag{11}$$

It can be implemented using a second order Impulse Infinite Response filter. This filter calculate new output using the current input along with past output. A digital IIR filter has better amplitude response, use minimal storage space and resemble analog filter output. The discrete tf of a filter is defined as,

$$\sum_{j=0}^{M} b_j z^{-j} Y(z) - \sum_{k=0}^{N} a_k z^{-j} X(z) \tag{12}$$

A second order filter from (12) is written as,

$$Y(z) = b_0 X(z) + b_1 z^{-1} X(z) + b_2 z^{-2} X(z) - a_1 z^{-1} Y(z) - a_2 z^{-2} Y(z) \tag{13}$$

where, b_0, b_1, b_2 - coefficients of zeros
a_0, a_1, a_2 - coefficients of poles.

X(z) - input signal
Y(z) - output signal.

From (11) the filter coefficients are estimated as
b_0=0; b_1=0.03007; b_2=0.02303 ;
a_0=1; a_1=1.38; a_2=-0.4487;

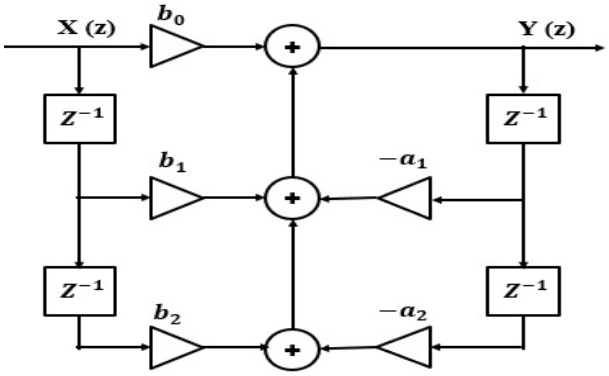

Fig. 1. Infinite Impulse Response Filter Direct Form 1

Replacing these coefficients in (11), it can be rewritten as,

$$Y(z) = 0.03007z^{-1}X(z) + 0.02303z^{-2}X(z) - 1.38z^{-1}Y(z) + 0.4487z^{-2}Y(z) \quad (14)$$

A Filter is designed in different methods. Direct form, canonical form and cascade form. Direct form I is often used to design filters of smaller order. The form I will execute the order of zeros initially followed by execution of poles in order. This helps to reduce errors occurring during run time.

IV. Emulator Design

A. Matlab Simulation Model

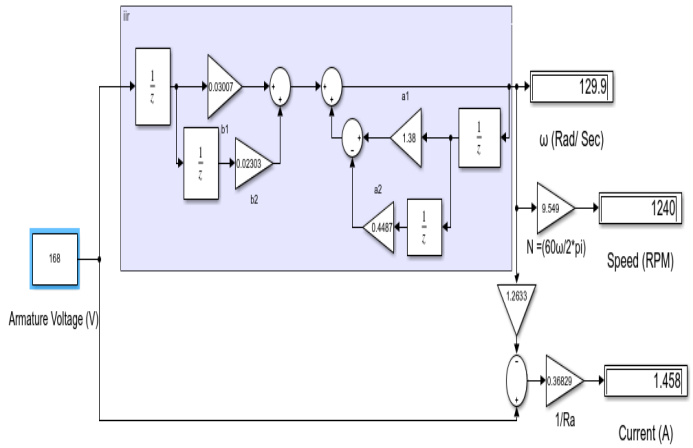

Fig. 2. Simulation of digital IIR filter using MATLAB Simulink

Fig. 2 shows the performance of digital IIR filter. model derived in (14) is simulated using using simulink. Input voltage, output speed and current values are shown in fig. 2.

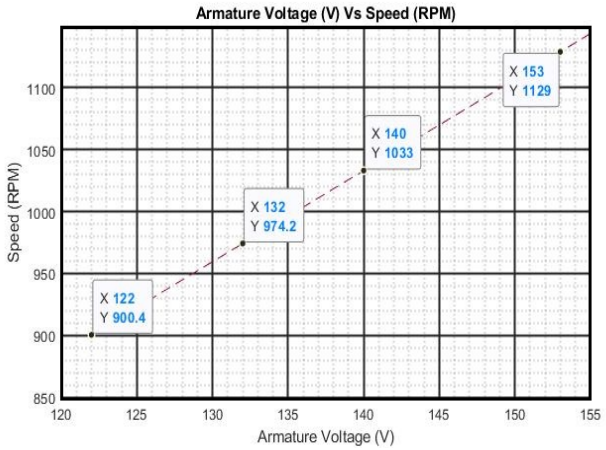

Fig. 3. DC motor Simulation Output for Speed in MATLAB Simulink

Simulation output of DC motor model is displayed in fig. 3. The input voltage Vs output speed characteristics of a motor is drawn using Matlab.

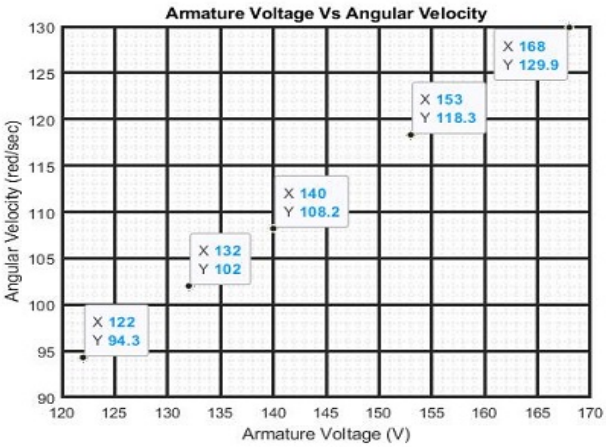

Fig. 4. DC motor Simulation Output for angular velocity in MATLAB Simulink

Simulation output of DC motor model for angular velocity is displayed in fig. 4.

B. Hardware Emulator Implementation

Eqn. (14) is used to design the DC motor emulator using IIR filter realization. Xilinx ISE software is used to design IIR filter in Verilog HDL. This IIR filter is implemented using multipliers, adders and delay units. The filter is synthesized and mapped on a Xilinx Spartan FPGA.

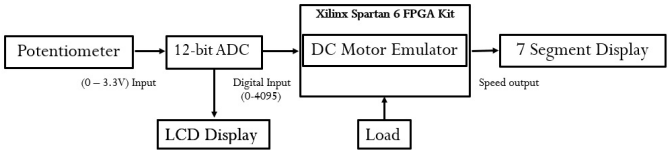

Fig. 5. FPGA Based Hardware Emulator Implementation Block Diagram

Fig. 5 represents the hardware implementation of the IIR filter emulator on a Xilinx Spartan 6 FPGA. A potentiometer is used to give input of 0-3.3V, which is discretized using a 12-bit ADC. The value is normalized according to the required 0-220 input and given to the emulator mapped on FPGA and the Speed output is shown using seven segment Display.

V. Results and Discussion

TABLE I
Comparison of Experiment, Simulation and FPGA output

Armature Voltage (V)	Experiment o/p		Simulation o/p		FPGA o/p	
	ω (Rad/Sec)	Speed (RPM)	ω (Rad/Sec)	Speed (RPM)	ω (Rad/Sec)	Speed (RPM)
122	95.82	914	94.3	900.4	93	887
132	102.6	980	102	974.2	101	964
140	108.5	1037	108.2	1033	107	1021
153	119.28	1139	118.3	1129	117	1116
168	131.69	1255	129.9	1240	128	1221

Table. 1 lists the comparison of experiment, simulation and FPGA emulator outputs to given armature voltage input and confirms that the emulator output is found closer to the actual motor speed.

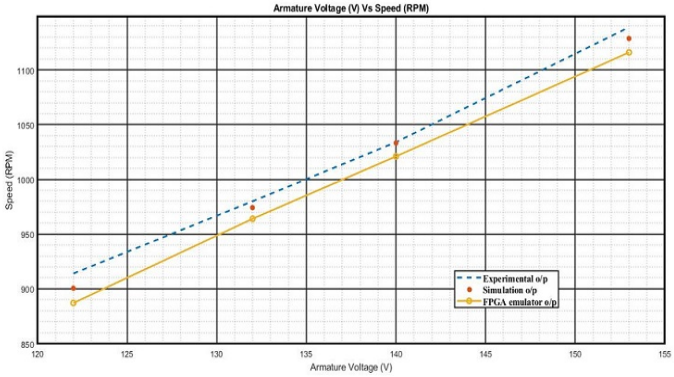

Fig. 6. Comparison among experiment, simulation and FPGA outputs

Fig. 6 shows the comparison of experiment, simulation and emulator outputs for given voltage input.

From table I, outcome of emulator with experimental and simulation outputs are found to be relatively similar. The hardware IIR filter is mapped and implemented on Xilinx Spartan 6 FPGA.

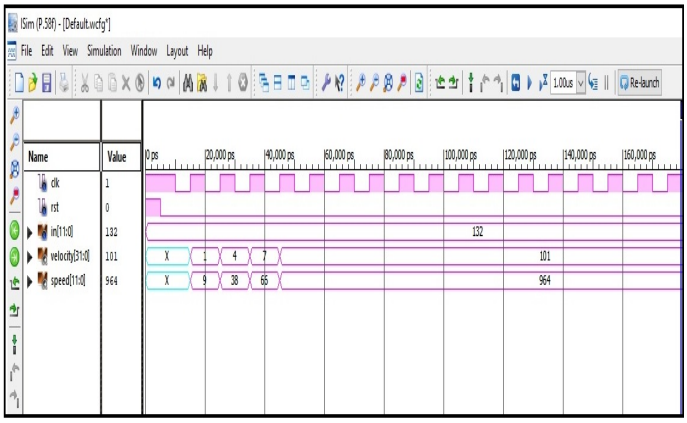

Fig. 7. IIR Filter Simulation for input=132 Using Xilinx ISE design suite

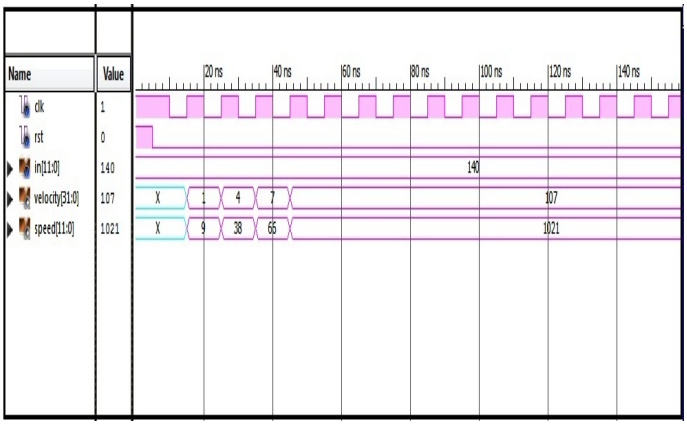

Fig. 8. IIR Filter Simulation Using Xilinx ISE design suite

Fig. 7 & Fig. 8 shows the IIR filter simulation output for various inputs in ISE software.

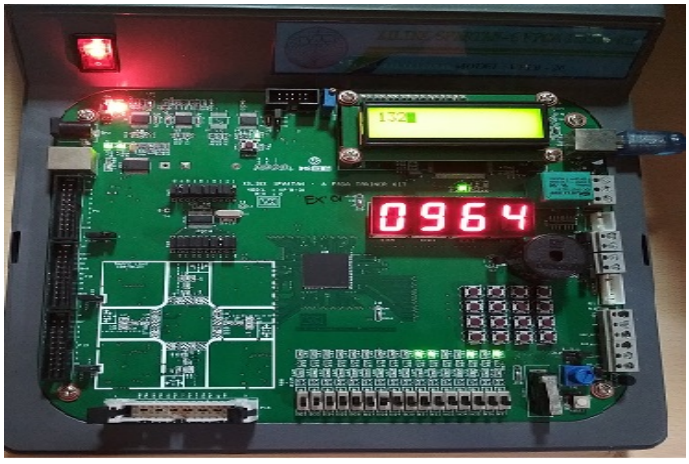

Fig. 9. Speed and ω output for armature voltage input=132V from emulator

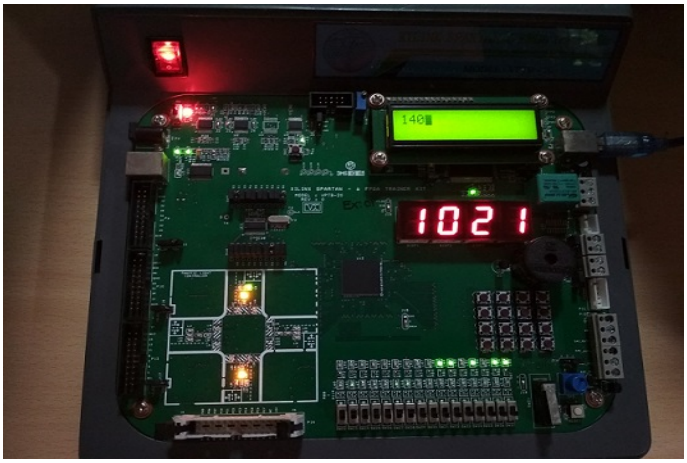

Fig. 10. Speed and ω output for armature voltage input=132V from emulator

The motor emulator results are shown in Fig 9 & Fig.10. Input armature voltage value is displayed in LCD, output velocity is shown using LED and output speed is shown using Seven Segment Display.

TABLE II
SYNTHESIS REPORT FOR THE EMULATOR DESIGN

Description	Used	Total
Number of Registers	191	18224
Number of LUTs	444	9112
Number of FFs	143	697
Minimum period	47.819ns	
Maximum Frequency	20.912MHz	

Table II specifies the utilization of resources to implement the emulator on an FPGA.

VI. CONCLUSION

Experiments are conducted on a 220V, 2HP, DC motor and its mathematical model is determined.The discrete function of the model is converted using Matlab Software. The obtained result is then realized as a second order IIR filter which is used for designing emulator. Hardware of this design is implemented in verilog and is mapped on Xilinx spartan-6 FPGA. The synthesis report is presented in Table II. The performance of the emulator is tested. Its speed and load characteristics are found to be same as the actual motor. In future, this FPGA based emulator may be used for the DC motor closed-loop speed control system.

***Abstract* - Rise of Over the Top (OTT) administrations like Netflix, YouTube, VIU and Cloud Services like S3 (AWS), Cloud Storage (GCP), and Dropbox are possessing a large portion of the piece of transfer speed. These sorts of administrations have direct association with increment or diminishing income of web access suppliers. Since the majority of Internet Service Providers give boundless plans, the need of proficient utilization of data transfer capacity has turned out to be essential for both income and QoS/QoE. By considering these genuine situations this paper builds up a framework which will powerfully put client's solicitation on uncommon paths i.e., Fast Lane and Slow Lane. In this model fast track will be designated to spilling administrations and moderate path will be distributed to document move administrations. For an Internet Service Provider this is chance to build incomes by offering control to the Content Provider (CP) who solicitations for exceptional paths for their buyers. The above control will be spread by means of API to the Content Providers. This model is actualized in two sections. The First part portrays framework plan which will have connection between's Content Providers and Internet Service Provider and extreme reason for existing is to give better QoS to customers. Second part is to build up a re-enactment model of this framework utilizing python.**

Keywords: Over The Top (OTT), Software defined networking, Quality of Service, fast-lanes, and slow-lanes.

I. INTRODUCTION

Over the top (OTT) is a term used to allude to content suppliers that disperse streaming media as an independent item straight forwardly to watchers over the Internet, bypassing media communications, multichannel TV, and communicate TV stages that generally go about as a controller or wholesaler of such substance. The term is most synonymous with membership put together video with respect to request benefits that offer access to film and TV content (counting existing arrangement gained from different makers, just as unique substance created explicitly for the administration), including Amazon Video, Viu, Hulu, Netflix, Now TV, Sling TV, MercTV, and Sky Go just as a Suburban broadband consumption is spreading quickly, extending the hole between ISP costs and incomes. Proliferation of web empowered gadget is blocking access systems, deteriorating end-client presentation and influencing content suppliers adaptation.

The earlier frameworks has the following limitations:
Adaptation: An ISP has a restricted reason to send administration quality components except if there are a business return. Customers have to spend much more considered amount for improvement in a good Quality of service. CPs presumably have a higher capacity to pay be that as it may, a current "paid peering" modifications. Quality just for explicit shoppers or certain substance, and these decisions can differ powerfully (for example contingent upon time-of-day or misfortune/defer execution of the system).

Bandwidth Dominance: Considering todays network scenario the ISP has dominance over Bandwidth, who especially has an own framework and also contraption setups, conceivable by techniques for instruments (for example checking, protection, asset reservation, and linking) using Difference-Serve mechanism. Customers are completely unknown about what ISP is doing from their side and has the impact on their quality of service and customers felt helpless. At another side, CP's expecting a good quality of service from ISP's. Even some ISP have special bond with content providers that they will provide a good quality of service but because of they have rights of better quality of service And sometime because of any technical issues if ISP fails to provide the better quality of service it will have direct impact on content providers revenue generation.

SDN has numerous points of view:

1. A focal "mind" for the system makes it simpler for the ISP to recognize (for example by means of APIs) administration

quality controls required by an outside gathering,

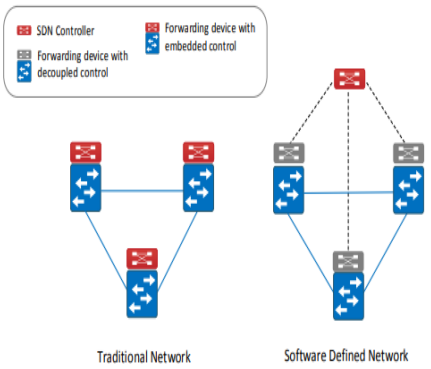

Fig.1 SDN vs. provision network architecture

for example the content providers we believe an API would be the outstanding way of data interchange instead of between associating existing conventions (for example RSVP) to outstanding gatherings.

2. The brought together cerebrum in SDN is progressively responsive for ideal Judgment making. Since the SDN controller has a worldwide perspective on assets, it can make educated decisions dependent on current accessibility and solicitations.
3. SDN gives the asset parceling which brought together programming over any sending component over any entrance innovation that underpins an institutionalized SDN interface, for example, Open Flow.

II. RELATED WORK

We first created four datasets of YouTube videos and two datasets of Netflix videos. The You Flash, YouHtml, YouHD, and YouMob dataset contain YouTube videos while the NetPC and the NetMob dataset contain Netflix videos [1] Based on data from a tier-1 European network, approximately 10 WhatsApp messages are sent and received per subscriber each day. Of these messages, 2.8% of all messages sent have a media file such as a photo or video attached. [2] Suppose that two adaptive HTTP streaming players share the same bottleneck. This can happen, for instance, when people in the same house watch two different movies - in that case the shared bottleneck is probably the residential broadband access link. [3]

Other work has proposed monitoring the user-perceived video quality, rather than just the network-level effects. A system to measure the user-perceived quality, taking into account the distortions in quality caused by losing particular packets, is discussed in this system [11] These Systems will provide quality of Service to end users. And data consumption by streaming services, what's app, HTTP requests. Whereas our contribution will work on the data consumption rate, quality of service and at network level.

III. USE-CASES AND OPPORTUNITIES

The course of action of employments that can benefit by unequivocal framework support for improved organization quality is tremendous and arranged: ongoing and spilling recordings can benefit by data transfer capacity affirmation, gaming applications, voice applications from low hardship, and so on.

IV. SYSTEM ARCHITECTURE

DNS Server: The system starts with the DNS Server. In this model the DNS server provide the functionality to other devices after receiving request from provider means Internet Service Provider the IP address is stored in the database of DNS Server.

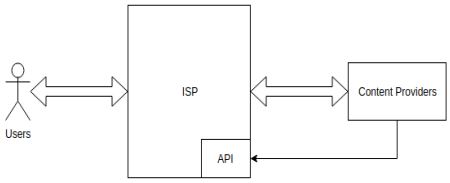

Fig 2. System Architecture

Internet Service Provider: The Internet service Provider will provide service to the customer by requesting them. Then Customers will give request according to their requirements. Then by serving the request the IP address will get stored in the database of DNS Server. System Architecture is shown diagrammatically in the Flow diagram.

SDN Controller: The SDN controller manages the flow control to improve network performance. The SDN controller uses TCP protocol to transfer data from source to destination. The Controller knows the source and destination address of the user. In the system model Socket-Server is used which is simpler form of writing a complex network server. And allows the request handler will allow that makes the file type of object that will lead to ease of communication. And provide a standard interface.

Controller-API: In this system REST API is used. API is Application Program Interface which use HTTP request to perform POST, PUSH, GET, DELETE operations. Significance of REST is

Representational State Transfer which is useful for web service development. API helps to visualize bandwidth of the data flow. According to given bandwidth the API will be called as API for Fast/Slow Lanes.

Client: Client will request for content, Request hit the API and data flow will start and simultaneously it will change the bandwidth.

While requesting special lanes. There is also possibility that the special lanes request cannot be fulfilled by the controller in that case minimum guaranteed bandwidth is allocated.

V. SIMULATION AND TRACE ANALYSIS

1. In this model we have a network switch and controller at ISP. Whenever request comes on network switch it enquires with the controller what to do about this flow. The controller installs default flow and the transfer of data packets begins.

2. The controller exposes REST API which the control provider can invoke. When any content provider invokes this REST API to request for special lanes, controller updates the switch flow table with modified flow. For Example host1 is requesting for www.netflix.com, the switch makes the connection and host get to see the content. Meanwhile Netflix also invokes the API provided by controller and request for fast lane.

3. Whenever the same host requests for video content their request is served using high bandwidth. The content provider is aware about the content length so they can also include time-out property

4. In this Model Long-Short-Term-Memory (LSTM) algorithm is used for storing bandwidth of users and Store it for some duration, So that it will be easy for controller to decide whom to assign how much bandwidth and ultimately it will be helpful in increasing quality of service to users and helps in increasing revenue of internet service providers and revenue generation of content providers

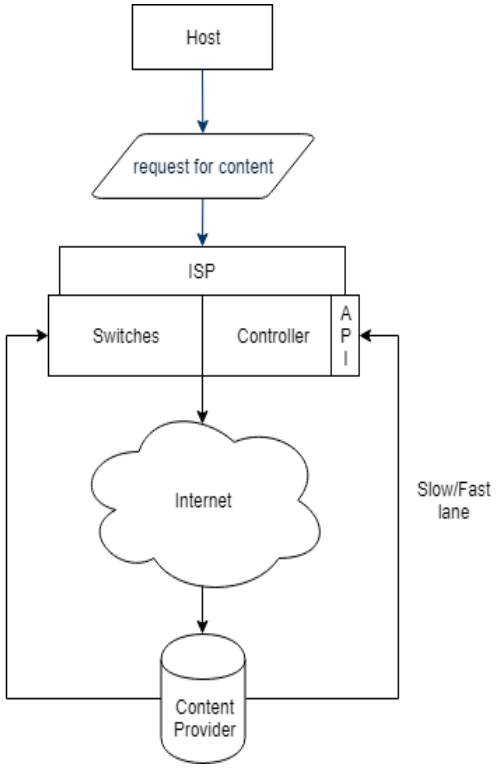

Fig. 3. Flow of typical residential broadband access network.

VI. EXPERIMENT RESULT

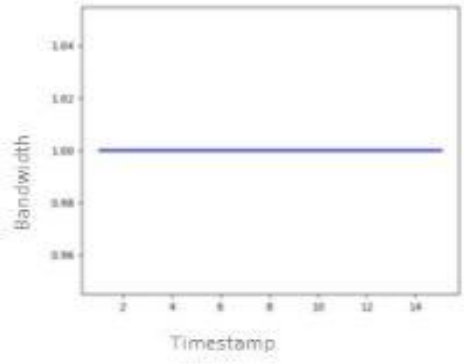

Fig. 4. Simulation result when bandwidth = 1

In the above figure we can see normal dataflow without reservations i.e., special lanes. Data is transferred using minimum guaranteed bandwidth. Here Y-axis represents bandwidth and X-axis represents timestamp.

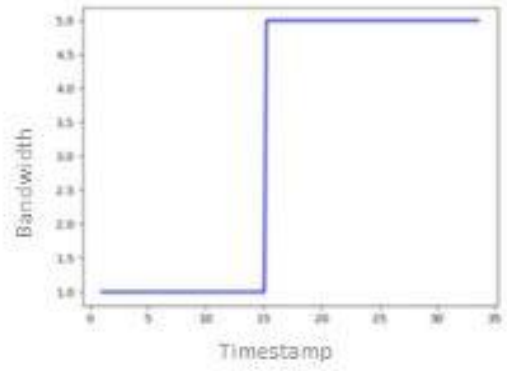

Fig.5. Simulation result when increase in bandwidth

Above figure demonstrates fast lane. When a host requests for content, the content provider immediately invokes controller API and reserves fast lane for the current dataflow. In above fig on X-axis the dataflow began with 1 Mbps and went up to 5 Mbps as per the provider's negotiation with

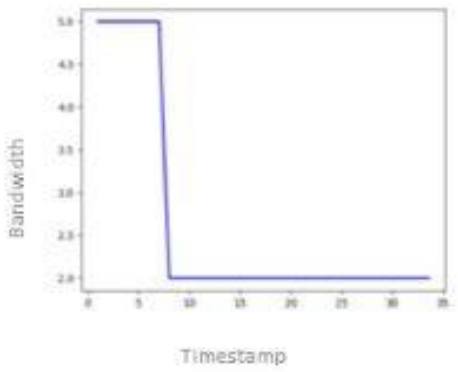

Fig.6. Simulation result when increase in bandwidth

Above figure demonstrates slow lane. Overall Procedure is same as compare with fast lane. Only difference is, when a host requests for content, the content provider immediately invokes controller API and reserves slow lane for the current dataflow. In above fig on X-axis the dataflow began with 5 Mbps and went down to 2 Mbps as per the provider's negotiation with the controller

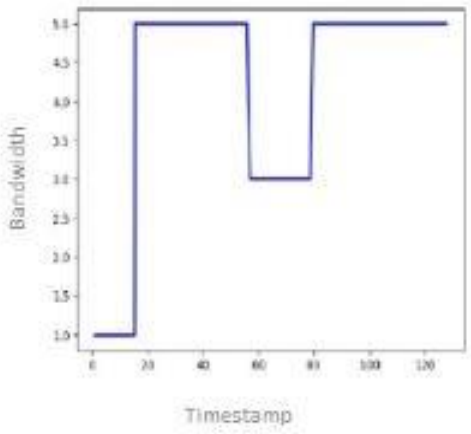

Fig.7.Simulation Result of Fast lane and slow lane.

In the above figure a request having fast lane reservation. When the switch gets new request and no bandwidth is available, controller temporarily modifies existing fast lanes with reduced bandwidth to accommodate the new requests and reverts the bandwidth to fast lane again

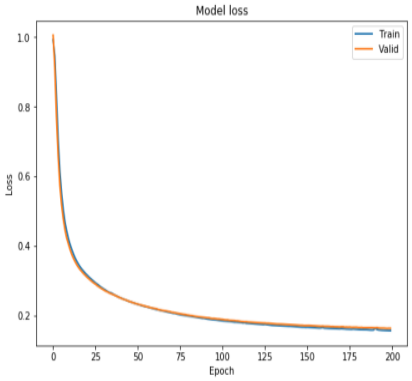

Fig.8. Model loss comparison between train data and test data.

Above diagram represents the model loss for train and test data. The LSTM has one data set where bandwidth of multiple users are stored. The model will run epoch for each user's bandwidth and it will calculate the loss according to it.

Fig.9 Reconstruction error with respect to threshold.

Above diagram represents the threshold which is nearly approx. 0.8. In the above graph the red line represents the threshold line and blue dots represent the true positive values and orange dots represents false positive values.
Below Table shows the Bandwidth (Mbps) according to user requirement.

Sr. No.	Title	Bandwidth
1.	Data Transfer Flow.	1 Mbps
2.	Fast Lane	1Mbps, 5 Mbps
3.	Slow Lane	5 Mbps, 2 Mbps
4.	Fast lane and Slow Lane Reservation.	(1 Mbps , 5 Mbps) And (5Mbps, 3Mbps)

Table 1. Simulation results of respective bandwidth variation.

VII. CONCLUSION

In This Paper we have effectively created Simulation model which shows Fast Lane and Slow Lane by hitting an API named as POSTMAN and Long Short Term Memory Algorithm which has Users Bandwidth Data set and distribute the Lanes to client as indicated by clients past transfer speed. The PUT request will be given to API where we have to enter the host at a server side then controller hits an API later as per customer demand information stream will begin. Depends upon This re-enactment model to comprehend the information which possesses more transfer speed for instance video records, And Creation of such paths will build the income of network access supplier. From the Body of an API source and destination IP address and Bandwidth. Will be set to accordingly. As soon as this request is sent the flow table will be updated. Simulation model runs in seven different terminal window where at First part registration of IP is done. After that controller will hit an API and according to client request the data transmission begins. This approach will be the initial move towards the consumer loyalty in light of the fact that by apportioning such paths will assist client with achieving such nature of administrations.

***Abstract*—In this paper, topology of Grid connected single step (GCSS) high gain buck-boost inverter with fuzzy maximum power point tracking (MPPT) controller is discussed. It can step up/down the output from PV & performs DC to AC conversion simultaneously in a single step with the help of fuzzy MPPT controller. This scheme has features such as high gain, less switching loss & with the help of fuzzy MPPT it tracks maximum power from PV very efficiently. Thus this scheme is conformable for PV applications with low voltage & varrying with time conditions. Design of proposed GCSS elements with derived equations & design of fuzzy MPPT is given in this paper. Presented topology is designed using MATLAB/SIMULINK. Detailed simulation of presented GCSS with fuzzy MPPT and it's results are given.**

***Index Terms*—Buck-Boost inverter, fuzzy MPPT, grid connected inverter, GCSS.**

I. Introduction

Non-renewable fuels are situated at selected places which are far away from load station. Hence, we need power transmission system to absolve power from generation stations to loads. The demand of power is increasing nowadays, which causes blackouts and also increases load above limit. Generation of electricity using solar PV can be an alternative to above problems [1]. As we know that solar voltage is variable due to atmospheric conditions like temperature, insolation, etc. We need a system which converts power from solar and used to deliver it to grid/load.

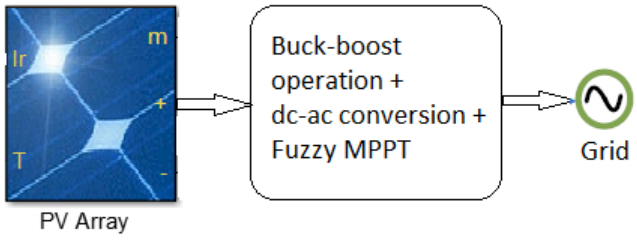

Fig. 1. GCSS PV system configuration

To deliver power to grid, conversion system has to buck/boost PV output voltage & convert it to ac. This type of conversion takes two steps hence called as two step conversion system.

Some of those two step grid connected system are represented in [2]. It has disadvantages like less certainty , more deprivations, broad size and costly [3]. In this case, we use power conversion system which does above two stage operation in one step along with fuzzy MPPT is required. Fuzzy MPPT is used to track maximum power from PV very efficiently. As single step conversion system is more certain, works at high efficiencies & less costly [4]. An ideal GCSS system with fuzzy MPPT controller is given in Figure. 1.

Related work

A GCSS boost dc-ac scheme is presented in [5], as given in Figure. 2.(i). This scheme has two boost converters are 180 degrees out of phase w.r.t each other & load is connected discriminatory across both converters. In this system, Operation of all switches are at high frequency in each half cycle of o/p voltage, which leads to more switching loss & EMI problems.

A half bridge buck-boost inverter conformation presented by kasa et al. [6]. shows that only two switches operating in half cycle. which has outcome of low conduction loss, less switching loss & low EMI problems. Only one PV source works for half time of operation is main disadvantage of this topology.

Hiren et al. presented double grounded GCSS in [7] as shown in Figure. 2.(ii). This system gives less gain. A GCSS which can step up, step down or step up/down to give ac output voltage is presented in [8] as given in Figure. 2.(iii). This scheme has some features like conciseness, low cost but this system can operate for less voltage gain conditions only. A system based on buck-boost operation with four active switches is given in [9], as shown in Figure.2.(iv). It has disadvantage of limited gain & more number of passive switches.

Some GCSS with large gain topologies are proposed in [10], [11] are given in Figure. 2. (v) and Figure. 2. (vi) respectively. Coupled inductor is used to get high gain. But there are baneful effects due to leakage inductance related with coupled inductor. Due to Leakage inductance there is

energy loss & voltage stress at switches. Topology presented in [12] is having high gain, minimum components & there is no need of capacitors to block leakage energy. Thus, this system is taken for grid connected applications with introduction of fuzzy MPPT controller to track maximum power efficiently.

The assistance of this paper are:

1) Presenting single step inverter system with large gain for connecting grid with PV system using fuzzy MPPT without any effect of leakage inductance.
2) Control of presented sytem to extract maximum power using fuzzy MPPT & deliver it to load/grid.

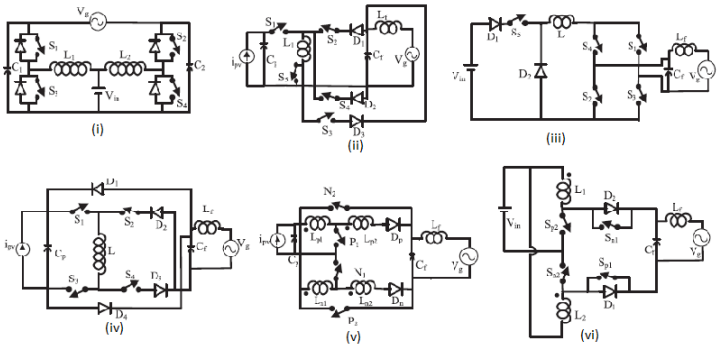

Fig. 2. Existing GCSS Systems

Presented GCSS with fuzzy MPPT controller block diagram is shown in Fig. 3.

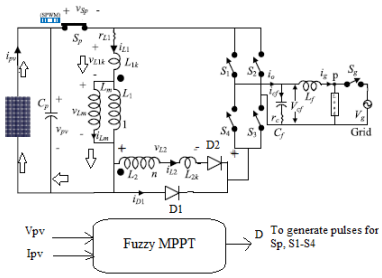

Fig. 3. Proposed GCSS with Fuzzy MPPT

Structure of paper is as follows. Section II gives description of GCSS operation. Section III gives components design. Tracking of MPP using fuzzy and GCSS control is given in section IV. Simulation &results in section V followed by conclusion in section VI.

II. Operation Of Single Step High Gain Inverter

Proposed GCSS consist of five active switches ($S_1 - S_4$, S_p) & two passive switches (D_1&D_2). Coupled inductors (L_1&L_2) is used to get high gain diode (D_1) is taken to avoid baneful effects caused because of leakage inductance of the coupled inductor. Filtering circuits at both input and output sides. The presented GCSS with fuzzy MPPT controller has following features.

1) It provides high gain with the use of coupled inductor.
2) Only one switch operates at high frequency & remaining operates at low frequency, hence it results in low switching loss.
3) Concise in size.
4) It requires simple sinusoidal PWM.
5) Maximum power from PV is tracked very efficiently with the help of fuzzy MPPT.

Let us assume duty cycle 'd' & T_s as switching period of S_p. In positive half cycle, switches (S_2&S_4) will be turned on & during negative half cycle switches (S_1&S_3) will be turned on. Converter topology works same & symmetrical in both half cycles of output voltage. It's working over a switching cycle is expounded as given.

A. Mode I ($t_0 - t_1$)

In this mode, L_m gets charged through S_p when switch S_p is on. Both diodes are reverse biased. Current in L_m increases in a linear way. Output capacitor (C_f) discharges through load as given in Figure. 4.

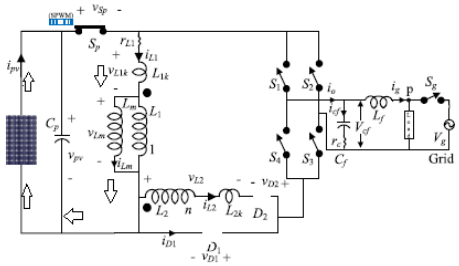

Fig. 4. Mode 1 working

B. Mode II ($t_1 - t_2$)

At S_p switched off diodes D_1&D_2 goes forward biased. Leakage energy related with inductance L_{1k} will be given to load through D_1. Current through L_1 decreases and at the same time current through L_2 increases. Remaining current from L_1 & L_2 will be taken by D_1. At the end of this mode, currents in both inductors become same, hence D_1 becomes reverse biased as given in Figure. 5.

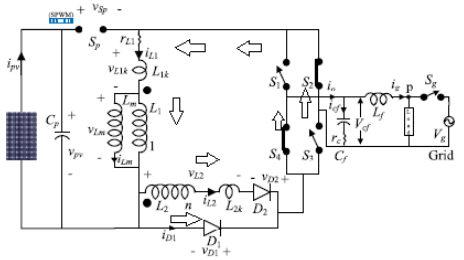

Fig. 5. Mode 2 working

C. Mode III ($t_2 - t_3$)

In this interval, D_2 is still forward biased, both inductors L_1&L_2 are series connected & feed power to load. Current in L_1&L_2 starts decaying. This interval ends when S_p is turned on again as shown in Figure. 6. As per number of turns of each inductor, output voltage is shown across both inductors.

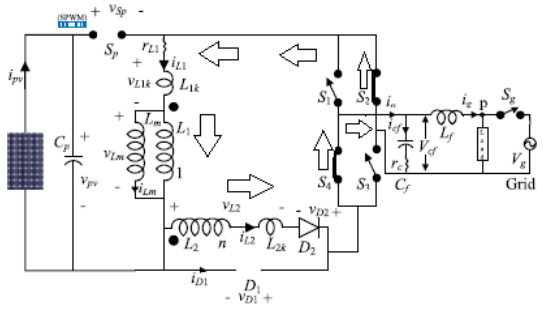

Fig. 6. Mode 3 working

D. Mode IV ($t_3 - t_0$)

When S_p is switched on, Diode D_2 still conducts due to very small current present in inductor L_2k & D_1 is still reverse biased. Negative voltage across L_2 resets current through it. Diode D_2 becomes reverse biased when current through L_2 becomes zero as shown in Figure. 7. & this mode ends. This Proposed scheme starts operating again from mode 1.

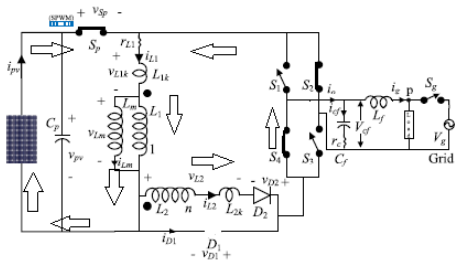

Fig. 7. Mode 4 working

mathematical waveforms of current through diodes D_1&D_2, L_1&L_2 inductors, voltage & current across C_f & gate pulse generation for a switching cycle are as given in Figure. 8.

In same topology, as switch S_p is turned on and operates with SPWM double the grid voltage frequency, a sinusoidal voltage across output capacitor C_f is developed. Mathematical waveforms of presented scheme for a full cycle of load voltage is as given in Figure. 9.

III. GCSS Input and Output Filter Design

A. Design of C_p

Maximum value of ripple in output voltage of PV is decided by input capacitor C_P. Maximum allowed value of PV voltage ripple & grid frequency is δVpv and f_g respectively. C_p value is given by [3].

$$C_p = \frac{2P}{4(2\pi f_g)\, V_{\text{pv}}\, \delta V_{\text{pv}}} \tag{1}$$

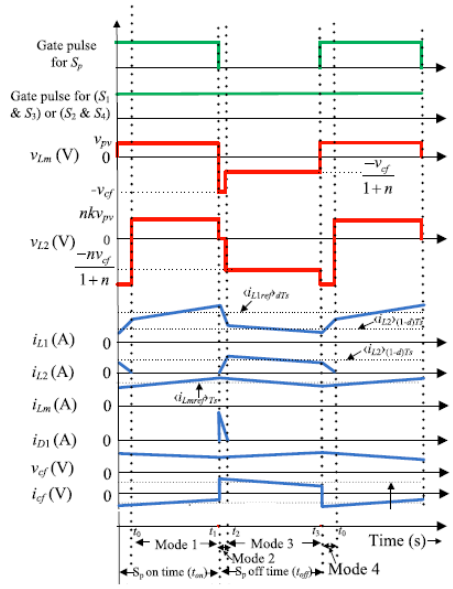

Fig. 8. GCSS working over a switching cycle

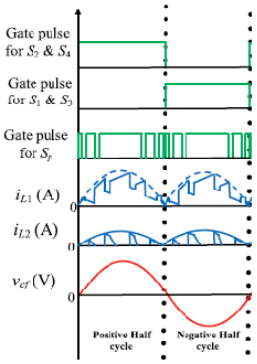

Fig. 9. GCSS working over a full cycle of output voltage

Where P = Tracked max. Power.

B. Design of L_f

Output inductor emaciate high frequency current which is given to the grid. Cut off frequency f_c should be taken as one tenth of switching frequency f_s for the design of output inductor [3]. Thus L_f is given by,

$$L_f = \frac{1}{(2\pi f_c)^2\, C_f}. \tag{2}$$

C. Design of C_f

The value of filter capacitance at output side is specified by the maximum energy through coupled inductor. By taking power factor of unity operation, transmitting power from i/p to o/p is high at grid voltage peak. By equating energy change in coupled inductor & filter capacitor C_f over switching cycle, result will be as given below.

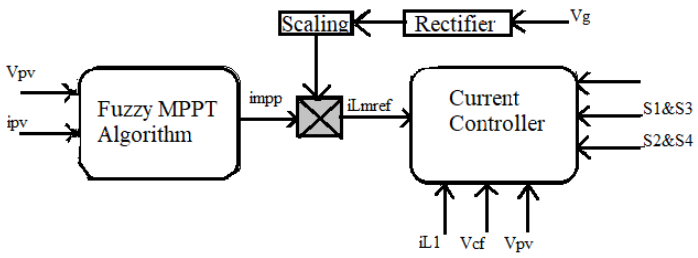

Fig. 10. Ref. current generation for mutual inductance current (i_{LM}).

$$\frac{1}{2}\times L_1\frac{(1+n^2+2n)}{1+n}\left[\left(I_{L1ref(\max)}+\frac{\Delta I_{L1}}{2}\right)^2 -\left(I_{L1ref(\max)}-\frac{\Delta I_{L1}}{2}\right)^2\right] = \frac{1}{2}\times C_f\left[\left(V_{g(\max)}+\frac{\Delta v}{2}\right)^2-\left(V_{g(\max)}-\frac{\Delta v}{2}\right)^2\right]. \quad (3$$

By rearranging the above equation we get capacitance value as,

$$C_f=\frac{L_1(1+n)I_{L1ref(\max)}\Delta I_{L1}}{V_{g(\max)}\Delta v}. \quad (4)$$

Where $I_{L1ref(\max)}$ is maximum primary inductor current w.r.t $P_{o/p}$ (rated) & Δv is maximum admissible ripple of output voltage (V_{cf}).

D. Design of Coupled inductor L_1 & L_2

Equation for coupled inductor L_1 & L_2 is designed using [4],

$$L_1=\frac{T_s\,V_{\rm pv}\,v_{g(\max)}}{\Delta I_{L1}[V_{\rm pv}(1+n)+v_{g(\max)}]}. \quad (5)$$

L_2 is calculated from

$$L_2=n^2L_1. \quad (6)$$

IV. Fuzzy MPPT and Control Techique

Fuzzy MPPT is a teachnique used to extract maximum power from PV under varrying irradiation and temperature conditions using converter system. Coordination between current control & MPPT is prescribed to feed maximum power to grid. MPPT is designed utilising Fuzzy logic controller[15]. Output of fuzzy MPPT is (i_mpp) multiplied with grid voltage V_g. Multiplied output further taken as reference current to track current in L_m by using current controller as given in Figure. 11. For practical purpose, initially proposed scheme must have to work in voltage control loop before linking it to grid as shown in Figure. 12. Hence, we conclude that both control loops are used for synchronization of given system with grid. Design and derivation of these control loops along with fuzzy MPPT algorithm will be presented in following subsections.

A. Current Control Loop Design

From Figure. 8, when switch S_p turned on, voltage is V_{pv} and during turned off time voltage is - v_{cf} /(1 + n). Average voltage over a switching cycle across L_m is given by,

$$\langle v_{\rm Lm}\rangle_{\rm Ts}=\langle v_{\rm pv}\rangle_{\rm Ts}d(t)-\frac{(1-d(t))\langle v_{\rm cf}(t)\rangle_{\rm Ts}}{1+n}. \quad (7)$$

By solving above equation duty cycle is,

$$d(t)=\frac{\langle v_{\rm Lm}(t)\rangle_{\rm Ts}(1+n)+\langle v_{\rm cf}(t)\rangle_{\rm Ts}}{\langle v_{\rm pv}(t)\rangle_{\rm Ts}(1+n)+\langle v_{\rm cf}(t)\rangle_{\rm Ts}}=B. \quad (8)$$

Where B is used to represent block in Fig.10. [14] Current through L_m is given by [4]

$$\langle i_{\rm Lm}(t)\rangle_{\rm Ts}=\langle i_{L1}(t)\rangle_{\rm Ts}\frac{(1+n)}{1+nd(t)}. \quad (9)$$

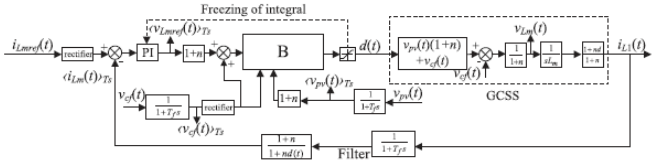

Fig. 11. Schematic of Current Control Loop

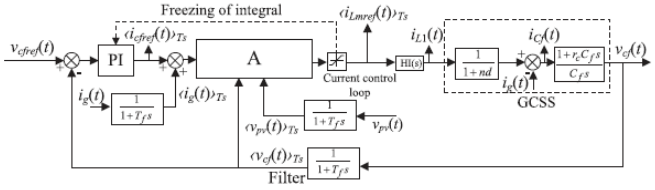

Fig. 12. Schematic of Voltage Control Loop

B. Voltage Control Loop Design

From Figure. 8, By considering contemptible leakage inductance & current ripple in inductors, Current i_{cf} for a switching cycle is given by,

$$\langle i_{\rm cf}(t)\rangle_{\rm Ts}=(1-d(t))\langle i_{L2}(t)\rangle_{(1-d)Ts}-\langle i_g(t)\rangle_{\rm Ts}. \quad (10)$$

From above equation i_{L2}(t)(1 - d)Ts can be written as,

$$\langle i_{L2}(t)\rangle_{(1-d)Ts}=\frac{\langle i_{\rm cf}(t)\rangle_{\rm Ts}+\langle i_g(t)\rangle_{\rm Ts}}{1-d(t)}. \quad (11)$$

From GCSS operation, i_{L1ref} and i_{Lmref} are equal during switch (S_p) on time [4]. Thus,

$$\langle i_{\rm Lmref}(t)\rangle_{dTs}=A= (\langle i_{\rm cf}(t)\rangle_{\rm Ts}+\langle i_g(t)\rangle_{\rm Ts})\left[\frac{\langle v_{\rm cf}(t)\rangle_{\rm Ts}+\langle v_{\rm pv}(t)\rangle_{\rm Ts}(1+n)}{\langle v_{\rm pv}(t)\rangle_{\rm Ts}}\right]. \quad (12)$$

Where, 'A' is exhibited as a block shown in Fig.12, Dual loop control presented in [14] is used to control voltage through C_f and current through L_m. Block diagram of voltage control is shown in Figure. 12. In that r_c is the equivalent series resistance related with C_f.

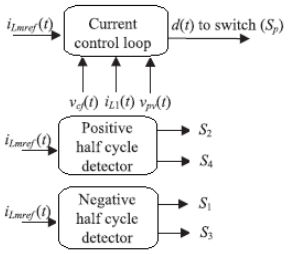

Fig. 13. Gate Pulse generation for Active switches

PI controller's gain are taken so as voltage and current loop are having bandwidth of 4000 Hz & phase margin of 60°. Gate pulse generation of all active switches is given in Figure. 13.

V. Simulation & Results

Presented scheme is designed using MATLAB/SIMULINK with parameters shown in Table I below. The topology is tested for different insolation level ($S = 1000W/m^2, S = 400W/m^2 and S = 600W/m^2$) at t = 0 sec, t = 1 sec, t = 2 sec respectively.

TABLE I
Simulation Parameters

Parameter	Value
Voltage ($V_{mpp}at1000W/m^2$)	38.6v
Current ($I_{mpp}at1000W/m^2$)	5.32A
Grid voltage (V_g)	110v(rms), 50Hz
Switching frequency (f_s)	50kHZ
Inductors (L_1 & L_2)	0.95mH & 1.90mH
Coupling Coeficient (k)	0.94
Output capacitor (C_f)	0.175 e-6
Filter inductor (Lf)	5.8 e-3
Filter capacitor (CP)	4.18 e-3

The Open loop simulation is carried out in the MATLAB/Simulink and the results are taken from that, Figure. 14. shows the open loop GCSS simulink model.

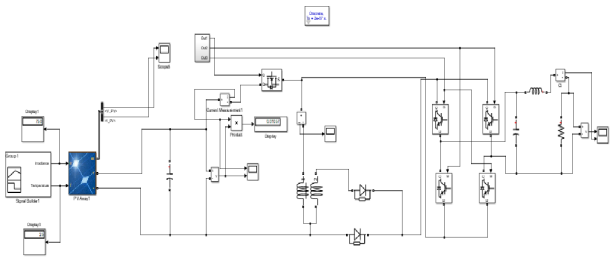

Fig. 14. Open Loop GCSS Simulink model

The voltage & current control loops are designed using derivations of voltage and current control loop in section IV, Figure. 15. shows the MATLAB/Simulink design for control loops,

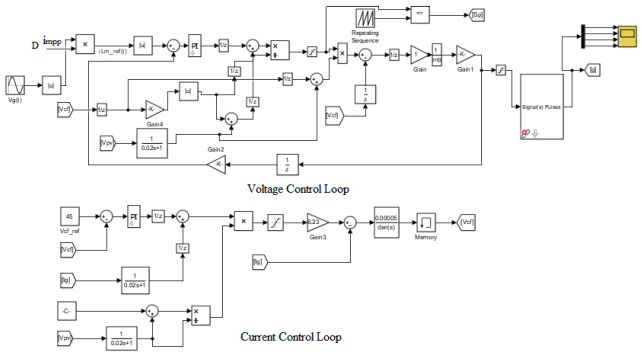

Fig. 15. Control Loop Diagrams for Proposed GCSS

Fuzzy logic controller block diagram is constructed with the help of MATLAB/Simulink and fuzzy logic design block diagram using mamdani fuzzy inference model is as given in Figure. 16 and Figure. 17 respectively [15]. There are two inputs fot fuzzy controller for buck and boost converters. The first input is error in the output voltage e and second is change in succesive errors ce. Output of fuzzy controller is change in duty cycle.Rule base or decision making are obtained from the analysis of system behaviour some of the control actions in the rule table are also obtained from trial and error.

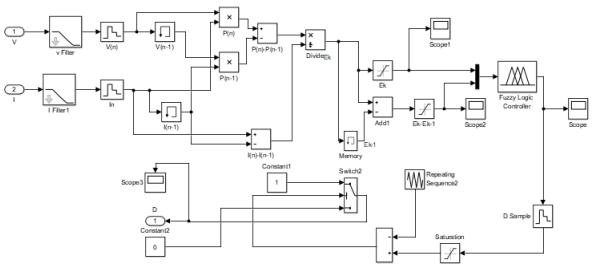

Fig. 16. Fuzzy Logic Controller simulation diagram

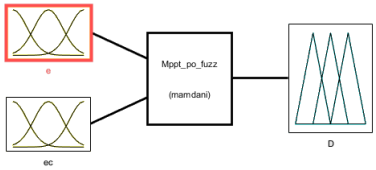

Fig. 17. Fuzzy Logic Design

Closed loop control technique of GCSS is discussed as follow. In this closed loop system, grid voltage is multiplied with duty cycle obtained from PV system Fuzzy MPPT controller. Multiplied output is given to current controller and then output of current controller is given to voltage controller. Gate pulse generation using current controller, positive and

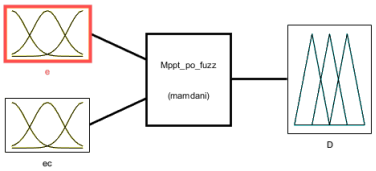

Fig. 18. Fuzzy Logic Design

negative half cycle detector is shown in Figure.13. The block diagram of the closed loop control as shown in Figure. 18.

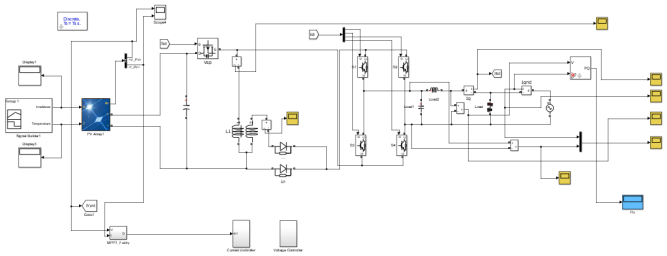

Fig. 19. Simulink model of Closed Loop GCSS with Fuzzy MPPT

Input side & Output side results are given in Figure. 19. & Figure. 20. respectively. In that, different Irradiation conditions are given with voltage across PV, current across PV. From the figure it is given that given topology is tracking MPP correctly.

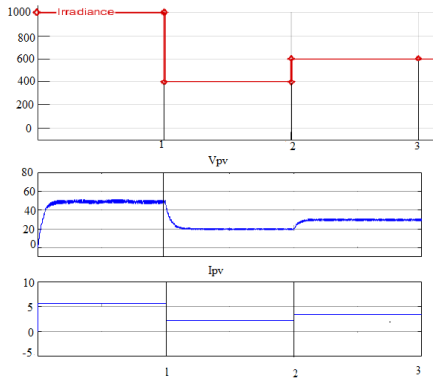

Fig. 20. Simulation results at PV side

Voltage across grid V_g, current across grid i_g and THD of current i_g is shown in Figure.19.

VI. Conclusion

Aim of this paper is to use fuzzy logic controller for grid connected single stage inveter system. This is done with help of the mamdani fuzzy model. Design of control loops along with fuzzy controller are given in brief. From the above results, the fuzzy logic controller can give the better results with less THD and it can deliver power from PV to load/grid efficiently with fuzzy MPPT. The open and closed loop system has been implemented in the MATLAB simulink. The implemented

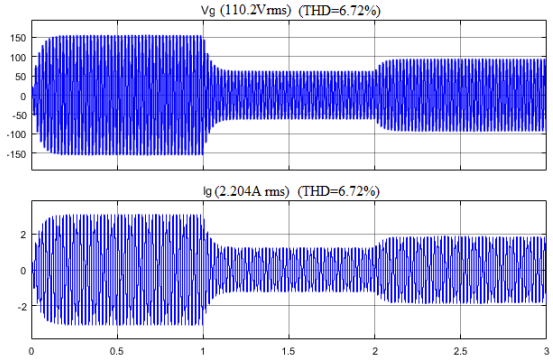

Fig. 21. Simulation results at Grid Side

circuit can work in the condition ($S = 1000W/m^2, S = 400W/m^2 and S = 600W/m^2$). Hence, this system can be used for PV applications with MPP tracking.

***Abstract*— In this paper, a new resource allocation paradigm is designed whereby a new SU is allowed to gain access to the spectrum of licensed PU. Appropriate bandwidth and power are the resources allocated to the SU during the inactivity of PU if the interference is below the maximum allowable IT limit of the channel. An efficient algorithm is developed for reconfiguration of SU's parameters using nature inspired computational intelligence technique named ADALINE i.e. Adaptive Linear Neuron. A demand supply based feedback mechanism is proposed to meet the data rate requirements of new unlicensed user. A scenario is considered wherein a single SU transmitter is able to initially coexist with the PU and then, is able to adapt its transmission parameters (bandwidth and signal strength) dynamically as per spectral availability and the demand of its receiving unit. The feedback system developed reduces difference from allowable IT limit and difference from the achievable capacity during each iteration, rendering efficient channel utilization and achieves user's data rate satisfaction.**

I. INTRODUCTION

Wireless Communication is an emerging trend for the worldwide connectivity that has revolutionized the human lifestyle. Electromagnetic radio spectra ranging from 3 kHz to 300 GHz is a natural hub for the wireless connectivity in various fields as military, health, transportation, education, marketing etc. Static frequency allocation (SFA) of electromagnetic spectrum by the regulatory body FCC has exacerbated the problem of spectrum inefficiency [1]. Exponential growth of wireless users has resulted in spectral congestion. An opportunistic SU can alleviate the problem of spectrum scarcity and underutilization. For this purpose, Cognitive Radio (CR) is envisaged as a vital technology, a concept propounded by Dr. Joseph Mitola III at the Royal Institute of Technology in Stockholm which incorporates software based dynamic transceiver operability [2]. The key feature of CR technology is to firstly identify spectrum holes [3] i.e. which portion of spectrum is vacant (spectrum sensing) [4] and determine the suitable frequency band as per the requirement of the non-legitimate user (spectrum decision) [5], then to update the operating parameters to enable concurrent usage of the spectrum by multiple users (spectrum sharing) [6] and handoff its operation to other available vacant band upon the reclamation of PU activity in its licensed band (spectrum mobility) [7].

Considering the spectrum availability from PUs and the requirement of SUs; appropriate power, frequency, time slot and/or bandwidth are the resources of the primary network that can be allocated to SUs to sustain an interference free operation with maximal usage of underutilized PU spectrum [18]. Different resource allocation methods such as water filling concept [8], distributed power allocation algorithm [9], maximizing power for far SUs while minimal power allocation for nearby SUs are applicable, to allow SUs to transmit simultaneously with the PUs with minimal interference to the existing licensed users. The author in [20], used Deep Neural Network (DNN), for allocating transmit power to the SUs. Previous works have rendered bandwidth sharing via sum rate maximization in an underlay [6] or overlay [11] cognitive radio network but they have not considered the characteristics of receiving units. We have developed a new algorithm by which SU in underlay [21] can be dynamically allocated the resources using a receiver based feedback mechanism.

The paper describes the system model to be used and proposes a feedback based model for resource allocation to the SU. Then an ADALINE NN methodology is detailed with mathematical formulations used followed by the flowchart along with simulation results and comparative analysis.

II. SYSTEM MODEL

A Cognitive Radio Network (CRN) model involving a Primary and a Secondary network is considered. The primary network has P number of transmitters (PU-Tx.) with index i, $i \in I$ and $I = \{1,2\ldots P\}$ serving as routers for R

number of receiving units (PU-Rx.) index *i, i ∈ I and I*= {1,2…R}. The secondary network has S number of transmitters (SU-Tx.) with index *i, i ∈ I and I*= {1,2…S} accessing the spectrum resources of primary network to serve M number of receiving units (SU-RX.) with index *i, i ∈ I and I*= {1,2…M}. We will design how one SU as shown in Fig. 1 will be allocated the services of the legitimate user on an opportunistic basis to run new user applications in an unlicensed manner.

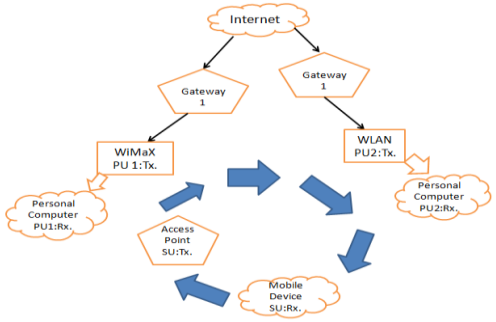

Fig. 1 System Model

III. PROPOSED FEEDBACK BASED MODEL

A system is designed to allocate bandwidth and appropriate strength to the SU in a manner that no hindrance is caused to existing PU services. The SU receiver unit in Fig. 2 will determine the availability of the spectrum of PU and will intimate the transmitter of the SU. The receiving unit (SU user) will specify its demands i.e. certain data rate and allowable interference level. Accordingly, the SU transmitter will be allocated certain set of bandwidth and power to achieve the user satisfaction. At each step, the SU transmission bandwidth and power will be updated based on the difference between achievable capacity and obtained data rate and the difference between allowable Interference Temperature [10] limit and achievable Interference Temperature caused by SU transmissions. Hence, the difference is reduced between the demand and supply.

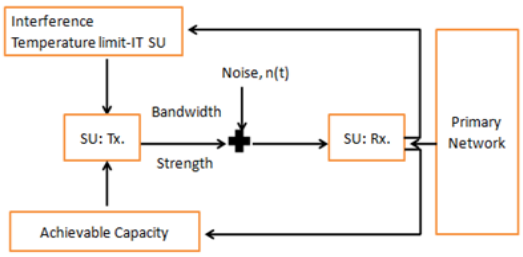

Fig. 2 Proposed Feedback Based Model

IV. MAPPING OF FEEDBACK BASED MODEL WITH NATURE INSPIRED NN TECHNIQUE

ADALINE is a single linear unit neuron which receives input from several units (x_i) and has one output unit (y). In the Fig. 3, ADALINE network is shown in which Bias (b) is a flexi-adjusting weight that enables best fit values for the network as required. The weights between the input and output units (w_i) can be adjusted to produce a desirable output with a learning parameter (α) that determines the step of updating.

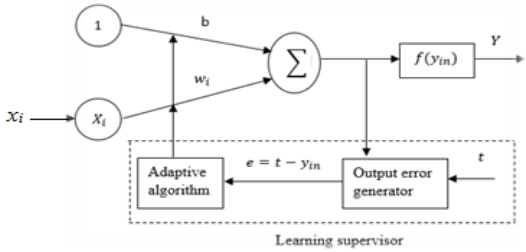

Fig. 3 ADALINE Neural Network [12]

The ADALINE network uses a Delta Rule or Widrow Hoff rule to update the weights between connections to reduce the difference (e) i.e. the error between net input to the output unit (y_{in}) and a desired target value (t) [12].

Mathematical formulas used:

Achievable Capacity for a user [13]

$$C^{i}_{av} = B*\log_2 (1+\frac{S}{N}) \text{ bits/s} \quad (1)$$

Data Rate achieved by each user [13]

$$R_i = \frac{Bi}{Ni} \log_2 (1+\frac{Pi(|h(i)|^2)}{No*\frac{Bi}{Ni}}) \text{ bits/s} \quad (2)$$

Interference Temperature Calculation [10]

$$T_c (f_c,bc) = \frac{pi(fc,bc)}{k*bc} \text{ dB Kelvin} \quad (3)$$

p_i is the signal power

f_c is the carrier frequency in GHz

b_c is the channel bandwidth in MHz

k= Boltzmann Constant =$1.38*10^{-23}$J/K

Weight updating formula [12]

$$w_i (new) = w_i (old) + \alpha(t\text{-}y_{in}) x_i \quad (4)$$

Objective

$$\min (IT_{av} - IT_i) \qquad \min (C^{i}_{av} - R_i) \quad (5)$$

We have used learning rate (α=0.5) for bandwidth and power reconfiguration by the Secondary User. At each step, difference between allowable IT_{av} limit for the channel and the IT_i due to individual user is found and also, and difference between capacity that could be achieved and the data rates achieved by current user transmission in the channel is calculated. Our strategy involves bandwidth adaptation by increasing number of subcarriers (N_i) per unit bandwidth using weight updating formula using different subcarrier spacing. Power is further increased step wise step using weight updating until the receiving unit gives the IT difference and capacity difference [19].

CASE: Single Secondary User accessing the Primary User spectral resource.

Primary device transmits in the licensed band but its transmission is not achieving the data rate demands of the user and the allowable IT limit of the system due to its fixed transmission parameters. Thus, the spectrum remains underutilized. So, it is possible to allocate certain bandwidth and signal strength to a new SU to coexist [14] with that PU such that SU transmission doesn't hampers the operation of existing PU. Then, we calculate the overall IT caused by both the PU and SU that is below the allowable IT limits. In case of PU inactivity, the IT falls and a sufficient gap from the allowable IT limit exists. Hence, an efficient resource allocation [16] mechanism is developed for adaptation and reconfiguration of the bandwidth and signal strength of the SU using NN to mitigate the gap between the receiver demands and the transmission done, so as to achieve the IT limit.

V. FLOWCHART

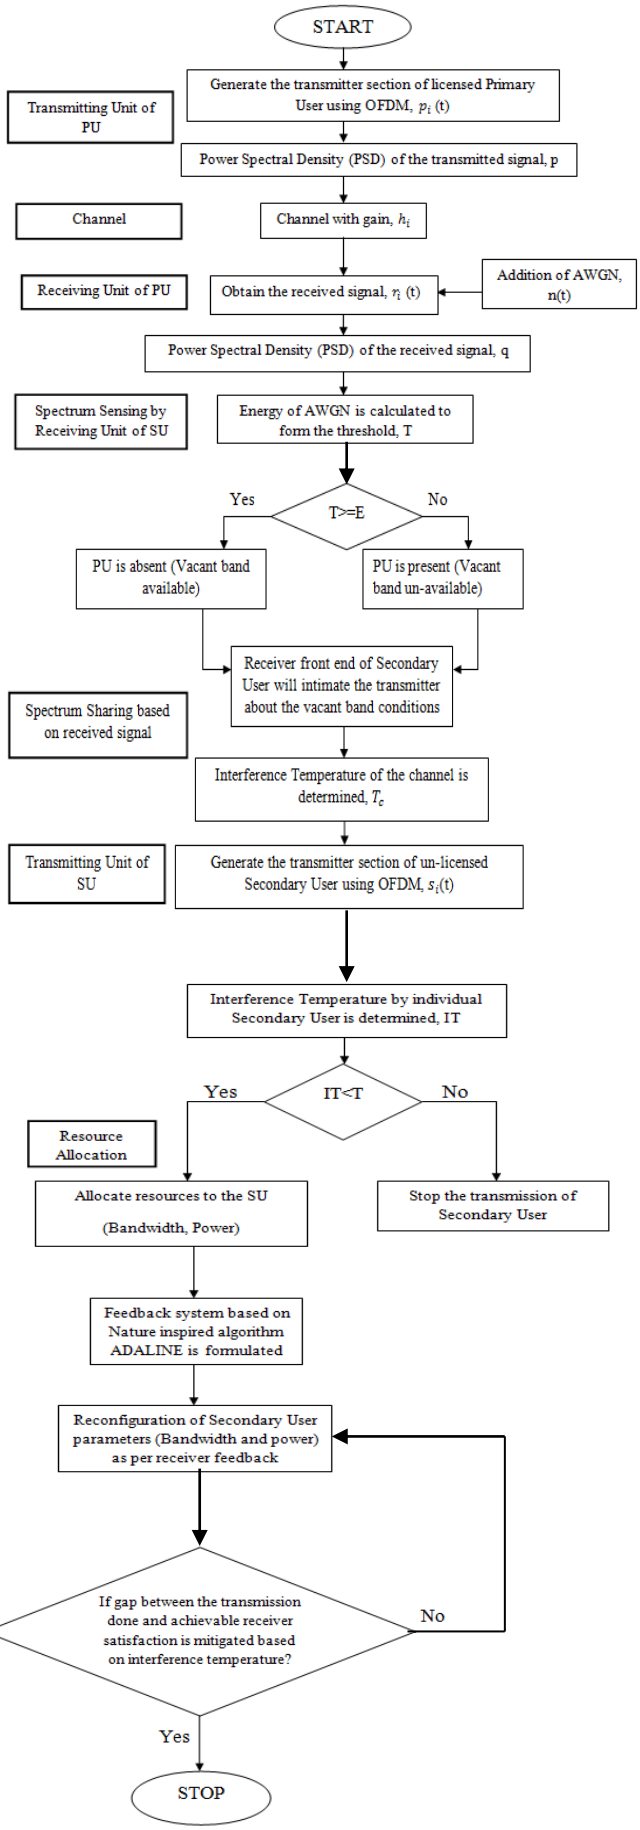

Fig. 4 Flowchart of Proposed Algorithm

The flowchart details the algorithm to be followed to enable resource allocation to the SU. Initially, an environment comprises of a PU transmitter, the signal of which is passed through an AWGN channel and the PSD of the received PU signal is obtained. To enable spectral access, the presence PU is firstly detected by SU receiver front end using Energy Detection based spectrum sensing method [4]. Comparison of PU signal energy (E) is made with that of the energy of noise (T). Absence of PU enables opportunistic transmission by SU. OFDM parameters are used to develop the signals of PU and SU. An allowable level of IT is fixed for the system. Transmission bandwidth and power is so allocated to the SU on an opportunistic manner that the interference caused by it does not cross the IT limit. At each step, the SU receiving unit provides feedback i.e. the difference from achievable capacity and gap from the IT limit. SU parameters are reconfigured using the NN until the data rate demands of the receiving unit within permissible limits of IT are achieved.

VI. SIMULATION AND RESULTS

The algorithm for the resource allocation is implemented in simulative form using MATLAB R2013b in which the code is written.

A. Primary User Simulation Parameters

An environment is created for simulation in which PU WLAN is allocated a frequency band from 1 GHz to 6.5 GHz. PU: WLAN transmits with 50dB power at centre frequency of 5.15 GHz. Table 1 details about the OFDM parameters [15] that are used to simulate the signal of PU.

TABLE I.
WLAN OFDM PARAMETERS

S. No.	OFDM PARAMETERS	SYMBOL	WLAN 802.11a
1.	FFT Size	N	64
2.	OFDM Bandwidth	BW	20 MHz
3.	Total No. of Subcarriers used	N_{ST}	52
4.	No. of Data Subcarriers	N_{SD}	48
5.	No. of Pilot Subcarriers	N_{SP}	4
6.	Subcarrier Frequency Spacing	F_{SP} = BW/N	312.5 kHz
7.	IFFT/FFT Period	T_{FFT} =1/F_{SP}	3.2 µs
8.	Guard Interval Time	T_{GI} = $T_{FFT/4}$	0.8µs
9.	Symbol Interval Time	T_{SYM} = T_{GI} + T_{FFT}	4µs
10.	Number of symbols allocated to Cyclic Prefix	N_{CP}= N*T_{GI} / T_{FFT}	16

B. Assumptions

We have assumed that the transmission of PU signal occurs over an AWGN channel with 10 dB noise SNR. Each OFDM user will have different subcarrier spacing. About 40000 samples are used with a sampling frequency of about 40 MHz.

C. Simulation Outputs

Fig. 5 illustrates the transmitted signal of the WLAN PU.

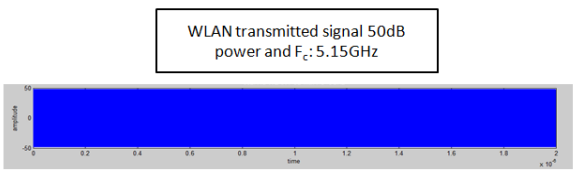

Fig. 5 Transmitted Signal of Primary User

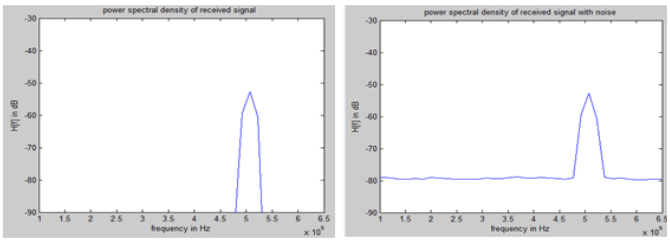

Fig. 6 Power Spectrum Density (PSD) of PU signal with and without noise

Fig. 6 illustrates the Power Spectral Density of the received PU WLAN signal at centre frequency of 5.15 GHz with and without noise.

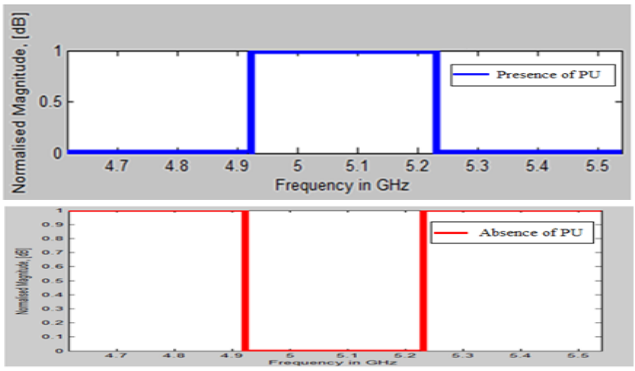

Fig. 7 Digital representation of PU signal and Vacant Band availability Using Energy Detection [4] based Spectrum Sensing

Fig. 7 demonstrates the detection of PU signal using Energy Detection based spectrum sensing [4]. In the digital representation binary 1 shows the presence of PU WLAN signal while binary 0 is indicative of absence of the PU.

TABLE II.

CALCULATION OF INTERFERENCE TEMPERATURE

Total allowable Interference Temperature limit	465 dB Kelvin
IT of PU in dB Kelvin	223.0641 dB Kelvin
IT difference	241.9359 dB Kelvin
Data Rate	54 Mbps
Achievable Bandwidth	20MHz
Achievable Strength	60dB
Achievable Capacity	87Mbps

Table II accounts that permissible IT limit of the system is 465 dB Kelvin which is not achieved by the PU transmission. Moreover, the data rate achieved by PU is also less due to less OFDM subcarrier density at a particular bandwidth. Also, allowed range of power for PU is 60 dB yet at certain time it is only transmitting at 50 dB power. Thus, the PU is inefficient in attaining complete spectrum utilization because of its fixed transmission parameters.

Due to spectrum underutilization by PU, gap of 241.9359 dB Kelvin from IT limit of 465 dB Kelvin persists. Thus, it becomes possible for the spectrum to be used for sustaining transmission by new opportunistic SU.

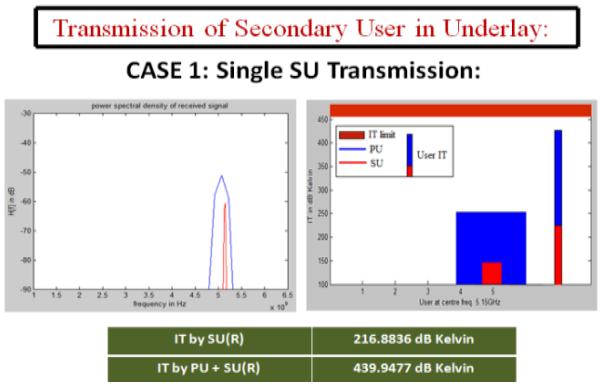

Fig. 8 Single SU Transmitting due to spectrum underutilization

Possible SU Wi-Fi transmission of 40 dB power and 5 MHz BW with OFDM subcarrier spacing (B/N_i) of 9.765625 KHz along with PU is indicated in Fig.8.

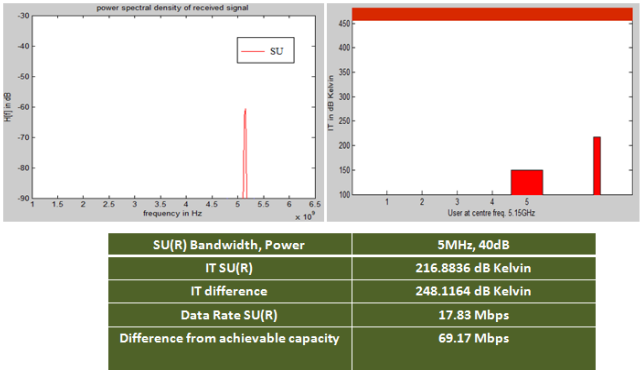

Fig. 9 Transmission of SU in case of PU inactivity

Fall in IT in caused during the case of inactivity of existing PU as indicated by Fig. 9. An oppurtunity is available for the SU to fully occupy the band and service in the underutilized spectrum.

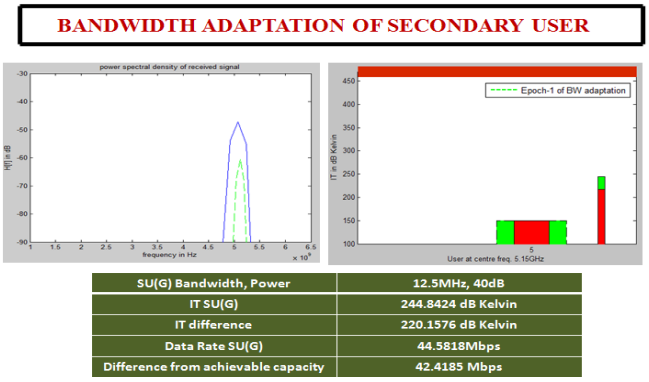

Fig. 10 Epoch-1 of the Bandwidth adaptation of SU

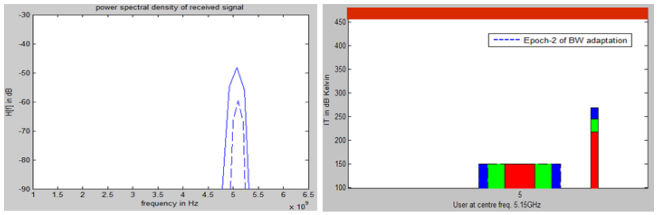
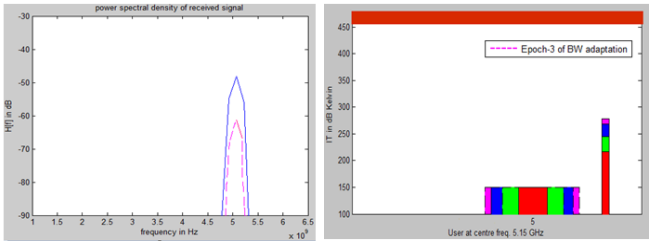
The SU enters into an adaptation mode once the PU gets inactive. At each epoch, the SU tries to readjust its bandwidth using the adaptive learing method until it covers the entire bandwidth of the PU that is available for it to access. Fig. 10 illustrates Epoch-1 of BW adaptation of SU in which it increases its subcarrier density at learning rate 0.5 attaining a BW of 12.5 MHz. The horizontal plot shows step increase in BW and column plot shows the rise in IT by SU BW adaptation.

Gap from achievable IT limit and achievable capacity leads to further epoches of BW adaptation based on difference given by the receiver.



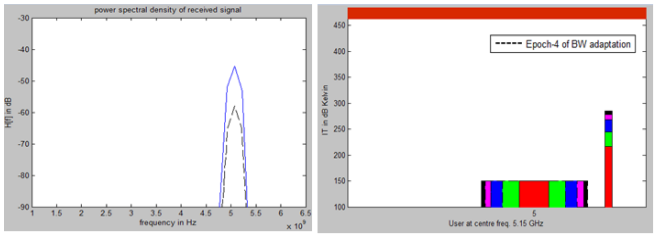
SU(B) Bandwidth, Power	16.25MHz, 40dB
IT SU(B)	268.1213 dB Kelvin
IT difference	196.8787dB Kelvin
Data Rate SU(B)	57.9553Mbps
Difference from achievable capacity	29.0447 Mbps

Fig. 11 Epoch-2 of the Bandwidth adaptation of SU



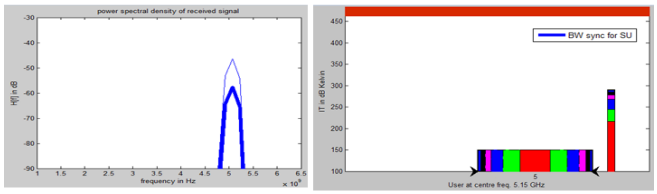
SU(M) Bandwidth, Power	18.1250 MHz, 40dB
IT SU(M)	279.0698 dB Kelvin
IT difference	185.9302 dB Kelvin
Data Rate SU(M)	64.6425 Mbps
Difference from achievable capacity	22.3575 Mbps

Fig. 12 Epoch-3 of the Bandwidth adaptation of SU



SU (BI) Bandwidth, Power	19.0625MHz, 40dB
IT SU (BI)	286.5078dB Kelvin
IT difference	178.4922 dB Kelvin
Data Rate SU (BI)	67.9861 Mbps
Difference from achievable capacity	19.0139 Mbps

Fig. 13 Epoch-4 of the Bandwidth adaptation of SU



SU(B) Bandwidth, Power	20 MHz, 40dB
IT SU(B)	290.9248 dB Kelvin
IT difference	174.0752 dB Kelvin
Data Rate SU(B)	71.33 Mbps
Difference from achievable capacity	22.3575 Mbps

Fig. 14 Epoch-5 leads to the Bandwidth synchronization for SU

Fig. 14 shows at Epoch-5 the SU attains a bandwidth locking condition where by it occupies fully the available bandwidth of the legitimate PU and provides significant hike in data rate as compared to the PU due to improved subcarrier density. Fig. 15 shows increase in data rate with BW adaptation by the SU at each epoch.

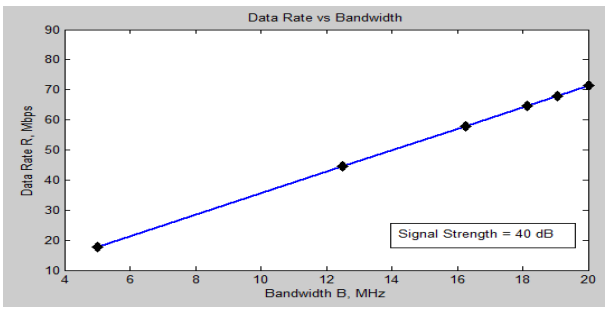


Fig. 15 Data Rate achieved after Bandwidth Adaptation

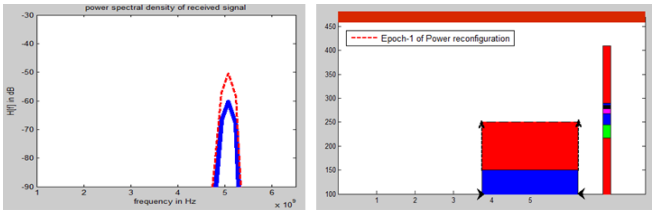
According to Shannon's Capacity curve [17], there is always a limit to increase the BW beyond which no significant increase in the data rate is achieved. Further, increase in the power is the alternative option to attain receiver satisfaction of data rates.

Presence of IT difference and gap from achievable capacity enables the SUs to increase their power. The receiving unit can change its position and thereby, demand of higher signal strength. For this, the SU transmitter follows power reconfiguration which is accomplished using the NN.

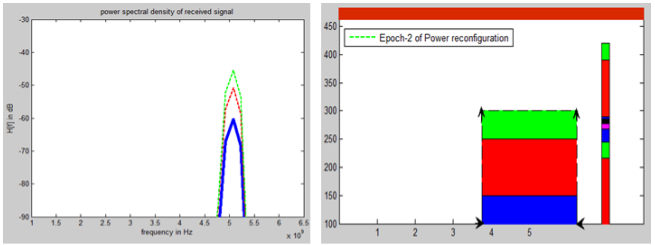
POWER RECONFIGURATION OF SECONDARY USER



SU(R) Bandwidth, Power	20 MHz, 50dB
IT SU(R)	385.5076 dB Kelvin
IT difference	79.4924 dB Kelvin
Data Rate SU(R)	79.41 Mbps
Difference from achievable capacity	7.59Mbps

Fig. 16 Epoch-1 of the Power Reconfiguration of SU

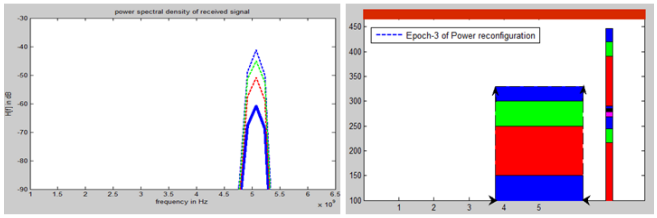
Fig. 16 illustrates how the SU increases its transmission power from initial 40 dB to 50 dB. At each stage of power reconfiguration, the value of IT is increased significantly as shown by thin bar column.



SU(G) Bandwidth, Power	20 MHz, 55.6dB
IT SU(G)	420.5078 dB Kelvin
IT difference	44.4922 dB Kelvin
Data Rate SU(G)	82.9575Mbps
Difference from achievable capacity	4.40425 Mbps

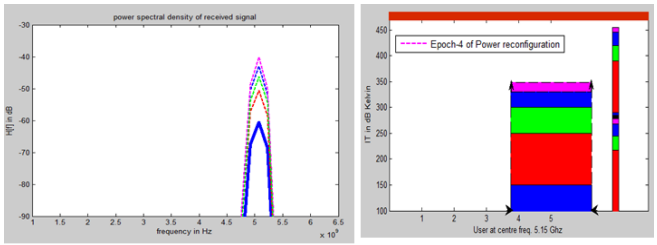
Fig. 17 Epoch-2 of the Power Reconfiguration of SU

This level of power reconfiguration is not possible in the case of PU as its operation is range constrictive due to fixed functionality and licensing by the government. Although the PU:WLAN in our case has been allowed a signal strength of about 60 dB but it is not fully transmitting using this signal strength at certain time. So, this range can be used for the dynamic SU transmission shown by different epoches until the levels of allowable IT are achieved.



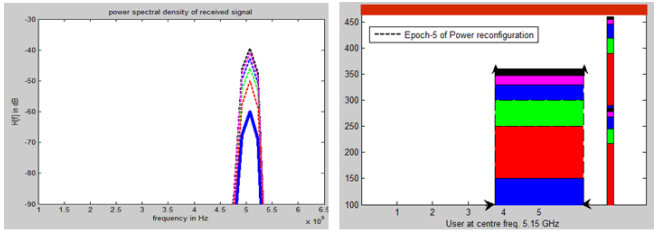
SU(B) Bandwidth, Power	20 MHz, 57.5dB
IT SU(B)	446.5078 dB Kelvin
IT difference	18.4922dB Kelvin
Data Rate SU(B)	84.6301 Mbps
Difference from achievable capacity	2.3699 Mbps

Fig. 18 Epoch-3 of the Power Reconfiguration of SU



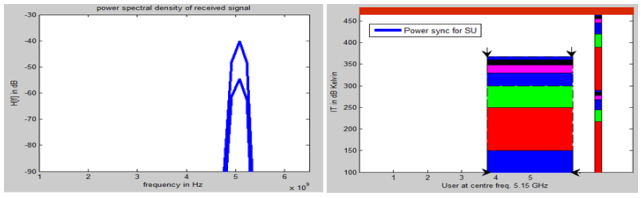
SU(M) Bandwidth, Power	20 MHz, 58.75dB
IT SU(M)	455.5078dB Kelvin
IT difference	9.4922 dB Kelvin
Data Rate SU(M)	85.4434 Mbps
Difference from achievable capacity	1.5566Mbps

Fig. 19 Epoch-4 of the Power Reconfiguration of SU



SU(B) Bandwidth, Power	20 MHz, 59.075dB
IT SU(B)	461.5078dB Kelvin
IT difference	3.4922 dB Kelvin
Data Rate SU(B)	85.6524 Mbps
Difference from achievable capacity	1.3476Mbps

Fig. 20 Epoch-5 of the Power Reconfiguration of SU



SU(B) Bandwidth, Power	20 MHz, 60dB
IT SU(B)	464.5078 Kelvin
IT difference	0.49 dB Kelvin
Data Rate SU(B)	86.2419 Mbps
Difference from achievable capacity	0.75Mbps

Fig. 21 Epoch-6 leads to Power synchronization for SU

Epoch-6 as illustrated by Fig. 21 accounts for the power locking condition for the SU at which IT limit is met and the receiver data rate requirement of 86.2419 Mbps is achieved. No further adaptaion is required as satisfactory levels of data rates for the receiver as shown by Fig. 22 are obtained by minimizing the objective function after significant epoches.

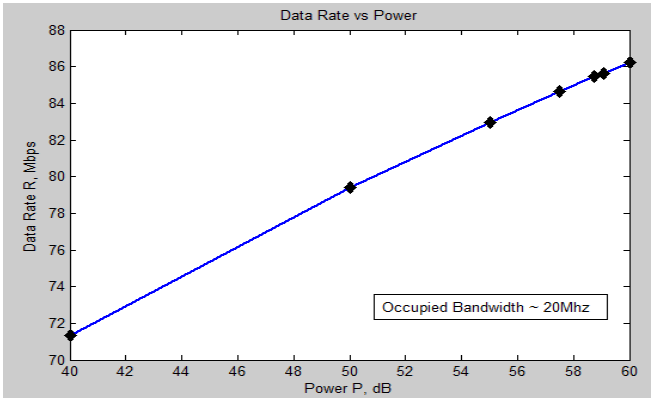


Fig. 22 Data Rate Achieved after Power Reconfiguration

VII. COMPARISON

Our proposed system provides channel utilization from 43% to 95% by proficient resource allocation to the Secondary User in contrast to existing systems without feedback as illustrated by Fig. 23.

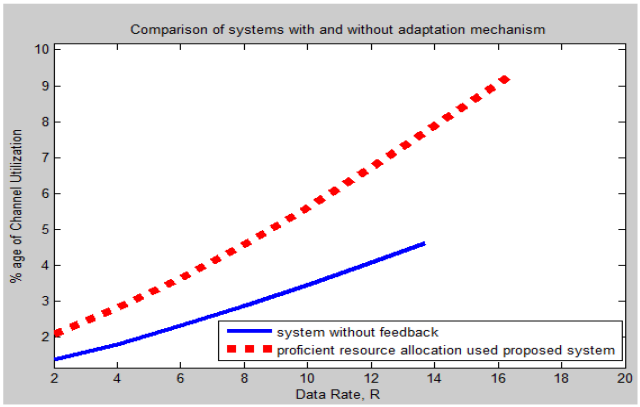

Fig. 23 Efficient channel utilization by our proposed feedback system

VIII. CONCLUSION AND FUTURE SCOPE

Cognitive Radio (CR) is envisioned as a promising technology to explore the underutilized portion of the electromagnetic spectrum and opportunistically gain an access to the vacant spectrum to service new wireless users. The paper focuses on how to provide appropriate resources to a new SU that can access the spectrum of the legitimate user. We propounded a feedback based resource allocation model to serve the SU. A reconfiguration algorithm was formulated to provide apt bandwidth and signal strength to the CR user during the inactivity of the PU. Significant iterations were carried out for SU bandwidth and power adaptation. The system IT constraints were met and the receiver data rate demands were satisfied upon the bandwidth and power locking conditions. Efficient channel utilization is attained based on the dynamic adaptation of

cognitive user using the nature inspired technique. The receiver feedback accounts for proficient resource allocation and improved spectrum utilization efficiency from 45% to 93% as compared to existing systems without feedback. Re-configuration of SU (bandwidth) achieves higher levels of data rates as per the user demands and re-configuration of SU (strength) achieves improved high range transmission for long distance communication.

In future work, hybrid computational intelligence techniques can be adopted using which multiple cognitive users would be able to adjust their transmission parameters to opportunistically access the spectrum of multiple PUs. Frequency Division Multiple Access (FDMA) and Time Division Multiple Access (TDMA) based transmission methods can be used for enhanced spectrum utilization based on feedback from the receiving units. Through FDMA multiple SUs can simultaneously be allocated the bandwidth and transmission power while TDMA may be expected to provide complete spectral access one at a time to the individual SUs. The feedback system of resource allocation can be used in FDMA and TDMA based Cognitive Radio Networks for improved spectral efficiency. Hardware and software implementation of cognitive modules can be developed for opportunistic services to new users. Improved methods of spectrum sensing apart from energy detection based sensing method which is vulnerable to noise uncertainties can be used.

***Abstract*—The popularity of unmanned aerial vehicles is increased with advancing technology, usage of sensors and advanced control systems have made them more progressive and less expensive. Wireless Communication is the fastest growing and most vibrant technological areas of transmitting information from one point to other, without using any physical medium. Real-time data monitoring and analysis of the flight parameters can enhance the performance and the data is logged for further scrutiny of the aerial vehicle. In this pursuit, a telemetry system design for a Unmanned Aerial Vehicle is discussed in this paper with 915MHz XBee Pro S3B modules for a data communication from on-board to the ground station. The telemetry system is tested in actual flight, and the reliability and feasibility are evaluated.It has been found that the proposed design can enhance UAV performance .**

***Index Terms*—UAV, XBee, telemetry, communication, 915Mhz**

I. Introduction

An unmanned aerial vehicle is an aircraft without a human pilot on board and is controlled by autopilot or a remote station. Effective communication is the solution for more crucial problems in our current socioeconomic climate. By measuring the current parameters of UAV [2] [11] in flight, sending and logging the data elsewhere can make the performance of the vehicle more efficient. As the art of technology plays an increasingly important role in every aspect of communication, XBee-Pro S3B [1] is one of the effective module for transmission and receiving of data and information [12] from one place to another under the range (frequency) of 915 MHz. XBee's can operate in a transparent data mode or in a packet-based application-programming interface (API) mode. In the transparent mode, data-packets coming into the Data IN pin is legitimately transmitted over-the-air to the predetermined receiving radios with no alteration. Approaching parcels can either be straightforwardly routed to one target (point-to-point) or communicate to different targets[3] [9]. This mode is essentially utilized in occasions where a current convention can't endure changes to the data-packets format. AT directions are utilized to control the radio's settings. In API mode, the data packets are enveloped by a parcel structure that considers tending to, parameter setting and bundle feedback, including remote detecting and control of digital I/O and analogue I/O pins[5].

Section 1 delivers introduction of the telemetry system and comparison of 915 Mhz. with 2.4Ghz.
Section 2 describes the system overall architecture and design with the components and assembly.
Section 3 reports the experimental data and the data logging in the ground station display.
Section 4 presents the conclusion of the work.
Section 5 presents the future aspects of the telemetry system.

A. Merits of using 915 MHz over 2.4 GHz frequency

- 915 MHz recurrence fixed radio connection can travel practically 2.67 times more than a 2.4 GHz band.
- 915MHz suffered much less loss going through obstructions including trees, buildings, metal (poles).
- 915 MHz module has better Signal to Noise ratio than 2.4Ghz module.
- 915 MHz module does not require any line of sight.
- 915 MHz has 20-30% longer range between nodes (endpoints).
- Security cameras, Cell phones, Bluetooth all communicate in the 2.4 GHz domain and interfere with ZigBee mesh protocols.
- 915 MHz band is much more regulated than the 2.4 GHz band. While it has lower propagation loss than the 2.4 GHz band.

II. System Overall Architecture and Design

The proposed design have an open-source microcontroller that can programmed as per the required refresh rate and delay with respect to the requirements of the sensors. A ATmega328P [4] based arduino uno is used, that has a circuit board and user interface IDE to write to the circuit board. Various pins are determined for input and output data transfer. A XBee-PRO 900 HP RF module has been selected that is commanded by 802.15.4, multipoint and Digimesh protocols, these codes are characterized by low power consumption, extended range peer-to-peer mesh and maximum capacity of connection of nodes. The challenge on developing the telemetry system [6] is to keep the system compact and with nominal power consumption but with high flexibility to measure the parameters and transfer them to the ground station

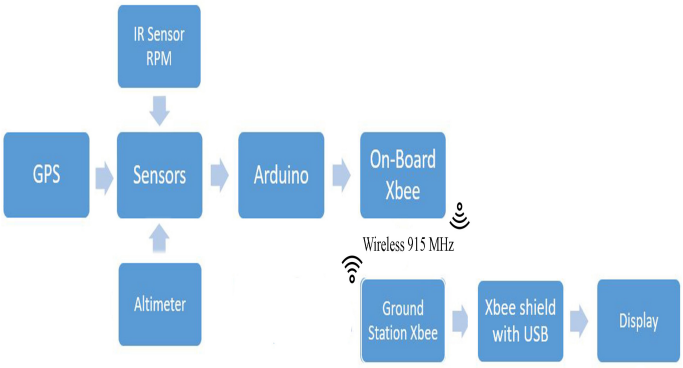

Fig. 1. Signal Flow of the Telemetry System

without losses. Figure 1 shows the signal flow in the telemetry system design.

For proper communication, both the XBees should have same parameters in settings and the transmitter should be set as coordinator and the receiver should be set as receiver. The coordinator will be placed with arduino setup on-board the UAV and receiver will be at ground station with XCTU software for receiving data and to display the data.

A. *On-board UAV : Sensors and signal conditioning*

The design architecture has the arrangement of sensors[7] required to measure the essential physical parameters on-board the UAV and a serial communication module for transmission of data through XBee PRO S3B module. The parameters that needs to be taken are current altitude, GPS location, Battery voltage, RPM of the motor and the temperature for the predictive maintenance that increases the efficiency of the actuator.

An XBee shield is used to connect the XBee S3B module to the arduino. The shields holds XBee pins to a solder pad. It provides digital 2 to 7 pins and the analogue inputs, which are given by the shield. With the jumpers in the USB position, the DOUT pin the XBee module is connected to the RX pin of the FTDI chip, and DIN on the XBee module is connected to the TX pin of the FTDI chip. This means that the XBee module can communicate directly with the computer.

The XBee-PRO S3B module allows wireless communication upto 6km range line of sight with 200 kbps RF data rate. It has a RPSMA connector dipole antenna with 2.1dB. The radio module equipment comprises of an Energy Micro EFM32G230F128 microcontroller, an Analog Devices ADF7023 radio handset, a RF power amplifier. A duck antenna is used to in the transmission[8].

Sensor converts the physical parameters into digital data. An MPL3115A2 employs a MEMS pressure sensor with an I^2C interface to provide accurate pressure data that is mapped to the altitude. Change in pressure vary the altitude with a 1.5 Pascal resolution and 0.3 meters altitude resolution. Its a low power module with the I^2C capability that uses SDA and SCL to transfer data. The sensor is connect to the microcontroller V+ and ground from its VDD and GND pins. As we employed a UNO, SCL to I2C clock analog pin 5 and SDA to I2C data analog pin 4. A MPL3115A2 library is installed to Arduino IDE to pull out the data from the sensor.

To locate the UAV current position in space a GPS sensor[10] is connected with the system, it provides real time latitude and longitude values with the heading direction . An Ublox NEO-M8N High Precision GPS Module with in-built compass module is used that includes an HMC5883L digital compass. This module have high level of sensitivity and features active circuitry for the ceramic patch antenna with the update rate of 5Hz and heading accuracy of 0.3 degrees.

To provide an efficient performance from the motor its working needs to be analyzed. A predictive maintenance setup is used in the UAV with implementation of sensors like temperature, RPM to log the performance of the motor in the flight.

A LM393 IR sensor is used in the setup to get the present RPM data of the power plant in the flight. The IR is connected to the power supply of the micro controller and to a digital pin that take in the data from the sensor. It works with detection of time difference between the same point in a propeller rotation. The RPM data is logged at the ground station for analysis.

The voltage of the battery is also determined with the voltage divider circuit from the UAV to the ground station. This help in increasing the performance and the endurance in the flight. It can also be used as the fail safe parameter once the battery voltage is below the limit it can give a warning to the ground station. Figure 2 shows the connection model of the on-board system and figure 3 shows the real model with sensors.

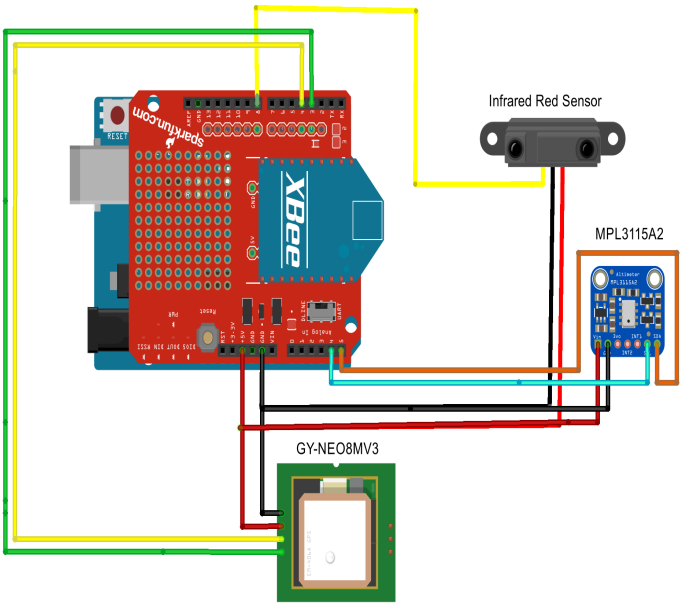

Fig. 2. Connection of the onboard system

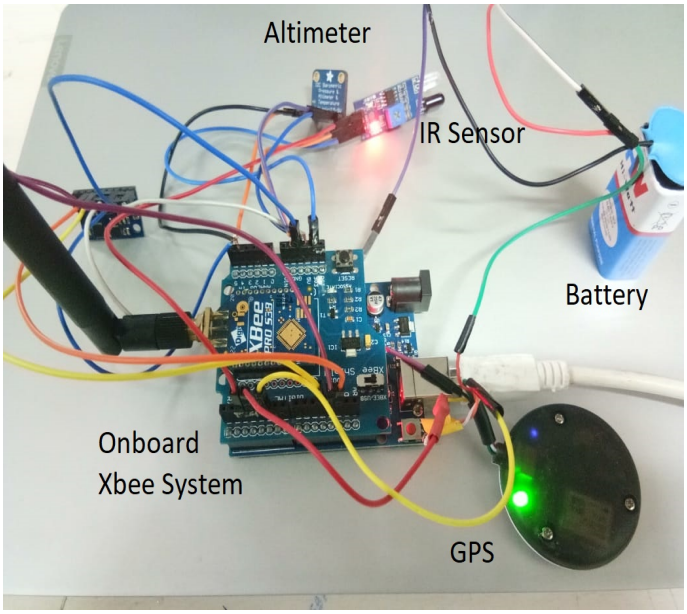

Fig. 3. Physical model of the on-board system

B. Ground Station Setup

The ground station setup has a receiver XBee mounted on a shield that is connected to computer through USB. Software like XCTU and Coolterm are used to display the data. The figure 4 shows the receiver setup.

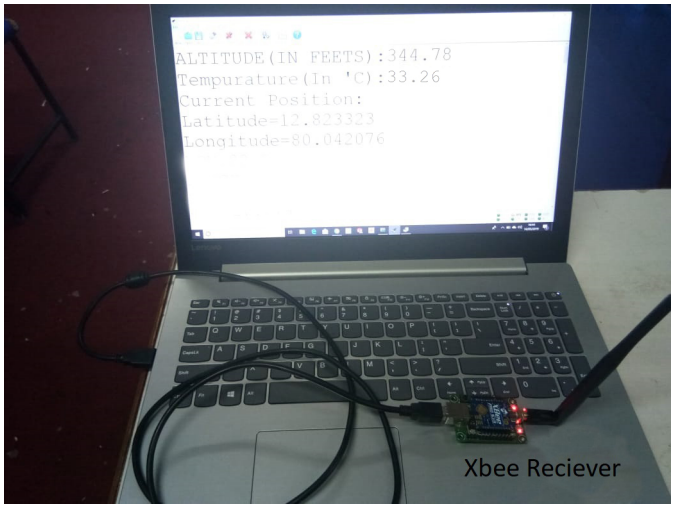

Fig. 4. Ground Station Setup.

1) XCTU software: XCTU is a free multi-stage application intended to empower developers to associate with Digi RF modules through an easy-to-utilize graphical interface. It incorporates new tools that makes it simple to set-up, configure and test XBee. XCTU incorporates the majority of the tools a builder needs to rapidly get ready for working with XBee. In XCTU we have to set up the default values in the module setting section. Accordingly we have used Transparent Mode in API Enable Mode. XCTU displays textual data and hexadecimal data.

2) Coolterm Software: CoolTerm simple serial port terminal application (no terminal emulation) with a need to exchange data with hardware connected to serial ports. The data received would be displayed on the software screen, it provides data logging and storage capability.

III. Experimental Results

The test results of all the instruments and components included in the setup at ground station and on-board responded effectively and the data is received is displayed on screen. The baud rate is 9600. Following figure 5 shows the required result received at ground station in XCTU software and figure 6 shows the result in Coolterm software.

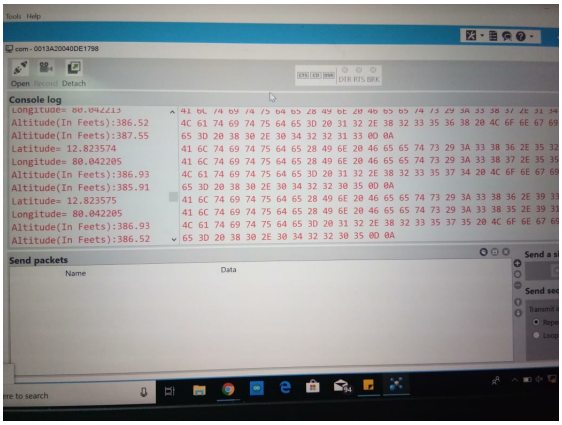

Fig. 5. Result in XCTU Software.

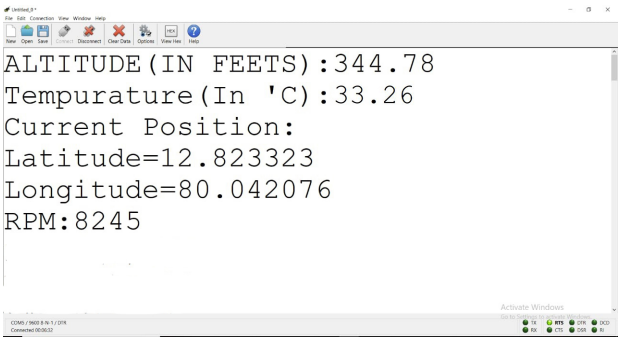

Fig. 6. Result in Coolterm Software.

Data logging is done by the Coolterm software. Maximum data rate that can be processed so that displaying visualization without pause is 20 data per second. The results of the data responses obtained can be seen in Table I.

The current altitude of the UAV is defined by the altimeter as the primary sensor and an altitude value is also available from the GPS. Comparing both the altitudes there was 97% accuracy of the data from both the sensors. By using the data the performance of the UAV can be altered as various parameters are available at the ground station by which the manoeuvring and motion of the UAV is controlled and monitored.

IV. CONCLUSIONS

From the tests performed, the system runs as determined. XBee Pro S3B on-board can communicate with other XBee module at ground station by receiving data obtained from senors with faster rate, minimal data loss and high range. From obtained results it can be concluded that the XBee-Pro S3b module can be used for telemetry efficiently and UAV parameters can be logged for flight path and the efficiency can be improved.

V. FUTURE WORKS

The telemetry data can to used in autopilot design to manoeuvre through various way-points in the space. Data can be used for payload drop in commercial applications.Predictive maintenance increase the efficiency and reduce the failure of the motor.

ACKNOWLEDGEMENT

This work was supported by Team SPARS, SRM Institute of Science and Technology.

***Abstract*—A compact Antipodal Vivaldi Antenna(CAVA) with the dimension 60 x 65 x 1.6 mm3 is proposed in this paper. The structural modifications emanated from the original fan shaped fin structure have increased the electrical length of the antenna and has ensued in reduction in the lower operating frequency from 4.8 GHz to 3.7 GHz which is close to the desired lower operating band for an UWB covering antenna. The proposed antenna follows a simple structure but delivers good plot impedance characteristic. The antenna is designed on FR-4 substrate with dielectric constant 4.4 and height 1.6 mm. The antenna design and simulation has been carried out using ANSYS HFSS 17.0 software which uses Finite Element Method(FEM) for its working. The designed antenna offers higher gain and flat gain over the 3.1 to 10.6 GHz UWB operating spectrum with peak gain of 6.4dB which is high for any compact structure. The structure is simulated for its return loss, -10 dB impedance bandwidth, radiating power patterns and compared with earlier results in an iterative manner. The designed antenna is an eligible candidate for various wide band operating applications including medical imaging, Ground Penetrating Radar applications etc.**

Keywords*— Finite Element Method, Antipodal Vivaldi, Ultra Wideband, Exponential tapering.*

I. INTRODUCTION

NOwadays microwave imaging technique is finding a great demand in various fields including imaging targets buried under lossy earth surface, see through wall imaging, concrete wall imaging for detecting of cramps and cracks and understanding mixture of concrete based composite materials, non-destructive medical imaging to detect malignant tumors in human body and tissues. To do these microwave imaging, the system requires operation at relatively low frequency [1-18 GHz] as low frequency signal components can reach the target area in shorter time interval and also can offer good penetration depth [16]. Ultra wide-band technology here becomes a better option for imaging applications to get better resolution images by offering a higher gain over a wider operating bandwidth. In recent years, there is an immense interest in design of microwave imaging systems for various applications. But the critical part in the design of microwave imaging system is the antenna. Antenna becomes very crucial and important key element of any microwave imaging system. This antenna should necessarily have high gain, wide bandwidth and low profile. This low profile demand becomes important as most of the modern imaging systems are becoming handy and light weight. So a need for compact and miniaturized UWB antenna becomes mandatory to be employed in these imaging applications.

Conventionally, there are many effective UWB radiators that include Dual Ridged Horn Antenna, Classical TEM Horn, Log periodic antenna etc. still exist. These antennas also offer a very high gain and wide bandwidth over the entire operating band. However, these antennas are relatively large and heavy. The prominent option would be the Vivaldi Antennas that can provide satisfactory radiation performance with its planar and low profile structure. This relatively low profile structure can help in achieving low cost fabrication and integration with its simple design.

II. ANTIPODAL VIVALDI ANTENNA

Vivaldi antennas are a special family of UWB antennas that are often referred as Tapered Slot Antennas in the literature [15]. As originally proposed in [2], these vivaldi antennas are travelling wave antennas comprising of an exponentially tapered radiation element which leaves a way for a slot to support the travelling of incoming waves along the entire radiative slot till it leaves the antenna at its edges. The tapered slot edge [3] defined by the exponential curve is used to improve the lower end radiation characteristics. Various remarkable works and literatures have been presenting various design level variations. These original vivaldi antennas are called as coplanar vivaldi antennas that supports coupled feed using strip line cutting across the radiative aperture for some unit cross section. However, these coupled feeding techniques posed a limitation in attaining a desired bandwidth. To improve the bandwidth, an alternative vivaldi antenna was initially developed by [4] which is known as Antipodal Vivaldi Antenna(AVA). There is again one more improvement on these AVA to achieve further higher bandwidth and gain which resulted in creation of Balanced Antipodal Vivaldi Antenna (BAVA). However, this BAVA is lacking researches due to its two-layer design complexity. With conspicuous understanding about the tradeoff between higher gain and design complexity this paper focuses on Antipodal Vivaldi Antenna and its size reduction.

However, there are also some key challenges in designing this type of Vivaldi Antennas is that, the stability in the radiation

pattern over the frequencies. Only the lowest frequency is having hold in the design of these antennas and the upper

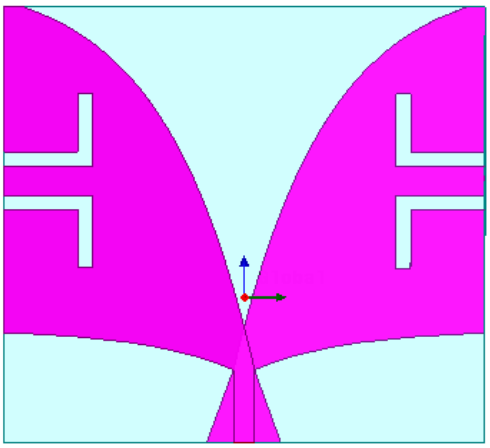

Figure 1a. Symmetric dual L-shaped slots etched on the outer edge of the fin.

operating frequency is not fixed. These antennas act as resonant antennas at lower frequencies and as a travelling wave radiator in the higher frequencies [5]. The waves travel along the inner edges of the flared aperture and couple to each other to produce required radiation [9]. For compact wireless systems it is essential to have a compact antenna geometry along with non-distorted radiation performance. The compact AVA means compactness with the fin body as well as with the feeding section of the antenna.

In couple of literatures [6] [7] [8], the compactness has been achieved by employing corrugations at the outer edge of the fins of the antenna. But this method brings additional design complexity.

In this paper, a compact Antipodal Vivaldi Antenna(CAVA) is designed without bothering the corrugations and the designed antenna covers 3.1 to 10.6 GHz allotted UWB band with notch behavior over 3.6-4.8 GHz which is the lowest band of UWB spectrum that is intended for the operation of Ground Penetrating Radar and several other imaging applications. Section III describes the evolution of the proposed antenna structure which doesn't suffer notch behavior but radiates from 3.7 GHz onwards in the complete UWB spectrum and section IV outlines the simulated results and its investigations. Section V is the conclusion of the letter.

III. PROPOSED ANTENNA STRUCTURE

Radiation characteristics of these type of Vivaldi antennas are decided by the exponential curves alongside the length of the aperture slots. Usually, compactness is brought by specific structural modifications such as etching specific slot geometry on the radiating fins to increase the electrical length in the space constraint applications without having need to modify the dimensions. Here, in this proposed structure the electrical length is increased by introduction of a rectangular cladding alongside the outer edge of the CAVA along with the introduction of the symmetric width slots on the outer edge of both the fins as shown in the Figure 1a and 1b. The current flow in the outer edge of the antenna is further reduced due to this additional structural combination. This way of increasing the electrical length wouldn't give rise to some additional radiation as in the case of the slotted fin antennas

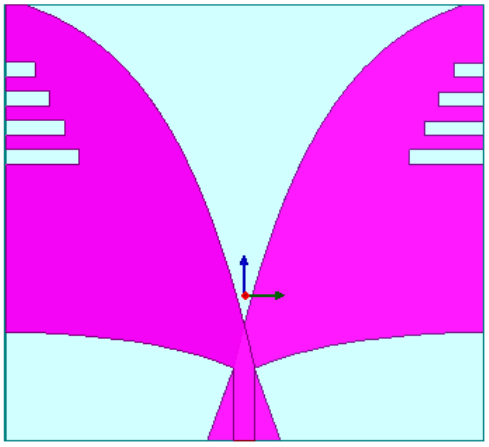

Figure 1b. Four equal width slots etched on the outer edge of the fin.

where the slots couple some amount of energy and adds to the total radiation which even worsen the radiation pattern by giving rise to unwanted side lobe level improvements. The proposed

antenna is carried out on the FR-04 substrate of dimensions of 60 x 65 x 1.6 mm^3. The substrate has dielectric constant of 4.4 and loss tangent of 0.01. Two symmetric shape fins are metallized on either side of the substrate (referred as upper and ground fin) responsible for the end-fire radiation, were created from two exponential curves with specific rate of bending. The exponential curve profile is defined by the following equations [1] - [3].

$$Y = C1e^{Rx} + C2 \quad \text{--(1)}$$

Where,

$$C1 = \frac{y_2 - y_1}{e^{Rx_2} - e^{Rx_1}} \quad \text{--(2)}$$

$$C2 = \frac{y1e^{Rx_2} - y2e^{Rx_1}}{e^{Rx_2} - e^{Rx_1}} \quad \text{–(3)}$$

Here, $C1, C2$ – Constants, R is the opening rate of the exponential curve and (x_1, y_1) , (x_2, y_2) are the start and end of the exponential curve respectively.

Table 1. Description of design parameters and its values.

Parameters	Values
Length of the substrate(Ls)	60 mm
Width of the substrate(Ws)	65 mm
Opening width of aperture(Wa)	60 mm
Length of Microstrip line(l)	10 mm
Width of Microstrip line(w)	3 mm
Width of ground plate head(Wg)	10 mm

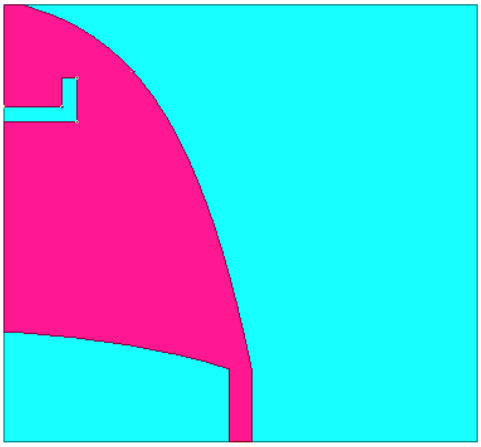

Figure 2a. Upper fin structure of the proposed antenna.

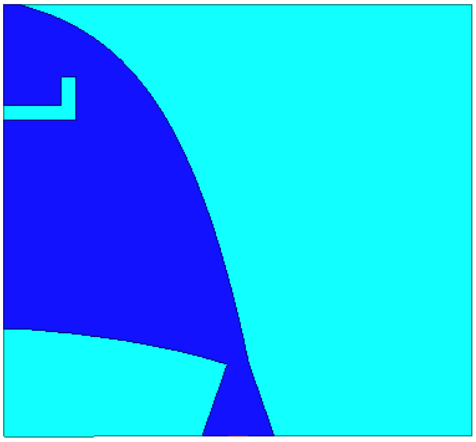

Figure 2b. Ground fin structure of the proposed antenna.

The proposed antenna design is shown in Figure 2a and 2b. The designed antenna is fed using Microstrip line feed having width 2.83mm and length 10mm to match the 50Ω impedance of that of the coaxial cable line. A transition plane as shown in Figure 2b is provided in the ground plane to convert the Microstrip feeding structure from unbalanced to balanced line. Triangular head is chosen for this purpose to provide a smooth transition from the feeding point to the fin structure. Smoother is the bending of the transition region, better is the obtained reflection coefficient and VSWR value. The values of each fixed design parameters are presented in Table 1.

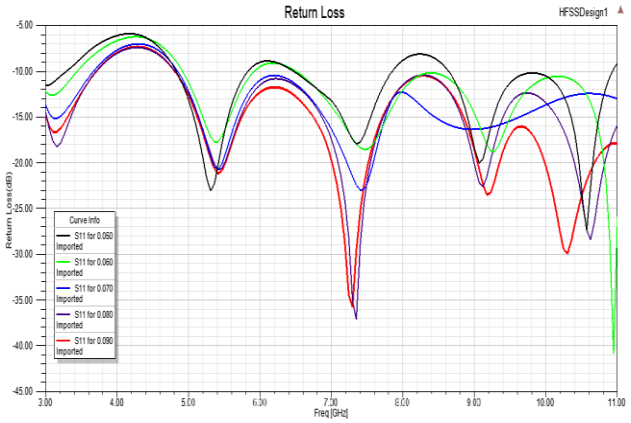

Figure 3a. S11 Performance characteristics of different rate parameters

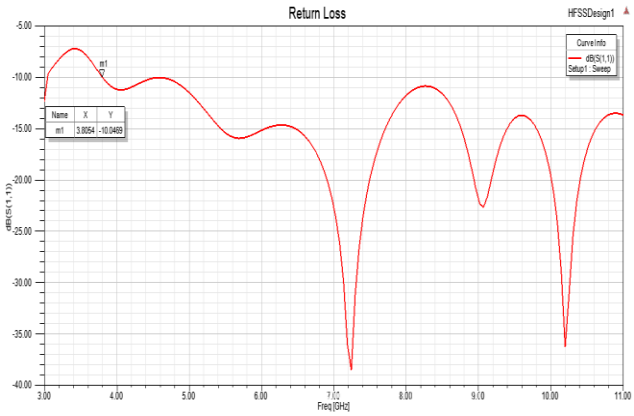

Figure 3b. Return Loss characteristics for proposed design

To reduce the overall form factor, the symmetric shape slots are opened on the outer edges of the fin structures which increases the electrical length and thereby pulling down the lowest operating frequency to some extent without the need to alter any other design dimension. According to the radiation theory of the tapered slot antennas, the flare is the main component of the radiation for the whole frequency band and the aperture opening width decides the lower cut-off frequency of the antenna which is described by the following equation [4].

$$W_a = \frac{c}{f_l}\sqrt{\frac{2}{\varepsilon_r+1}} \quad \text{--(4)}$$

Where, W_a – Aperture Opening width
c – Free space velocity
ε_r – Dielectric constant of the substrate
f_l – Lower frequency of operation

IV. Results and Discussion

The optimal dimensions of the proposed antenna structure are as follows: 60 x 65 x 1.6 mm^3 with la=10mm and w=3mm of that of the Microstrip line. The proposed antenna structure and its performance are optimized and analyzed using ANSYS HFSS 17.0 software. The computation is based on Finite Element Method(FEM). First of all, the variation with respect to the rate parameter is broadly investigated for different rates 0.050, 0.060, 0.070,0.080 and 0.090 in the chronological order. The comparison of S11 plots for different rate parameters are plotted in Figure 3a. An analysis on based on the resonance behavior over the wide spectrum is taken into consideration. It is understood that he antenna structure with highest rate parameter (0.090) performed well with good reflection coefficient. Secondly, the slot studies were carried out with equal width slots etched one on the upper fin and other on the ground fin in the symmetrical manner. Etching slots on the outer edge of the antenna increases the electrical length by some additional length of the slot. The number of slots were increased and the effect of these slots of different number are analyzed.

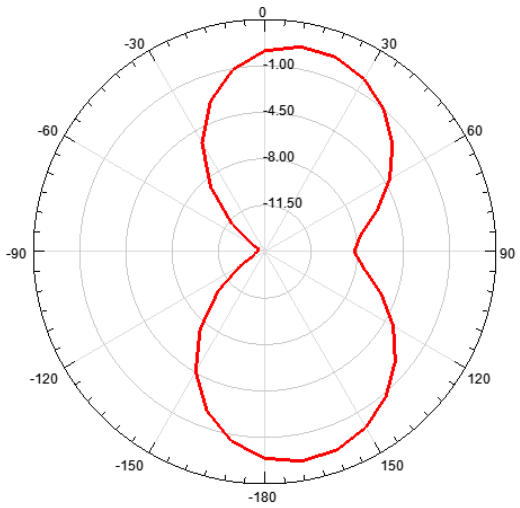

Figure 4a. E-plane radiation pattern for the proposed design

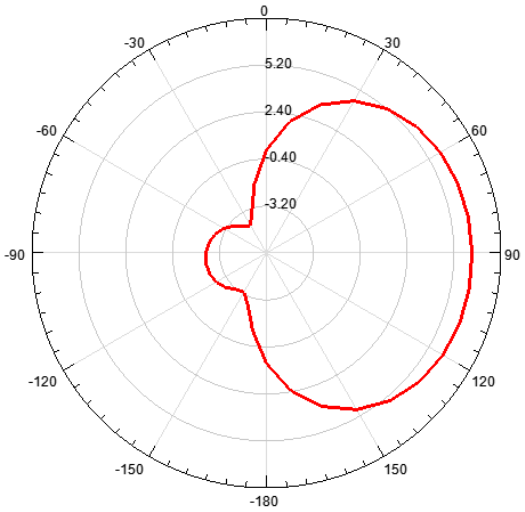

Figure 4b. H-plane radiation pattern for the proposed design.

Finally, the 3 slotted fin structure is fixed based on the return loss and radiation performance. The 3 slotted fin structure improved the overall gain of the antenna by nearly 3dB from its original structure. Similarly, two symmetric L shaped slots are also investigated. These dual L-shaped structure delivered higher radiation performance and the peak gain was nearly 6dB for the fixed dimension of the L-shaped slot. But however, the E-plane radiating pattern is changed as these Dual-L shaped slots couples some energy to radiate thus changing the end fire radiation and showing a perverse radiation characteristic.

Finally, a single L-shaped slot model for the both fin structures is proposed for which different dimensions of the L-shaped slot is studied and analyzed in an iterative way. The proposed fin structure here uses 16 mm x 2 mm as length and the width respectively. The s11 plot of the proposed model is presented in Figure 3b.

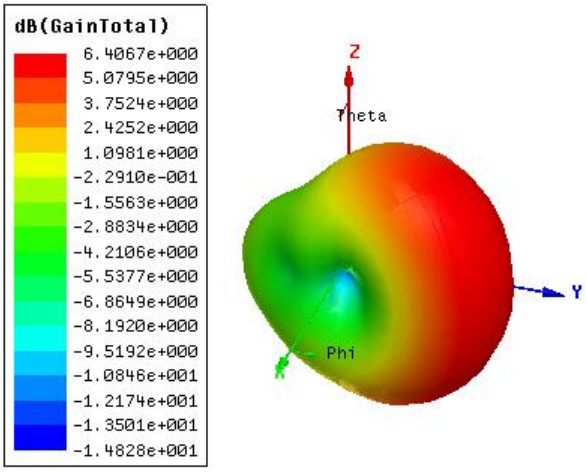

Figure 5. Gain performance of the proposed antenna.

The E-plane and the H-plane radiation pattern of this proposed antenna are depicted in Figure 4a and 4b respectively. The radiation performance in the term of gain is presented in Figure 5.

The peak gain of the proposed antenna structure is 6.4 dB. The slotted heads in the outer edges of the antenna has contributed to the additional radiations in the end-fire direction which has significantly improved the peak gain of the resonant structure.

V. CONCLUSION

In this paper, a compact Antipodal Vivaldi Antenna(CAVA) is presented with the dimension of 60 x 65 x 1.6 mm^3 keenly operating from 3.7 GHz to over 20 GHz. The L-shaped structural in the proposed antenna greatly reduced the lower operating frequency from 4.8 GHz to 3.7 GHz and achieved this without any alteration in the antenna's physical dimension. The antenna is studied for its tunability with the variation in the rate parameter of the inner edge and also the different slots and their performance are discussed. In future, the work will be furnishing the notions and effects of dielectric filling on these type of antennas. The proposed antenna shows a directional and stable radiation pattern which is highly desired for certain high resolution imaging applications. The proposed antenna delivers a peak gain upto 6.4 dB. The proposed antenna has eliminated the natural band limiting characteristic over 3.7 – 4.8 GHz in the earlier design. The design and simulation is performed using ANSYS HFSS 17.0 software. The various simulated results are presented in detail.

ACKNOWLEDGMENT

We are extremely grateful to our beloved Chancellor, Dr. Mata Amritanandamayi Devi, also known as Amma, for providing us the guidance, motivation and the support environment to work on this project.

***Abstract*—Many Wireless Sensor Network named as (WSN) have the resource constrained sensor nodes, that are predictable to work autonomously for long-time, such as months / years. Because of there stricted accessibility of the power supply, the main worry in the WSN is energy preservation. Throughout previous phases of the development of WSN, the nodes were static & communication between any of 2 hubs was completed through utilizing the multi-hop pathway. Usually, the Minimum Spanning Tree named as (MST) utilized the optimum data aggregation tree for an energy-efficient routing. Earlier the consumption of energy condensed through the hop basis data transmission include the help of the Prim's Algorithm. In this article, K-Medoids clustering based algorithm utilized to create clusters & then tree creation to enhance the effectiveness of network. Simulation has been done on the tool of MATLAB & outcome display that the proposed work has better first dead node time.**

Keywords—Wireless Sensor Network, Energy, MST, Prim's Algorithm, Optimal Route.

I. INTRODUCTION

Developments in the integrated circuit technique have allowed large-scale production of small, the cost-effective, & the energy efficient wireless sensor named as(WS) tools with the processing abilities of on-board. Mobile & pervasive computing development has formed novel applications for them. The applications which is based on sensor extend an extensive range of the region, with the remote monitoring of the seismic events, the ecological aspects (example, water, air, wind, soil, chemicals), smart-spaces, the condition-based maintenance, the soldierly shadowing, the exactness farming, transport, the factory instrumentation, & the inventory tracing [1]. The WSNs has various small, lower cost hubs equipped with the sensor, microchips, wireless transceivers, memory, & battery-operated. They examine a physical, ecological condition & collect & transmit the data at one / more of the base-station. WSN consumes energy throughout the collection of data. Because of this there are various types of applications in different areas. The WSNs termed as (WSN) is a co-operative gathering of the sensor hubs, every has the dispensation capacity. The routing in the WSN is various as of the conservative fixed network routing through the numerous ways. The WSNs infrastructure is low, incredible wireless links, there are sensor hubs that can fail, & its routing protocols face the harsh energy reserves necessities.In contrast, the WSNs are wireless schemes with the incomplete power, are reserved in dynamism ingesting, & with dynamism have the actual time with the different sources [2].

The rest of the paper has various sections which have been described as: in section II, routing techniques of WSN are explained which has two techniques such as single & multi hop routing. In section III, Minimum Spanning Tree has been described with some detailed explanation and section IV described Prim's Algorithm. Section V discussed about some literature surveys to understand the concept. In section VI and VII, proposed work and result analysis has been described respectively.

II. ROUTING TECHNIQUES IN WSN

Routing is a procedure for structuring route amongst destination as well as destination to send information to request. This involves transmission of info after nodes, which assists as well as analyzes this info to BS to assist in decision-making process. There are numerous types of constructions to route information after nodes to BS, which are designated as surveys:

I. Single Hop Routing:

First & easiest method was an instant broadcast of data. Inside the given method every sensor hub will find & move its data directly to BS except the help of any middle hub. The form of BS is located on a distance as of sensor nodes named as (SN), this tell about the extended transmission expenditure of the info, because of which nodes energy reduces rapidly & thus the lifetime of SN's is small.

II. Multi-Hop Routing:

In it, every SN's conveys their data to their instant neighbor, & include the many hops data of neighboring nodes is moved to BS. In the multi-hop networks, each of the hub devours the fewer energy to transmit its data than the Single-hop. The Multi-hop WSN is most efficient then the single-hop types network. Inside the actual world annotations, the single-hop system is most effective if multi-hop network is in single-hop less package for future. This

architecture present the hubs located near the BS have higher load, so they expedite its dynamism faster than new nodes, that effect lifetime of network [3].

III. MINIMUM SPANNING TREE [MST]

Suppose indirect, associated graph. The spanning tree of particular graph will be sub-graph which joins altogether of vertices of tree. There may be several spanning trees in a single graph. If every weight is allocated some weight / numbers, then MST is a lower weight tree compared to the any other spanning tree in that particular graph.Figure 1 represent a graph. Each branch has been entrusted with weights. As has been seen, tinted tree is recognized spanning-tree. Several other spanning trees could too be made through joining vertices of this fig into various ways [4]. The edge-weighted graph is a diagram that we connect with weight as well as cost at every end. An MST of edge-weighted graph is a comprehensive tree whose weight (its weight besides its shaft joint) is no more than some other spanning tree.

- The graph is associated. Tree conditions in our definition show that graph must be connected to presence of MST. Uncertainty no graph is connected, then we can optimize our algo to calculate MST of each associated component, which is composed known as minimum spanning tree..
- Edge's weight is not far. Geometric awareness is sometimes valuable, nonetheless weight of side may be arbitrary
- Edge weight may be zero or negative, as well as if age weight is all positive, then subtract MST with minimum total weight connecting all verticals is enough.
- Edge Weight is dissimilar condition edges of ends are equal, then incomplete spanning trees are not single. Creation this assumption makes our evidence informal, nonetheless all of our algorithms work well in presence of equal weight.

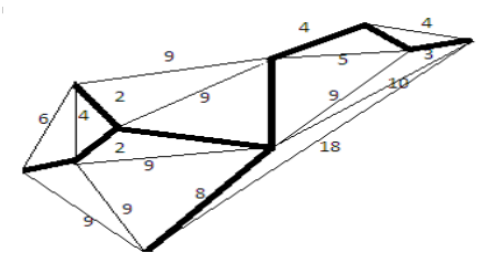

Fig 1. Edge weighted graph and it's MST

IV. PRIM'S ALGORITHM

Prim's algorithm is algo inside a theory of graph which looks aimed at minimum spanning tree toward an associated weight graph. Algo of prim's extends the minimum spanning tree named as (MSE) by increasing subtrees sequence. In this sequence, the primary sub-tree contains a solo vertex chosen randomly from set V of the vertices of graphs. Inside a following iterations, recent tree increases greedily, easily not connecting it to that tree with the adjacent vertex to the top. (Through adjacent vertex, the vertex not in tree associated to the vertex in tree through power of minimum weight.) Afterward being included in the creation of graph, the algorithm stops after adding vertices of all the graphs. However, algorithm extends a tree through just a vertex over its each iteration, overall numeral of their iterations is n-1, here n represent sum of vertices in graph. Tree created through algorithm is attained because edges set utilized to the development of tree. The algorithm of Prims nature create it required to offer each of the vertex not in recent tree include the info around a smallest edge joining vertex to the vertex of tree. Info is given through joining the 2-labels on the vertex: adjacent vertex of tree name & related edge length (weight). The vertices which aren't nearest to any vertices of tree could be provided ∞ tag indicative of its "infinite" distance to the vertices of tree & null tag to adjacent vertex of tree name. include these tags, verdict subsequent vertex to be added to recent tree represent as T = (VT, ET) turn out to be easy challenge of verdict the vertex includes minimum distance tag in set V – VT [5].

V. LITERATURE SURVEY

In given article [8], for WSN, the optimized routing protocol is implemented. We are attentive in building the effective routing spanning tree which reduces energy ingesting amongst all of the hubs in n/w & fit to WSN include decreased energy to attain the extended life-time. Keyconcept of such algorithm arises as of MST theory of graph. Such method attentions over minimum hop sum of every node to grasp target (basin-node) include the optimum pathway.

In [3] article, the protocol termed as Tier Based Minimum Spanning Tree Protocol also named as (TBMSTP) is implemented. This approach is on the basis of Tier idea that is dividing a n/w into the portions based on the hubs distance from a BS & MST building. We are utilized 2 level MST idea that is, a MST on the level of hub include the tier & the another on level of cluster-head among the various tiers to decrease load & intensification a WSN network life-time.

In [6] research paper, the algorithm based on networking-associated termed as local minimum spanning tree named as (LMST) working where as cooperating at the problems of energy balance, which is leading the network for brief life-

time, & implement the algorithm of energy-balance. The algorithm examines the energy usage completely to connect the remaining energy of data communiqué and communication nodes, to obtain balanced energy and to avoid complications related to excessive consumption of energy once intermediate node functions forwarding function, Like this. Expand the network life cycle. Simulated investigational results displayed the large capacity of the implemented algorithm which could capably extend the lifetime of the n/w & ensure a long-term performance of network, whereas another n/w's ensure act gauges, like the throughput & rate of delivery.

In[7] research paper, we join the routing features which is based on cluster for the cluster creation & the selection CH & the usage the (MST) for the communication of intra-cluster. The proposed method is based on optimizing MST using the Simulated Annealing named as (SA). In given research, mobility standards which is normalized, delay & residual energy are measured for discovering the optimum MST. The outcome which is given by simulation, determine the efficiency of implemented technique to improve package distribution proportion & reducing end-to-end delay.

VI. PROPOSED METHODOLOGY

The clustering of *k*-medoids is a dividing method which is usually utilized in the areas which need toughness to the outlier-data, metrics of arbitrary distance, / or for which there is no clear definition of mediod or median, requires strengthening.

This is same as to the *k*-means, & both approaches goal is to partition the measurements set / explanations in the *k*-subsets / clusters, so that sub-sets minimalize sum of the distances among the measurement & the center of measurement's cluster. In the algorithm of k-means, subset center is measurements mean into sub-set, frequently named the centroid. In the algorithm of *k*-medoids, sub-set center is a subset member, named as a medoid.

The algorithm of *k*-medoids returns the medoids that are real points of data in data-set. This permits you to usage the algorithm in the conditions wherever data mean doesn't occur include the data-set. This is key various among *k*-medoids & *k*-means algorithm where centroids give back through the k-means algorithm can't be include data-set. Hence forth the *k*-medoids algorithm is beneficial to cluster the definite data wherever the mean is dreadful to describe/understand.

The function k-medoids provides several iterative types algorithms which minimalize number of distances as of every item to its medoid of cluster, total clusters. Most of algorithms is called partitioning around medoids (PAM) which proceeds in two steps.

1. Build-step: Every *k* clusters is related include the possible medoid. Such task is done utilizing the method stated through 'Start' value name couple argument.
2. Swap-step: Inside each of the cluster, every point is examined the form of possible medoid through examination whether the sum of the distances of within-cluster becomes the lesser utilizing that particular point the form of medoid. If thus, point is definite the form of novel medoid. Each of the point is allocated to cluster include the the neighboring medoid.

The algo generates swap-steps and repeats until medoids are transformed or termination criteria are not completed. Consuming minimum control parameters of details, including early values of K-meridian, cluster meridian as well as maximum number of iterations. Through default, k-medoids usage k-mean ++ algorithm aimed at cluster medoids initiation, as well as a quadrangular Euclidean matrix.

In previous work, smallest spanning tree created with all the nodes in network. In this letter, we offer a customized route protocol aimed at wireless sensor nodes. We want to create a skilled routing tree that is compatible with low-power WSN, which reduces energy consumption and has longevity of all nodes in network. The main idea of this algo is as of minimum spanning tree (MST) graph theory. This method focuses on minimum hop calculation of every node to extent endpoint (sink node) within optimum pathway. After that data transmission performed among sink and the nodes. But this is very time consuming to create shortest route aimed at data transmission. So to overawed this problem as well as improve network competence, innovative method is introduced.

Consider the whole network in which the sink node is placed at (0, 0) coordinate and others are deployed randomly. Firstly, the network is divided into small groups known as clusters. This step is performed by K-Medoids algorithm to form optimal clusters. Now perform the minimum spanning tree formation using Prim's Algorithm by considering sink node as an input. Lastly, the data transmission performed through cluster heads of each clusters instead of each nodes which makes them more efficient then earlier.

Proposed Algorithm:
Step 1: Start
Step 2: Place sink node at (0, 0) coordinate
Step 3: Put all nodes randomly in two form i.e. 30 and 100 nodes
Step 4: Divide the network into clusters
Step 5: Apply K medoids algorithm
Step 6: Involve the network graph G(V, E), k is no. of clusters to be shaped, where V as well as E is the nodes also wireless links respectively
Step 7: Select k nodes arbitrarily as first cluster heads, also usage m to mean set of those k cluster heads
Step 8: CH performs by distance computation

Step 9: Formation of Minimum Spanning Tree
Step 10: Data transmission performed through cluster head
Step 11: Repeat step 10 until it reached destination node
Step 12: Stop

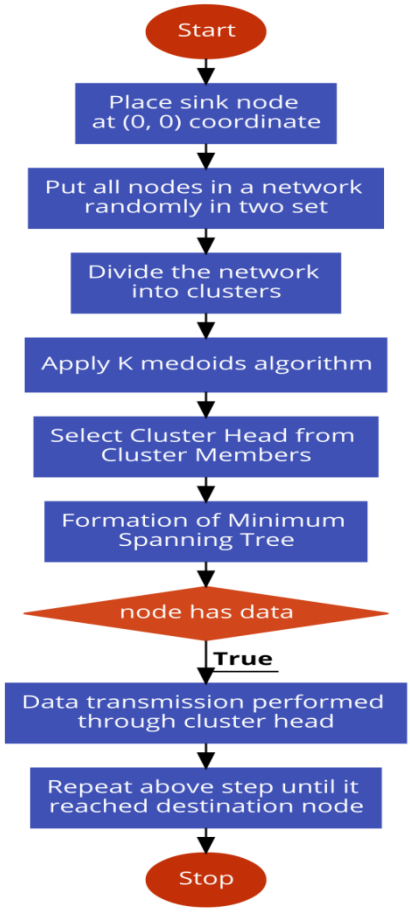

Fig.2. Proposed Algorithm Flowchart

VII. RESULT ANALYSIS

The simulation performed to illustrate the propose work by using MATLAB tool. We accept that confident measures of sensor nodes are consistently organized in a 100×100 square area. Initially 30 nodes are deployed in the network and then 100 nodes are deployed. Sensor nodes have following physiognomies: (1) in network, altogether protuberances are static after being organized; (2) altogether nodes are of same quantity of original power; (3) sink may be deployed at (0,0) in monitoring area; (4) altogether nodes have similar sensor radius, meant as *R*.

A. Scene1 (30 Nodes)

Here 30 nodes are deployed in the network and then the graph shows the variance of energy. The number of cluster heads formed is 15.

Our Proposed	781	667	573	501

Conclusion

Sensor nodes in a WSN are examples of resource constrained devices, because the processing power, The sensor nodes of memory as well as supply power distribution are limited. Wireless sensor networks, as a promising technology, are acceptance more as well as more interest from a wide range of applications for research communal. Detailed WSN applications comprise frequent distributed-deployed sensors as well as one or more base stations. Every sensor may understand, collect as well as transmission data aimed at sync in continuous or event-driven fashion. This paper improves network performance by generating clusters and then performed data transmission through the MST. From the result comparison, it can be demonstrated that 30 nodes has greater time for the node communication. In scene 4, the nodes become dead early with respect to the other scenes.

***Abstract*—This paper presents the use of hyperspectral image processing as an alternative to traditional mineral exploration techniques for identification of regions in the study area rich in zinc mineral. Zincian Dolomite is a known ore of zinc found in the study area. The Hyperion sensor dataset of a study area in Rajasthan, India is obtained from the USGS (United States Geological Survey) Earth explorer and pre-processed using ENVI (Environment for Visualizing Images) software to remove noise. The pre-processed data is later exported to a dedicated python program which uses machine learning algorithms to identify the regions rich in Zincian Dolomite. The proposed technique form mineral exploration is faster and cheaper than the traditional techniques and is also found to be very accurate in identification of the minerals.**

Keywords— ENVI (Environment for Visualizing Images), Hyperspectral remote sensing, Machine Learning, Mineral exploration, Hyperion, USGS Earth Explorer.

I. INTRODUCTION

Nearly 312 million Indians are at direct risk of zinc deficiency, which leads to stunted growth in children, diarrhea, impaired immune functions, reduced appetite and many other diseases. More than 50% of land under cultivation in India is zinc deficient, which is directly responsible for various crop related diseases.

Rajasthan is one of the most mineral abundant regions in India. It is also one of the largest Zinc exporting state in India. Proper identification of previously unidentified zinc rich regions can increase the production and export of zinc, not just for industrial use but also for producing zinc supplements and zinc rich fertilizer. The traditional identification methods involve manual soil sample collection from the region of interest and chemically analyzing each sample for finding traces of zinc, making it both costly as well as time consuming.

Remote sensing technology was developed in the late 1800s for covering more area in less time. Its application was mostly limited to the military until the 1970s, when its effectiveness for mapping was discovered. Grayscale imaging was used for the purpose of mapping and monitoring natural resources. Multi-spectral imaging, an upgrade of the grayscale imaging, was later found to be effective for mineral exploration. Multi-spectral remote sensing works on the principle of reflectance spectroscopy. Every chemical compound tends to absorb a few wavelengths and reflect the other wavelengths incident to it. Such absorption or reflection corresponds to the different chemical energies of the compound, such as bond energy, vibrational energy, etc., which can be used to identify the compound [2]. These absorptions and reflections are unique to every element/compound. Multi-spectral imaging gives us discrete information of very few wavelengths of the reflected spectrum. Hyperspectral Imaging is an advancement of multispectral imaging. It provides us with continuous data of hundreds of wavelengths. Continuous reflectance data can be used to identify major chemical properties of the region under study, which can be used to identify any/all the chemical compounds present in it [1].

Hyperion is a Hyperspectral sensor on board of the Earth Observing – 1 (EO-1) satellite launched by National Aeronautics and Space Administration (NASA) on 21st November 2000. The Hyperion sensor is capable of recording nearly 220 wavelengths ranging from 400 nanometers to 2500 nanometers, with a spatial resolution of 30 meters. The Hyperion dataset is one of the most widely used datasets in the field of hyperspectral imaging.

This study aims at identifying Zincian dolomite rich regions in the study area of Rajasthan, India using the data obtained from hyperspectral remote sensing.

The Hyperion sensor dataset is downloaded and then pre-processed using the ENVI tool to eliminate noise in the dataset. The Section II deals with the three machine learning algorithms, namely k-Means, Support Vector Machine and Random Forest which are used to independently identify the regions in the study area contain Zincian Dolomite. Finally, in section III the accuracy of the three algorithms are found by comparing their output to the actual ground truth and the Random Forest algorithm is found to be more accurate than the other two.

II. METHODOLOGY

The Hyperion sensor data for the study area is downloaded from the USGS Earth Explorer website in the L1R format. The dataset contains data of nearly 242 bands and represents 7.5-kilometer by 100-kilometer area on ground.

A. Sub-Setting

The raw data obtained needs to be properly pre-processed to remove noise and boost up the signal. The processing time

of the data is directly proportional on the size of the dataset. Unwanted regions and unwanted bands only increase the processing time; thus, it is imported to remove such data from the initial dataset for faster processing. Spatial and spectral sub-setting is the first step of pre-processing our data.

The dataset represents an area of 100 kilometer by 7.5 kilometer on ground and contains lot of cloud covered regions. Spatial sub-setting is done by selecting the area with the least cloud cover. Of the 242 bands in the dataset, bands (1-7), (57 - 77) and (225-242) are completely affected by noise. Spectral sub-setting is performed on the dataset to remove these bands. After the spatial and spectral sub-setting is completed, the resultant dataset represents a smaller area with each pixel containing information of 196 bands [3,4].

B. De-Stripping

Few bands in the dataset have almost no data present in them. Such bands are needed to be manually identified and their reflectance values are to be replaced by the average reflectance values of the two adjacent bands [3,4].

C. Radiometric calibration

Hyperspectral imaging works on the principle of reflectance spectroscopy. Sun is the source of energy used. Few of the incident wavelengths on the soil get absorbed and the remaining wavelengths are reflected back to the space. These reflected wavelengths travel 705 kilometers to reach the EO-1 Satellite with the Hyperion sensor. Cloud, water vapor, aerosols, pollutants, etc. may absorb some of these reflected wavelengths to further reduce the signal strength. Radiometric calibration is used to convert the sensor data into reflectance data by using gain and offset value for each wavelength [3,4].

D. FLAASH atmospheric correction

The components present in the atmosphere (water, aerosol, industrial soot, dust, etc.) not only suppress reflected wavelengths reaching the Hyperion sensor, but also add noise to some of the wavelengths. The noise is added during the propagation of the reflected wavelengths. The received signal is a mixture of the properties of the pixel under observation, the atmospheric components and also the effects of the surrounding pixel reflectance. FLAASH (Fast Line of sight Atmospheric Analysis of Spectral Hypercube) is an atmospheric correction algorithm developed by the Air Force Research Laboratory, Space Vehicles Directorate (AFRL/VS), Han-scom AFB and Spectral Sciences, Inc. (SSI) in order to properly analyze the reflectance data and remove any noise caused due to the environment. The algorithm makes use of the atmospheric data such as water content, temperature, aerosol content, etc. for each region and season and uses that to nullify the effects of the atmospheric noises [3,4].

E. K-Means

K-Means is a simple unsupervised learning algorithm used to group the previously uncategorized/ungrouped data. The algorithm divides the data into 'K' number of groups. It works iteratively and based on the features that are provided, it groups all the similar featured data points to one of the 'K' groups. The algorithm iterates between the Data Assignment step and the Centroid Update step. In the Data Assignment step, squared Euclidian distance is calculated between each data point and all the centroids, and the data point is assigned to the nearest centroid. In the Centroid Update step, the position of the centroid is changed to the mean position of all the data points assigned to the centroid. The algorithm iterates between both the steps until no data point changes clusters, or until the limit to the number of iterations is reached.

F. Support Vector Machine (SVM)

Support Vector Machine is a supervised machine learning model used for classification and regression analysis of data. Being a supervised model, it learns the classification parameters from a set of pre-classified training examples to build a hyperplane, which it then uses to classify unclassified data. A hyperplane is a plane which separate and classifies the data points. The accuracy of the hyperplane increases by increasing the number of training data. The shape of the hyperplane is decided by constructing it such that is farthest from the nearest points on either side of it [5].

G. Random forest

Random Forest is a supervised machine learning algorithm. As evident from its name, it creates a forest, consisting of random decision trees and gives the output the maximum no. of decision trees have given. By doing this, higher accuracy is achieved and the output is more stable. Random Forest grows the trees by searching the best feature among a subset of random features instead of searching for the most important feature. This algorithm uses only a random subset of features to split a node. Additionally, random thresholds for features can be used instead of using the best thresholds to grow more random trees. As this algorithm is supervised, the training data set is used to find out importance of each feature, which can then be used to give more preference to results which use those features [6].

III. RESULTS AND DISCUSSION

An area south of the city Ajmer, in Rajasthan state of India is chosen as our study area. The district of Ajmer is rich in minerals. It is known to host Dolomite (chemical formula Ca Mg $(CO_3)_2$). Metals like Zinc, Cobalt or Lead are known to be natural replacements to Magnesium in dolomite. Zinc rich dolomite (chemical formula Ca Zn $(CO_3)_2$) (see Fig. 1), commonly known as Zincian Dolomite is known to be found in our study area. Zincian Dolomite is the most popular source of Zinc in India and can be found in states of Rajasthan, Andhra Pradesh, Arunachal Pradesh and Uttarakhand. The Geological Survey of India (GSI) has manually sampled a few regions throughout India and located a few regions where zinc can be found. The GPS coordinates of these regions have been shared under the National Data Sharing and Accessibility Policy (NDSAP), and the study area has one of those coordinates.

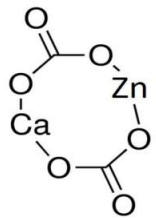

Fig. 1. Chemical Structure of Zincian Dolomite.

Traditional methods of identifying deposits are very accurate, but it is also time consuming and costly. Technological developments in the field of remote sensing have enabled us to accurately identify mineral deposits in a relatively cheaper and faster method. Hyperspectral image processing technique is used in this project for identifying dolomite mineralization. The Hyperion sensor of the EO-1 satellite gives us spectral information of 220 bands in the range of 400 nanometers to 2500 nanometers, with a spectral resolution of 10 nanometers and spatial resolution of 30 meters. As the sensor collected data from 705 kilometers from earth surface, the signal is weak in strength and contains noise. Hence, the data needs to be pre-processed to remove noise and boost up the signal. ENVI software is used for pre-processing the data.

Sub-setting is the first step used for pre-processing. As the sensor scans 100 kilometers by 7.5 kilometers on ground, and as each pixel contains data of 242 bands, it is important to reduce the size of the dataset to reduce processing time. The Hyperion sensor data is downloaded from the USGS earth explorer in L1R format. This data is imported in ENVI software, where spectral and spatial sub-setting is done on the data. The area with the least cloud cover is selected as the region of interest in the image for the spatial sub-setting part (see Fig.2). Bands (1-7), (55-77) and (225-242) are removed in the spectral sub-setting part, as these bands are known to be full of noise. After spatially and spectrally sub-setting the data, the number of pixels in the dataset decreases and the number of wavelengths is reduced to 196 bands for each pixel. This data is then saved in .hdr format.

Fig. 2. Study area after spatial sub-setting loaded in RGB bands.

Even after sub-setting, the data may contain bands with no information. These bands are identified by manually loading them in the ENVI classic software and identifying any black columns in the grey scale image. The black columns indicate that no data is present in them. That column's data is replaced by the average data of its two adjacent columns. This is done using the spatial pixel editor tool in ENVI classic. This step ensures continuity in the data.

After correcting the data using the spatial pixel editor tool, it is exported back to ENVI software for radiometric calibration. Radiometric calibration converts the sensor data (see Fig. 3) into reflectance data by multiplying a gain and adding an offset specific to each band. This step strengthens the signal and also converts the data from raw sensor data to proper reflectance data. The output of the radiometric calibrated data is in terms of percentage reflectance.

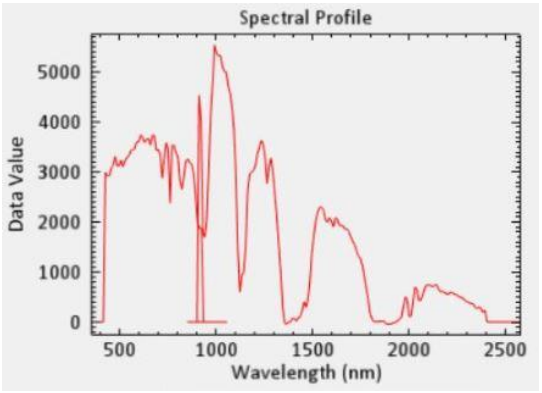

Fig. 3. Pixel data before radiometric calibration.

After converting the data in the 196 bands in terms of percentage reflectance, the next step is to apply FLAASH atmospheric correction to remove known noises from the signal. Water vapor, aerosols, industrial soot, and all the other particles in the atmosphere interfere with the wavelengths reflected from the study area, causing not only the signal strength to decrease, but also adds noise in a few bands. These atmospheric constituents also absorb sunlight and reflect a few wavelengths based on their chemical properties, which interferes with the reflected wavelengths from the area of interest. After manually configuring the FLAASH module based on the sensor used and the area of interest, the module uses known atmospheric data to effectively suppress most of the noise (see Fig. 4). In Fig. 4, red color is used to represent reflectance data before FLAASH correction and blue color is used to represent reflectance after FLAASH correction. The FLAASH corrected file is then saved in .hdr file format so that it can be exported for processing.

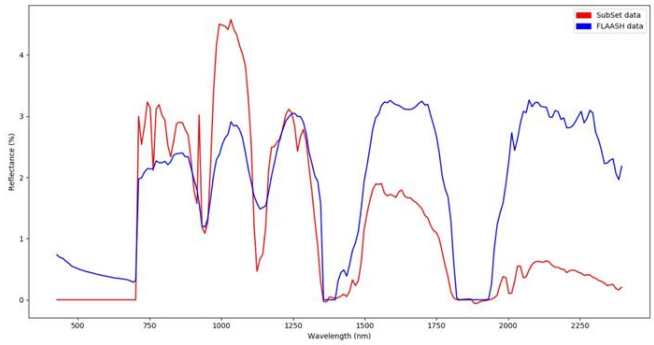

Fig. 4. Pixel reflectance data before and after FLAASH correction.

After pre-processing the data by sub-setting, de-stripping, radiometric calibration and FLAASH atmospheric correction, the data is fit for classification. The FLAASH corrected .hdr file is imported on the python code. The data is of the format (x, y, λ) where x and y denote the row no. ranging from (0-1330), and the column no. ranging from (0-255) and λ denotes the band number ranging from (0-195). Taking a look at the spectral signature of dolomite obtained from the ECOSTRESS spectral library [7- 9], 9 important wavelengths have been identified for the classification of dolomite. These wavelengths (in nanometers) are (1669.1, 1780.09, 1911.27, 2052.45, 2153.34, 2294.61, 2365.2, 2375.3 and 2395.5). A 3-dimensional array of size (x, y, 9), where x and y are the number of pixels in the x-axis and y-axis of the FLAASH corrected file, is initialized and the reflectance data of only the 9 bands out of 196 bands available is loaded into the array for each pixel.

The first algorithm used is k-means. The algorithm requires no training as it is unsupervised. k = 2 is selected and the algorithm segregates the data into two different clusters (Zinc cluster and Not Zinc Cluster). The GPS coordinate of the pixels containing dolomite in the study area was extracted from the Ministry of Mines database and the information of the 9 bands for one of the pixels was exported into a single dimension array of size 9. The k-means algorithm segregates pixels into one of the two clusters. The output of the k-means algorithm is a black and white image where black pixels represent the cluster having their cluster center nearest to the values saved in the single dimension array. Thus, the black pixels will denote pixels classified as dolomite and the white pixels will denote pixels not classified as dolomite (see Fig. 5(a)).

The second classification used is Support Vector Machine (SVM). It is a supervised machine learning model and requires a training dataset to build a hyper-plane. The pixels corresponding to GPS coordinate used in the k-means step (25˚46’00’’N, 75˚14’00’’E) is used to train the database for Zinc class. The Not Zinc class is assigned few pixels which are classified as not zinc by the k-means algorithm. Nearly 100 pixels each are used to train both the classes. Then, SVM algorithm uses the entire hyperspectral image as testing data and classifies each pixel individually. As nearly 200 pixels are used for training the hyperplane and each pixel is classified individually, the training: testing ratio is nearly 200:1. The output of the SVM module is also a black and white image where white pixels represent dolomite and black pixels represent region not having dolomite (see Fig. 5(b)).

The third classification used is Random Forest model. Being a supervised machine learning model like SVM, it also needs training dataset to configure the output of the decision trees. The same pixels used to train both the classes in SVM model are used here. As it is used for binary classification, its output is also a black and white image where the white pixels denote dolomite deposits and the black pixels denote regions not having dolomite (see Fig. 5(c)).

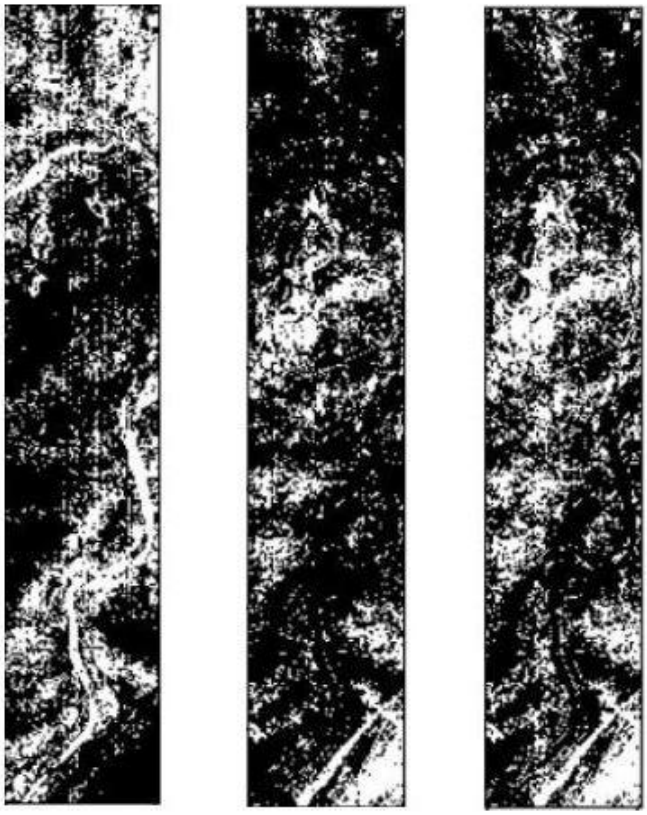

Fig. 5. Results of (a) k-means, (b) SVM and (c) Random Forest.

The region marked by Geological Survey of India as Zincian Dolomite deposit is also classified by the k-means, SVM and Random Forest modules as dolomite. Random Forest algorithm is known to be superior to the SVM and k-means models. As the ground information of each pixel in the study area is not available, finding the accuracy of the models directly is not possible. Instead, the Jasper Ridge dataset [10] is used to test the accuracy of the Random Forest model. After similarly pre-processing the dataset and classifying it using the Random Forest module, the output of the module is compared to the ground truth information available for the dataset and the confusion matrix is used to find the accuracy. The accuracy is found to be 99.27% (see Fig. 6). Thus, the output of the Random forest classification for our region of interest can be considered to be very accurate.

(b)

Fig. 7. Accuracy estimation of (a) k-means and (b) SVM modules.

The GPS coordinates of the pixels classified as dolomite can be extracted and can be used to properly plan for mining the dolomite to extract zinc in an environment friendly way. The availability of spectral signature of Zincian Dolomite can make the classification even more accurate.

IV. Conclusion

Pre-processing the entire dataset using ENVI takes nearly 10 minutes and the three classifications implemented in python code takes one minute to execute. K-means being an unsupervised classification model gave only a 64.67% accurate output. Being a supervised model, SVM algorithm has an accuracy of 91.05% for our study area. Random Forest algorithm uses multiple decision trees for generating the output and has an accuracy of 99.27%. The Random Forest algorithm is found to be more accurate than other algorithms in the field of hyperspectral image processing and can be considered as a replacement to the existing mineral exploration techniques.

***Abstract*—In this paper, a converter architecture which will provide a three-phase ac output and a boosted dc output simultaneously from a dc source in not more than one conversion stage is studied. This circuit known as 3-ϕ HBC (3-ϕ hybrid boost converter), is obtained from the traditional dc-dc converter operating in boost mode, where a three phase bridge circuit takes place of control switch. HBC shows immanent shoot-through protection proficiency. Such converter with better multi-output competency and authenticity is befitting the systems with both ac & dc loads in simultaneous mode e.g. PV charging stations, residential and industrial applications, etc. Independent regulation of Both the three-phase ac output and step-up dc output is attainable in case of HBC. For our intent to regulate dc as well as ac output, appropriate PWM control scheme is given in brief. To validate the converter operation, simulation results are demonstrated with resistive and inductive loads and the steady state performance analysis is done.**

***Index Terms*—Three-phase Hybrid Converter, pulse width modulation control, dc-dc boost converter, LCL filter.**

I. Introduction

Simultaneous ac and dc loads pervades most of the electric power distribution systems. Residential nano grids, electric vehicles, marinecraft power distribution are some of the typical examples of simultaneous ac and dc loads. So hybrid converter techniques are often used in all of these systems. Multiple voltage source inverters (VSI) and dc-dc converters are cascaded together to provide ac and dc outputs simultaneously, supposing that both ac and dc loads are simultaneously present. Multi-output dc-dc converters or many dc-ac inverters are used conventionally in above cases [1].

Using a hybrid-converter topology, a similar system can be obtained, which provide 3-ϕ AC and DC outputs concurrently with single circuitry. This architecture is named as a hybrid converter and is built from a boost converter where a 3-ϕ bridge network replaces the controlled switch [2]. The Hybrid converter when compared to traditional VSI, has built-in shoot-through protection capacity.

A dc-ac inverter and dc-dc converter are replaced by hybrid converter to minimize switching losses as conversion stages required are less. In the resulting hybrid converter, the essential number of switches is less to produce both 3-ϕ ac and dc outputs with enhanced reliability. Independent regulation of both the the three-phase ac and step-up dc output is possible in HBC [3]. A befitting PWM control technique [2] can be chosen to regulate both the outputs (dc and ac).

Section II presents development of hybrid boost converter. It gives insight to concept of HBC and its derivation from conventional boost converter. Section III presents the filter design both dc side output [4] and ac side output [5]. Section IV presents implementation of HBC in MATLAB simulink with experimental and graphical results for different types of load.

II. Development of Hybrid Boost Converter

As mentioned earlier, the HBC is used in marine-craft power distribution, residential Nanogrids [7], hybrid electric vehicle [8], airplanes etc.

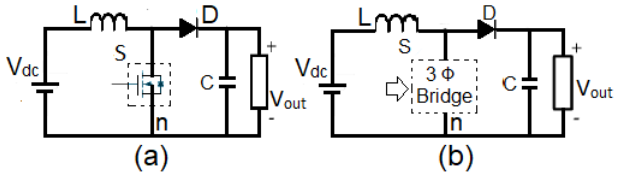

Fig. 1. Derivation of 3-ϕ HBC. (a) Traditional boost converter (b) Hybrid converter

The concept of HBC is as shown in figure 1. In Fig. 1(a), the traditional boost converter having a controlled switch S is shown.

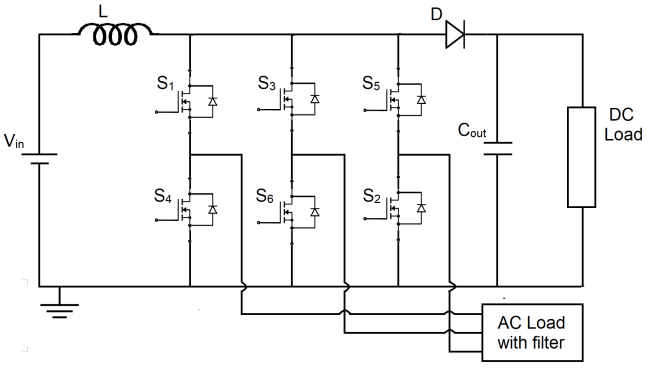

Fig. 2. Three phase hybrid converter

In case of 3ϕ HBC shown in Fig. 1(b), the three phase bridge circuit takes the place of controlled switch S. The resulting scheme shown in figure 2 is used to produce 3-ϕ ac and dc outputs.

A. Steady state operation

The regulation of both ac and the dc outputs is done by six switches of 3-ϕHBC. Converter operation can be explained through three operating intervals during its switching interval relied upon the switching states of all the six switches [2]. By turning ON both the switches of a particular limb of inverter simultaneously, the boost operation of HBC can be realized. This is similar to the condition of shoot-through, which is prohibited in traditional VSI.

The operating conditions and related intervals of the HBC are explained in this section and for entire analysis, the mode of operation assumed is continuous mode.

1) First interval : Shoot through (ST) $[(t_j - t_a)\&(t_e - t_f)]$*:* According to phase voltage magnitude, two switches of a specific leg are both turned on during this interval. The equivalent circuit diagram of hybrid converter during its first interval is shown in figure 3.

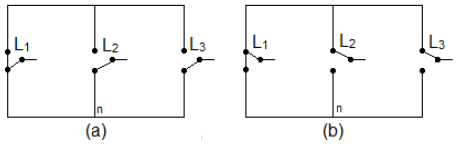

Fig. 3. Shoot through interval

Regulation the dc output is done by controlling the time duration of this interval, termed as D_{st}. This interval of HBC is analogous to the boost converter's diode 'D' being reverse biased while controlled switch being on [2]. In the first interval, the inverter output current circulates within the 3ϕ bridge circuitry. Therefore, the HBC enables an additional state that is prohibited in a VSI.

2) Second interval : Power (P) $[(t_b - t_d)\&(t_g - t_i)]$*:* In this interval any bottom or top switch of a leg and the opposite two switches of remaining legs is 'on' as shown in figure 4.

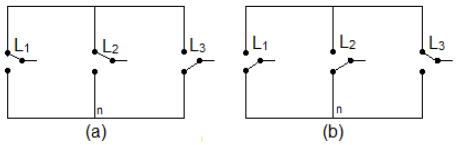

Fig. 4. Power Interval

During the second interval, the power is supplied from the source to the 3-Φ ac load. The diode D is conducting during the second interval, and 3ϕ ac current flows to the ac load [2].

3) Third interval : Zero (Z) $[(t_a - t_b), (t_d - t_e), (t_f - t_g)\&(t_i - t_j)]$*:* In the zero interval of HBC, either all the upper or all the lower switches of 3ϕ bridge network are kept 'on', as shown in figure 5.

The inductor which was charged during previous interval gets discharged during this interval. The diode D is conducting at this time and current is circulated. The third interval occurs when the inverter current gets circulated within switches of 3ϕ bridge network and does not supply any load. The key

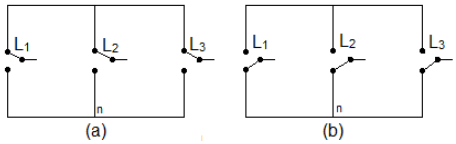

Fig. 5. Zero Interval

modification done in the states of switching is insertion of shoot-through period within the zero interval. Because of this alteration, there is no change or distortion in the magnitude or nature of ac outputs.

B. Modified pulse width modulation technique

For the purpose of regulation and control of HBC output a befitting PWM technique is described in this section and is shown in figure 6. For the 3ϕ HBC, a modification in

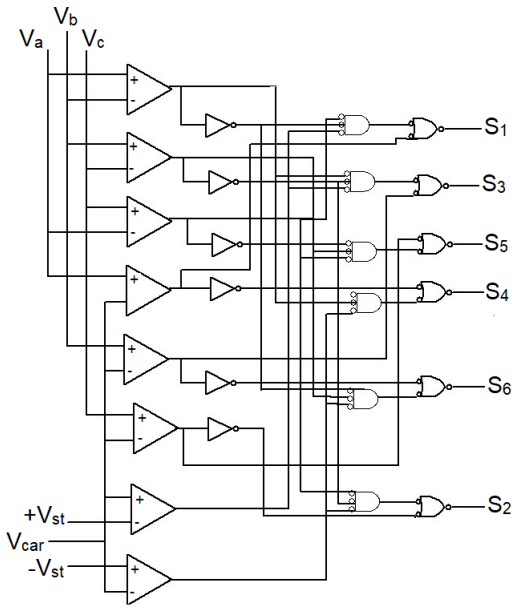

Fig. 6. Modified PWM control strategy based gate pulses for the 3-Φ HBC.

the traditional sinusoidal pulse width modulation scheme is given. This modified SPWM control strategy have a constant frequency shoot-through interval and is termed as CFST-SPWM technique [2].

In this modified PWM technique, the performed shoot-through period depends upon the relative voltage levels of the respective phases. Figure 7 shows the gate pulses obtained from the control logic where $v_a > v_b > v_c$ are the respective voltages of the three phases.

In the illustration shown in figure 7, switches S_1 & S_4 goes in shoot-through mode. To regulate and control both the 3ϕ

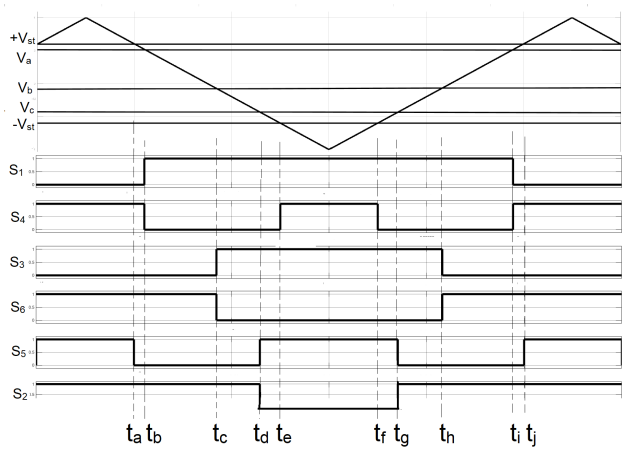

Fig. 7. Modified PWM control strategy for the 3-Φ HBC.

ac and dc outputs some references are required for generating gate pulses: v_a, v_b & v_c are the three reference ac signals which decides the modulation index and helps regulating the 3ϕ ac outputs. Magnitude of $+V_{ST}$, and $-V_{ST}$ are decided by the shoot-through duty cycle which controls the dc output.

III. Filter Design

Three phase voltage source inverters (VSI) are used widely In most of the grid connecting applications. The distorted grid current affects the performance of VSI. The use of power converter devices is very vital in enhancing power transmission from source to the utility grid. Harmonics are the main factors causing problems to apparatus and the loads connected to it, substantially for the applications above several KW, where the appraise of total harmonics distortion (THD) and filters is also an important regard in the systems designing. LCL filter has come into wide use in the grid connected inverter applications. What is the most difficult is that how to select the parameters and control the resonance [5].

A. DC-DC converter side

1) Boost Converter: A boost converter is used to step-up a dc voltage. The output voltage of boost converter is greater than the input voltage. The amplitude of the output voltage rely on duty cycle [4].

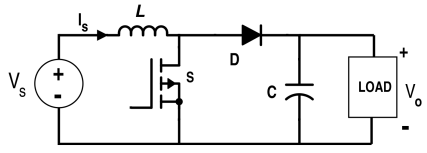

Fig. 8. Boost converter.

Figure 8 shows boost converter scheme. When 'S' is turned off, the inductor gets charged and energy is stored in it. If the switch opens, the energy stored in inductor is given to the load through diode 'D'.

The total power is conserved at the both ends, despite stepping up or stepping down of voltage level. The law of a conversion of energy can be expressed as,

$$Input\ \ power(P_{in}) = Output\ \ power(P_{out}) \tag{1}$$

The o/p voltage should be greater than i/p voltage ($V_{out} > V_{in}$) for the step up mode. Therefore the output current is less than the input current.

$$V_{in} < V_{out}\ \ and\ \ I_{in} > I_{out} \tag{2}$$

The voltage across inductor is,

$$V_L = L\frac{d_i}{d_t} \tag{3}$$

The ripple current in the inductor can be given as follows,

$$\Delta I = \frac{V_s}{L} \tag{4}$$

2) Necessary Parameters for the calculation: Following are the necessary parameters while calculating input inductor and output capacitor values [4]:

1) Input Voltage: V_{in}
2) Output Voltage: V_{out}
3) Max. Output Current: $I_{OUT(max)}$

After getting these parameters, calculation can be done as follows.

3) Determination the duty cycle: First it is essential to determine operating duty ratio D, for a particular level of input voltage.

$$D = 1 - \frac{V_{in} \times \eta}{V_{out}} \tag{5}$$

Where, $\eta =$ Converter efficiency, estimated value is 85 %

4) Input inductor selection: A fine estimate of the inductor ripple current is 20 % to 40 % of the obtained output current.

$$\Delta I_L = 1 - (0.2\ \ to\ \ 0.4) \times \frac{V_{out}}{V_{in}} \tag{6}$$

The calculation for the input inductor can be done as follows,

$$L = \frac{(V_{in} \times (V_{out} - V_{in})}{\Delta I_L \times f_s \times V_{out}} \tag{7}$$

Where, $f_s = Switching frequency$

5) Output capacitor selection: To calculate the appropriate output capacitor, following equation can be used [4].

$$C_{out} = \frac{(I_{out} \times D)}{f_s \times \Delta V_{out}} \tag{8}$$

Where, ΔV_{out} is the ripple in output voltage, we can take upto 1% of V_{out}

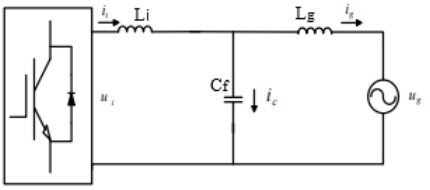

Fig. 9. LCL filter.

B. DC-AC converter side

Nowadays LCL filter is used replacing the traditional L-filter to get a ripple-free output current. The ability of LCL filter to lessen the amount of current distortion, makes it suitable for grid connected inverter systems [6].

A significant reduction in the total harmonic distortion (THD) can be obtained with the help of a LCL filter. Not only it lowers the current ripple across the inductor, but also it prevents direct coupling between filter and grid impedance. Hence, a suitable LCL filter is chosen for our application [5].

1) Essential Parameters for the calculation: Following are the essential parameters for calculating the filter parameters:

1) Inverter Output power: P_n
2) Expected inverter output voltage: E_n
3) Input voltage: V_{dc}
4) Switching frequency: f_{sw}
5) Operating frequency: f_n

2) Base values for inverter: While designing the LCL filter some base values are taken as reference and the LCL filter parameters will be determined in a percentage of it. The base capacitance and base impedance are calculated as follows. Thus,

Base impedance:

$$Z_b = \frac{E_n^2}{P_n} \tag{9}$$

Base capacitance:

$$C_b = \frac{1}{(w_n \times Z_b)} \tag{10}$$

3) Inverter side inductance: While designing the LCL filter components, first we will design the inverter side inductance. This inverter side inductor will suppress the current ripple by a significant percentage. It can be calculated as follows [6],

$$L_i = \frac{V_{dc}}{(16 f_s \times \Delta I_{Lmax})} \tag{11}$$

where, ΔI_{L_max} is the ac output current ripple which can be given as follows,

$$\Delta I_{L_max} = 0.1 \frac{\sqrt{2} \times P_n}{E_n} \tag{12}$$

4) Filter capacitance: To design the filter capacitance, the base capacitance value is taken as reference and value for filter capacitance is calculated as follows,

$$C_f = 0.05 \times C_b \tag{13}$$

Here, the estimated power factor variation seen is taken as 5%.

5) Load side inductance: Load side inductance is taken as r fraction of inverter side inductance and is calculated as follows,

$$L_g = r \times L_i \tag{14}$$

6) Resonant frequency: The calculation for resonant frequency for the L-C-L filter can be done as follows,

$$f_{reso} = \frac{1}{2\pi} \times \sqrt{\frac{L_i + L_g}{L_i \times L_g \times C_f}} \tag{15}$$

7) Damping resistance: To avoid resonance, the filter capacitor is kept with a damping resistor in series. It can be given by following equation [5],

$$R_d = \frac{1}{3\omega_{res} \times C_f} \tag{16}$$

Following are the system parameters obtained and used for implementation of HBC in MATLAB Simulink.

TABLE I
SYSTEM PARAMETERS

	Parameters		Parameters
DC	V_{in}=48V	AC	P_n=15W

IV. IMPLEMENTATION OF HBC IN MATLAB SIMULINK

Implementation of HBC is done in MATLAB Simulink along with the designed filter. The simulation results are taken for different types of loads. The effect of variation of modulation index and duty cycle are plotted in a graphical manner.

A. Load parameters of System

Following are the system load parameters used while developing and implementing the HBC.

TABLE II
LOAD PARAMETERS OF SYSTEM

	Parameters
DC load	R_{dc}=50ω
Resistive ac load	R_{ac}=50ω
Inductive load	R_{ac}=50ω ; L_{ac}=19.49mH

B. Simulation Results

By using the given system parameters, the simulation is done in MATLAB simulink for resistive load and inductive load. The simulation results are illustrated in fig 10, fig 11 and fig 12 for inductive load on HBC with filter. Fig 10 shows dc output current & dc output voltage for input voltage of 48V. The modulation index and the shoot through duty cycle taken for this particular simulation result are 0.55 and 0.4 respectively.

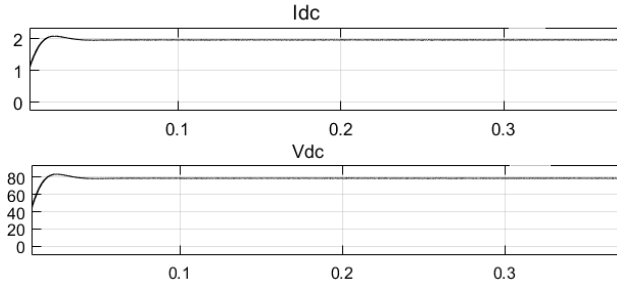

Fig. 10. DC Output of 3ϕ HBC.

Figure 11 illustrates the ac outputs i.e. phase current, phase voltage and line voltage where the dc input is 48V. In figure 12 FFT analysis window is displayed which gives THD in phase voltage which is approximately 1.55 %

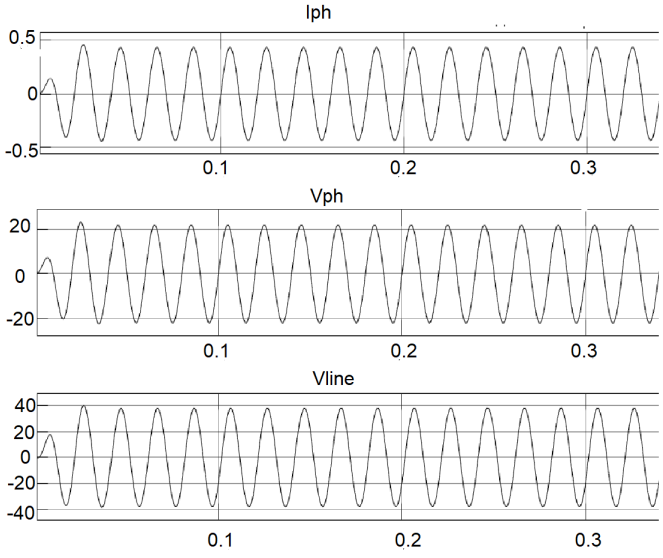

Fig. 11. AC Output of 3ϕ HBC.

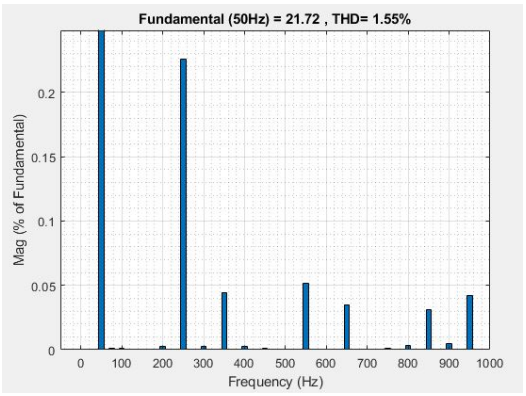

Fig. 12. THD in phase voltage of 3ϕ HBC

C. Graphical results

For different loadings, the observations are taken and results are plotted for the particular type of load. The objective is to see the effect of change in modulation index and change in shoot through duty ratio on both the outputs (dc output and ac output).

1) Resistive load without filter: First we vary the modulation index by keeping D_{st} constant and then we vary D_{st} by keeping the modulation index constant. By taking the observations as shown in above tables, we plot the graphs for THD V_s M, V_{dc} V_s M, and V_{ph} V_s M by varying modulation index as shown in fig 13(a) and THD V_s D_{st}, V_{dc} V_s D_{st}, and V_{ph} V_s D_{st} by varying shoot through duty cycle (D_{st}) as shown in fig 13(b).

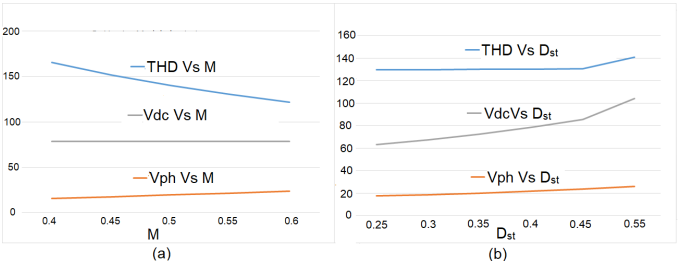

Fig. 13. Resistive load without filter (a) By varying M. (b) By varying D_{st}.

2) Resistive load with filter: After getting the observations for the simulation without using filter, the LCL filter designed in section III is used further. Here We plot the graphs for THD V_s M, V_{dc} V_s M, and V_{ph} V_s M by varying modulation index as shown in fig 14(a) and THD V_s D_{st}, V_{dc} V_s D_{st}, and V_{ph} V_s D_{st} by varying D_{st} as shown in fig 14(b).

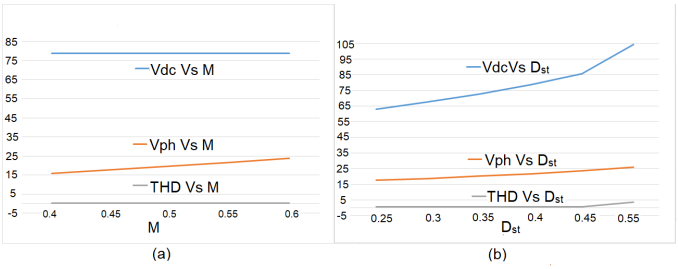

Fig. 14. Resistive load with filter (a) By varying M. (b) By varying D_{st}.

3) RL load with filter: First we vary the modulation index by keeping D_{st} constant and then we vary D_{st} by keeping the modulation index constant.We plot the graphs for THD V_s M, V_{dc} V_s M, and V_{ph} V_s M by varying modulation index as shown in fig 15(a) and THD V_s D_{st}, V_{dc} V_s D_{st}, and V_{ph} V_s D_{st} by varying D_{st} as shown in fig 15(b).

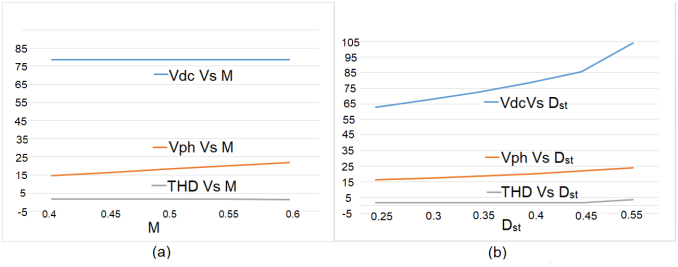

Fig. 15. RL load with filter (a) By varying M. (b) By varying D_{st}.

V. Steady State Analysis

For the purpose of steady state analysis of HBC, the mode of operation assumed is continuous conduction. The step-up dc output voltage is related to the dc input voltage as follows [2],

$$\frac{V_{dcout}}{V_{dcin}} = \frac{1}{1 - D_{st}} \tag{17}$$

For the modulation index 'M', relation between the ac output line voltage and dc input voltage can be given by following expression,

$$\frac{V_{acout}}{V_{dcin}} = 0.612 * \frac{M}{1 - D_{st}} \tag{18}$$

From the relations (17) and (18), it can be concluded that the shoot through duty cycle D_{st} regulates only the dc output and modulation index M regulates the ac output. Compared to the modulation index, if the variation of D_{st} is assumed to be small, then independent control of both the outputs can be achieved [2]. The magnitude of the input current of a HBC can be given by,

$$I_{dcin} = I_L = \frac{V_{dcout} I_{dcout} + 3 V_{ph} I_{ph} cos\phi}{V_{dcin}} \tag{19}$$

where, V_{ph}, I_{ph} and cosϕ are the ac output phase voltages, phase currents and load power factor respectively and V_{dcout}, I_{dcout} are the dc output voltage and output current respectively.

Expressions (20) and (21) show the expressions for dc and ac output power for the HBC [2]. Here, the loads at the dc and ac outputs are considered purely resistive, and equal to R_{dc} and R_{ac}.

$$P_{dc} = \frac{V_{dcin}^2}{R_{dc} * (1 - D_{st})^2} \tag{20}$$

$$P_{ac} = \frac{3 M^2 V_{dc_i n}^2}{4 R_{ac} * (1 - D_{st})^2} \tag{21}$$

In HBC, both the dc and ac outputs are regulated using two control variables within the same switching period. Hence, for independent control of each output, following relation must be satisfied [2].

$$M + D_{st} \leq 1 \tag{22}$$

VI. Conclusion

A three phase hybrid converter with ac and dc outputs in simultaneous manner is simulated. From the above observations and simulation results, it can be easily concluded that the HBC topology is advantageous over conventional multi-converter based topologies. It exhibits immanent shoot-through protection capability. In HBC switching loss is minimized by integrating a dc-ac converter and boost converter into a single converter architecture. The simulation results shows the potency of the modified PWM technique. DC output is regulated by D_{st} and is dependent only upon D_{st}. AC output is regulated by M and is dependent upon both M and D_{st}.

***Abstract*—The principle thought behind the sentiment analysis is to predict the emotions or opinions of the general population towards a specific subject from organized, semi-organized or unstructured literary information. With the rapid growth of internet, people around the world are increasingly passionate about expressing their emotions and opinions on the internet. Most of the industries and organizations formulate significant decisions based on customer reviews available on social websites. Due to the fast advancement in text data processing, sentiment analysis has turned into a significant research direction in Natural language processing (NLP). In recent days, the popularity of the deep learning techniques is also gaining attention which in turn contributes to enhancements in existing sentiment analysis techniques. In this paper, we perform analysis of movie reviews using a combination of deep learning techniques, LSTM and CNN. CNN is a commonly used deep learning method used for feature learning. LSTM is a unique sort of RNN, which is equipped for adapting long term conditions. This model allows remembering of information over a much longer period. We apply two different deep learning models to classify IMDB movie reviews. The first model is a hybrid LSTM- CNN and second is hybrid CNN-LSTM. We found that LSTM-CNN model outperformed CNN-LSTM model with an overall accuracy of 79%.**

Keywords: CNN, Deep Learning, Machine Learning, LSTM, RNN

I. INTRODUCTION

Due to the popularity of internet and new technologies, the measure of data delivered by humanity is developing quickly every year. Big data refers to collection of large datasets that cannot be processed using traditional computing techniques. Huge information isn't simply information; rather it has turned into a total subject, which includes tools, techniques and frameworks. It utilizes predictive analytics, client behavior analytics, or certain other propelled data analytics techniques that extract valuable information from data. This is known as big data analytics. The essential objective of big data analytics is to help organizations settle on progressively educated business choices by empowering data scientists, predictive modelers and other analytics professionals to analyze huge volumes of data, just as other types of data that might be undiscovered by conventional business intelligence (BI) programs.

Analysis of sentiment has become an important research direction in the processing of natural language. The main idea behind the sentiment analysis is to predict people's emotions or opinions from structured, semi structured and unstructured textual data towards a particular topic [1]. The text data contains human more elevated level sentimental characteristics. With the quick development of internet, individuals around the world are progressively passionate about communicating their feelings and opinions on the web. Most companies and enterprises analyze customer satisfactions based on their reviews on various social internet sites. In most organizations, more than 75 percent of information is about how customers engage with the product. Tracking this relationship using text mining is essential when designing major tactics in any company. The large user-generated content requires the use of automated text mining and analysis technique as crowd sourced mining and analysis are often filled with errors, expensive and scale- free. In the early days people will seek opinions from colleagues, relatives and neighbors before purchasing an item or service. In recent days, people will get opinions from various social websites. For example, if a person wants to buy a new mobile manufactured by a particular company and he/she require the mobile with best camera clarity. Suppose he/she finds a review like, "The picture clarity of this mobile is very bad and doesn't provide zooming option properly", the user can opt for another mobile since the opinion is negative. In such situations, sentiment analysis plays a crucial role.

Sentiment analysis is done with the help of machine learning, which is an application of artificial intelligence (AI) that gives frameworks the capacity to automatically learn and improve from experience without being explicitly customized. The fundamental reason of machine learning is to construct algorithms that can take input information and utilize statistical analysis to foresee an output while refreshing output as new information becomes available. Deep learning is a data mining process [2]using deep neural network architecture, that are specific types of artificial intelligence and machine

learning algorithms that have become extremely important in recent years. Deep learning enables us to teach machines how to finish difficult tasks without coding them explicitly to do so. Machine learning methods detect the pattern available from given set of text data automatically. Deep learning is an advancement of machine learning.

This paper is to use deep learning techniques such as Convolutional Neural Network (CNN) and Long Short Term Memory (LSTM) network to analyze film reviews. Recently, deep learning methods have shown good results across different NLP tasks. We apply two different deep learning models to classify IMDB movie reviews. The first model is a hybrid LSTM- CNN and second is hybrid CNN-LSTM. We found that LSTM-CNN model outperformed CNN-LSTM model with an overall accuracy of 79%. Hybrid CNN-LSTM and LSTM-CNN architectures are implemented on the data set and results are compared.

II RELATED WORKS

Sentiment analysis method can be split into dictionary based and machine learning based. Two types of dictionary based methods are WordNet and Senti WordNet. WordNet is a lexical English language data base that combines English words with synonyms called synset. It distinguishes nouns, verbs, adjectives and adverbs. Next is the SentiWordNet is a WordNet extension. For each WordNet synset, Senti WordNet sets positive and negative sentiment scores. Using a positive and negative score, the object score can be calculated. We obtain object score as a summation of positive score and negative score subtracted from 1.Tokenization,speech tagging ,word sense disambiguation (WSD),Senti WordNet interpretation, sentiment orientation and tweet classification are used to perform dictionary based methods [3].Dictionary based approaches major downside is the inability to evaluate opinion words with domain and context.

Machine learning methods are categorized into two, supervised learning techniques and unsupervised learning techniques. Supervised learning uses labelled training documents. Training data includes a pool of training examples. Each example of supervised learning consists of an object of input and a value of output. Unsupervised methods of learning don't use the documents labelled. They create use of the statistical properties of the document for example, word co-occurrence, existing dictionaries with passionate words and natural language processing. Natural language or human objects such as photographs, news articles and audio recordings are unlabelled data, whereas each set of unlabelled data with meaningful tags is labelled data. For example, photo is an unlabelled data but that photo is an elephant that is labelled data.

Various machine learning methods [4] are used for classification of sentiments but are associated with certain disadvantages. For example commonly used machine learning methods are Support vector machine (SVM), Maximum entropy (ME) and Naive Bayes (NB) everyone has advantages and disadvantages. SVM and ME are complex models that take longer train. Naïve Bayes approach does not take the word order from the text input and therefore leads to a less accurate model. Another method of modeling is n-grams, but this has a fixed range and cannot be learned for long-term dependencies. Also, these approaches often refuse to categorize sentences with negation. Using deep learning methods, these problems are overcome.

A future where in machines will do many of the jobs right now being finished by people previously, we'd need to expressly program a PC well-ordered how to take care of an issue. A lot of if-then statements, loops, and logical operations were involved. Later on, machines will show themselves how to take care of issues; we simply need to give the information. Give us a chance to find out about the methods that enable profound figuring out how to take care of an assortment of issues. Deep learning is a data mining process using deep neural network architecture, that are specific types of artificial intelligence and machine learning algorithms that have become extremely important in recent years. Deep learning enables us to teach machines how to finish difficult tasks without coding them explicitly to do so. Machine learning methods detect the pattern available from given set of text data automatically. Deep learning is an advancement of machine learning.

By far most of studies have used SVM, Naïve bayes and other conventional strategies, which subject to physically labelling of a ton of energetic qualities, anyway paid a surprising expense. Hadi Pouransari et al [5] utilized the dataset given by Kaggle and connected the bag of words, and skip-gram word2vec models to represents words numerically. We at that point utilized a few classifiers, including random forest, SVM, and logistic regression to play out the binary classification task. The authors facing one of the difficulties is to aggregate word vectors into a solitary element vector for each review. We attempted vector averaging, and grouping to deliver the aggregated feature vectors. Be that as it may, these experience the ill effects of losing the order of words in sentences.

To improve this situation, Liu Yanmei et al [6] additionally examined deep learning and Micro-blog sentiment analysis, and introduce deep learning CNN with SVM classifier. This Framework maintains a strategic distance from issues because of the explicit feature extraction however numerous troubles are looked in emotional analysis utilizing deep learning. Creator doesn't discover great answer for this. This paper exhibits that, this structure is great to upgrade the exactness of sentiment analysis, anyway there are up till now various issues in the investigation of emotional analysis using deep learning, the accompanying stage will be to also think about the deep learning systems for finding a progressively sensible sentiment analysis.

Yaya Heryadi et al [7] use CNN, Stacked LSTM, and CNN-LSTM models to find fraudulent card transaction. In this paper obtain both short-term and long-term transaction pattern with the help of CNN and LSTM. Results of the experiment showed that CNN is more robust than SLSTM and CNN-LSTM as an imbalanced dataset classifier. It is further assumed that CNN layers contribute to the CNN-LSTM model's high performance.

Alec Yenter et al [8] This work utilize the benefits of both CNN and LSTM.CNN goes about as a good feature learner yet CNN doesn't catch long term dependencies .This issue defeat with the assistance of LSTM.LSTM layer is stacked above of convolutional layer. Output of the convolutional layer served as an input to the LSTM. While over fitting was a challenge for most forms of the model, appropriate layers and parameters had the option to decrease the disintegration and achieve new accuracy on the dataset.

III BACKGROUND

Basis of deep learning method is an Artificial Neural Network (ANN).An ANN is an information processing system that is simulated through biological nervous systems, meaning it contains lots of neurons, which are the key element of this paradigm and information about processes. An ANN is designed through a learning process for a particular application, e.g. hidden pattern recognition or data classification. Artificial neural network comprise of 3 layers named as input layer, hidden layer and output layer. Input layer, which connects to the input vector and output layer, which relates to the output vector. Moderate layer is called hidden layer, which play out some calculation with the assistance of some activation functions. Essential computational element of neural network is called activation function. Generally utilized activation functions [9] are sigmoid function, hyperbolic tangent function (tanh), or rectified linear function (ReLU). A line between two layer is indicates an association for the progression of data. Every association is related with an value is called weight, that controls the signal between two neurons. The common deep learning methods used for sentiment analysis are discussed here.

1) Convolutional Neural Network (CNN)

Convolutional neural networks [9] are deep neural networks that are utilized basically to classify pictures (for example name what they see), cluster them by similitude (photograph seek), and perform object recognition inside scenes. They are algorithms that can distinguish faces, people, road signs and many other different parts of visual information. The viability of convolutional net in image recognition is one of the principle reasons why the world has woken up to the adequacy of deep learning. Recently CNN can also be applied to text analysis.

CNN model comprises of one input layer, multiple hidden layers which are convolutional layers, pooling layers, fully connected layers, and one output layer. CNN contain some Convolutional layers that apply a convolution task to the input, and the outcome is going to the following layer. Convolutional layer contains different filters that do convolutional action. The filter is extremely an assortment of number or weights. After convolutional operation we get numerous number of feature maps. Next comes the pooling or down sampling layer, which comprises of applying some activity over regions in the input feature map and removing some delegate an incentive for every one of the examined regions. The pooling operation is utilized to consolidate the vectors coming about because of various convolution windows into a single dimensional vector. Finally the yield is goes to the fully connected layer of neural system for classifying.

2) Long Short-Term Memory (LSTM)

LSTM is a sort of Recurrent Neural Network (RNN)[8]. In conventional Neural Networks, all data sources are independent of each other. While this methodology is wasteful for certain assignments in NLP for this situation it is critical to realize the past word so as to foresee the following word in context. LSTM neurons have an association with the past neuron state notwithstanding the layer inputs. It's demonstrated extraordinary achievement in numerous NLP tasks. LSTM units have a memory which catches data in subjective, long sequences. The LSTM model comprises of memory cells to keep up information over extensive stretches of time with the assistance of gating units. The gating units are choosing what information to store and when to apply that information. Every memory cell isolated in to 3 gates named as input gate, forget gate and output gate.

Every one of the neural networks handles one time step. Rather than bolstering the information at every individual time step, you give information at all-time steps inside a window, or a context, to the neural network. The cell is in charge of monitoring the dependencies between the components in the input sequence.

IV PROPOSED WORK

In this area, we include the details of two proposed deep learning architecture hybrid CNN-LSTM and LSTM-CNN method. Proposed method comprises of pre-processing module, embedded module, feature extraction module and classification module.

A) Existing Method

Figure1 shows the architecture of CNN-LSTM method. Abdalraouf Hassan [10] et al introduces a deep convolutional and recurrent layer approach for sentiment classification. In this paper, Maxpool layer is replaced with recurrent layer in order to catch the long term dependencies. We are implementing CNN-LSTM framework without replacing the maxpool layer.

a) Text Reviews

System input consists of reviews of movies. Only English reviews are included, and there is a white space around punctuation such as period, bracket, and commas.

b) Pre-Processing
To improve the performance of our model we need to perform pre-processing steps. To begin with, we performed data pre-preparing steps on the dataset before bolstering them into the deep learning model. We expelled punctuations, stop words, brackets numbers and also perform stemming by using regular expressions. After cleaning the dataset next perform tokenization with the help of tokenize API. Tokenization is the process of converting words into a unique integer. Then we created a vocabulary to map these words into a integer.
c) Embedded Layer
Embedded layer takes the input text reviews as a sequence of words and embeds each word into a vector of a particular size

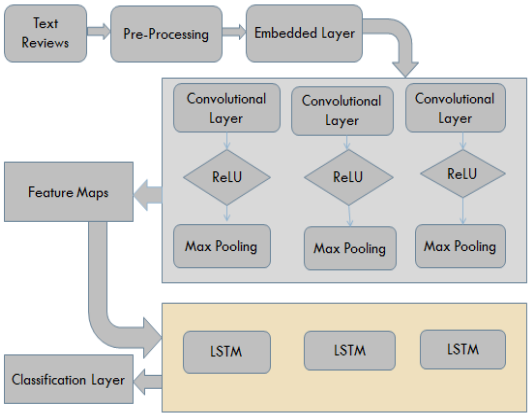

Figure 1 : Existing CNN - LSTM Architecture

d) Convolutional Layer
Convolutional layers can obtain feature horizontally from multiple words. For classification tasks, these characteristics are essential .Convolutional layer that will take word embedding as input. Numerous convolutional layers apply a convolutional operation to the input; the outcome is going to the following layer.
e) Max Pooling Layer
Pooling layer is likewise called sub sampling layer, which can minimize the number of features and the computational intricacy of the system. Sub sampling step retain most significant data.
f) LSTM Layer
Extracted features are classified with the help of LSTM layer. It is a special kind of RNN, which is equipped for adapting long term dependencies. LSTM's viability is its capacity to catch changing sentiments in a tweet. That has a memory that "remembers" previous data from the input and makes decisions based on that knowledge. The layer's steadiness permits learning of past info to impact subsequent input.
g) Classification Layer
Fully connected layer acts as a classification layer. The LSTM outputs are then fed to a Fully Connected Layer (FCL) which was built using Keras dense layer. A simple sigmoid activation function follows this layer to confirm the output somewhere in the range of 0 and 1.

B) Proposed Method
Proposed system used IMDB movie review dataset which contains positive movie reviews and negative movie reviews. The system is implemented in Anaconda(Python Distribution).Keras is used to implementing deep learning layers .It is an easy to use and powerful python library for deep learning. Tensor flow is set as a backend of Keras and Matplotlib is used to analyse the graph. Windows 8.1 is the Operating System. The system in which it is implemented is a 64 bit system with Intel Pentium CPU and 4 GB memory.

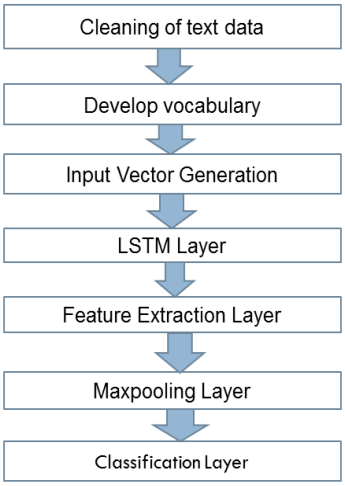

Figure 2 :Flow Diagram of LSTM-CNN Architecture

a) Cleaning of Text Data
Input of the system consists of text movie reviews. It is comprised only English reviews and there is a blank space around punctuation like period, bracket and full stop. This text data need a cleaning that implies remove punctuation from words, evacuate tokens that are simply accentuation, expelling tokens that contain numbers, expelling tokens that have one character and evacuate tokens that don't have much significance with the help of a regular expression.
b) Develop Vocabulary
We joined each review sentences as a string and split the sentences to make a list of all the individual words that appeared in the dataset. Then, we created vocabulary to map these words to integers. Each words in the vocabulary represented by a unique integer. We can keep track of the vocabulary in a Counter, which is a lexicon of words and their count with some additional convenience functions. Then needs to add every one of the tokens to counter and update count with the assistance of an update function. Then needs to add all the tokens to counter and update count with the help of an update function on the counter object.
c) Input Vector Generation
Input vector generation done with the help of an embedding layer [11]. the model will take as input an integer matrix of size (batch, input length).Embedding layer design with the help following function *" Model. Add (Embedding (vocab*

size, 100, input length))". Here, vocab_size indicate the magnitude of the vocabulary, 100 indicate the magnitude of embedding vector and input_length indicate length of input sequence.

d) LSTM Layer

LSTM is progressively viable to defeat the sequence data weakening issue when the text sequence data is somewhat long. Even though the input text sequence is long LSTM layer is able to capture long term dependencies efficiently. LSTM layer is designed with the help of LSTM function that contain 100 LSTM units represented as a *"model.add(LSTM(100,return_sequence=True)"*.Then,the LSTM output are fed to a convolutional layer

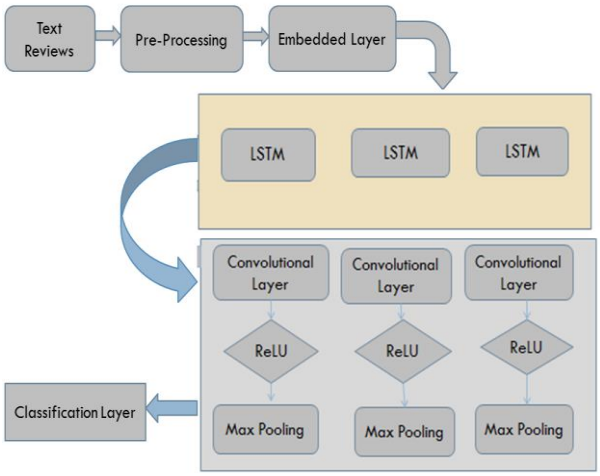

Figure 3 : Proposed LSTM-CNN Architecture

e) Feature Extraction

Convolutional layer acts as a feature extractor. Convolutional layer performs convolution operation with the help of filters. The filter is used to scan the input vector and get number of feature maps or activation map. Convolutional layer design with the help of following function *"model.add(Conv1D(filters=32, kernel size=8, activation='relu'))"*.Here filters indicate number of filters and kernel size represents size of the convolutional window. After convolutional task, applies a rectified linear unit (ReLU) activation function to the CNN layer's output. This layer substitute zero for any negative output. The output of this layer is a similar to input shape.

f)Maxpooling Layer

Subsampling layer is used to minimize the spatial size of the representation thus reduces the network computational complexity. Commonly used subsampling operation is maxpooling. Maxpooling layer retain most important feature maps or information and others are discarded. Maxpooling layer designed with the help of following function *"model. Add (MaxPooling1D (pool_size=2))"*

g) Dense Layer

Fully connected layer acts as a classification layer. The Pooled outputs are fed to a Fully Connected Layer (FCL) which was built using Kara's dense layer. A simple sigmoid activation function follows this layer to confirm the output somewhere in the range of 0 and 1.The final yield is a single output 0 which represents an adverse feeling and 1 represents positive feeling.

V RESULTS AND DISCUSSIONS

The proposed system uses IMDB movie review data set which contains 1000 positive reviews and 1000 negative reviews. For training and validation, we arbitrarily split the full training examples. Input dataset divided into two, training dataset and validation dataset. Keras provide two methods to evaluating deep learning model. First one is automatic verification of dataset and second is manual verification of dataset. Keras separate one portion of training data into validation data and then assess the performance of our model on that validation dataset on every epoch. Experiment used the following parameters which we fine-tuned through manual testing.

Embedding Dimension	100
Epoch	10
Filters	32
Kernel Size	8
Pool Size	2
Dropout	0.5

Table 1: Hyper parameters

A) Accuracy

The proposed LSTM-CNN network reached 79% accuracy in 10 epochs. Accuracy of the system is directly proportional to epochs.

	Epoch 10	Epoch 20	Epoch 30
	Average Accuracy	Average accuracy	Average Accuracy
LSTM-CNN	78%	79%	79.5%
CNN-LSTM	51%	51.5%	51.75%

Table 2: Comparison Table

From the Table 1 it is clear that LSTM–CNN model achieved a satisfactory accuracy score compared to CNN-LSTM model

B) Performance Analysis

Learning curves are widely used as performance analysis tool in case of deep learning. The model can be assessed on the training dataset and validation dataset. Graph that looks at the performance of a model on training and testing information over a fluctuating number of training instances. We should

generally observe performance improve as the number of training point's increments.

There are mainly two learning curves namely train learning curve and validation learning curve. If there should arise an occurrence of train learning curve, the learning curve is determined from the training dataset that gives a thought of how well the model is training. While if there should arise an occurrence of validation learning curve, the learning curve is determined from hold-out validation dataset that gives a thought of how well the model is generalizing. It is entirely expected to make double learning curves during training on both the training and validation dataset.

Here the horizontal axis denotes the Epochs while the vertical axis denotes the Accuracy and loss for the performance analysis of IMDB movie review dataset. Epochs represents the number of iteration taken by our project. Time taken by the method is directly proportional to epochs.

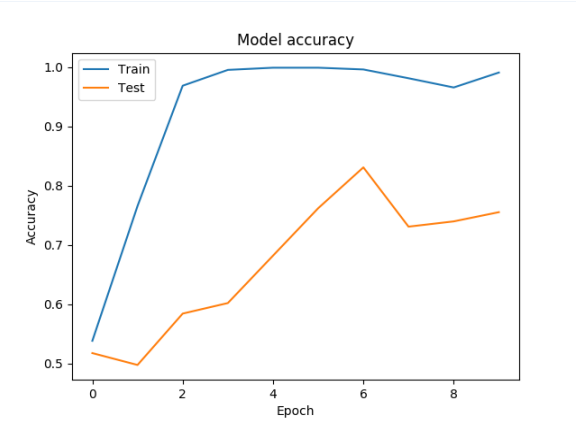

Figure 4: LSTM-CNN Accuracy

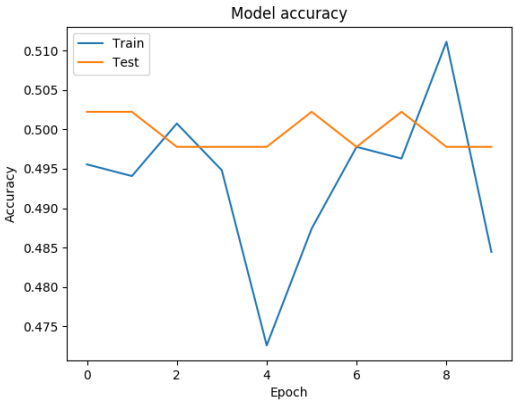

Figure 5: CNN-LSTM Accuracy

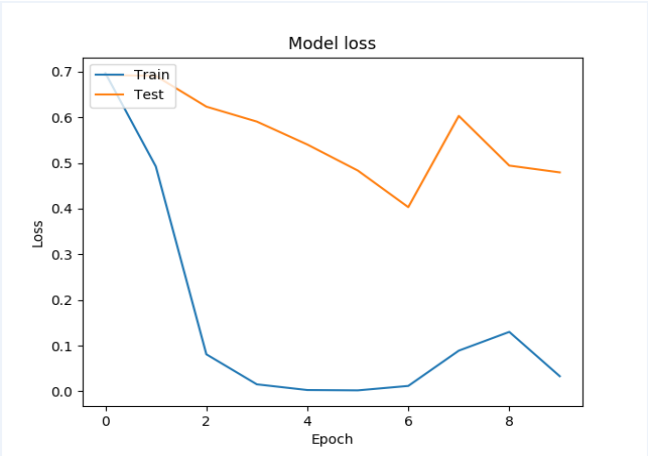

Figure 6: LSTM-CNN Loss

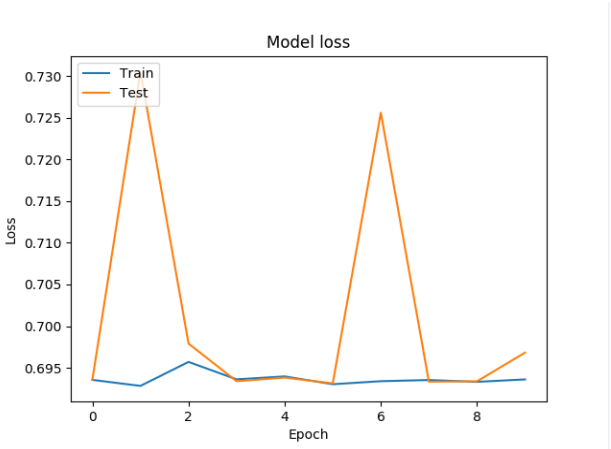

Figure 7: CNN-LSTM Loss

For each epochs during training, training accuracy and training loss as well as the validation accuracy and validation loss is calculated. Figure 4 and Figure 5 represents the LSTM-CNN and CNN-LSTM accuracy graph for IMDB reviews. LSTM-CNN accuracy graph shows great results in just 10 epochs compared with CNN-LSTM accuracy. In Figure 4, Curves indicate that the model is trained right. Figure 6 and Figure 7 represents the validation loss and training loss of both LSTM-CNN and CNN-LSTM model.

CONCLUSION

In day by day the velocity and volume of the text data increment rapidly. Sentiment analysis plays an important roles in our daily decision making process. Sentiment analysis is done with the help of various methods. In recent years deep learning methods provide better accuracy for sentiment classifications compared with traditional methods. Convolutional Neural Network acts as a good feature learner and extract features horizontally from various words. These characteristics are essential for classification tasks. Long Short Term Memory Network keeps long term dependencies in long sentences. LSTM's viability is its ability to catch changing sentiment in a tweet. That has a memory that "remembers"

past information from the input and takes decisions on that learning. Our framework utilizes the advantage of both CNN and LSTM.

In this project, we investigated two distinctive deep learning models for analyzing IMDB movie reviews. First is hybrid CNN-LSTM model and second is hybrid LSTM-CNN model. Our approach performed well on IMDB movie review dataset and achieved a better accuracy compared with other traditional models. In terms of future work, like to test other types of LSTMs (for example Bi-LSTMs) and CNN (for example multilayer CNN).In future this system implemented with a large datasets.

***Abstract*—** VoIP is Voice over Internet Protocol which is a real time application which allows transmitting voice through internet protocol. It provides various services from which one of the important services is phone service over dedicated IP network. The important quality which is perceived by the users of VoIP telephony is speech quality. The quality of speech is degraded by various factors such as packet loss, delay, jitter, etc. This paper concentrate in making better speech quality and to improve the MOS score by using standard PESQ over WIMAX system. Tool used for this purpose is MATLAB R2013b.

Keywords—VoIP, Codecs , MOS

I. INTRODUCTON

VoIP is one of the applications which provide better quality of experience to the users. VoIP uses internet as a medium to transmit for telephone calls to send voice data as packets using IP network instead of PSTN. This is because the main benefit of IP network is that it can able to carry 5 to 10 times voice calls than circuit switch network. VoIP technology has various advantages which includes large savings and provide scalability [1]. The disadvantage of VoIP is that it requires Internet connection with large bandwidth. There are various codecs that VoIP uses (i.e. G.711, G.729, G.722, G.723.1, G.726, G.728 etc).The codecs have three basic tasks such as Encoding and Decoding, Compression and Decompression, Encryption and Decryption. There are two common codecs which are used such as G.711 and G.729. G.711 require higher bandwidth than G.729 (i.e. 64 kbps whereas G.729 requires 8 kbps).

Table.1 Audio Codecs [1]

ITU no.	Rate[kbps]	Algorithm
G.711	64	Pulse Code Modulation
G.723.1	5.3/6.4	Multipulse maximum likelihood quantization/algebraic-code-excited linear prediction
G.726	16/24/32/40	Adaptive differential PCM
G.728	16	Low-delay code-excited Linear prediction
G.729	8	Conjugate-structure algebraic-code-excited linear prediction

.

II. WIMAX

WIMAX is World Interoperability for Microwave Access. It is 4G promising technology which brought many different changes in industry now-a-day. WiMAX provides two different type of services such as line of sight (LOS) and non line of sight (NLOS). The radio coverage distance if WiMAX is 50 kilometers and data throughput is 70 Mbps. WiMAX is IEEE 802.16 standard which is considered as Broadband Wireless Access (BWA) because of high speed, worldwide and cost effective access. WiMAX is also considered as Metropolitan Area Network (MAN). The main purpose for designing WiMAX model using AWGN channel to make system compatible with atmospheric conditions. The WiMAX model with AWGN channel involves the following such as [2]:-

- Randomizer.
- Convolution encoder
- Quadrature Amplitude Modulator.
- AWGN channel.
- QAM demodulator
- Viterbi decoding.
- De-randomizer.

Randomizer is basically used to convert a large signal into bits (0's and 1's) so that the performance of coding can be improved. Convolution encoder is the forward error correcting code which is used to correct the error during the transmission of data. Hence, the output of convolution encoder removes the additional bit from the encoded streams and also remove bits depends upon the code rate.QAM modulator is used to map the incoming bit-stream onto the Constellation. AWGN channel is the channel which adds white Gaussian noise to input signal (real or complex signal). Viterbi decoding helps to

decrease the computational load. It basically involves calculation how to measure the similarities and distance.

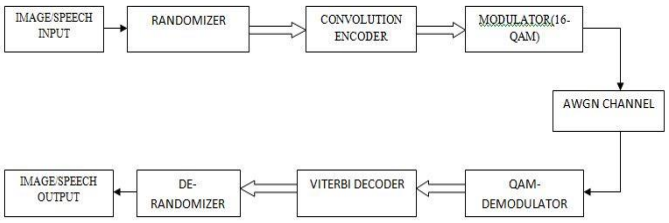

Figure 1.General Block Diagram of WiMAX

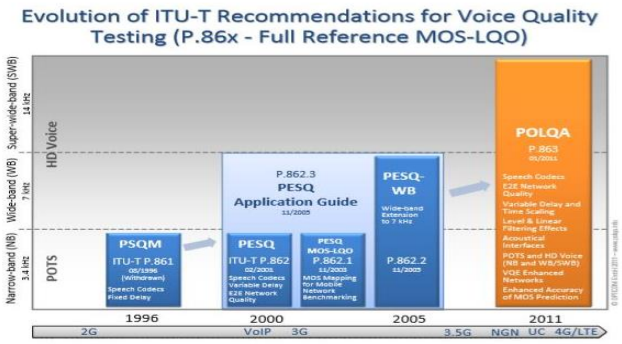

Figure 2. Perceptual Evaluation of speech quality [5]

III. PESQ AND MOS

MOS is considered as the most applicable test because it is person who uses voice network and whose opinion is counted. Basically, MOS is used to measure subject call quality for calls. The range for MOS score is 1 for unacceptable and 5 for excellent.

To calculate MOS value we have the following methods:

- PSQM.
- PESQ.
- POLQA.
- E-Model

The PSQM is Perceptual Speech Quality Measure which only assesses the speech codecs and does not have any proper account for filtering, variable delay and short localized distortions whereas PESQ uses this address with the equalization of transfer function alignment of time and new algorithm to average distortion over time [3]. PESQ is Perceptual Evaluation of Speech Quality. The PESQ speech quality uses 3.1 KHz. PESQ calculates the effect of one-way speech distortion and noise on speech quality. There are various effects such as loudness loss, delay, side tone, echo and so on , are considered as two-way communication which is not considered to calculate PESQ.

For PESQ, we consider an original signal x(t) and degraded signal y(t). Basically, PESQ compares the original signal with the degraded signal by passing the original signal over communication system. Hence, the PESQ output is the prediction of perceived quality given to the degraded signal by particular subjects in subjective listening test. The range of the P.862 score provided is -0.5 to 4.5. The mapping function from PESQ to MOS LQO is [4]:-

$$y = 0.999 + (4.999 - 0.999)/1 + e^{(-1.495x + 4.6607)}$$

Thus, the inverse function that allows the transformation to raw P.862score is given as:-

$$x = (4.6607 - \ln(4.999 - y)/(y - 0.999))/1.4945$$

IV. PROPOSED TECHNIQUE

FEC is the Forward Error Correcting technique which is used to correct and to detect the error i.e. there is continuous transmission of data, if errors are detected during the transmission and they must be corrected at receiver side. The work of FEC is to add the data at the transmitter side so that the one can receive the data without any error at the receiver side. The purpose of error correcting code is to improve the capacity of the data by the addition of some redundant nits while the data gets transmitted through the channel. It is very important in digital communication that data gets transmitted efficiently and reliably. There are various types of FEC codes such as:-

- Convolution code.
- Reed Solomon code.
- Linear Block code.
- Turbo code.
- Bose-Chaudhari-Hoequenghem code.

CONVOLUTION ENCODER

The work of encoding and decoding to translate the message that can be easily understood. Convolution code is the error correcting code which generates the parity symbol through the sliding application of Boolean polynomial function to stream of data.

VITERBI DECODING

Decoding is the inverse process of encoding i.e. encoded data is converted into the original state. The process of converting code to plain text or in any other format which is useful for further process is called decoding. The Viterbi algorithm is use for Viterbi decoding to decode the bit streams which are encoded using convolution encoding [6]. The Viterbi decoding

is consider as the most resource consuming. The constraint length that is used to decode the Convolution code is K<=10. But practically, the value that is used is K=15. There are three tasks for Viterbi decoder process are Branch Metric unit (BMU), Path Meteric Unit (PMU) and Trace back unit (TU).

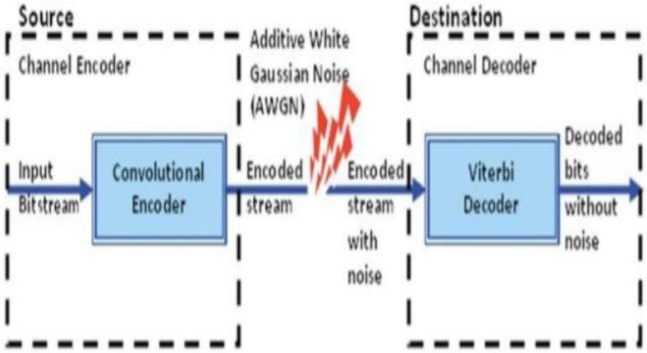

Figure 3. Convolution Encoder and Viterbi Decoder [6]

V. METHODOLOGY

1. At 8 bits per second, the audio signal (.wav) is processed.
2. At 8 KHz, sampling is done.
3. With the quantization level +0.5 and -0.5, the quantization is done.
4. Binary data (0's and 1's) is produced for the audio signal (Randomizer).
5. Convolution encoding is done on this binary data stream.
6. Then after the convolution encoding, the modulation is done and the signal is passed over AWGN channel.
7. At receiver side, demodulation and decoding is done to reconstruct the signal. For decoding, Viterbi decoder is used .
8. Once the decoding is done then signal is reconstructed.
9. Hence, PESQ is calculated and MOS value is obtained.

The following is the diagram of the methodology for transmitter section and receiver section [7] :-

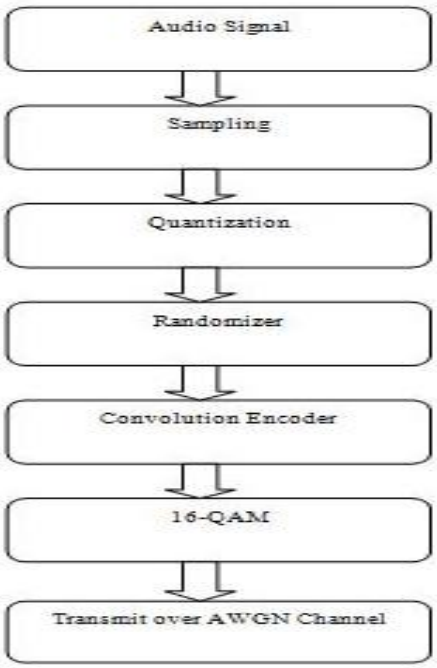

Figure 4. Transmitter Section

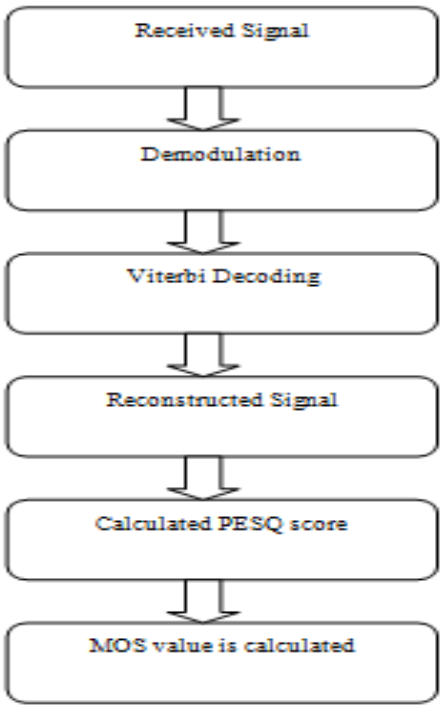

Figure 5. Receiver Section

VI. PERFORMANCE ANALYSIS

Here, the input parameters taken during the simulation process and the results are discussed below:-

A. Input Parameters

Table 2. Input Parameters

PARAMETERS	SPECIFICATION
n-bit PCM value	8
No. of samples/sec	8000
Max levels of Quantization	+0.5
Min levels of Quantization	-0.5
No. of Quantization levels	256
Modulation	16-QAM
Standard used to calculate MOS	PESQ

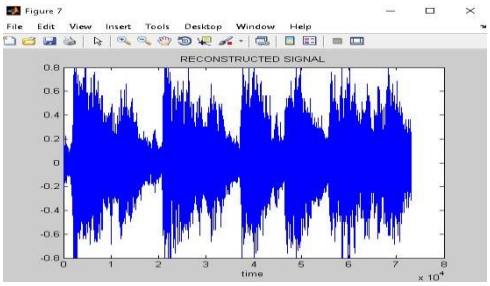

Figure 12. Reconstructed Signal

The simulation results of transmitting the signal using proposed algorithm over WiMAX system using AWGN channel in comparison with WIFI system (Rayleigh channel and Rician channel) are shown below:

Table 3. Comparison for AWGN and Different Fading Channels for proposed algorithm [7]

SYSTEM	PESQ	MOS
AWGN channel	4.500	4.548
Rayleigh channel	4.0498	4.2025
Rician channel	4.0118	4.1445

VII CONCLUSION

This paper is to provide better call quality at the output for VoIP. The same has been achieved using the proposed algorithm and there is an improvement in the voice quality at the receiver end which is determined by calculating the MOS. The MOS calculated for proposed algorithm is 4.548 which is compared which different fading channels and standard existing codecs. Hence, the proposed algorithm has been able to provide improved call quality at the receiving end using AWGN channel**.**

***Abstract*— Cognitive radio based internet of things is another new need of the hour as all the internet of things objects are not very expedient without holding cognitive capabilities. Cognitive radio is the only solution to the Issues like Spectrum scarcity and spectrum sharing, which are posing serious challenges to internet of things paradigm. This paper is a step forward in achieving the most optimal cognitive radio based internet of things system. For this, a recently developed optimization technique, named whale optimization algorithm is suggested for optimizing the transmission parameters of cognitive radio system by obtaining user defined QoS. The results obtained by whale optimization algorithm are compared with literature based biogeography based optimization, simulated annealing and genetic algorithm to ensure the utility and efficacy of whale optimization algorithm for cognitive radio system designing.**

Keywords—cognitive radio; internet of things; optimization whale optimization algorithm

I. INTRODUCTION (*HEADING 1*)

Internet of things (IoT) refers to a network of physical devices which are connected via internet for information exchange, bypassing any human interference. A complex network consisting of large number of physical devices requires a good amount of wireless spectrum to make communication possible [1]. Spectrum is limited. Advent of cognitive radio (CR) by joseph mitola [2] gave a ray of hope in solving spectrum problem by allowing the access of licensed band to even unlicensed user after avoiding interference. Hence a CR design is a handy tool for smooth implementation of IoT networks [3]. For generating the most efficient and effective CR enabled IoT, it becomes vital to begin with the optimality of CR system itself.

One of the ways of obtaining optimized design of CR system is to obtain the optimal values of its transmission parameters by aiming at certain objectives [4]. This is accomplished by using a number of optimization techniques available in literature. TR Newman first suggested this kind of work where he designed a cognitive engine using GA [5]. Later the same engine has been designed by many researchers using various techniques individually or in hybrid form [6-13]. Most of the CR systems discussed before have highlighted only two transmission parameters with an intention to fulfill three objectives. Present authors have suggested five transmission parameters and five objectives in a CR system design by using SA [14] and BBO [15], This paper focuses on use of another novel Whale optimization algorithm for CR system's optimal design that could blend with IoT.

Whale optimization algorithm (WOA) is another feather in the cap of mirjalili [16], who is parent to many other optimization techniques, including gray wolf optimization GWO [17], moth flame optimization MFO [18], ant lion optimization ALO [19], dragonfly optimization DF [20], SCA sine cosine algorithm [21], and SSA salp swarm algorithm [22]. WOA is inspired by humpback whales that create a bubble spring trap for their hunt. The provision of dedicating first few iterations to diversification and last few iterations to intensification makes it's a stable algorithm in terms of exploitation and exploration [16]. The successful implementation of WOA on many problems from diverse fields like economic dispatch [23], optimal power flow [24], image segmentation [25], neural network weights [26] etc. have persuaded the authors to design an optimal CR system using WOA.

Nest section of the paper illustrates WOA briefly, followed by CR problem definition in section 3. Simulation and results are discussed in section 4 with conclusion at the end.

II. WHALE OPTIMIZATION ALGORITHM (WOA)

Whales, the largest mammals on the earth are the smartest creatures after humans, even at par to humans. Whales have now inspired even an optimization algorithm too, named Whale optimization algorithm by mirjalili [16]. Out of their variant species, humpback whales are of interest to this algorithm. The bubble net feeding trap created by them during prey finding is the heart of WOA. After taking a deep dig in water, humpback whales suddenly follow a upward spiral path

forming bubble net around their target. WOA is mathematically modeling of this behavior.

Step by step procedure of WOA can be put in words as:

1. Algorithm Initialization: This algorithm begins with arbitrary initialization of the whales population (*N*), each whale has *n* dimensions within boundary constraints:

$$X_{i\ j} = X_{\min\ j} + rand\,(X_{\max\ j} - X_{\min\ j}) \quad (1)$$

for i= 1,2,3…*NP*; j= 1,2,3…*D*

Where X_{min} and X_{max} are lower and upper bounds for j^{th} component or decision variable.

2. Fitness Evaluation: Calculate the fitness for each possible solution (search agent) in population *N*.

3. Define the best search agent as (*X**), the fittest. This is assumed to be victim initially.

3. Until a termination criteria is reached (maximum iterations), repeat the steps 4 to 11.

4. Ensure all search agents are in the search space, otherwise alter them.

5. Variable initialization: Update all necessary variables, $\vec{a}$, $\vec{A}$, l, $\vec{C}$, p. Here $\vec{A}$ and $\vec{C}$ are coefficient vectors and are calculated form $\vec{a}$ and $\vec{r}$ as given below. $\vec{a}$ is gradually decreased from 2 to 0 as iterations falls from maximum to minimum and $\vec{r}$ is random vector.

$$\vec{A} = 2\vec{a}.\vec{r} - \vec{a} \quad (2)$$

$$\vec{C} = 2.\vec{r} \quad (3)$$

6. Encircling prey: Humpback whales use shrinking circling and spiral movement in upward direction to encircle their victim, both with 50% probability. These techniques are referred as bubble net attacking method and helps in exploitation of solution. A variable p is used to decide which movement will be selected by whales from these two using below equation;

$$\vec{X}(s+1) = \begin{cases} \overrightarrow{X^*}(s) - \vec{A}.\vec{D} & if\ p < 0.5 \\ \vec{D}'.e^{bl}.\cos(2\pi l) + \overrightarrow{X^*}(s) & if\ p \geq 0.5 \end{cases} \quad (4)$$

Where $\vec{D} = \left|\vec{C}.\overrightarrow{X^*}(s) - \vec{X}(s)\right|$ *and* $\vec{D}' = \left|\overrightarrow{X^*}(s) - \vec{X}(s)\right|$, b describes the shape of logarithmic spiral and l is random number [-1, 1]. S is number of iterations.

7. Searching prey: Instead of p, $\vec{A}$ (randomly selected values higher than 1) is deciding factor to use appropriate technique for searching agents, leading to exploration of solutions. Unlike exploitation, here position updating of agent is done on the basis of any randomly chosen search agent instead of best search agent.

$$\vec{X}(s+1) = \overrightarrow{X_{rand}} - \vec{A}.\vec{D} \quad (5)$$

$$\vec{D} = \left|\vec{C}.\overrightarrow{X_{rand}} - \vec{X}\right| \quad (6)$$

Where $\overrightarrow{X_{rand}}$ is randomly chosen whale (position) from current whales.

8. Solution found: Hence the better solution from a large search space is generated for the upcoming generation and the process continues until the termination criterion is met.

Complete algorithm can be understood better form its flowchart in figure 1.

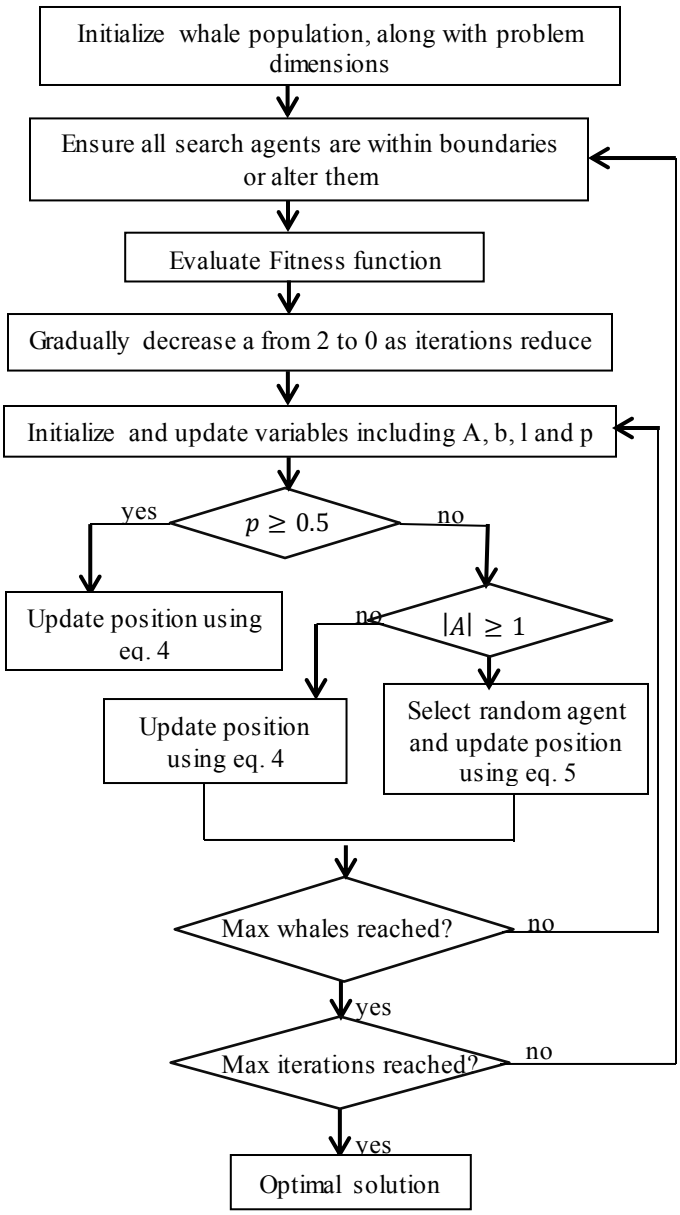

Fig. 1. Flow chart of WOA

III. COGNITIVE RADIO

A. Cognitive Radio System

For a cognitive radio system enabled IoT, a CR model consisting of a primary user (PU) and a secondary user (SU), is studied in this work. To design it in the most optimal way, its

transmission parameters are to be optimized with an intention to accomplish certain goals [5].

B. Cognitive Radio Parameters and Objectives

The adaptable transmission parameters optimized by WOA lists Transmitted Power (P), Modulation Type, Modulation Index (M), Bandwidth (B), Time Division Duplexing (TDD) and Symbol Rate (Rs). Bit-error-rate (BER), signal-to-noise ratio (SNR) and the noise power (N) are the considered environmental parameters in this work. Anticipated QoS goal of CR are met by establishing five objectives. Their fitness function are demarcated in the below section, in order to move the system towards an optimal region.

C. Formulation of Fitness Functions in Cognitive Radio System

Optimization the above enlisted transmission parameters of SUs is done to reach the preferred QoS, which is declared by five objectives.

1. Minimize power consumption: Shrink power to be consumed by the system.

$$f_{\min\ power} = \frac{P}{P_{max}} \tag{7}$$

where P is the average transmit power, and $P_{\max}$ is the maximum available transmit power.

2. Minimum BER: Decrease BER of the communication environment.

$$f_{\min\ ber} = \frac{log_{10}(0.5)}{log_{10}(P_{be})} \tag{8}$$

where P_{be} represents the BER of the modulation type being used, we have used QAM type. For M-ary QAM, the BER is defined as :

$$P_{be} = \frac{4}{log_2(M)}\left(1 - \frac{1}{\sqrt{M}}\right)Q\left(\sqrt{\frac{3log_2(M)P}{(M-1)N}}\right) \tag{9}$$

where P is the average transmitted power, M is the modulation index and N is the noise level equal to 0.1mW.

3. Maximum Throughput: Raise the throughput of radio transmission.

$$f_{\max\ throughput} = 1 - \frac{log_2(M)}{log_2(M_{max})} \tag{10}$$

where M is the modulation index of a single carrier, and $M_{\max}$ is the maximum modulation index.

4. Minimum Interference: Reduce the radio's interference contributions.

$$f_{\min\ interfernce} = \frac{(P+B+TDD)-(P_{min}+B_{min}+1)}{P_{max}+B_{max}+100} \tag{11}$$

where B is the bandwidth required for a single carrier, B_{min} and B_{max} is the minimum and maximum bandwidth available. TDD is time division duplexing, i.e. time taken for transmission and Rs is the symbol rate and Rs_{max} is the maximum symbol rate.

5. Maximum Spectral Efficiency: Maximize the proficient use of frequency spectrum.

$$f_{\max\ spectral\ eff} = 1 - \frac{(M \times B_{min} \times R_s)}{(B \times M_{max} \times Rs_{max})} \tag{12}$$

where M is the modulation index, B is the bandwidth used, Rs refers to the symbol rate.

Using weighted approach, these five multiple objectives are combined into one objective function. This conversion is exposed in equation (13).

Then the final combined objective is given as:

$$f_{five\text{-}objective} = w1 * (f_{min\text{-}power}) + w2 * (f_{min\text{-}ber}) + w3 * (f_{max\text{-}throughput}) + w4 * (f_{min\text{-}interference}) + w5 * (f_{max\text{-}spectraleff}) \tag{13}$$

In certain studies, only three objectives are considered, forming a combined three multi-objective function

$$F_{three\text{-}objective} = w1 * (f_{min\text{-}power}) + w2 * (f_{min\text{-}ber}) + w3 * (f_{max\text{-}throughput}) \tag{14}$$

w1 to w5 are the weights, multiples of each objective respectively. Five CR scenarios are created by these five weights. Table I carries the prerequisite weight values to accentuate the search on preferred path for a particular scenario [5].

IV. Simulations and Results

In this work, WOA is applied to CR system for optimizing its transmission parameters by achieving certain objectives. To make simulation results more clear and to ensure the satisfactory implementation of WOA for optimal CR design in comparison to its predecessor techniques [BBO [15], SA [14] and GA [5]], the simulation results are divided into two sections. With first section dealing with only three objectives and letting us optimize only two parameters, power (P) and modulation Index (M). Second section accomplishes five objectives and helps in obtaining optimal values of five transmission parameters.

A. Only three Objectives

In this subsection, only three objectives corresponding to eq. are optimized and two parameters, namely transmitted power and modulation index are worked upon. The range of transmitted power (P) varies between 0.1 mW and 2.4808 mW. QAM modulation scheme is used with number of symbols (M) ranging from 8 to 64 [5]. WOA related all parameters are tabulated below in table II.

The results obtained in terms of optimal values of transmission parameters, objective function value and the values of the objectives that are intended to be achieved are put up in table 3. They could be fairly compared with results those obtained by BBO [15], SA [14] and GA [5], cited in the same table. WOA is successful in achieving the targeted objective in that particular scenario (mode of operation). The results are

superior to SA and GA. But they are totally at par with BBO. Due to simplicity of problem same results have been produced by WOA and BBO while working on only three objectives. Picture is going to be clearer as problem density increases in next section.

B. Five objectives

Here, WOA is applied to CR system for optimizing its five transmission parameters by achieving five various five objectives. On the basis of these five objectives that are discussed in above section, five scenarios are created. Each scenario is mainly focusing on only one objective at a time. The range of five transmission parameters is predefined and is kept intact as available in literature [5, 14, 15] to ensure rational comparison. The transmitted power (P) varies between 0.158 mW and 251 mW. QAM modulation scheme is used with number of symbols (M) ranging from 2 to 256. Bandwidth (B) available is from 2 to 32 MHz. TDD percentage is taken between 25 and 100%. Symbol rate (Rs) is between 125 Ksps and 1 Msps. WOA related all parameters are tabulated in table III. Table IV hold all the values of optimized parameters, objectives, and fitness functions for all five scenarios for a CR systemobtained by applying WOA. Bold values illustrates that WOA has reached the intended objectives in all modes except interference mode. Interfernce is minimal in power mode whereas it is expected to be minimum in min interference mode. This happened because of interference's direct dependency on transmitted power. These results obtained by WOA are compared in table V with those obtained by BBO [15], SA [14] and GA [15]. As visible, for WOA, fitness values are best for all five modes. Talking about objectives, except in power and interference, WOA is performing best for other three objectives. SA managed to bag first position for power and interference.

Another feather in WOA's cap is least number iterations required to reach the optimal value. Fig.2 and Fig.3 are comparison characteristic curves for minimum power and maximum spectral efficiency mode respectively obtained by WOA, BBO, SA and GA for 300 iterations. These graphs narrate the story behind the search of the best value by every algorithm. WOA finds the best (minimum) form all in minimum iterations, making it superior than BBO, SA and GA for cognitive radio problem. Ability of WOA to assign some iterations in the beginning to exploration and then concentrate on exploitation in last iterations helps it in being fairly balanced algorithm.

V. CONCLUSION

An optimized cognitive radio system is designed for internet of things network using a newfound whale optimization algorithm. Internet of things, being a new and beneficial trend needs cognitive radio services for efficient use of spectrum, which is a limited resource with high demand. One of the ways of designing an optimal cognitive radio is by working on its transmission parameters. Here, five transmission parameters of cognitive radio system are optimized with an intention to achieve five objectives that are vital for user oriented quality s services. Whale optimization based results of optimal parameters, fitness functions, objectives are compared with those obtained earlier in literature using GA, SA and BBO. Convergence characteristics of all these techniques are also used a major performance metric. Owing to fine balance between intensification and diversification, superiority of WOA is established through simulation outcomes and graphs for optimal cognitive radio designing.

***Abstract*— Most of the web (mobile) applications are using cloud computing technology. Developers who want to develop an application can make use of the provisions and services provided by a cloud service provider. There are a number cloud service providers (CSPs). Each of these cloud service providers offer a number of services. Going through all the services of all the CSPs and finding out what service matches the requirements in the SLA document, manually is time consuming, error prone and tedious. And opting for all the services will add extra charges for the owner. Hence it is important to have a system that can match the requirements in the SLA (Service Level Agreement) document with the APIs (Application Programming Interfaces) of the cloud service providers. This paper proposes a method to match the requirements of a businessman with the APIs of the CSPs. The requirements are written in a text document and the description of the APIs of CSPs are written in another text document. Then using text similarity in natural language processing, the APIs that satisfy the requirements in the text document are identified.**

Keywords*— *Cloud service providers, Service Level Agreement, Natural language processing, Application programming interface, text similarity

I. INTRODUCTION

Many web applications, mobile applications and internet businesses are using cloud computing environment. Small-scale businesses, technical giants and entrepreneurs opt for cloud computing for their applications. Cloud computing is delivery of IT services like data storage, computation, network resources, hardware and software resources which are provided by a third party vendor. The clients use these services and pay based on usage. The third party vendors who provide these services are called cloud service providers (CSP). These CSPs provide Application Programming Interfaces (APIs) that help to develop applications.

Many businessmen and entrepreneurs who wish to establish their online businesses opt for cloud computing. There are many cloud service providers. Each of these service providers have their own set of APIs to provide services. An application does not need all the services of a CSP for developing it. More over opting for all the services of the CSP makes the consumer to pay for the services which he does not need and use. Hence the developer of the application should know what services the application should provide and in turn what APIs of the CSPs are required to implement these services. Going through all the APIs of different CSPs manually is tedious, time consuming and error prone. In order, to overcome it, a method has been proposed that automatically matches the APIs of different CSPs with the requirements of the user. This method can be used as a recommender system that recommends the APIs to the developer of the application based on the requirements of the businessman.

The system is trained with the description of APIs of different CSPs. The businessman lists a set of requirements in the Service Level Agreement (SLA). The SLA is given as an input to the system. Both the APIs training set and the requirements list is pre-processed to extract the keywords individually. Using similarity measure, the APIs that match the requirements in SLA are fetched.

The paper is organized into five sections. Section I gives the introduction to the topic. In section II, relevant work has been surveyed. Section III gives the methodology of the proposed work and section IV gives the results of implementation of the proposed work. Section V includes the conclusion.

II. RELATED WORK

Many researchers are carrying out their studies to improve the text similarity and to improve the performance of the information retrieval systems.

[1] The authors use natural language processing techniques to extract knowledge from various cloud service providers to from knowledge base from text documents. [2] The authors discuss the existing methods for search operation such as inverted index, its limitations. They also propose a new method such as interval list to store and process indices that reduces the storage space.

Maake Benard Magara, Sunday O. Ojo , T. Zuva [3] try to find out what algorithms and what combinations of metrics of similarity can be used to optimize the search operation to recommend the relevant articles in a research paper recommender system. The authors used non-linear classification algorithms with text similarity metrics.

Marouane Birjali, Abderrahim Beni-hssane and M. Erritali in [4] propose an approach for measuring similarity between documents in a large corpus. The proposed approach was compared with other previous methods using MapReduce algorithm. It was found that the new MapReduce algorithm outperformed the previous ones with its running time and value of text similarity.

Chaobo He, Yong Tang, Feiyi Tang and Atiao Yang in [5] discuss the disadvantages of traditional approaches of document similarity and present a new structure of distributed inverted index, the algorithms based on MapReduce model and the architecture of cloud computing platform. Experiments have been carried out using the proposed approach and the results show that this approach is effective for computing similarity of large documents and is scalable also.

Yilin Feng, Jie Tang, Meilin Liu, Chongjun Wang and Junyuan Xie [6] propose a two step similarity measure of documents in on GPUs in CUDA environment. The results of the experiments show that the proposed approach solves the problem faster than the existing methods.

Sung-min Kim and Young-guk Ha in [7] present a method for finding similarity between movies with the help of movie scripts. The new method is about matching the documents using cosine similarity measure which overcomes the traditional matching keywords.

P. Vigneshvaran, E. Jayabalan and K. Vijaya in [8] developed a tool to calculate the similarity between key and source documents in a corpus. The experiments were done on the assignments submitted by the students to test the students' modesty. The tool can be used to find the similarity index of documents and remove the duplicate documents from the repository.

Ashraf S. Hussein [9] in his paper propose a content-based method to analyse document similarity and visualization.
Kishore Varma Indukuri, Anurag Anil Ambekar and Ashish Sureka [10] in their paper propose a method to find similarity analysis between two different patents using natural language processing techniques. The authors also built a GUI tool for the same.
Taeho Jo [11] in his paper propose a version of K Nearest Neighbour that considers similarity among attributes to compute similarity between feature vectors.
Qamar Mahmood, Muhammad Abdul Qadir and Muhammad Tanvir Afzal [12] in their paper propose a method to find document similarity by using semantic social network analysis techniques on RDF graphs of citations of research papers.
Sun Park, Dong Un An and Choi Im Cheon [13] in their paper propose a document clustering method which uses weighted semantic features and cluster similarity.
Xiaojie Yu, Xiaojun Chen and Jinqiao Shi in [14] present a vector based document similarity and a new protocol which uses latent semantic analysis.

III. METHODOLOGY

The methodology consists of two modules namely pre-processing and pattern matching. The APIs help file consists of the description of APIs of different CSPs that are available in their web pages.

Fig. 1. Shows the architecture diagram of the system. In this the system is trained with the APIs of different CSPs. The input to the system is the SLA document which consists of the requirements from the businessman. Both the documents are pre-processed to extract keywords from them. Then the common keywords from both these documents are identified in the pattern matching.

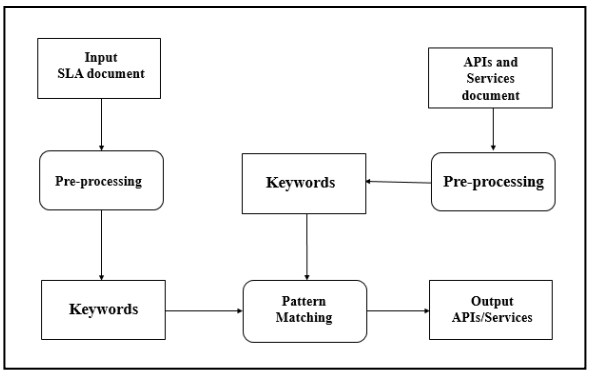

Fig. 1. System architecture of the system.

A. *Pre-processing module*

Fig. 2. Represents the pre-processing of training data. The input is the APIs help file. The content for this APIs help file is obtained from the description or documentation pages of the APIs of different CSPs. The steps performed in pre-processing are as follows:

a) Sentence tokenization:

The input document consists of a number of sentences. It is necessary to process each sentence in the document. So the content of the document is divided into its constituent sentences. The sentences are stored as keys of a dictionary like data structure.
For example, a document may contain 10 sentences, the number of keys in the dictionary data structure is 10 which are the same sentences in the document.

b) Word tokenization:

The sentences obtained from the previous step is given as input to this step. A sentence is usually made up of a number of words. In order to

find the list of common words between two documents, it is important to break the sentences into words. So each sentence is then split into its constituent words.

For example consider a sentence "A boy is playing with dogs". The result would be an entry in the dictionary where the key contains the sentence and its values will have the words – "A", "boy", "is", "playing", "with", "dogs".

c) Stopword removal:

Words like "a", "an", "the" and others which are frequent are not considered important. Such words are called stopwords. These words do not contribute for pattern matching as they do not carry any special meaning. Such words are removed from the document.

For the above example, this step will remove the words "A", "is", "with" from the value set of the dictionary.

*d) Lemmatization***:**

The words usually have prefixes, suffixes and will be in one of the eight different parts of speech.it will be easier to compare the documents if their constituent words are in the same form. So it is important to normalize the words. So each word in the document is converted into its root or base form. For the above example the words "boy", "playing", "dogs" are converted into "boy", "play", "dog".

The output of pre-processing is the keywords extracted from the APIs document. These keywords are stored as values of the dictionary whose keys are the sentences in the APIs help file. Similarly, the SLA document is given as input file which consists of the requirements needed to develop the application. The document consists of sentences where each sentence is a requirement. This is also pre-processed to obtain the keywords from each requirement. And the result is stored as another dictionary where the keys are the sentences (requirements) in the SLA document and the values are the keywords extracted from these sentences. These two dictionaries are then given as input to the pattern matching module.

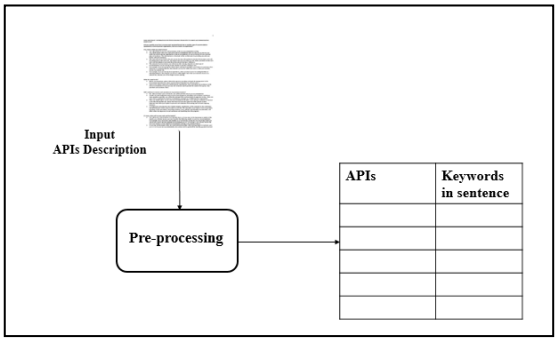

Fig. 2. Pre-processing of training data.

B. *Pattern matching module*

Fig. 3. Shows the pattern matching process where the keywords from both the input SLA document and the APIs help file are matched to fetch the required APIs.

The keywords obtained from the pre-processing of APIs help file is stored as a dictionary like data structure where the keys contain the APIs' names and the values contain the corresponding APIs' keywords. And the SLA document is stored in a different dictionary where the keys contain the sentences (requirements) and the values contain the keywords extracted from that sentence. The pattern matching technique involves finding the common keywords between the two dictionaries.

An intersection of the keywords in both the dictionaries is performed and stored in another dictionary. If a requirement in the SLA contains a threshold number of keywords that are present in the API dictionary's value set, then those corresponding APIs are the ones that match with the requirements of SLA. These APIs are fetched as the required APIs to the businessman. In the experiments conducted the threshold number of keywords that are matched is set to two.

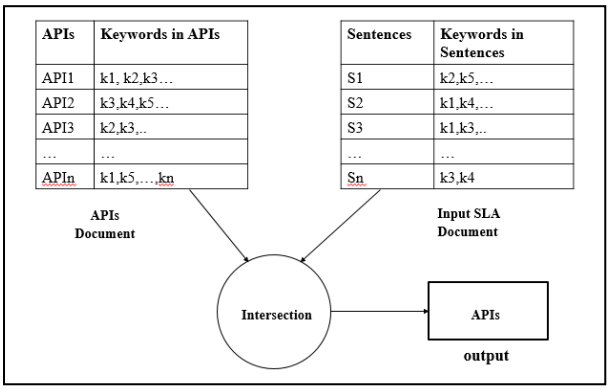

Fig. 3. Pattern matching

IV. RESULTS

APIs of Google Cloud were given as the APIs help file and a sample SLA document with ten requirements was given as input to the system. The system returned the APIs for five of the given requirements correctly. Figure 4 shows the result which shows a resultant dictionary which has the requirements that found matching APIs as keys and values as the respective APIs.

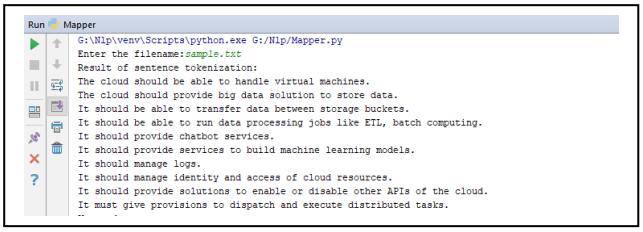

Fig. 4. Result of sentence tokenization.

Fig. 4. Shows the result of sentence tokenization where the content of input SLA document is split into sentences.

Fig. 5. Result of keyword tokenization.

Fig. 5. Shows the result of keyword tokenization where the sentences in the input SLA document is split into its constituent words.

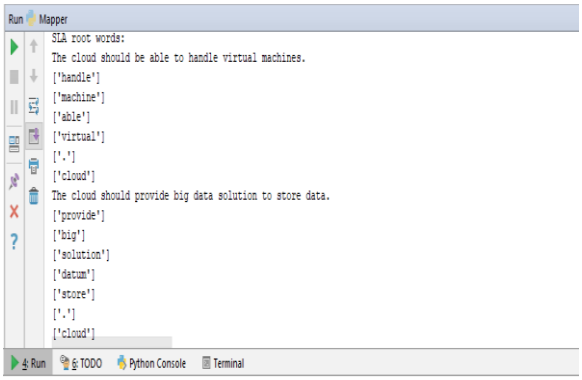

Fig. 6. Result of Lemmatization.

Fig. 6. Shows the result of lemmatization where the words in the input SLA document are converted into their root forms.

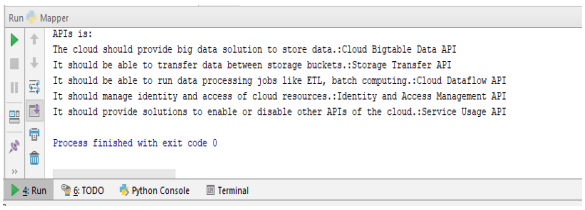

Fig. 7. Screenshot of APIs.

Fig. 7. Shows the APIs that matched with the requirements in the given input SLA document.

V. CONCLUSION AND FUTURE WORK

This paper proposes a method to match the requirements in an SLA document with the APIs of different CSPs. This system is useful to the developers who develop the application with cloud computing. It reduces the time taken to manually select the required APIs. It can be used as a recommender system by developers to match the requirements needed to develop an application with the APIs of different CSPs.

***Abstract*—**
Electricity is fuel for today' s automated world, in near future scarcity of electricity will be major problem for all developing countries. Dependency on fossil fuel will not be feasible option and hence, people around world started deploying renewable energy sources on a larger content. The DC microgrids are serving the purpose by interconnecting the renewable sources to the power system. Proper management of renewable energy sources can be accomplished by using DC microgrid. But DC microgrid suffers from a disadvantage of energy efficiency. In the proposed method bus voltages are deployed for shifting modes thus does not require additional communication channel for controlling the grid voltage.

Keywords — Autonomous DC Micro grids, Power control, Bus signaling, Bus Management, Renewable sources, etc.

Introduction

Smart grid and microgrid will be the future of electricity distribution. Hence, researchers worldwide focus improving efficiency, performance and automated operation of these grids [1]. Pilot projects in few parts of world in been implemented for power generation, distribution and consumption in small area by forming microgrid [2][3]. There are various possibilities for operation of the microgrid either it can be part of the grid or standalone system. Stand alone systems may suffer from various disadvantages and frequent outages if energy demand is not met properly. Energy management systems will be a essential component for power sharing and maintaining voltage profile in microgrid. Traditional techniques use MPPT algorithms in case of wind and PV, in this case battery is treated as slack and leftover power is used for charging battery. However, overcharging of the batteries must be prevented to avoid damage to battery terminals. Normally, constant voltage – constant current charging is been used considering operational constraints of wind system. To regulate operations in this environment non linear control strategies with power curtail options may be deployed for controlling microgrid. Standalone DC microgrid are widely accepted as they possess few more advantages over other kinds of network e.g. no need of complicated control strategies and other AC electrical system parameter.

Centralized controller for controlling operation of the grid is better option for optimal operation of the various parameters. It suffers from the disadvantage of dependence on communication link. Moreover, in traditional grids droop control is implemented which gathers local information but doesn' t have capacity to utilize microgrid resources optimally. The mentioned drawback can be overcome by using DC bus signaling method (DCBSM) was tried but failed as it was not capable of considering battery status. Condition of state of charge is taken care by primary control on DCBSM. Secondary control is designated for adjustment of bus voltage. In case of DC microgrid battery is responsible for regulating the bus voltage, system reliability may deficit. Decentralizing operating regions is done through primary control DC bus voltage, along with coordination with secondary control midst various devices. In this case surplus generation is dealt using dump loads. In this paper various deploys different control strategy considering DC bus voltage variation to maintain voltage profile under continuously changing generation and storage condition. DC bus voltage is been used to read the DC microgrid status. Two different control loops are used for optimizing the system parameters and to improve efficiency.

I. . System Structure

DC microgrid stability is accessed by measuring DC bus voltage level [4]. Voltage source converters used in grid acts as slack terminals for regulating the voltage of microgrid. System shown in fig.1 is considered for simulation and developing hardware, system has two ADCMGs far from one another and has considerable line resistance between them.

Each ADCMG equipper two photovoltaic systems and batteries are used to represent any other equivalent renewable energy source and storage device. DC loads are generally

resistive in nature and also treated as constant power load (CPL), which are interconnected by using DC-DC converters. By using DC-DC converters we can ensure fixed output power irrespective of fluctuation in DC bus voltage. Photovoltaic systems are connected directly to DC bus by using boost converter. For connecting storage devices and batteries bi - directional devices are used. Interconnection of ADCMG is done with DABC for interfacing. DABC ensures isolation between two systems and also has high frequency feeding capacity in both the directions along with transformer (high frequency). The transformer uses the H-Bridge converters for producing the high frequency AC from DC. Ideal location of placing DABC would be near to low voltage DC system, so the losses can be avoided and communication can be made faster. Bus voltage data obtained from line between two ADCMG' s. If this line experiences open circuit fault voltage is measured at C_1 (i.e. V' a). In this case V' a is also utilized for BDC triggering at ADCMG1. If connection between both ADCMG is healthy then current flowing through the line is being measured to know the voltage drop (i.e. xp1 x R). To obtain the voltage at ADCMG1 V' a can be added to DABC high voltage side. This facilitates power exchange without any communication link.

II. Power Control and Management Strategy (PCMS)

The coordination of the grid is achieved by voltage as a signal to the coordination system. By Coulomb method of counting, the SoC is given by:

$$SoCi = SoCo - \frac{1}{CN}\int \delta\, ibat\, dt \quad \text{.....(1)}$$

Where
SoCi→ Instantaneous SoC
SoC0→ Initial Capacity
CN→ Nominal Capacity
ibat→ Battery current
δ → Loss coefficient (Range 0.98 – 1)

By controlling the charging and discharging current SoC can be limited.

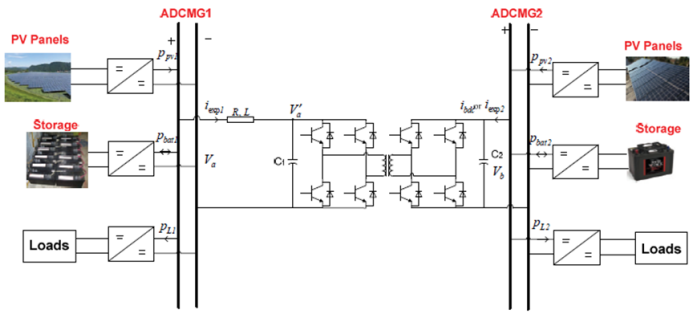

Figure1.Interconnection of two ADCMGs

Working of ADCMG is divided into five zones depending upon bus threshold voltage as shown in Fig. 2

Zone-1 (Balanced power mode):
In this zone power generated by photo voltaic systems is less or equal to load PL_1 in ADCMG1. Hence, batteries are any other storage device if any remains idle. Little fluctuations in load will not switch on storage units as a system is designed to sustain small fluctuations or load variations. Voltage regulation at a constant point is not possible in this case. As, reference voltage is missing, hence voltage varies between VaH1 and VaL1. Power exchange between two ADCMG is not done in this mode.
Status of various units in ADCMG1 are given by

$$P_{PV1} \cong P_{L1};\ P_{bat1} = 0;\ V_{aL1} < V_a < V_{aH1} \quad \text{..... (2)}$$

Where

Pbat1→ ADCMG1 Instantaneous battery power

Zone-2 (Battery discharging mode):
Power produced by photovoltaic systems cannot meet demand, bus voltage cannot be maintained. Once bus voltage falls below threshold voltage Val1, then power is derived from the storage systems to fulfill the demand. Battery power maintains the bus voltage in limit by using bus regulating mode. If ADCMG2 has excess power, ADCMG1 may absorb without reverse transfer of power.
ADCMG1 conditions is expressed as

$$P_{PV1} + P_{bat1} = P_{L1};\ V_a = V_{aL1} \quad \text{.....(3)}$$

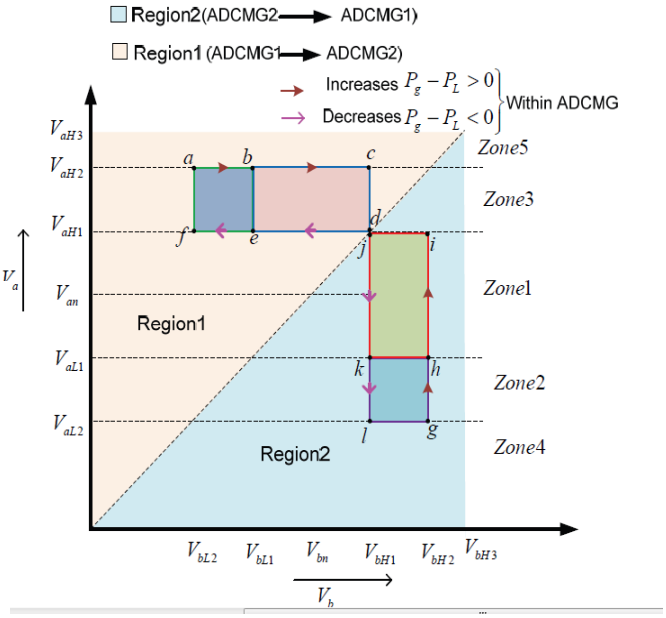

Figure2. Proposed PCMS between two ADCMGs

Zone-3 (Battery charging mode):
Power generated by photovoltaic is more than the demand, in this condition voltage Va increases due to availability of surplus power and reaches up to VaH1 this charges the battery. Battery is charged to maximum limit till it fully charged. In this case ADCMG1 will not exchange power with ADCMG2. At the same time it can absorb the power Vb and Vbh2 and battery in ADCMG1 is not fully charged.

$$P_{PV1} > P_{L1};\ P_{bat1} = -(P_{PV1} - P_{L1});\ V_a = V_{aH1} \quad \ldots\ldots\ldots(4)$$

Zone-4 (Power deficit mode):
If the demand is more than the battery charging rate, system is in zone-4 of operation. Battery has a capacity of draining the power when operated continuously. ADCMG1 can import proper from ADCMG2. In case 2, power is not taken from ADCMG2.
Case1:
ADCMG1 always check status ADCMG2 for availability of surplus power by measuring bus voltage Vb. In the same way voltage Va gives status of ADCMG1. If Vb=VbH2&Va≤VaH1, power flows from ADCMG2 to ADCMG1 by DABC.
Transferred power pushes the ADCMG1 for operation at various operating points dependent on imported power (pimp1) in region 2 as shown in fig. 3. Operating modes equations are explained further.

$$V_a = \begin{cases} V_{aL1} & ;if\ P_{PV1} + P_{bat1} + P_{imp1} = P_{L1} \\ V_{aL1} < V_a < V_{aH1}\ ;\ if\ P_{PV1} + P_{imp1} \cong P_{L1} & \\ V_{aH1}\ ;\ if\ P_{PV1} + P_{imp1} > P_{L1}, P_{bat1} = -(P_{PV1} + P_{imp1} - P_{L1}) & \end{cases} \quad \ldots\ldots (5)$$

Case2: Here, power transferred from ADCMG 2 to 1 is not sufficient or zero. It leads to load shedding in ADCMG1. The main cause is decrease in voltage beyond permissible limits.
The insertion of the voltage by means of renewable generation could help in this situation to restore the voltage level. The case is expressed as:

$$P_{PV1} + P_{bat1} + P_{imp1} < P_{L1}$$
$$P_{PV1} + P_{bat1} < P_{L1};\ P_{imp1} = 0 \quad \ldots. (6)$$

5) Zone-5 (Excess power mode):
Operation of this mode is further divided into two groups, depending upon ADCMG1 exporting excess power and without exporting excess power.

Case1:
There are ways to operate in this mode either excess generation or drop in load. If excess power remains in grid bus voltage will start rising. ADCMG status is been monitored by measuring its bus voltage. If ADCMG2 goes into excess power state (i.e. Vb≤VbH1), it causes the flow of power from ADCMG 1 to 2.

Case2:
This is similar to earlier case with little difference where ADCMG2 will not be capable to absorb the surplus power available at ADCMG1 which increases the bus voltage (Va). If the bus voltage Va above threshold voltage VaH2, control loop will change and all photovoltaic system will change operation from the MPP to bus voltage regulating mode which increases VaH3.

Mathematical equations of ADCMG1in zone5 is given by

$$V_a \begin{cases} V_{aH2}\ ;if\ P_{exp1} > 0 \\ V_{aH3}\ ;if\ P_{exp1} = 0;\ V_{PV\backslash ref} = V_{aH3} \end{cases} \quad \ldots\ldots(7)$$

Where
Pexp1→ power (instantaneous) exported from ADCMG 1 to 2.
VPV1→ PV voltage reference

III. SIMULATION RESULTS

Model of the implemented system is shown in fig.3. It is simulated on real time digital simulator (RTDS) for validating with PCMS. System is implementation is done on RSCAD/RTDS.

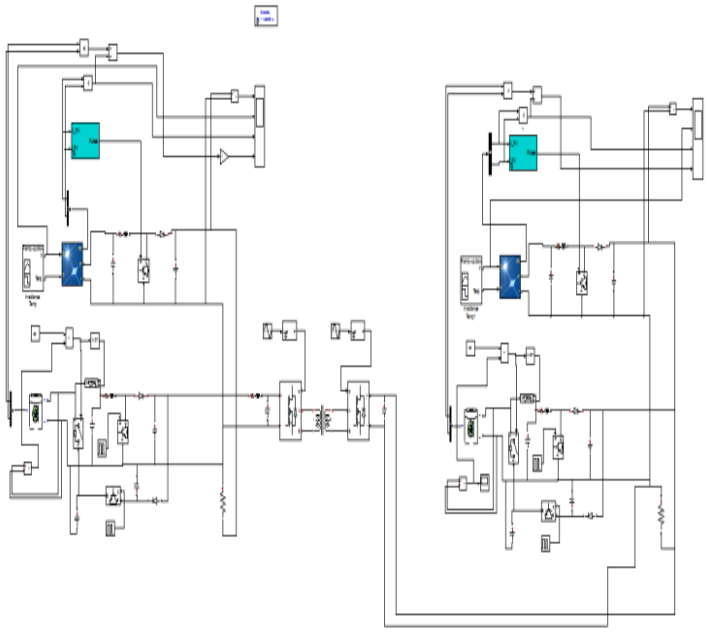

Figure3. Simulation Model

Representation of critical and non critical load is mentioned to the system. This discrimination is needed in order to shed non critical load in power crisis situation. Proposed PCMS is explored for different operating situations of ADCMG which also includes the extreme environmental situations of battery and grid.

A. Individual DC Micro grids
Different operating parameters of ADCMG 1 are depicted in fig.4. The batteries are having the voltage above cut off (lower) by small amount. Each zone has a voltage bandwidth

of 10V and tolerance limit of 5% of the nominal bus voltage. From the fig. 4 it is observed that generated power and demand is same in time period between 0 to t1 which is indicated as operating zone -1. In this mode bus voltage varies in upper and lower limit. At t1, power in grid is more than the demand, which charges the battery and it starts regulating bus voltage Va up to VaH1. Catastrophic change in load demand happened at 2t which impels the battery charging current to outstrips saturation limit, which causes rise of V since excess generated electrical power is not accepted by other ADCMG or any load. This causes PV mode to change in bus regulation mode and photovoltaic system changes state from MPP to bus regulation mode as shown in fig.5, typical zone -5 operations. Incorporated PV control bus voltage controls the regulated bus voltage up to time period 3t. At 3t bus voltage gets lesser than VaH2 due to fall of PV power with decay in irradiation. This causes zone-3 operation and same is visualized in time period 3 t to 4 t. At time 4 t, rapid increase in load causes the zone-2 to appear.

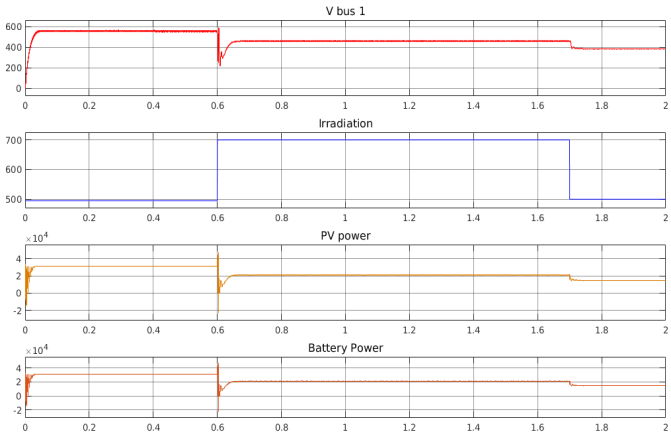

Figure4. Parameters of ADCMG1: (a) Bus voltage, (b) Irradiation, (c) PV output power, (d) Battery output power

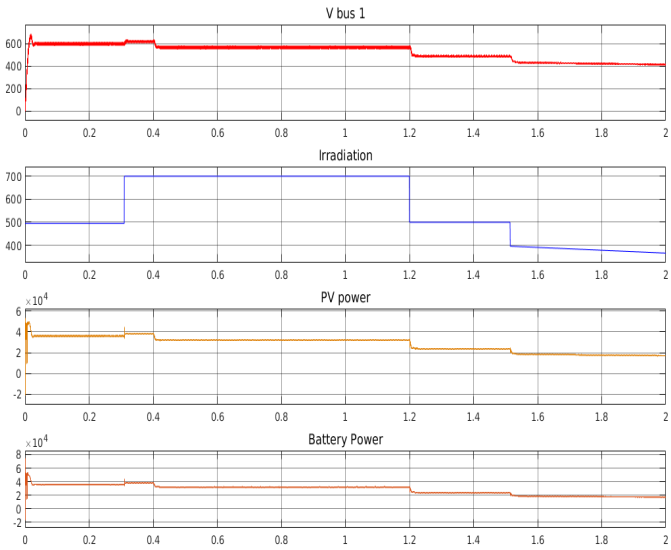

Figure5. Parameters of ADCMG2: (a) Bus voltage, (b) Irradiation, (c) PV output power, (d) Battery output power

TABLE I
SIMULATION PARAMETERS

Components	Parameters	ADCMG1	ADCMG2
PV Capacity	Maximum power@1000W/m2	4.5kW	750W
Battery	Capacity	10AH	10AH
	Nominal Voltage	90V	22V
Nominal grid voltage	Rated Voltage	380V	48V
Voltage Thresholds	V_{xH3}	410	54 V
	V_{xH2}	400	52 V
	V_{xH1}	390	50 V
	V_{xL1}	370	46 V
	V_{xL2}	360	44 V
DC Load	Fixed load	1kW	200W
	Variable load	2kW	300W
Line parameters	Resistance ®	0.15Ω	
	Inductance (L)	0.24mH	

In time period t4 to t5 demand is more than the generation excess needed power is provided by the batteries or any other storage devices in the system. The execution of load shedding is done at 6t as load is more than power in grid, shedding a load will bring ADCMG in normal condition. Time period 5 t to 6 t depicts the operating zone-4. Once load is shed, it is in zone-2. ADCMG2 operates in coordination with ADCMG1.

CONCLUSION

A well harmonized, multivariable continuously monitored NMPC control strategy is demonstrated in this paper for getting optimal EMS in microgrid. Bus signaling method is used for PCMS, implemented PCMS system is mainly used for DC grid power flow and between ADCMG' s. Two microgrids of 380V and 48V are considered for simulating the environment in real time simulator. Developed simulation is operated in normal and extreme conditions and simulated and same results are obtained on developed hardware. Developed system gives isolation and improves reliability of the system.

***Abstract*—As technology is growing at fast rate, things are getting connected with each other through internet thus producing huge amount of data that need processing. Cloud computing provides the processing, storage and analysis of the collected data, but inspite of the fact that cloud usage is increasing rapidly still, there are various limitations such as unreliable latency, lack of mobility support and location awareness. High redundancy, high communication bandwidth and latency adds extra burden to process the data at the cloud. Fog devices located at the edge of the network solves these problems by processing the generated data locally closer to the end devices and hence avoiding the transmission latency and network bandwidth by not sending each and every bit of information to the cloud for processing. In this paper offloading policy at the Fog layer is proposed and it is also discussed how the Fog computing is efficient than Cloud computing in terms of latency.**

***Index Terms*—Priority, offloading, arrival rate, service rate, Queue.**

I. Introduction

The Internet of things is the interconnection of physical or virtual devices having sensing and networking capabilities and which can be accessed from anywhere through internet.IoT is increasing at a very rapid rate and thus sensing data from the environment that needs processing. The processing of the data can be either done in the IoT devices themselves or can be outsources to the cloud or the fog. The IoT devices as such are resource constraint devices, so to process the big data locally at the IoT devices is not an efficient way. The Cloud rich in resources provides the services from the pool of resources based on the demand of the users that can be easily accessed or released with the minimum effort [1]. But due to the various limitations like centralized approach, location unawareness, lack of mobility, multi hop distant from IoT node, huge bandwidth requirement cloud cannot be effectively used to process this big data generated by the IoT devices. So the need for another computational model arises, the Fog computing, which includes Fog devices like gateways, routers, access points etc was coined by Cisco [2]. It provides various services as like in cloud, but the Fog devices are resource constraint as compared to the cloud by having limited storage and processing capabilities. So the both cloud and the Fog cannot be used independently due to their limitations, they had to be used aggregately so as to maintain the quality of service. Kevin Ashton coined the term internet of things in 1999 [3]. Since then growth of IoT has increased in the exponential manner and is predicted by some major companies [4] [5] [6]. Offloading is the transfer of computational work from one device to another inorder to reduce the time of execution. Various work had been done by various authors, In [7], authors considered a three level architecture comprising of IoT level, Fog level and the cloud level. very level consists of multiple nodes and they are aggregated into various domains. The tasks can be either processed in IoT layer locally or can be send to the Fog or Cloud layer, internally Fog nodes can process requests or can forward the requests to other Fog nodes depending upon the estimated waiting time. They have considered centralised and distributed mode of interaction between Fog nodes. In centralised mode , a central Fog node controls ooading decision and interaction between Fog nodes. All the Fog nodes send their estimated waiting time to the centralised Fog node and the central node distributes that information to all the Fog nodes present in the domain, the estimated waiting time information is storing in the reachability table of every node. When the decision about the offloading has to be taken, the nodes looks into the reachability table and offloads to that node which has the least estimated waiting time listed in the table. In the distributed mode of interaction a distributed protocol is used to distribute the state information of nodes to each and every other neighbouring Fog node. A reachability table is maintained comprising the entries of estimated waiting time and round trip time. A best neighbour is selected which has the minimum estimated waiting time and half of round trip delay. When a task is submitted to the Fog node, if the estimated waiting time is smaller than the threshold, then the task is processed by that node otherwise the node offloads the task to its neighbouring nodes. If the ooad limit is greater than the number of times task is offloaded, the task will be forwarded to the cloud. In [8] transmission delay and power consumption are considered as parameters in fog cloud system. A tradeoff between these two parameters is proposed. It is shown that fog computing outperforms cloud computing by saving communication bandwidth and reducing service delay. GBD and Hungarian algorithm are used for solving optimization problem. In [9] a fog computing model and an offloading policy which effectively improves the

performance of the system is proposed. Offloading policy takes both energy and execution performance into consideration and they both need to be improved at the same time. In [10], Two layered architecture for Fog computing is considered, comprising of Fog nodes and Fog access points. Fog nodes are battery powered and are less computationally, storage and range powerful than Fog access points. Fog access points are connected to electrical supply and to the higher computational powers. Tasks submitted to the Fog nodes can be either processed locally on that Fog node or can be offloaded to the neighbour Fog nodes or can be offloaded to the Fog access points in range. The main of the paper is to select the amount of task or data that is to be offloaded to the candidate nodes in order to minimise the total energy consumption and the task processing delay. Firstly the Fog nodes are classified into low power and High power Fog nodes based on the amount of energy left within them. Secondly the low power Fog nodes offload their portion of task to either high power Fog nodes or to the Fog access points depending upon the coverage area. Thirdly the portion of task that is to be computed locally is calculated keeping node energy consumption and task processing delay into consideration. Lastly the portion of task that is offloaded is calculated by considering the data rate and the amount of data to be offloaded. In [11],main focus is on the communication between the Fog nodes. Fog nodes can communicate with each other within specific range, they have computational and storage capabilities and are battery powered. A cluster base offloading scheme is proposed, in which Fog nodes are classified as Fog cluster heads and Fog cluster members based upon the amount of energy left. Fog cluster heads have more left energy than Fog cluster members. There can be many clusters in a fog layer. Each cluster consists of one cluster head and many cluster members. Cluster members can offload their tasks to their cluster heads for computation. The fog nodes are classified into High power Fog nodes, Medium power Fog nodes and Low power Fog nodes using a quantile function based on the remained energy. Fog cluster heads can be selected from either High power Fog nodes only or from the high power Fog nodes first then from Medium power Fog nodes. Fog cluster members can be selected from either Low power Fog nodes only or from the Medium power Fog nodes then Low power Fog nodes. After selecting the Fog Cluster head, if there are no Fog cluster members remained then a cluster is formed with a single node performing local computation. The clusters are periodically updated because the Fog cluster heads will spend energy in computation of offloaded tasks and by updating Fog cluster head can be selected as the next Fog cluster member due to reduction in its energy. In [12], offloading in cloud and fog servers using hybrid policy is proposed. Tasks are allocated in such a manner so that total energy and processing delay is minimised. Offloading problem is solved by breaking the problem into four sub problems based on delay and energy efficiency. It is observed that the proposed policy performs better than conventional schemes. In this paper we study the delay minimisation in the Fog computing by formulating the offloading policy of centralised approach. Same offloading policy is applied for both Cloud, Fog and IoT layer and finally we will compare the delay obtained at different arrival rates. The remainder of the paper is organised as follows: section II will discuss the system model, in section III we will discuss the mathematical model concerned, section IV discusses the evaluation and results and finally in section V we will have the conclusion and future work.

II. Proposed Architectural Model

We are considering the three layered architecture consisting of lower IoT layer, middle Fog layer and top Cloud layer. The data generated by the sensors is collected at IoT layer and can be either processed or offloaded to the upper levels for processing. Each layer consists of multiple nodes, the data can be offloaded to any node depending upon the offloading policy. Each node has a queue associated with it. We are considering the centralised approach for offloading, from among n nodes a node is choosen as a coordinator depending upon which node receives receives request or the node which is at least distance from the data generating device. The rest n-1 nodes respond to the coordinator with their estimated waiting time. The waiting time in the queue plus the service time of the request forms the estimated waiting time. The coordinator will take the offloading decision depending upon the waiting time, the task is offloaded to the node with least waiting time. The work of the coordinator is only to take the offloading decision. If all nodes respond with the same waiting time, then any node is chosen as candidate for offloading. If all nodes are unreachable, then the task is offloaded to the cloud for processing. In case if the coordinator fails, the node with the least waiting time is chosen as coordinator. Tasks received by any node are forwarded to the coordinator for offloading decisions. In our offloading policy the tasks are offloaded based on the estimated waiting time and priority of the task. We divide the tasks in two types: type 1 of high priority tasks or class 1 tasks and type 2 of low priority tasks or class 2 tasks. Class 1 tasks has got priority over class 2 tasks. If the class 2 are are in processing stage and class 1 tasks arrive at the system, the class 2 tasks are pre-empted and class 1 tasks are processed first. The processing of class 2 tasks are never carried out when there are class 1 tasks in the system. System is implemented by the single server Markovain queuing system with infinite capacity. Requests generated by the devices are either processed locally within the micro controllers at the IoT layer like Arduino or the requests can be offloaded to the Fog or Cloud layer.

III. Mathematical Model

In our paper we are implementing same offloading policy for all the layers, so the equations to calculate the delay will be same for all the layers. Let N represents the set of nodes, all the nodes are assumed to be homogeneous:

$$N = n1, n2, n3, ...nN \tag{1}$$

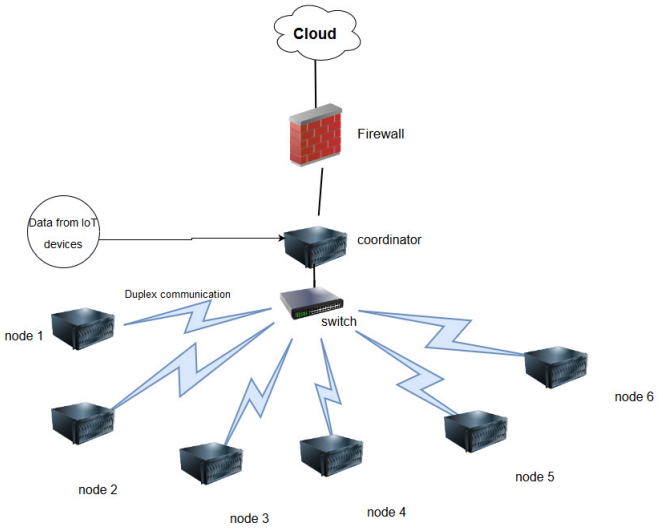

Fig. 1. Architectural Model.

We will choose among these N fog nodes a coordinator depending upon which node receives the request. All other nodes respond to the coordinator with their estimated waiting time. In order to model this we will consider a single server pre-emption priority queue model for the coordinator and rest of the nodes. We are classifying tasks or requests into two types, high and low priority tasks. Each request arrives according to the Poisson process having data rates $\lambda 1$ and $\lambda 2$ respectively. We have chosen the single queue for high and low priority requests. The service time for each class of requests are assumed to be independent with service rate μ. It is called M/M/1 because of memoryless property [13] [14].
The system is stable if:

$$\rho 1 + \rho 2 < 1 \tag{2}$$

$$\text{Where } \rho i = \frac{\lambda}{\mu}, i = 1, 2$$

The service of the class low priority requests is never carried out if there is a request belonging to the high priority class; means that class 1 request has absolute priority over class 2 requests. When class 2 requests are being processed and class 1 request arrives, the class 2 request is pre-empted and the system proceeds with the class 1 requests. The interrupted class 2 request is fed back to the system and is processed only when there are no class 1 requests in the system. Both class 1 and class 2 follows the first in first out queuing discipline. Average time class 1 requests are processed in the system is given as:

$$W_1 = \frac{1}{\mu - \lambda 1} \tag{3}$$

$$or \quad W_1 = \frac{\frac{1}{\mu}}{1 - \rho 1} \tag{4}$$

Where W_1 is the average time a request of class 1 spend in the system [11][12]. As class 2 requests are effected by the class 1 requests, so average time a request of class 2 spends in the system is given as:

$$W_2 = \frac{\frac{1}{\mu}}{(1 - \rho 1)(1 - \rho 1 - \rho 2)} \tag{5}$$

Where W_2 is the average time a request of class 2 spends in the system [3]. Total delay in coordinator is given as:

$$P_{cd} = W_1 + W_2 \tag{6}$$

Other n-1 are modelled same as the coordinator by single server markovanian queueing system. The total delay for each node is given as:

$$P = W_1 + W_2 \tag{7}$$

Total delay for a system is given as:

$$P_{total} = P_{cd} + \Sigma_1^{n-1} p_n \tag{8}$$

Average delay for the system is given as:

$$P_{average} = \frac{P_{cd} + \Sigma_1^{n-1} p_n}{n} \tag{9}$$

In case of Fog and Cloud computations, tasks need to be transmitted across the network so there is addition of the transmission delay.

$$RTT(ms) = 0.05 * distance + 5 \tag{10}$$

where RTT is round trip time

$$T_d = \frac{RTT}{2} \tag{11}$$

Therefore equation 10 can be written as:

$$P_{average} = \frac{P_{cd} + \Sigma_1^{n-1} p_n}{n} + T_d \tag{12}$$

IV. Results and Analysis

Simulation is performed in MATLAB and Simulink. System is analysed at different arrival rates and transmission delay for fog and cloud is taken as 0.5 seconds 2.5 seconds respectively [10].
We have considered a single queue for both types of tasks. It is observed that when the arrival rate of the tasks or the jobs from the IoT devices are lower, Fog layer processes the tasks in least period of time or with the minimum delay because the transmission delay for the Fog layer is lower than that of Cloud. No doubt Cloud had huge processing power but at the same time has got larger transmission delay. Processing the data at the IoT layer by IoT devices themselves is inefficient because they have got least processing power among the Fog and Cloud. When the arrival rate is increased beyond threshold, the cloud will efficiently handle the data because the Fog devices have got limited storage and processing capabilities, when the arrival rate is increased beyond threshold the queue length will get increased and hence will add to the delay which would be much larger than the transmission delay of the Cloud, hence Cloud performs better. So inorder to efficiently handle the data or to maintain the quality of

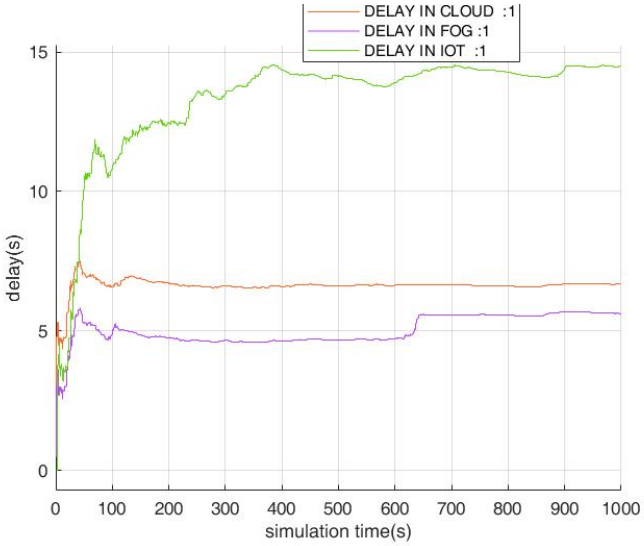

Fig. 2. when $\lambda 1$ =0.2 and $\lambda 2$ =0.4

service we have to make the use of both Cloud and Fog layers aggregately.

Case A: $when \lambda 1 = 0.2$ and $\lambda 2 = 0.4$

$\lambda 1$ and $\lambda 2$ are the arrival rates of the high priority and low priority tasks respectively. As we can see from the figure 2 that the fog computing outperforms cloud and IoT computing at this arrival rate.

Case B: when $\lambda 1$ =0.4 and $\lambda 2$ =0.2

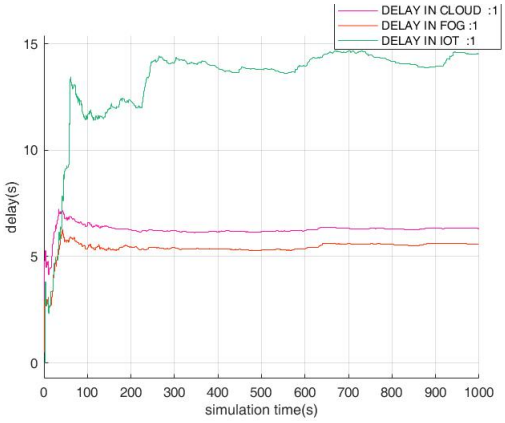

Fig. 3. when $\lambda 1$ =0.4 and $\lambda 2$ =0.2

Here we have taken arrival rate of high priority task greater than low priority tasks. Stop time for simulation is fixed as 1000 seconds and from the figure 3 it is observed that fog computing outperforms.

Case C: when $\lambda 1$ =0.3 and $\lambda 2$ =0.3

When the arrival rate of both the tasks are same, it is observed that the fog computing still outperforms the cloud computing and the computation at the IoT layer as shown in figure 4.

Case D: when $\lambda 1$ =0.3 and $\lambda 2$ =0.52

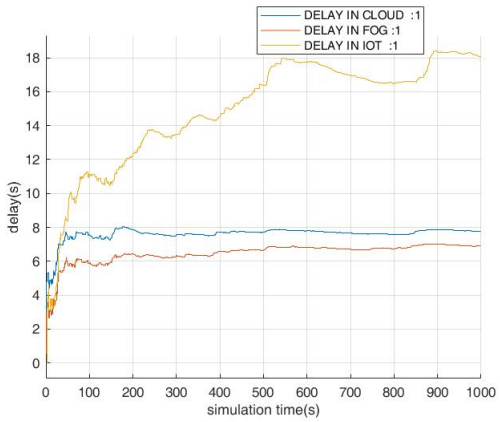

Fig. 4. $\lambda 1$ =0.3 and $\lambda 2$ =0.3

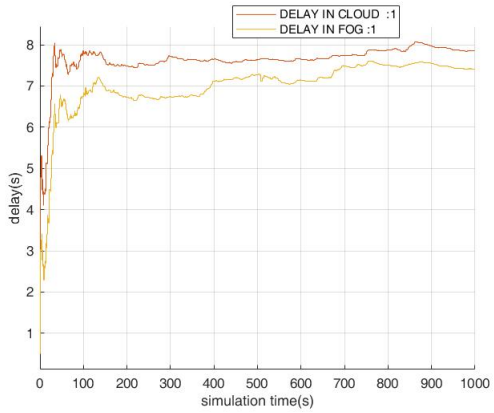

Fig. 5. $\lambda 1$ =0.3 and $\lambda 2$ =0.52

At this arrival rate fog computing outperforms as shown in figure 5.

Case E: when $\lambda 1$ =0.3 and $\lambda 2$ =0.53

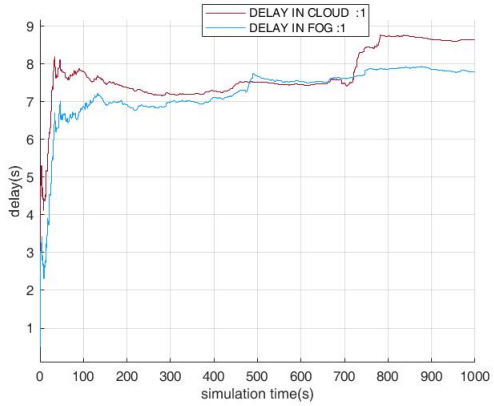

Fig. 6. $\lambda 1$ =0.3 and $\lambda 2$ =0.53

At this arrival rate there occurs small flactuations in the waiting time as shown in figure 6.

Case F: when $\lambda 1$ =0.3 and $\lambda 2$ =0.54

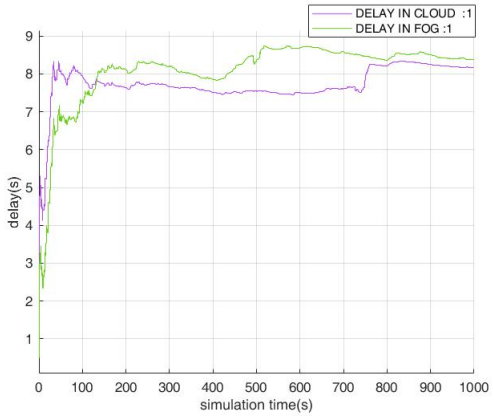

Fig. 7. $\lambda 1$ =0.3 and $\lambda 2$ =0.54

As we observe from the figure 7 that at this arrival rate, cloud computing outperforms the fog computing because the service rate of fog computing is lower than cloud computing. Cloud computing can easily handle the increased traffic rate due to its huge computational power. It is observed that upto arrival rate of 0.83 ($\lambda 1$+ $\lambda 2$), the fog computing outperforms and when the arrival rate is increased beyond 0.83, the cloud computing efficiently handles the traffic and outperforms. So 0.83 is the threshold up to which fog computing efficiently handles the traffic.

V. Conclusion

Fog computing has resulted in the making the system the system more efficient by minimizing the delay. We analyse the delay at different data arrival rates at three layers of IoT, fog and cloud. It is found that when the arrival rate is below certain threshold computation at fog layer produces minimum delay and when arrival rate overshoots limit or when number of tasks overshoots the threshold, the cloud computing efficiently handles the traffic and produces minimum delay. So to build an efficient system we need to have a mixture of both Cloud and Fog computing. In future one can compare this model with some existing model and compare the results, one can analyse the system.

***Abstract*—This paper discusses a Help Spot System as a senior design project. Nowadays, the education organizations have become huge and divergent. Finding resources and tools that are related to the subjects is challenging for students. Therefore, a website work as a communication medium between students, alumni and faculties will help to solve the problem by letting them stay in touch whenever they need anything related to their major. To develop Help Spot system, we use latest technology and components such as, Beaglebone, Smart Door Latch, Logitech Webcam. This design was found to satisfy the project objectives and solve the problem in the shortest period of time. Based on the requirements three alternatives design were generated as a solution for the project problem. The first and second alternatives is about using three tier architecture and fortify. The 3rd alternative is the best solution which consists of a website, mobile application, and a locked locker to provide a self-delivery option. Moreover, the website is adaptable for different screen size. Automatic monitoring and guaranteed malware removal and open source programming languages are used. Along with several features such as chatbot.**

Keywords—help spot, QR code, website, mobile app, communication, lockers, web-based services.

I. INTRODUCTION

Each year and semester there is a batch of graduates and a new batch that come to the university. Each new batch used to struggle just to find college supplies related to their major. This is due to many factors like rarity of items, high cost textbooks, etc. Basically, students should have relatives or friends who have studied the same subjects as they will, so they can buy needed supplies as used products with much lower cost, or borrowing it for free, which is not always the case! Also, if a student wants to order books from Amazon or any other online stores, it may take long time to be delivered. So, there is a need for an effective communication medium between students and faculties to help them stay in touch whenever they need anything at any time. This problem is usually overcome by exchanging the needed resources within the college, communicate with older students through social media, and order the needed resources from abroad. All these solutions are temporary and inefficient. The most efficient and effective way is to automate the process of exchanging items to follow kingdom's 2030 vision and enhancing the progress of E-government by contributing in E-commerce . the problem can be tackled by implementing an online store that provide the ability of offering/selling items from one side and borrowing/buying items from other side. The organization of the paper is as follows: Section 1 introduces the problem, section 2 discussing the exiting technologies in the field, the next section describing the baseline design of the product, the following section is about the approach and the results of the project and the last section including the references.

II. LITERATURE REVIEW

A. Websites

Website is information and documents that can be stored and accessed through the Internet that help people to connect with large audience. The first website was created in 1991 by Tim Berners-Lee[1], Since then approximately one billion sites have been created for a huge variety of purposes. Every website has a unique (URL) to provide easy access to it. Websites are constructed using Hypertext Markup Language (HTML), a specialized language mixture of human language with computer-centric coding. Most sites contain of one page or more, depending on the website purpose. Designers create and develop websites with a vast array of features according to user requirements. Once a website is completed, it must be launched onto the World Wide Web to make it accessible to the public [2], [3] .

The first World Wide Web was conceived in 1989 by British physicist Tim Berners-Lee. Berners-Lee devised a method to allow the exchange of information with people via computer network. By 1991, he has created the first Website in history, which introduced his vision for a World Wide Web that would link information across the globe. Although this website was simple and pragmatic, it demonstrated the enormous potential of Berners-Lee's creation. Since then governments, businesses, schools, and individuals added their own sites to the network of publicly shared information, such as Yahoo, Google, Amazon, IMDb, and eBay [2].

The early 2000s brought with it an increase of support for CSS language, which allowed for the separation of content and design. Along with this, the ability to create a good website entailed far more than just knowing how to write the code. Accordingly, a science of website design has arisen. This gave greater creativity to web designers and developers. It made websites easier to maintain (less code and complexity), more flexible, and quicker to update.

Ultimately, the designer needs to study every design element in such a way and to bring the most relevant content to the user in the most efficient and effective way. People

want to access information to find what they need at any time, so any site that makes this job easier for a user, the user will be benefited [4].

By September 2014 one billion active websites could be found on the World Wide Web. After only two decades from the publication of first website, online shopping has established itself as an irreplaceable component of any good marketing strategy. Nowadays, websites help in performing various tasks like registration, purchase, payments, etc. In addition, websites provide an easier way for customer service. Websites can contribute to reduce customer service costs, saving time and money, and providing more information. Likewise, the education field, facilitate services between students, faculty, administrative staff and visitors, provide valuable academic information and services to its users without any difficulty [3]-[5].

The following Table is about implemented websites in real life that let people to lend their stuff for other people to borrow it by lower cost.

TABLE I
ADVANTAGES AND DISADVANTAGES OF EXISTING WEBSITES

Project	Peerby website [6]
Advantages	- Enables people to borrow from their neighborhood. - Save money. - People can borrow form Peerby anything they need.
Disadvantages	- Not supported by English language. - Delivery service is not available in the lending process

Ultimately, how websites started simply for the purpose of communication between people, to these days where one website can provide a lot of services that make life easier. A website is online and accessible 24 hours a day and can sell products at any time.

B. Mobile Applications

"Enterprise applications have the reputation for being business and educational tools. However, with the success of platforms such as iOS and Android, consumer expectations have raised the bar on what constitutes an acceptable user experience. Enterprise apps are now starting to feel the impact of this renewed focus on ease of use and visual design. Recent initiatives inside of IBM have launched IBM into a new world where it is no longer sufficient for an enterprise app to be merely functional. With our new focus, apps must also be easy to use, visually appealing, and engaging" [7].

The five major platforms in developing mobile applications are: Android, iOS, RIM (Blackberry), Symbian, and Windows [8]. For developing their apps, all these platforms use some C programming language and/or Java. Using their own developing environment and programming interface. The following Table 2 shows each platform with its core language and environment.

TABLE III
MOBILE OSPLATFORMS

Mobile Platform	Core Language	Environment
Android	Java or C++	Eclipse
iOS (Apple)	Objective-C	Xcode
RIM (Blackberry)	Java	Eclipse
Symbian	C++	Multiple choices
Windows	C#	Visual Studio

Recent market share information shows the number of apps available in leading app stores as of the 1st quarter of 2018 shown below in Figure 1. This alone shows that Android and iOS are the leaders platforms in mobile apps industry.

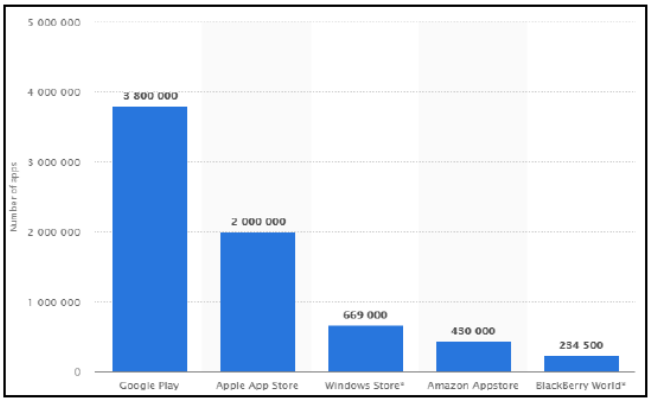

Fig. 1 Number of apps available in leading app stores as of 1st quarter 2018 [9]

To narrow the options more, Table 3 below shows a comparison between Android and iOS platforms.

TABLE IIIII
COMPARISON BETWEEN ANDROID AND IOS

	iOS	Android
Development Environment	Freely Available	Freely Available
Annual Fee	99$	Free
Technical Support	Paid	Free
Mobile Device Emulator	Available	Available

By means of this, all the elements pointed to Android platform as the most appropriate developing environment for students and beginners due to how affordable it is [10].

The following Table shows similar mobile applications related to universities, books, supplies, and education which are the scope of our project.

TABLE IVV
ADVANTAGES AND DISADVANTAGES OF EXISTING APPLICATIONS

Project	My college bookstore [11]	Marketplace [12]	Student desk [13]
Advantages	-Tracking the status of the bookstore orders. -Browsing articles about tips and advices for college. -Renting date reminders	-Variety of items to be traded. -Searching by community.	-Ability to rent or exchange books. -Availability of communities
Disadvantages	-No communication between the bookstore and students.	-No communication between the bookstore and students.	-No communication between the bookstore and students.

To solve lack of communication within universities, our project aims to be the medium of communication between students, which the previously mentioned mobile apps does not provide. Furthermore, all supplies can be can be offered, not only text books. In conclusion, our goal is to provide better services that previously implemented mobile applications and avoid their disadvantages.

C. Electronic Lock System

The most important thing to secure the self-delivery service's process is providing a secured place/locker for delivery and receive the items have been sold. Only a specific person must have access to the locker, so the best way to secure it, is an electronic lock system.

Electronic lock systems depend on controlling a small motor connected to the door bolt by an actuator. The motor is controlled by an electrical impulse, which may be triggered in many ways, such as a keypad, or a QR reader. This means that the electronic door lock will not start the motor-driven actuator until it has received the expected electronic input [14].

Keypad lock is an electronic lock for use with lockers assigned for transitory or permanent use, it has a keypad for entering a pre-selected sequence of digits. It has two modes: transitory mode and a longer term assigned locker mode. In the transitory mode, it is programmable for each use, the lock shifts a latch to the locked position on a first entry of a sequence chosen by the user and retracts the latch to unlocked position when the same sequence is re-entered by the user. A subsequent user of the locker (when unlocked) can enter any sequence of digits desired. In the mode of a longer-term assigned locker, the electronic lock is programmed by the user, and the same combination is retained as long as desired. In this mode, the selected sequence is used only to unlock, with the latch or mortise being spring-biased. The construction of the electronic lock is modular, easily fitting on nearly all contemporary locker designs, retained by only a few screws [15].

Many improvements have been made to keypad locks; one of the highly advanced locks is WIFI Smart Lock, as shown in Figure 2. It gives the user both wife-connected and no-internet lock control. But either way, the user should change the password each time manually, as he desires.

Fig. 2 WIFI Smart Lock [16]

A QR code (quick response code) is a type of 2D barcode that is used to provide easy access to information through a smartphone, using a barcode reader app. Figure 3 shows an example of a QR code.

There are two types of QR code: static and dynamic codes. Static codes have used to disseminate information to the public, as what often displayed in advertising materials everywhere, while the dynamic codes are more functionally and can be edited by the code owner [18].

Fig. 3 QR Code Example [17]

A great feature of QR codes is that they can be auto-generated, in contrast to keypad locks, which make the QR code reader lock more preferred to apply in the "Help Spot System". The QR code-based Door Lock System is a QR reader lock project. It used a simple web interface; approved users are added to the system via their email addresses. Once added, these users are sent a QR code via Email, that when held up to the system, allows them to unlock the door. After each scanning, the QR code will be expired and a new one will be auto-generated and sent to a specific person [19].

D. E-commerce

Electronic business or as it is known as E-business is "the process of buying and selling goods or services electronically rather than using conventional means" [20]. One of the functions of E-business is E-commerce, it involves commercial transactions done using an electronic

transmission medium and requires the use of a website. E-business is the broader concept including pre-sale and post-sale efforts, while E-commerce is the narrower concept and is restricted to buying and selling. In general, E-business is any electronic transactions, such as: information exchange which subsumes E-commerce. There are many applications of e-commerce, including online retailing, online banking, electronic markets, online auctions and others.

"Electronic commerce improves the efficiency and effectiveness of business, governments, and not-for-profit agencies" [21]. The ability to conduct business all over the world 24/7 is a major advantage of being online. "According to the U.S Department of Commerce, between December 1998 and August 2000, the share of American households with Internet access jumped from 26.2% to 41.5%. In 2000, more than half of U.S houses had PCs" [21]. All these factors have encouraged E-business and E-commerce in the last decade. For example, Nestle was one of the initiating companies in leading the E-commerce revolution. Peter Brabeck- Letmathe, CEO of Nestle, believes in this transformation and calls the process "E-revolution" [22].

E-commerce sites are either pure E-business, such as Amazon, or they have an E-commerce presence, such as Wal-Mart stores. The backbone of E-commerce is the Internet. Simply, it can be referred to as "network of networks" [21]. There are many popular services available on the Internet that support E-commerce program and enhance E-business, such as: E-mail, discussion groups, Internet Relay Chat (IRC), Instant messenger and others.

The popularity of e-commerce has increased due to the rapid development of the Internet which has motivated companies to enter the online market [23]. In the era of speed, E-commerce has impacted the community positively. There are many advantages of E-commerce which can be identified by three types. These include perceived economic, relationship-related, and strategic benefits. The speed and automation of the E-commerce applications help to improve the efficiency in the business process. Which directly affects the economy in a positive manner, including the reduction of transaction costs, administrative expenses, and time-saving from a faster trading cycle. Internet applications can increase and enhance trading partner's productivity and increase their capability to communicate globally [23], [24]. Despite the advantages of E-commerce, it may carry enormous risks for both retailers and customers. In fact, the travelling of information over the internet passing through many inter-mediating nodes before reaching the final destination is still a nightmare for many people.

III. Product Baseline Design

A. Block Diagram

The block diagram describes the process that happen to Help Spot system starting from developer and end with achieved goal of system.

First of all, the developer creates a database using SQL server store and retrieve information in a way that is accurate and effective. The Website is going to be programmed using Visual Studio and C# language. The website has Several features: Responsive which mean have one design but is adaptable with any screen size, Chatbot that answers all customer's doubts, Search engine optimization-friendly since it displays a search history for each user. GoDaddy is response about hosting and security of the website. The mobile app is connected to the same database for the website and is going to be programmed using Xamarin and C# language. Second stage the seller will register to website as seller then offer and item in the Website and select the payment method after getting approval from admin. In other side the buyer will register to website as buyer and then choose item, there will be contact between seller and buyer to decide the delivery method. Third stage is locker secured with QR code, the locker has a camera that scan QR code and translated into string and compared if it is identical the locker will be opened otherwise nothing will happen. When the item gets purchased and delivery method is selected to be self-service a QR code will be sent for seller and buyer, therefor seller will put the item in locker using that QR code, and buyer can take the item from locker by using same QR code after that QR code will be expired. By the end of this process the goal of Help Spot will achieved since we get Effective Communication.

B. System Description

The initial design of the circuit consists of beagle bone board powered by a 5V power supply, with a webcam connected to it through its USB port, in addition to an electric door strike connected to its pins. Also, there are two LEDs, green and red connected to the board pins with resistors. The user who owns the QR code will scan it using the webcam. If the QR code was valid, the green led will turn on and the electric door strike will turn on for few seconds, then it will turn off automatically. In case the QR code was invalid, the red led will turn on till the user scan the valid QR code. Figure 5 shows the circuit initial design.

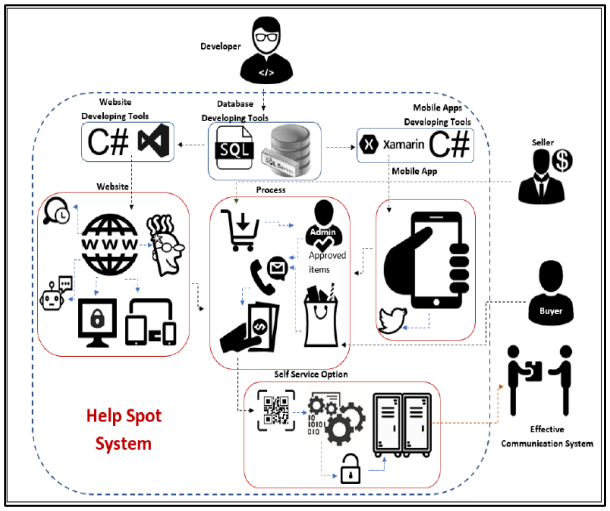

Fig. 4 The block diagram of the system

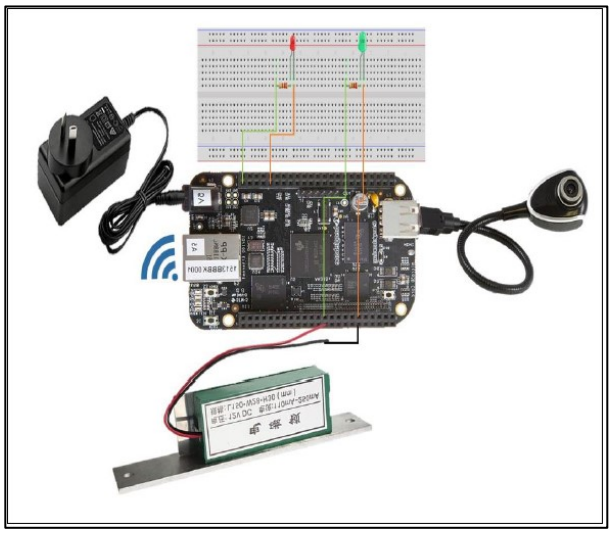

Fig. 5 The circuit schematic of the project.

The following flowcharts are explaining the flow of the system, and how the software and hardware parts are connected. The flowchart shown in Figure 6 can be applied on both website and mobile application, which starts by checking whether the user is registered or not. If registered, the user will be redirected to the home page, then for each role, an action can be taken. The admin can approve the offered items by the sellers, sellers can offer items for purchasing or borrowing in addition to selecting the payment method. Finally, buyers can search for an item according to certain categories, after selecting an item, the delivery method can be selected after coordinating with the seller. No need for coordinating with the seller about the delivery method if the method used is self service delivery, because a QR code will be generated and sent to both buyer and seller. After generating the QR code, it will be sent through WIFI to the beagle bone board to be compared with the scanned QR code by the camera after translating it to a string. Finally, once the scanned QR matches the one stored in the beagle bone board, the locker will open to put or pick up items. The hardware part process is shown in Figure 7.

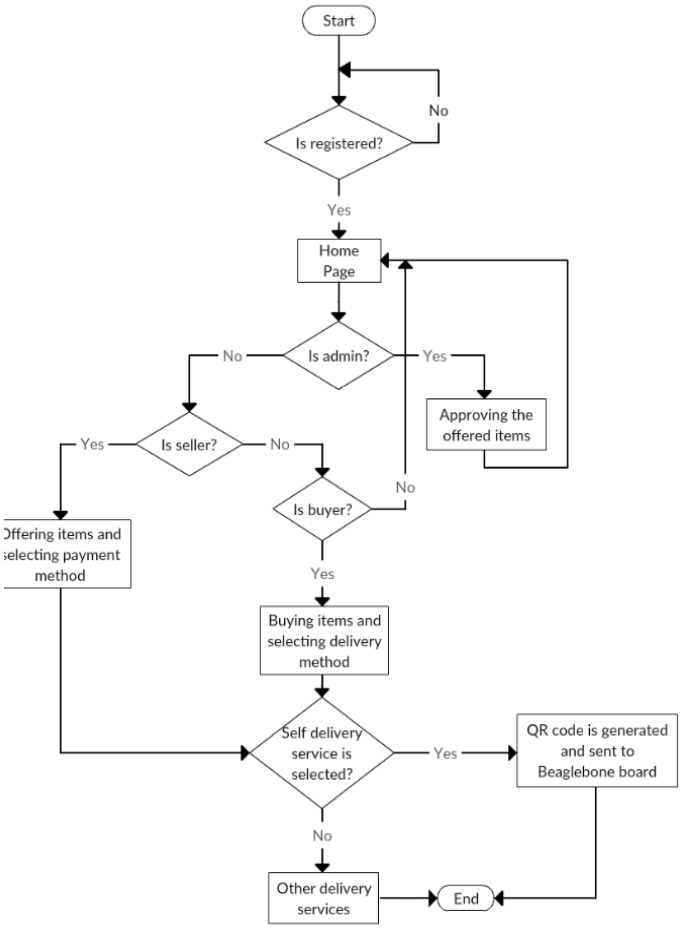

Fig. 6 Flowchart for QR code lock process

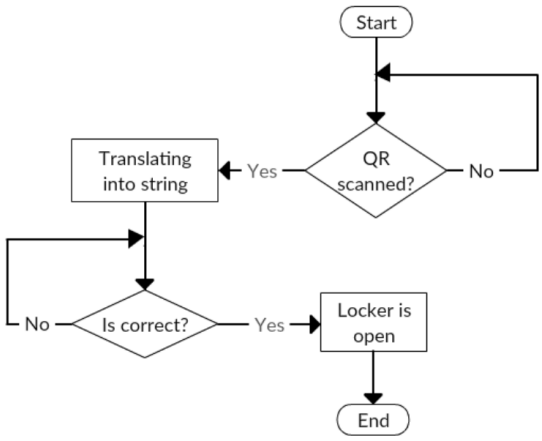

Fig. 7 Flowchart for website/mobile application process

C. *Impact of the Engineering Solutions*

Impact assessments are to assess impact of Help Spot system to ensure the system are economically viable, socially equitable and environmentally sustainable.

Implementing this system will provide effective communication between students in the campus to help them stay in touch whenever they need anything at any time.

The benefit of applying Help Spot system is more efficient in saving data from lost since all the data through the years are saved in database. Also, the website will save time, reduce effort since there is no need for more than one

admin responsible about all process in website, paper transactions will be canceled, so a lot of wastes will be reduced. Moreover, the delivery method will reduce pollution that come from transportation since the supplies can be received through campus.

IV. Approach And Results

This project is a system that consists of three main parts, website, mobile application, and secure locker. It aims to provide an appropriate medium to exchange, sell, and buy study resources for university students. The website and application allow the user to add items for sale and buy them; while the website provides a feature of self-delivery service, which is made through the locker after choosing the credit card as the payment method.

The idea of the locker is that it is locked by a QR code that is sent to the customer. This code will be valid for one scan only. After the scan, a new code is generated and becomes ready to be sent to the next customer. The one-scan validation makes the locker safe enough to send and receive items between customers

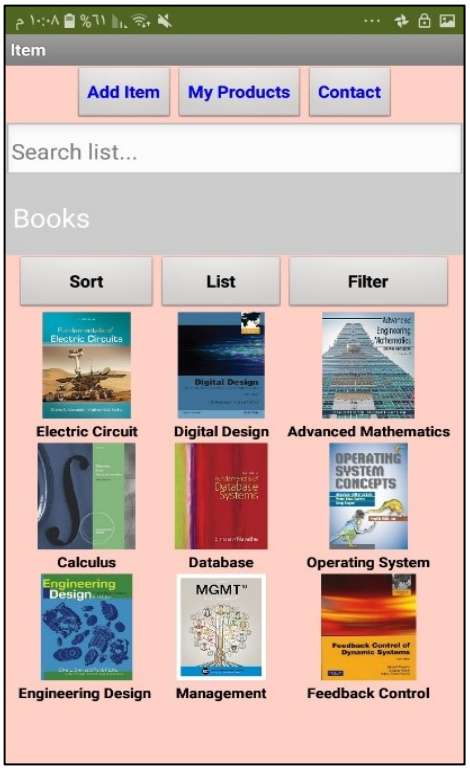

Fig. 9 Help Spot mobile application home page

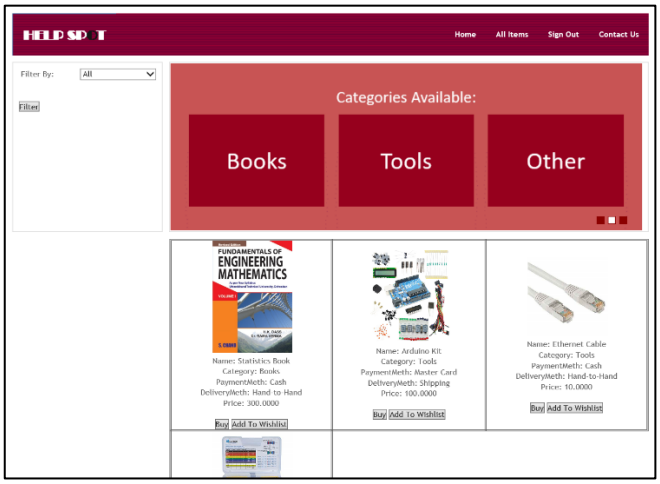

Fig. 8 Help Spot website home page

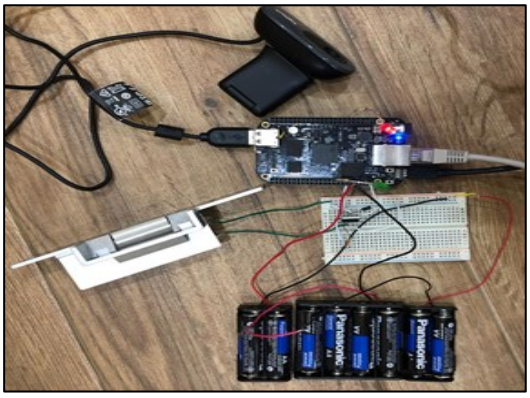

Fig. 10 Secured locker connection

V. Conclusion

The project aims to solve the student's problem of spending a lot of money on the needed supplies, from books, tools, to resources that are related to their field. Usually the students prefer to borrow these supplies from the older students within the university, but the lack of communication between the students will make this process harder. Hopefully, this system will help the students and faculties to find whatever they need whenever they want. There are many recommendations to improve the system in the future and make it capable to serve more customers efficiently. These suggestions are as follow: Targeting the educational bookstores as partners to provide books and sell them via Help Spot System. This will make the system's items rich with useful books for students, partnering with a delivery company to provide delivery service with revenues, making Help Spot System services available for other universities students.

***Abstract*—Keeping in mind the advancement of implementing the A-EVs on road, this project includes designing of a control system for a 4 wheeled autonomous electric vehicle using MATLAB/Simulink environment. The vehicle can travel to a predefined destination avoiding obstacles coming its way. The features and algorithms required to developed the robot is illustrated. MATLAB and Simulink environment is an ideal platform for developing such kind of projects. A typical scenario is shown to demonstrate the functionality of the robot. Autonomous electric vehicles come with their own procs and cons. Huge investment has been made by automobile companies to come over A-EV's limitations and make a breakthrough in the automobile industry.**

Keywords—Automation; four wheeled chassis; Arduino Mega 2560; rechargable battery; MATLAB/Simulink ; DC dual axis gare motor, SHARP IR sensor.

I. INTRODUCTION

Human life is dynamic. One of the greatest invention for the modern world is vehicle undoubtedly. The recent research of the transportation says that the main medium of travelling through the world is car and there are more than 900 million of passenger car moving on the track throughout the world. The self driving cars may be interpreted as the upgraded versions of our current vehicles that are competent enough of taking over control from the driver under certain situations. Robotic cars that are highly automated do not possess steering wheel or pedals that are installed for the driver. Fast development in electric vehicles has been leading to the need for the academic & industrial world. With hike in server environment problems around the globe, exploration of extraction of energy from undepletable has become a censorious topic. An essential part of transportation in the 21st century, vehicles are pervasive but also one of the main cause of pollution. Overall electric vehicles have an added advantage over the petroleum vehicles of being more hygienic, more energy efficient and environmentally friendly. Smart grid technology has become universal and is playing a major role in advancement of autonomous electric vehicles. Huge financial investment has been made by automobile manufactures around the world for research and abiding changing technology. The combination of an autonomous and battery powered vehicle has proven to be a breakthrough in automobile industry. Today thriving developers both hardware and software specialised are involved in sensors, plotting, machine learning, advanced assistance systems for drivers, car pool platforms & neural networks for transportation. Autonomous Electric Vehicles (A-EVs) use AI, next-generation batteries and other technologies and could transport passengers more efficiently, without the need for drivers or fossil-fuel-driven internal combustion engines (ICEs).Some of the autonomous electric cars in the industry today are: BMW Vision iNeXT, Volvo 360c, Renault Ez Ultimo, Chrysler Electric CARJAM TV, Mercedes Vision EQ etc. The thesis addresses developing an autonomous electric vehicle prototype. Keeping in mind the advancement of implementing the A-EVs on road , this project includes designing of a control system for a Four wheeled autonomous electric vehicle using MATLAB and Simulink environment that is capable of detecting obstacles and avoiding it in order to reach its destination. The core control mainly consists of controlling the motors speed and direction. Models to achieve the objective are developed in Simulink environment using Simulink tolls and packages.

A] POTENTIAL BENEFITS AND PROBLEMS OF AUTONOMOUS ELECTRIC VEHICLES

Automobile quality includes a set of benefits, like freedom of transportation for those that will afford to possess the automotive or perhaps shared automotive pools. Amusement technology like video screens, music etc. might be used by the driver without causing any hinderance in driving. Human drivers knowing or unknowingly tend to break rules and risk their lives, however autonomous cars can adapt each road rule and denote ordinance. Traffic jams and bottlenecks can reduce drastically in urban areas due to eminent coordination hence commute times will be reduced drastically. Poor navigation and driving fatigue would be things of the past. Those people who have difficulty driving such as the differently abled , elderly voters, and children would be able to travel alone safely. Along with efficient travelling comes benefits of cost cutting, lower fuel consumption else use of renewable resources like battery in electric vehicles and reduced negative impact on the environment.

A self-driving automobile would be unaffordable for many individuals accounting over $100,000 according to sources. There is a possibility that bus drivers, cab drivers like Uber or Lyft etc may tend to loose their posts as autonomous vehicles come into picture. Also minor crash in the computer like a glitch would simply cause a threatening accident than something human error may generally experience. Navigating crowds, pedestrians and deciding human intention on road baffles the vehicle under certain conditions and puts it in a position to take decisions that may be out of its scope. Snow interferes with cameras and heavy rain with roof mounted Laser sensors. Hence change in weather condition can hinders its smooth operation. The infrastructure and road system would doubtlessly need major customization for autonomous vehicles to collect data and run on them, for example Traffic lights ,caution light, street lights, would need upgrading. Hackers getting into the vehicle software, fetching the driver's location, personal detail and administrating and affecting the cars functioning would be a major concern and will violate the Data Protection and Privacy laws.

B] LEVELS OF AUTOMATION

SAE classifies automation in 6 levels, explained below:

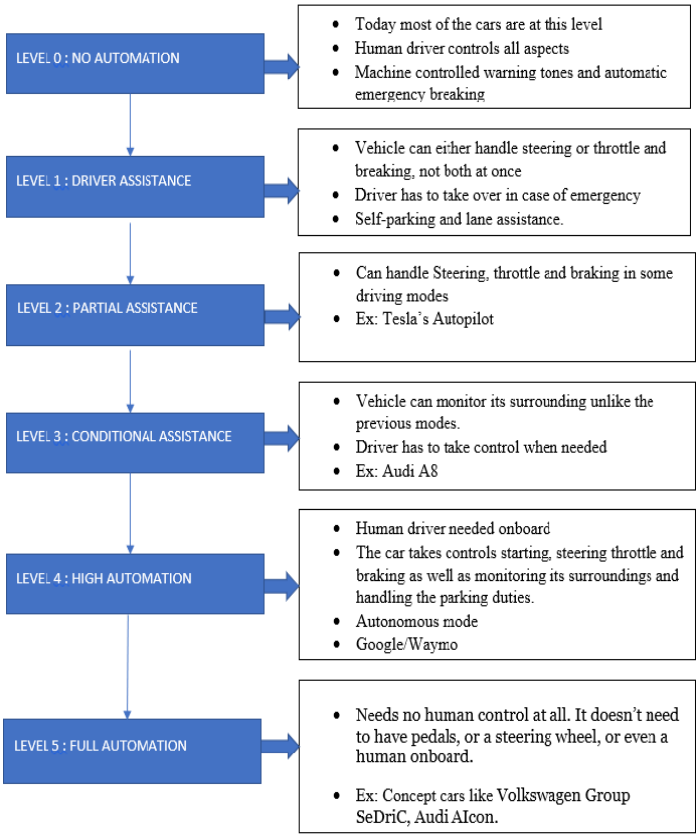

Figure 1 – Levels of automation flow chart

C] AUTONOMOUS VEHICLES IN VOGUE

Waymo has been acknowledged as a leader in the autonomous vehicle technology. It originated as a project of Google in December 2016 it become a subsidiary of Alphabet Inc. In April 2017, Waymo started a self-driving taxi service trial in Phoenix, Arizona. It uses LiDAR for navigation. Constant upgradation and transformation of the vehicle brought into picture new sensors and chips that are less expensive to manufacture, wipers to clear the LiDAR system and cameras that improve visibility. Waymor began designing its own LiDAR as a part of in house manufacturing of self-driving hardware. It eventually reduced its dependency on suppliers that lead to overall cost cutting. Sensors are used for 360°view, short range lasers are used to focus on the near objects approaching the car, long range Lasers can cover up to 300 meters. Radars are used to look around the car and detect moving objects. As of 2018, Waymo has driven more than 5 billion miles on road. But still waymo struggles to satisfy Level 5 expectations.

Tesla created a boom in the automotive industry by launching Model S, Model X, and the new Model 3. Tesla models do not come under completely autonomous or level 4 category. It provides a more advanced driver assistance system and is of Level 2. In recent times Tesla has started using its own custom chip for the Model S and Model X. Also a few days back they used it in Model 3. Two different advanced driver assistance packages offered by Tesla are: Autopilot and Full Self-Driving. The concept of Autopilot incudes an inline processing of better control on the steering and at the same time monitors the lane disciplines. This is now made available as a customized feature in new cars. Given that now this feature is included in the cars the price of car is also increased. The driverless cars, costs an additional $5,000 (And to be more specific, these cars are not completely self-driving).
Full Autonomous cars includes functions to command, uses wayfinding system on autopilot, uses an built-in guidance system which navigates a car on and off the highway ramp. Once the driver enters a destination for that trip into the navigation system, "Navigate on Autopilot" mode can be enabled.

Uber first announced its intentions of manufacturing automatic cars in February 2015. The cars were infused with around seven lasers, a Global Positioning System, radar detectors and LiDAR. Initially they started their research and service in Pittsburgh, where group of researchers were hired . They opened a Advanced Technologies Center. Uber couldn't find much luck in this sector as well as in march 2018, an Uber self-driving car in Arizona hit a lady who sadly died.
Companies like Volvo, BMW, Audi have taken keen interest and are in race for successfully manufacturing a fully autonomous vehicle.

II. LITERATURE SURVEY

The purpose of my project is to built up a car that can move without any driver. It just needs a command from the user and it will start moving towards the destination. I have researched

about my project and I found some equipment that I need to build my vehicle. Some of them are LiDAR, Radar, GPS, Sensors etc. RADAR and Ultrasonic sensors will work as the sense of the vehicle and provide a remarkable amount of information in the range of 750 MB/s, which is more than a human driver could even attain. I have referred the paper "LIDAR based Perception Solution for Autonomous Vehicles" by Domínguez R. to learn more about LiDAR sensing. A LiDAR can process a detailed 3D image and 360-degree map of the place. To know more about simulation in Simulink reference has been taken from "Electric vehicle drive simulation with MATLAB/Simulink" by David McDonald. Simulation is a tool that helps develop designs. It reduces the overall cost of product development. The design process includes constructing models that are capable of performing functions. Engineers can efficiently decrease the cost and time of the design both by integrating simulation within the design process thus companies can complete and validate the designed items. Jiajia Chen, University of science and Technology China Hefei, China, describes autonomous vehicle as a breakthrough in the automobile industry to decrease traffic accidents dramatically. The lane detection and changing for an autonomous vehicle is important for the system and also to generate a new way to pass the front vehicle without having any collision and maintaining safe distance. Geetinderkaur, Sourabh Joshi, Jaspreet Kaur, Samreet Kaur, Going Driverless with Sensors, International Journal of Science, Engineering and Technology, Volume 2 Issue 5 June 2014. This paper gives the information about the google driverless car. Google maps provides the information about the road, traffic signs etc. the second part is the different types of hardware sensors such as lidar, video camera, position estimator, distance sensor, aerial and computer these sensors are used for obstacle detection.

III. DESIGN AND SETUP

A] SCOPE OF WORK

To design a core control system that will autonomously drive a 4 wheeled vehicle which allows the vehicle to move to a predefined point or destination and avoid obstacles during the motion using the information got from sensors which are installed in the car. During navigation, if the car doesn't find enough space to pass through the obstacles it must stop there itself. The control system will be designed in Simulink environment. The vehicle will be battery powered. Core control mainly includes controlling the direction and speed of each wheel.

B] HARDWARE AND SOFTWARE USED

Hardware: Four wheeled chassis kit, Arduino Mega 2560, DC 3V - 6V Dual Axis Gear Motor, L298N Dual - H Bridge DC Stepper Motor Driver Module – Green, Micro Servo motor, Infrared sensor (IR sensor)- SHARP 2Y0A21 F 82 ,Short range (10 to 80 cm) and SHARP 2Y0A02 F 88, long range (20 to 150 cm), IR sensor module (10 cm), Rechargeable battery, wires.

Software: MATLAB/Simulink
MATLAB or Simulink environment software is used to model the functionality of automated driving cars and also develop algorithms of control development and computer vision. Most of the companies choose to go with MATLAB and Simulink as these platforms provide a better and an fused environment that makes it easy for engineers to model and validate perception algorithms that collect data from vision, Radar, and LiDAR . Sensor fusion technique helps create environment, vehicle, and driver models. Simulink, an bonus product to MATLAB, provides a synergistic, diagrammatic environment for designing, simulating, and scrutinizing of dynamic systems. It has a complete library of blocks whose function is predefined and utilized to build graphical designs of systems using select-and-place mouse operations. Sensor fusion is performed using a library of tracking and data association techniques including point and extended object trackers. To estimate vehicle position and orientation, simulate measurements from IMU/GPS sensors, and design fusion and localization algorithms. Hence, I have chosen to use Simulink environment to develop my model.

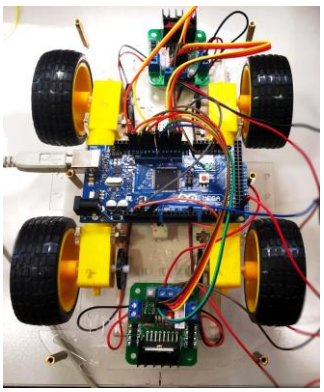

Figure 2- Four wheeled chassis kit along with Arduino Mega and L298N motor controller

C] SKID STEERING SYSTEM

Skid steering concept is used achieve the principle of driving at different speeds in forward and reverse course considering the wheels on each side. The main moto behind this is that the wheels on the same side should be driven at a similar rate. To achieve the zero radius turn in right that is clockwise direction the wheels on the DC motor at the left side drives the left wheel forward and the wheels on the right side are driven backwards as the DC motor spins in the opposite direction. The drawback is that moving in a straight path demands that wheels on each side to be should turn at the same RPM, which can be tricky to achieve. The advantage of this steering is increased grip of the car on the road.

D] PATH FINDER ROBOT EXPERIMENT

To configure the control system of the car we first need to develop an algorithm based on mathematical formulas and

sensor values. In the following experiment two obstacles are present at different distances from the car as shown in the figure 3.

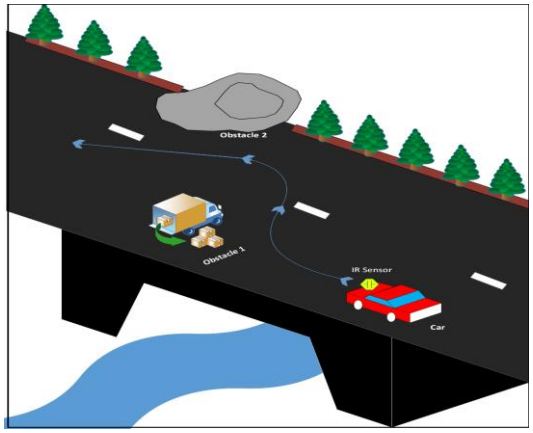

Figure 3-Senerio of an autonomous car overcoming obstacles

As the car moves forward it senses two obstacles. Using its artificial intelligence, it calculates the possibilities to pass through. The steps followed for the same are as per the flowchart below.

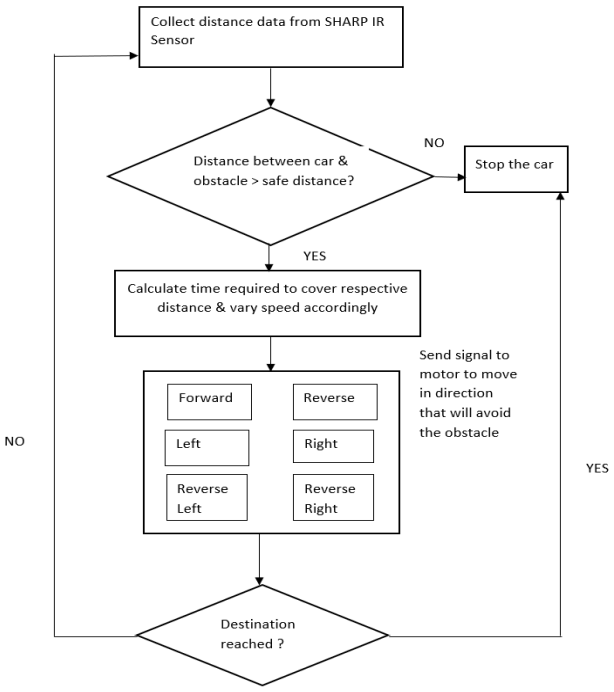

Figure 4 – Flow chart of the the motor algorithm

In figure 4, the following steps are executed in a series:

1. The car obtains the distance values from the short and long range Sharp IR Sensors that are fixed at different heights in the anterior section of the car. The IR sensor is placed on a servo motor that keeps rotating from 0°to 180°continuously.
2. Let distance between obstacle1 and the car be D1 and distance between obstacle2 and the car be D2. Using Pythagoras theorem and mathematical formulas distance between the two obstacles is calculated,D3.
3. An algorithm for the car to move forward, reverse, left, right, reverse left and reverse right is created.
4. Time can be calculated for the car, for example to move forward time is calculated using speed and distance relationship. In Simulink, time is used as a signal to trigger the direction of the vehicle.
    i. Time= Distance / Speed
5. With reference to the diagram, the car first moves forward. Based on what distance would be safe for the car to take a turn, signal is given to the motor to move right. Then maintaining a safe distance from obstacle2 and keeping D3 value in mind, the car turns slightly towards the left and then moves forward again.

IV. IMPLEMENTATION OF CORE CONTROL IN MATLAB/SIMULINK ENVIRONMENT

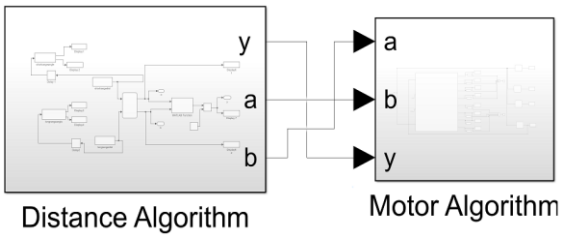

Figure 5- Integration of algorithms in Simulink

In figure 5, distance and motor algorithms are integrated. The motor algorithm consists of state flow diagrams, within it logic for the direction of the motor is implemented. It is time dependent for toggling from one state to another. Output of the state flow is connected to Digital Output block whose pin number is connected to the Arduino board.

A] ALGORITHM FOR CONTROLLING THE DIRECTION OF THE WHEEL

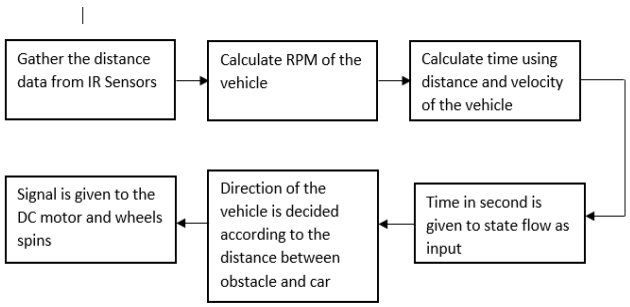

Figure 6- Direction control system of the vehicle

As shown in figure 6 ,distance coming from the short and long range IR Sensor is captured when an obstacle is detected from 0 to 180 degree. Based on the RPM of the vehicle and the distance data, time taken to more say foreward is calculated that is given as input to the state flow diagram. Within the state flow chart logic used for the car to turn in different directions is written . It is based on binary values. Transition from one state to another depends on input, time. Output of the state floe is given to the input of Digital output where the pin number is defined . The motor is connected to the arduino board via a motor controller-L298N. Hence each wheel has capability to turn in different directions.

B] ALGORITHM FOR CONTROLLING THE SPEED OF THE WHEEL

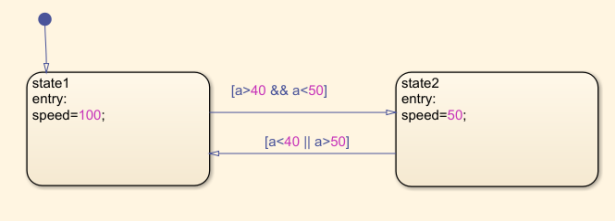

Figure 7- State flow diagram for speed control

In the above example, Figure 7, the speed of the motor is controlled. It is dependent on the distance coming from the short-range IR sensor (a). If the distance in between the car and obstacle is lesser than a predefined safer distance then the car must slow down its speed to say 50 meter/minute. If not speed of the vehicle will remain 100 meters/minute. Output of the state flow is given to the PWM (Pulse width modulation) block whose pin number is connected to the Arduino board. Hence Speed can be varied.

V. RESULTS

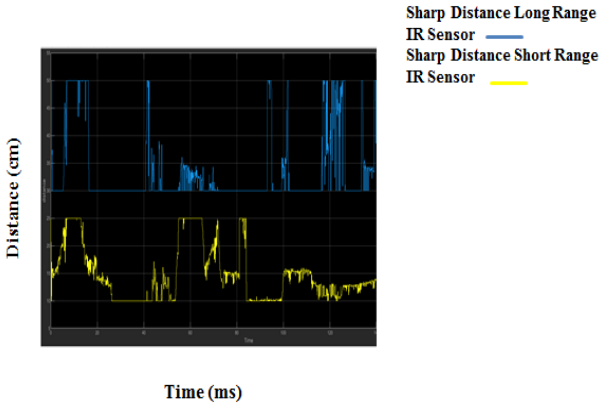

Figure 8- Distance v/s Time graph for SHARP IR sensors

figure 8 displays the distance of car from the obstacle while the IR sensor is moving from 0 to 180 degree. The steep changes that occur in the graph are when an obstacle is just detected or when the obstacle ends.

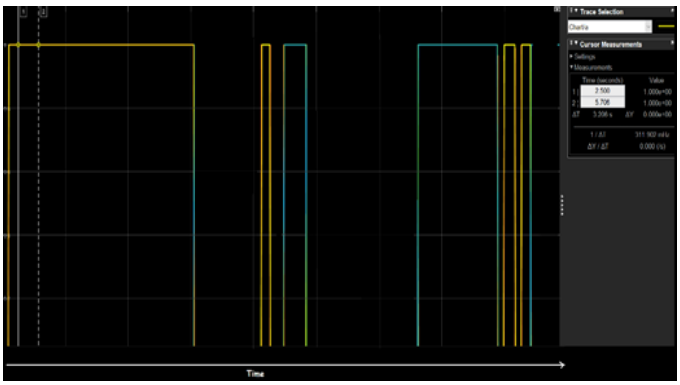

Figure 9- Motor control graph displayed on scope for two channel output

Output of the motor is displayed on the scope. If the car changes its direction the output waveform switches from high to low and vice versa. The time period for which the vehicle is in one direction, say forward can be easily calculated. In figure number 7, the speed of each wheel of the car can be changed by changing the RPM value. The PWM values used to control each wheel is first found out using open loop controller and LN393 (speed measuring sensor). These PWM values are used in Closed loop PID controller to control the overall speed of the car i.e. all wheels are capable of running at a same speed and in the same direction.

VI. FUTURE SCOPE

In order to archive more accuracy in detecting the distance values, LiDAR can be replace IR sensors. LiDAR's have high accuracy and quick response. Even a combination of camera and IR sensors can be used to effectively run an autonomous car. Image processing may be used to process the distance data.

VII. CONCLUSION

Building a obstacle avoidance robot that uses IR sensors & Arduino in Simulink environment is successfully completed. Programing the car to Level 2 automation for a prototype model is achieved. The car can now detect obstacles that comes it way and is able to reach its destination efficiently.

VIII. ACKNOWLEDGEMENT

I am pleased to present this paper. I feel blessed to be a part of such a wonderful college. I'm grateful to the entire staff. I would like to thank Tata Technologies,Pune for sponsoring my project and helping me expand my knowledge, I also express my deep sense of gratitude to my guides for their valuable guidance, encouragement and kind co-operation.

***Abstract*— In recent scenario Distributed Static Compensator (DSTATCOM) resolves the current related power quality problems and Dynamic Voltage Restorer resolves the voltage related power quality problems. The Unified Power Quality Conditioner is the integration of DSTATCOM and DVR with common DC link. Due to the major advancements in Solar PV systems and its availability in reasonable cost at consumer end the world is moving ahead for Solar PV system for renewable energy generation. Generally, the electrical power to the DC link is supplied from source side. This paper presents the UPQC with Solar PV system. In proposed system the electrical power is supplied to DC link of UPQC using Solar PV system. The proposed system is designed and implementation in MATLAB simulink environment. The performance of the proposed system is analyzed under various conditions of source voltage variation, load unbalanced condition. After MATLAB simulation the proposed system is implemented in OP4510 Real Time Digital Simulator.**

***Keywords*— DSTATCOM, DVR, DG, UPQC, MPPT**

I. INTRODUCTION

India is having rapidly growing economy with 1.3 billion peoples that facing an immense energy demand. India is the fifth in number on the basis of production and consumption of electricity. This country is having tremendous scope for the generation of solar energy and because of that central government of India has derived the solar energy policy that contains several guidelines and other aspects. There are several countries which are global leaders in solar energy generation such as United states, Germany, Japan, China. Solar power plants are installed in various regions in India and the performance of that solar PV systems is analyzed on the basis of various factors like temperature, humidity, wind speed, Rainfall and solar intensity in that particular sector [1] [2].

Solar power is discontinuous in nature. while connecting the solar PV system directly to the power grid without power grid management there may be power quality problems comes on that particular grid like voltage sag, voltage. For the management of solar PV generation in India there must be need to improvement of electricity grid codes for the satisfactory operation of power grid [3]. Solar PV systems is the combination of the various subsystems of solar PV panel, power conditioner/PWM inverters, Maximum power point tracker. This inverter is of various types like Micro inverters, String inverters. As the development in the computer technology and reduced in cost proportionally the use of software simulating tools rapidly increased. The widely used simulation software is MATLAB. For the real time performance analysis of the three phase residential solar PV system having control based on ANN is proposed in paper [4]. This papers explains solar PV generator reconfiguration for PV system which is formed by standalone and single central inverter driven by conventional MPPT algorithm. The effects on distribution transformer due to variable voltage of Solar PV system is presented in paper [5]. The Interharmonics are observed at the load end in the practical solar PV system and this journal presents analysis and modeling of the Interharmonics in this [6]. Introduction to power quality, power quality standards and monitoring, active and passive compensating devices, series and shunt compensating devices and loads that causes power quality problems are explained in paper [7]. The power electronics converter topologies used in various solar PV systems for increasing the reliability, cost effectiveness is proposed in paper [8]. Due to demand of clean power along with power quality improvement device the integrated photovoltaic dynamic voltage restorer system configuration is a good option. For the control of solar integrated DVR the synchronously rotating reference frame theory is proposed. Design control and operation of a DSTATCOM is explained in paper [9] [10]. The operation of shunt active filter based on synchronously rotating reference signal generation method is proposed in this journal [11].

A switching signal generation is the main function for control of DVR, DSTSTCOM and UPQC. The reference signal generation methods are broadly classified into time domain and frequency domain techniques. Time domain techniques are commonly used because of their lower evaluation time and faster operation. The commonly used time domain methods are IRP theory, SRF theory. The main concern with SRF theory is during load unbalanced condition second order harmonic is existing in the d axis of current [12] [13]. The IEEE prescribed standards for harmonic control in electric power system are proposed in [14] [15].

II. PROPOSED SYSTEM ARCHITECTURE

A. Distributed Generation System

In proposed work the solar photovoltaic system is used as the distributed generation. During darkness the solar PV system does not give rated voltage or current. Hence PV generators are neither be considered as constant voltage source or constant current source. If PV generators are connected to load it generates current which is called as diode current I_o and that diode determines the V-I

characteristics of the PV cell. The PV array is developed with the combination of the series and parallel solar cells. This solar cell equivalent circuit is represented in Fig. 1.

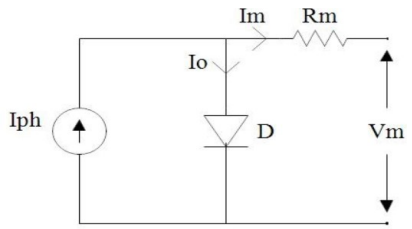

Fig. 1. Solar Photovoltaic cell circuit

The above circuit can be represented in equation

$$V_C = \frac{AKT_C}{e} ln\left(\frac{I_{ph} + I_D - I_M}{I_O}\right) - R_S I_M \quad (1)$$

Where the symbols are determined as fallows

V_C: output voltage V.
I_M: output current A.
I_O: diode current A.
R_M: resistance Ω.
T_C: Temperature C.
I_{ph}: photocurrent.
K: Boltzmann constant.
e: charge.

B. MPPT Circuit

MPPT system selects the output of the PV cell and implement the appropriate resistance for obtaining maximum power for particular environmental condition. In this paper incremental conductance method is implemented and this method design is based on observation of PV characteristics of solar cell. The output power from solar PV system is given as

$$P = V.I \quad (2)$$

When there is increasing change in voltage and current the improved power given in equation 3 and after neglecting the small terms, the equivalent equation is given in 4.

$$P+\Delta P = (I+\Delta I).(V+\Delta V) \quad (3)$$

$$\Delta P = \Delta V.I + \Delta I.V \quad (4)$$

`

At the peak point ΔP must be zero hence the hence the dynamic impedance of the source is given as

$$\frac{dV}{dI} = -\frac{V}{I} \quad (5)$$

The MPPT circuit consist converter having very high efficiency which selects optimal electrical load for the solar PV system.

C. Proposed System for UPQC

The UPQC is the integration of voltage quality improvement device connected in series and current quality improvement device connected in shunt with the system which contains nonlinear load. It is used in various combinations like right shunt and left shunt UPQC.

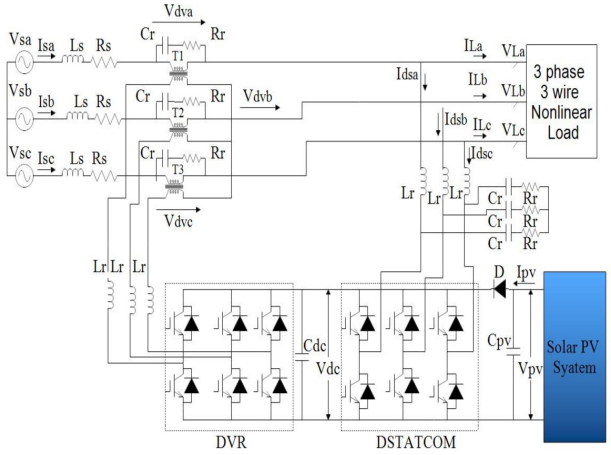

Fig. 2. Proposed UPQC system

The presented UPQC is right shunt UPQC. This system is having two inverters which are connected successively by a common dc link and power to that dc link is fed from the supply system through interfacing inductors. The series connected transformer is used to inject the voltage induced by the DVR into supply system. In the circuit nonlinear load is used as the diode bridge rectifier with RL load. Because of the switching action of the inverter switches the ripples are creating in to the system and to compensate this effect the ripple filters (RC filter) is used. The Fig.2. shows the proposed unified power quality conditioner circuit.

D. Design of proposed UPQC

Design of the three phase three wire UPQC consist of design of the shunt connected device and series connected device ripple filter dc link voltage interfacing inductors.

1) Design of shunt and series connected devices

a) 1.1 Dc Link voltage and bus capacitor rating

The capacitor is connected to common dc link of two inverters and acts as an energy barrier and set up the dc voltage for normal functioning of the UPQC. The least value for dc bus voltage across capacitor must be greater than two times of the maximum value of phase voltage of the system where the UPQC is connected.

$$V_{dc} = \frac{2V_{LL}\sqrt{2}}{m\sqrt{3}} \quad (6)$$

Where
m = modulation.
V_{LL} = line voltage for inverter.

For calculating the magnitude of the capacitance for the dc bus consider the principle of energy conservation.

$$C_{dc} = \frac{3KatI_{sh}V_{ph}}{0.5(V^2_{dc} - V^2_{dc1})} \quad (7)$$

Where

V_{dc} = nominal dc link voltage 700 volts.

V_{dc1} = least voltage level of the dc link 650.

O = overburden 1.2.

V_{ph} = voltage 239 volts.

I_{sh}= phase current 10 amp.

t = time required for dc voltage to come at rated value,20 msec.

K = constant 0.1.

Cdc = 10^{-3} farad.

b) Selection of series connected transformer for DVR

The voltage rating of transformer is determined by voltage to be added and the dc link voltage of the inverter. For compensating voltage difference and The turns ratio for the series connected transformer is calculated from equations.

$$V_{DVR} = X\ V_S = 95.84 \quad (8)$$

$$K_{DVR} = \frac{V_{VSC}}{V_{DVR}} = 3 \quad (9)$$

The voltage and current (VA) rating for series connected transformer has calculated 10 KVA.

c) Interfacing Inductors for DSTATCOM and DVR

The selection of interfacing inductor for DSTATCOM is depends upon various factors and some of the factors are Fs, dc link voltage (Vdcl). The equation 10 and 11 shows the interfacing inductors calculations for DVR and DSTATCOM

$$L_{rdstat} - \frac{mV_{dc}\sqrt{3}}{12af_{sh}I_{cr,pp}} - 2\text{mH} \quad (10)$$

$$L_{rdvr} = \frac{mV_{dc}K_{SE}\sqrt{3}}{12af_{SE}I_r} = 4\text{mH} \quad (11)$$

Where

m = modulation index = 1

a = overloading factor = 1.2

$I_{cr,pp}$ = current ripple = 15%

F_{sh}= switching frequency = 10 KHZ

d) Design of ripple filter

The switching frequency for the device is 10 KHz and because of that ripples are superimposed in to source voltage. To compensates this ripples in voltage the LC filter with appropriate time constant is used. The ripple filter Rating for DSTATCOM is R=0.2 ohm and C= 20 microfarad and ripple filter ratings for DVR is R=0.15ohm and C= 25 microfarad.

III. PROPOSED CONTROL ALGORITHEM

The control algorithms are mainly divided in to time zone algorithms and frequency zone algorithms. Some of the time zone algorithms are IRP theory, DQ theory, PB theory, ANN theory etc. some of the frequency zone algorithms are Fourier algorithm, DFT algorithm, FFT algorithm, wavelet transform algorithm etc. The frequency zone algorithms are accurate but sluggish and slow response. Hence these algorithms are used in power quality monitoring devices where the accuracy is constraints and operating time does not constrain.

For real time control the time domain algorithm is preferred because of faster dynamic response. Here the SRF control algorithm is used for control operation for UPQC.

A. Control structure for dynamic voltage restorer

The series compensator injects the active power in series with the system and this power is provided by solar system through dc bus of the UPQC. The PCC voltage and load voltage is sensed and converted into DQ reference frame theory. During the conversion the phase locked loop (PLL) block is used for calculating fundamental component of PCC voltage. Among the various classifications of UPQC UPQC-P is considered for in proposed system. The DVR is dealing with active power only therefore reference for Q axis component is set to be zero and reference for D axis is set as the peak value of the load voltage.

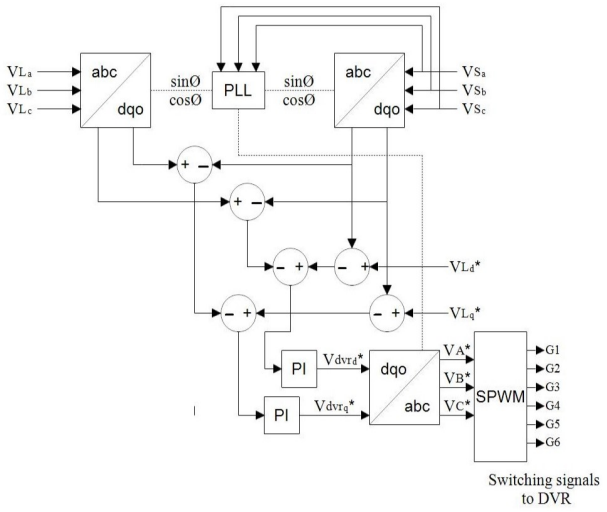

Fig. 3. Control structure for DVR

For calculating the reference voltage of the series compensator the subtraction of load reference voltage and PCC voltage is carried out. Again for calculating actual voltage to be compensated by series compensator the subtraction of load voltage and PCC voltage is carried out. To get appropriate reference signal from the control circuit the subtraction of reference voltage and actual voltage is estimated and output is passed through P-I controller. The switching pulse generation for inverter is obtained from reference signals passed through the pulse width modulation technique (SPWM) method.

B. *Control structure for distributed static compensator*

The solar PV system is connected to common bus of two inverters and voltage across that bus is maintained constant using PI controller. The load current is converted to dqo domain and low pass filter is used to estimate fundamental component of the load current. Estimated currents are then added to other currents which are getting from PI controller which are loss current and solar PV array current. Adding all the currents that generates fundamental reference current I sd*. In this control algorithm active power of the current is compensated hence I sq* is kept as zero and because of the three phase three wire circuit the I so* is also kept as zero. This above all the fundamental reference currents are converted into abc domain and passed through the hysteresis current controller. This PWM control algorithm compares the reference signals with the actual signals and gives appropriate pulses to the voltage source inverter.

$$I^*_{sq} = 0 \qquad (12)$$

$$I^*_{so} = 0 \qquad (13)$$

$$I^*_{sd} = I_{Ldf} + I_{Loss} - I_{Pvg} \qquad (14)$$

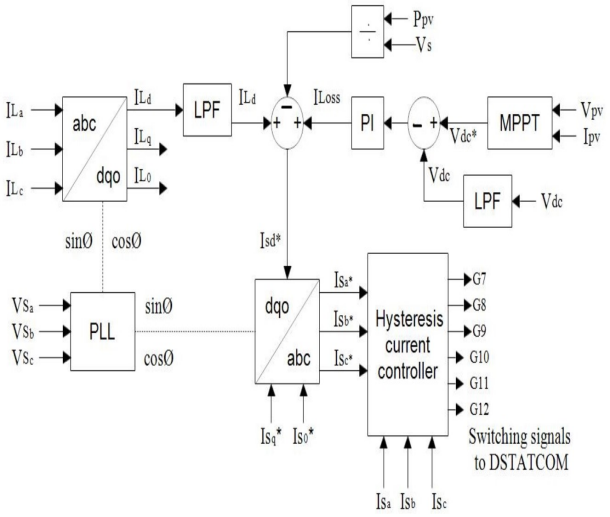

Fig. 4. Control structure for DSTATCOM

IV. MATLAB SIMULATION OF PROPOSED PV UPQC

In this study the solar integrated UPQC is designed in MATLAB Simulink environment. The result analysis is carried out under various conditions. That conditions are particularly of source voltage sag/swell condition and varying load unbalanced condition. The Matlab simulation for Solar PV system is given in Fig. 5. The temperature is considered at 30 degrees for the normal operation of the solar system. The Matlab simulation for UPQC with distributed generation is given in Fig. 6.

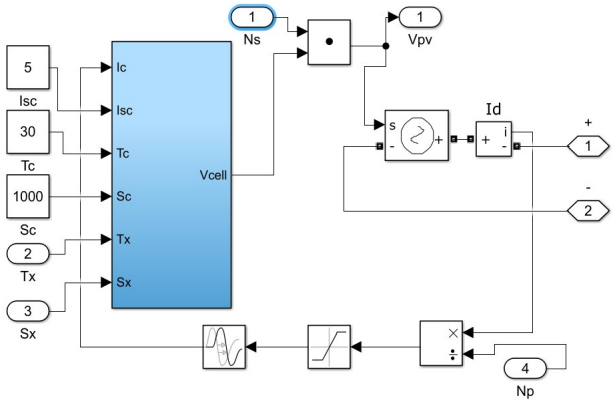

Fig. 5. Solar PV system in Matlab Simulink

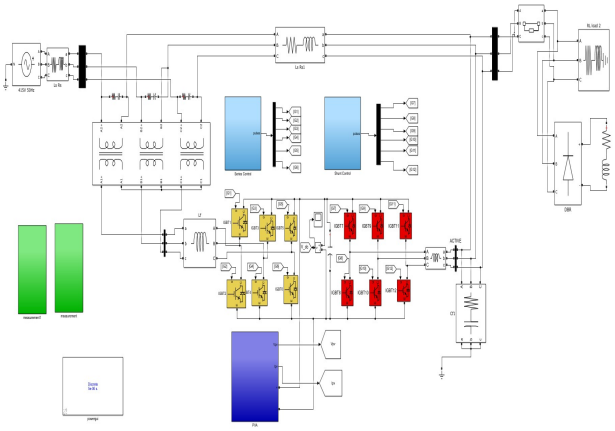

Fig. 6. UPQC with DG in Matlab Simulink

A. *Under source voltage sag and swell circumstances*

The performance of proposed UPQC with distributed generation under source voltage variations (swell and sag condition) is introduced in Fig. 7. The series compensator in the proposed UPQC with DG system settles the voltage across the load to a rated value under source voltage variations. The various observed waveforms are source voltage, shunt compensator current, load voltage, series compensator voltage, dc bus voltage, load current.

The voltage sag of 0.4 per unit and voltage swell of 0.4 per unit is considered in the source voltage. In source voltage sag condition the series compensator injects 0.4 per unit voltage in phase with source voltage and keeps load voltage constant at particular magnitude and in source voltage Swell condition the dynamic voltage restorer add the voltage into source voltage in such a way that the load voltage remains unchanged and settles at rated value which is 230-volt phase to phase. The source current takes some time in microsecond for stabilization. The load current nature does not get affected and changed when there is source voltage variation. In this condition it is clearly seen that there is no effect of voltage sag and swell on DC link voltage. The DC link current is increased in voltage sag condition and decreased in source voltage swell condition.

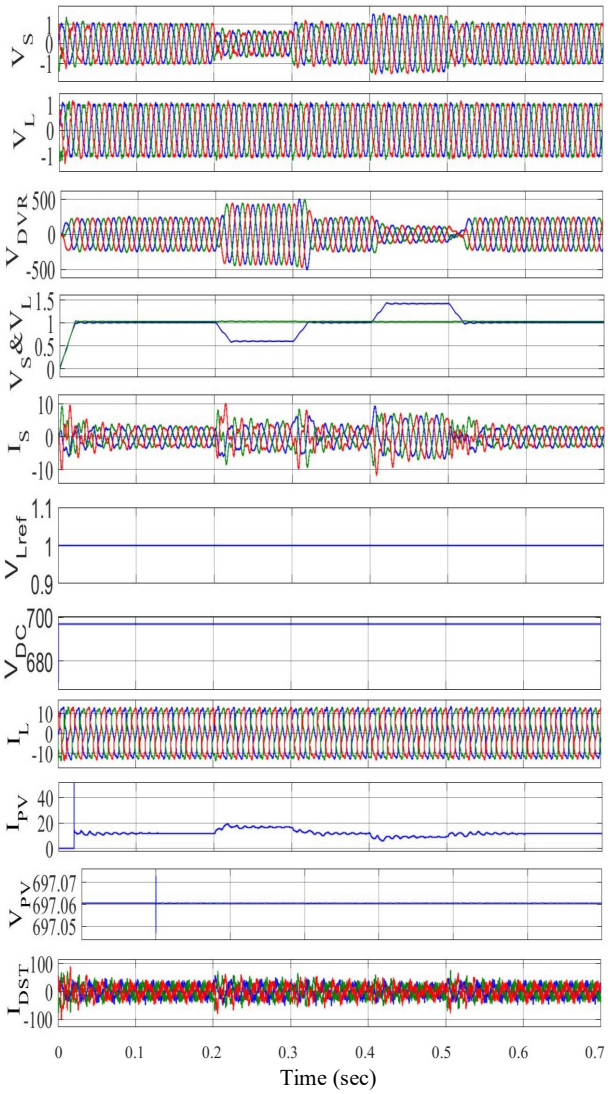

Fig. 7.MATLAB results of UPQC during source voltage variations

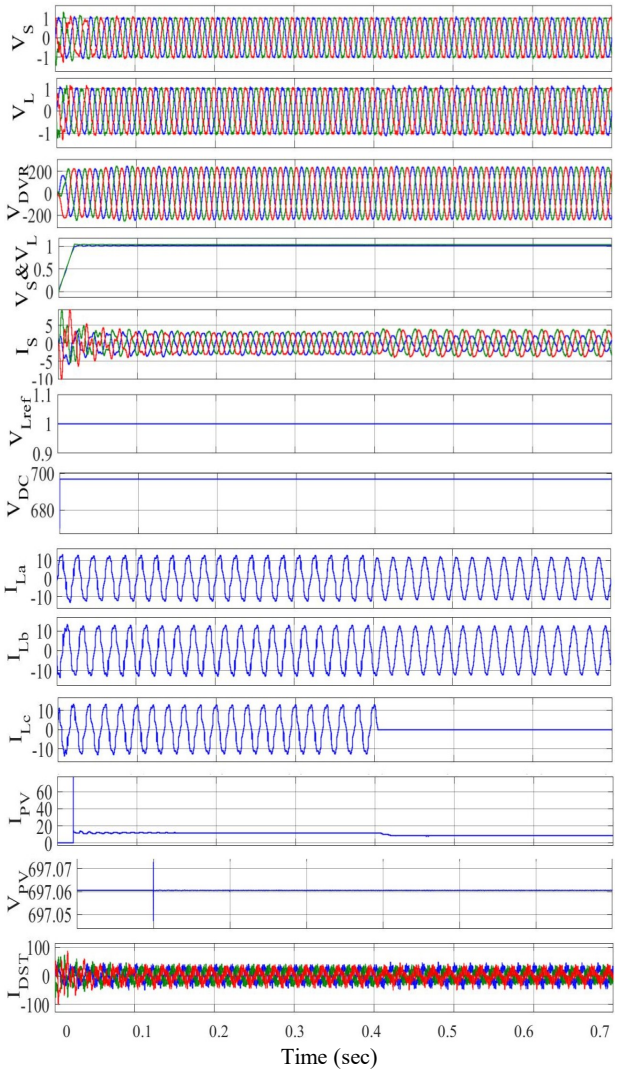

Fig.8. MATLAB results of UPQC during load unbalance condition

B. Under load unbalanced circumstance

The simulation results of proposed UPQC with distributed generation during load unbalance situation is presented in Fig.8. Load unbalance condition is generally observed in three phase system. During unbalanced condition the source current is sinusoidal with unity power factor and the effective source current is increased because of reduction in total effective load. For making the load unbalance the phase C of the load is deactivated at particular time. During load unbalanced circumstance the load voltage and source voltage remains sinusoidal in nature. These voltages do not get disturbed and remains at the constant rated value. The voltage generated in distributed generator and DC bus voltage is also not affected during load unbalanced condition. The DC bus voltage is remained constant at nearly 700 volts. Normally in load unbalanced condition the voltage rises but the Dynamic Voltage Restorer prevents this voltage rise. From Fig. 8 it can be observed that the control circuit for DVR works properly.

V. REAL TIME IMPLEMENTATION OF PROPOSED UPQC

In this study the real time digital simulator OP4510 is used for estimating and analyzing the performance of proposed solar integrated UPQC. The advantages of real time simulator are lowest cost required for hardware, increases test functionalities and reduces the personals risks. OP4510 has 4 cores with 3.5 GHz Intel processor and 4 i/o modules which are analog in (16channels), analog out (16 channels), digital in (32 channels) digital out (32 channels). It also has FPGA version kintex-7 along with the target computer having 16 GB RAM and 128 GB SSD. The hardware setup of OP4510 is shown in Fig. 9. For communication between host computer and target computer the communication protocol RS-232 (TCP IP4) is used. The software in loop (SIL) and hardware in loop (HIL) simulation is performed with the help of OP4510. Fig. 10. shows the MTLAB simulation file which made compatible with OP4510. In simulation file consist of two subsystems which are SM_MASTER and SC_CONSOLE runs at step time of 20 micro seconds.

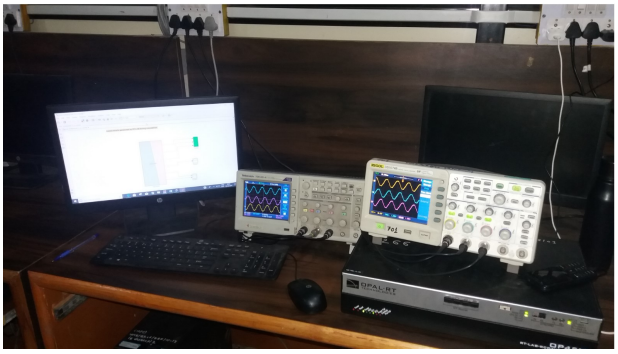

Fig. 9. Hardware Setup of OPAL-RT (OP4510)

For the communication of two subsystems the OPCOMM block is used. The analog signals in HIL simulation are taken out from OP4510 by using OPCONTROL block and ANALOG OUT block.

Fig. 10. Implementation of solar integrated UPQC on opal RT

The signals which are taken outside are source voltage without UPQC and source current without UPQC. These signal waveforms are shown in Fig. 11. Fig. 12. The THD analysis is carried and the THD comes for source voltage without UPQC is 24.58% and source current absence of UPQC is 27 % which is given in Fig. 13.

Fig. 11. Source voltage on digital oscilloscope

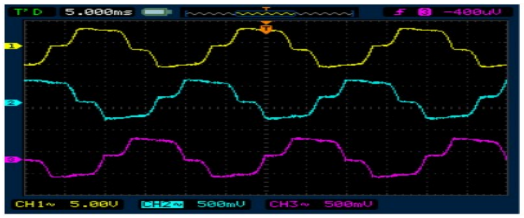

Fig. 12. Source current on digital oscilloscope

The other two signals are taken outside from OPAL-RT that are source voltage with UPQC and source current with UPQC shown in Fig. 14. and Fig. 15. THD analysis of this two signals are carried out and THD comes for source voltage Vs is 0.06% and for Is it comes as 5% which is shown in Fig. 16.

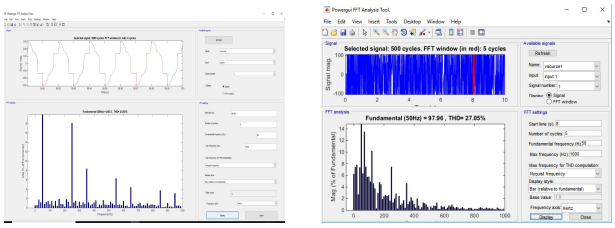

Fig. 13. THD analysis of Vs and Is

Fig. 14. Source voltage on digital oscilloscope

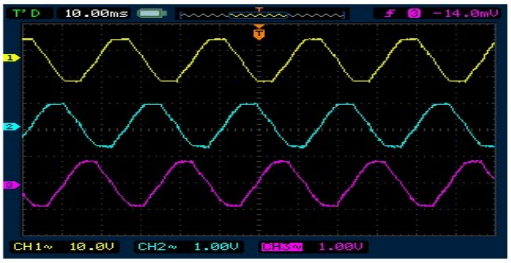

Fig. 15. Source current on digital oscilloscope

The total harmonic distortion for source voltage with UPQC and source current with UPQC is as per the standards of IEC61000-3. The THD analysis is carried out considering the Matlab generated window in Real Time Digital Simulator.

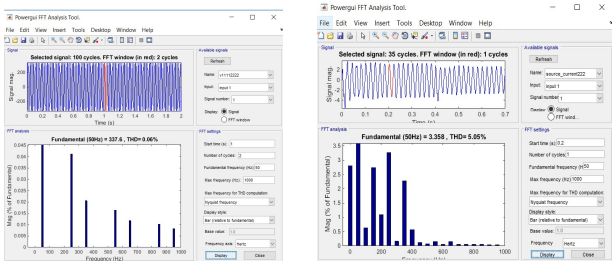

Fig. 16. THD analysis for Vs and Is after UPQC operation

VI. CONCLUSION AND FUTURE WORK

The UPQC with Distributed generation has been proposed in this paper. The proposed UPQC model with distributed generation has been designed and analyzed in Matlab Simulink environment. The various dynamic conditions for system are created at source side and load side. The response of proposed UPQC system has been analyzed during various system scenario. The proposed UPQC system is then implemented in OPAL RT OP4510 environment. The simulation results are discussed in detail and outcome of the simulation shows the proper operation of the controller and all the results comes as per the IEC61000 standards.

The future work for this solar integrated UPQC system is the replacement of the Solar system with wind generation system or BESS. The new time domain base control algorithms can also be applying to the above mentioned systems.

Abstract:

IOT means internet of things. Here as the name suggests IOT has turned into a hugely developing technology in which billions of devices are interconnected by providing people with different services. Because of this huge connectivity among devices there may arise situations that will endanger the security and integrity of IOT systems and this threatens the security of data which is transmitted through those systems. In this paper, we will be discussing about the security problems of IOT and how they are caused. Then we would discuss how a widespread technology like block chain will provide security to IOT networks.

Keywords—IOT, Blockchain, Security

I. Introduction

IOT (Internet of Things) is a technology which is used to interconnect devices over a global network like internet. In this all the devices like computers, cameras, sensors etc. are considered as a thing and all these things are connected to each other and data transmission takes place between the systems. When data is transferred it also need to be stored. For that we would need a virtual infrastructure which will be provided by the cloud computing. The whole IOT thing is a mixture of sensor, networks, communication and computing technologies and the interconnectivity between them [1]. The whole IOT thing is a centralized model it means that these systems are identified individually, and they are provided with unique identity numbers, after that these devices are connected over internet, and services are provided using the cloud services. IOT made things simple to use and work with. IOT keeps the track about the devices, it reduces errors and showcase many complex systems into a simple structured network [2]. The structural part would be explained next.

II. IOT Architecture

IOT has four main levels [3].

Perception layer: The first one is perception layer. Here the objects or the things present in IOT environment are recognized.

Network Layer: After perception layers there will be a network layer. In network layer a network is formed between the objects.

Middle-ware Layer: The third layer is middleware layer where the data analysis is done by processing the information.

Application Layer: Then in application layer data is represented graphically and the data is used for creating smart applications using IOT. These smart applications are used for different purposes like system

management and business models can be created by using the applications.

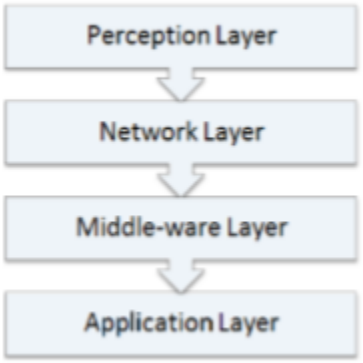

Fig 1: Structure of IOT

All the above-mentioned layer is important. The whole working of IOT is based on three major components i.e.

(1) hardware- These contributes the sensors, cameras and actuators.

(2) Middleware- These are the storage and computation section of the whole IOT systems which is basically cloud and analysis through big data.

(3) presentation- These are the application which give user interface to provide proper interpretation of the data [4].

III. Applications of IOT

IOT is an important area of technology which is grabbing attention from many industries [5]. The different domains of IOT and its applications are as below.

Despite of all these applications IOT has few challenges which will question the security and integrity of the services provided by the IOT systems.

IV. Challenges faced by IOT Devices

IOT is a centralized model connecting number of devices over a network. It is difficult to maintain those billions of devices; the maintenance cost will be high.

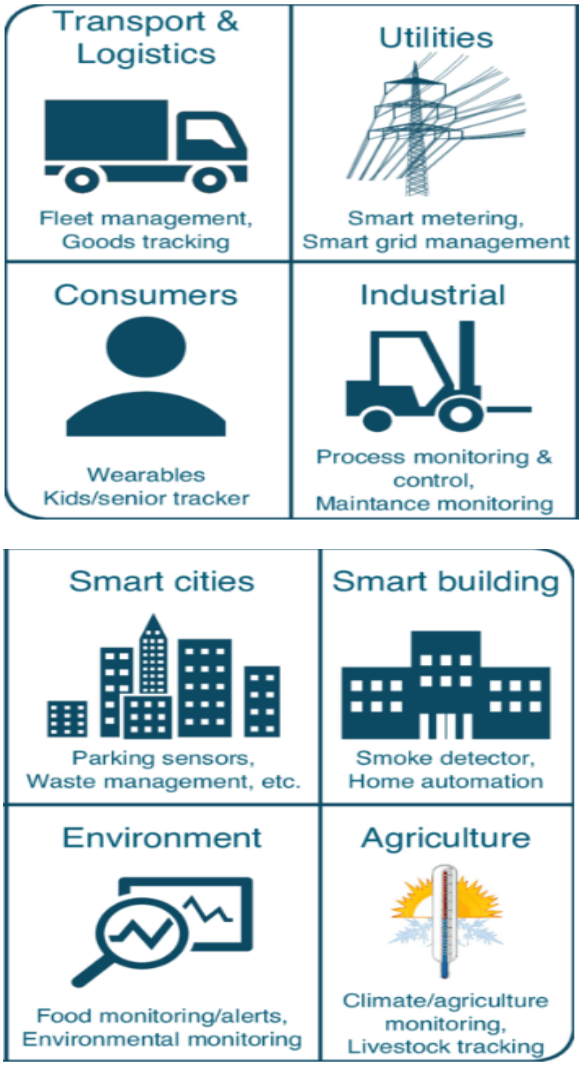

Fig 2: Applications of IOT

The major problems will be related to security of data that is transmitted through the network. During the IOT process data should pass through many devices, networks and frameworks[16]. All this would contribute to threaten the integrity of data. Few challenges faced by IOT are

A. Cost and capacity:

It will be challenging to maintain the devices. As there is exceptional growth in number of IOT devices.

Garter mentioned that by 2016, 5-6 million IOT devices are connected to each other every day over internet [6]. By 2020 the network will increase drastically.

B. Federated architecture:

The architecture of IOT does not have universal policies or standards that keeps the design in control to provide certain kind of security [7]. This scenario leads to denial of service attacks, data theft, hacking etc.

C. Inaccessibility to cloud Services:

Sometimes the cloud services are not available due to cyber-attacks, power, bugs and many other problems [8]. At that time the whole network shutdowns as the information is present in the cloud system.

D. Privacy issues:

The information present here in cloud is susceptible to be manipulated [9]. So that the information can be accessed and used for inappropriate uses.

All these problems can be solved by providing security to IOT devices using blockchain.

V. Blockchain Overview

A blockchain is a digital ledger in which blocks are connected and is used for transition [10]. Blockchain is a decentralized system. The basic concept of blockchain is that it is a tamperproof storage used for transaction.

The valid transactions are stored in blocks and each block is liked to previous block in the chain process. The first block is a genesis block and later all the new blocks have hash codes and change in hash code will take place if already existing block has changed information in it. The change in the hash code will be visible to all the users in that blockchain. This is the reason block chain is said to be secured. The structure of a block chain is like

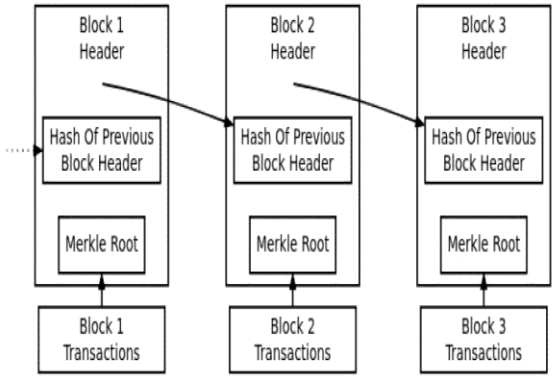

Fig 3: Block Diagram of Blockchain

The structured block chain has an ability to create, store and transmit different assets. It is tamperproof. Block chain was originally designed for transaction of ledger for bitcoin [11]. After bitcoin the scope of block chain was discovered in many other domains. IOT is one of the domains whose security issues can be solved by blockchain technology.

VI. Secured IOT devices using Blockchain

A. Some of the issues of IOT can be easily solved by blockchain technology. IOT is a centralized model. It will have huge infrastructure and the maintenance is also high. when it comes to block chain it is a decentralized model. This decentralized system will eliminate failure points and form a précised system of network.

B. Decentralization can provide a peer to peer networking [12]. As IOT

things are increasing every year decentralization is a better option.

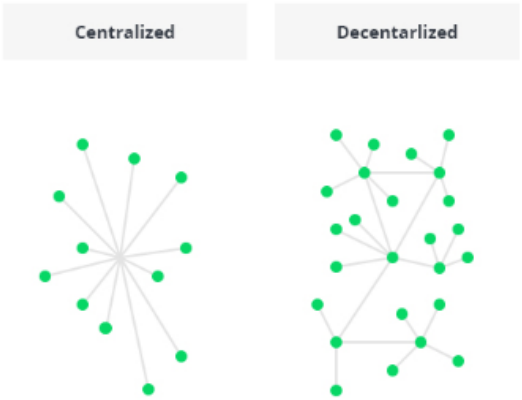

Fig 4: Differentiating Centralized and Decentralized model.

C. Like IOT the block chain does not have a deficient architecture. Here the data transaction between the devices is secured. The legitimacy of gadgets is checked, exchanges are marked, and they are cryptographically confirmed to know whether the inception of the message is from the sender itself.
D. Considering the server failure problems in cloud. We don't have any such issues in blockchain because the records or identical data are on different systems. So even one system is down we can retrieve data from other systems.
E. The control of information can be recognized and avoided in blockchain. The gadgets in blockchain are interlocked. On the off chance that one framework is refreshed. If any system is updated the changes will be rejected by the system with prior verification.
F. The cryptographic algorithms which are used in the block chain will provide proper security to the data which we accumulate from the IOT devices.

VII. Reference Work

There are different situations where there was a threat to smart home devices. Even basic devices like smart bulbs, smoke alarms are hacked [13]. In this smart home technology, the services are vulnerable to attacks even though the home gateway controls the exchange of packets [14]. The blockchain based architecture does performance evaluation. Here the actions of encryption and hashing takes place. Blockchain refers to a baseline method. Here IPv6 is used over WPAN as a communication protocol [15]. This whole thing will be suitable to provide security to smart homes.

VIII. Conclusion

Both IOT and blockchain are individually contributing a lot. IOT made everything so simple whereas block chain is providing a great security to financial modules like bitcoin. When we combine both technologies, the result will be a strong IOT system. Basically, IOT is a centralized module by decentralizing it the maintenance cost can be reduced and security issues are taken care of. Blockchain technology can be perfect solution for IOT security issues. So, IOT which is already a developed technology can be more security when it uses the Blockchain technology and its algorithms.

***Abstract*—Phase shift full bridge (PSFB) DC-DC converters are used to convert high voltage to low voltage for medium and high power applications. In this paper a PSFB DC-DC converter is designed for converting 350 V DC supply to a constant output voltage of 12 V with a maximum load of 2 kW. It is desired to satisfy a stringent set of time domain specifications on settling time, steady state error and peak overshoot (to be less than 50 ms, 200 mV and 25% respectively) over a wide range of operating conditions. To obtain this objective, we propose a genetic algorithm (GA) based PI controller tuning for PSFB DC-DC converter. Simulation results show that K_p and K_i values that obtained using GA help to vary the load from 100 W to 2000 W, with steady state error, settling time and peak overshoot less than the specified limit. The system also supports an input voltage range from 300 V to 500 V and an output voltage from 8 V to 18 V. Fragility of the controller is analysed and the results show that controller is nonfragile.**

***Index Terms*—Phase shift full bridge (PSFB) DC-DC converter, Proportional integral(PI) controller, Genetic algorithm (GA), Fragility**

I. INTRODUCTION

PSFB DC-DC converters are widely used in high power applications because of their capability to handle higher power and zero voltage switching (ZVS) due to phase shift modulation technique. ZVS reduces the switching losses and improves the overall efficiency of the system [1]. High power handling capacity of MOSFET helps to achieve high power density [2] and it supports high switching frequency. Use of high frequency transformer in the PSFB DC-DC converter provides an isolation between high voltage input side and low voltage output side. Due to these advantages, they find applications in renewable energy systems, uninterruptible power supplies (UPS), hybrid electric vehicles (HEV) and telecommunications systems [3].

It is important to control the output voltage of PSFB DC-DC converter according to their applications. Different controllers are used for controlling the output voltage of DC-DC converter, namely sliding mode controller [4], PI controller, Linear quadratic regulator controllers [5], Adaptive controller [6] etc. By using these controllers, system has to satisfy certain time domain specifications such as maintain settling time, steady state error and peak overshoot with in certain limit. Most popular controller used in the industrial application is PI controller, due to its capability to achieve zero steady state error [7], better stability and reduced peak overshoot. Different types of tuning methods such as Ziegler-Nichols frequency domain method (ZNFDM), Damped oscillation method (DOM) and Good gain method (GGM) [8] are available for tuning the PI controller parameters for DC-DC converter. But these methods may not ensure minimum settling time, steady state error and peak overshoot. So an optimized tuning method is required to arrive at the PI controller parameters.

GA is used to find the optimum solution for different engineering problems [9]. The main advantage of this method is that it gives global optimum according to the type of solution required [10]. GA helps to find out the parameters that optimize the particular objective function. Tuning of PI controller parameters of DC-DC converter can be done by using GA method [11]. However most of the papers are dealing with the tuning of PI controller for single switch DC-DC converter with not much emphasis on the validation of time domain specification over the wide range of operating conditions. During controller design another aspect that must be taken into account is fragility analysis [12]. Fragility test helps to find out the robustness of controller against the model uncertainty.

In this paper a PSFB DC-DC converter is designed for a maximum load of 2 kW with a nominal output voltage of 12 V. The main aim of this paper is to find PI controller parameters, that maintain the settling time, steady state error and peak overshoot with in specified limit for all given operating conditions. Tuning of K_p and K_i value is done with the help of GA optimization method and Fragility of the controller is tested.

The rest of this paper is organized as follows: In section II a brief description about the working of PSFB DC-DC converter is given. Section III describes how GA can be used for tuning PI controller parameters for PSFB DC-DC converter. Simulation results are given in Section IV. Section V concludes the work of this paper.

II. PHASE SHIFTED FULL BRIDGE DC-DC CONVERTER

Full bridge DC-DC converter which uses the phase shift between gate signals as the output voltage control technique is known as PSFB DC-DC converter. Though Increased operating frequency offers reduction in the size of components and ripple in the output voltage, it causes an increase in the switching loss. One of the main advantages of phase shift modulation technique is that it allows ZVS. ZVS is achieved with the help of parasitic capacitance of MOSFET and leakage reactance of transformer. This soft switching technique helps to reduce the switching losses and improve the overall efficiency of the system.

Fig. 1 shows the circuit diagram of PSFB DC-DC converter. It consist of a full bridge inverter having four MOSFETs S1, S2, S3 & S4, a high frequency center tapped transformer is followed by a full bridge diode rectifier and an output LC filter. Each switch has a duty cycle of 50% as shown in Fig. 2. Two switches on the same leg are turned on complimentarily with each other. A phase delay is given to the gate signal of second leg (for S3 & S4) which is directly proportional to the required value of output voltage. Fig. 3 shows the primary transformer voltage and current corresponding to the gate signal shown in Fig. 2.

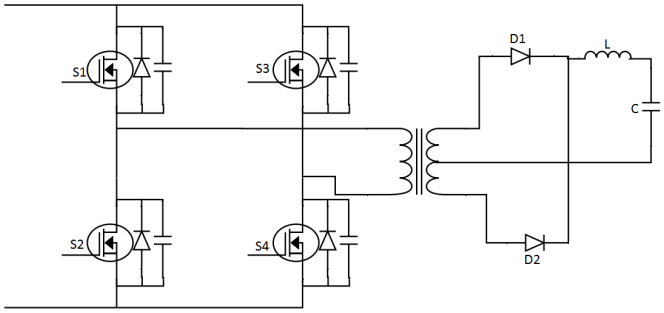

Fig. 1. Circuit diagram of PSFB DC-DC converter

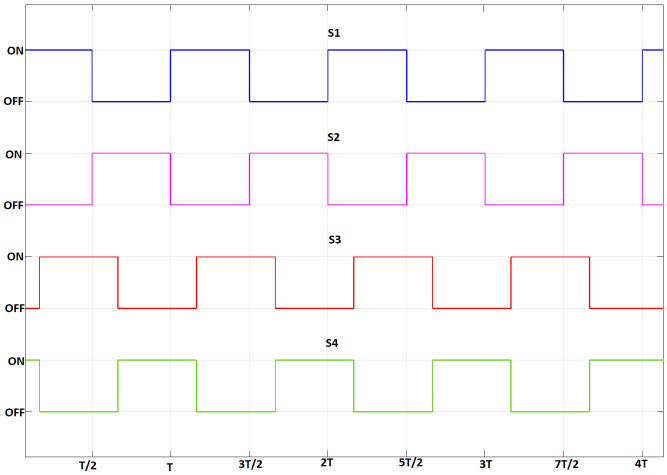

Fig. 2. Gate signals of PSFB dc-dc converter

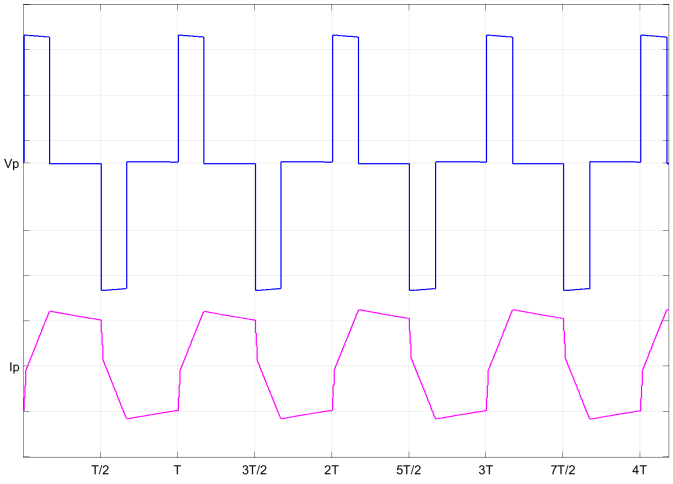

Fig. 3. Primary transformer voltage and current of PSFB DC-DC converter

III. PI CONTROLLER TUNING BY GA FOR PSFB DC-DC CONVERTER

In this paper output voltage of PSFB DC-DC converter is controlled by using PI controller, which is governed by equation (1). Our intention is to find out K_p and K_i values that minimize the steady state error, settling time and peak overshoot using a suitable optimization technique. GA can help to find out the global optimized value for PI controller parameters.

$$P_{out} = K_P e(t) + K_i \int_0^t e(t)dt \tag{1}$$

e(t) = setpoint - actual value
P_{out} = Controller output

A. OBJECTIVE FUNCTION

Most important step in the GA is the selection of the appropriate objective function. Actually objective function is an indicator for how well the individual is suited for the given application. For PI controller tuning the objective is to find out K_p and K_i values that minimize the difference between actual output and setpoint. Equation (2) shows the objective function used for tuning PI controller parameters, in this paper.

$$ITAE = \int_0^t t \mid e(t) \mid dt \tag{2}$$

Where ITAE is integral time absolute error.

B. FITNESS VALUE

PI controller is used to minimize the output error by minimizing the value of objective function. The fitness value can be defined as

$$\text{Fitness value} = \frac{1}{\text{Objective function}}$$

C. INITIAL POPULATION

First set a lower boundary and an upper boundary for the parameters to be determined. These boundaries are created in order to ensure that many of generated parameters do not lead to an unstable response. Initial population is created randomly within the boundaries.

Fig. 4 shows the the flow chart of GA optimization method used to tune PI controller parameters for PSFB DC-DC converter. At the beginning an initial population is generated randomly. Next step is the evaluation of generated population using the fitness function. After evaluation select the individual with highest fitness value. Selection process is followed by crossover and mutation. The above process will continue until it reaches the given number of maximum generation.

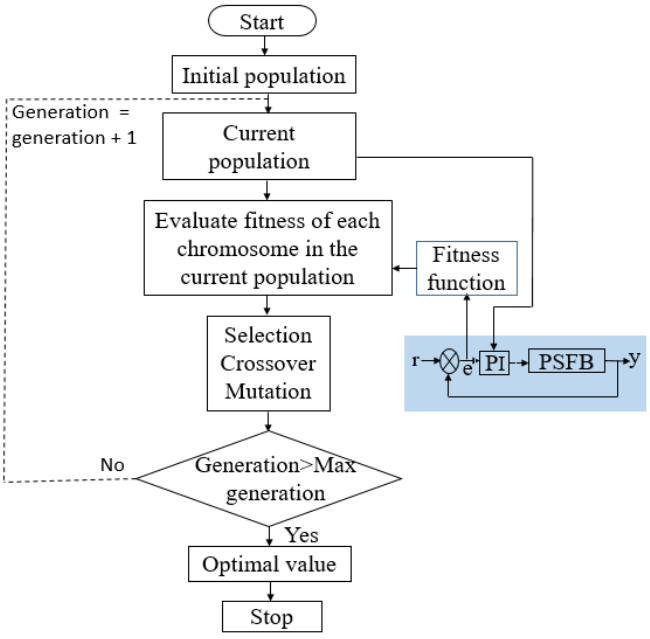

Fig. 4. Flow chart of GA optimization method

IV. SIMULATION RESULTS

Table I shows system parameters used for simulating a PSFB DC-DC converter in the MATLAB/Simulink. Output filter of the converter is designed for inductor ripple current of 10 % and 1 % ripple in the output voltage. GA parameters used for the tuning of DC-DC converter are shown in Table II.

TABLE I
SYSTEM PARAMETER OF PSFB DC-DC CONVERTER

Parameters	Values
Input voltage range	300 V-500 V
Nominal input voltage	350 V
Output voltage range	8 A-18 A
Nominal output voltage	12 V
Maximum load	2 kW
Switching frequency	100 kHz
Inductor	3.75 μH
Output capacitor	6.91 mF

Fig. 5 shows the block diagram of the complete system which includes PSFB DC-DC converter and control loop. Here output from the converter is compared with the setpoint voltage and the error is given to a PI controller.

Controller parameters are found with the help of GA through offline method. By using GA parameters in the Table II, K_p and K_i values are obtained as 4.9787 and 4661 respectively. Output of the controller will be a phase delay, required to reduce the error between actual output and the setpoint value. This phase delay is given as an input to the pulse generator.

Fig. 6 shows the output voltage during the load variation. The input voltage and setpoint voltage are kept as 350 V and 12 V respectively. Load is varied every 100 ms. Steady state error, settling time, overshoot and undershoot during each load variation given in Table III, show that the time domain specifications are satisfied.

TABLE II
PARAMETER OF GENETIC ALGORITHM

Parameters	Values
Population size	20
Maximum Generation	100
Mutation	.1 %
Upper and lower limit of K_p	[0 5]
Upper and lower limit of K_i	[0 5000]

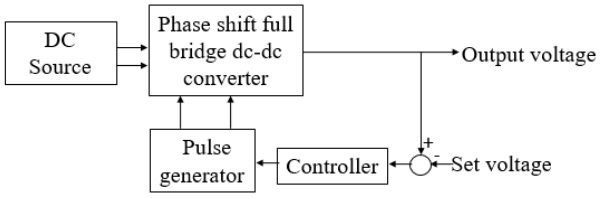

Fig. 5. Block diagram of complete PSFB DC-DC converter system

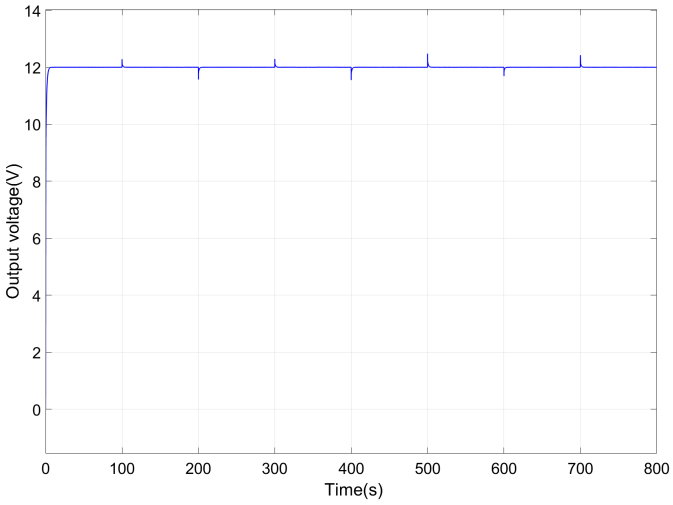

Fig. 6. Output voltage during load variation

TABLE III
STEADY STATE ERROR, SETTING TIME, OVERSHOOT AND UNDERSHOOT DURING EACH LOAD VARIATION

Load varition (W)	Time (ms)	steady state error (mV)	Settling time (ms)	Peak overshoot (V)	Under shoot (V)
1000	0-100	7	3.714	0	0
1000-100	100-200	6	.285	12.282	0
100-1500	200-300	5.58	.78	0	11.569
1500-500	300-400	6	.455	12.291	0
500-2000	400-500	6	.92	0	11.55
2000-500	500-600	6.5	.94	12.476	0
500-1500	600-700	6	.4	0	11.69
1500-500	700-800	7	.62	12.423	0

Fig. 7 shows the output voltage during different setpoint voltage conditions. Simulation is done for a load of 1500 W and input voltage of 350 V. In between the setpoint voltage from 8 V to 18 V, output voltage settles on their respective setpoint value satisfying all time domain specifications.

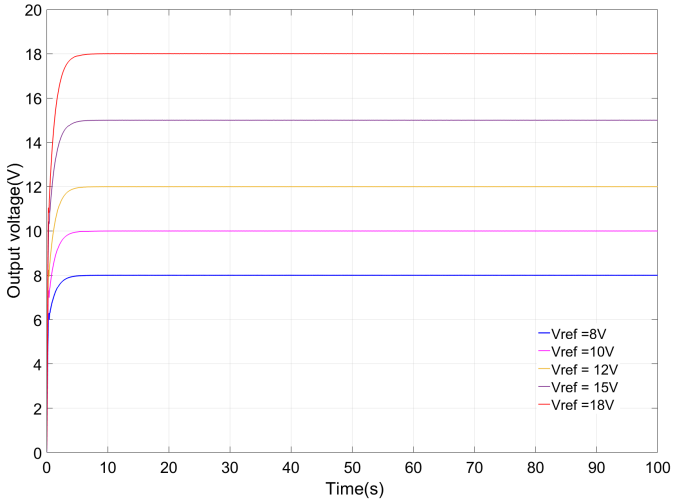

Fig. 7. Output voltage during different setpoint voltages

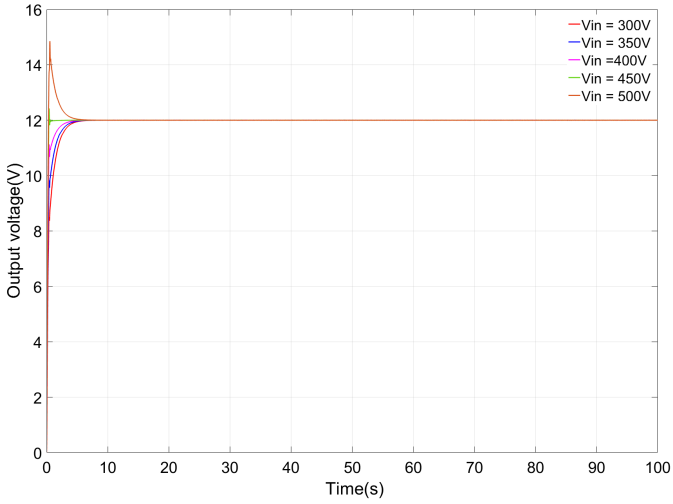

Fig. 8. Output voltage for different input voltages

Fig. 8 shows the output voltage for different input voltages. During simulation load and setpoint voltage are kept at 1500 W and 12 V respectively. In between 300 V to 500 V input voltage, settling time of the response is less than 5ms. For an input voltage of 300 V to 400 V there is no peak overshoot. If input voltage is 450 V then the peak overshoot is 12.425 V and if increased it up to 500 V then peak overshoot is 14.852 V. They are within the specified limits.

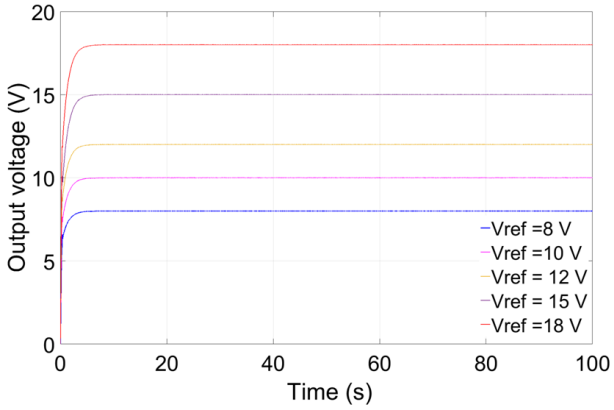

Fig. 9. Output voltage for different setpoint voltages with increased K_p,K_i

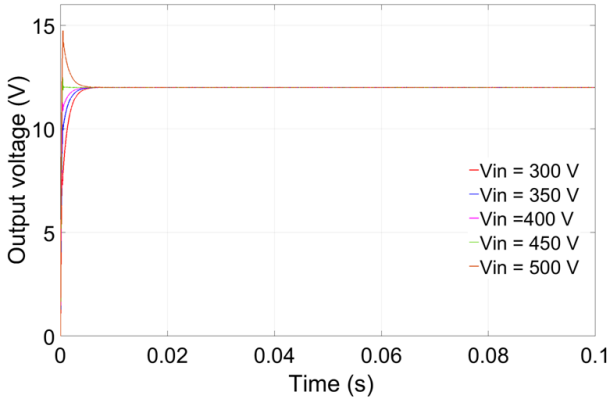

Fig. 10. Output voltage for different input voltages with increased K_p,K_i

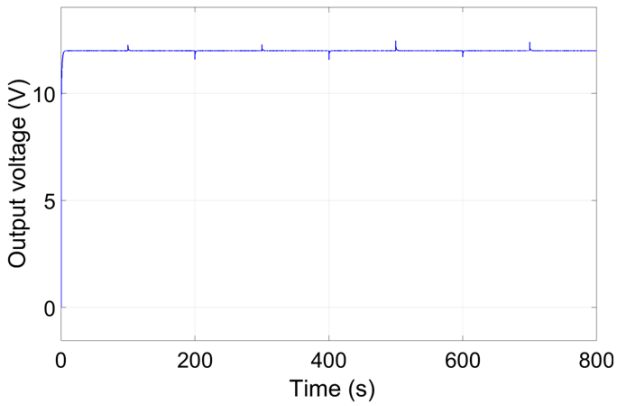

Fig. 11. Output voltage for different load with increased K_p,K_i

It may not be possible to realize the nominal PI controller parameters, 4.9787 and 4661. So fragility analysis of controller is carried out by varying the PI controller parameters with in $\pm 10\%$ of it's nominal value.

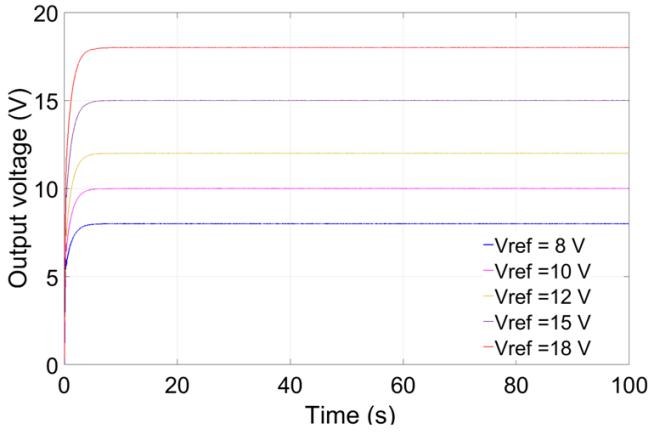

Fig. 12. Output voltage for different setpoint voltages with decreased K_p, K_i

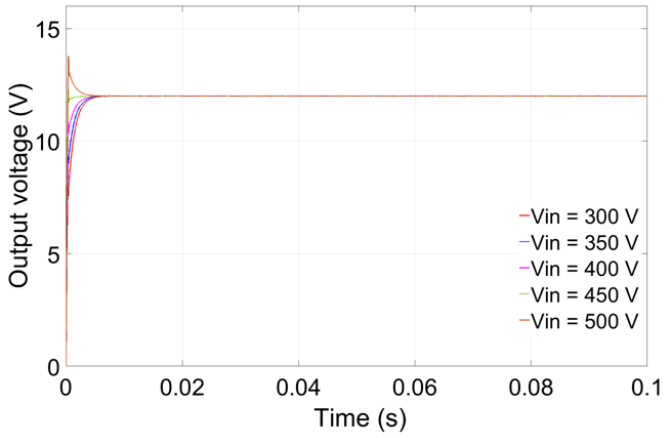

Fig. 13. Output voltage for different input voltages with decreased K_p, K_i

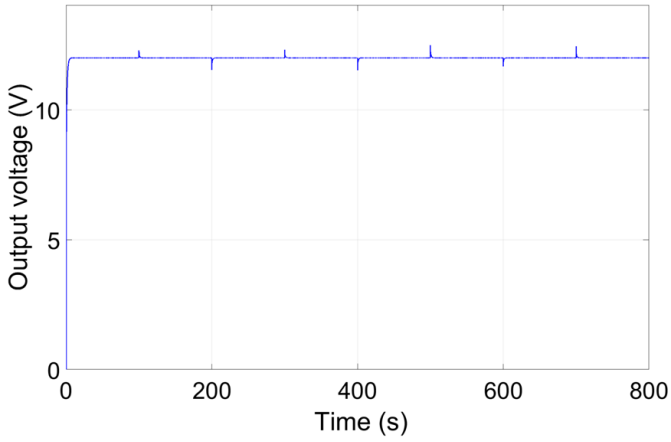

Fig. 14. Output voltage for different load with decreased K_p, K_i

Figures 9, 10 and 11 show the responses of the system for 10% increase in K_p and K_i values. For different load, setpoint and input voltage, this increased values of K_p and K_i satisfy all time domain specifications. Figures 12, 13 and 14 show the responses of the system for 10% decrease in K_p and K_i values. Here also all the time domain specifications are satisfied for all given operating conditions.

V. CONCLUSION

In this paper, a PSFB DC-DC converter is simulated using MATLAB/Simulink and its controller parameters K_p and K_i are found out using GA. By using a population size of 20 and a maximum generation of 200, K_p and K_i values are obtained as 4.9787 and 4661 respectively. With these controller parameters load can be varied from 100 W to 2000 W with steady state error, peak overshoot and settling time with in the specified limit. It also gives satisfactory performance for the variation of the input voltage from 300 V to 500 V and setpoint voltage from 8 V to 18 V. GA based PI controller parameter estimation gives a robust response. Fragility test is conducted by considering 10% increment and decrement in the nominal controller parameters and the result shows that controller is nonfragile.

***Abstract*—Primary concern of Wireless Sensor Network(WSN) is energy efficiency. We need to increase the life span of the WSN. This work we uses the Unscented Kalman Filter (UKF) for reducing the communication energy cost of cluster based wireless sensor network. For transmission of data will require 1000 times more energy than computation. So for reducing this transmission UKF algorithm is used. The proposed UKF algorithm will run in the WSN and reduce the transmission of data. UKF algorithm run in the leaf node and head node to predict the value by computation, computation of the network will increase. But computation requires only less power than transmission. By using UKF technique, we can cut down the communication cost of cluster based wireless sensor network with a good data quality. Compare with the normal one to one communication we can save about 0.2Joule of energy, as we go for more number of transmission more amount energy can save. By using UKF technique we can achieve energy efficient system with increase in life span of the network.**

***Index Terms*—wireless sensor network(WSN), unscented Kalman filter(UKF), energy conservation**

I. Introduction

In cluster based WSN consist of large number of sensor nodes. Most of the WSN are not rechargeable they are battery driven. WSN is used to monitor the physical world for few months or even decades, energy utilization is the key problem. To decrease the energy utilization of the WSN and increase the life period of WSN, UKF technique is used [3].UKF algorithm will predict the present values using the past values. In this way transimmision between the head node and leaf node can reduce. Radio communication is the one of the most energy demanding process. It will consume large amount of energy [2]. One of the most energy-demanding process of WSN is the wireless communication. Transmission of data will consume 1000 more energy than computation [1].For transmission of data packets energy is needed to radio start up, accessing the channel, controlling the data packets, etc. Kalman filter (KF) based algorithm is used in WSN, because of its low complexity and accurate data quality. In kalman filter, UKF technique is used here. This technique will reduce the unnecessary tansmission between the head node and the leaf node.

In the cluster based WSN the sensor node will sense the data from the physical environment that data is transmitted to the head node [13]. Data process takes place in head node and send to sink node [4]. From the sink node the users can access the data. The sink node and the cluster head are some distance apart so continuously transmitting the data will require more energy. To reduce this transmission we are using the technique UKF. UKF algorithm is implemented in the head node and leaf node. The UKF will predict the next output with the help of the previous data. When the error between the predicted value and the original exceeds the threshold value the next transmission will takes place.

WSN is a collection of massive number of sensor nodes. Nodes are mostly placed in the environment to monitor the changes happening in the surrounding. Each node will rigged with memory, battery and transceiver [2]. The node will have processing, communication and sensing capabilities [8]. The nodes are placed in the environment where the humans have difficulty. Nodes are battery powered, we cannot recharge or replace the battery frequently, so we need to increase the life span of the battery [5]. Nodes will group together and form a cluster, each cluster will have head node. Node will sense the data from the surroundings and it is send to the head node. From the head node the data is transferred to the sink node. User can access the data from the sink node. In the cluster based wireless sensor network we can transfer data efficiently [7]. Cluster based WSN will minimize the energy utilization and reduces the data transference over the network this will improve the lifetime of the WSN.

Two-modal transmission is the one of the technique for reducing the energy consumption of the WSN. In this method they are using the predictive coding to reduce the transmissions. This is used for data compression and then transmissions can reduce in this way we can minimize the energy consumption. Each node will have the prediction based algorithm it will generate the next data with the help of past values. Information fusion is the another method used for reducing the communication cost of WSN.Information fusion is commonly used to detect events, target tracking, filter out the noise.WSN will considered as distributed database that can be accessed by the query language. These queries are computed with the help of information fusion. Clustering is the one of the method for improving the life span of WSN.

There are different clustering methods for increasing the life span of WSN. Mainly 3 types of clustering methods are discussed they are centralized, distributed and hybrid. After surveyed about the clustering technique they come to a conclusion that, by using unequal clustering life span of cluster head close to base station can increase in this way network life time also increase. Unequal clustering algorithms such as LEACH and HEED will give better performance [10]. Data compression is the one of the techniques For reducing the power consumption of WSN. Energy-efficient medium access control technique is used to reduce the communication between the inter-node. inter-node transmission will consume more power. By using this technique they analyse the performance and limitation of the WSN.Another method used for reducing the power consumption of WSN is Fuzzy approach. Fuzzy approach is used according to the battery level of network and sleeping time of the network is monitoring based on IEEE 802.15.4 protocol [7]. For real time monitoring of data is done and life time of WSN is increased with the help of fuzzy approach. They are taking the real time values so there will be certain limitations will be there and cannot achieve the better performance in the case of real time data monitoring case.

In this paper UKF is used in WSN to reduce the communication cost by reducing the transmission of data between the head node and the leaf node [10]. The UKF will predict the next value with the help of the pervious value. UKF is a prediction based technique for tracking the value with the help of the previous value. In the cluster based WSN, UKF algorithm is implemented in the cluster head and also in the sink node. In both the head node and in the leaf node the data will predict when the error increases a certain limit next transmission of data will takes place [11]. By using this technique we can reduce the transmission of data in that way we can cut down the communication cost of the wireless sensor network.

For non linear estimation UKF is used. UKF will overcome the resemblance problem of Kalman Filter(KF) and Extended Kalman Filter(EKF). UKF also called as the sigma point Kalman filter or linear regression Kalman filter [10]. UKF is used to linearize the nonlinear function. In UKF the state distribution is represented using the sigma points. UKF will contain 2 steps, model forecast and data assimilation. In the UKF the state distribution is characterised by Gaussian random variable (GRV), with the help of deterministically chosen sample points it is specified. True mean and covariance is captured by these sigma points. These sigma points transmitted through nonlinear system and take the posterior mean and covariance to 2nd order for any nonlinearity [9]. The process of estimating the mean and covariance with the sigma points is called unscented transform.

II. System Overview

The overview of the proposed system is explained in this section. The main idea behind this work is to reduce the energy utilized by the WSN, during the transmission of the data from leaf node to the cluster head. For reducing the energy consumed by the WSN we are using UKF technique.

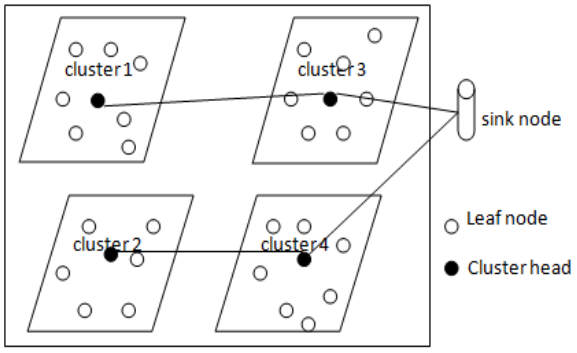

Fig. 1. Cluster based WSN.

First we need to form a cluster which consists of nodes and head node. The leaf node is the sensor and that will sense the environmental changes and transferred it to the cluster head. We need to reduce the communication between the nodes and the head nodes [10]. Transmission of data will require more energy than computation of data. So we use UKF algorithm to reduce the communication. The UKF algorithm will predict the future value with the help of present value. In UKF we will compute the sigma points, UKF algorithm will run with these sigma points. So we will get more accurate result than other KF. We will run the UKF in leaf node and cluster head. In leaf node the filter will filter out the noise from the sensor data. In the cluster head the UKF will predict the next value with the help of present value.

Wireless sensor network consist of the nodes and in center the head node. The leaf node will act as the sensor node and they will collect the information [17]. It is a self-configuring device it will communicate through radio signals. Nodes in the sensor network is called the mote [13]. The main application of the WSN include industry, science, transportation, civil infrastructure, and security [6]. The WSN is mostly of battery powered device. 802.15.4 and Zigbee are the 2 wireless standards used by WSN. These are low power protocols, because it will work on low duty cycles means most probably transceiver is in sleeping mode at the time of transmission and reception it will consume only the small amount of energy. Maximum distance the WSN can access is about 100m.

III. Methodology

Unscented kalman filter (UKF) technique is used in wireless sensor network for reducing the communication cost. UKF will predict the next value with the help of present value, so we can reduce the communication between the nodes and the head node. Transmission of data between the node to cluster head will consume more energy than computation. UFK will reduce this transmission by predicting the next value, for that there will be predict and update equations are used. Nodes

of the WSN will randomly arranged in the grid and form the cluster and cluster head is also selected [15]. Many clusters will together called as the cluster based WSN. The idea of the project is to reduce the transference between the head node and the nodes. The sensor node will sense the information from the surroundings and it is send to the head node. The head node will predict the current data by using the previous data with minimum error.

In the leaf node the KF run to filter out noise and produce the optimal value [14]. To reduce the energy consumed by WSN, UKF algorithm is run in the head node and also in the leaf nodes.Head node and in leaf node the UKF will runs and predict the value with the help of the past value [12]. If the prediction error exceed the given threshold value the transmission of the data from head node to the leaf nodes will takes place [18]. Next prediction will takes place by using the new transmitted data. By using this UKF technique we can reduce the transmission in this way we can reduce the tranmission cost and also the life span of the WSN.

For non linear estimation UKF is used. UKF will overcome the resemblance issues of KF and EKF. UKF also called as the sigma point kalman filter or linear regression kalman filter. UKF is used to linearize the nonlinear function.

There will be two state equations for all the adaptive filters

At time k the true state is emerge at time (k-1)

$$x_k = Ax_{k-1} + Bu_k + w_k \tag{1}$$

where A represents state transition matrix, B represents control input matrix, w_k represents the white Gaussian noise.

Observation equation of true state at time k is mapped to H.

$$z_k = Hx_k + v_k \tag{2}$$

where H represents observation matrix, v_k represents the white gaussian noise.

predict Phase

For generating the a priori estimate of present state, state estimate of the past sate is used.

$$\widehat{x}_k = A\widehat{x}_{k-1} + Bu_{k-1} \tag{3}$$

From equation 4 Uncertainity of the prediction is calculated uncertainity is calculated from covariance of error

$$\widehat{P}_k = AP_{k-1}A^T + Q_k \tag{4}$$

Update phase

In update phase the present measurement and a priori estimate will together form the improved a posteriori state estimate.

In the update phase we add average weight,it is called kalman gain

$$K_k = \widehat{P}_k.H^T.(H.\widehat{P}_k.H^T + R_k)^{-1} \tag{5}$$

Equation 6 is the update estimate of the system.

$$\widetilde{x}_k = \widehat{x}_k + K_k.(z_k - H.\widehat{x}_k) \tag{6}$$

Equation 7 is the final estimate of the system.

$$P_k = (I - K_k.H).\widehat{P}_k \tag{7}$$

After many iterations values become constant, where the covariance and kalman gain become constant value. after that the future value is predicted.

A. Unscented Kalman Filter

For non linear estimation UKF is used. UKF will overcome the resemblance problem of KF and EKF. UKF also called as the sigma point Kalman filter or linear regression Kalman filter. UKF is used to linearize the nonlinear function. In UKF the state distribution is represented using the sigma points. UKF will contain 2 steps, model forecast and data assimilation. True mean and covariance is captured by these sigma points. These sigma points transmitted through nonlinear system and take the posterior mean and covariance to 2nd order for any nonlinearity [11]. The process of estimating the mean and covariance with the sigma points is called unscented transform.

UKF will linearize the non linear functions. Compared to KF and EKF, UKF will improve the performance of the system. UKF will take bundle of points and we are approximating the Gaussian around that bundle of points, in this get we get improved approximation that traditional kalman filters [**?**]. The bundle points we choosen is called sigma points. From the source Gaussian we take some points and mapped to the destination Gaussian. These selected points pass through non linear function and then determine the new mean and variance of the Gaussian function. It is very challenging to reconstruct all state distribution through non linear function. But few points of state distribution, reconstruct very easily, that points are called sigma points. These sigma points are used for the UKF algorithm processing. We need to add weights to the sigma points so the sigma points are called weighted sigma points. Ukf transform Gaussian does not remain same as Gaussian function when it moves through the non linear system, but we relate from the resulting Gaussian figure. This process in UKF is called Unscented Transform.

IV. Result and Discussion

Random signal tracking using UKF is shown in Fig 2. From the figure we can see that the output signal exactly track the input signal path. The UKF algorithm is suitable for tracking the non linear signals. This UKF algorithm is used in the WSN nodes for reducing the communication cost.

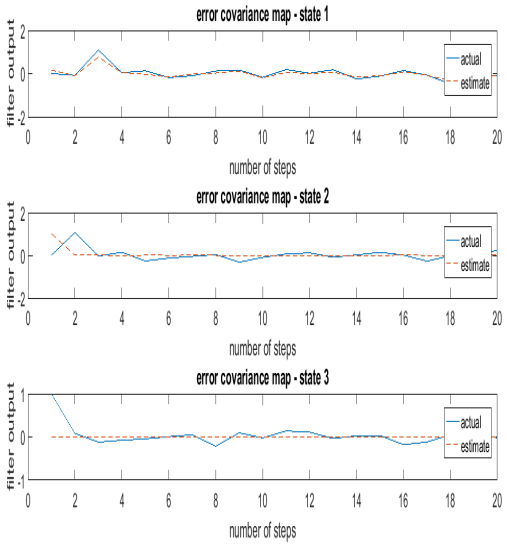

Fig. 2. Tracking of random signal using UKF.

Fig 3 is the tracking system of the UKF . In this the UKF track the true value with less error. This tracking system is implemented in the WSN and we can increase the life time of the network by reduce the energy consumption. We are giving some signal as input and UKF track the signal with minimum error.

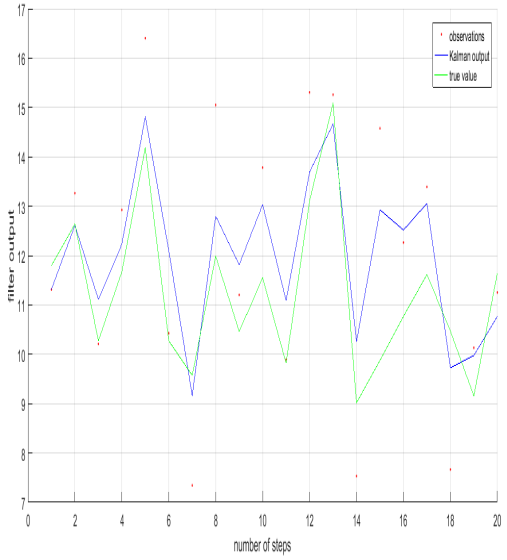

Fig. 3. Tracking system of UKF.

WSN cluster is shown in Fig 4 nodes are arranged randomly. One node which is closer to the center is selected as the cluster head and remaining nodes will be leaf nodes. The communication is done between the node and the head node.

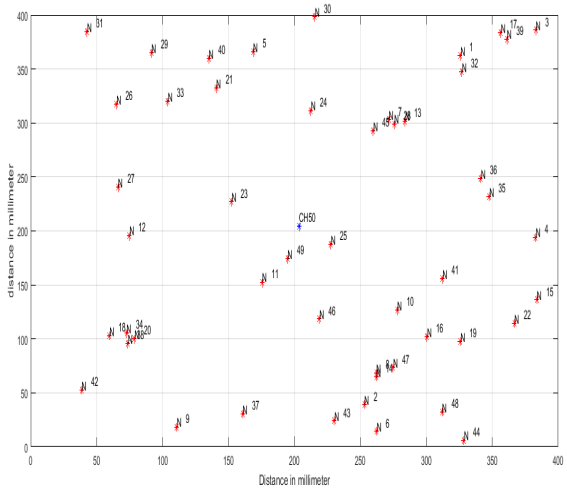

Fig. 4. Arrangement of nodes and cluster head as cluster.

Fig 5 is the comparison graph showing the energy efficiency of WSN with the normal communication and UKF after 10 communication. By using UKF method energy consumption is less compared to normal method. After 10 communications we can save about 0.3Joule of energy.

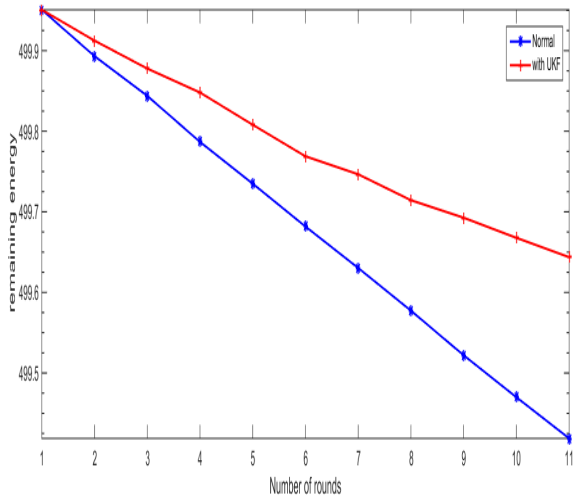

Fig. 5. Energy consumption after 10 communication.

Graph on the Fig 6 represents the energy comparison. This graph shows the remaining energy in the network after 25 communication. As number of communication increases we can save more amount of energy.after 25 communication we can save about 2Joule of energy. As number of communication increases we can save more energy.

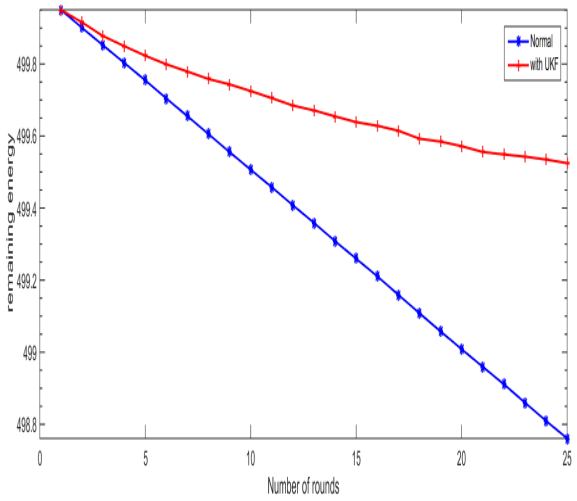

Fig. 6. Energy consumption after 25 communication.

Table I represents the remaining energy in the network after transmission. By using UKF method the energy utilization is less compared to the normal method. As the number of communications increases the energy consumption is more in the case of normal method. In UKF method energy consumption is comparatively less.

TABLE I
REMAINING ENERGY IN THE NETWORK

No.of communications	UKF method	Normal communication
10	499.6625	499.4333
25	499.4793	498.7211
50	499.3770	497.4625
75	499.2161	496.3032
100	499.1128	494.9663
150	498.7967	492.3048

Table II shows how much energy can be save for each number of communication. As number of communication increases, we can save more amount of energy. For 10 communication only 0.3Joule of energy is save but as we increase the number of communication we can save more energy

TABLE II
ENERGY SAVINGS IN UKF COMPARED TO NORMAL METHOD

No.of communication	Energy
10	0.3
25	0.7
50	1.9
75	2.9
100	4.1
150	6.4

V. CONCLUSION

UKF algorithm is used in the WSN for reducing the communication cost of network. UKF algorithm run in the leaf node and the head node of the wireless sensor network for reducing the communication cost. Initially the transmission will takes place, with this initial value further predicts will takes place in leaf node and head node, if the predicted value exceed the threshold value then next transmission will happen. UKF algorithm will give more accurate value than conventional kalman filtering technique. By using UKF method the energy consumption of WSN decreased when compared to the normal KF based technique. After 10 communications we can save about 0.3Joule of energy than the traditional method. As we are doing more communications we can save about more energy and the life time of the network can be increased. UKF method will save more energy in this way the life span of the sensor network will increase.

ABSTRACT-

This paper represents automatic Star – Delta Starter of Three-Phase Induction Motors using soft switches, it overcomes all the disadvantages of conventional contactor based starters. This project is designed to provide low voltage start to induction motor. In this unit Arduino micro controller is used as base drive circuit and it makes the star delta conversion fully automatic. IGBT's are used as soft switches; each switch consists of two cascaded IGBT's. Now a day's automation is required in almost all industries, so this proposed unit can be effectively used. The Arduino is programmed in such a way that the starter operation automatically takes place based on the time delay provided. Since this unit uses soft switches, it will acquire less space with negligible maintenance. This system is more reliable than the conventional contactor based starter.

Keywords-

Arduino, Opto-isolator, Static Switch Module, Three - Phase Induction Motor

I. INTRODUCTION

Induction motors are popular due to their low cost, robust construction, low maintenance and good efficiency. An Induction Motor during start behaves like a short circuited transformer, when the supply is given to the stator windings; it draws high current. The starting current of Induction Motor is 6-7 times the full-load current. Starters are employed to reduce the starting current. [1]

The Star-Delta Starter is used to limit the starting current of induction motor. To limit starting current, the motor winding is connected in star configuration during starting and then in delta configuration. In star configuration

voltage across the winding will reduce by 0.57 times the line voltage thus the current will also reduce. To connect the windings in star and delta configuration static switches are used, each switch consist of two cascaded IGBT's. [2]

Arduino microcontroller is used as base drive circuit & it is programmed such that it will give gate signal to switches to connect the winding in star and delta configuration with certain delay. The gating signals from Arduino microcontroller are connected to each IGBT through an opto-isolator which provides the isolation of controlling circuit from power circuit. The Arduino controller is a sensitive device, so it is powered from a SMPS; which gives a constant DC voltage to the controller.[3]

II. EXISTING STAR DELTA STARTER BASED ON CONTACTOR-

Present star delta starters use three electromagnetic contactors, namely main, star& delta, and an electronic timer. At the first star and primary contactors are closed, after a short time interval the timer changes its switch positions such that star contactor gets opened and delta contactor gets closed for the remaining operating time of the motor.

At the time of starting the motor windings are star associated and each stator winding will receive $V_L/\sqrt{3}$, where V_L is the supply line voltage. Hence the line current drawn by the motor at starting is reduced to a safe limit.

Although these type of starter limit the starting current and start the motor safely but some drawbacks are associated with such starters those are- Coil may burn which would cause no magnetic field, hence the contactors won't close and the contactor wouldn't operate, Contacts may also weld shut which may cause the load to keep running even when there is no control voltage which may cause unsafe machine or damage to machine, The insects can get in the contacts which may cause the contactor failure which may ultimately cause the equipment failure. Since it uses three electromagnetic contactors which occupies relatively large space which is not suited for some application.

III. AUTOMATIC STAR-DELTA STARTER UNIT

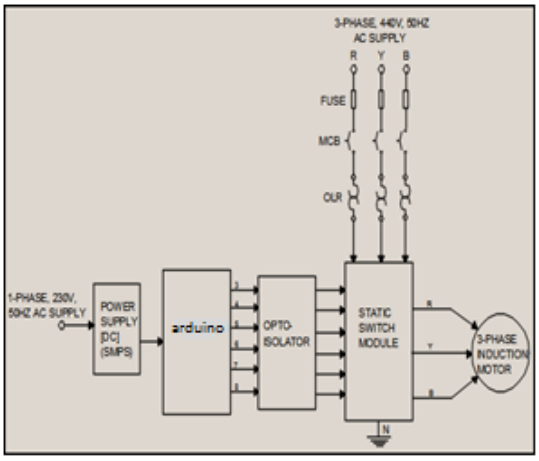

Fig. 1:Block diagram of Star-Delta Starter Unit

Figure (1) shows the block diagram of Star-Delta Starter Using Static switches. Single phase 230V supply is given to the SMPS which converts AC to DC. 5V DC supply is provided to the Arduino, when it is switched ON the Arduino starts executing the programs from its 1st instruction. This will give high output logic 1 to its pins 2, 4, 6 so the output of these pins is given to the Opto-isolator in order to give protection for the Arduino from the high voltage power circuit. From here it is connected to the Static Switch Module. It consists of 6 static devices IGBT's (IGBT/MOSFET/Power Transistor). Three static switches for Star connection and remaining three static switches for Delta connection.[4] When pin number 3, 4, 5 is at logic 1 the three Star connection static switches will turn on and three phase motor gets connected

in star fashion that is A2, B2, C2 winding terminals gets shorted through static switches. After few seconds delay (say 10 seconds according to the program) provided by Arduino pin number 3, 4, 5 will goes to logic 0 state and pin number 6, 7, 8 is at logic 1 at the same time star connection is converted into delta connection. And three phase motor gets connected in delta fashion that is A1-C2, B1-A2, C1-B2 winding terminals gets shorted.[5]

Hence with the help of this unit we are completely eliminating the use of contactors from the circuit operation of Star-Delta starters and making the operation easier and reliable. [6]

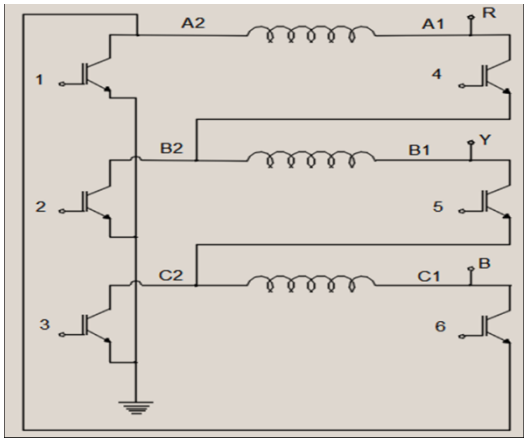

Fig.2 Static Switch Module

Figure (2) shows the static switch module which consists of 6 static switches used for Star-Delta Conversion. Switches 1, 2 & 3 for star connection and 4, 5 & 6 for delta connection respectively. These switches get the gate pulses from the Arduino.[7]

At the starting condition the motor is connected in star connection and switches 1, 2 & 3 are on and remaining switches are in off condition hence the current flows from A1-A2, B1-B2 and C1-C2 from RYB supply after the set delay in the arduino according to the time which motor takes to switch from starting condition to running condition. [8]

After the provided delay the motor switches from star to delta, in this state the switches 1, 2 & 3 are off and switches 4, 5 & 6 are gets turned on and hence switching to the delta condition from the star connection in this case the current flows from A1-B2, B1-C2 and C1-A2 from the RYB supply. [9]

IV. ADVANTAGES

- The motor can be controlled from any place with the help of GSM modem.
- The system is cost effective.
- The system is highly accurate & reliable & it requires less space.
- The effect of Gravity & Sparking can be eliminated.
- The system has a longer life.

V. DISADVATNTAGES

- If there is some malfunction in the Arduino, the system may misbehave. But chances of occurring such malfunction are almost nil.

VI. CONCLUSION

The automatic Star-Delta starter using Static Switches is having several advantages over the conventional methods. The system uses static switches instead of contactors which makes the proposed system more advantageous. This system uses Arduino microcontroller as a base drive circuit so it require less space.

***Abstract*—The wireless sensor network is increasingly gaining attention due to the ubiquitous Internet of Thing (IoT). The wireless sensor network (WSN) basically consists of several nodes which are having the capability to communicate with each other over the wireless media. Further, in terms of network architecture, the most part of the WSN is infrastructure-less, however, the core of such network may comprise of the infrastructure including an access point (AP). The implementation of a particular routing protocol from the bunch of available, is of a great dilemma. Thus, this paper evaluates the effectiveness of different routing protocols for wireless sensor network applications. The effectiveness of the routing protocols is evaluated on the basis of different network performance matrices such as average End-to-End Delay (ETD) and Packet Delivery Ratio (PDR). To evaluate, the performance of WSN, QualNet 5.2, a network simulator is used which is accepted as one of the best network simulators to correctly represent the real-time scenario.**

Keywords—Wireless sensor networks, IoT, Ad-hoc network, Routing protocols, QualNet

I. INTRODUCTION

As a result of Internet of Things and its reach in the different area of applications, there have been tremendous amount of deployment of millions of intelligent devices embedded with technology to communicate with each other and to other network devices. The wireless sensor network is one of the major part of the implementation of IoT in which the devices are expected to communicate with each other over the wireless medium. The wireless network broadly classified in to two categories: 1) infrastructure Network and 2) Ad-Hoc Network. The WSN is always seen as the Ad hoc network as in this, every node is capable of sensing the information, gathering and forwarding the data, generating specific commands for communication, etc. Further, the ad-hoc network provides a high degree of freedom in terms of deployment as each of the participating node in this can behave as a router to forward the packets depending upon the routing algorithm. The higher degree of freedom and no requirement of infrastructure makes the WSN more pertinent for the communication, particularly, focusing the IoT applications.

Wireless sensor networks are expected to perform a numerous task ranging from environmental monitoring to battlefield surveillance, and it includes almost all the applications of IoT and paves an important role for the next generation of WSN [1]. There has been enormous amount of research on the performance WSN due to several routing protocols. X. Cai *et.al.,* in [2], reviews the literatures which shows the in-effectiveness of the certain routing protocols for large scale WSNs, and simultaneously, they propose AODV-RIRC (AODV-Route identification & RREP Capturing) routing protocol which is an amalgamation of Ad-hoc On-Demand Distance Vector (AODV) and AODV/Jr. with link layer feedback for large scale WSNs. The scalability analysis including, node mobility, node density and traffic load, is carried out by the authors in [3] in the context of WSN. A short and comprehensive analysis of a few most important routing protocols, DSR and AODV apart from TORA and LAR, in the context of infrastructure-less networks have been discussed by the authors in [4]. As the scalability of AODV is expected to be better as compared to its counterpart DSR [5], Xin Zhang et.al., in [3], evaluates the performance of infrastructure-less networks with AODV protocols.

In this article, we firstly overview different network layer routing protocols in the context of wireless sensor network prior to discussing the performance of some important protocols on the network performance. A wireless local-area-network (WLAN) is designed to study the behavior of the protocols within and outside the LAN [6]. To understand the effect of routing protocols on larger scale, the wide-area-network is designed which comprises of several local-area-networks [7]. The performance of the networks under consideration is analyzed by implementing the networks in QualNet 5.2 network simulator which is a discrete event simulation of communication network stack [8]. The reason of choosing the QualNet is that it is believed as a best network simulator to mimic the real world scenario.

The organization of rest of the paper is as follows: The Section II starts with an overview of routing protocols applicable in the context of WSNs. The complete modeling and design of WLAN and WAN under consideration is presented in a unique and the simplest way for understanding in section III. In Section III, the network is simulated using QualNet 5.2 to analyze the performance of different routing protocols under consideration. A detailed analysis on the simulation results are also described in this section. At the end, this paper includes Section IV, which concludes the research work and suggest some future work in this direction

II. OVERVIEW OF ROUTING PROTOCOLS IN WSN

In the last few decades many routing protocols have been proposed and tested in the literature [9] and few of the papers [10-12], also compares the performance of such protocols. For WSNs, the broad classifications of routing protocols are: flat routing protocols, hierarchical routing protocols, location-based routing protocols [13]. Among all, the routing protocols for ad-hoc networks are divided into two major categories- reactive (on-demand) and proactive (table driven). The destination sequenced distance vector protocol (DSDV) are selected as an example of proactive protocols, whereas, both AODV and DSR are selected as the examples of reactive protocols [14].

A brief overview some of the protocols for evaluating the network performance on the networks under consideration are presented in this section.

A. *Bellman-Ford*

The basic principle of DSDV is Bellman-Ford algorithm which works on the distributed approach. Each node stores the routing information and shares the information to its neighbor. DSDV effectively resolves the looping problem in routing. Further, it also eliminates the counting-to-infinity problem in routing. However, in terms of scalability, it does not provide the good outcomes.

B. *DSR*

Unlike, DSDV which uses hop-to-hop routing, it implements source routing. The route discovery and maintenance are the two important phases in DSR [15]. The necessity of flooding the network with update information as required in table-driven protocols, is eliminated in DSR, and thus, reduces the overhead in the network. However, this is achieved at the cost of higher connection set-up delay.

C. *AODV*

AODV works in the similar fashion as that of DSR [16]. The Route_Request message is used to establish a route from source to destination. The next node information is stored at the source as well as each intermediate nodes and the information is updated with respect to each flow. The routing information of a node is updated if and only of the destination sequence number (Des_Seq_Num) of the recent received packet is greater than that of the last stored packet at the corresponding node.

III. Network Design and Simulation

This section presents the simplified network design and simulation scenario of the network under consideration.

A. *WSN on the Perspective of Network Design*

To understand the network scenario under consideration, a simplest representation of the scenario is depicted in figure 1. A WSN consists of sensing devices and actuators represented by different symbols in the figure. A WSN along with the other end devices connected over a LAN, forms a WLAN which basically consists of routers, switches, end-devices, gateways, servers, sensors, actuators, etc. The devices over WLAN are connected through Wi-Fi technology using 2.4 GHz Channel represented by dotted line, and each WLAN are having an edge router which is used to establish the connection of WLAN to the rest of the IP networks.

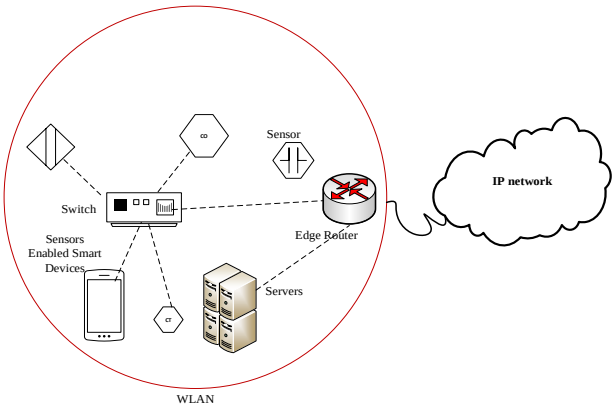

Fig.1: A Simplified Conceptual Representation of WSN

The different end devices communicate with each other over 2.4 GHz wireless channel. A wireless switch is utilized to interconnect several devices. The sensors and actuators work on the client-server based application layer protocols such as MQTT (Message Queuing Telemetry Transport) establishing a secure and low latency communication path for small amount of expected data in this application. The monitoring and controlling of the end devices can be achieved using any smart devices such as smart mobile phone, computer, laptop, etc., which are used to see the performance of the network in real-time. Despite of consisting many routers, all such WLAN will comprise of at least one edge routers, which is used to route the data from one WLAN to other WLAN. The figure 1 depicts all the necessary (but not exhaustive) components of the wireless sensor network under consideration. The other parts of the internet (named as '*IP Network*') are connected to the WSN under consideration using edge router.

B. *Network Design and Simulation Setup in QualNet*

The WSN under consideration is now designed in QualNet software to analyze the performance of this network for different routing protocols. The basics setups characteristics of the simulation is listed in the table 1 below.

Table 1: Simulation Setup in QualNet

Coordinate System	Latitude	SW Corner = 21.3022
		NE Corner = 29.422
	Longitude	SW Corner = 74.5784
		NE Corner = 93.4439
Altitude	1000 m	Above Sea level
Weather mobility		100 msec
Propagation Channel Frequency	2.4 GHz	
Propagation Path Loss Model	Two-Ray	

The WSN under consideration is designed and implemented in QualNet which is depicted in Figure 2. For the implementation of the WSNs, an area covering latitude of 21.3022 South-West corner, 29.422 North-East corner; and longitude of 74.5784 South-West corner, 93.4439 North-East corner is considered. This large geographic area is divided into a large number of small areas, where each small area is assumed to have a WSN of basic structure as shown in figure 1. Due to varying elevation profile at different coordinates, an average altitude of 1000 meter is considered above the mean sea level. This is worth noting that the effect of several weather related phenomenon viz., wind characteristics (e.g., direction and speed), temperature, rainfall, etc., cannot be ignored; and thus 'random' weather mobility pattern with interval of 100 msec is configured to replicate its effect in simulation. As a physical layer protocol, the IEEE 802.11 based on 2.4 GHz technology is utilized. The core (also referred to as backbone) of the network is designed by optical fiber to achieve maximum reliability with less communication failure probability. The backbone connection is shown in 'blue' color and the WSN is shown by the cloud symbol in figure 2. In figure 2, server at different location is also designed to collect and process the data. The 'green' color connection is used to represent an application layer protocol between source and destination node.

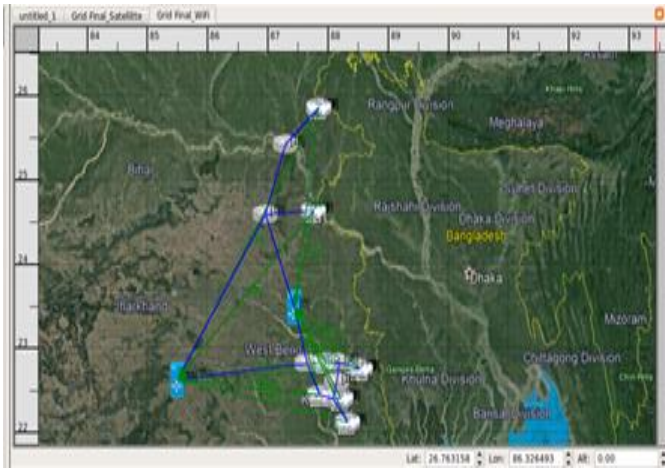

Fig.2: Implementation of WSN in QualNet

C. *Simulation Results and Analysis*

This section describes the simulation results and presents in-depth analysis on the result obtained. The simulation is run for 64 Kbps data rate using constant bit-rate (CBR) application layer properties in QualNet. Three different routing layer protocols are considered one-by-one: Bellman-Ford, DSR, and AODV to analyze the performance of the network.

The PDR metric is recorded for 300 sec simulation time and the plot of the same is shown in figure 3 below.

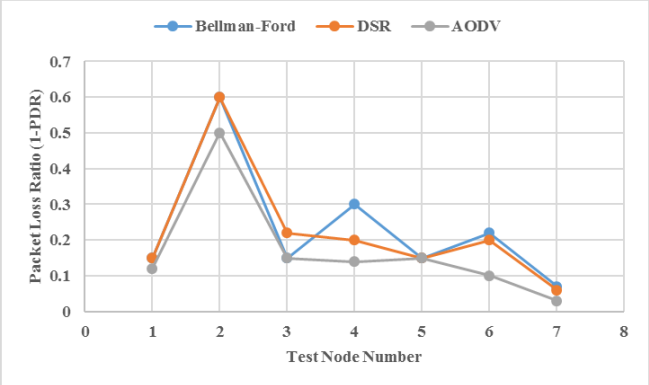

Fig.3: Effect of Routing Protocols on the Performance of WSN w.r.t PDR metric

The PDR indicates the network capability to tolerate the congestion and is calculated as the ratio of packet received successfully to the packet transmitted from the source. i.e.,

$$PDR = \frac{\text{Number of Received Packets}}{\text{Number of Transmitted Packets}} \quad (1)$$

The less value of PDR indicates that the network throughput is less as a result of discarding more packets on the network. Thus, a network with high PDR value gives maximum throughput and less packets will be discarded by the networks. The figure 3 indicates the percentage loss is less for AODV protocol as compared to Bellman-Ford and DSR protocols. As the less percentage loss indicates high PDR values and thus, WSNs with AODV as routing protocols performs better in terms of throughput. This is also worth noting that as there is less periodic update of the routing table information in AODV, which saves the bandwidth consumed significantly.

For a run time of 300 seconds, average end-to-end delay for the data to reach from source to destination is collected. These data are utilized to plot a graph of test node Vs ETD which is depicted in figure 4 below.

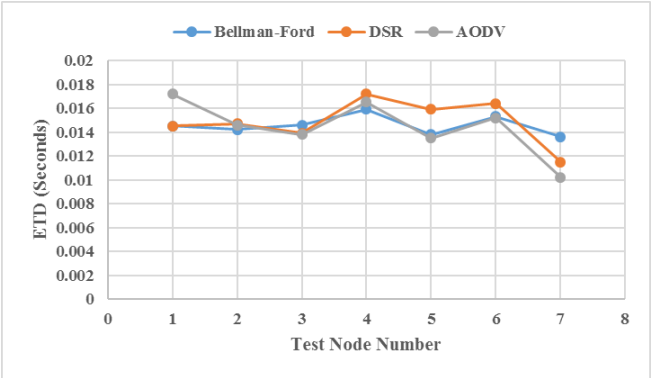

Fig.4: Effect of Routing Protocols on the Performance of WSN w.r.t ETD metric

The graph for average end-to-end delay plotted in figure 4. From the figure, it is observed that average end-to-end delay is more in DSR which is due to the connection set-up time as compared to that of AODV and Bellman-Ford protocols. The minimum delay is obtained for test node 7 for the ad-hoc on demand distance vector routing protocols and the maximum end-to-end delay is obtained for test node 4 for the DSR routing protocols. This is worth of mentioning that the values of ETD also depend upon the propagation time which is almost negligible in this case.

In depth analysis, thus, signifies that the AODV routing protocol performs better for wireless sensor networks as compared to the DSR and Bellman-Ford. However, this performance results are exclusively obtained for the two most important network parameters, average end-to-end delay and packet delivery ratio.

IV. Conclusion and Future Scope

The WSN is designed and implemented in QualNet which summarizes the effectiveness of several routing protocols in the following important conclusion. In wireless sensor network, AODV protocols gives maximum throughput, and consequently less packet loss as compared to DSR. However, DSR perform better than the Bellman-Ford in terms of PDR, but at the cost of higher end-to-end delay. On the other hand, AODV performs better in terms of PDR as well as ETD as compared to both Bellman-Ford and DSR. Even though, edges with negative weightage can be resolved using bellman-ford, AODV is shown to be performed better for wireless sensor networks in terms of PDR and ETD with a condition of non-existence of negative edges.

The performance analysis of these protocols with respect to scalability of dense WSN networks including MANET and VANET is the future work, which authors want to explore in the future.

***Abstract*—The maintenance and controlling of certain parameters of large-scale hydrothermal power plant is of great challenge. In this paper, certain characteristics of the hydrothermal power plant are controlled using Proportional-Integral-Derivative (PID) controller. The PID controller is used to get the desired response of such power plant. The parameters of PID controllers are tuned to the optimum values using various available optimization methods such as Particle Swarm Optimization (PSO), Genetic Algorithm (GA) and Fire-Fly algorithm (FFA). All these algorithms evaluate controller parameter using different cost function such as Integral Time multiplied by Square Error (ITSE) and Integral-Time Absolute Error (ITAE). The hydrothermal power plant under consideration is implemented in MATLAB and simulation is carried out to get the optimum values of controller parameters. This paper also presents a comparative analysis of effect of different optimization algorithm under different cost function in the context of the power plant.**

Keywords—Hydrothermal Power Plant, PID Controller, Optimization Techniques and MATLAB

I. INTRODUCTION

The recent research in the area of hydrothermal power plants is focused on reducing the operational cost, particularly, the maintenance cost of the system. The power plants should be pro-active in the sense that it reduces the mismatch between demand at the load side and the generation at the generator side. Further, the mismatch cannot be reduced to zero, and therefore, variation in it should be limited to certain levels, precisely, as low as possible. In the real time, load (both real and reactive) from the demand side is always variable which is high in the day time and very low during the night time. However, the power generation at the generator side mostly remains constant. So, the variation in load causes the mismatch between total demand and total generation, which if not controlled, increases the loss and thus, the operational cost is further increased. A power system is viewed as multiple interconnected power generators, loads and tie-lines. The Automatic Generation Control (AGC) is viewed as the methodology by which the deviation in frequency of the system and tie-line power flow is maintained to the certain limits [1]. For a power system, the two variables: tie-line power and frequency of the system, are to be controlled and should be limited to certain deviation. The combination of these two variables are referred to as Area Control Error (ACE) [2].

The various research works have been carried out in the direction of modeling a hydro, thermal and their combinations in the liner fashion [3,4]. The problems of AGC and its implementation in the context of power system is also carried out in the literatures [5-8]. The different methods of controlling the characteristics of the power system is also discussed in the past such as, A.A.F.M Carniero, *et.al.*, in [9] proposes the fuzzy logic based controller for the operation of the hydrothermal power systems. Authors in [10], proposes the self-tuning of AGC using Proportional-Integral (PI) controller based on fuzzy logic for interconnected areas. A unique way for AGC technology based on Phase Measurement Unit (PMU) is proposed by the scholars in [11]. Apart from these, a numerous research finding on grid communications are also available in [12]. Further, the tuning of parameters of several controllers including PID is carried out in the literature [13]. Moreover, the various optimization algorithms such as PSO, GA, fuzzy logic control and firefly, are explored in the past for tuning of the parameters of the controllers to get its optimum values [14-18].

The linearized model of the hydro-thermal power system is presented in this paper. The paper addresses the challenges of maintaining the constant system frequency and tie-line power flow for the interconnected power stations. The deviation in the ACE which is combination of system frequency and tie-line power flow, is limited automatically using the PID controller. The parameter of such controller is optimized using algorithms such as PSO, GA and FFA based on ITSE and ITAE objective functions.

The proceedings of remainder of the paper are as follows: Section 2 starts with the linear modeling and design of hydrothermal power system and reviews the PID controller and the PSO optimization technique. In Section 3, the system is implemented in MATLAB for simulation to validate the design followed by the detailed analysis of the results. At last, Section 4 concludes the research work with a way forward.

II. MATHEMATICALLY MODELLING OF THE SYSTEM

This section focuses on the mathematical modeling of the system under consideration. A brief review of the controller and optimization techniques is also presented here.

A. Transfer Function of the Dynamic System

The PI controller is used to control the hydrothermal power plant system. The system under consideration is composed of thermal- a non-reheat turbine, in connection with hydro unit. The system transfer function is as shown in figure 1. For the analysis, step response of the system is considered using PI controller. To get the transfer function of the system is state space method is utilized which is given in equations below.

$$\dot{x} = Ax + Bu \tag{1}$$

$$y = Cx + Du \tag{2}$$

Here,

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

x: State Vectors

u: Input Vectors

y: Output Vectors

Further, A, B, C and D are the system dependent real constant matrices.

$$x=\left[\Delta f_1,\Delta P_{mech1},\Delta P_{v1},\Delta f_2,\Delta P_{mech2},\Delta P_1,\Delta P_{v2},\Delta P_{12},\Delta P_{ref1},\Delta P_{ref2}\right]^T \tag{3}$$

$$u=\left[\Delta P_{L1},\Delta P_{L2}\right]^T \tag{4}$$

$$y=\left[\Delta f_1,\Delta f_2,\Delta P_{12}\right]^T \tag{5}$$

By using differential equations and analyzing the transfer function of each block independently, one can obtain the following equations necessary for the state matrix. Dynamic of power system is important because operating condition changes continuously such as load demand, output of the thermal and hydro plant.

$$\dot{x}_1=-\frac{1}{T_{p1}}x_1+\frac{K_{p1}}{T_{p1}}x_2-\frac{K_{p1}}{T_{p1}}x_8-\frac{K_{p1}}{T_{p1}}u_1 \tag{6}$$

$$\dot{x}_2=-\frac{1}{T_{t1}}x_2+\frac{1}{T_{t1}}x_3 \tag{7}$$

$$\dot{x}_3=-\frac{1}{R_1T_{g1}}x_1-\frac{1}{T_{g1}}x_3+\frac{1}{T_{g1}}x_9 \tag{8}$$

$$\dot{x}_4=-\frac{1}{T_{p2}}x_4+\frac{K_{p2}}{T_{p2}}x_5+\frac{K_{p2}}{T_{p2}}x_8-\frac{K_{p2}}{T_{p2}}u_2 \tag{9}$$

$$\dot{x}_5=-\frac{2T_2}{R_2T_1T_3}x_4-\frac{2}{T_w}x_5+\left(\frac{2}{T_w}+\frac{2}{T_3}\right)x_6+\left(\frac{2T_2}{T_1T_3}-\frac{2}{T_3}\right)x_7-\frac{2T_2}{T_1T_3}x_{10} \tag{10}$$

$$\dot{x}_6=-\frac{T_2}{R_2T_1T_3}x_4-\frac{1}{T_3}x_6+\left(\frac{1}{T_3}-\frac{T_2}{T_1T_3}\right)x_7+\frac{T_2}{T_1T_3}x_{10} \tag{11}$$

$$\dot{x}_7=-\frac{1}{R_2T_1}x_4-\frac{1}{T_1}x_7+\frac{1}{T_1}x_{10} \tag{12}$$

$$\dot{x}_8=T_sx_1-T_sx_4 \tag{13}$$

$$\dot{x}_9=\left(\frac{B_1K_{pr1}}{T_{p1}}-K_{pr1}T_s-K_{i1}B_1\right)x_1-\frac{B_1K_{pr1}K_{p1}}{T_{p1}}x_2+\ldots$$

$$\ldots K_{pr1}T_sx_4+\left(\frac{B_1K_{pr1}K_{p1}}{T_{p1}}-K_{i1}\right)x_8+\frac{B_1K_{pr1}K_{p1}}{T_{p1}}u_1 \tag{14}$$

$$\dot{x}_{10}=K_{pr2}T_sx_1+\left(\frac{B_2K_{pr2}}{T_{p2}}-K_{pr2}T_s-K_{i2}B_2\right)x_4-\ldots$$

$$\ldots\frac{B_2K_{pr2}K_{p2}}{T_{p2}}x_5+\left(-\frac{B_2K_{pr2}K_{p2}}{T_{p2}}+K_{i2}\right)x_8+\frac{B_2K_{pr2}K_{p2}}{T_{p2}}u_2 \tag{15}$$

After analyzing these equations, the real constant matrix obtained as follows:-

$$A=\begin{bmatrix}
-\frac{1}{T_{P1}} & \frac{K_{P1}}{T_{P1}} & 0 & 0 & 0 & 0 & 0 & -\frac{K_{P1}}{T_{P1}} & 0 & 0\\
0 & -\frac{1}{T_{t1}} & \frac{1}{T_{t1}} & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
-\frac{1}{R_1T_{g1}} & 0 & \frac{1}{T_{g1}} & 0 & 0 & 0 & 0 & 0 & \frac{1}{T_{g1}} & 0\\
0 & 0 & 0 & -\frac{1}{T_{P2}} & \frac{K_{P2}}{T_{P2}} & 0 & 0 & \frac{K_{P2}}{T_{P2}} & 0 & 0\\
0 & 0 & 0 & \frac{2T_2}{R_2T_1T_2} & -\frac{2}{T_w} & (\frac{2}{T_w}+\frac{2}{T_3}) & (\frac{2T_2}{T_1T_3}-\frac{2}{T_3}) & 0 & 0 & -\frac{2T_2}{T_1T_3}\\
0 & 0 & 0 & -\frac{T_2}{R_2T_1T_2} & 0 & -\frac{1}{T_3} & (\frac{1}{T_3}-\frac{T_2}{T_1T_3}) & 0 & 0 & \frac{T_2}{T_1T_3}\\
0 & 0 & 0 & -\frac{1}{R_2T_1} & 0 & 0 & -\frac{1}{T_1} & 0 & 0 & \frac{1}{T_1}\\
T_s & 0 & 0 & -T & 0 & 0 & 0 & 0 & 0 & 0\\
A_{9,1} & -\frac{B_1K_{pr1}K_{P1}}{T_{P1}} & 0 & K_{pr1}T_s & 0 & 0 & 0 & (\frac{B_1K_{pr1}K_{P1}}{T_{P1}}-K_{i1}) & 0 & 0\\
K_{pr2}T_s & 0 & 0 & A_{10,4} & -\frac{B_2K_{pr2}K_{P2}}{T_{P2}} & 0 & 0 & (-\frac{B_2K_{pr2}K_{P2}}{T_{P2}}+K_{i2}) & 0 & 0
\end{bmatrix}$$

where , $A_{9,1}=(\frac{B_1K_{pr1}}{T_{P1}}-K_{pr1}T_s-K_{i1}B_1)$

$$A_{10,4}=(\frac{B_2K_{pr2}}{T_{P2}}-K_{pr2}T_s-K_{i2}B_2)$$

$$B=\begin{bmatrix}
-\frac{K_{P1}}{T_{P1}} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{B_1K_{pr1}K_{P1}}{T_{P1}} & 0\\
0 & 0 & 0 & -\frac{K_{P2}}{T_{P2}} & 0 & 0 & 0 & 0 & 0 & \frac{B_2K_{pr2}K_{P2}}{T_{P2}}
\end{bmatrix}^T$$

$$C=\begin{bmatrix}1&0&0&0&0&0&0&0&0&0\\0&0&0&1&0&0&0&0&0&0\\0&0&0&0&0&0&0&1&0&0\end{bmatrix}$$ and

$$D=0;$$

The transfer function *H(S)* using state space model is given as:

$$H(s)=C[sI-A]^{-1}B+D$$

On analyzing the above matrices, transfer functions of the system can be evaluated as follows:

Transfer function $=C\left[SI-A\right]^{-1}B+D$

The order of transfer function is (3× 2) matrix.

$$\Delta f_1=\frac{\Delta f_1(s)}{\Delta P_{L1}(s)}\Delta P_{L1}+\frac{\Delta f_1(s)}{\Delta P_{L2}(s)}\Delta P_{L2} \tag{16}$$

$$\Delta f_2=\frac{\Delta f_2(s)}{\Delta P_{L1}(s)}\Delta P_{L1}+\frac{\Delta f_2(s)}{\Delta P_{L2}(s)}\Delta P_{L2} \tag{17}$$

$$\Delta P_{12}=\frac{\Delta P_{12}(s)}{\Delta P_{L1}(s)}\Delta P_{L1}+\frac{\Delta P_{12}(s)}{\Delta P_{L2}(s)}\Delta P_{L2} \tag{18}$$

B. PI Controller

The PI controller is used which includes advantages of proportional plus integral controller by mitigating the disadvantages of the individual. The transfer function of a typical PI controller is given by equation (19) where, K_p and K_i are the parameters of PI controller.

$$H(s)=\frac{U(s)}{E(s)}=K_p+\frac{K_i}{s} \tag{19}$$

The time domain representation of the PID controller is also shown by equation (20). Where, *u(t)* is the response due to the error input *e(t)*.

$$u(t)=K_p+K_i\int e(t)dt \tag{20}$$

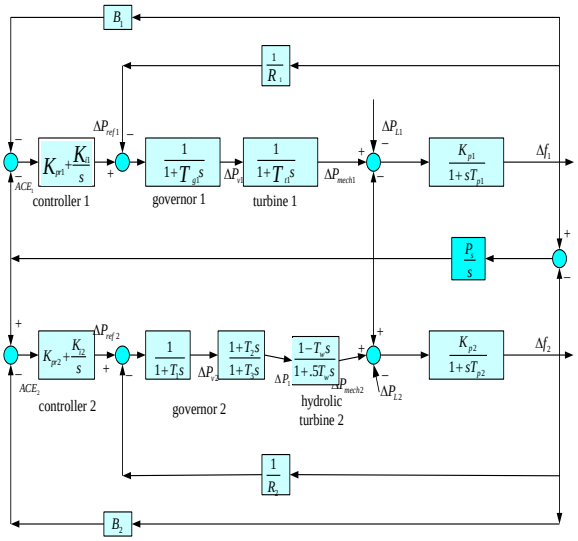

Fig.1: A Transfer Function Model of Interconnected Hydro-thermal Power System

C. Optimization Techniques

The optimization techniques viz., PSO, GA and FFA are used in order to tune the parameters of PI controller. Details of the particles swarm optimization can be understood in [18] whereas Genetic Algorithm (GA) and Firefly Algorithm (FFA) details are elaborated in [19] and [20] respectively. Since, the optimum values of controller parameters are unknown, initial values of these parameters are chosen randomly which are to be tuned using optimization algorithm. Since, all the optimization algorithm optimize the parameters based on the cost function, also referred to as objective function, we choose ITAE as one of the objective function. Further, to understand the effect of cost function in optimizing the parameters, ITSE as another objective function is chosen for comparison. The ITAE and ITSE objective functions are represented mathematically in equations (21) and (22).

$$ITAE=\int_o^\infty t\times|e(t)|dt \tag{21}$$

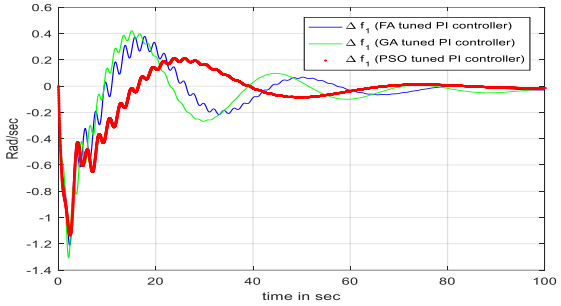
$$ITSE=\int_o^\infty |e(t)|^2\times t dt \tag{22}$$

III. Simulation Results and Discussion

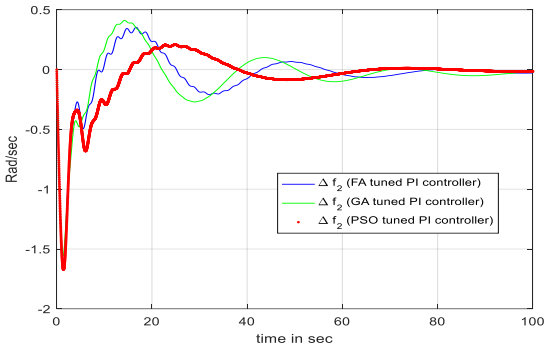
This section presents the implementation of the system under consideration in the MATLAB to validate the results obtained.

A. CASE I : Performance using ITAE as Objective Function

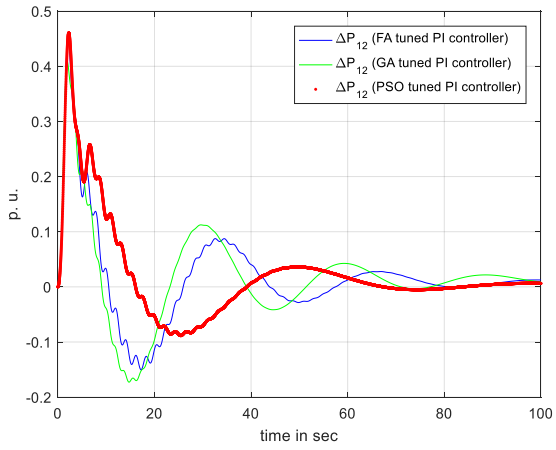
Two area hybrid hydro-thermal power system has been considered as depicted in Fig. 1. Load has been changed in both areas to analyze the performance of Load Frequency Control (LFC). Tuning of the PI controller's parameters have been done by three well-known optimization techniques (GA, PSO and FA) and comparison have been made among all when ITAE performance indices is used as the objective function. (Pd1=0.2 pu. and Pd2=0.3 p.u.). Perturbation response of the frequency in each area and also the change in Tie-line power flow have been observed by varying the loading in respective area and comparison have been made among all the three optimization methods. Fig. 2 show the perturbed response for all the state variables and also Table I show the optimum parameters of PI controllers with different optimization techniques.



(a) Load Frequency of Area 1



(b) Load Frequency of Area 2



(c) Tie-line Power Flow

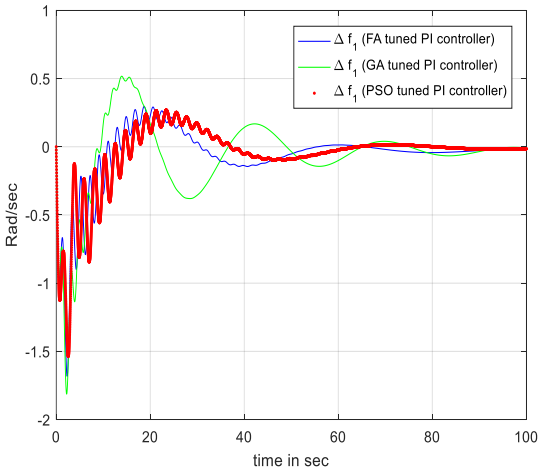
Fig. 2: Perturbed response of the system for Case 1

Table I: Tuned Parameters of PI Controllers with different optimization techniques for Case I

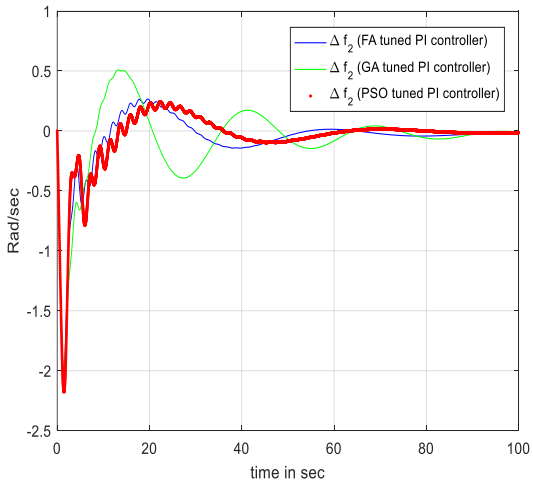
O.T	Time	K_{p1}	K_{p2}	K_{i1}	K_{i2}	ITAE
FA	260.718	0.289	8.531	0.999	0.041	$5.82x10^4$
GA	115.433	0.942	10.577	0.472	0.001	$7.13x10^4$
PSO	101.684	0	3.941	0.942	0.059	$4.77x10^4$

B. Performance using ITSE as Objective Function

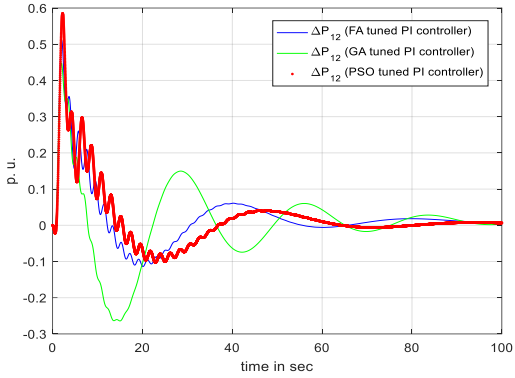
Tuning of the PI controller's parameters have been done by three well-known optimization techniques (GA, PSO and FA) when load have been changed to 0.4 p.u. in area 1 and 0.2 p.u. in the area 2. Here ITSE has been considered as the objective function to be minimized by three optimization methods. (Pd1=0.4 pu. and Pd2=0.3 p.u.). Perturbation response of frequency effect in area 1 and area 2 as well as the change in Tie-line power flow for the case II have also been observed in respective area and comparison have been made among all the three optimization methods. Fig. 3 show the perturbed response for all the state variables and also Table II show the optimum parameters of PI controllers with different optimization techniques.



(a) Load Frequency of Area 1



(b) Load Frequency of Area 2



(c) Tie-line Power Flow

Fig. 3: Perturbed response of the system for Case II

Fig. 2 and 3 show the perturb response of all the state variables for both the hydro and thermal area subjected to any change in the loading in the demand side. Case I has been shown in the detail with Table I (optimum parameters of PI controller) and also the settling time and overshoot of all the state variables in Table III. Analysis of Case II is shown in Fig. 2 (perturbed response of state variables), Table II (optimum parameters of PI controller) and settling time and overshoot also in Table III. Eigenvalues for both the cases have been shown in Table IV. By observing the above responses, it can be concluded that among all three optimization methods used for the tuning the PI parameters through simulation, PSO shows the better response with respect to the settling time and overshoot. Also the ITAE performance indices is showing better capability of handling the system responses and bring them back to the stability as compared to ITSE performance indices.

Table II: Tuned Parameters of PI Controllers with different optimization techniques- Case II

O.T	Time	K_{p1}	K_{p2}	K_{i1}	K_{i2}	ITAE
FA	93.217	0.504	5.755	0.758	0.033	$8.46x10^3$
GA	95.67	0.766	11.853	0.177	0.001	$2.03x10^4$
PSO	92.474	0.9588	4.235	0.941	0.059	$8.14x10^3$

Table III: Settling time and Overshoot of the test system

		Case Study (ITAE)		Case Study (ITSE)	
O.T	**State Variables**	**Overshoot/ undershoot**	**Settling time (*msec*)**	**Overshoot/ undershoot**	**Settling Time (*msec*)**
FA	Δf_1	-1.2	80	-01.70	85
	Δf_2	-1.6	78	-02.00	82
	ΔP_{12}	0.42	81	0.52	87
GA	Δf_1	-1.3	85	-01.85	80
	Δf_2	-1.6	90	-02.00	83
	ΔP_{12}	0.42	95	0.45	90
PSO	Δf_1	-1.18	60	-01.50	63
	Δf_2	-1.70	61	-2.20	62
	ΔP_{12}	0.45	64	0.58	65

IV. Conclusion and Future Scope

The hydrothermal power plant is analyzed and implemented in MATLAB. The system parameter is

controlled using PI controller whose parameter is optimized using PSO, FA and GA algorithms. All these algorithms evaluate controller parameter using various cost function such as Integral Time multiplied by Square Error (ITSE) and Integral-Time Absolute Error (ITAE). By observing the above responses, it can be concluded that among all the three optimization techniques used to find the optimal parameters of PI controllers, PSO shows the better response with respect to the settling time and overshoot.

Abstract— Fastest revolution among the region of information communication technology with digital things forcing fastest formation of IoT over the world. In IoT, communication is considered either by Pushing or Polling protocol. Push protocol is more suitable for IoT devices because of its light-weight and high productivity. There are many Push protocols available for IoT such as XMPP, MQTT and AMQP in which MQTT is most widely used. To ensure reliability of message transmission, MQTT supports three levels of QOS. The main feature of MQTT is its light-weight and bandwidth efficiency. MQTT can be designed by using many Brokers, with each broker has its own restriction. This paper provides necessary information about the MQTT architecture, brokers and issues related to MQTT.

Keywords— Internet of Things, Push Protocol, Message Queuing Telemetry Transport, Publish/Subscribe

1. INTRODUCTION

The network of smart devices approach was discussed in 1982, with a revised Coke machine at Carnegie Mellon University comely the first internet connected machine, in a position to report its catalogue and whether newly loaded drinks were cold. However the word "Internet of Things" is molded by British entrepreneur Kevin Ashton, executive director of Auto-ID centre in the year 1999. Nowadays, communicating between similar objects or dispatching instructions to home appliances is never thought anymore with evolution of wireless transmission mechanism, small-scale and less-potential appliances [2].

In IoT, transmission of data between different devices is important because an IoT appliance has to deliver an instruction to a further appliance to manage system [1]. Compared to polling protocol, Push protocol can be the best protocol for the communication of data for IoT appliances, since it is available in poor bandwidth network. MQTT, XMPP and CoAP protocol were implemented through these push message services [6]. These protocols are applicable according to different situations [5]. In particular, MQTT has been utilized as part of many IoT gadgets and instant message delivery systems because it was calculated to be working on little potentiality [2]. The rest of the article is analysing about introduction to MQTT protocol, architecture of MQTT protocol, utilization of MQTT protocol, brokers of MQTT and at last gives the termination of MQTT protocol.

II. MQTT PROTOCOL

Publish/Subscribe protocol is also called as MQTT protocol which was discovered in 1999 by IBM. MQTT was planned to send a data accurately under the long network delay and low-bandwidth network condition [34].

In MQTT, communication is based on changing of control packets in a specify manner [7]. There are fourteen control packets and each hold three section as shown in figure 1.

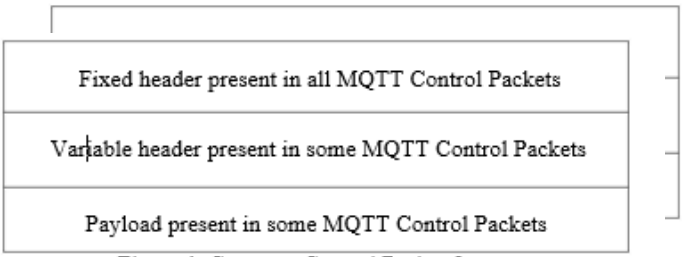

Figure 1. Common Control Packet format

A. MQTT concepts:

1) Publish/subscribe: In MQTT protocol, the client publishes messages to the subscribed topics and on other side the subscriber will be subscribed to those topics. Here, the topics can be used in order to differentiate the subscribers and this can be referred as Publish/Subscribe model [8].

2) Topics and subscriptions: In MQTT, the topics is used as a id for the subscriber and the client sends the data to that topic and the subscriber subscribes to that topics will receives the messages . The Subscriptions of topics can be express, that restricts the data which are collect to the particular topic [8]. Topics contain two wildcard level, to get data for a range of related

topics.

3) Quality of service levels: This protocol describes the Quality of Service (QoS) levels that are a deal within two parties of a message with respect to the assurance of distribution of data [2]. It supports three level of Quality of Services which are narrated beneath.

a) QoS0 (At most once): The message is sent at most once and it does not provide guarantee delivery of a message.

b) QoS1 (At least once): The data is sent at least once and it is possible to deliver a message more than once by setting the value of duplicate flag by 1.

c) QoS2 *(*Exactly once): The message is sent exactly once by using 4-way handshaking [9].

4) Retained messages: The information will be kept back in the broker after publishing it to all available clients. At the point, if a new subscriber gets subscribed to the same topic then the same information will be sent to the new customer [8].

5) Clean sessions and reliable connections: At the point when a subscriber associates with the broker, clean session association is considered as permanent, if its value is false. In this task, consecutive messages which come out conveying a highest QoS assignment are reserved for delivery when the association is resumed [10]. Use of these flag is optional.

6) Wills: A client tells the broker that it contains a will (message) which is need to be distributed to a particular topic or topics in case of a unantici-pated detach [8]. These will is especially valuable in the system such as security or alarm settings where managers instantly notified just as a sensor has extinct connection with the system.

III. MQTT ARCHITECTURE

The MQTT architecture splits into two main components as seen in figure 2. Each element is narrated beneath.

1) Client: The main work of the client , either can be a publisher or the subscriber to the broker and performs the following things as listed below[7]:

- ∑ Sends data to the broker.
- ∑ Subscribes to the broker in order to get the messages from the broker published by the client.
- ∑ Unsubscribe to extract within subscribed content..
- ∑ Can remove the connection with the broker.

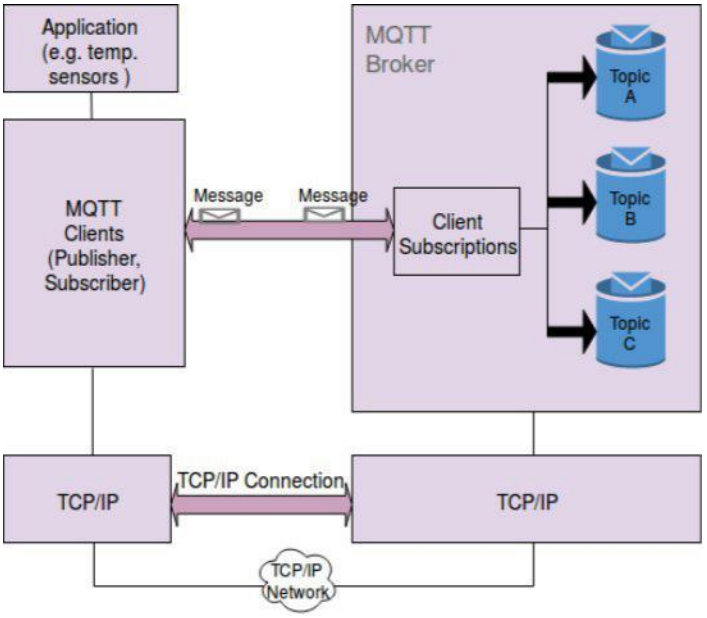

Figure 2. MQTT Architecture

2) Broker: Broker act as a server between the publisher and subscriber, where the client publishes the messages to the broker and the subscriber subscribes to the broker will receive the messages. The function of the broker is described below[7]:

- ∑ Broker will acquire the request from the client.
- ∑ Also receives the published messages from the users
- ∑ Broker also processes the requests like Subscribe and Unsubscribe within the users.
- ∑ The broker sends the messages to the interested subscribers after receiving the messages from the Publisher.

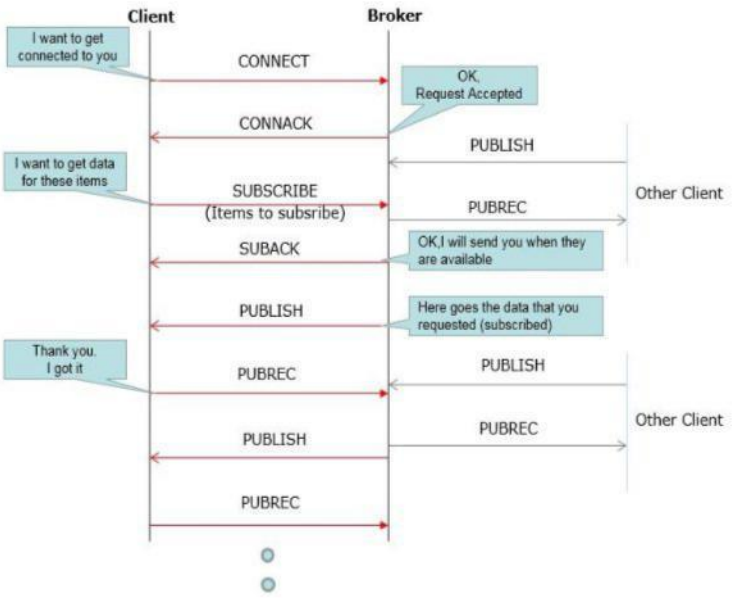

Figure 3. MQTT operation

IV. WHERE TO USE MQTT

MQTT can be used in many applications which are given in details below [8].

1) Healthcare*:* By using an MQTT, a healthcare association is required to create a flexible checking solution. Following are the arrangement expected to address of victim care:

- ∑ Keeping the track of victims besides they go away from the clinic.
- ∑ Upgrading the effectiveness of subsequent tests.
- ∑ Achieving advanced industry information catch principles.

The organization worked with IBM to make an answer in which an MQTT customer is inserted in a home observing machine that gathers diagnostics at whatever point the victim is in nearness to a base system. Then it forwards the indicative information through the web to the main domain, which is given to an application which analyses the measurements and aware the healthcare team if there are hints the victim perhaps carrying trouble. It spares cash for the association also its victims, as there is constrained requirement for victims to go hospital for regular check-ups if they are doing fine.

2) Energy and utilities: A service organization was confronted with increasing expenses to deliver power among with rising interest for electricity by their client root, which was not able, normally, to spend forever expanding amounts. Therefore instead of quickly carried out generation charges that their clients possibly couldn't spend, the organization first looked for an answer for decrease general request for power by putting smart meters in clients' apartments to remotely manage the application of definite power absorbing device. In any case, the arrangement expected to minimize utilization of accessible information network, for that the organization salaried according to the quantity of information transferred.

Making of Virtual power plant (VPP) was the arrangement which sits between the organization's producing origins and their clients. Smart meters gather use information for the different devices which are utilized there in-home apartment. At that point, apartment gateway examines, furnished with a progressed MQTT customer, distribute the utilization information to the VPP at normal interval throughout the nearby cell phone arrange.

3) Social Networking: A long range interpersonal communication organization experienced latency issues during transferring information. The strategy the organization utilized to deliver data was stable yet time-consuming, and if it remained to utilize the similar mechanism then the solutions were restricted [11]. Another structure for a constant association among the servers lacking absorbing more battery power was required, that is basic to clients of the organization's civic communication site.

Using MQTT protocol the organization's designers tackled the issue in social networking. With keeping up a MQTT association also directing data via MQTT's conversational channel (chat pipeline), the organization was capable to accomplish data distribution by speeds of 1×105 microseconds, instead of several minutes.

V. BROKERS OF MQTT

The MQTT broker is the heart of each MQTT arrangement. It provides connecting link between applications or physical devices and enterprise systems. Brokers are in charge of subscription, determined sessions, missed messages and general security, including authentication and authorization. The follow table describes mostly used brokers with their features and limitations [5].

Table 1:
Brokers with features and limitations

Broker	About	Features	Limitations
Mosquitto	It supports MQTT version 3.1 and it is an open source.	- All QoS - Authentica-tion - Bridge - Dynamic topics - Web sockets	- Clustering - Fewer Configuration Not allow simultaneous connection with using authenti-cation
RSMB (Really small message broker)	It is a tiny broker which supports V3 and V3.1.	- All QoS - Bridge - Dynamic topics	- Security - Web sockets - Cluster
MQTT.js	It is an MQTT broker among client/server API production recorded in JavaScript.	- All QoS - Dynamic topics - Web sockets - SSL	- Bridge - Authenti-cation - Cluster
HiveMQ	HiveMQ empowers organization to attach all devices and services with nominal effort by victimization the de-factor	- All QoS - Bridge - Dynamic topics - Web sockets - TLS/SSL - Cluster	- Open Standard - Performance degradation because of TLS

VI. MQTT DRAWBACKS

MQTT has its own restriction, which can be narrated as shown below:

1) Message Expiry: Right now in MQTT there is no message expiry, so in the event that you put a message in a broker and then forget to gather it or nobody ever comes to pick it up, it remains there forever. As a result, the broker is overloaded with messages and it degrades the overall performance.

2) Security: MQTT protocol provides username and password for authentication .So security in MQTT depends on the use case and selection of broker [19]. Mostly brokers provide security based on TLS, but TLS infect the improvement.

3) Ordering: The key challenges for a reliable data transmission organization in IoT environment are ordering messages and resending messages which lost during transmission. MQTT provides guaranteed delivery of messages, but maintain ordering of messages in MQTT is a challenging task.

4) Priority: MQTT does not support a feature called priority of messages. If any system has more important data then it must be immediately available to all the subscribers, for example the data which is gathered from fire alarm system is more important than temperature or pressure sensor data so it must be available first to all receivers. So for that priority of messages are required then sending data in order.

VII. CONCLUSION

IoT is assumed to provide advanced connectivity of services, devices and systems which is above machine-to-machine associations (M2M), which includes more number of applications, protocols and domains. The significance and evolution of MQTT in IoT, operation of MQTT, MQTT uses, different brokers used in MQTT and also discuss about the limitations of MQTT.MQTT can be used with minimum bandwidth along with less memory in IOT application.

A Review on tumor segmentation techniques for Magnetic Resonance Images

R. Sakthi prabha[1], Dr. M. Vadivel[2]

Research scholar, Sathyabama Institute of science and Technology, chennai[1]

Associate professor, Vidhya Jyothi Institute of Technology, Hyderabad[2]

ABSTRACT

Segmentation is defined as the process of splitting or dividing a digital image into multiple region. It plays a vital part in the field of medical image processing. At current scenario, tumor is represented as one of the most quite common dangerous disease found among the human beings. In general, tumor is defined to be an abnormal mass of tissue which can be either looks like a solid or fluid filled substance For detecting and fixing this kind of tumor different types of imaging methods are available, such as Computed Tomography (CT scan analysis), Positron Emission Tomography (PET scan analysis) and Magnetic Resonance Imaging (MRI scan analysis).. When a comparison is done between all these imaging modalities, each imaging modalities has its own individual specific mechanism in which the MRI imaging modality (scan detection) is considered to be one of the best defined system for its effective output. The target of the segmentation process is to define or to locate the tumor region and the extension of the tumor core, where it is said to be the active tumorous region. Even though several techniques has been implemented in image segmentation process, but still there is no accurate solution for image segmentation issue. Hence this survey explains briefly about various different types of image segmentation techniques which are used for MRI images.

Keywords- Segmentation, MRI image, Tumor FLAIR, SLIC

I. INTRODUCTION

Generally, segmentation process is classified into three different types such as manual segmentation, semi-automatic segmentation and fully automated segmentation. In manual segmentation as the name suggests, the entire work is done with the help of human intervention the work is done manually. Manual segmentation is considered to be one of the most easiest methods, whereas the accuracy level is less, with more time consumption Here the radiologist or the experts whoever does this work need not only have the present information from the image but also they need some more additional information related to the particular medical area. Whereas in semi – automatic segmentation, half of the work is done with the help of human intervention.

As we make a comparison between the previous methods the semi-automatic segmentation is considered to be the superior one, whereas the accuracy level is improved and the time consumption is also drastically reduced. And in fully automated segmentation method, the entire work is done with the absence of human intervention. So here we use some soft computing tools, human intelligence, etc., while a comparison is made between all these three various types of segmentation methods, fully automated segmentation is considered to be the superior one where it produces a high accuracy level, with drastically reduced time consumption and also thereby reducing the probability of error rate.

Even though several segmentation method has been implemented for tumor segmentation, but still there is no accurate solution for the segmentation problem. Hence the ultimate aim is to identify the tumorous core region at the same time to segment tumor core region with the extension of the tumorous core region namely the active tumorous core region. In addition to this we have various factors to be considered while performing the segmentation process such as removal of noise, spotting the specific region with less intensity boundaries, less prediction of tiny particles, etc., A wide variety of image segmentation techniques are available which produces more effective segmentation output. The remaining paper is organized as follows: In section II the literature survey with various techniques are discussed, which is followed by various Image segmentation techniques in section III and thereby section IV provides the overall conclusion about the related work.

II. RELATED WORK

Kavitha A.R et.al [1] proposes a algorithm with the help of fuzzy initialization and seeded region growing(GFSMRG) method using neural network algorithm (BPNN). In this framework the problem addressed is to improve the level of accuracy in the identification of tumor thereby to improving the execution faster for performing the segmentation process. The methodology adopted here is, pre-processing as the initial step followed by the segmentation process and then the segmented output undergoes feature extraction and finally Classification is done. Hence in the proposed framework it's been found that it is proposed and thereby, the parameters like accuracy and time complexity is considerably improved and hence the achievement of the proposed work was verified by both quantitatively and qualitatively.

Bonte S et.al [2] defines a proposed framework in this paper with random forest model combined with the three dimensional co-ordinates and undesirable features analyzed and detected on the various relaxation times such as T1 and FLAIR Magnetic Resonance Imaging. Here, first the RF model determines and finds out the probability of the tumor class and the normal one. Similarly as a second step the algorithm is applied for the tumor segmentation process. This technique is suitable much for the high grade glioma. Here the propose method is trained on BRATS2017 database and validated. In this framework the T1 and FLAIR MRI image sequence are considered, since it provides much complementary information. The steps involved here is; first pre-processing is done wherein transforming brain scan into high dimensional feature vectors for every voxel. As a second step the obtained features (voxel) are now applied with Random Forest algorithm which determines and finds out the voxel based probabilities for the tumor tissue and the healthier one. And finally, the input is provided based on the Gaussian Mixture Model(GMM) probabilities. One of the parameter named dice score has been achieved of about 70%. Hence in this paper two types of features are extracted and analyzed they are advanced texture feature and abnormality feature

Jothi G. and Hannah Inbarani H [3] proposesa new framework algorithm, Hybrid Supervised algorithm namely Tolerance Rough Set Firefly based Quick Reduct (TRSFFQR) framework isproposed and much suitable and applicable for the MRI images. Hence two different types of hybridization techniques are applied in this work namely Tough Rough Set(TRS) and Firefly algorithm(FA). The steps involved are; First pre-processing is done. This step includes increasing the size of the image and thereby decrementing the noise without disturbing any of the relevant features. Once the preprocessing stage has been completed, the output image obtained from the above process is subjected for skull stripping process. Hence once skull stripping is done, the output hence carried is followed with various different types of segmentation techniques. And finally the feature extraction process is done for the segmented output image. The feature extraction process is done by using two methods. They are; Texture based feature and Intensity based feature. The proposed framework is also termed to be supervised features selection algorithm (TRS and FA). Finally a comparison is done with various algorithm and it's been concluded that Tolerance Rough Set (TRS) can be used as one of the real time medical image applications due to the various special features of it like its simplicity, consistency and Robustness.

Zaka Ur Rehmana et.al, [7] proposes a Random Forest (RF) algorithm based on regional classifier is considered. The Region based feature parameters considered is statistical, Textron histogram and fractal feature. In this proposed work the major parameter found is pixel level accuracy, Dice score, precision and specificity. The work flow is done in both training and testing phases. Hence the image is splitted into different square shaped patches named as super pixel of equal size with the help of the technique named Simple Linear Iterative Clustering (SLIC) and also finally feature extraction also can be done. The workflow for training phase of this paper includes, pre-processing as the initial stage and then feature extraction then feature selection and normalization. Then the output is fed for class balancing and further classifier training process is done. Similarly, in case of testing phase initially pre-processing is done followed up with feature extraction and the training mode is classified their by segmenting the tumor using super-pixel classification.

Chandan Singh and Anu Bala [4] addressed segmentation of MRI image has become a tedious job nowadays. It's mainly because of the Rician noise and intensity in homogeneities in the MRI images. The previous methodologies completely deals with these issues under spatial domain, and while dealing the case when the noise is removed from the sample image, some of the image data content is also lost, this must be rectified. As moment domain to be one of the factor is completely dealt in this proposed

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

framework. So they have chosen Zernike moments which use the local and nonlocal information's, which discards the different types of noises from MRI images. Hence this algorithm can be applied to the various types of tissues available in brain such as Grey Matter (GM), white Matter (WM) and Cerebro Spinal Fluid (CSF).The proposed algorithm on the overall it's called to be intelligent knowledge driven approach. There is no human intervention during the segmentation process. Here, Local Zernike method (LZM) based on non-local means fuzzy C-means (LZM-UNLM-FCM) approach. The proposed work is compared with the existing work and thereby which gives improved segmentation accuracy level. LZM reduces the rician noise by holding the fine structure, edges and the other details available in the moment domain.

Kai Roman Laukamp et.al [5] defines that meningiomas is a kind of tumor that always are found on membranes, which covers the brain and spinal cord which is inside the skull. As stated by World Health Organization (WHO) the abnormal mass of tissue are categorized into different types of grades such as grade I, grade II, and grade III. In which grade II and grade III are considered to be at increased risk stage. Grade III are found often with irregular size and shape. The problem addressed in this paper is eventhough several type of techniques are available but still there is no radiological criteria for categorizing the grade I and grade II lesions. The proposed algorithm in the paper is an automatic detection and segmentation using deep learning mode is proposed. Angu lakshmi and Lakshmi priya [6] defines a newly proposed framework which is based on walshhadamard texture feature for using in multi modal brain tumor segmentation which is used for MRI images.

Mahmooda,b,A et.al [8] proposes a fully automated unsupervised segmentation framework method is implemented in MRI images. In this proposed frame work the technique provides high degree of accuracy level while performing the segmentation on both the synthetic and real T1 MRI image. The proposed method is validated for varying noise level aswell as spatial intensity level. The performance is also compared with various different types of segmentation toolboxes. The following are the steps involved. They are, pre-processing wherein brain extraction is done followed with bias field correction and the Bayesian AMS is applied. Nameirakpam Dhanachandra et.al, [9] proposes an algorithm that comprises of a group of techniques namely partial contrast stretching, subtractive clustering, etc., They observed that once the segmentation is done a comparison is made between the existing and proposed and it's been found that the quality level of the segmented output(proposed framework) seems to be higher than the existing one. It is also verified and checked with the help of various parameters such as RMS and PSNR.

Sangeetha K Siri, Mrityunjaya V Latte [10] applied neutrosophic set concept to image processing along with Chan -Vese model. The image is first read, noise is reduced using a median filter and a random section of liver is segmented for which a neutrosophic set is generated. They observed that the proposed algorithm is useful for the detection of tumor within the organ aswellas it is used for detecting the boundary of it. The important parameters such as its volume and area can be found which is used in diagnosis and liver transplantation. Hussain Alahmer, Amr Ahmed [11] proposed a new technique using multiple Region of Interest. Hence the liver is segmented with the help of fuzzy C-means clustering algorithm liver is segmented with the help of binary liver mask and divided into three classes. They observed whether the tumor is benign and malignant with the help of an proposed automated approach system and thereby the border area accuracy improved to 98%.

III. IMAGE SEGMENTATION TECHNIQUES

The main objective of image segmentation technique is, an image can be segmented based on the variation in intensity values, which is of discontinuity or similarity [8]. An image can be segmented wisely based on the sudden variations in the intensity levels or else an image can be segmented based on some of the segmentation methods which is widely used are classified as follows;

1. Threshold based segmentation method
2. Edge based segmentation method
3. Region based segmentation method and
4. Cluster based segmentation method

Generally all these method is done based on the following two types. They are;

1. Boundary based segmentation and
2. Region based segmentation.

3.1 Threshold based segmentation

Threshold based segmentation paves a major role in the image segmentation due to its simplicity of implementation, user friendly nature etc., The steps

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

involved in this type of segmentation is pre-processing, followed by the segmentation process and as a final step the segmented output is given to the filtering process to get a clear segmented noise free output. Here the images can be divided into multiple numbers of regions based on the intensity values [12]. For example if a bright object is placed in front of a dark background, the object(region) can be extracted easily by identifying the intensity values. With the help of the provided technique, the given sample data which is to be performed. Hence the threshold based segmentation process is done successfully due to the intensity level of the pixel.

3.2 Edge based segmentation

In the given sample image an edge based segmentation is done with the help of sudden change either increase or decrease in the pixel intensity which is found closer to the edges. A binary image is obtained as an output for the edge based segmentation thereby edges of the each object in an image is detected and segmented accurately. The edge based segmentation is further classified into two types they are gray histogram and gradient based methods.

3.3 Region based segmentation

Segmentation is defined to be splitting or dividing a single image into multiple number of region. Such kind of splitting an image can be done either by finding out the boundaries between the regions based on the discontinuity in the intensity level between the regions or else the partition can be done with the help of certain criteria. One of the most commonly used segmentation method is Region growing method. The steps involved here is region splitting and region merging. The technique follows by choosing a set of seed points and thereby increasing the region by including neighborhood pixel, based on the value of the threshold, the process will be terminated once all the pixels under same threshold value are grouped together. Region growing technique is especially applied for simple images such as tumors etc.,

In case of region splitting and merging based on some of the properties and conditions an image is splitted into different types of regions. Once the region splitting process is done it is again further merged. At initial step the entire full image is described to be the single image wherein which the factor known as standard deviation is calculated for the internal similarity of the given image(sample data). Based on the variation range the image is divided into multiple number of regions, completely depending on the value of the threshold. The above process can be continued till there is no further splitting can be done. One of the most commonly used data structure for dividing the region is quad tree. The images which comes with contrast distribution of pixels or the images which comes with a great difficulty in differentiating both the foreground and background due to the variation in the intensity level can be used with watershed segmentation technique. In order to determine the weak edges in a given image watershed algorithm can also be used for better output.

3.4 Clustering based segmentation

One of the most commonly used technique in Magnetic Resonance Imaging (MRI) is the clustering method, here each pixels are splitted into multiple number of region[14]. The region is splitted based on the maximum probability range. In the cluster based segmentation the training process of the pixel is done with the help of analyzing the pixel characteristics and its properties.

a) K-means clustering algorithm

Based on the properties of pixel it's been concluded that this algorithm is one of the simplest of the existing algorithms. The clustering based segmentation involves the following steps; initially seed points are fixed for the objects that are grouped together and then assume the objects to a single group which possess the nearest centroid points. Once the objects are fixed again determine the value of the centroid. The K-means clustering algorithm can able to group multiple number of pixel together for a numerous region. Hence this technique is said to be hard clustering, moreover each clusters are separated by a long distance and each one of the pixel is allocated with a membership function, it is termed to be a hard clustering algorithm. Even though the clusters are located in distance all of them belongs to a single group of region

b) Fuzzy C means clustering algorithm

One of the unsupervised method for the analysis of the provided various input images are fuzzy c means clustering. Each and every pixel in an image is assigned a membership function based on the distance from the different cluster center by the clustering algorithm. Whereas the number of pixels which is placed nearer to the cluster head seems to possess higher membership function toward the given pixel. On the other side an algorithm groups various data objects available in an image to a groups of clusters, such algorithm is named as hierarchical

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

algorithm. Whereas in hierarchical algorithm it is not needed to address the required number of clusters to be used in prior or in advance.

Different types of segmentation algorithm are available. They are as follows, fuzzy c-means algorithm, Region growing algorithm, Watershed segmentation and different types of clustering algorithm such as K means clustering algorithm, Fuzzy C means clustering algorithm, Region based segmentation and Threshold based segmentation, and so on. Based on all these segmentation process the following parameters can be analyzed. They are Global consistency error (GCE), peak signal to noise ratio (PSNR), Random Index (RI), variation of information(VOI), Boundary Displacement Error (BDE), Absolute Error (MAE) etc., For the better segmentation results the value of PSNR and RI must be higher and at the same time the parameters like GCE and VOI must be low

The paper presents an overall conclusion about the different types of available existing methodologies for image segmentation. Selection of a proper and exact segmentation technique mostly depends on the type of image used and to which application it's been used. Based on various obtained results it's been said that evaluating the obtained results of image segmentation is considered to be a tedious task. Also so many factors are taken into consideration while an image segmentation is performed, such as contrast, homogeneity, compactness, continuity, etc., there is no algorithm that is always the most accurate. Thereby generating a group of base learners which when combined provides high accuracy. The techniques such as fuzzy logic and Artificial Neural Network (ANN) is found to be the most suitable for image segmentation technique

In this paper, several existing techniques which is related to the brain tumor detection and segmentation is found and discussed for various brain MRI images. The various existing segmentation techniques like threshold based segmentation, region based segmentation, edge based segmentation and cluster based segmentation techniques are described for the removal of active tumorous core region from the MRI images. Some of the methods which gives better output results for intensity based thresholding techniques but gives very poor output for the high contrast images. Whereas for high contrast images region based segmentation is considered to be the best and superior one for providing the better output. When compared with all the other segmentation, edge based segmentation obtains an efficient output irrespective of noisy. If noise is of a major concern then clustering based segmentation is chosen to be one of the best, simple and highly efficient method for providing better output.

IV CONCLUSION

Hence in case of image processing techniques segmentation process is considered to be one among the most important process. In this review work, various techniques of image segmentation has been discussed for Magnetic Resonance Imaging modalities. Various kinds of algorithms and methods which is used for image segmentation process has been discussed elobaratively. Image segmentation algorithms are mainly focused to improve the efficiency of the detected tumor region. Even though several techniques has been implemented but still there is no accurate solution for image segmentation problem. Hence in future work, it's been concluded to propose a novel technique where in which tumor segmentation process can be done efficiently and accurately irrespective of its location, shape and intensity when compared with the existing techniques, thereby will be helpful for the radiologist in evaluating the MRI to produce accurate results

Abstract—**In the contemporary power system, the load frequency control (LFC) of two area thermal power plant has broadly expended in frequency control suitable to having the quick replies. The fuzzy logic controller is considered for two area power plant. The pattern of system with fuzzy controller is imitation in MATLAB/SIMULINK. The dynamic replies of LFC with fuzzy and it equated through PID of frequency control for system. The success of the proposed fuzzy is better-quality the outcomes of power system in provisions of settling time and peak undershoot time**

Keywords- Load Frequency Control (LFC), Fuzzy logic controller, Proportional-Integral-Derivative (PID) controller, Frequency Deviation.

I. INTRODUCTION

In arrears to the status of the apportionment of electrical authority, the power establishments are accountable for stipulating, incessant, consistent, proficient and operative power source to their purchasers with an adequate superiority. Contemporary power organization system is completed active of numerous controlled expanses and for established process of power system components, the entire generation of individually controlled extent must competition with aggregate load strains favorable linked system losses and normalizes system frequency and conversations tie-line power consequently. This is entitled as automatic generation control (AGC) and LFC. Which performances an significant position in power system procedure and regulator [1]. For a consumption of Power system is important to remember the incessant source of electric authority to the purchaser without any commotion. For an steadiness, the power system is to continue a stability amongst load demand of the purchaser and power engendered of the power plant. Due to cumulative the complication in the world, the power petition is also intensifications. The load claim of the purchaser rises due to a frequency is renewed from its insignificant value. So, it is compulsory to keep the system frequency is to be continual. LFC is single of the rudimentary policies to reach complementary amongst the reactive power and real power. LFC is uninterruptedly supervising the system frequency and tie-line power. Estimate net variations of similar from their supposed standards (recognized as area control error, ACE). Consequently control the regulator settings of generators therefore as to retain ACE to its smallest worth. AGC initiatives ACE to zero and spontaneously together frequency and tie-line power will spontaneously transfer to zero [2,3]. The huge, composite and inter-linked power systems contribution with a massive number of nonlinear possessions consequently, fuzzy controller is single of the improved controller of these organizations. This article, the fuzzy controller is expended for LFC of the two areas system. The fuzzy is established on fuzzy set theory and being signified with the involvement and acquaintance of a anthropological operative of the system [4,5,6,7]. A power system contains of a generation, transmission and distribution of electrical supplies. Huge organized quantity of fundamentals consequences to a difficult power system which is generally associated via tie lines. In current periods, it is attractive a problematic duty to power engineer for sustaining the amplified power petition from the contemporary power system. The protected and consistent procedure of a huge organized multi-area power system necessitates the complementary amongst the producing load demand and power [8]. In [9], have proposed Grey wolf optimization (GWO) technique, Linear Quadratic Regulator (LQR) PSO-PID [10], BSA-PID [11], TLBO Optimization [12], chaotic optimization [13], Automatic Control Error (ACE) [14], LQR [15].

This paper performs a significance of lfc for two area power plant. The propositioned fuzzy logic is participate and significant part to get improved occurrences. This article, fuzzy controller has been pertained to accomplish the project features for power plant.

This paper is equipped in five sections. LFC for two area including mathematical modelling and state space equation are denoted in section 2. The fuzzy and PID controller denoted in section 3. The proposed fuzzy logic controller is compared by the PID controller. Frequency deviation in relations of settling time and peak undershoot of the is described in section 4. The conclusion of this paper is accessible in section 5 and involves of nomenclature, appendix and references.

II. MATHEMATICAL MODELLING FOR TWO AREA REHEAT-THERMAL POWER PLANT

The network frequency is contingent on active power and voltage enslavement on reactive power boundary. The network is divided into two autonomous complications. An significant responsibility of LFC is to reserve the frequency unconventionality constant in contradiction of due to incessant

discrepancy of loads. Which is correspondingly mentioned as un- known outside load interruption. Power conversation fault is an significant responsibility of LFC. Normally a power system involves of numerous generating elements associated composed. These generating constituents are inter-connected via tie-lines to developed fault accepting. This consumption of tie-line power produces contemporary fault in the control difficulty. Area controller error (ACE) is performance main character in interconnected network. Area 1 and area 2 are interconnected to separately previous by using a tie-line. The modification of tie-line power of each areas by transformation in restriction values. The elementary two area control block diagram is figure1.

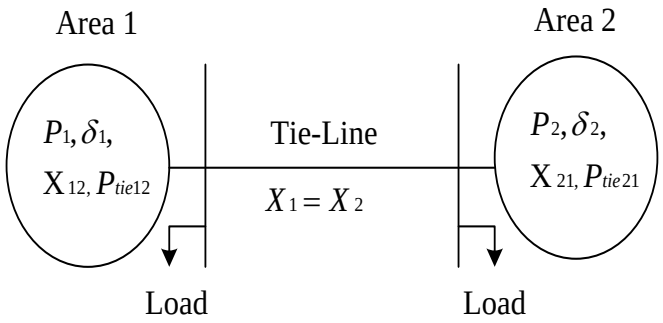

Figure 1. Basic control diagram of two-area power plant.

The basic control diagram of non-reheat thermal-thermal power plant is exposed in figure 2. Both areas have consumed a 2000MW rating and working on 1000MW nominal load. The speed governor, steam turbine and units of power system is consumed in both interconnected areas.

The power of area-1 is transfer to area-2 and its certain by equation (1)

$$P_{tie12} = \frac{|V_1||V_2|}{X_{12}} \tag{1}$$

In two areas the intend of load is depend on power angle. Both Δδ1 and Δδ2 is change incremental in configuration of δ1 and δ2. The power of change is specified by eq. (2) and eq. (3).

$$P_{tie12} + \Delta P_{tie12} = \frac{|V_1||V_2|}{X_{12}} \sin[(\delta_1 + \Delta\delta_1) - (\delta_2 + \Delta\delta_2) \tag{2}$$

$$P_{tie12} = \frac{|V_1||V_2|}{X_{12}} \cos(\delta_1 - \delta_2)(\Delta\delta_2 - \Delta\delta_2) \tag{3}$$

$$T_{12} = \frac{|V_1||V_2|}{X_{12} * P_1} \cos(\delta_1 - \delta_2) \tag{4}$$

$$\Delta P_{tie12}(p.u) = T_{12}(\Delta\delta_1 - \Delta\delta_2) \tag{5}$$

$$P_{\max 12} = \frac{|V_1||V_2|}{X_{12}} (\Delta\delta_1 - \Delta\delta_2) \tag{6}$$

$$T_{12} = \frac{P_{\max 12}}{P_1} \cos(\delta_1 - \delta_2) \tag{7}$$

$$2\Pi\Delta f = \frac{d\delta}{dt} \tag{8}$$

The incremental output power of tie-line of area1 is certain by eq. (9).

$$\Delta P_{tie12}(p.u) = 2\Pi T_{12}\left(\frac{\Delta f_1}{s} - \frac{\Delta f_2}{s}\right) \tag{9}$$

Applying the Laplace transform in both sides.

$$\Delta P_{tie21}(s) = \frac{2\Pi T_{12}}{s} (\Delta f_2(s) - \Delta f_1(s)) \tag{10}$$

Put T21=a12T12

$$\Delta P_{tie21}(s) = \frac{-2\Pi T_{21}}{s} (\Delta f_1(s) - \Delta f_2(s)) \tag{11}$$

Swing equation conferring to [4]. In area 1 the load is increase, the power is certain in eq. (12).

$$\Delta P_G - \Delta P_D = \frac{2H}{f^0} \frac{d}{dt} \Delta f + B\Delta f \tag{12}$$

Here in eq. (12).

H - Inertia constant, f0- Nominal frequency, Δf - Revolution in frequency, B - Parameter of area. Two area power is certain by eq. (13) and (14).

$$\Delta P_G - \Delta P_D = \frac{2H}{f^0} \frac{d}{dt} \Delta f + B\Delta f + \Delta P_{tie12} \tag{13}$$

$$\Delta P_G(s) - \Delta P_D(s) = \frac{2Hs}{f^0} \frac{d}{dt} \Delta f(s) + B\Delta f(s) + \Delta P_{tie12}(s) \tag{14}$$

$$\Delta f_1(s) = \frac{\Delta P_{G1}(s) - \Delta P_{D1}(s) - \Delta P_{tie12}(s)}{B_1\left(\frac{2H_1 s}{f^0 B_1} + 1\right)} \tag{15}$$

$$\Delta f_1(s) = \left[\Delta P_{G1}(s) - \Delta P_{D1}(s) - \Delta P_{tie12}(s)\right]\left[\frac{K_p s}{1 + sT_p s}\right] \tag{16}$$

Where

$$K_p s = \frac{1}{B_1} \text{ and } T_p s = \frac{2H}{B_1 f^0}$$

Similarly,

$$\Delta f_2(s) = [\Delta P_{G2}(s) - \Delta P_{D2}(s) - \Delta P_{tie21}(s)]\left[\frac{K_p s}{1 + sT_p s}\right] \tag{17}$$

In power network system, area control error is generated by a input of controller.

$$ACE_i = \sum_{j=1}^{N} \Delta P_{ij} + B_i \Delta \omega_i \quad (18)$$

Here,

N is total animated of consistent areas is depend on i. and P_{ij} is deviation of power and it is depending on both i and j areas.

In article, a two areas network have reserved. The power system involves of a governor, non-reheat turbine and power system load model in configuration of transfer function. Speed regulation are constant. The frequency of bias factor is contingent on reaction of output. The frequency deviation in power system is specified as Δf. Area-1 frequency deviation isΔf1 and area-2 frequency deviation is Δf2. The increment for area-1 is ΔPl1 and the augmentation for area-2 is ΔPl2. This power petition is specified in step load procedure. The fuzzy controller are expended for controlling the frequency. Power deviation in two area is controlling by proposed fuzzy. The block diagram of two area network shown in Fig. 2.

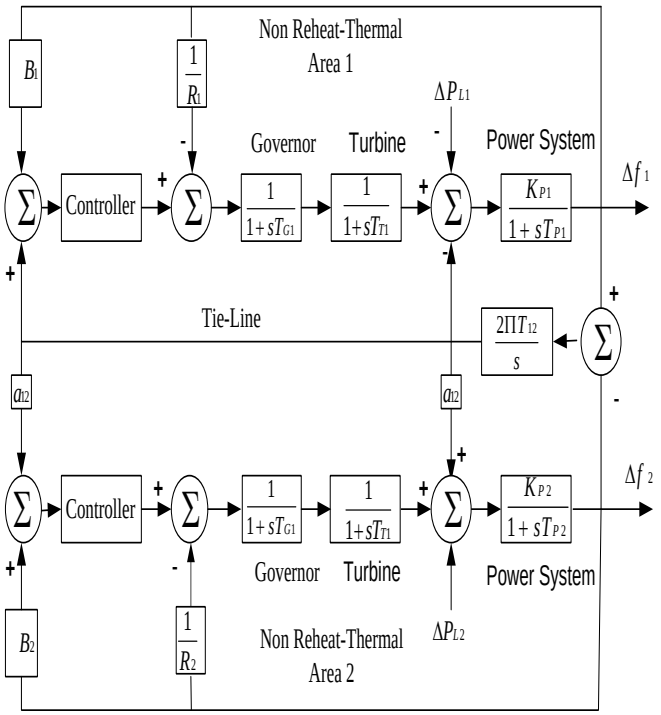

Figure 2. Block diagram of two area non re-heat thermal-thermal power plant with controller.

2.1 The state space equation of two area non-reheat thermal power plant.

This paper, the state space model is using for two area power system. System is continuous-time linear. The equivalent results for discrete-time systems, gained through division with continuous-time models. The state space network is continuous-time dynamic system. It terminate be resultant either from the network given in the time field. The illustration of differential equation or transfer function is giving equation form. The state space equation for two-area network is understand in this equation.

$$\frac{d}{dt}(\Delta f_1) = \frac{1}{\tau_{ps1}}\left[-\Delta f_1 + K_{ps1}\Delta P_{G1} - K_{ps1}\Delta P_{D1} - K_{ps1}\Delta P_{TL}\right] \quad (19)$$

$$\frac{d}{dt}(\Delta f_2) = \frac{1}{\tau_{ps2}}\left[-\Delta f_2 + K_{ps2}\Delta P_{G2} - K_{ps2}\Delta P_{D2} + K_{ps2}\Delta P_{TL1}\right] \quad (20)$$

$$\frac{d}{dt}(\Delta X_{E1}) = \frac{1}{\tau_{sg1}}\left[-\Delta X_{E1} + \Delta P_{C1} - \frac{\Delta f_1}{R_1}\right] \quad (21)$$

$$\frac{d}{dt}(\Delta X_{E2}) = \frac{1}{\tau_{sg2}}\left[-\Delta X_{E2} + \Delta P_{C2} - \frac{\Delta f_2}{R_2}\right] \quad (22)$$

$$\frac{d}{dt}(\Delta P_{G1}) = \frac{1}{\tau_{t1}}\left[-\Delta P_{G1} + \Delta X_{E1}\right] \quad (23)$$

$$\frac{d}{dt}(\Delta P_{G2}) = \frac{1}{\tau_{t2}}\left[-\Delta P_{G2} + \Delta X_{E2}\right] \quad (24)$$

$$\frac{d}{dt}(\Delta P_{TL1}) = 2\pi T_{12}^0\left[\Delta f_1 - \Delta f_2\right] \quad (25)$$

$$\begin{bmatrix}\Delta X_{E1}\\ \Delta X_{E2}\\ \Delta P_{G1}\\ \Delta P_{G2}\\ \Delta f_1\\ \Delta f_2\\ \Delta P_{TL1}\end{bmatrix} = \begin{bmatrix}\dot{x}_1\\ \dot{x}_2\\ \dot{x}_3\\ \dot{x}_4\\ \dot{x}_5\\ \dot{x}_6\\ \dot{x}_7\end{bmatrix} = \begin{bmatrix} -\frac{1}{\tau ps1} & 0 & 0 & 0 & \frac{Kps1}{\tau ps1} & 0 & -\frac{Kps1}{\tau ps1} \\ 0 & -\frac{1}{\tau ps2} & 0 & 0 & 0 & \frac{Kps1}{\tau ps1} & \frac{Kps1}{\tau ps1} \\ -\frac{1}{R1\tau sg1} & 0 & -\frac{1}{\tau sg1} & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{R2\tau sg2} & 0 & -\frac{1}{\tau sg2} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\tau t1} & 0 & -\frac{1}{\tau t1} & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{\tau t2} & 0 & -\frac{1}{\tau t2} & 0 \\ 2\Pi T_{12}^0 & -2\Pi T_{12}^0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix}x1\\ x2\\ x3\\ x4\\ x5\\ x6\\ x7\end{bmatrix} + \begin{bmatrix}0 & 0\\ 0 & 0\\ \frac{1}{\tau sg1} & 0\\ 0 & \frac{1}{\tau sg2}\\ 0 & 0\\ 0 & 0\\ 0 & 0\end{bmatrix} \begin{bmatrix}u1\\ u2\end{bmatrix} + \begin{bmatrix} -\frac{Kps1}{\tau ps1} & 0 \\ 0 & -\frac{Kps2}{\tau ps2} \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix}p1\\ p2\end{bmatrix} \quad (26)$$

III. CONTROLLER

3.1 Fuzzy Logic Controller

Fuzzy logic control is provides in artificial intelligence and control system engineering. Fuzzy controller is formed on a reasonable system called fuzzy logic. Fuzzy logic controller is developed a three components like as first is fuzzification (The breakable inputs are delineate with fuzzy parameters), second is rule base fuzzy (To implement the output for follow the each rule is giving for a fuzzy predecessor and to find out all collective outputs to follow a rules of fuzzy logic) and third is defuzzification (The breakable output are delineate by using a fuzzy parameters) is given in Fig (3).

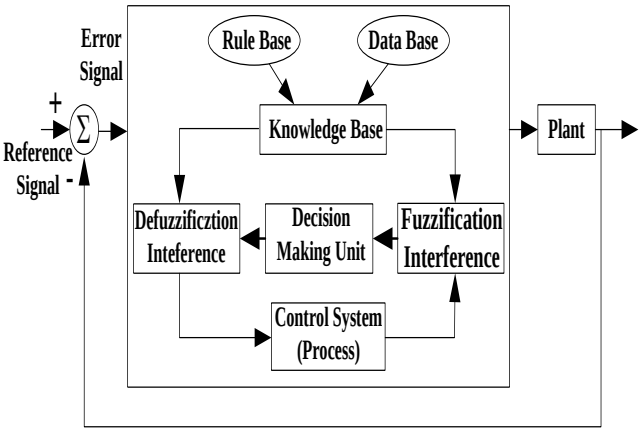

Figure 3. Block diagram of fuzzy logic controller

3.1.1 Fuzzification

Fuzzification is the method of changing a actual significance input indication into a syntactical parameter. Input signal is Knowledge base signal and it is a amalgamation of rule base and data base. Fuzzification is a work from two types, first accept the signal from knowledge base unit then send to decision making unit. And second is receive the signal from controlled system and send to decision making unit in fig (3). The actual significance inputs for a two areas thermal power plant is error and derivative of error. Mamdani configuration of fuzzy interface stage deliver amongst the inputs signal and the output signal. This paper a two kinds of input signal are used and included a five-linguistic parameter like as NB (negative base), NS (negative short), ZZ (zero), PS (positive short) and PB (positive base) is exposed in fig (4).

TABLE 1. RULE BASE TABLE FOR LFC.

Frequency Derivation error	Rate of change of frequency derivation error				
	NB	**NS**	**ZZ**	**PS**	**PB**
NB	S	S	M	M	B
NS	S	M	M	B	VB
ZZ	M	M	B	VB	VB
PS	M	B	VB	VB	VVB
PB	B	VB	VB	VVB	VVB

3.1.2 Rule Base Fuzzy

The rule base fuzzy includes of fuzzy if- then rules. The fuzzy rule could comprise fuzzy parameters and fuzzy subsection considered by member function. The fuzzy rule base as specified in Table 1. The rules are produced in this method: if the variable of error is NB (negative base) and the variable of derivative of error is NB (negative base) then the output control signal variable is S (small). Expending these member function and variable, the entire number of 49 rules are produced.

3.1.3 Defuzzification

Defuzzification converting the output fuzzy variable to a actual value indication. The centroid technique applied for defuzzification progression.

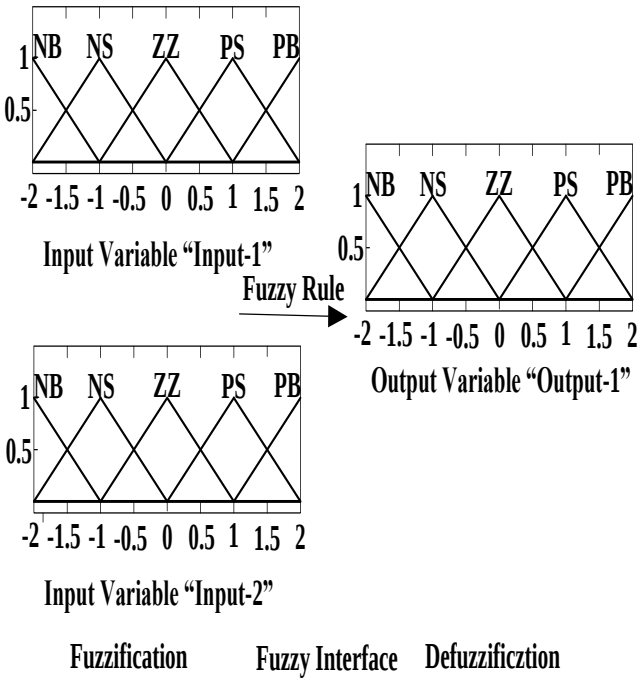

Figure 4. Inputs and outputs membership function for LFC.

IV. SIMULATION RESULTS AND DISCUSSION

In simulation research, we simulate power system with fuzzy logic controller. In this segment, we equated the presentations of thermal power plant with fuzzy logic controller through the PID controller. The reply of system parameters of PID controller is arranged in Table 2. Performance Comparison.

TABLE 2. PARAMETER VALUE OF PID CONTROLLER

S. No.	Method	Two Area PID Controller Parameter		
1.	PSO-PID Ragini, 2015 [11]	Area - 1	Kp1	0.6412
			Ki1	0.9459
			Kd1	0.4866
		Area - 2	Kp2	1.4907
			Ki2	2.0000
			Kd2	1.3564
2.	BSA-PID, Ragini 2015, [11]	Area - 1	Kp1	1.1154
			Ki1	0.9665
			Kd1	0.8358
		Area - 2	Kp2	1.1274
			Ki2	2.9687
			Kd2	1.3701
3.	A.Pritam 2017 [12]	Area - 1	Kp1	1.6301
			Ki1	1.9999
			Kd1	0.8038
		Area - 2	Kp2	1.2349
			Ki2	0.4976
			Kd2	1.5291
4.	Farahani M, 2012, [13]	Area - 1	Kp1	0.6003

			Kd1	0.5224
		Area - 2	Kp2	0.3000
			Ki2	0.7319
			Kd2	0.3654

The two area non-reheat thermal power system is measured for load. We associated the replies of fuzzy controller with PID controller replies in relations of settling time, peak undershoot in confirmation in table 3

TABLE 3. COMPARISON ANALYSIS OF SETTLING TIME AND UNDERSHOOT TIME

S. No.	Method	Two Area Setting Time and Peak Overshoot Parameter		
		Areas	Setting Time (Seconds)	Undershoot
1.	Proposed Fuzzy	ΔF1	40.284	-1.583
		ΔF2	36.772	-1.564
		ΔP_{tie}	24.415	-0.300
2.	BSA-PID, Ragini 2015, [11]	ΔF1	45.688	-1.581
		ΔF2	40.781	-1.904
		ΔP_{tie}	32.434	-0.254
3.	PSO-PID, Ragini 2015, [11]	ΔF1	46.707	-1.793
		ΔF2	43.535	-2.219
		ΔP_{tie}	26.563	-0.290
4.	Pritam, 2017, [12]	ΔF1	52.164	-1.563
		ΔF2	52.822	-1.784
		ΔP_{tie}	42.850	-0.244
5.	Farahani M, 2012, [13]	ΔF1	75.682	-1.756
		ΔF2	88.494	-1.641
		ΔP_{tie}	20.691	-0.381

The proposed fuzzy has minimum settling time as associated to the PID controller and controller better the demonstrations of the system. The qualified investigative of settling time of proposed controller and PID controller for network is shown in Figure (5), (6) and (7).

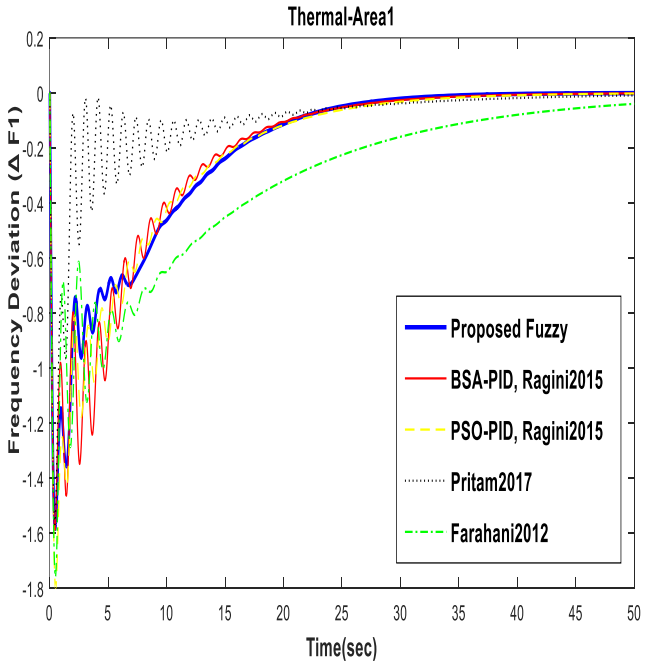

Figure 5. Comparison of thermal area-1 (frequency deviation Δf1) of proposed fuzzy with PID [10], [10],[11] and [12].

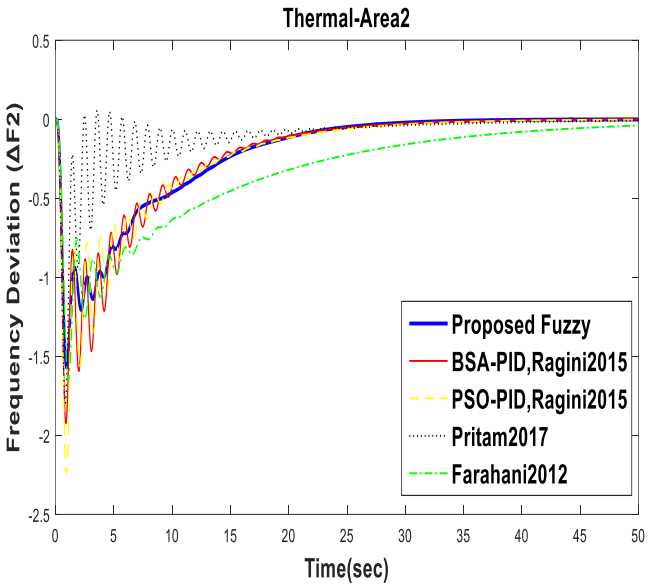

Figure 6. Comparison of thermal area-2 (frequency deviation Δf2) of proposed fuzzy with PID [11], [11], [12] and [13].

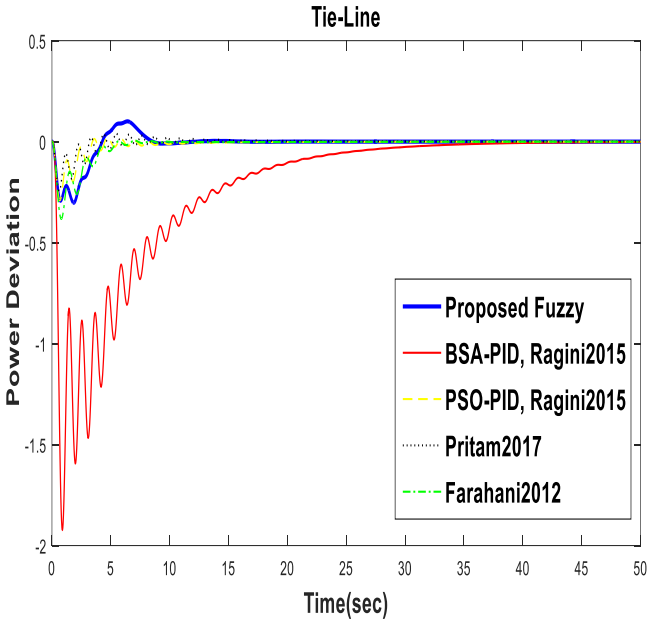

Figure 7. Comparison of tie-line of proposed fuzzy with PID [11], [11], [12] and [13].

V. CONCLUSION

In this article, the fuzzy logic controller are using for disentangling the load frequency predicament. A relative study was accessible using PID controller. Fuzzy logic controller and PID controller constraints are pertained to a two area non-reheat thermal power system. The core purpose of this paper is to better the dynamic implementations of the power plant. The condescension of proposed controller has been expressed for two area power plant. The simulation results countenance that the proposed fuzzy logic controller has superior carrying out

than the recommendation PID controller. The settling time and peak undershoot time of the two area non-reheat thermal power system measured by fuzzy logic controller gives superior result.

NOMENCLATURE

T_G : Stem governor time constant
T_T : Stem turbine time constant
K_{ps} : Power system gain constant for area.
T_{ps} : Power system time constant for area.
T_{12} : Co-efficient of synchronizing.
R_1, R_2 : Constant of speed regulation for area.
B_1, B_2 : Constant of frequency bias factor for area.
Δf_1, Δf_2 : Frequency deviation for area.

APPENDIX

Parameter of two area power plant.

Area-1
P_{r1} = 2000 MW, P_L = 1000 MW, T_{P1} = 20s, B_1 = 0.425 p.u. MW/Hz, R_1 = 2.4 Hz/p.u. MW, K_{P1} = 120, T_{t1} = 0.3s, T_{g1} = 0.08s.
Area-2
P_{r2} = 2000 MW, P_L = 1000 MW, T_{P2} = 20s, T_{12} = 0.545 s, a_{12} = -1, B_2 = 0.425 p.u. MW/Hz, R_2 =2.4 Hz/p.u. MW, K_{P2} = 120, T_{t2} = 0.3s, T_{g2} = 0.08s.

Abstract— **With the advent of technology the use of power electronic devices rapidly increasing. Most of the power electronic devices require the rectifier i.e. AC- DC power converter for their working or charging purposes. Use of the power electronic converters introduces harmonics in the system thereby violating the limits of the international standard and also as the power level increases the harmonics of lower order which will deteriorates the power factor and thus affects the efficiency to a great extent. All these problems arises a great need of power factor correction. Here, in this paper analysis of different power factor correction topologies is done to understand their various techniques like passive and active and after that types of active power factor correction types are visualized and analyzed. The simulation result of the PFC buck and PFC boost converter communicate that both the techniques help to improvise the power factor .**

Keywords – Power factor, Passive PFC, Active PFC ,Buck converter,Boost converter

I. INTRODUCTION

Power factor is the measure of how effectively power is transferred from the source to load. Therefore, it is very important aspect of any power system but with the increasing use of power electronic devices in the power system for various purposes deteriorates the power factor as the power electronic converters introduce harmonics in the system. The leading and lagging power factor means there are transmission and distribution losses in the system due to which the power is not effectively utilized .A good power factor i.e. close to unity power factor implies effective utilization of power and low power factor implies that the power is not utilized properly. To overcome this problem many power factor correction techniques have been implemented so far. These PFC technologies help to meet the requirements of international standards, such as IEC 61000–3–2 and IEEE-519.

The need for the improvement of power factor arises from the fact that the rectification of alternating current is very ineffective process because it leads to the distortion of the waveform of current drawn from the input. This will give rise to large number of harmonics that will intervene with the working of other equipment. As the power level increases this intervention may become even worse as the harmonics enter in the power utility line this in turn increases the size of transformer and other equipment thereby increases the overall cost and decreasing the efficiency. All these problems greatly demand the requirement of the power factor correction. The various techniques of correcting the power factor of low power AC – DC converter [1],[8] evolved so far. Active PFC techniques using DC-DC converter is described in [2],[3].The performance evaluation of PFC boost converter given [7],[9] given. Power factor correction for switched mode power supplies presented in [4].Bridgeless power factor correction techniques [5] reduces the number of devices used. The research is done on single stage techniques of correcting the power factor [6].Some calculation for buck boost presents in [10].A voltage double circuit is represented in [12].[11] gives the correction of power factor by using switched inductor circuit.

This paper presents analysis of different techniques of power factor correction. The power factor technologies include both active and passive PFC techniques. Among the various types of active techniques here the PFC buck and boost techniques are visualized and simulated. The simulation result shows that the techniques help to obtain the power factor close too unity. Thereby, making the circuit cost effective and improves efficiency.

The section I of this paper includes the introduction of the power factor and different methods of its improvement. Section II represents the different techniques of improving power factor. The best techniques of power factor correction i.e. power factor boost converter is represented in section III. Finally, the simulation result and conclusion is presented in section IV and V.

II. TECHNIQUES OF CORRECTING THE POWER FACTOR

The PFC helps to obtain the maximum efficiency in the distribution of power. The power factor correction can be listed mainly into two groups:

- Passive PFC
- Active PFC

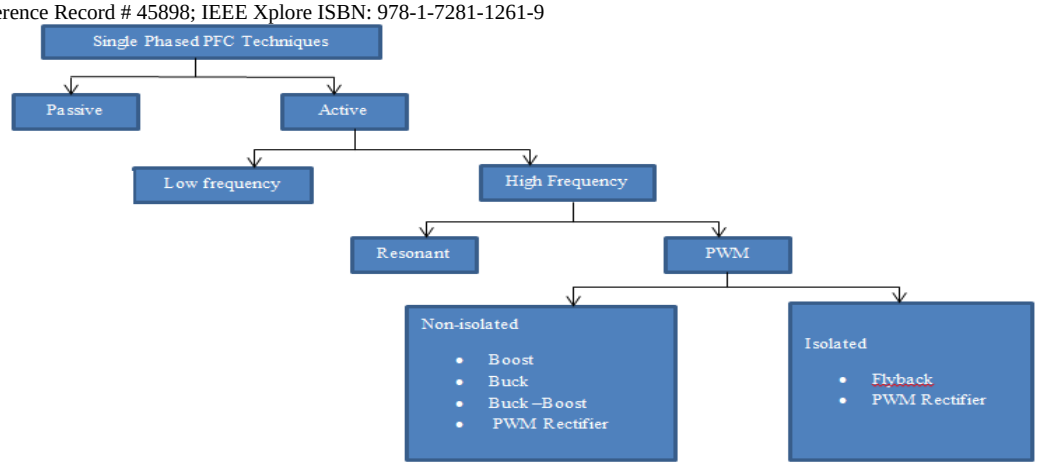

Fig 1. Power Factor Correction Techniques

The Various types of Power factor correction techniques are represented in Fig 1.

Passive Power Factor Correction

The passive power factor correction is the simplest way to remove the harmonics with the help of passive filters like capacitors, inductors, RC and LC filters .These filters allows the line current of a particular frequency (50 Hz-60 Hz) range only thus minimizing the total harmonic distortion (THD) and maintaining it with in the limited standard range. The disadvantage of this technique lies in the fact that the passive filter is bulky in size, thereby requiring the use of large value of inductors and capacitors. All this leads to increase in the cost of the circuit. Thus, generally another technique of PFC i.e. active PFC is preferred to passive PFC.

Active Power Factor Correction

The Active PFC technique utilizes the different power electronic devices to control the power travelling from source to load so that power factor close to unity can be easily achieved. These switching techniques consist of different types of switching regulators which consists of active elements like Field effect transistor, MOSFET, IGBT and diodes. Active power factor helps in increasing the power factor and lower the value of THD making the circuit cost effective. Active PFC techniques not only shape the input current but also lower the harmonics and regulate the voltage at the output with the help of feedback. Some examples of active PFC are boost converter, buck converter, dual boost converter, etc. Out of all these techniques the most preferred is boost one owing to its excellent current shaping ability.

III. THEORITICAL ANALYSIS OF ACTIVE PFC TECHNIQUES

A. PFC Buck Converter

Buck converter is DC to DC converter which is used to lower the value of voltage i.e. stepping down of voltage. This converter works only when the instantaneous voltage at the input is greater than the instantaneous value of the voltage at the output due to this reason the current at the input is distorted during some initial cycles. Fig 2 represents the basic PFC buck converter.

Working

- When the switch S_a is on the diode D_e is reverse biased and the inductor charges from the source.
- While when the switch S_a is turned off the diode is forward bias and the inductor discharges its energy to load.

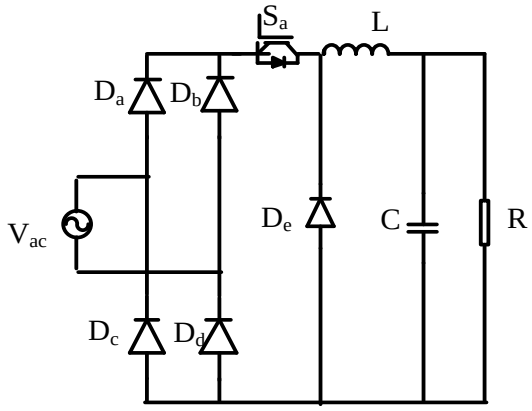

Fig 2. PFC Buck Converter

The duty cycle of buck converter is given by :

$$D = \frac{V_o}{V_{in}} \quad (1)$$

B. *PFC Boost Converter*

Boost converter is a DC to DC converter which is used to step up the voltage .PFC boost converter is the widely accepted technique of power factor correction because of its excellent current shaping ability and efficiency. Fig.3 displays the basic PFC boost converter.

Working

- When Switch S_a is on the DC energy converted from AC energy by rectifier charges the inductor during this time the voltage at the output is maintained by the capacitor by the previously stored energy in it.
- On the other hand when the switch is off the DC energy and the energy stored in the inductor is transferred to the load thereby boosting the voltage at the output. The voltage at the output can be controlled by controlling the duty cycle of the switch.

The value of different parameters of PFC boost converter can be calculated from the following equations:

$$D = \frac{V_o - V_{in}}{V_o} \quad (2)$$

$$L = \frac{R_L \times D \times (1 - D)}{2 f_s} \quad (3)$$

$$C = \frac{V_o \times D}{f_s \times \Delta V \times R_L} \quad (4)$$

where ,
R_L= Load resistance
f_s = switching frequency
ΔV = Output voltage ripple

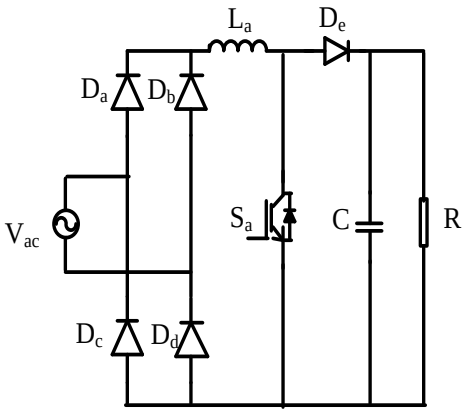

Fig 3. PFC Boost Converter

IV. SIMULATION AND VALIDATION OF THE PFC CONVERTER

Here MATLAB simulation result is presented. The input voltage V_{ac} = 220 V_{rms} and switching frequency f_s is taken as 20KHz.

Fig 4 displays the switching waveform of both the PFC buck and PFC boost converter. The switching waveform is essential to control the working of the circuit as by varying the duty cycle of the switching waveform the time of ON and OFF of the switch can be varied.

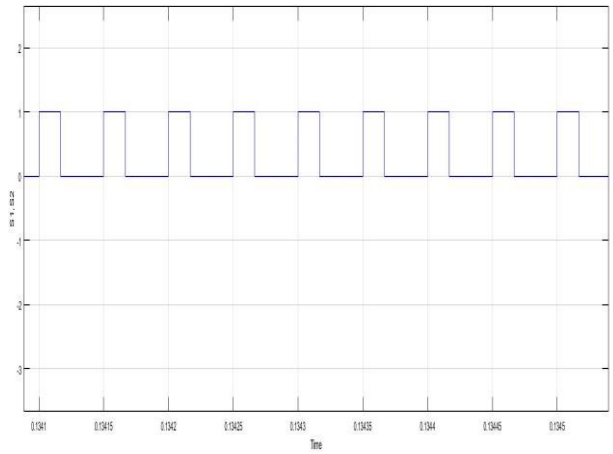

Fig 4. Switching Waveform

A. Simulaion Of PFC Buck Converter

- Fig 5. represents the Simulink model of the PFC buck converter.
- The waveform of the current at the input and voltage at the output of the PFC buck converter is being displayed in Fig 6.
- By observing the two waveforms it can be concluded that the two waveforms are in phase i.e. the voltage and current are in phase which represents that the unity power factor or the power factor is close to unity. Thus, power factor is improved by using the PFC buck converter.
- Fig 7. displays the output voltage waveform of the power factor correcting converter based on buck converter.

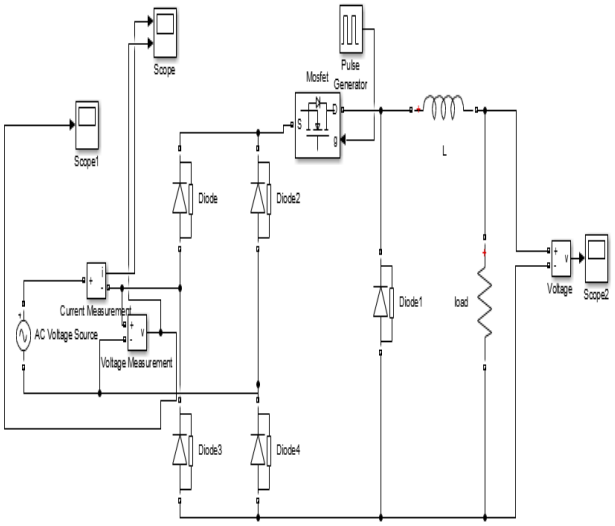

Fig 5. Simulink Model of PFC Buck Converter

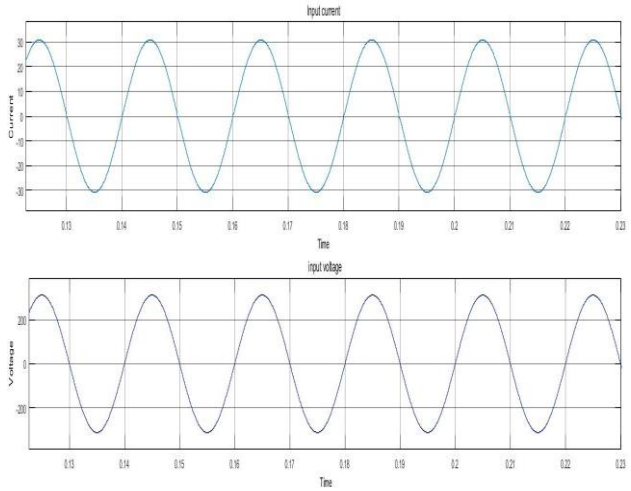

Fig 6. PFC Buck Converter Waveforms of Voltage and Current at the input

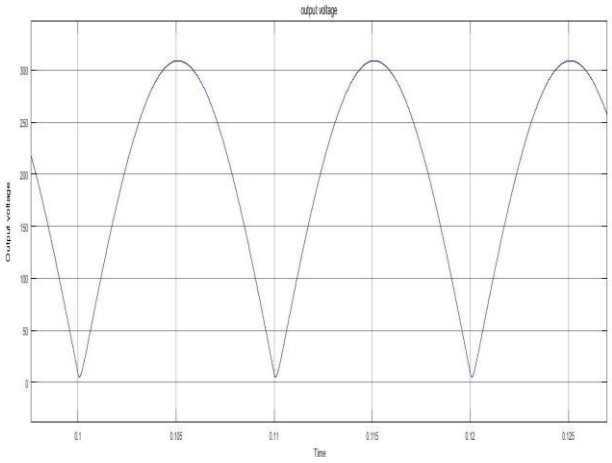

Fig 7. PFC Buck Converter Waveforms of Voltage at output

B. Simulaion Of PFC Boost Converter

- The Simulink model of the PFC boost converter is represented in Fig 8. The switching waveform of the switch of PFC boost converter is given by the pulse generator here.
- The waveform of the current at the input and voltage at the output of the PFC boost converter is being displayed in Fig 9.
- By observing the two waveforms it can be concluded that the two waveforms are in phase i.e. the voltage and current are in phase which represents that the unity power factor or the power factor is close to unity. Thus, power factor is improved by using the PFC boost converter.

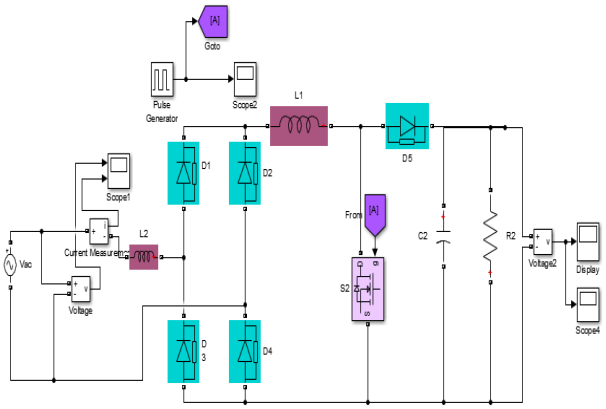

Fig.8. Simulink Model of PFC Boost Converter

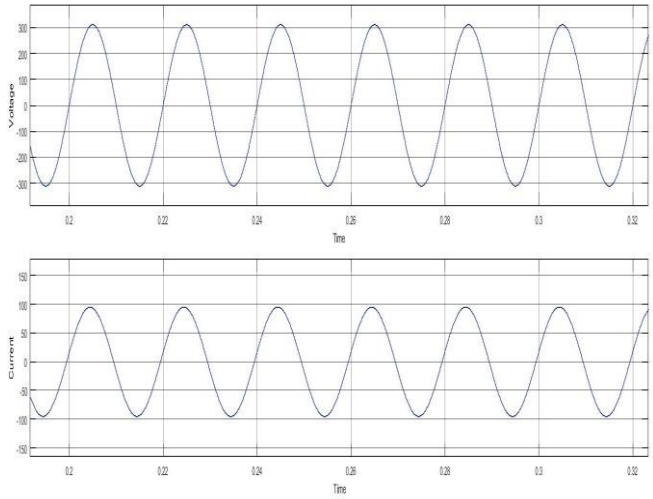

Fig 9 . PFC Boost Converter Waveforms of Voltage and Current at the input

- Fig.10. represents the voltage at output of the PFC boost converter which approximates to a constant value of 600 V.

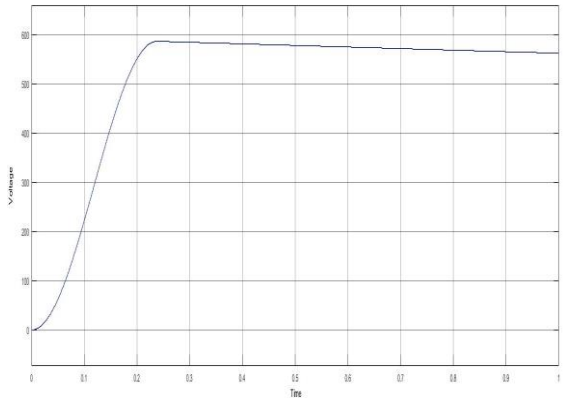

Fig 10. Output voltage of PFC boost Converter

V. CONCLUSION

Analysis of various techniques of correcting the power factor of the AC – DC converter is presented in this paper. The two types of active PFC methods based on PFC buck and boost converter is explained and simulated results of the two topology represents that the two converters obtain the power factor close to unity as the waveforms of the input voltage and the current is in phase ,thus the two converters correct the power factor to a great extent . Out of these topologies the PFC boost converter is the most preferred owing to its excellent current shaping ability and ability to remove harmonics. The future scope of the power factor topology includes the PFC converter based on SEPIC converter.

***Abstract*— Public distribution scheme is a structure promoted by government and includes chain of shops. This scheme aims to provide food grains and commodities to people at affordable price. Public distribution scheme ails at many factors such as availability, overcharge, timing, undersupply illegal smuggling of goods and corruption. Intelligent Public Ration Distribution System (IPRDS) is similar to an Automated Vending Machine which allows customers to complete purchases and transactions of basic ration commodities with ease. The customer identification, distribution of commodities, billing and data updation etc. are automated. The customer identification is done by the finger print verification. The system was prototyped and tested to distribute three major commodities; rice, wheat and kerosene. The proposed scheme can be directly implemented in the existing ration shops and thereby reduce the labor works associated with distribution of commodities. Since all the activities will be monitored by the food supplies department, all activities takes place in accordance with the rules and regulations.**

Keywords*— *GSM Module, Finger Print Modue R307

I. INTRODUCTION

Govt. of India issues Ration Cards, with which families are able to buy commodities like Rice, sugar etc. at subsidized rates. The subsidized rates and the quantity of the materials are conditioned based on the family income and the number of members. This framework by the government aids several poor and needy families. However, this facility provided by the Government sometimes fails to reach the target group owing to human errors, inaccuracy in weighing machines, selling of leftover materials without the knowledge of the government and other forms of corruptions.

The propsed work attempts to bring out a system to eradicate the drawbacks in the chain of ration distribution and to ensure proper service of the system. The designed system is dubbed as "INTELLIGENT PUBLIC RATION DISTRIBUTION SYSTEM (IPRDS)" .With the implementation of IPRDS in all the existing ration shops, the data management becomes simpler and unfailing.

The major objective of this work is to automate the public ration distribution process. At present, ration distribution is carried out through ration shops which may neither work daily nor keep regular hours. This cause limited accessability and channelise the undisposed grain and other products to the open market. By this users do not get their rightful entitlement in terms of quantity. Moreover, the overcharging more than the mandated rate, and under-weighing of commodities are also widespread. These drawbacks of existing system can be reduced by the suggested IPRDS. Quality and quantity issues of supplied goods are also addressed in this work.

The IPRDS can be installed in existing ration shops or can be implemented even as a mobile ration shop. Since the user verification is done using fingerprint, chances of illegal transactions are minimized. The available quota of customers can be updated by the Central agencies through GSM. The details of every transaction can also be updated.

In the existing ration distribution system, the Ration Card brought by the customer is verified by the shopkeeper and thereby the materials are manually measured and supplied. Recently fingerprint system has also been introduced, which has reduced the rate of corruption occurrences. The present ration distribution system has categorized the people under 4 different categories and differentiates them by giving different colors to their Ration Cards. The yellow Ration Card is issued for the most economically backward section of society, pink for priority or Below Poverty Line (BPL) section of society, blue for non-priority subsidy or Above Poverty Line (APL) section of society and white for non-priority section of society.

Several attempts have been made in order to resolve the above discussed issues. An Automated Ration Distribution System using RFID and GSM module [1], Digitalized Ration Distribution System etc. Has already proposed.

K. Balakarthik proposed the "Cloud-Based Ration Card System using RFID and GSM Technology" [2], presents an efficient method for the user to buy the products in the ration shop by just flashing the card at the RFID reader.
A.N. Madur developed the "Automation in Rationing System using Arm 7" [3], Proposed the "Automatic Ration Material Distributions Based on GSM and RFID-Technology" Here each customer is provided with RFID cards.
In all these proposals the commodities are not weighed .

II. PROPOSED SYSTEM

The IPRDS is a microcontroller based system to control all the operations in the ration distribution system. It has a user interface with a keypad as input and LCD display as output. The customer has to provide his/her fingerprint to access the system. Once the fingerprint is authenticated, the system provides access to the customer's account. The quantity of commodities available to the specific customer is displayed on the LCD display. Now, the customer can enter the required amount of the commodities and the system will automatically distribute the commodities to the containers provided in the shortest possible time. A bill regarding the transaction is also generated and sent to the customer's mobile number.

After the process, the IPRDS will display the remaining quota available to the consumer and also update this data to the central agency by GSM method. The central agency can also control and modify the consumer allocation and data wirelessly.

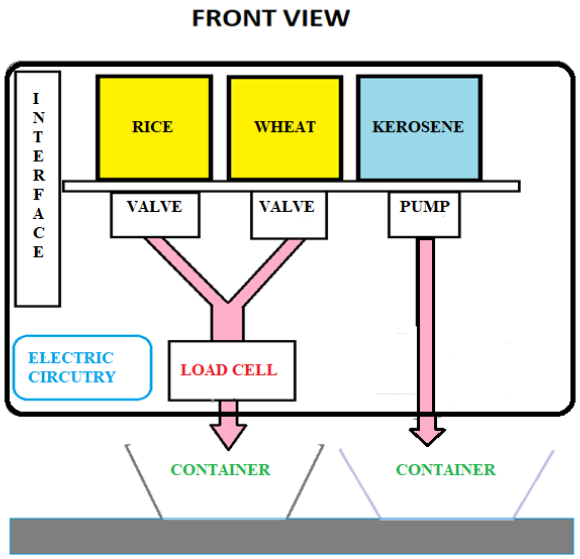

Fig 1: Structure of the proposed system.

A cross sectional view of the proposed system is shown in fig.1. There are storage cabins for wheat, rice and kerosene. These storage cabins are placed at the top and are operated using individual Servomotor valve mechanisms. The cabins are placed in such a way that the commodities in the cabin could easily flow towards the load cell by its own gravitational energy. The load cell is used to measure the quantity of grains such as wheat, rice, sugar. Whereas, the kerosene is supplied through a pre-calibrated submersible water pump. When the load cell reading is matched with the quantity entered by the user, the microcontroller provides a signal to close the valve mechanism and interrupts the grain flow. By this, the commodities can be effectively distributed to external containers. The block diagram of IPRDS is shown in fig.2. The microcontroller used is ATMEGA 2560. It controls the fingerprint sensor, load cell, pump and the valves.

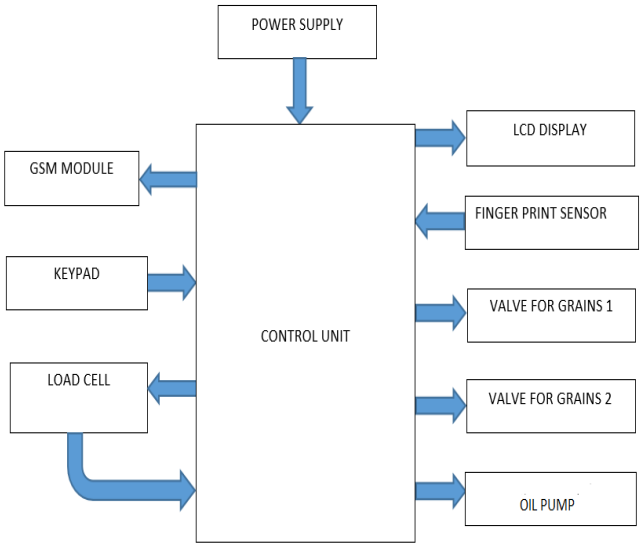

Fig 2: Block diagram of proposed system

III. WORKING

The system consists of mainly a valve mechanism, interface, electric circuitry, load cell and submersible pump. The interface acts as a medium between the customer and the system. Once the customer approaches the IPRDS, they are asked to verify their fingerprint. The fingerprint verification is done with R307 Module. The enrolment and deletion of customer fingerprints are done with the help of SFG Demo Software through a computer system.
Once the fingerprint of user matches with the stored data, the display shows the details of the Ration Card holder including the name, Ration Card number and their category. Then the display shows the available quantity of the materials allotted to the specified category from which the customer can select the needed commodity.
The user instructions are then verified by the microcontroller and control signals are given to the valve and pump mechanisms. The valve mechanism is designed with the help of a servomotor and used for the distribution of grains. Whereas the submersible pump is used to distribute the kerosene. Both valve and pump are operated till the necessary interrupt signal is received from the microcontroller.. The load cell weighs the distributed quantities from valve and pump and

continuously provides an output signal towards the microcontroller. Once the load cell reading is matched with the value entered by the user the microcontroller provides an interrupt signal to stop the operations of valve or pump. Once the process is finished the user can collect the commodities from the container provided externally.

A. Circuit Design

Arduino Mega is used as the prime controller. The Arduino first scans the fingerprint using R307 fingerprint module. R307 has an inbuilt memory having a capacity to store 1000 fingerprint modules. It takes less than 0.3 second to read the fingerprint image. Once the scanning process is done, the 20x4 LCD display shows the details of the corresponding person. The LCD display is controlled using I2C LCD controller. The conventional LCD display requires at least 6 pins for its functioning while I2C controller requires only 2 pins. The requirements are selected using a 4x3 Matrix Keypad. After the verification and the decision making process, the commodities are delivered. The grains are delivered via valves. The valves are operated using servomotors (SG90 Servo). The weight of the commodity is measured using Load cell. As the requirement is fulfilled, the servomotor operates to close the valve.

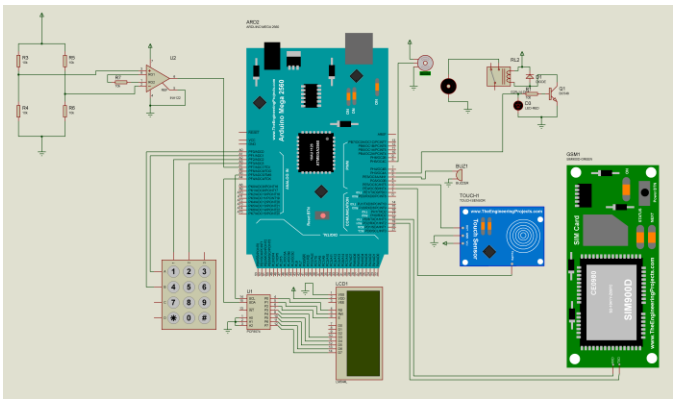

Fig 3: Circuit Diagram

The kerosene is supplied using Submersible Mini Water pump which is controlled by a relay circuit. As the grains are ready to be loaded, the consumer is alerted using a buzzer. This helps the person to ensure that the grains are collected properly. All these functions make way for reducing manual intervention.

A GSM module installed in the circuit ensures that the Ration Card Holder is informed about the collection of the commodities. It sends a message stating that the monthly Ration is dispersed and collected to the Registered Phone Number.

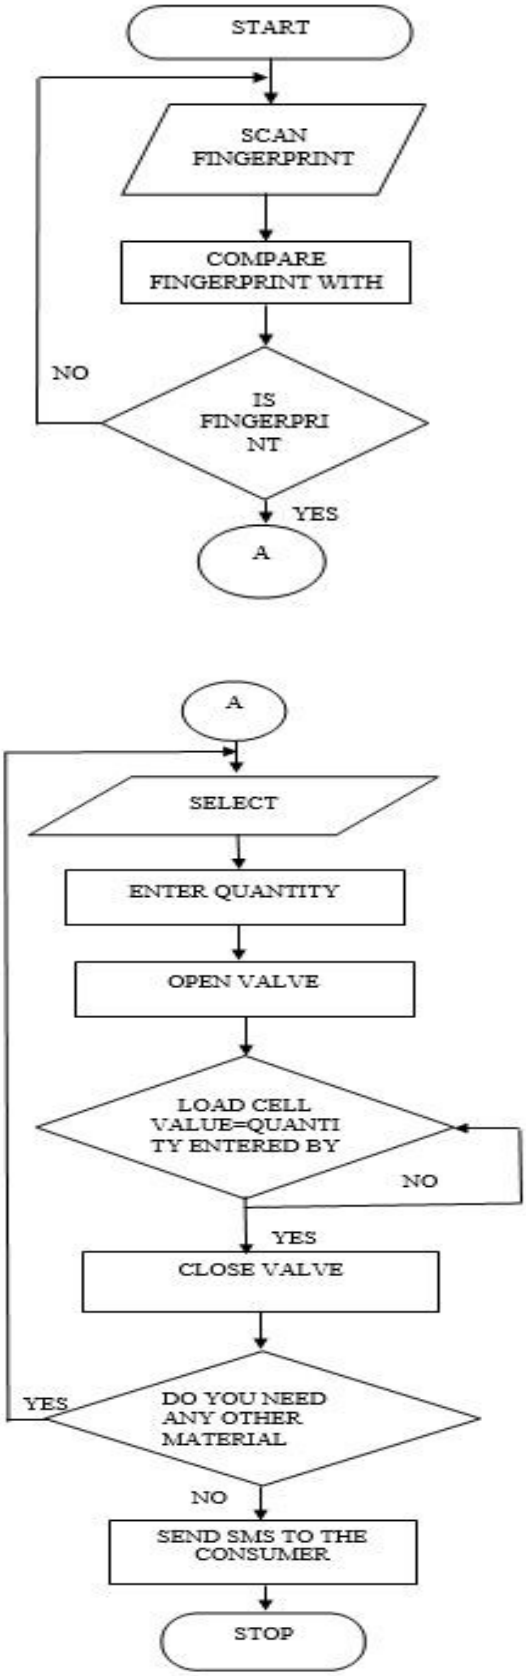

Fig 4: Flow Diagram

The program flow chart for the system is shown in fig.4. The consumer is granted the permission to access his requirements using the keypad.

IV. RESULT

The suggested IPRDS system was enacted as a prototype. The project model developed is shown in fig.5.

Fig 5: Project Model

V. CONCLUSION

This paper brings out a new venture to ensure full-fledged and transparent Ration Distribution system. Every user can collect their monthly ration and ensure its delivery via message sent to their registered phone number. The data updating and processing is made easy using the proposed system and hence saves a lot of paper work time. Any further extension to the existing model can be deployed by enabling IoT. More security aspects like face identification can be incorporated to secure the Ration Distribution system.

Though the system has to incur initial investment costs, the long term benefits overshadow it. Message will be sent to the government about the dispensing after each item being sold. Through transparency in all transactions, corruptions can be eliminated to an extent. For the completion and installation of this work in Ration Shops, the Government must ensure that the Ration Card is linked with the Adhar. If implemented in all the existing stores can revolutionize our public distribution system.

The systemcan be further developed to incorporate Online payment, which can reduce the time associated with the distribution and the use of paper currency.

With IOT the system can be made to work as a cloud based systemin which all the data regarding transactions, customers etc can be accessed from a single database.

VI. ACKNOWLEDGEMENT

This endeavour stands incomplete without expressing our gratitude to everyone who has contributed a lot towards the successful completion of this work. This project is funded by the Kerala State Council for Science Technology and Environment (KSCSTE).

Abstract- The application that are envisioned with IoT has a vital role played by the security. we make use of reliable Constrained Application protocol to sense the threat for the security purpose for any applications associated to IoT devices in a wireless sensor network environment. The task of Sensors sensing and the devices associated to it is, included with the end to end support system for the interior and exterior communication systems, which are always prone to all threats and attacks. Thus, we here propose a novel framework to sense and avoid the attacks in the framework of Internet-incorporated CoAP communication atmosphere. We here try to consequently estimate efficiency of reliable CoAP to sense and avoid attacks with respect to the DOS attacks in the communication protocol for IoT devices.
Keywords: IoT; reliable; DOS; CoAP; internet-incorporated

1.INTRODCTION

A Wireless sensor network with respect to IoT has many oblige comparable to energy, memory, performance and security. Talking of the Today's IoT security risk premeditated for typical IoT [1]. The pile being arranged with the protocols alike as 6LoWPAN, RPL and CoAP Constrained Application Protocol [2].We here divide the pattern for security sense and avoid attacks into two major section in this paper .First sector ,we identify the security encounters of reliable sense and avoid in the framework of IoT communication atmosphere , and view the present losses related to the solutions intended for Internet-incorporated CoAP and 6LoWPAN message atmosphere. In Second sector, we propose the design work for the reliable sense and avoid technique to employ the anomaly detect protocol by analysing the output from the experiment estimation. The Obtained results are purely based on the incongruity of the reliable the CoAP to sense and avoid attack in WSN's for IoT devices.

2. DETECT SECURITY AND RELIABLE THE IOT

2.1. Security in the Context of Internet-Incorporated Sensor Networks

The present pile of communication has enormous constrain, so we shift our interest on the CoAP [3], which is having standard reputation, to prove its potentials to perform a chief regulation in enabling the IoT. CoAP was intended in the force to put forth the Representational State Transfer, construction of the web to incorporate sensors and their devices. Here the CoAP protocol with respect to the security at application layer, share URL familiarity as well as the error codes which is alike to operations compared to the (ReST) with the Creating, Updating, Deleting and read only. At the transport layer the aim is to do safe communication between devices, CoAP envoys its provision to the Datagram Transport Layer Security protocol at the transport-layer. Here it also helps the devices to authenticate with the help of the DTLS by using the, public-keys, also the beforehand-shared keys or digital certificate X.509 .Thus ,its vital inspite of secured key sharing between the users in the system is already known , where it cannot guarantee the no-attack from various external and internal attacks in the culmination to culmination communication organization. Despite of this kind of attacks which has the cache manipulations, there exist a suspicion of DDoS amplified attack, man in the middle attack, which in turn has fooling(spoofing) and fractious(cross) layer attacks. Where these internal attacks will spoof the rules and regulations with the normal work of the CoAP protocol. Henceforth, endwise security devices could be accompanied by suitable sense and avoid methods positioned in this situation of the Internet-incorporated WSN, which is main moto of our work.

2.2. Reliable Detection methods on the Internet

It is importanat to know the role of the reliable detect are incorporated in techonologies with respect to the real systems and, . Host realted IDS incorparted are most rigourously given emphasis on one-to-one care and perceiving the detect action on the doubtful actions in hosts, which has the capacity to monitor every behaviour that is dynamic in nature and the system of with the dynamic state . today the IDS is the best solution to the internet which employed with the detect form in the classifications as: SO signature-oriented detect , anomaly-oriented detect and SPA State full protocol analysis[6].An anomaly is characterized to deviate from the traditional

(predictable) activity of network, to particularly built up form of activity of the network , which helps in the regular activity of the network.Here we can catogories to this into host-realted (HIDS), network-realted (NIDS) and wireless-realted (WIDS) [7]. By the analysis of the network jam ,here we capture the traffic rate of the network at tactical positions of communications organization. WIDS are way familiar to the NIDS,whereas in this case we concetrate more on the wireless communication state.

2.3. Detect Reliable the IoT

Here, we are known with the attack that are encountered while the devices are connected in the wireless state for communication, which are to be treated with suitable solutions. Hence this known attack is to be detected well in before. We take in to point that the attacks from the security, against the stable internet incorporated restricted sensing and associated devices. We may consider the varied layers of communication stack; hence we here consider to map up for application layer using the CoAP point of the IEEE 802.15.4[4]. In [4] the authors propose REATO, a regulations-oriented description with dynamism to detect and contract with DoS attacks. The structure here is premeditated to implement, with the evaluation for DoS attack in a numerous circumstance in directive to wedge unexpected communications circumstances. For example,the jamming and collisions attacks are encountered as expected DoS attacks in contradiction of IoT communication area, snooping whichever present at the route , application layers or link layer.Authors in [5], an fusion IDS attack to detect the contradiction of routing with RPL, which fuses the features of SO and AO reliable CoAP. Thus, suggestion is estimated with the concluded simulation for outcomes oriented with sinkhole attacks.

3. Reliable CoAP to sense Internet-Incorporated WSN

Here we extant the structure with framework of the reliable detection of DoS attacks for the applications layer in contradiction of the CoAP Protocol [6].

3.1. Considered Method

The method well thought-out in here could be considered from the taxonomy given in [7], which is given bellow:

• Network architecture of the existing system replace: Here a defend and detect the attacks on the CoAP with the help of the centralized method, which will destabilize the client serve model in the communication system.

•Method used to handle the web: familiar to other WSN's we consider hierarchical model, CoAP, 6LoWPAN and, RPL at the advanced layers and hop by hop communication support IEEE 802.15.4 at connection(link) layer [13].

•Collection of Data: data collection in centralized, here we target a particular node in the web to capture the data, known from the nature of traffic oriented web .Also the component to collect the data uses the .For traffic collection an agent IoT-LAB sniffer node used for specific locations or area.

•Type of the Data: the data type is pcap (Packet Capture) presentation for WSN's traffic.

•Detect Time: the off line implementation.

•Condition of being granular: intermittent (batch) method implemented for traffic capturing.

•Method to process: Detect attack and gather data makes use for processing a centralized method [4].

•Discipline to Detect: To restore the evaluation that is state-based with the discipline is used and, IDS intelligences if node is normal or negotiated state. We here recognize and mention the past as "NORMAL" through the paper and future as "RELIABLE".

•Method of Detection: as mentioned before in this paper, we in these circumstances of the projected framework, we deliberately analyze, instrument and estimate reliable CoAP to sense and avoid attack in WSNs.

3.2 structure Planning

To demonstrate the structure well-thought-out, the resolving of method to instrument and estimate reliable CoAP to sense and avoid attack in WSNs. in Figure 1. This structure planning is done deliberates to employ the 6LoWPAN edge routers (6LBR) arbitrating transport network, amid the internet devices in addition to WSN, here we use CoAP identifying(sense) and actuating(sensor)devices [10], also for the external (different WSN or internet devices) or internal (same WSN) for the hosts. Therefore, CoAP customers subordinate by means of CoAP attendants helps in directive to request, will stimulate otherwise perceive specific properties accessible at the application layers [7].

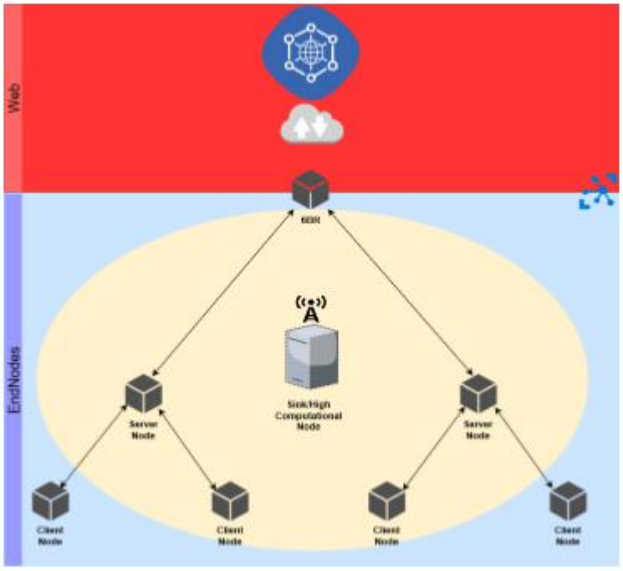

Figure 1. Structure for reliable CoAP sense framework of Internet-incorporated WSN's

As exemplified in Figure 1, Let us presume device employ to sustenance reliable CoAP sense processes. The device

possesses the properties essential for execution seizing of the transport network in the array within it, therefore substitute as a web sniffer in it. One more vital condition is that, this device employ for the anomaly detect through the machine learning language by supporting high level language. In this present employment of this architecture, this task is taken into the consideration by the 6LBR, and device is accountable for filtering (intermediating) between internet and WSN.As mentioned before, for the focus to employ ,anomaly-detect to experiment and implement by evaluating it, here uses the IoT LAB [4-8] stage, incorporated to provision a multi-hop topology. In place of a constraint to GET requests only for CoAP in this platform and enactment of numerous devices is completed by Contiki operating system, in specific by build above the basis (source)code intended for border router (6LBR), the implementations of the examples with respect to CoAP server and CoAP client [8].

4. Experimental Evaluation

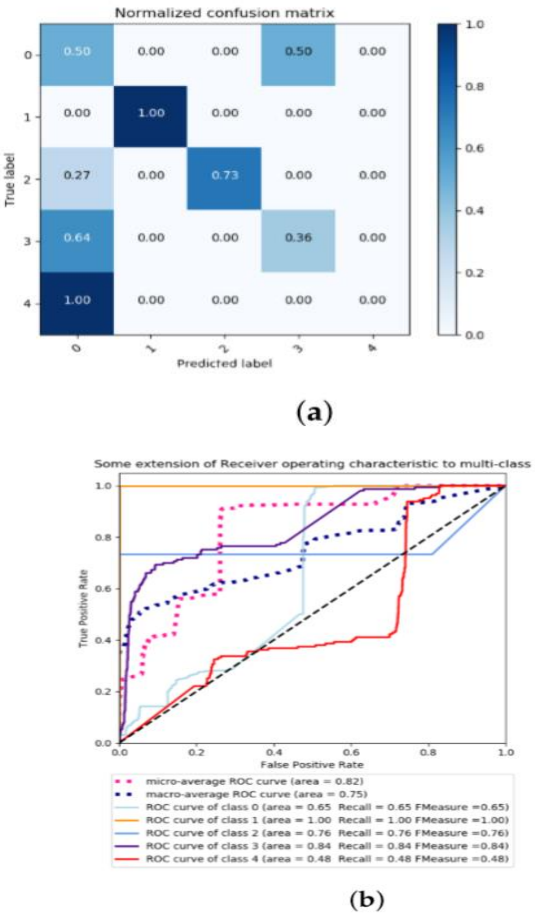
We ensue by output analysis, attained from our evaluated experiment, for sense sense methods, begin with an analysis forwards through the experiments, till it is implemented and automate.

4.1. Automation and Implementation of Experiments

The first and foremost step to select the operating system to be employed, for implement and automate.It is necessary to provision, to gather the statistical data and component for reliable detection in architecture [9]. The OS working for persistence of supportive reliable CoAP to detect in the Contiki [10], because of its constancy, hardware affinity and attribute of credentials at indicator. According to this podium of OS, here working with the IoT-LAB to incorporate, a podium(platform) that enables the method of disposition in the ease way.

4.2. A problem for Multi class

The results obtained from the analysis of the pcap(packet capture) files are comprise to observe and consist of ,arrays of structures ordered as a rectangular matrix. These annotations are given in to data pre-processing, dimensionality reduce and classifier physical activity. The proportion of the number of NORMAL vs. inaccurate annotations (thus, result from the disobedient node) is of 2 to 1, thus for each two NORMAL observations we observe one inaccurate observation [11].In this process we employed the following SVM Kernels: Linear, RBF, polynomial and sigmoidal. The obtained results are illustrated in Figures 2



(a)

(b)

Figure 2: Problem Multi-session—Net Exploration SVM thru: RBF Kernel, purpose outline one against. Rest choice, 30 reiterations and keep score standard of exactness, Mix-up (confusion)Matrix (a) and ROC (Receiving Operator Characteristic) Curvature (b)[11-12].

4.3 Evaluation Strategy

The classification so for, on the reliable CoAP detect method are evaluate throughout the working out period, and in this context, take in count the basic metrics in the routine, specific Accurateness, the Recollection of True positive Proportion, Precision, False positive Proportion and F Degree, elucidate as beneath [12]:

$$Recall = \frac{TP}{TP + FN}$$

$$Accuracy = \frac{TP + TN}{n}$$

$$Precision = \frac{TP}{TP + FP}$$

$$False\ Positive\ Rate = \frac{FP}{FP + TP}$$

$$F_Measure = 2 \times \frac{Precision * Recall}{Precision + Recall}$$

From the preceding precision in the count of numbers, TP means true positives, TN true negatives, FN false negatives, FP false positives and numeral explanations to consider [4-12]. Hence the particular metrics, estimated deliberate through the mix-up(confusion) matrices and ROC curvatures, in cooperation with binary classes as well as the, multiple classes methods for analysis.

5.Conclusion

In this paper, we partake projected a framework for the IDS, reliable CoAP to sense and avoid attacks in wireless sensor networks for IoT devices. The above framework used to evaluate efficiency required to employ the process of reliable CoAP by means of detect, as well in preventing the DoS attack, in contradiction of this communication atmospheres. As of a real perception with respect to the IDS structure, the Internet-incorporated CoAP detecting(sense) applications, it's vital in averting the extreme reliable a probable one. Whereas correspondingly, at times it assures for a truncated rate of FN, though there is unfluctuating cost of cumulative FP, we obtain the maximum output for managing the security. By identifying specific attack, the problem with respect to the multiple class method is suitable for, interior and Internet-originated attacks in contradiction of the security devices. Further consideration of additional reliability for the intrusions in future developments, predominantly concerning about the attack absorbed on disrupting the traditional rules and the protocol semantics of CoAP, either by interior or exterior attacks.

***Abstract*—Radiation intensity which is measured in power per unit area is used to analyze the extent of effect of radiation and can be used for analytical studies. In this paper, a real time monitoring system is proposed to collect the intensity of sunlight and transmit the data using wireless communication for a suitable range with less transmission loss. Two radiation sensors are used to measure the intensity of light - one is to quantify intensity of directly incident light and other for reflected light from earth. It works on the basis that intensity of light is directly proportional to the voltage. This data acquired is transmitted using a powerful Sub-1GHz wireless microcontroller. The proposed system was tested at different intervals of time. The results showed stable voltage readings proportional to the light intensity. These radiation values were transmitted successfully in wireless mode for a range upto 250m without any transmission loss.**

Keywords—Solar radiation; Sensor networks; Data acquisition system; Wireless communication.

I. INTRODUCTION

Solar radiation is the major source of radiation affecting the entire universe as sun being the basic source of energy. The range of this radiation can be understood from the analysis of the amount and intensity of sunlight. The sunlight is a part of electromagnetic spectrum which includes infrared, visible and ultraviolet regions. The intensity of solar radiation is measured in power per unit area. This measurement is an integration of the solar irradiance and the solar insolation considered together. Solar irradiance is the amount of sunlight directly incident on the earth or the measuring equipment at any particular instant. This value ranges from 0 kW/m^2 at night to a maximum of 1kW/ m^2 throughout the day. Solar insolation is the amount of light that falls on the earth's surface and gets reflected to the atmosphere. This measurement is accurately made using a pyranometer and pyrheliometer for global radiation and direct radiation respectively. This knowledge of solar irradiance can be utilized for various analyses like predicting energy generation from solar power plants, and in weather forecasting and other climatological studies [1].

A Data Acquisition System (DAQ) functions to measure or control the physical signals of real world and convert it into digital values that can be manipulated using a computer. A DAQ system is generally comprised of sensors, DAQ device and a computer. Fig.1 shows the block diagram of a DAQ system. The sensor is used to convert the physical signals to voltage, resistance, current or any other electrical characteristics that varies over time. The physical signal can be temperature, pressure, light intensity, sound etc. The output from the sensor may have noise elements. The DAQ device mainly does signal conditioning, analog to digital conversion and transmission of the instructions and data measured using any proper bus. The commonly used bus for interfacing DAQ device to a computer are USB, PCI express and Ethernet. Recently, for wireless transmission 802.11 Wi-Fi, Bluetooth or other RF modules are used. The computer part includes driver software and application software. Driver software is for simplification of communication with DAQ device while application software is used for collecting, processing and presenting the data to user [2].

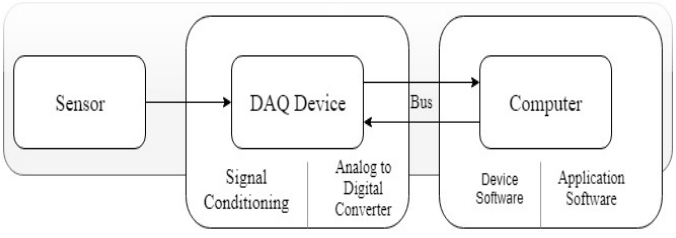

Fig. 1. Block diagram of a typical Data Acquisition System[2]..

Nowadays, wireless communication is being extensively used in various applications like medical [3], military, data communications, sensor networks [4], energy transfer, security [5] and many more. To collect data from remote areas like underground, underwater extreme hot and cold locations

wireless technologies are best in terms of energy efficiency and less transmission losses. Commonly, the wireless technologies use radio waves. Zigbee wireless technologies, Bluetooth, GPS, and Wi-Fi are also widely used .Wireless sensor networks transfer data collected via multiple nodes and gateways to networks like Ethernet. The wireless data transfer can be done between two microcontrollers also. In such a case any kind of wireless technology can be used as a bus to carry out the data transmission.

In this project, intensity of light from the sun is measured using sensors- one for the incident light and one for the reflected light. This data is collected and stored in a microcontroller which has its own radio to transmit the data. The transmitted data is received at a distant location using another microcontroller. The obtained data is processed understand the radiation intensity and proceed for further studies. The microcontroller used works in Sub-1 GHz radio frequency.

The related works are indicated in Section II and the proposed system is presented in Section III. The different components used in the project are explained in detail in Section IV. The experimental setup is familiarized and the performance evaluation is carried out in Section V. The work is concluded in Section VI.

II. Related Work

The remote data acquisitions system is of great importance in this era of unforeseen advancement in technology. The collaboration of sensor networks and or transmission modules makes it possible to collect the remote data and transmit over a large distance. As mentioned the data acquisition find its application in almost all fields. For example, the importance of a DAQ system in providing better mobile health care services is mentioned clearly by Chanhee Lee *et al.* [6] in their paper. The DAQ system is put in action by using USB, Ethernet or wireless means for testing, estimating and automation of data. Chanhee Lee introduce a data acquisition software using database querying facility along with mobile sensor networks to ease the process of filtering out of the unwanted overhead medical data [6].

The DAQ is also applied in recording signals from infrasound events. In the paper by José Chilo and Thomas Lindblad [7], the output signal from infrasound sensor is transformed into digital signal by a 16-bit ADC. It also employs an anti-aliasing filter for noise elimination. A multi-sensor DAQ system is used to analyze the thermo acoustic performance of refrigerator in the paper by Yuriy P. Kondratenko *et al.* [8]. The system uses an Ethernet and RS232 to communicate between sensors and end PC.

In the paper, Zhao Jinxiang and Sun Chuanwei [9] use a CC3200 MCU in remote data acquisition. Here, the data is accessed from cloud server by the use of the Wi-Fi module embedded in CC3200. Compared to all other methods of DAQ, this provides a low cost and less complex way of remote data sensing. The wireless data transmission is efficient as it makes the device simple and is cheaper in long range communication when compared to wired transmission. So, this paper presents the use of wireless sensor networks in data acquisition.

III. Proposed System

The system proposed is a combination of data acquisition system and wireless communication for acquiring the radiation intensity of sunlight in a particular area. It comprises of two radiation sensors and microcontroller used as transceiver. Power supply is also given to the microcontroller system and photodiodes. Fig. 2 shows the block diagram of the proposed system.

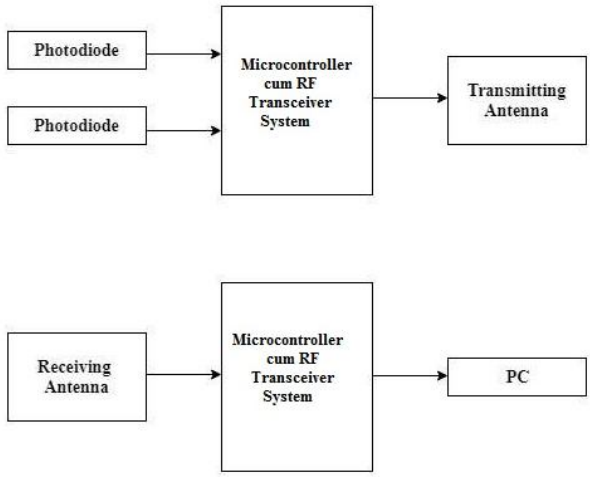

Fig. 2. Block diagram of the proposed system.

The photodiode shown in the block diagram is the radiation sensor. UDT-455UV is the photodiode used. It is a photodiode-amplifier hybrid. For the microcontroller system TI Launchpad Kit with CC1312 MCU is used is. The top microcontroller system is the transmitter and the bottom one act as receiver. The transmitting and receiving antennas are inbuilt within the transmitter and receiver MCUs. There is a PC (laptop or a desktop) connected to the receiver end to visualize the received data from MCU to the user.

IV. System Description

A. Radiation Sensor

The radiation sensor detects the incident light and converts the intensity of the incident light to voltage or related electrical parameters that varies over time. This conversion of light to electrical parameter is called photovoltaic. Photovoltaic detectors or photodiodes are usually employed to do this conversion due to its fast response, amplification, low noise, high sensitivity and wide dynamic range. The responsivity of a detector is the ratio of measured current and the input light power. It is an important characteristic feature.

Photodiode is a PN- junction diode that works in reverse bias condition [10]. The working is being explained as, when

light photon strikes the diode, an electron hole couple is generated. This is the inner photoelectric effect. If absorption occurs in depletion region, the holes move to anode and electrons move to cathode and photocurrent is generated. There are three modes of operation namely, photovoltaic (PV) mode, photoconductive (PC) mode and avalanche diode mode. PV mode is zero biased mode while the rest are mostly in reverse biased. An operational amplifier is connected to the photodiode to approximate to zero bias and to direct the signal to feedback resistor.The UDT 455-UV is a type of photodiode-amplifier hybrid that is used in this project as a radiation sensor. It is manufactured by UDT Sensors. Inc. This belongs to the Photops^{TM} series general purpose detectors and has a spectral range of 200nm to 1100 nm [11]. This series of photodiode has an operational amplifier connected internally to the detector.

UDT 455-UV has 8 pins arranged in a circular fashion. Pin numbers 1 and 5 are assigned as offset null. Pins 2 and 3 functions inverting input and non-inverting input respectively. V (+) and V (-) are assigned to pins 4 and 6 respectively. Output is taken from pin 6 while detector anode is connected to pin 8. It typically works for supply voltage of ±15 V and can withstand a maximum of ±18V. Fig. 3 shows the schematic diagram of the photodiode. In this the connection between pins 8 and 4 is avoided since only the PV mode is considered. A 0.1µF capacitor is connected in parallel to the 0.1µF to store more energy. Here, the light falls on the diode and is passed through RC circuit generating a voltage proportional to the intensity of light. The op-amp connected in the PV mode approximate the biasing to zero bias and directs the signal current via feedback resistor R_F.

$$V_{OUT} = I_D \times R_F$$

where V_{OUT} = output voltage,

I_D = intensity of light and

R_F = feedback resistance.

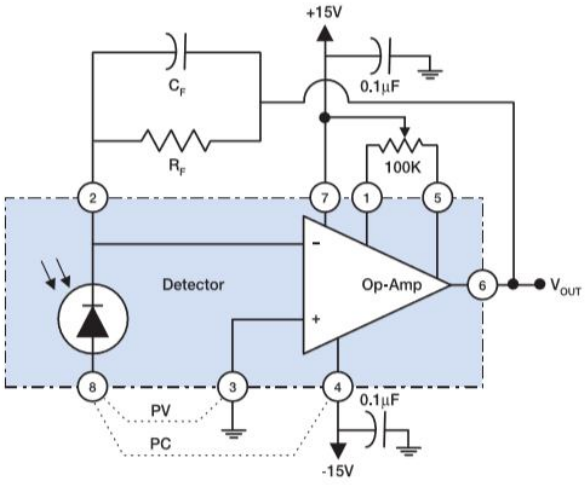

Fig. 3. Schematic diagram of UDT 455UV.

The feedback capacitor and resistor values are taken as 15.9pF and 100kΩ respectively to achieve operating frequency of 100 Hz.

B. Transceiver Unit

The radiation data collected by the sensor needs to be stored and transmitted to the receiver end. Transceiver is used to establish this wireless communication. In this project, TI Launchpad with CC1312 microcontroller unit is used as transceiver. The CC1312R device embedded in the Launchpad is a powerful wireless MCU that works in Sub-1 GHz frequency. The CC1312R is highly integrated single chip with an active RF core and inbuilt DC-DC converter. It has a 352 KB In-system programmable Flash, 256 kB of ROM and 8KB of cache SRAM. The compatible supply voltage range is 1.8 V to 3.8V [12].

The major parts in the functional block diagram of the device are system CPU, RF core, sensor interface and general peripheral devices and other modules. The device has three strong processors embedded in a single chip namely, ARM Cortex-M4F processor for system CPU, ARM Cortex-M0 processor for the RF core and another ARM processor for the sensor interface. The programming of these three processors is done using different soft wares like code composer studio, RF smart studio and sensor controller studio respectively. The CC1312R is 48 pin IC in which all the pins are general purpose input output pins. This IC along with a debugging portion presents the Launchpad. The Launchpad comes with 40 pins each with its own functions. Among the 40 pins, 8 numbers of pins are analog. Fig. 4 shows the Launchpad kit used as transceiver. It comes with a monopole antenna.

Fig. 4. TI Launchpad with CC1312 MCU.

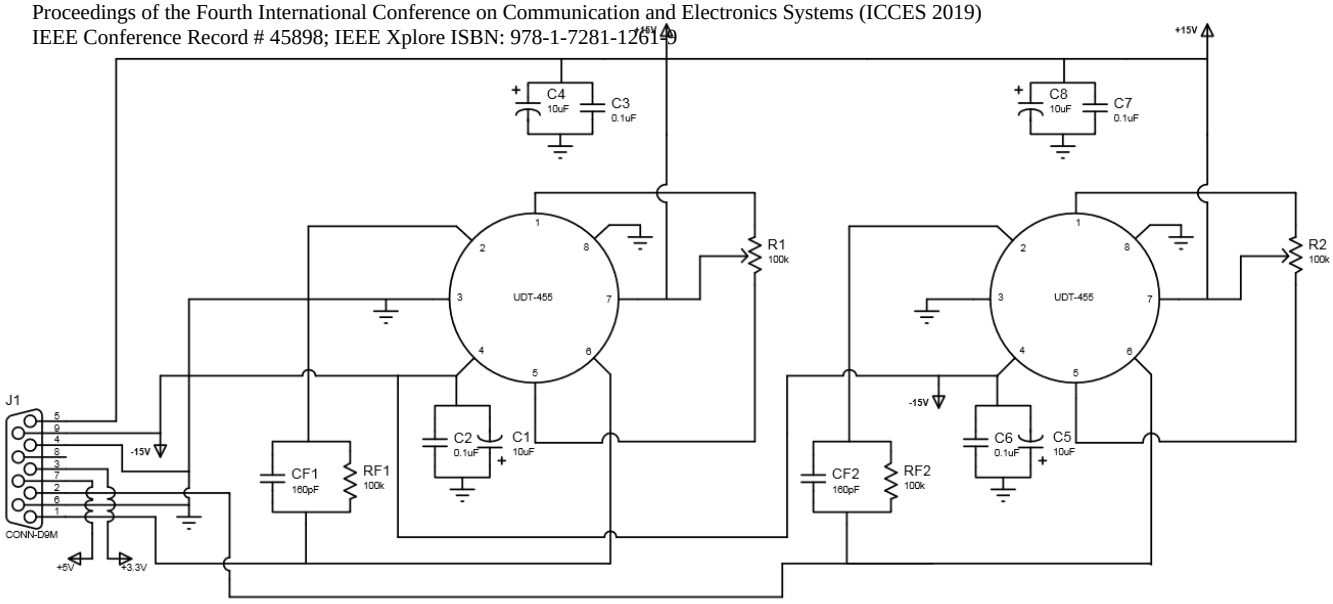

Fig. 4. Circuit diagram of radiation sensors drawn in Proteus software.

The sensor controller (SC) in the CC1312R is a core 16-bit. The SC is of ultra-low power and is not dependent on other parts of the system like Arm Cortex-M4F and RF core. It is user friendly and easily programmable. The code is executed from a dedicated memory of 4KB of RAM. SC has the right to program and execute analog and digital peripherals. If the MCU is in sleep mode, the SC will store the data to memory. Once the MCU is active, the SC will notify the main MCU. It has some additional perks like it can carry out advanced tasks like capacitive touch and inductive sensing.

The Arm Cortex M4F processor core of CC1312R has a 48 MHz RC oscillator and a 48 MHz crystal oscillator. When the device needs to work in low-power mode, the 32-kHz RC oscillator, 32-kHz crystal oscillator or 48 MHz crystal oscillator is used generate clock for timing maintenance. It also have Arm Cortex Sys Tick timer, an integrated system timer. Sys Tick supplies a basic, 24-bit, clear-on-write, decreasing, and wrap-on-zero counter with a varying control mechanism. The device also has Nested Vector Interrupt Controller (NVIC). It is deterministic and carries out robust processing of interrupts. The security core of CC1312R has Advanced Encryption Standard (AES) module. It also has 256-bit key support, DMA efficient and a local key storage. The device supports serial communication in both asynchronous and synchronous modes. It includes two UART modules, I2C module, I2S module and two SSI (SPI) modules.

V. Result Analysis

A. Experimental Setup

The hardware components used in the proposed system includes two UDT-455UV sensors, two CC1312R Launchpad kits. The schematic diagrams for each component are drawn in Proteus software. Fig. 6 shows the schematic diagram of two radiation sensors drawn in Proteus software. The connections

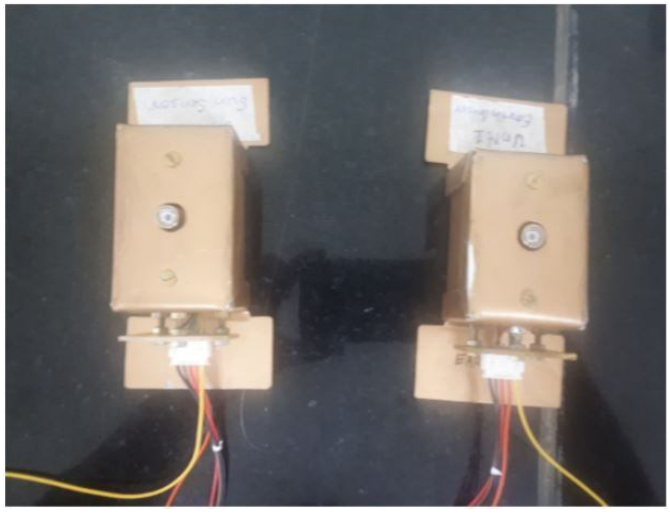

Fig. 5. Sensors enclosed in teflon casing.

are made according to the schematic diagram and each sensor is enclosed within a Teflon case. There are four connection wires V+, V-, ground and output from each sensor. One sensor is to measure the direct light and other is to measure the reflected light. These sensors and enclosed in Teflon case. Fig. 5 shows the sensors enclosed in the case.

Fig. 6. Experimental setup.

The experimental setup of the sensors is shown in Fig.6. In the figure brown coloured boxes are the radiation sensors and the white coloured device is a standard radiometer. The sensors were placed on a pole at a fixed height from the ground. One of the sensors (say, sun sensor) was placed upwards so that the direct sunlight falls on it. The other sensor was placed downwards to measure the intensity of light reflected from the earth's surface. Both are given a ±15V supply voltage using a dual DC power supply. Using a multimeter the output voltages for each instant of time at short intervals is taken and tabulated. Along with the sensors a standard radiometer was also placed and values were noted for comparison. Now, the output wires from both sensors are connected to the two analog pins in the TI Launchpad kit.

In the receiver part, another TI Launchpad kit is connected to a PC. Both the transmitter and receiver kits are supplied with a voltage of 5 V and are placed at non-line of sight path. The maximum distance up to which the data can be accurately transmitted is quantified. The software part of the system has SmartRF Studio 7. The transmitting and receiving packets specifications could be set in this software.

B. Results and Discussions

The experiment was carried out in two phases. In phase 1, the sensors were connected to the power supply and the output voltages from both the sensors were measured using a multimeter. The values were taken for different instants of time for a short interval of 5 minutes. Refer to Table.1. Whenever there is a change in the light intensity, the sensor gives a stable output voltage at each point. The voltage versus time graph obtained is shown in Fig. 7. When there is no light, multimeter shows zero voltage. The values obtained can be used to plot a graph of time versus radiation density graph.

TABLE I. RADIATION SENSOR TEST RESULTS

S. No.	Radiation Sensor Values		
	Time	*Sun Sensor (in V)*	*Earth Sensor (in V)*
1	15:00	2.297	0.567
2	15:05	2.2	0.579
3	15:10	2.199	0.619
4	15:15	2.174	0.589
5	15:20	2.128	0.58
6	15:25	2.617	0.537
7	15:30	2.065	0.515

The obtained graph is similar to that of Fig. 8. It shows the intensity of solar radiation throughout a day measured in the absence of clouds using existing method i.e., a standard radiometer. It shows a Gaussian curve. While testing the proposed system, only short duration of time is considered. It clearly shows that using two radiations sensors solar irradiance can be accurately measured. Hence, the proposed system may be used to replace the existing ones in future.

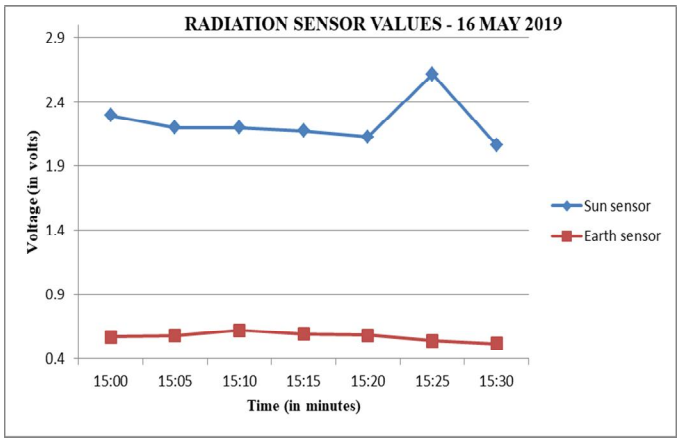

Fig. 7. Voltage versus time graph showing the radiation sensor values at different time intervals.

The phase 2 focuses in transmitting the obtained radiation data over wireless communication to a receiver located at distance. Receiver MCU is first placed at a near distance. The transmitter MCU was connected to the sensors. The output from the sensors was transmitted through it. Initially the receiver is kept in line of sight with the transmitter. At that point the data collected by sensors were transmitted accurately. Then, distance is increased. Finally the receiver is placed at non-line of sight path. The maximum distance up to which the transmitter data could reach the receiver MCU effectively in the non-line of sight path is found to be 250m. Beyond this distance, there were anomalies in the transmitted and received data. The system was tested taking the transmitter power as 14dBm. The antenna used in the MCUs was a monopole antenna. Hence, its alignment was also taken care of.

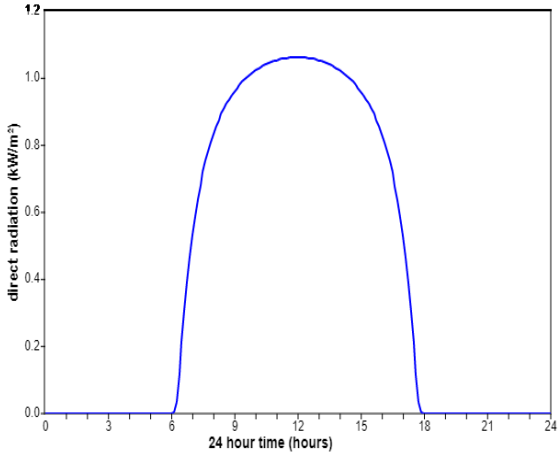

Fig. 8. Graph showing intensity of solar radiation in a day using existing method [13].

It was evident from the repeated tests that for transmitting power less than -100 dBm, the receiver showed varying results. So, the transmitting power of transmitter antenna needs to be more than -100dBm.

VI. CONCLUSION

The study of radiation effects on the atmosphere opens the door to manifold analysis. It is vital because by knowing the level of exposure to sunlight, photovoltaic systems could be designed with maximum efficiency. The use of sensor networks to acquire these data is efficient due to the high sensitivity, ultra-low power operating conditions of photodiode used. Data acquisition systems are useful to acquire data from remote places to make it easier for humans to monitor various types of data. This proposed system employs a wireless transceiver in combination with sensor networks to carryout data acquisition efficiently. Normally, to transmit data of sensor networks to a PC or user friendly device wireless modules could be used. In this system, by using a powerful microcontroller as transceiver the wireless communication is effectively done. It shows that by using the proposed system wireless communication can be used for data acquisition for a maximum distance of 250m. Here, only a photodiode is used to collect data. Since, a strong wireless MCU is employed as transmitter more sensors like temperature, humidity and pressure sensors could be incorporated to the existing system to collect more data from the area under observation.

ACKNOWLEDGEMENT

The authors would like to extend their gratitude to Rajiv Ranjan, Scientist, VSSC and other working members from Vikram Sarabhai Space Centre (VSSC) for providing space and help for the successful completion of this project.

***Abstract*—IOT based smart home with cloud analytics are becoming popular, as it helps in analyzing the real time power consumption. Home Automation System [HAS] and remote control system in a smart home opens up many ways to control the loads in a smart home. But, there are a lot of challenges when all these features are combined together to make a low cost smart home system. Often in the design, the HAS and remote controllability can conflict with each other when trying to control the same load. This paper outlines the design of a low cost smart switch that incorporates HAS, remote controllability and IOT cloud platform. It also describes the challenges faced and a possible solution.**

Keywords—Smart Home, Home Automation System [HAS], IOT, Real time Monitoring, Cloud Analytics, Visualization

I. INTRODUCTION

The modern era is in the cusp of automation where most of the electrical systems are becoming automated in home, malls [1], industries [2] and hospitals [3].etc. Home automation is one among them, where the human effort and energy consumption can be reduced. Also, the remote controllability in smart home is becoming very popular as the cost of wireless solution is becoming cheaper. Implementation of both Home Automation System [4] and remote controllability [5] in smart home opens up more options to the user. But, there will be a conflict between them when HAS and remote user is trying to control the same load. There are various approaches to solve this issue. One could be to prioritize between these modes. But, prioritization is very subjective and differs from person to person. CISCO predicted that 50 Billion devices would be connected to IOT by 2020 [10]. This target can be reached comfortably if there is a smooth transition from a contemporary house to a smart home. Also, there is a large section in the society who would like to retain the manual controllability. But, because of mechanical switches, the signals have bouncing issues, which needs to be taken care of in the design.

In this paper we describe simple steps to build a smart switch for a smart home that can accommodate HAS, remote controllability and cloud analytics. The user shall be able to perform remote controllability when the system is in remote control mode. When the system is in HAS mode, the load will be automated to save energy. It also sends the power consumption data to the cloud-based server for the power analysis. This power consumption data can be accessed by the user while making decision to optimize the power consumption. This system also helps in not overloading the power grid at the peak usage time and avail lower tariffs if provided by the electricity board. All these features were implemented on an embedded system based on an Arduino UNO board, which tests the efficiency of the system.

In Section II, literature work of the existing home automation systems has been discussed. Section III elaborates the system architecture of the proposed work. Section IV highlights the methodologies used. Section V explains the detailed analysis and discussion. Finally, the conclusion and future work is discussed in Section VI.

II. RELATED WORKS

Kumar, Ramu, et.al., proposed a low cost IoT based home automation system by using Arduino board. An Android mobile application is developed to control the load. The proposed architecture is for indoor home automation using Bluetooth and the outdoor home automation using Ethernet [7].

The proper analysis of various sensor parameters and the data acquisition modules play a major role for building a Smart Home with Internet of Things [8]. The proposed framework utilizes Temperature and humidity sensors for continuously capturing the corresponding measurement parameters and to provide context aware services based on three-level context aware model with the help of Internet of Things.

Akorede, Fatigun, et.al., developed a remote control system for elder's safety [9]. A GSM modem and a Wi-Fi module are the major parts of the proposed model and can act as a client and server respectively. AT commands and SMS service in the GSM module and the STM32 microcontroller is integrated to control the state of the electrical switch based on the SMS and to turn ON/OFF the home appliances accordingly. They have segregated the commands in different zones (coded version), each command will perform the

functions accordingly. But the transmission can range from a short distance of 100-200 meters. This application does not store high memory status thus needs to erase the zones after reaching to certain limitations manually.

A proposed system of Husni Teja Sukmana, Muhammad Ghiyast Farisi, et.al., focused on three major process: home entertainment, remote monitoring and home automation [10]. Passive Infrared (PIR) sensor is used to detect the motion of the user and it is attached to an Arduino UNO microcontroller. After detecting the motion of the user, a lamp is turned ON through command from web application. There are chances of false alarms due to overheating due to the PIR sensor is kept ON for a long time, fluctuation in heat and temperature variations.

Ramlee, Othman, et.al., presented a paper that provides assistance and support for elderly and disabled persons in home. The proposed design is a Home Automation System with remote controllability and lower cost [11]. The system utilizes Bluetooth technology for providing remote accessibility of the smart home using Smartphone or Laptop. The traditional electrical switch is converted into a low voltage switch for giving safe environment to the user. The controller board is directly attached to the electrical switch. A relay is used to control the switch connections.

III. System Architecture

The overall system architecture shown in Fig. 1. can be classified into three main categories:

- Home Automation Systems [HAS]
- Remote control system.
- Cloud analytics in IOT

To eliminate the conflict between automation and remote controllability, the proposed system has two different modes and the selection of these mode is based on the position of the mechanical switch. When the mechanical switch is in the ON position, the microcontroller puts the system in home automation mode and when the switch is in the OFF position, the system will be in remote controllability mode. Generally, when users leave the house, the mechanical switch position will be in the OFF position.

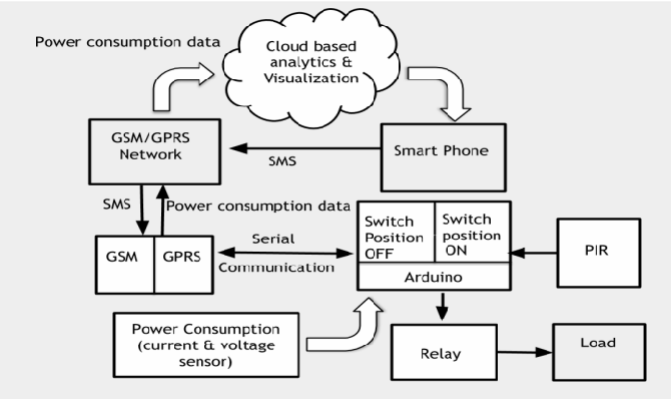

Fig. 1. Smart Home Architecture

A. Home Automation Systems [HAS]

In home automation system, the user will be able to control the load with the mechanical switch just like in traditional ways. But, with the addition of PIR sensor, unnecessary power wastage can be prevented when PIR senses the absence of users around it.

B. Remote Control System

In this mode, the user has to send an SMS request to the number associated with the Subscriber Identification Module (SIM) used in the GSM module [12]. The microcontroller then controls the load through the relay based on the received message.

C. Cloud Analytics in IOT

Power consumption of the smart home can be regularly monitored using current and voltage sensors and this data is sent to the cloud server through GPRS. User gets a notification from the cloud server, when the power consumption is more than the threshold value. Based on this a relevant action can be taken by the user. This cloud server supports analytic and visualization of the data.

IV. Methodology

Methodology has two sections: the hardware design and software implementation.

A. Hardware

The SIM-800 wireless module with an arduino enables remote controllability and the PIR sensor with an arduino enables home automation capability. The load is controlled through a relay and the switch SW1 position defines if the system is in HAS or remote control mode.

1) Wireless Module for Remote controllability and Cloud based IOT:

SIM-800 module has both GSM and GPRS features. As shown in the schematic (Fig. 2.), UART serial communication protocol is being used between the Arduino UNO and the SIM-800 module [13]. The SMS request over GSM network enables the remote controllability and TCP/IP protocol over GPRS enables the connection to the cloud server.

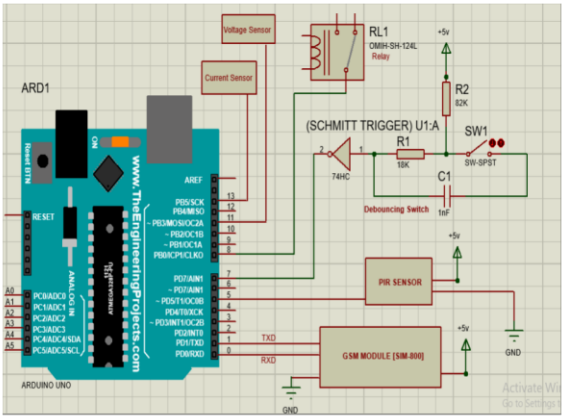

Fig. 2. Schematic of the smart switch

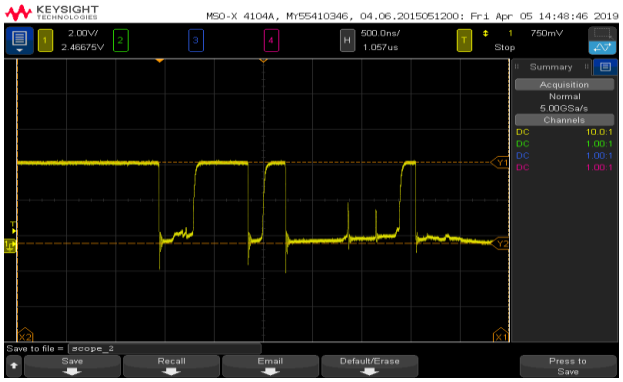

Fig. 3. Bouncing effect

2) Sensor for Home Automation.

PIR sensor detects the infrared light radiating from objects in its range. The presence of human beings near the sensor is depicted by an active high output signal from the PIR sensor. Once a human activity detected, the microcontroller starts counting the timer for 5 minutes and keeps the load in ON state for that duration. If there is no human activity detected in this duration, the load would be turned off [14] after 5 minutes.

3) Debouncing Circuit.

In order to read the status of the mechanical switch using a microcontroller, AC voltage is replaced with 5V DC at the input of the switch. Microcontroller controls the load through a relay, based on the mode selected by the user as explained previously. The inherent bouncing effect of mechanical switches creates issues in automation as shown in Fig. 3. Because of this problem, a single press of the mechanical switch is reflected as a multiple presses electrically. It can be solved by using a debouncing circuit as shown in Fig.4. The circuit consists of a schmitt trigger IC, resistors and capacitors which filters the ripple signals and give clean signals at its output.

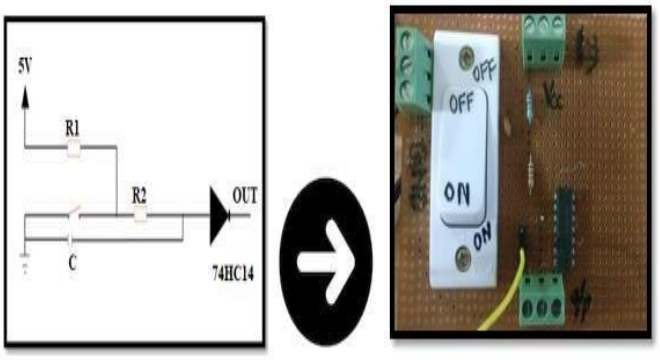

Fig. 4. Debouncing circuit and the hardware setup of the switch

B. Software Design

1) Home Automation and Remote Controllability:

The flowchart of the software for HAS and remote controllability is shown in Fig. 5. After initializing the GPIO pins of the Arduino UNO and GSM/GPRS SIM-800 module, the mechanical switch position is inspected. The switch is in the OFF position indicates the user is not in the home and the user will have privilege to control the load remotely by SMS.

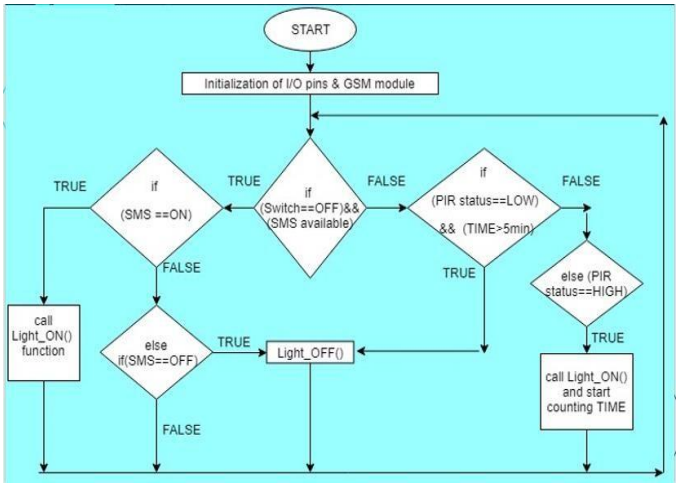

Fig. 5. Flow Chart for HAS and Remote control of the load

The user needs to send an SMS message to turn on the load (SMS==ON) or to turn off the load (SMS==OFF); the corresponding output pin of the microcontroller will control the load through the relay appropriately.

The mechanical switch in the ON position indicates the user is present in the room. As explained earlier, this mode works similar to manual mode. If the sensor detects human presence, its output will be a high pulse, which turns ON the load. But, then if the PIR sensor output continues to be low for more than 5 minutes, the load will be turned OFF. This process repeats as shown in the flowchart to control the load in smart home using a smart switch.

2) Communication and Data analytics:

The overall framework of the monitoring and visualization part is shown in Fig. 6. ThingSpeak is an open source Internet of Things (IoT) cloud platform service provides web services on the cloud to store and retrieve data. The power consumption data collected from the sensors are sent to the ThingSpeak over TCP protocol. User can view the real-time visualization of this data [16].

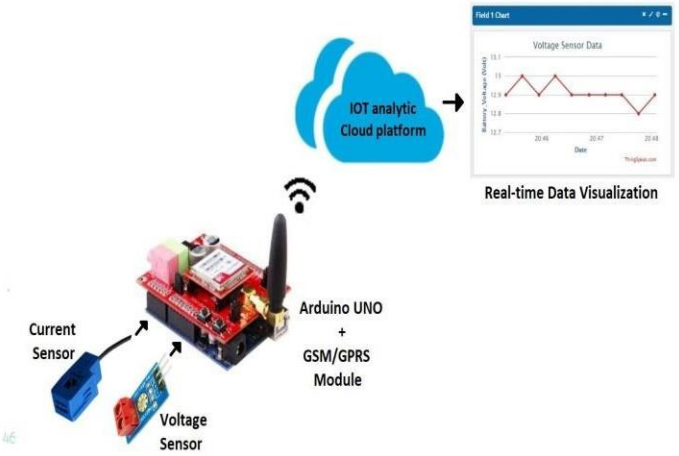

Fig. 6. Monitoring & Visualization

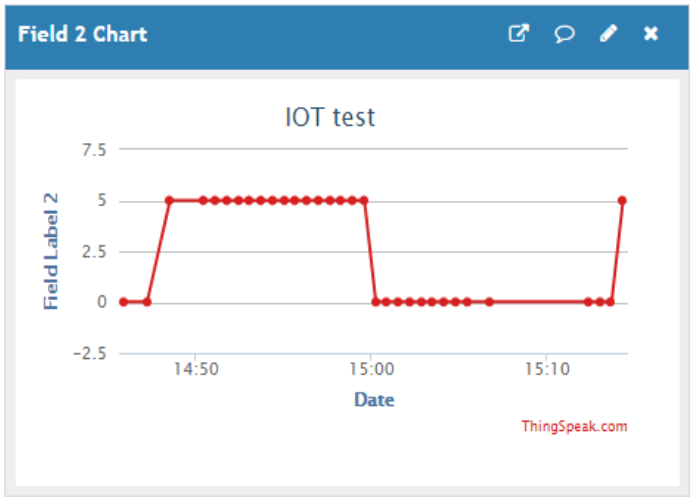
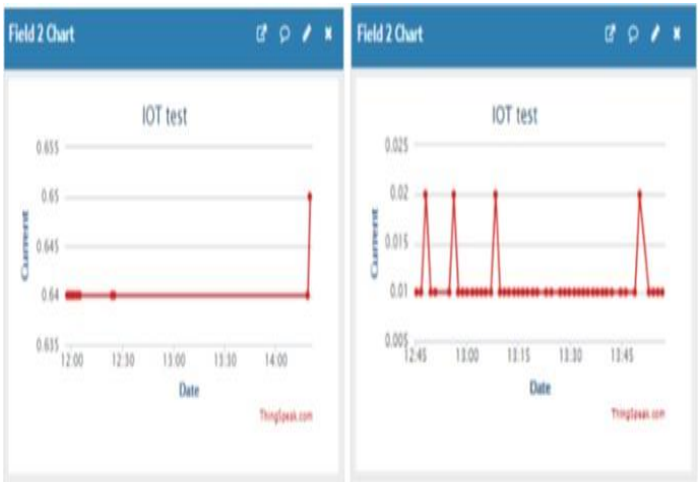
Steps to configure SIM-800 module to Communicate with ThingSpeak:

Step 1: Closing all the existing PDP context.
Step 2: Verifying the device is ready for communicating to the ThingSpeak application.
Step 3: Configure the device for single/multiple IP connection.
Step 4: Attach the device to packet domain service for - controlling load through SMS.
Step 5: Setup the APN with ISP name.
Step 6: Bring up the connection.
Step 7: Return the local IP address.
Step 8: Start a TCP connection.
Step 9: Send the data to ThingSpeak field using TCP - connection.
Step 10: Start the loop again.

V. Analyses and Results



(a)



(b) (c)

Fig. 7. (a) Voltage reading & (b) Current consumption when the load is ON, (c) Current consumption when load is OFF

The Fig. 7. (a) represents the voltage values with respect to the switch position. When the voltage is at 5V, the switch is in the ON position and the corresponding current consumption of 0.64 Amps is shown in Fig. 7. (b). When the voltage is at 0V, the switch is in the OFF position and the corresponding current 0.01 Amps is shown in Fig. 7. (c).

As stated earlier the switch position configures the system in HAS or remote controllability mode. The sensors in HAS mode and the wireless module in remote controllability mode controlled the load successfully without any conflict. Implementation of cloud platform like ThingSpeak helped in analysing the real time data [15].

VI. Conclusion and Future Scope

The proposed work delivers the smart switch for Home Automation System [HAS] and remote controllability of the load. A complete functionality test was performed to validate the design of smart switch system and verified that the remote controllability and HAS does not have any collision while controlling the load. The debounce switch circuit is verified using the oscilloscope. The real time voltage and current values are sent to the cloud server to analyze the power consumption data. The user can access this real-time data to make decisions to optimize the usage. In future, we aim to build a Zigbee mesh communication network using multiple smart switches as nodes with Raspberry Pi as gateway and only the gateway can send the aggregated node data to the cloud server, which makes a better architecture. Also, Arduino UNO can be replaced with a low power consumption microcontroller with sleep mode [6]. ThingSpeak can give out warning twitter messages, which can be implemented to make quick decisions at crucial times.

Acknowledgment

We express our sincere gratitude to our beloved Chancellor and world-renowned humanitarian leader Sri. Mata Amritanandamayi Devi (Amma), for the inspiration and motivation in all our endeavors. We would like to thank our teammates and colleagues in the Amrita Center for Wireless Networks & Applications.

***Abstract*—The basic operation of computer vision is filtering. It is the overture process in applications of biomedical image processing. MRI denoising improves the diagnosis accuracy, quality of image with operations performed on it such as image segmentation and registration; and also parameter estimation. It has been observed that the noise in MRI follows gaussian and rician distribution. In this paper, algorithms are applied on multispectral brain MRI that are either T1-weighted or T2-weighted. The proposed method Multispectral non-local means with statistical nearest neighbor is applied and the results are compared with other NLM filters available. The experimental results show that proposed method provides better noise reduction than NLM with nearest neighbor and adaptive NLM.**

***Index Terms*—MRI, NLM, Multispectral, T1 and T2- weighted images.**

I. Introduction

THE radiology technology that uses radio waves, magnetism, and computer for producing images of different body structures are called Magnetic Resonance Imaging that is what we call MRI. When various tests fails to diagnose any disease, MRI comes into picture. Its an extremely accurate process for detection of disease throughout the body. The MRI gets affected by different parameters such as it gets affected by environment also due to equipment's and operators performance. These leads to the noisy images. So, we need appropriate techniques to get rid of noise from data. Removing the noise from the data becomes important because noisy image leads to improper diagnosis. The goal of any noise removal technique is to effectively get rid of noise without affecting the data available in the image.

The types of noise that are observed in MRI are Gaussian and Rician nosie. Gaussian noise is noises which have a probability density function (PDF) i.e. equal to the normal distribution, this is also known as the Gaussian distribution. We can also say that the values of noise are taken are Gaussian-distributed. Gaussian random variable z has probability density function p and is given by:

$$p_G(z) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(z-\mu)^2}{2\sigma^2}} \quad (1)$$

where z defines the grey level, mean value is given as μ while Standard deviation defined as σ.

Major noise seen in MR images is Rician noise; this noise arose from complexity of Gaussian noise that are introduced in original frequency domain measurements. If x is the corrupted

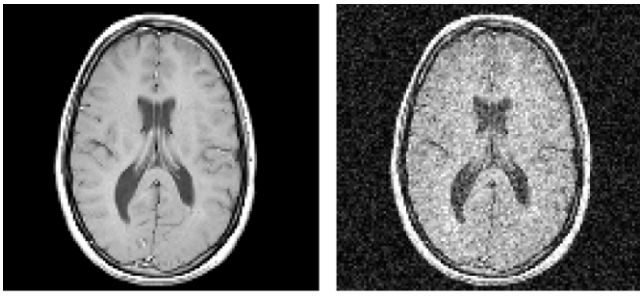

Fig. 1: Rician noise

intensity of image then, Rician probability density function will be given by:

$$p(x) = \frac{x^2}{\sigma^2} exp(-\frac{x^2 + A^2}{2\sigma^2}) I_0(\frac{xA}{\sigma^2}) \quad (2)$$

where A - amplitude of a noise-free image, σ^2- the Gaussian noise variance, I_0 - modified zero order Bessel function.

Diagnostic MRI frequently requires high SNR and high spatial resolution. SNR can be improved by applying image filtering during post acquisition. Different denoising techniques available are anisotropic diffusion filter(ADF)[1], [2],[3], [4]; bilateral filter [5], [6]; trilateral filter [7], [8]; wavelet domain transform, NLM [9]; discussed in Section III.

II. List of the Notations and Abbreviations:

NN	Nearest neighbor
SNN	Statistical nearest neighbor
NLM	Non-local means
NLM-NN	NLM with nearest neighbor
NLM-SNN	NLM with statistical nearest neighbor

MS-NLM-NN	Multispectral NLM-NN
MS-NLM-SNN	Multispectral NLM-SNN
A-NLM	Adaptive non-local means

III. Related Work

Some work done in this area are decribed below. The work is decribed in reference to the methods. The methods in which the work is decribed are:

- Anisotropic Diffusion Filter (ADF)
- Combination of range and domain filtering techniques:
  - Bilateral filter
  - Trilateral filter
- Wavelet domain transform
- Adaptive Non-local means

A. Anisotropic Diffusion Filter (ADF)

Perona and Malik [2] developed the schemes such as edge detection and also multiscale smoothing, and are called as anisotropic diffusion filter (ADF). This filter overcome spatial filtering drawback and it also significantly improved the quality of image i.e. by preserving boundaries of the object, efficient removal of noise from homogeneous regions and also sharpening of edges. This filter cast the problem in the heat equation form i.e based on 2^{nd} order PDE (Partial differential equation). Diffusive process formulation is done for smoothening. The process is stopped at boundaries. This is done by selection of local gradient strengths over various directions. Here, image u is just convoluted in orthogonal way to that of image gradient. This ensures the edge preservation. The repetitive process of denoising for beginning image u_0 cab be given as:

$$\begin{cases} \frac{\partial u(x,t)}{\partial t} = div(c(x,t)\nabla u(x,t)) & u(x,0) = u_0(x) \end{cases} \quad (3)$$

In ∇u(x, t); x voxel's image gradient & t is the iteration, while ∂u(x, t)/∂t is u(x, t) 's partial temporal derivation and

$$c(x,t) = g||\nabla u(x,t)|| = e^{(-||\nabla u(x,t)||/K^2)} \quad (4)$$

K here consists of diffusivity parameter. For denoising MRI, Gerig et al. [3] has proposed the filter for 2D and 3D images. Although noise filter performance over images are excellent, the image model underlying has slow variance. A gray value constant slope is obtained due to edge sharpening. Here the noise of the image is considered to have zero means and also its Gaussian distributed. According to [4], adaptive anisotropic diffusion filter does not retain edge sharpening property. Here, level contours of local intensity orientation and its curvature is used to control the filter kernel and shape instead of local gradient strength. These ensured the preservation of edges and corners throughout the process.

B. Combination of range and domain filtering techniques

Bilateral filter:

An alternative for anisotropic diffusion filter i.e. bilateral filter was proposed by Manduchi and Tomasi [6]. These approaches smoothens the image and preserve the edges. Single iteration is enough for bilateral filter implementation. It does not involve PDE solution unlike anisotropic diffusion. Two Gaussian filters are combined to get this filter i.e. range and domain filter. The domain filter weights and geometric distance (i.e spatial) of a voxel/pixel are proportional around pixels neighborhood. Whereas, the range filter coefficients and intensity (photometric) distance are proportional around the pixel neighborhood. When average value replaces each pixel intensities in the image, we obtain filtered image. The average value is weighted with in a spatial window by the intensity and geometric similarities amongst the pixels.

[5] has proposed a filter named guided bilateral filter, which is a new way for deriving the joint/cross bilateral filter. Its for a particular case with more generic filter. Its generic, iterative and also inherits robustness properties of robust bilateral filter. It also uses a guide image.

Trilateral filter:

Trilateral filter was aimed by Wong et al. [7], [8] for reducing the noise within the MRI which works on the same line as bilateral filter.In addition to bilateral filter, trilateral takes local structures similarity into account for smoothening of the image. Using local structure's information, the non-homogeneous regions can be identified. In case of the homogeneous region, only the low pass filters are applied. In case of region that are non-homogeneous, each pixel intensity value is substituted by average value measured within a spatial window by three components i.e. photometric, geometric and local morphological similarities in amongst neighboring pixels. For edge prevention while smoothing narrow spatial window is used.

C. Wavelet domain transform

Robert D. Nowak [10] presented two methods on wavelet domain filtering for removal of noise from MRI. In case of high SNR, the MRI data governed by Rician distribution and is estimated as the Gaussian. The first algorithm is simple and also effective on noise removal for above mentioned cases. Gaussian is no longer valid at low sound-to-noise (SNR). Two degrading effects in Rician distribution are signal dependent bias and pixel value's random fluctuation. Due to which image contrast gets reduced. For such complications, wavelet domain filter was derived that would operate on squared magnitude image. The second algorithm works on the noise removal and bias removal from squared magnitude image.

D. Adaptive Non-Local means:

There are many filters which considers the noise is equally distributed throughout the image. If this consideration fails, the filter used gets suboptimal. This becomes the case with MR images which has spatially changing noise levels. These noises are obtained due to parallel imaging, surface coil-based acquisitions or intensity inhomogeneity-corrected images. In A-NLM, the information of local image and its noise level

are used for adjusting denoising strength amount of the filter. This data is automatically received from the images by using a new method explained in [11] and is named as a new local noise estimation method.

IV. Methodology

Defined on decrete grid I, lets consider multispectral images which are perfectly registered. These explains bounded spatial domain that are 3D and traversed by image, S = {S(i)| i ∈ I , S(i) ∈ R^K }. Here K is considered as number of frames that are of the multispectral data set. Spectral dimension is the a frame k taken as a peculiar image from the mutispectral dataset, obtained at peculiar value of a changing acquisition parameter. Measured signal intensity denoted by $S_k(i)$, obtained from frame k, voxel i which is calculated from conditional Rician probability $p(S_k(i)|A_k(i), \sigma_k(i))$, considering $A_k$as unknown underlying amplitude & $\sigma_k$as unknown noise std. deviation and is assumed spatially constant & set as σ.

A. NLM Filter with nearest neighbor:

Buades et al. [12], initially introduced NLM i.e the nonlocal-means filter. The voxel i intensity is approximated as the signal intensities' weighted mean that is computed over entire voxels j in R size large searching window that is centered across voxel i which is of interest [13], [14], [11], [12]. The weight w(i, j) measuring the resemblance between those two voxels i, j; in the frame k is estimated as

$$w_k(i,j) = \exp\left(-\frac{d_k(i,j)}{h^2}\right) \tag{5}$$

h is the smoothing parameter which paramaterize the GWED weighting. And in case of magnitude MRI, the estimate $\hat{A}_k(i)$ of amplitude $\hat{A}_k$ in kth frame and voxel i ,is given by

$$\hat{A}_k(i) = \sqrt{\max\left\{\frac{\sum_j^R w_k(i,j)\, S_k^2(j)}{\sum_j^R w_k(i,j)} - 2\hat{\sigma}^2, 0\right\}} \tag{6}$$

This is a modifiction to [15].

B. MS-NLM Filter with nearest neighbor:

Wiest-Daesslé et al. and Manjón et al. have expanded the NLM filter such that it includes data from MRI which are received with weightings various parameters in computation of w(i , j) [16], [17], [18], achieved by simply replacing GWED in Eq. 5 by its extension due to multispectral data by

$$w_k(i,j) = \exp\left(-\frac{\sum_{k=1}^K d_k(i,j)}{Kh^2}\right) \tag{7}$$

The estimate $\hat{A}_k(i)$ of the amplitude of kth frame and voxel i is calculated by

$$\hat{A}_k(i) = \sqrt{\max\left\{\frac{\sum_j^R w_k(i,j)\, S_k^2(j)}{\sum_j^R w_k(i,j)} - 2\hat{\sigma}^2, 0\right\}} \tag{8}$$

C. NLM filter with statistical nearest neighbor:

The noise free patch estimate's prediction error is reduced in Statistical NN (SNN). NN blurs low-contrast image with low SNR. But it is more in SNN.

An improvement in the quality of perceived image is observed due to SNN. It is assured by measuring over serveral metrics of quality; applied on some standard datasets of images. This improvement is observed in both white and colored Gaussian noise. It is also observed that, if SNN is applied with NLM that image quality enhances as compared to state-of-art with computational cost being much lower.[19]

Lets see how the neighbors are selected. NLM denoising [13], [20] averages similar patches in the image and in final stage averages are aggregated. Assume the representation in vector of S × S × C noisy reference patch is given as $\mu_r = [\mu_r^0, \mu_r^1, ..., \mu_r^{S^2C-1}]$, whereas for patch of noisy neighbor γ_k, the squared distance between $\mu_r$and γ_k is given by

$$d^2(\mu_r - \gamma_k) = \frac{1}{P} \cdot \sum_{i=0}^{P-1} \left(\mu_r^i - \gamma_k^i\right)^2 \tag{9}$$

where P=S^2C. If $\mu_r$and the neighbor $\gamma_k$are two noisy replica of the same patch; where $\mu_r$is the reference patch and $\gamma_k$is its neighbor; then what we get is

$$d^2(\mu_r - \gamma_k) = \frac{2\sigma^2}{P} \cdot \sum_{i=0}^{P-1} G(0,1)^2 \tag{10}$$

where $G\left(\mu, \sigma^2\right)$ means Gaussian random variable having mean $\mu$and σ^2variance. The summation of P squared normal variable have P degrees of freedom and χ_P^2distribution; therefore we can say that $d^2(\mu_r - \gamma_k) \sim \frac{2\sigma^2}{P} \cdot \chi_P^2$ and

$$E[d^2(\mu_r - \gamma_k)] = 2\sigma^2 \tag{11}$$

Hence we can conclude that the expected squared distance is not zero for two replicas of same patch.

Inspired by Eq. 11, an alternative to NN is collecting neighbors having squared distance close to expectation from the reference patch. SNN are the $\{\gamma_k\}_{k=1.....N_n}$ patches which minimize the following equation:

$$|d^2(\mu_r - \gamma_k) - o.2\sigma^2| \tag{12}$$

o is the additional offset parameter which helps to go from the traditional approach of nearest neighbor ($\sigma = 0$) to SNN approach($\sigma = 1$).[19]

V. Results

The results are analyzed on the basis of numerical as well as visually.

The fig 2. shows the visual impact of the algorithms - NLM-NN, NLM-SNN and A-NLM over an MRI image. Fig 2. shows the output of the traditional methods developed. Whereas fig 3. shows the visual results for multispectral data over the various algorithm mentioned in Section IV. The first row shows the working of the multispectral algorithm over T1 image whereas the second row shows the working of the same methods over T2 image data. To get a better visual clarification, fig 4. shows the zoomed part of image.

Table I and II shows the numerical analysis of the algorithms mentioned in Section IV. The results are evaluated on the basis of mean square error, peak SNR and SNR.

VI. Conclusions

MRI images gets affected by external elements, the output images get inculcated with noise. Hence for better diagnosis this noise must be removed with any proper methodology. Hence we came up with a method. And this method is applied over different T1 and T2 weighted brain MRI images along with other methods. The conclusions are drawn based on the peak sound-to-noise ratio. The numerical analysis are shown in Table I and Table II. We can say that the peak SNR (PSNR) is high for MS-NLM-SNN for both T1 and T2 weighted brain images. Also we know if PSNR is high the quality of image is good. So, we can say that, this method is better than other two since it has high PSNR. Also we can observe that the mean square error for MS-NLM-SNN is less as compared to MS-NLM-NN and A-NLM. Fig. 2 and Fig. 3 shows the visual results.

***Abstract*—Machine Translation is the programmed interpretation of one natural language to another natural language. Human languages can be processed by computers via grammars/rules or via statistics/data. There are many machine translation techniques which are either Rule-based or Knowledge-based. In this paper we will discuss the Statistical Machine Translation (SMT) techniques. The Statistical Machine Translation makes use of statistics or data to find the translation of a given source text. In word primarily based SMT, the simple unit of translation is a word. As a consequence words in an input sentence are translated phrase by phrase individually and these words are than sooner or later organized in a particular way to get the target sentence. The paper discusses numerous fashions for the word based Statistical Machine translation. The paper is written with reference to Kashmiri Language, as not much work has been done in this regard.**

Keywords—Machine Translation;Word based Statistical Machine Translation;Kashmiri,Kashur.

I. INTRODUCTION

One of the most successful approach to machine translation [1] is Statistical Machine Translation (SMT) [2]. Statistical system translation begins with a totally big facts set of right translations, that is, a corpus of texts which have already been translated into multiple languages, and then uses the ones texts to routinely infer a statistical version of translation. That statistical version is then implemented to new texts to make a guess as to a reasonable translation. The systems learns automatically how to translate text from source language to a target language using a large corpora of analogous translations .The corpora [3] used is a bilingual or parallel corpora. The notion of Statistical Machine Translation was conceived by IBM in early 1990's.The SMT was inspired by Shannon's Information Theory [4], but was not feasible with early computers.Inorder to use statistical models, we need to create many alternatives called hypothesis. Each hypothesis is then assigned a particular score. The best hypothesis is then searched using this score. The SMT can be word-based, phrase-based and hierarchical phrase–based system. The word –primarily based SMT method is relatively simple and green. The main downside of the system is that the oversimplified word by word translation of sentences, may additionally reduce the performance of the interpretation system.

II. LEXICAL TRANSLATION

The simple representation for statistical machine translation is defined using lexical translation, which is actually interpretation of each word without any regard to other words. In a Kashmiri-English dictionary we may find that most words have multiple translation E.g. Utensils, Dish **(**بانه), Mountain, Ball (بال) .Some translations for a particular word may be more likely, whereas others are used in certain circumstances. Statistical Machine Translation makes use of statistics. In case of the example given below, we can count how often (بانه) is translated to utensils and dish by looking at a corpus of Kashmiri [5],[6] to English translations.

Translation of بانه	Count
Dish	1600
Utensils	8000

Fig. 1.Different translations of Kashmiri word in English

These numbers can be used to calculate a lexical translation[7] probability distribution, which says that the function $\mathbf{P_f}$ should yield a maximum value if a given English word e is a most used interpretation or should give a low value if a given English word e is a infrequent interpretation. The function $\mathbf{P_f}$ is required to have two properties.

$$\sum_{e} Pf\ (e) = 1$$

Where e: $0 \leq Pf \leq 1$

II. MAXIMUM LIKELIHOOD ESTIMATION

The probability distribution may be given by calculated the ratio of counts. Consider an instance where we have 12000 incidences of the word بانه in the text and 8000 of these are translated as utensils and 4000 are translated as dish. If we

calculate the ratio for each translated word, we can get the probability for each translated word used. Therefore,

P (بانہ) (Utensils) = 8000/12000 =0.6

P (بانہ) (Dish) =4000/1200=0.3

Thus we end up with the following function.

P_f (e) = 0.6 if e = utensils

= 0.3 if e = dish

This estimation is called Maximum Likelihood Estimation [8]. For a Statistical Machine Translation system, we require a huge equivalent or bilingual corpus also known as bitext. This corpus consists of a document in source dialect and its translation in the target dialect. Using this corpus we can automatically find those sentences which are translations of one another. These word – aligned sentence pairs are used for automatic estimation of a statistical model. If a new text is given to translate, we apply this model to get most probable translation. Consider a Kashmiri sentence taken from Kashmiri-English corpora.

انسان چھٕ پنہ نہن کامین ہند پانہ ذمہ دار

We will use lexical translation probabilities for the above mentioned sentence. A lexical probability function say P (e l f) which denotes the probability of interpreting a Kashmiri word f into an English word e.

Following this word to word translation of the Kashmiri sentence **(**انسان چھٕ پنہ نہن کامین ہند پانہ ذمہدار**)**.The one possible translation is

"Man is responsible for his own deeds".

The next step is to align or map from English words to Kashmiri words.

ذ مہ دار	پانہ	ہند	کامین	پنہ نہن	چھ	انسان
7	6	5	4	3	2	1

Man	is	responsible	for	his	own	deeds
1	2	3	4	5	6	7

Fig.2.Depiction of Kashmiri Sentence and its English Translation

Alignment function **a** plots each output English word at location **j** to each given Kashmiri word at location **i.** Therefore alignment function can be denoted as.

a: j -> i

For the above example the alignment function can be determined as:

a**: {1->1,2->2,3->7,4->5,5->3,6->6,7->4}**

ذ مہ دار		پانہ		ہند		کامین		پنہ نہن		چھ		انسان	
e	**P(e|f)**	**e**	**P(e|f)**	**e**	**P(e|f)**	**e**	**P(e|f)**	**e**	**P(e|f)**	**e**	**P(e|f)**	**e**	**P(e|f)**
Responsible	0.7	Own	0.8	For	0.7	Deeds	0.8	His	0.8	Is	0.9	Man	0.7
Liable	0.15	Personal	0.16			Actions	0.5	Own	0.2			Human	0.4
Blamable	0.25	His	0.7			Conduct	0.2	Personal	0.15			Fellow	0.01
Accountable	0.5					Manner	0.05						

Fig.3.Depiction of Lexical Probability Distribution

We need to take care of certain things here.
1. It is possible that languages have different word order (sentence structure)
E.g. English has [SVO] word order whereas Kashmiri has [SOV] word order.
2. Languages also differ in number if words required to express the same concept.
E.g.

به چھس وقتك پابند
I am punctual

3. Words in one language say English may have no relative Kashmiri input word .To represent this a special symbol known as NULL is used.
E.g.

آب جھ وشن
The water is hot

a : {1->0,2->1,3->2,4->3}

III. MODELLING IN STATISTICAL MACHINE TRANSLATION

A. NOISY CHANNEL MODEL

If we wish to form a machine translation system for a given foreign sentence say "f" in Kashmiri language and produce its translation say "e" in English language by combining the interpretation model and the language model. To find the interpretation of sentence "f" in Kashmiri dialect, choose the English sentence "e" which maximizes **P (e|f). P(e|f)** is a sequence of words "**e"** in the translated dialect i.e. English is the translation of a sequence of words "**f** "in the source dialect i.e. Kashmiri. Modelling the probability distribution **P(e|f)** may be approached with Bayes Theorem.

$$P(e|f) \propto P(f|e)P(e)$$

- **P(f|e)** is the interpretation version ,that is the chance that the supply string "**f"** is the interpretation of the translated string "**e".** The translation version cares approximately selecting **e** phrases that were possibly used to generate **f (FAITHFULNESS**).
- **P(e)** is the Language version ,which gives the probability of on the grounds that translated language string or the form of sentences which are likely inside the goal language.
- The Language Model cares about picking **e** words that are likely to be said in English and that fit together (**FLUENCY)**.

We have to obtain the following.

$$\mathbf{argmax_e\ P(e|f)}$$

Thus we have to find an English sentence **e** that gives the highest value of **P(e|f).**Thus applying Bayes' Rule.

$$\mathbf{argmax_e\ P(e|f) = argmax_e\ P(f|e)\ P(e)\ /\ P(f)}$$

As P (f) is a constant we can drop it.

$$\mathbf{argmax_e\ P(e|f) = argmax_e\ P(f|e)\ P(e)}$$

B. IBM MODEL 1

IBM Model 1 produces varied interpretations for a sentence, each having diverse likelihoods .This model uses lexical translation probabilities. For each output word say **e** that is given by means of the version from an enter phrase **f**, we find translation probability **t(e|f)**. The interpretation probability for a overseas sentence in Kashmiri say **f=(f1,f2,…,flf)** of length **lf** to an English textual content **e=(e1,e2,…,ele)** of duration **le** with an alignment of every English word **ej** to a Kashmiri phrase **fi** as in step with the alignment function. **a:j-> i**

$$\mathbf{P(e,a|f)= Ɛ/(lf+1)^{le}}\ \prod_{j=1}^{le} t(\ ej|f\ a(j)\ )$$

Where,

- $\prod_{j=1}^{le} t(\ ej|f\ a(j)\ )$ is a product of all the lexical interpretation likelihoods for all generated English words e_j.
- **le** is no. of English words.
- $\mathbf{Ɛ/(lf+1)^{le}}$ is used for normalization.
- **Lf +1** is no. of input words .A special NULL token is also included.
- There are $\mathbf{(lf+1)^{le}}$ varied arrangements that plots **lf+1** into le output words.
- **Ɛ** is a normalization constant.

C. EXPECTATION MAXIMIZATION MODEL

The lexical translation models based on probability distribution can only be used if we have a word-aligned bilingual corpora. But we usually have sentence aligned bitext .We use Expectation Maximization (EM) Algorithm to look at interpretation opportunity distributions from a sentence-aligned matching textual content. Thus we have a sentence – aligned bitext corpus .We have to find the alignment between the words of the sentences. The EM model involves initializing the model parameters, assigning probabilities to the missing data, estimating parameters of model from completed data and the final step involves iteration over these previous steps. Consider the example of three Kashmiri sentences given below.

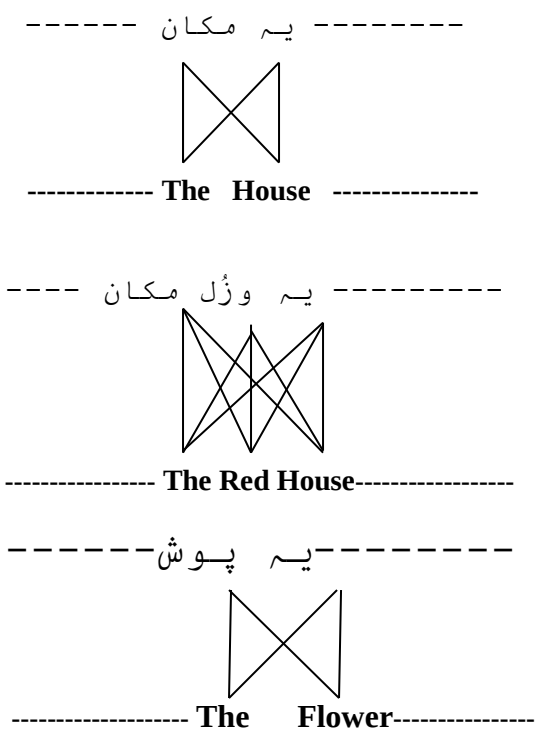

Fig.3. Depiction of alignments for first iteration

In the initial step all alignments are equally likely. The model learns here that یہ is often aligned with **The.** After first iteration the alignments between یہ and The are more likely.

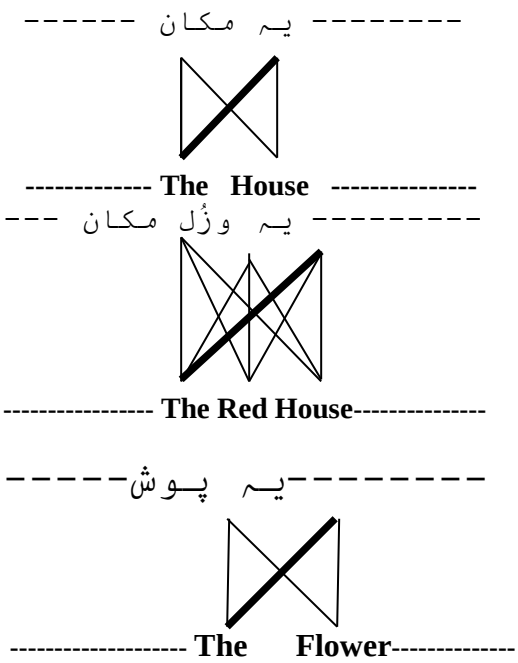

Fig.4. Depiction of alignments for second iteration

After another iteration it becomes clear that alignments between پوش and flower are more likely.

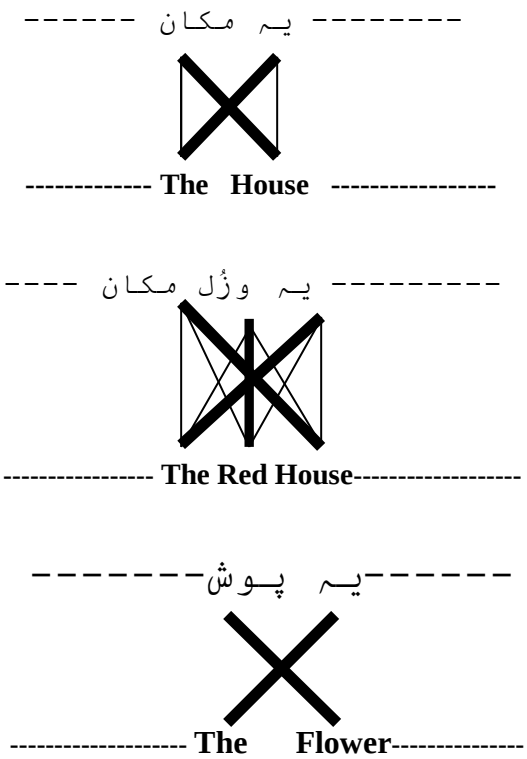

Fig.5.Depiction of alignments after many iterations.

After many iterations the following structure is revealed by Expectation Maximization Model.

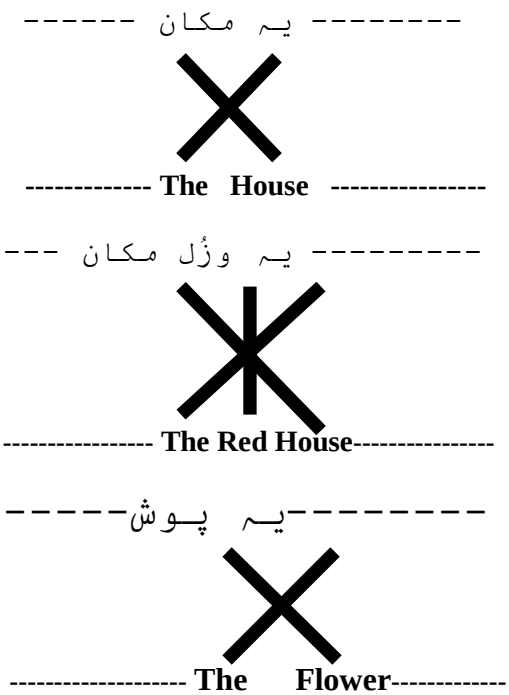

Fig.6. Depiction of alignments for final iteration

P (یہ **| the) = 0.534**

P (مکان **| house) = 0.443**

P (وزُل **| red) = 0.635**

IV. CONCLUSION

The Statistical Machine Translation [9] can be classified into word based, phrase-based and hierarchical-phrase based model. SMT systems are constructed by the usage of big collections of formerly translated texts (parallel textual content corpora), which can be instinctively aligned at the sentence and word ranges, that are saved as huge databases of terms, which can be translations of every other. The translations for new textual content are generated by way of wise search algorithms that recombine the segments from the database into a faithful and natural translation. SMT systems have quicker development cycle, are greater accurate in resolving ambiguities. Similarly, they require greater storage area and use greater computational power. The above paper discusses diverse models used for word-primarily based SMT .These models help us in finding the greater accurate translation of a given text by estimating the maximum likelihood probability .The Statistical Machine Translation system provides countless excellence when affluent and qualified corpora are available. The interpretation is accustomed and significant, if it uses well and qualified corpora .Formulating from huge parallel corpora is computerized and less expensive. Thus in any way, preparing on wide-ranging dialect corpora, importance content other than the preset space, is poor. Usually they run as web services on effective servers or computer clusters, which restrict their use for off-line cellular applications. At last Statistical Machine Translation requires huge equipment to assemble and oversee infinite interpretation models.

***Abstract*— In this paper, we propose a hybrid approach for wireless sensor networks which can reduce the total energy consumption of network operation therefore improving network lifetime along with complete coverage of remote monitoring field. The proposed method named as Hybrid Weight based Coverage Enhancing Protocol (H-WCEP) helps to select appropriate cluster heads and their respective cluster members by using weighted sum method and subsequent routing path by genetic algorithm. The network lifetime and coverage lifetime are computed by implementing this approach to achieve continuously monitoring of remote monitoring areas. The results of H-WCEP outperform as compared to other existing protocols. The network lifetime and full coverage lifetime of H-WCEP increase by 48 percentage and 42 percentage approximately respectively.**

Keywords—wireless sensor networkS; network lifetime; full coverage lifetime.

I. INTRODUCTION

Recently, remote sensing systems have received significant attention in electronic and computer science applications. In wireless Sensor Networks (WSNs), tiny component known as sensors are perform sensing and on-board processing, communication and storage facilities. The WSN provides remarkable benefits for a number of real world problems such as military surveillance, agricultural monitoring and oil pipelining monitoring [1] etc. The WSN has come to stay as one of the highly advanced technologies that can immediately respond against the rapid change in sensed data and send this to data analysis center in areas which could not be connected through cabling. Various applications of WSN are discussed in [2].

In order to tackle design challenges of WSNs, clustering algorithms play a very significant role. The clustering algorithms in WSN can greatly contribute to lifetime, energy efficiency and scalable issues of network [3]. The large number of sensors is deployed in remote monitoring field. In clustering, the sensor nodes are grouped into clusters. Each group/cluster of sensors is managed by a specific sensor called as Cluster Head (CH) and other group/cluster members in cluster are known as Cluster Members (CMs). The CMs monitor or sense the specific environment periodically. The CMs process the

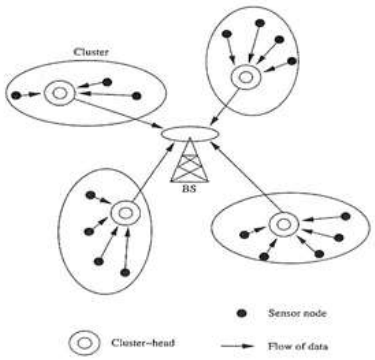

Fig. 1. Cluster based WSN

sensed data and transmit to their respective CH. The CHs aggregate data from their respective CMs and then transmits it to BS. In this way, clustering reduces the energy consumption and numbers of messages communicated to BS decreased. Moreover, data at BS can be encrypted in efficient manner before further transmission to any data centre[4].Thus, clustering achieves prolonged network lifetime [5].The measurements of various performance metrics viz. total energy consumption, network lifetime, number of CHs selected in each round, number of alive nodes in each round, and QoS support like coverage etc. are used to determines the performance of clustered based WSNs.Fig.1 indicates the clustered based network WSN architecture.

The prime objective of this paper is to present an energy efficient clustering protocol which is suitable for remote military area surveillance for achieving prolonged lifetime. Recently, proposed algorithm Weight based Coverage Enhancing Protocol (WCEP)[6] provides the full coverage for longer time as compared to existing clustering protocols. The WCEP works on the basis of weighted sum theory and it increases the lifetime and full coverage by minimizing the energy consumption during cluster formation. But, unable to minimize the energy consumption during inter cluster communication phase.

In this paper, Hybrid-WCEP (H-WCEP) is proposed to decrease energy consumption of the network by using Genetic Algorithm (GA) during data transmission of WCEP. A hybrid approach of weight based method for clusters formation and GA for data transmission is opted to achieve the objective of prolonged full coverage. The cluster head nodes (CHs) and cluster member nodes (CMs) are selected on the basis of coverage governing parameters. The coverage governing parameters taken for this selection procedure are; network remaining total energy, overlapping, node density and degree of sensor node. To conserve the energy consumption, weighted sum method is used. In this method, different weight values are assigned to governing parameters. The optimal set of CHs and alive nodes (as Cluster Member nodes CMs) are selected. Since simple evolutionary optimized algorithm GA has more capability to determine optimal path from CHs to Sink, this GA adopted in inter cluster communication of data transmission in order to conserve the energy consumption.

The rest of the paper is organized as follows. Section II discusses the literature review. Section III discusses the proposed H-WCEP. In Section IV, experimental results are discussed and finally in Section V, the paper is concluded.

II. LITERTURE REVIEW

In literature review, we studied different approaches to optimized energy usage to improve Quality of Service (QoS) in WSNs. The cluster based protocols mimic remote sensing in real time situations. Generally, these protocols are criticized for energy efficiency that involves limited QoS in WSNs. The brief description of related literature is as follows:

[7]proposed distributed cluster based routing protocol namely Low Energy Adaptive Clustering Hierarchy (LEACH) protocol for micro-sensor networks. LEACH improved the network life time, latency and application perceived quality in micro sensor network. However, the study does not investigate good distribution of CHs in the network and sink is assumed only one hop far away from other nodes/ CHs which is not feasible in geographically large network. The work had been extended further based on centralized approach, namely LEACH-C protocol. Still, it cannot solve the limitation of scalability in network. To extend network life time by uniformly CH distribution across the network and load balancing, the amalgamated concept for CH selection, [8] introduced a Hybrid Energy Efficient Distributed Clustering (HEED) protocol. The HEED incorporates two parameters: residual energy of node and node's proximity to its neighbors. However, the rise in iterations involved in cluster formation can lead to overhead cost.

[9] Proposed Distributed Weight-based Energy-efficient Hierarchical Clustering protocol (DWEHC) that designs multi-level structure in intra-cluster communication and limits a number of children of parent node. The author introduced the idea to select CH by calculating weight based on its residual energy and distance to its neighbors. This newly proposed technique improves HEED protocol by developing balanced size clusters and optimizes intra-cluster communication using location

In [10], the authors proposed a protocol incorporating residual energy and other metrics like distance to aggregation point, node reliability, and mobility for CH selection by using evolutionary computing method with purpose of maximizing network life time.

The CHs election techniques called as Coverage Preserving Clustering Protocol (CPCP) was proposed with aim of coverage preservation [11]. The CPCP is based on four coverage aware cost metrics which selects CH, active nodes and routing nodes from densely deployed sensors respectively. The CPCP integrates problem of coverage and energy consumption in network. But these cost metrics cause a large computational burden on sensor nodes. The CPCP is also unable to minimize redundantly covered area in each round.

In [12], the authors described a multi-function based on two factors i.e. choosing optimal CHs locations and minimizing transmission distance. In this protocol, topology of network is designed with three level hierarchical levels. Two CHs at level 2, One CH at level 1and sensor for collecting data placed at level 0. The BS knows the position of all nodes. Thus achieves the minimum distance for transmission.

A GA-based adaptive clustering protocol was proposed by [13] to achieve good performance in network life time in WSNs. Additional information was updates before beginning of first round. In this phase, role of node as sensor or CH, node identifications and geographical position are send to BSs. GA finds an optimal probability of nodes being CHs by minimizing the total energy consumption in one round. The optimal probability was determined by an evolutionary optimization process. This process incorporated non-deterministic rules in probabilistic transitions for prolonging the network life time.

The Distributed Energy Efficient Clustering Algorithm with Improved Coverage (DEECIC) was implemented to increase network lifetime and coverage using average number of clusters in scheme [14]. In this, CH is opted from a crowded area with more remaining energy and more degree of sensor.

Coverage aware Unequal Clustering Algorithm (CUCA) is distributed scheme to prevent hot spot issue and achieves energy efficient coverage preservation in WSNs [15]. The CUCA targets to obtain network load distribution uniformly. The CUCA necessitates overburden of control packets in routing purposes. As a result, unnecessary consumption of energy in each stage takes place that is unacceptable.

The WCEP is an energy efficient full coverage protocol [6]. The WCEP reduces computation burden of sensors and attains pro-longed full coverage with improvement in scalability. The WCEP incorporate the concept of clustering and sleep scheduling efficiently[16]. The WCEP is based on weight values which are assigned to certain governing parameters viz. network remaining total energy, overlapping degree, node density and degree of sensor node. These governing parameters affect the energy and coverage issues magnificently. However, main focus of WCEP is optimal selection of CHs and CMs, whereas energy consumption during data transmission is ignored.

The CPCP [11] and WCEP [6], both primarily focuses on cluster formation process but there is significantly less

importance given to energy consumption during data transmission phase of clustering. Therefore, motivation behind this proposes work is reduction in energy consumption during data transmission phase of WCEP. This has led to more conservation of residual energy and helps in more coverage.

III. PROPOSED WORK

The proposed work presents a hybrid approach using weighted sum method and evolutionary method to achieve coverage of remote and harsh environment for longer period of time. The proposed work is based on Weight based Coverage Enhancing Protocol (WCEP) for clustering and Genetic Algorithm (GA) for transmitting the data to end user controller. In clustering, CHs and CMs are selected in appropriate number for maintaining full coverage in each communication round. The process of clustering considers assigning weight merits to remaining total network energy, overlapping, node density and degree of sensor. The weighted sum method helps in conserving energy using different weight merits to respective governing parameters depending upon situational requirements. Further, GA based optimization procedure performed with each communication round to conserve the energy. The proposed hybrid approach is named as Hybrid -Weight-based Coverage Enhancing protocol using Genetic Algorithm (H-WCEP). The stepwise procedure of H-WCEP is discussed below:

A. *Information Update*

We assume that 'N' sensors are deployed in squared remote monitoring field in uniformly random manner. The deployment of sensors is such that they confirm the 100% coverage at the start of network procedure. The sensors are assumed stationary after deployment and each sensor is awared its own location and BS. The BS is placed at fixed point. The wireless communication channel is symmetric which means monitoring and communicating range is same. The range of sensor and transmission range is modeled as disk sensing model [8]. The transmission range is considered at least double the sensor's range. The network considered for proposed work is homogeneous i.e. all sensors have same computing and communication capacity.

B. *Network Model*

In this step, four coverage observing parameters are incorporated to assign a value to each sensor. These governing parameters are residual/remaining total network energy, overlapping, node density and degree of sensor. At each communication round, sensor dissipates part of their limited energy. As a result, remaining energy is called as residual energy of sensor need to be update periodically. The other governing parameters are node density, degree of sensor and overlapping degree are calculated only once at the start of network procedure. For each sensor, energy dissipation in transmitting and receiving 'L' bit information by each sensor is measured using simple radio model [6], [7], [11]. Equation (1) represents energy consumed by transmitter for performing transmits circuitry operation and Equation (2) indicates receiver's energy consumed due to receiver circuitry when it is receiving data.

$$E_{Tx}(L,d) = L\,E_{elec} + L \in d^{\alpha} \quad \text{where } \alpha=2 \text{ or } 4$$
$$\begin{cases} L\,E_{elec} + L\,\epsilon_{fs}\,d^2 & d < d_0 \\ L\,E_{elec} + L\,\epsilon_{fmp}\,d^4 & d \geq d_0 \end{cases} \quad (1)$$

And Equation [7] indicates formula for energy consumption in receiving L-bit packet.

$$E_{Rx}(L) = L\,E_{elec} \quad (2)$$

In equations (1) and (2),

L=Length of transmitted/ receiving packet,
d=Distance between transmitter and receiver,
d_0=Threshold distance (d_0) calculated from Equation (3):

$$do = \sqrt{\frac{\epsilon_{fs}}{\epsilon_{fmp}}} \quad (3)$$

The electronics energy E_{elec} controlled by digital coding, modulation of signal, filtering of packets, and spreading of the signal.

If $d < d_0$, then free space model is used. It means =2, and amplifier energy becomes $\epsilon_{fs}\,d^2$. Otherwise, $d \geq d_0$ multipath fading channel model is applied which means $\alpha = 4$ and amplifier energy becomes $\epsilon_{fs}\,d^4$.

With each communication round, residual energy is given by Equation (4):

$$E(residual) = E(initial) - E_{Tx} \text{ or } E_{Rx} \quad (4)$$

The other governing parameters such as node density can be calculated by obtaining number of sensors within its cluster range. The degree of sensor is determined by number of covered points in its range. The overlapping degree is number of sensors which produces overlapping area in the monitoring field. Higher the values of these governing parameters (residual energy ($E_{residual}$), overlapping degree ($O_{lapping}$) , node density (ND) and degree of sensor(D_s) for particular sensor make that eligible to become live sensor. The weight w_1, w_2, w_3 and w_4 are assigned to governing parameters using weighted sum method in order to calculate the weight value of each sensor. Equation (5) represents the formulation to compute sensor weight.

For a specific covered point, higher the weight of sensor, higher the chance to become live, otherwise idle or sleep.

$$Sensor.wt = E_{residual}.w_1 + O_{lapping}.w_2 + D_s.w_3 + ND.w_4 \quad (5)$$

Equation (6) is used to obtain CH role for a sensor in terms of CH weight.

$$CH.wt = Sensor.wt + (\text{distance between Sensor and Sink}) \quad (6)$$

C. Clustering Method

In the clustering method, set of sensor nodes are selected as CMs/ CHs which will be active and rest will be in sleep mode for a particular communication round. The proposed clustering algorithm comprises of two phases: cluster formation phase and data transmission phase.

- Cluster Formation Phase:

  The cluster formation phase of proposed algorithm uses a weight based method along with sleep scheduling mechanism to conserve energy while maintaining prolong full coverage of the monitoring field. The total weight of each sensor is calculated on the basis of governing parameters $E_{residual}$, $O_{lapping}$, ND and D_s. The selection of sensor as live sensor is based on maximum value of total weight of sensor for specific covered point. The total weight of sensor and distance from sink determines the CHs. These selected CHs find live sensor as part of cluster and termed as CMs within its cluster radius. These appropriate numbers of specific CMs and CHs are selected repeatedly that maintains the coverage in each communication round.

- Data Transmission Phase:

  In the data transmission phase, intra and inter cluster communication ensures that live sensors communicate to their respective CH directly using single hop method during intra cluster communication. The CHs transmits data to sink via multi hop method. The data transmission phase is optimized using energy and distance parameters using GA. The GA helps to determine path with minimum energy consumption to transfer all data from sensor CHs to sink. To find out an optimum path, the GA generates all possible paths for each of CH. Then, each path is evaluated to determine fitness value using fitness function of GA. The best chromosome is selected among number of generations by means of minimum energy consumption and minimum distance during data transmission. The data transmission phase of WCEGA is further elaborated in Algorithm 1, as follows:

  Algorithm 1: Data Transmission using GA

  D= cumulative distance between sensor and Sink
  w1=weight for residual energy

IV. RESULTS AND ANALYSIS

In this section, the impact of governing parameters on performance metrics for remote WSNs has been investigated. The results of WCEGA protocol is compared with common coverage aware clustering protocol (CPCP) and Weight based Coverage Enhancing Protocol (WCEP). The CPCP discussed four coverage aware cost metrics i.e. energy-aware (Cea), minimum-weight (Cmw), weighted sum (Cws) and coverage redundancy (Ccc). The CPCP (Cmw) focuses longer 100% coverage of monitoring field. Therefore, out of four CPCP cost metrics, CPCP (Cmw) is taken for comparison in these simulations. Generally, coverage related clustering protocols are compared with coverage, lifetime and energy consumption of the network.

In simulations 200 nodes, each with initial energy 1J are taken into monitoring field. The sensors are distributed randomly across 100x100 square units monitoring field. The implementation of WCEGA is iterated based on lifetime of network i.e. energy level of sensors become equal to threshold energy of sensor. The threshold level of energy is assumed zero in this paper. In all communication rounds of network operation, live sensors are selected to collect the sensing data and transmit them to their CHs using single hop communication. Once CH obtained data from its cluster then it transmits the data further to sink using multi-hop communication by GA method. The sink is located at (50,50) co-ordinates. The radius of each sensor is 15m and their communication radius is 30m. The parameters of proposed model are given Table I and parameters for GA approach are listed in Table II.

TABLE I. SIMULATION PARAMETERS

Parameters	***Value***
Initial Energy (E_{int})	1 J
Transmission/Receiving electronics circuitry constant [7]	50 10^{-9}J/bit
Amplifier circuitry constant [7]	10 $^{-12}$J/bit/m^2
Size of Data Packet [7]	240bits
Sensing Range (Rs) [7]	15m
Cluster Radius(Rc) [7]	30m
Transmission Range	40m

TABLE II. SIMULATION PARAMETERS

Parameters	***Value***
Population Size	20
Generation	10
Crossover	0.05
Mutation	0.01
Weight1 for distance factor	0.3
Weight 2 for energy factor	0.7

A. Coverage lifetime Energy Consumption Comparison

The H-WCEP outperforms in comparison to other similar protocols i.e. CPCP and WCEP. By decreasing the consumption of energy during data transmission, it increases the coverage of network. The Fig. 2 depicts comparison of coverage of network in H-WCEP with WCEP and CPCP (Cmw) with time.

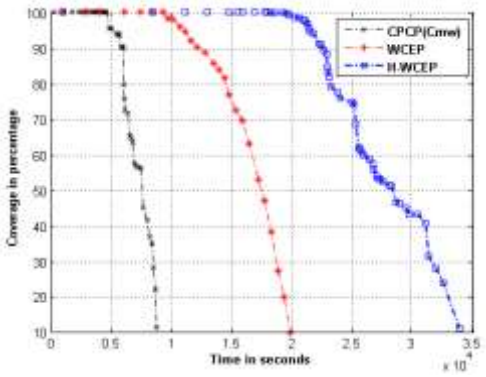

Fig. 2. Comparison of Coverage lifetime with Time for WCEP, CPCP (Cmw) and H-WCEP

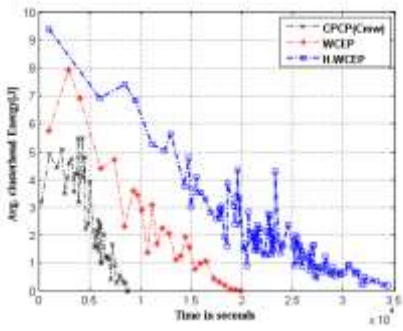

Fig. 3. Average CHs energy with Time for H-WCEP in comparison to CPCP (Cmw) and WCEP

The Fig. 3 indicates higher value of average residual energy of CHs in H-WCEP in comparison to WCEP and CPCP (Cmw) with time.

On the other hand, an important criterion to evaluate energy consumption of WSNs is the average number of CHs with time. If the Number of CHs are high, energy consumption increases. Fig. 4shows that H-WCEP has relatively low number of CHs as compared to CPCP(Cmw) and WCEP.

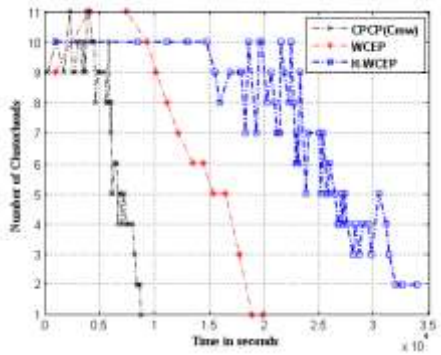

Fig. 4. Comparison of number of Cluster Heads Vs Time for H-WCEP, CPCP (Cmw) and WCEP

B. Lifetime comparison

Network lifetime is defined as start of specific WSNs to death of first sensor. Generally, lifetime of WSN is determined by time taken by First Node Dead (FND), Half Node Dead (HND), Last Node Dead (LND) and these are considered for evaluate performance of cluster based WSNs [11]. Further, FND indicates start of network operation to death of First sensor Node Died. The HND indicates start of network operation to death of Half sensor Node Died. The LND indicates start of network operation to death of Last sensor Node Died. The Fig. 5 represents that H-WCEP exhibits better results than other considered protocols.

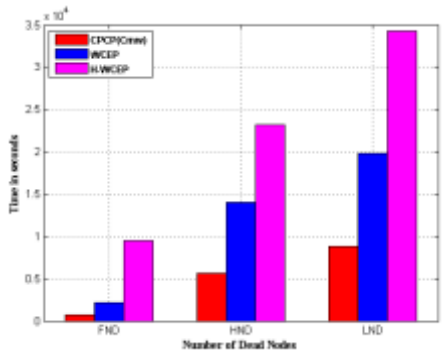

Fig. 5. Lifetime of WCEP, CPCP (Cmw) and H-WCEP in terms of FND, HND and LND

V. CONCULSION

In this paper, an evolutionary based method has proposed to improve longer full coverage in energy efficient clustering protocol. The proposed hybrid method helps in determining efficient optimal path for effective set of CHs and its members. The H-WCEP uses genetic algorithm based routing method that consider distance between cluster head and sink and sensor node's residual energy. Therefore H-WCEP achieves increase in network lifetime and full coverage lifetime. Thus, our hybrid approach uses network energy in effective manner for enhancing the full coverage lifetime in WSNs.

In our future work, we can extend this work by incorporating mobility of sink and pre-determined sensor deployment to enhance the coverage lifetime.

***Abstract*—This paper presents performance analysis of switched boost dc-dc converter for distributed generation system in CCM (continuous conduction mode) operation, which combine the conventional switched-boost circuit with the switched-capacitor and switched inductor switching structure. Compared with the conventional boost converter, which uses convenient duty ratio, the presented topology is utilized to uplifting in voltage gain. The proposed topology exhibits advantages of the continuous current at the input and boost voltage conversion ratio without use of high duty cycle (approx less than 1) and transformer. Proposed converter supports in producing high output voltage gain by operating in different modes. The simulation result brought out from MATLAB 2016 b.**

Keywords— ***DC-DC converter, Switched-boost network, Boost-ability, closed loop system, duty ratio, continuous conduction mode***

I. Introduction

Renewable energy sources based distributed generation (DG) system shows the trend of future generation system. [1-2]. In the distributed generation system, electrical power is generated and that have many benefits to renewable energy sources, which comprises wind power, photovoltaic (PV) cells and fuel cells. During this, the photovoltaic arrays are the new energy resources according to the utilization method, which have been take places in non-conventional energy resources. Block diagram of Power flow of the two-stage photovoltaic energy system is depicted in Fig. 1. PV stack has usually low output dc voltage. Thus, it is necessary to step-up the voltage by High step-up converter which has been included in the first stage of power flow diagram. This first stage is required to provide high gain of output voltage for DC/AC inverter. Thus, high gain of output voltage is provided by high step-up dc/dc converter. Then, second stage considers DC to AC power conversion and provides the desired power due to conversion of DC in AC. After conversion AC supply can be supplied to the utility grid and load as depicted in Fig. 1. Therefore, high step-up dc/dc converters are employed to interface the renewable energy source (PV stake) and inverters connected grid [3]. High step-up dc-dc converters have high voltage conversion ratio and have been utilized in numerous application such as uninterruptible power supply, power supply for electrical vehicle, medical x-ray appliance system and discharge headlamps of high-intensity etc. Renewable energy sources based on solar and wind are very much efficient and present in abundant amount as compared conventional energy sources and due to this reason demand of PV modules increases. To improve power quality, boost sustainability distributed generation technologies is more important and it also reduce energy costs. [12]

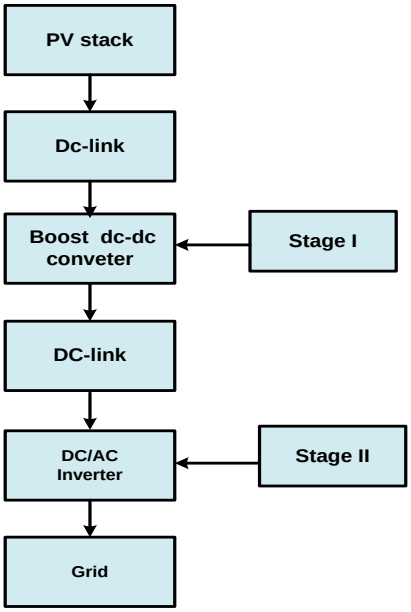

Fig. 1 Power flow diagram of two-stage PV Energy system

Diverse topologies of dc-dc converter have been evolved to increase a high voltage gain with low duty ratio. Converter's topologies like Isolated or non-isolated dc-dc converter [4-5], z-source impedance network have been utilized to achieve high voltage gain.

Isolated dc/dc converter can provide high conversion ratio with increasing turns ratio in transformer but it will lead to large leakage inductance due to high turns ratio. These converters can be create large voltage stress and spikes across switching devices. Further non-isolated can also be categorized as: coupled and non-coupled inductor. Couple inductor based dc to dc converters reduce current ripple of inductor and avoid the switching losses. However, these converter does not reduce the voltage spikes of switches (like IGBT and MOSFET) [4-7] and efficiency will be reduce.

However, these conventional converter topologies are not suitable and more reliable compare to proposed converter due to be less efficient and more expensive and manufacturing cost is also high. Transformer step-up dc-dc converter can be obtain high voltage gain with reduce the voltage and current stress which has been presented [10]. Same as z-source impedance network have been presented which has little number of passive components [14]. In addition, to achieve high step-up capability, switched capacitor-diode cells have been proposed in [9]. In that manner, techniques and topologies can also be employed in boost dc-dc converter are presented in [11]. Figure (3) shows the diagram of switched-capacitor dc-dc converter. The switched-capacitor converter has one switch (IGBT) and has different switching to proposed converter.

Key merits of these converter which have –

1) *No magnetic elements*
2) *Minimal electromagnetic interference*

But it has high inrush current at start up and inherent power loss which is disadvantages of switched-capacitor converter.

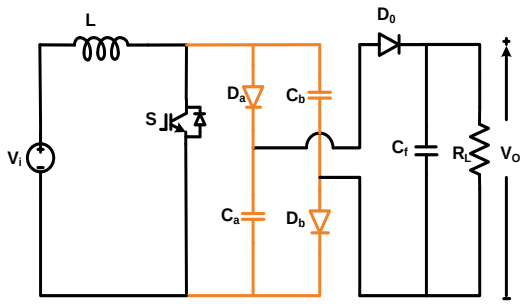

Fig. 3 Switched-capacitor converter (SC)

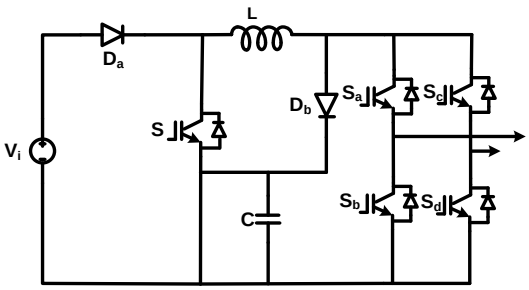

Fig. 4 switched-boost converter (SBC)

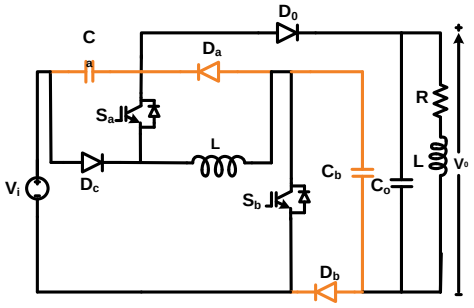
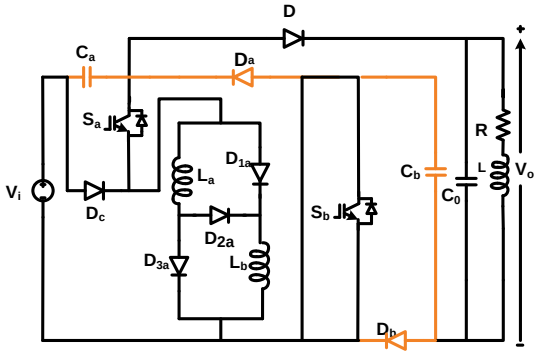
Switched-boost network has been presented and which is depicted in Fig. (4). However, output voltage gain of switched boost converter is not high enough in comparison with conventional Z-source converter [9]. This paper based on the conventional presents that topology is related with switched-boost converter, which is based on cells of SC/SL (switched-capacitor/switched-inductor) to boost the voltage at the output. The proposed topology has the advantage to nullify the voltage stress across the switches and diode [15].

II. Topology of Presesnted Converter

In the presented converter, switched capacitor combine with main network of switched boost converter as shown in figure. The basic circuit diagram of present converter SC-SBC is operating along with switched capacitor branch according to Fig 5(a) SC-SBC circuit of proposed converter have inductor L, diode D_0 and D_c, both switch S_a and S_b, is used IGBT in this circuit diagram and switched-capacitor cell is consisted of capacitor C_a, C_b with diode D_a, D_b.



(a)



(b)

Fig. 5 circuit diagram of SBC (a) SC and (b) SC/SL

Combination of switched boost dc-dc converter, switched capacitor and switched inductor forms the proposed converter shown in fig. 5(b).This circuit diagram consist the different switching structure in compare Fig. 5(a) to obtain the high gain of voltage at the output. In Fig. 5(b) the switched boost converter consists inductor L is replaced with switched inductor cell which have the inductor L_a, L_b and diodes D_{1a}, D_{2a}, D_{3a}. SC/SL cell is combined with switched boost circuit S_a and S_b (power switches) are switched on, the input voltage charge the inductors and when S_a and S_b (power switches) are switched off inductor transfer the energy to charge the capacitors, SCs are conducted with series to supply the load. In consequence converter can generate a high voltage gain at output.

III. Operating Modes Of Presented Converter

To simplify the analysis, all the frequency independent, time invariant and linear components are assumed to be as passive components. These components are ideal resistor, capacitor and inductor.
The performance of the presented converter operated without any interruption in the power supply.

A. Operating Modes of the SBC with switched capacitor

Proposed converter of SC-SBC operates in two modes and equivalent circuit structure is depicted in Fig. 7(a). Waveforms of SC-SBC proposed converter operating without any interruption in CCM operation is depicted in Fig. 6

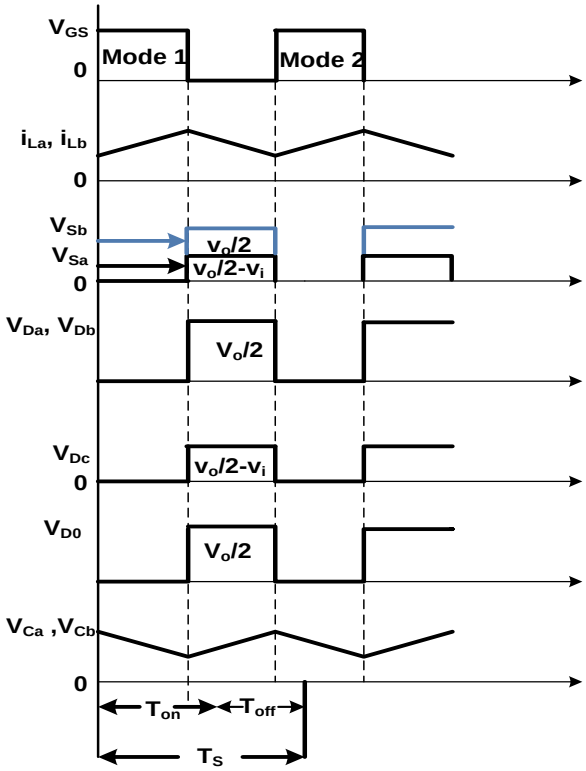


Fig. 6 Waveforms of the presented switched capacitor-switched-boost converter (SC-SBC

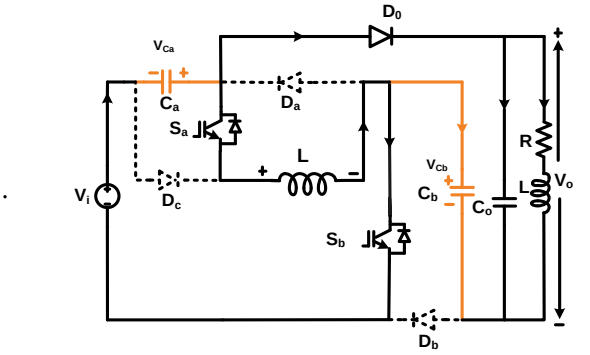
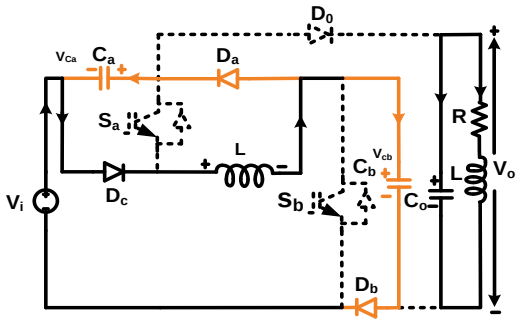
***1) Mode 1*:** In this mode of state, according with time interval, S_a, S_b (power switches) are switched on with the same control of switching and D_a, D_b and D_c (diode) are off which have reverse parallel connection with capacitors. In this state, circuit of proposed converter (SC-SBC) have two loops:

- In first loop of circuit, current is passing through the V_i (input voltage), C_a, S_a (switch), L (inductor), and S_b (switch). V_i and Capacitor C_a release the energy to inductor L.
- In second loop of this circuit current is passing through the V_i, C_a, D_o, C_o, *load(R, L)*, C_b and S_b.To supply of the load, capacitor C_a and C_b are in series with the input source *Vi* through S_b.



(a)



(b)

Fig. 7 Equivalent circuit structure of SC-SBC with step-up topologies

***2) Mode 2*:** in Fig. 7(b) S_a and S_b (switches) are switched off. In this state D_a, D_b, D_c (diodes) are on and D_O is reverse blocking. Three loops are considered in this state:

- In first loop, current is passing through L, D_a, C_a, and D_c. Capacitor is charged by the inductor L.
- In second loop, current is passing through V_i, D_c, L, C_b and D_b. V_i and L releases the energy to C_b
- In third loop, current is passing through C_o and R_L. The load is operated by capacitor C_o.

The duty ratio of S_a and S_b (power switches) which is defined as $d = Ton/T$. Switching period on-period of power switches represented as T_s, T_{ON} respectively.

$$u_L = V_i + V_a \quad (1)$$

$$u_L + V_{C_a} = 0 \quad (2)$$

$$V_{C_b} = V_i + V_{C_a} \quad (3)$$

$$V_{C_a} = \frac{d}{1-2d} V_i \quad (4)$$

$$V_{C_b} = \frac{1-d}{1-2d} V_i \quad (5)$$

$$V_O = \frac{2(1-d)}{1-2d} V_i \quad (6)$$

Eventually, the proposed converter of SC-SBC has output voltage gain which can be derived as:

$$G = \frac{V_0}{V_i} = \frac{2(1-d)}{1-2d} \quad (7)$$

B. Operating modes of SBC with switched capacitor/ switched inductor cell

The proposed converters have waveforms without any interruption which represents the CCM modes in Fig. 8. Further, the equivalent circuit diagram with boost topology is depicted in Fig. 9. It can be seperated in to two operating modes.

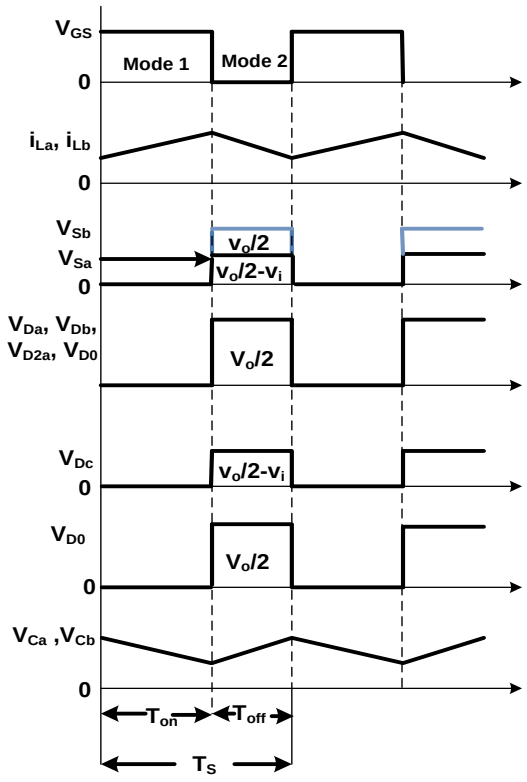


Fig. 8 Waveforms of the (SC/SL-SBC)

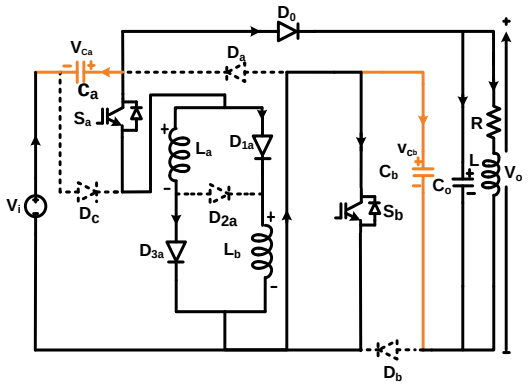
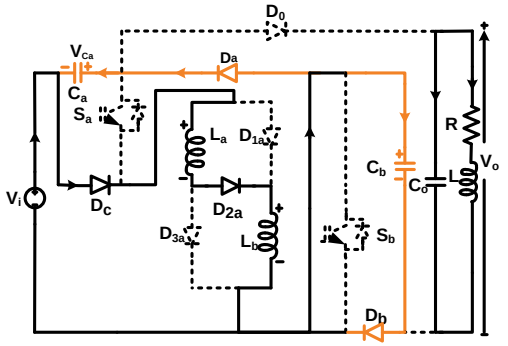
Mode 1: In this state, S_1 and S_2 are switched on with same switching control at same time which shown in Fig. 9(a). D_a (diode), D_b (diode), D_c (diode) and D_{2a} are off. V_i (input voltage), and C_a (capacitor) charge the two inductors L_1, L_2.

Meantime, Vi, C_a and C_b supply the load by S_b. Thus following equation is derived as

$$u_{L_a} = u_{L_b} = V_i + V_{C_a} \quad (8)$$



(a)



(b)

Fig. 9 Equivalent circuit structure of the proposed SC/SL-SBC with step-up topologies

2) Mode 2: $S_1$and S_2 are switched off, simultaneously shown in Fig. 9(b). Diodes D_a, D_b, D_c, and D_{2a} (diode) are on, D_{1a} *(diode)*, D_{3a} *(diode)*, and D_o (diode) are reverse biased. and L_a and L_b *(inductor)* release the energy to capacitor C_a in series.

Meantime, Series connected Inductors L_1 and *L2* with *Vi* charged the capacitor C_b and *load* is conducted by capacitor C_o

$$u_{L_a} + u_{L_b} + V_{C_a} = 0 \quad (9)$$

$$V_i = V_{C_b} - V_{C_a} \quad (10)$$

$$V_{C_a} = \frac{2d}{1-3d} V_i \quad (11)$$

$$V_{C_b} = \frac{1-d}{1-3d} V_i \quad (12)$$

Therefore, G represents the voltage gain ratio of SC/SL-SBC converter in equation 14

$$V_o = \frac{2(1-d)}{1-3d} V_i \qquad (13)$$

$$G = \frac{V_0}{V_i} = \frac{2(1-d)}{1-3d} \qquad (14)$$

Improved output voltage gain is achieved with SC/SL-SBC than that is obtained with SC-SBC, according to equation (7) and (14).

C. Voltage loop control

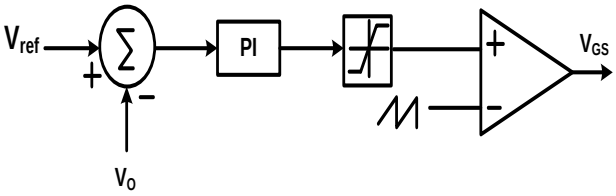


Fig.10 Control principle of proposed converter

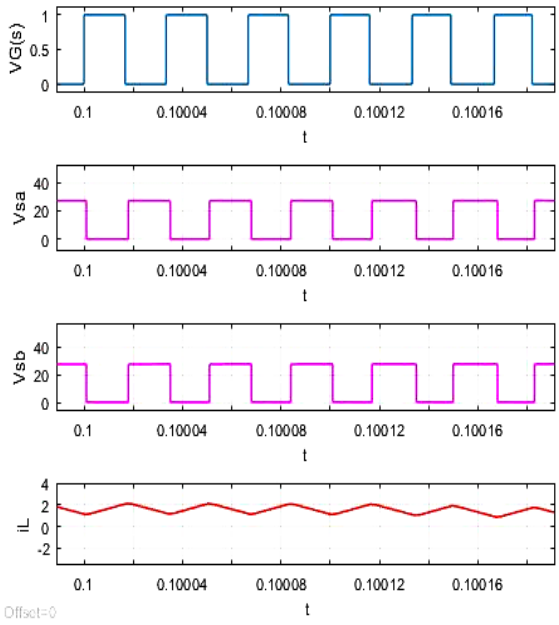
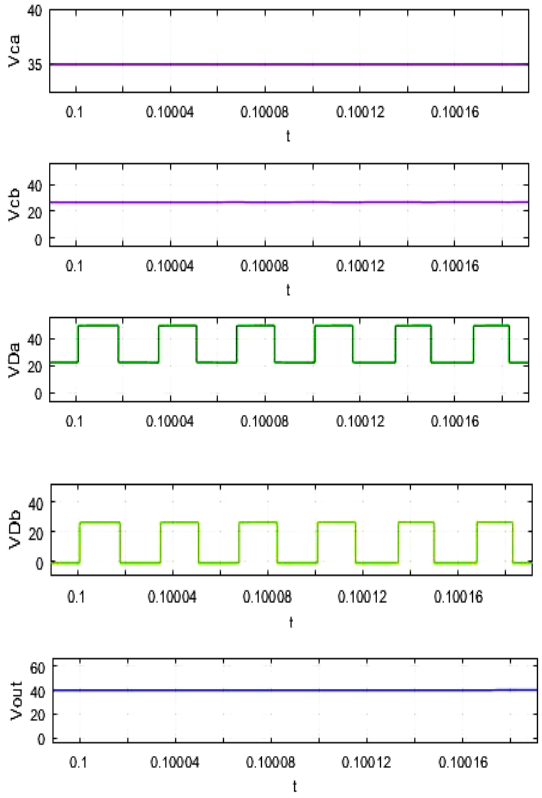
Gate pulse can be controlled by the control principle .To obtain the ripple free step-up output voltage, the control strategy have been used in the proposed converter. That is shown in figure (8).

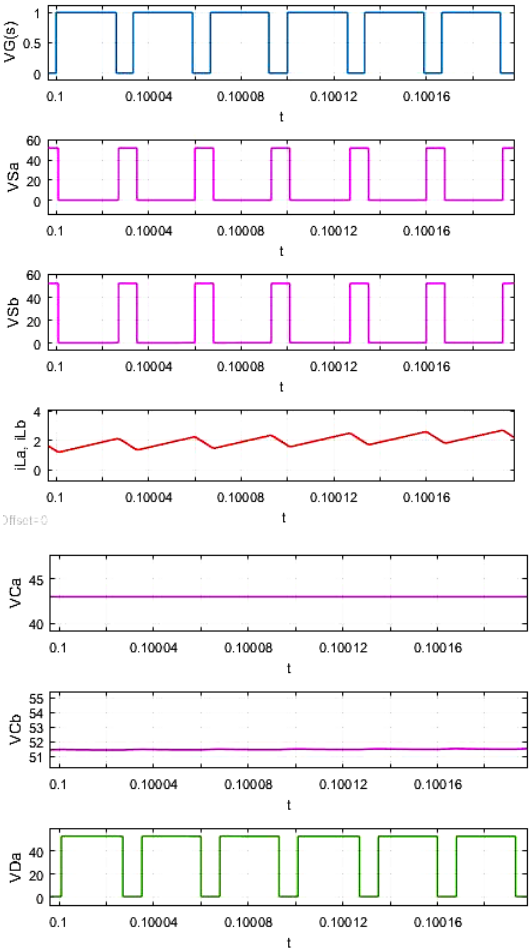
IV. Simulation Results

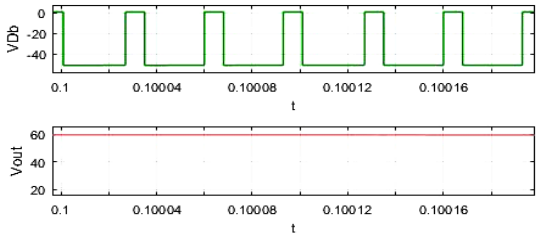
According to design parameters of simulation are selected: input voltage V_i=10V, switched inductors L_a=L_b=220uH, switched capacitors C_a=C_b=330uF, filter capacitor at output C_o=470uF, switching frequency f_s=30 kHz, and the load R_L=100Ω.





(a)





(b)

Fig.11 Simulation result for SBC with (a) SC (b) SC/SL

The simulation results of both type of converters are demonstrated in Fig.11. Fig. 11(a) shows the waveforms obtained with Switched-capacitor SBC. As can be observed that when d (duty ratio) is considered to be 0.5, the capacitor voltages V_{C1} and V_{C2} are magnified up to 25V and 35V, respectively, and the magnitude up to of obtained voltage gain V_o is 40V. While d (duty ratio) is considered to be 0.8, capacitor voltages V_{C1} and V_{C2} are 41V and 51V and thus, the output voltage V_o is 60V in fig11(b). This implies that with the same duty ratio, high voltage output is obtained with SC/SL SBC in comparison with that is obtained by SC SBC.

V. Conclusion

The combined switched boost converter has been presented in this paper. Presented converter is a combination of conventional dc-dc converter with switched capacitor and switching structure of switched inductor. These proposed converter large step-up capability with reducing voltage stress and spikes across active switched and output diodes than conventional switched-boost converter. Operating principle based on continuous conduction mode, combined switched boost topology and simulation results are presented. Thus presented structure enhances the performance for different applications with better achievements. Further, cascading cells can be propagated to obtain very high gain voltage at output.

***Abstract* - Nowadays, Electric vehicles (EV's) have received much consideration as a substitute for conventional Internal Combustion Engine (ICE) vehicles for having exceptional highlights, for example, low emanation, high proficiency, calm activity, and so forth. But the major issues faced with EV (related with Control system) are Acceleration and Range (travelling distance). The use of the Regenerative Model in (EVs) offers regenerative of energy, battery protection, and improved vehicle increasing speed. The regenerative model for EVs driven by PMDC motor has three modes Normal vehicle mode, Regenerative mode and Battery charging mode. During Regenerative mode (No acceleration, vehicle is in motion) the PMDC works like a generator and this energy is harvested. Henceforth, by utilizing a suitable switching control, the DC voltage is enhanced and the energy is exchanged from the capacitor bank to the battery. The Regenerative Model improves the bank is used to develop vehicle battery security.**

Keywords — Electric Vehicle, Capacitor Bank.

I. INTRODUCTION

Electric Vehicles (EV's) have received much consideration as a substitute for conventional Internal Combustion Engine (ICE) vehicles. EV's uses battery framework which can be energized from standard electrical plugs. Since the demonstration qualities of EVs have become analogous to which is not better than, those of conventional ICE vehicles [1]. The chemical batteries have many deficiencies such as short cycle-life, less power density, as well as high cost, capacitors bank, offer numerous highlights like, high power, long life-cycle [2]. Although the capacitor bank offers better features in most of the characteristics, it cannot be used as principle component for storage since its energy capacity is generally low so the battery must be utilized as a principle energy storage unit. The converter is used to control the power stream between the battery and the capacitor bank. The converter is important to coordinate the power levels of the capacitor bank, so as to use the abilities of the capacitor bank, adequately.

The measure issues faced with EV (related with Control system) are Acceleration (pick-up), Range (Traveling distance), and Speed range (Maximum). The batteries have numerous inadequacies such as short life-cycle, less power capacity and high cost. Due to the limited capacity of a battery, it can travel up to a few kilometres only in one charge [9]. In this model, a structure of collaboration of battery and capacitor bank is suggested [8]. The designed regenerative model is made out of a capacitor bank, battery, buck/boost circuit, and diode. Different working modes of the suggested Regenerative model are:

1. Vehicle normal mode.
2. Regenerative mode.
3. Battery charging mode.

In this paper, different modes of Regenerative Model have experimented and they are as above mentioned. These modes of operation can give better performance Characteristics of EV's with ON – GO charging and increase the traveling distance. The remaining part of the paper is structured as follows: Section II describes the block diagram and detailed circuit diagram. Section III describes different modes of operation. Section IV discusses the results achieved. Section V concludes the paper.

II. BLOCK DIAGRAM

The block diagram presented in Figure (1), comprised of a capacitor bank to store the harvested energy, battery is the main storage, buck/boost converter is to convert voltage to appropriate battery level, and a diode. Diverse activity methods of the proposed regenerative model are advised in details. During Idle state, using a relevant switching control for the converter. Hence, the diode will be forward biased and the energy reproduced is collected by the capacitor bank without employing extra power converter. Voltage in the capacitor bank is balanced by PWM control through variation in duty cycle in converter. Consequently, when the capacitor bank is nearly charged, regenerative braking can be acknowledged by methods for the battery pack in the proposed strategy. Figure (2) represents the detailed circuit diagram of

the Regenerative Model which consist of 4 switches for operation of different modes.

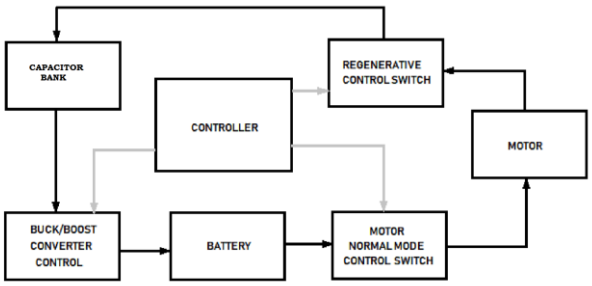

Figure 1: Block diagram of Regenerative Model

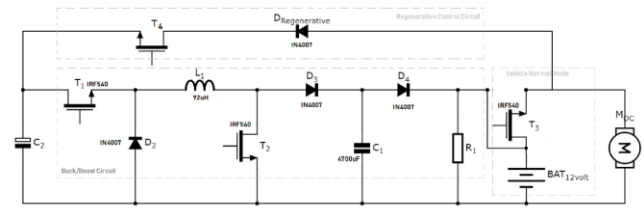

Figure 2: Circuit diagram in details

III. Functioning of Different Modes

The suggested Regenerative Model are categorized by its different modes of operation which are briefed as follows:

A. *Vehicle Normal Operation Mode*

The energy stream in the normal operation mode is shown in Figure (3). Here, the capacitor bank voltage is greater than the battery voltage hence, D1 is reverse biased. Furthermore, the capacitor bank module is idle as the buck converter is turned OFF. Hence, the battery exclusively supplies the energy to DC motor.

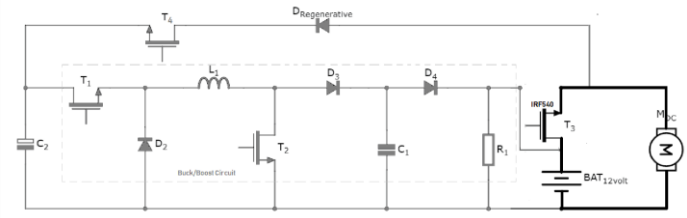

Figure 3: Vehicle Normal Mode operation

B. *Regenerative Operation Mode*

Figure (4) represents current flow during Regenerative mode with capacitor bank. It ought to be noted that the regenerative operation is initiated only if the vehicle in motion (no acceleration applied). High power capacity of the capacitor bank be able to be used to adequately collect the kinetic energy of vehicle (in motion) during this condition. Subsequently the regenerated energy could be efficiently saved, the driving scope of the vehicle can be impressively expanded. For Safety considerations and efficiency the Capacitor bank is proposed.

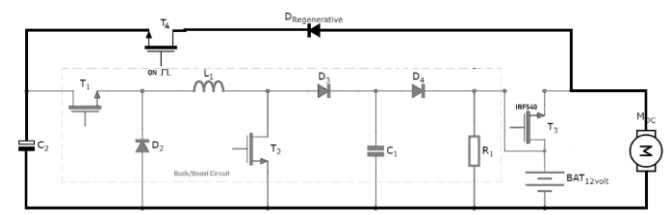

Figure 4: Regenerative operation with capacitor bank

C. *Battery Charging Operation Mode*

In this mode, energy is moved from the capacitor bank to battery through the buck-boost circuit and henceforth, regenerative braking energy is collected by the battery. Figure (5) indicates the current flow path during battery charging from capacitor bank through the Buck/Boost circuit. The DC voltage be able to boost/buck in the identical way and the energy is moved to battery through D3 and D4. Considering the changing aspects of the regenerative procedure, battery charging, and capacitor bank charging, it results that the impact of the capacitor bank is meaningfully greater than the battery for collecting the energy.

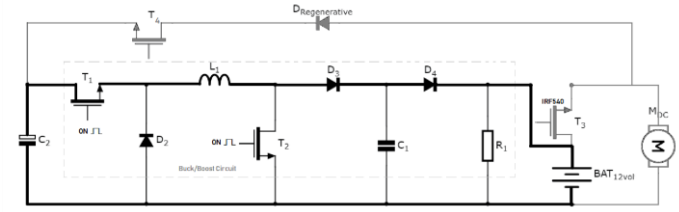

Figure 5: Battery charging from capacitor bank through Buck/Boost circuit

IV. Results & Discussion

Results are divided according to different modes of operation:

A. *Vehicle Normal Mode*

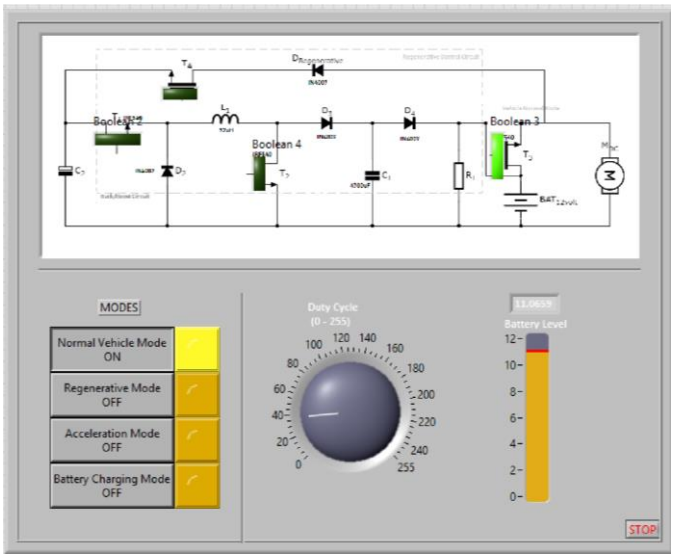

Figure 6: Vehicle Normal Mode Control

Table 1: Vehicle Normal Mode Working

Mode	T1	T2	T3	T4	$D_{Regenerative}$	Description
Normal Vehicle Mode	OFF	OFF	ON	OFF	OFF	T3 switch is made 'ON', Regenerative model operate the vehicle in a forward motoring shown in Figure (7)

Figure (6) shows the control panel for regenerative vehicle normal mode when the normal mode button is ON the motor starts rotating.

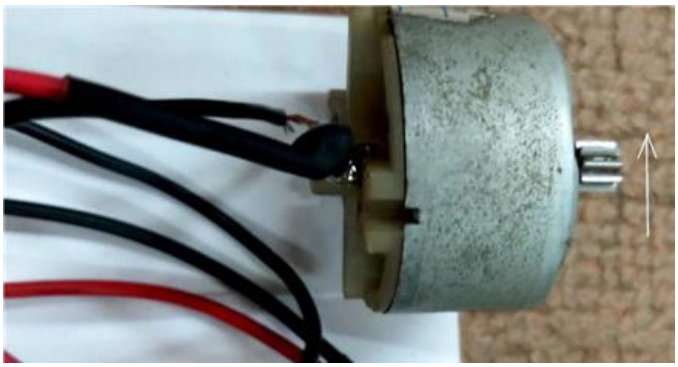

Figure 7: Motor rotating in a forward direction

Figure (7) shows the motor rotates in the forward direction when the regenerative model in Normal Vehicle Mode. Table (1) show the component which will be ON and OFF during this Mode.T1, T2, T4, and $D_{Regenerative}$ be OFF and T3 is ON.

B. *Regenerative Mode*

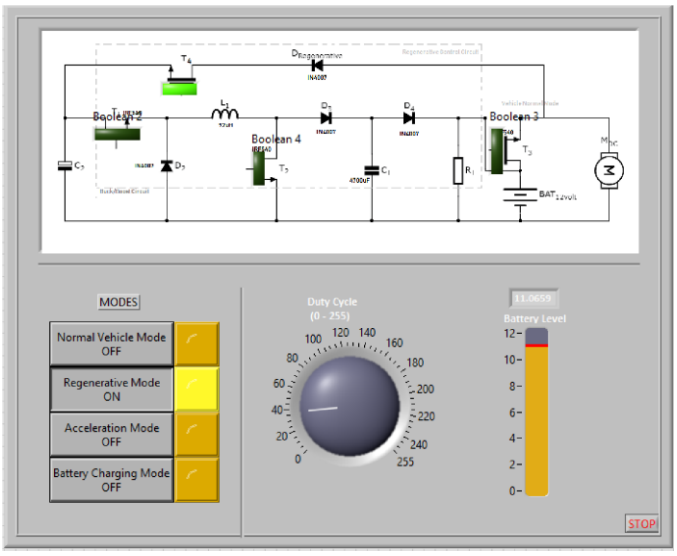

Figure 8: Regenerative Mode Control

Table 2: Regenerative Mode Working

Mode	T1	T2	T3	T4	$D_{Regenerative}$	Description
Regenerative Mode	OFF	OFF	OFF	ON	ON	$D_{Regenerative}$ Diode act as forward biased and the T_4 switch is 'ON', the energy is absorbed and stored using capacitor bank. The harvested voltage 2.21v by capacitor bank in shown in Figure 9.

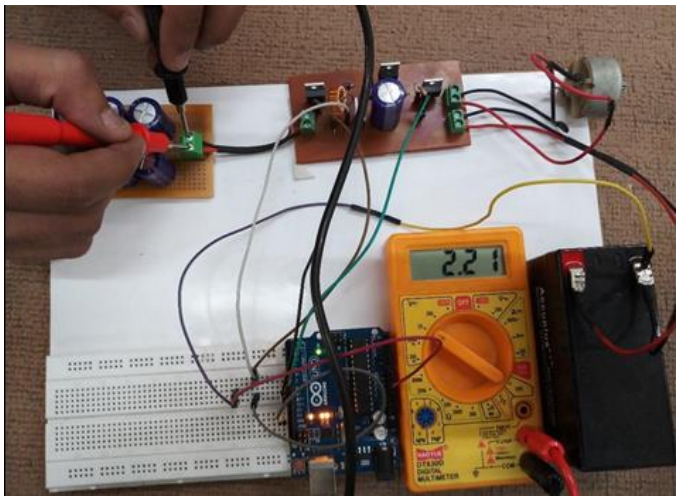

Figure 9: Voltage stored in the capacitor bank

In Regenerative mode, the energy generated by the motor is harvested and stores into the capacitor bank. Figure (8)

shows the control where Regenerative mode is ON. Table (2) shows the ON and OFF status of Components here T4 is ON and $D_{Regenerative}$ diode forward biased. Figure (9) shows the voltage stored in the capacitor bank during this mode.

C. *Battery Charging Mode*

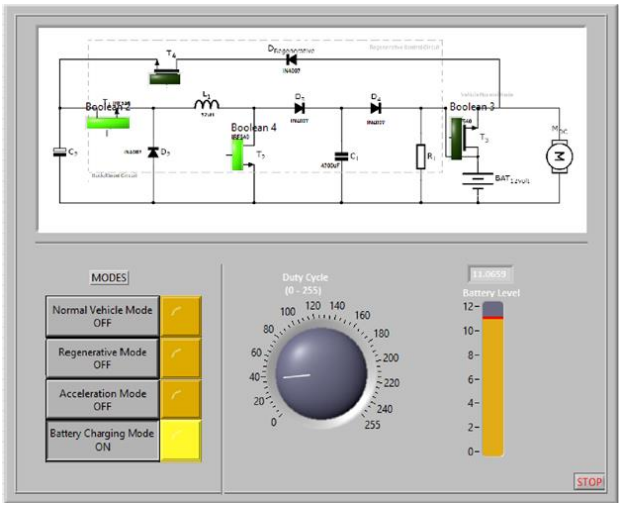

Figure 10: Battery Charging Mode Control

Table 3: Battery Charging Mode Working

Mode	T1	T2	T3	T4	$D_{Regenerative}$	Description
Battery Charging Mode	ON/ OFF	ON/ OFF	OFF	OFF	OFF	T1 and T2 switches are made 'ON/OFF' according to Buck and Boost Operation.

By using the applicable switching control, voltage is Boosted/Bucked by power converter. The voltage is tuned over variant of the duty-cycle of PWM. Hence, regenerative energy can be collected by means of the battery. Shown in Figure (11). Table (3) shows the Battery Charging Mode Operation.

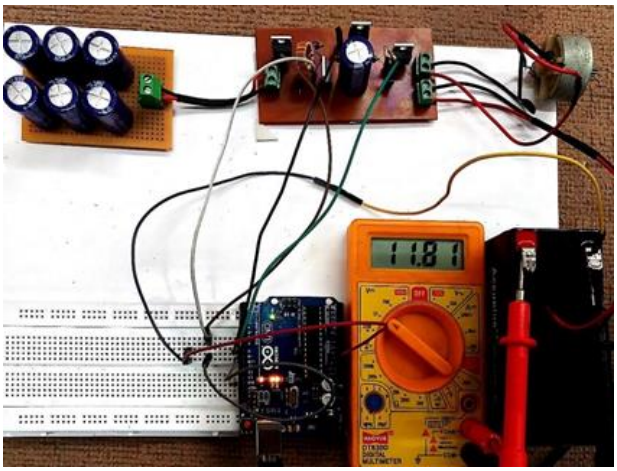

Figure 11: Battery voltage

V. CONCLUSION

Utilization of Regenerative model is suggested for EV's with PMDC motor. The Regenerative model circuit for EV's application is successfully designed and implemented. During this mode, kinetic energy of vehicle is harvested by capacitor bank.

The results are achieved for EV when the motor is driven in normal mode and in Regenerative mode. The Energy harvested is 16.66% of total battery capacity during the Battery Charging mode. The outcomes for Acceleration Mode are still under review.

In the future, the issues faced with Electric vehicle can be solved by employing an automatic control system for different modes of Regenerative model in appropriate conditions along with better acceleration, battery safety with ON-GO Charge.

Abstract— **Data acquisition is a ubiquitous application for multiple fields and multiple environments. Till today, there is a vast demand and requirement of data loggers in automobiles to monitor and control several parameters. Therefore, data acquisition system for automobile application is discussed in this paper. While we are driving a vehicle, we sometimes take a left or right turn to overtake the other vehicle. While we are overtaking this there may be a chance of hitting the other vehicle or may be a chance of accidents. To avoid this, there should be an auto left or right indicator control with the help of accelerometer sensor. In addition to this, auto air conditioning in automobiles can be controlled by using temperature and humidity sensors. The proposed system is discussed about design and implementation of data acquisition system used for automobiles to perform above said applications. It is implemented using reconfigurable device, appropriate sensors and computer aided design tools. The communication of these sensors is performed with serial peripheral interface.**

Keywords—Analog to Digital Conversion, Data logger, Field Programmable Gate Array, Peripheral Module, Serial Peripheral Interface.

I. INTRODUCTION

Data acquisition system is the process of digitization of the data in a format that computer or a system can understand. High speed data acquisition system means sampling the data rate at high speed. Here, we are using a sampling rate of up to 1 million samples per second. Hence, proposed system is designed to acquire high speed data acquisition system for automobiles. As automobiles are increasing in day to day life, and driving with heavy speed, accidents are occurring.There are few ways to reduce that. one of the ways to reduce the risk of accidents is by keeping acceleration monitoring and controlling instrument.

In the proposed system, the monitoring is done by 3-axis accelerometer sensor [6], temperature and humidity sensors. 3-axis accelerometer sensor is used to measure static acceleration of gravity in tilt sensing and temperature and humidity sensors are used to monitor the AC temperature based on the sensor values.

Like any other data acquisition system, the automobile data acquisition system also consists of sensors, whose output signals are in analog form that has to be converted in to digital form to understand, process, and display the acquired results. The analog data from different sensors can be accessed by 4 channel or 8 channel multiplexers or data selectors. Between sensors and multiplexers, signal conditioning is required. The data access can be done by either serial or parallel manner depending on the required applications. If it is serial communication, we can use either Inter-Integrated Circuit I^2C or Serial Peripheral Interface SPI.

The main objective of this research work is to design high speed data acquisition system suitable for automobile applications. It is developed using Very High-Speed IC Hardware Description Language. Reconfigurable device, FPGA is used as the core of the data acquisition system, which collects, process and displays the data. FPGAs are the high-speed reconfigurable devices to process high-channel-density signals.

The organization of the paper is explained in XI sections including introduction. Section II is discussed about the history of the data acquisition system used in automobiles. Architecture design of the proposed system is explained in section III. Here, the interfacing of the sensors with the FPGA board is discussed in detail. Software Design Flow of Data Logger is explained in section IV. Section V shown about Results and Discussion of the proposed data logger system.

II. LITERATURE SURVEY

Prevention of accidents due to automobiles can be reduced by monitoring the vehicle velocity and acceleration using Raspberry Pi [1]. The communication used here is I2C protocol, the velocity and acceleration values are stored in SD card of Raspberry Pi, and there are some results of velocity and acceleration with respect to time.

The author in [2] explains about the acceleration data which is acquired from MEMS accelerometer and processed

through Spartan-6 FPGA. It was developed with VHDL and implemented in the Spartan-6 FPGA.

Tilting angle can be detected by using 3-axis accelerometer ADXL335 and Arduino Uno board was used to process the data. Tilt is measured towards its left or right direction[3].

To improve reliability and safety of automobile applications, real time embedded systems for automobiles that are used different sensors like MEMS Accelerometers, gyroscopes, pressure sensors, magnetic field sensors [4].

An efficient system has been designed in [5] for prevention of accidents in automobile systems. The main objective of the project is to design an app for car driver for safe driving of vehicles. The sensors are interfaced with Raspberry Pi, to monitor the required data.

The 3-axis MEMs accelerometer using AT89C52 microcontroller for the activation of airbag system for automobile applications discussed in [6]. They have used GPS and GSM SIM 900 to know the vehicle location exactly and it will drop a message.

The design of data acquisition system in [7] proposed a mechanism for patient monitoring in medical applications using FPGA. Here, they have used temperature and pulse rate sensor and produced some ECG waveform results.

Implementation of data transfer using Ethernet with a development board of Virtex-5 FPGA is discussed in [8]. Here, the results were displayed through SCD nothing but GUI and hyperterminal.

References [9], [10] and [11] are referred for the specification details of accelerometer, humidity and temperature sensors. The Zybo board architecture is referred from the references [12] and [13]. Finally, referred the software tool details from references [14] and [15].

III. Architecture design of the proposed system

In this design, we have used three sensors:accelerometer, temperature and humidity sensors. The ADC is used for converting the signals from analog to digital signals. The design is loaded in Artix 7 FPGA which consists of programmable logic, and interfacing of sensors are performed by processing system and ARM9 processor. The sensor interfacing with FPGA, which holds the automobile data acquisition system is illustrated in Fig.1.

A. Interfacing of Temperature Sensor

Temperature monitoring and measurement can be done with a temperature sensor LM35 in this proposed system. As it can measure the temperature range from −55°C to 150°C, and can have the calibrated value. It converts the voltage levels to temperature by using the relation as follows. VOUT = 10 mV/°C × T. Where, VOUT is the LM35, output voltage and T is the temperature in °C [10].

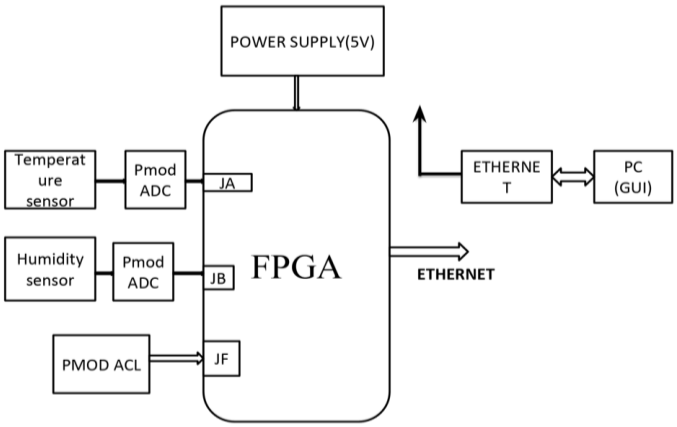

Fig.1 Interfacing of sensors with FPGA Board

The purpose of using this temperature sensor is used to know the exact temperature accumulated in the vehicle. Based on this temperature value, air conditioning (AC) can be maintained with a constant flow of conditioned air according to the passenger required option. The operating voltage of LM35's range is from 4V to 30V. It has 3 pins with naming VCC, GND and VOUT pins.VCC pin of LM35 is connected to VCC pin of ADC, GND pin of temperature sensor is connected to GND pin of ADC and VOUT pin of the sensor is connected to A0 pin of ADC peripheral module.

B. Interfacing of Humidity Sensor

In addition to temperature sensor, humidity sensor is also used to control the AC used in vehicles. The part number of humidity sensor used in the proposed work is SY-HS-220. Humidity is defined as the amount of water present in air. The operating range of humidity is 30-90% RH [11] and storable temperature range is from -30°C to 85°C and its current consumption will be less than 3mA. It consists of 3 pins namely VCC, GND, and VOUT as shown in Fig.2. VCC pin is connected to VCC pin of ADC peripheral module and GND pin of the sensor is connected to GND pin of PMOD ADC and output pin is connected to A1 pin of PMOD ADC.

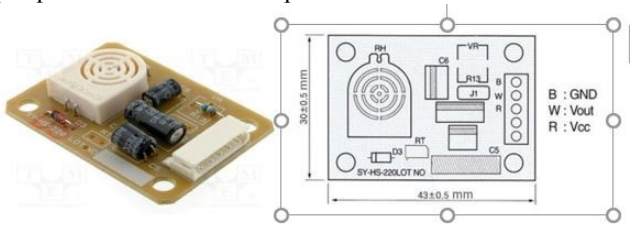

Fig.2 Humidity Sensor

In the proposed system, temperature and humidity sensors are connected to external ADC. It is 12 bit Analog to Digital Converter with part number AD7476A and the sampling rate of 1 million samples per second.

C. Interfacing of AccelerometerSensor

One of the most commonly used sensors in automobile system is accelerometer sensor. This sensor is used to measure the tilt angle in three dimensions. Based on the tilt angle, the indicator direction can be decided by the control unit used inthe automobile system.

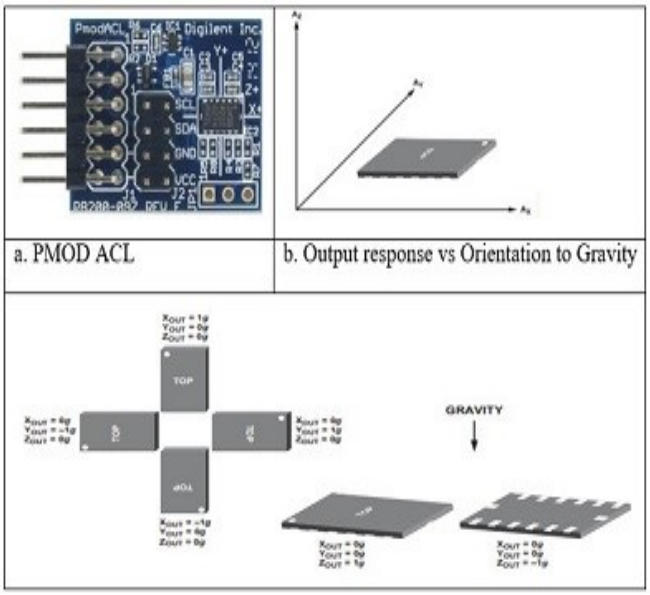

Fig. 3.Accelerometer sensor

Peripheral module for 3 axis accelerometer sensors used in the proposed work is ADXL345. It can measure the range up to ±16 g. It measures the gravity in tilt sensing applications. It gives the acceleration of gravity in x, y, and z axis respectively. It is interfaced with FPGA using serial peripheral interface (SPI). CS is the serial port chip select pin that is controlled by the serial peripheral interface. SCLK is the serial port clock. SDO and SDI is the serial data output and input respectively. It has 12 pin PMOD port with SPI interface [9].

The algorithm for single axis is illustrated in Fig.4. Raw angle is calculated by integrate the rate sensor output in real time. The accelerometer, ADXL345 is used to measure the direction of gravity and infer a tilt angle. The error signal can be calculated by calculating the difference between raw angle and gravity angle. Now, the stabilized angle can be calculated by mixing the raw signal with k times the error signal as shown in Fig.4. For example, if we get 0.1 G acceleration in the x-axis, then, it indicates a tilt of arcsine (0.4) = 23.57°. Once, if we could find the tilt angles, gravity of acceleration can be measured on x, y and z of accelerometer axes. Consider a rotation matrix with x, y and z axis aligned with the automobile, using pitch and roll, can rotate acceleration vector to the equivalent vector level with respect to earth as shown in Fig.5. In this system, gravity is completely vertical, therefore the level of x and y axes can measure motional acceleration, not gravity. The system discussed here can be implemented in real time, inexpensive system for vehicle motion testing.When these tilt value exceed the specified limit with respect to left or right then there will be auto indication of light.

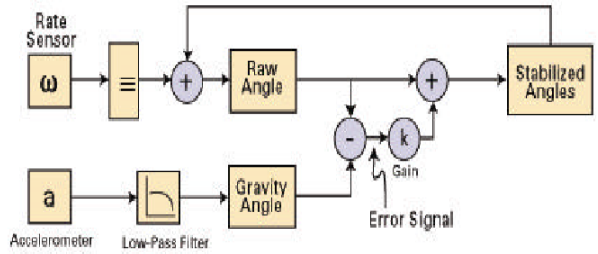

Fig.4 Stabilized angle calculation

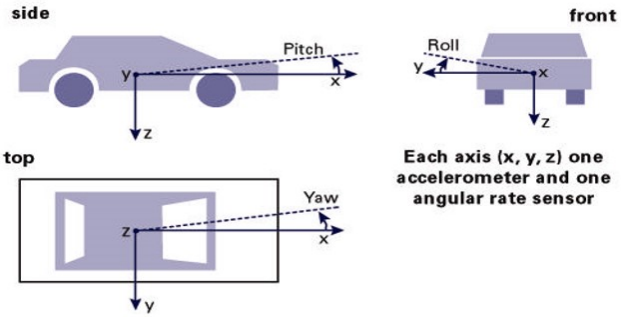

Fig.5 Sensor axis on automobiles

In the proposed system, the Zybo- FPGA development board which consists of Zynq processor and Artix 7 FPGA that are used to meet the specifications of high-speed data acquisition, high performance, with low power consumption. The Zynq-7000 SOC architecture consists of two major sections known as Processing Systems (PS) and Programming Logic (PL). FPGA comes under PL which holds the design logic and ARM Cortex-A9 Processor comes under PS which is used to control the peripheral interface. There are six PMOD connectors in this Zybo board. We connected temperature, humidity and accelerometer sensors to this FPGA board using PMOD connectors: JA, JB and JF respectively as shown in Fig.6.

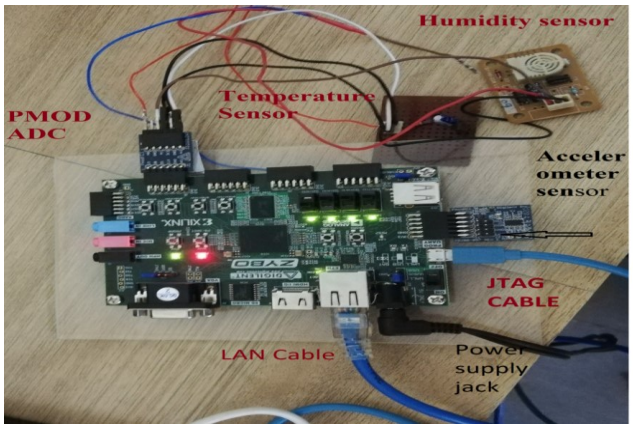

Fig. 6. Interfacing of three sensors with FPGA using Zybo development board

IV. Software Design Flow of Data Logger

To design data logger system, RTL design is created using hardware description language and XILINX 1SE 14.7 front end software tool. After verification, next step is we need to add required GPIO's in EDK (Embedded Development Kit). Then implement the design and generate bitstream for data logger design. After generating bitstream file, we need to export Hardware Design to software development kit (SDK) including the bitstream file. At SDK, we need to create application project along with application software developed in C and select as Light Weight Internet Protocol (lwIP) for Ethernet communication.

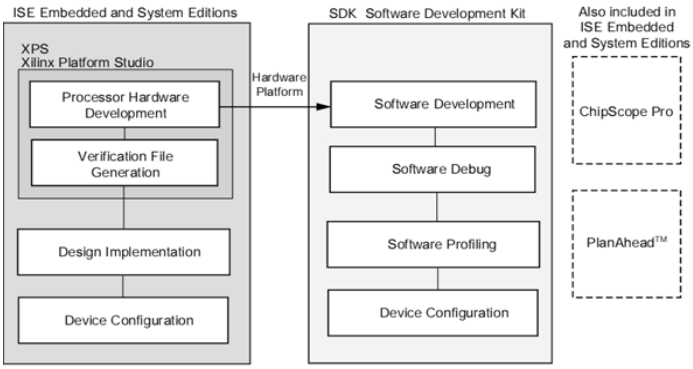

Fig. 7Embedded Design Process Flow

V. Results and Discussion

At SDK, board support package (BSP) is used to build the project. Once, the application project has built without errors and warnings, we can program the FPGA and then launch the hardware to verify the results. Make sure, the hardware setup has to be done and connected to a system where we can process all these steps. The Zybo board is connected to Ethernet cable using TCP/IP protocol. The communication between FPGA and PC is via Ethernet cable. The data is displayed using GUI. We need to assign IP address to PC which should be same as the board IP address. Now, Batch file need to be loaded into FPGA using JTAG cable. Now, we can ping the IP address. Then, after the establishment of proper link there will be a communication between board and system.

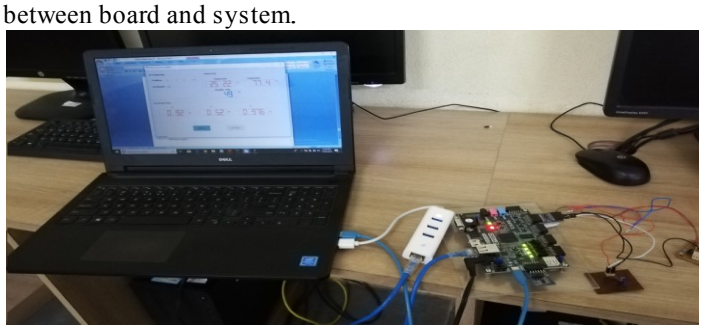

Fig.8 Experiment Setup for the data logger

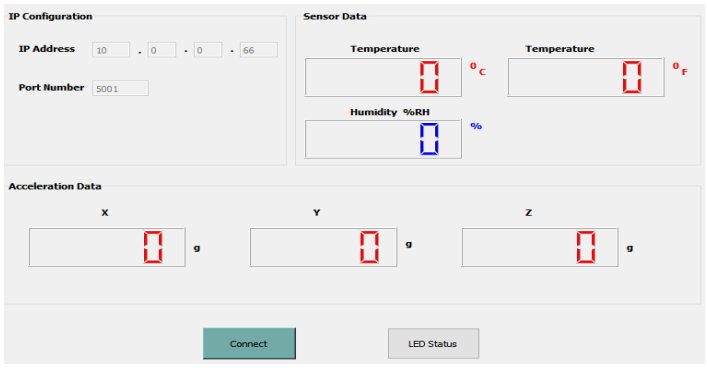

Fig.9 GUI display of data logger when no sensor is enabled

When no sensor is connected to proposed Data logger, then we can observe zero values at the GUI display as shown in the Fig.9.

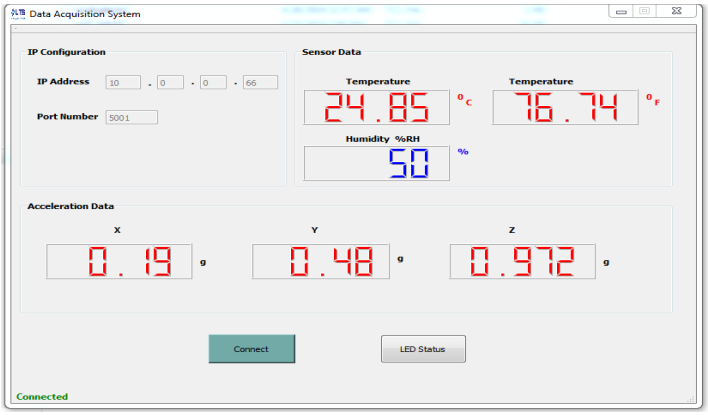

Fig:10 GUI display of data logger when sensors are enabled

When sensors are connected to proposed Data logger system, then we can observe respective measured parameters of the sensor values at the GUI display as shown in the Fig.10.

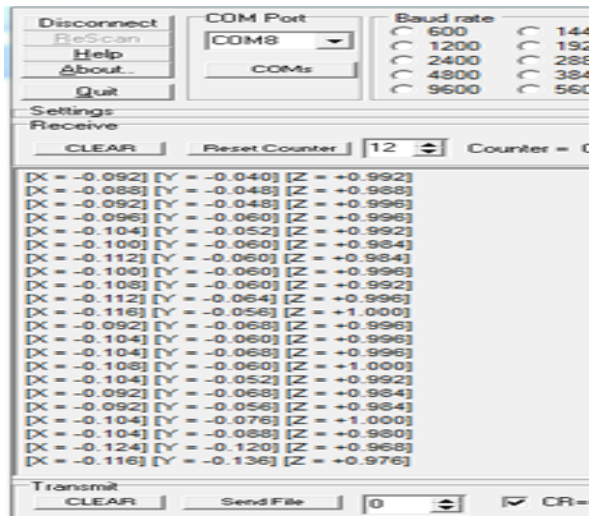

Fig. 11 Output results through terminal(acceleration tilting angle in x,y,z axis)

Terminal view for accelerometer sensor of x, y and z axis can monitor the gravity of acceleration in all x, y and z axis according to the movement of the vehicle. TeraTerm terminal is used when COM Port is connected.

VI. Conclusion

In the proposed data logger system, auto indicator options can be deployed based on the tilt angle of the accelerometer sensor. In addition to this, auto air conditioning feature also performed with reliable sensors and reconfigurable device. Based on the experiment results we can conclude that the proposed design gives accurate, high speed and reliable monitoring is possible in real time automobile applications.

Multiple sensors can be used for providing more comforts and security related features in automobiles like navigational system, tyre pressure monitoring, auto parking, telematics and alcoholic detection, back up collision sensors and many more.

Abstract— **Now-a-days, digital image processing in medical diagnosis is essential in almost all medical fields. Human eye is usually used to visually interpret a processed image as how well a particular technique used for its processing has worked. In medical diagnosis, two important techniques viz computed tomography (CT) offers less distortion with better information on denser tissues while magnetic resonance image (MRI) offers high distortion with best information on soft tissues. The multimodality of medical images in clinical applications has framed the idea of combining clinical images of distinct modality in medical applications. This knowledge of fusing clinical images has raised a new promising research field. The experiments on image fusion technique shows that it could extract useful information from distinct source images in fused images in order to obtain clear images. In this paper, an image fusion system with standalone hardware implementation framework is proposed. Xilinx platform studio (XPS), Visual Basic (VB) software's and FPGA Spartan 3 image processing kit is used for implementation. Firstly, input images are converted to .h files using MATLAB GUI. Then XPS is used to pick software and hardware components for fusing the images by incorporating source and .h files and converting them to bit streams for downloading them to FPGA Spartan3 kit. The fused image as obtained from FPGA can be seen using Visual Basic Graphic User Interface (GUI) on the monitor.**

Keywords— FPGA based implementation, SFTA, texture feature extraction, DWT.

I. INTRODUCTION

Recently, the huge advance in medical diagnostics methods has greatly improved the performance of assessment and reflection. The latest advances in magnetic resonance imaging (MRI), nuclear resonance instrumentation (NMRI) and Computed Tomography (CT) are used to picture the body's anatomy and physiological procedures. MRIs and CT's offer a 3D perspective and other high resolution features on distinct rates to detect any disease or abnormality.

This research focuses on the wavelet texture based function assessment of brain MR and CT pictures and their FPGA execution. Texture analysis (TA) has been demonstrated as an effective technique to detect any disease, such as brain tumor, etc. TA is the collection of matrices that offers the basis for the assessment of any specific picture and to check if the analyzed picture has texture similar to its sample.

Magnetic Resonance Image (MRI) offers high distortion with best information on soft tissues. The multi-modality of clinical images in medical applications has framed the to combing clinical images of distinct modality in medical applications

A. Brain MR and CT imaging

MRI is a clinical method for scanning inner nerves and tissues additional to X-ray and CT scans. The MRI of the brain system is made up of radio waves and magnetic field used to produce accurate brain pictures. It is capable of producing a three-dimensional brain perspective used to analyze any brain tumor diseases. The brain comprises of three main constituent groups of soft tissues like gray matter, white matter and cerebrospinal fluid. So, the quantity of GM, WM and CSF and their special allocation inside and chronological modifications need to be measured for the diagnosis of different brain diseases. The brain three tissue categories are shown in Figure 1. The three distinct planes i.e. axial plane, sagittal plane and coronal plane MRI are shown in Figure 2. This helps in study brain disorders such as various sclerosis, brain tumor Alzheimer's illness etc.

MRI and CT can identify various circumstances such as kysts, bleeding, Brest lesions, inflammation skeletal defects, ear diseases and blood vessel problems. Brain MRI and CT considers it useful to access the issues like dizziness, headaches, vulnerability and blurry. It can imagine the brain parts capably and at several resolution levels that X-ray and CAT scan cannot produce.

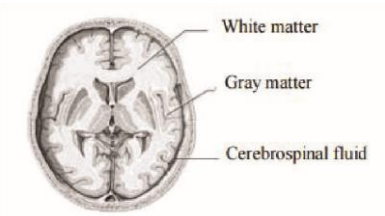

Figure 1. Brain MRI main tissue classes

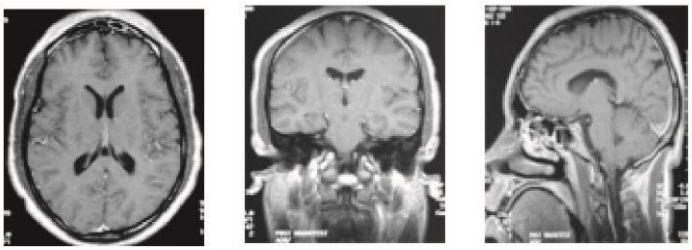

I. Axial View II. Coronal View III. Sagittal View

Figure 2: Different views for Brain MRI

TA plays a crucial role in diagnosing various diseases types and wavelet transformation along with gabor filter provides a framework for assessing the texture of brain MRI. TA includes extract, segment, classify and reconstruct features.

B. Discrete Wavelet Transform

Recently wavelet conversions that decompose a message into two parts, namely approximate and comprehensive part, are gaining more exposure. Freedom to choose the scale of decomposition is another advantage. So essentially this is a multiresolution analysis of brain MR images using three-dimensional resolution at different scales.

The discrete wavelet transformation (DWT) contains data about location information and frequency. The picture is decomposed into 4 sub parts LH1, LL1, HL1 as shown below in Figure 3 and Figure 4 for two different resolutions.

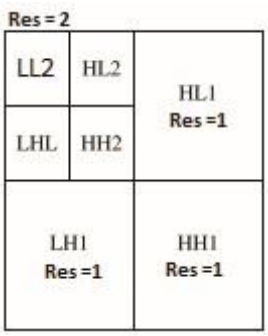

Figure 3: Single level Data/Image decomposition

Figure 4: Double level Data/imaged decomposition

The three parts of sub bands LL1, HL1, HH1, are called the numbers of estimation and element of LL1 is called precise index. The estimation ratio includes the peak sample data and can be used to divide the picture further in LL1. Figure 4 demonstrates the double-level picture regression using wavelet where the subbands are created again from LL1 as LL2 (ratio of estimation) and the comprehensive values are HL2, LH2, AND HH2. Similar to tier one decay, it is also possible to use LL2 subband to further decompose the message. LL subband is referred to as the crude point coefficient as it includes the highest data in all stages of decomposition. The converted indices are helpful for color assessment and discrimination at all subband concentrations. The numbers acquired in the pictures subband and/or their proportions portray the images texture distinctly.

C. Image fusion rule

Image fusion method is mostly performing a very fundamental operations such as pixel selection, addition, subtraction or averaging.

Simple Average: It is a fact that higher pixel intensity can be seen in the focused regions of the images. Hence, this method is a simplistic way of getting an output image with all regions that are in focus. Each image pixel value is taken and added. After this sum is divided by 2 to acquire the average value. Average value is allocated to the corresponding pixel of the output image. In the same way it is repeated for all pixel values.

Select Maximum: The pixels have greater values for more focused regions of the image. This rule suggests that it selects the in-focus areas from each input image by selecting the greater value for each pixel, resulting in highly focused output. Hence, each image pixel value is taken and compared to each other. The pixel having greater value is assigned to the corresponding pixel [22] [23].

Average of approximation coefficients is chosen in our Image fusion for both decomposed images so that low frequency information which is approximate information is not lost and high frequency information which is detail information is preserved. Therefore, corresponding vertical, horizontal and diagonal coefficients of both source images are compared and select maximum rule is applied to get maximum coefficient value that is assigned to corresponding coefficient in fused image.

D. Image fusion using DWT and inverse DWT.

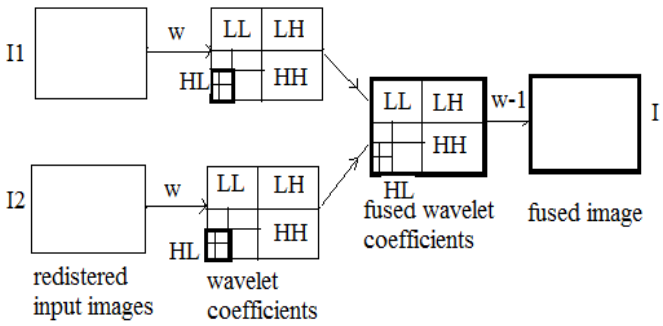

Figure 5. Process of fusing an image using DWT and Reverse DWT Methods

The development of DWT is used to apply the transformation technique to the digital information. The signal is disintegrated by the filter banks' low-pass and high pass filters. Image fusion steps are explained in detail based on WT in Figure 5.

- The input images I1 and I2 are first registered to arrange the equivalent pixels.
- DWT transformation is applied on the registered input images. The images are decomposed using wavelet bases. Here, wavelet transformation uses K-level decomposition on the registered images to obtain single low-frequency portion (LL band) and high-frequency 3K portions (HL bands, HH bands and LH bands).
- Different portions of the DWT image having with transform coefficients are achieved with an average of approximation fusion rule as explained in section I(C)
- The construction of fused image is done by performing inverse WT

Filter banks are used to decompose the signal into low and high-frequency components. Generally, most of the information of the signal lie at low frequency components. More details of the signal are available at high frequency components. Two-channel filter bank is used to implement wavelet decomposition technique. The decomposition of the image is done column by column and row by row. For illustration, the method to an M x N image as follows.

- The filter distinguishes each row and down-sample to obtain two M x (N/2) images to form H and L images.
- H and L images are formed using the formula

  H= odd-even = G1;

  L= round (G1/2) +even;
- Again, the filter combines each column and subsample of the filter to get output forming 4 (M/2) x (N/2) images. This is obtained using.

  LH= odd – even = G2;

  LL= round (G2/2) + even;

  HH= odd – even = G3;

  HL= round (G3/2) +even;
- G1, G2, G3 are reference parameters. The sub-image formed by low pass filtering is taken as LL image. in the same way using filtering other three sub bands formed are LH, HL and H. The sub images formed above can again be sub divided using filters and can form sub-sub bands and can be continued till desired filter images are obtained.
- Average of approximation fusion rule is applied on each pixel of the subbands of both the DWT images of the corresponding pixel to obtain a pixel with a single transform coefficient of the subband.
- The obtained sub bands of both images are having combined transformation coefficient. Using the combined transformation coefficient, the inverse or reverse DWT technique is applied to get fusion image. The fusion image obtained has the characteristics of both the DWT images that is useful for further observation.

E. Implementation tool:Field Programmable Gate Array (FPGA)

FPGA Procedure allows consumers or developers to develop logic circuits that could be reconfigured in real runtime, FPGA technology provides hundreds of combination of logic sets, a big range of entry output buttons and interconnections that are used depending on the provided logic.

The Zynq Evaluation and advanced board (ZedBoard) was used in this work to introduce the image handling scheme centered on extracted features. Xilinx ISE/Vivado HLS has been selected to program the FPGA board. The Xilinx ISE takes advantage of the concept of using intellectual property (IP'S) as section models and subsequently generates chip code for integrated layout. It includes the required features and can allow customization according to the chosen device by allowing creation of the custom computer logic. The board's expandability characteristics makes it perfect for rapid prototyping and proof-of-concept creation. Software portion can be coded using C, C++ and OpenCV for image processing tasks. Implementing the wavelet conversion on FPGA offers the advantage of reconfigurability at real runtime, simultaneous handling and execution of speed could be comparable to those achieved in software implementation.

II. BACKGROUND

There are basically two primary measures to follow for the diagnostic procedures in pathology. First procedure is that the tissue will be observed by a pathologist to recognize certain characteristics. The second step is to interpret and come up with a response. Several techniques to section and estimate the brain tumor have been suggested so far. Hall and Clark [1] suggested the picture mosaic as an assessment technique to assess the defects of the MRI scan. 57 Mosaic pictures were created by slicing ordinary fabric into different forms and sizes of defects. Using sophisticated diameter methods, Ibrahim and Khalid [2] suggested cancer identification using MRI information. Parra and Ifetekharuddin [3] suggested a scheme that automatically segments a tumor in the human brain's MRI. In [4], an improved application of the artificial neural net work software is used to block brain MRI information processing vector quantization and the findings achieved indicated great brain tissue segmentation.

Many algorithms for extraction of features are also used in this aspect. One among them is Texture Assessment (TA). TA performs a major part in the assessment of image segmentation. It has several applications like earth source mapping, medical processing, distant viewing, performance monitoring etc. Because TA is a sophisticated method and is linked to the local models of a picture, both picture removal and quantization are permitted. TA performs a major part in the assessment of image segmentation. It also out-performs the techniques of individual outcomes assessment and produces more precise diagnostic accuracy outcomes. Analysis of texture comprises essentially four steps [5]. Firstly, extraction of textual features, secondly, segmentation, thirdly, classification of texture

discrimination/classification, lastly, reconstruction of shape. Many algorithms are currently used to do so, but the most common of all current techniques to date are statistical methods and techniques appropriate for sophisticated medicinal imaging applications [6]. Most of the arithmetical methods are focused on temporal gray tier reliance model (TGTRM), gray point cooccurrence matrices [7], dominant cycle distance matrices (DCDM), statistical approaches centered on the use of textual assessment methods like Markov's test fields [10], fractal methods/models [11], and so many methods are appropriate for applications like textual characterization [8]. Since image analysis is conducted on a solitary scale, even though the visual cortex in a natural pictorial scheme is designed for depiction in a collection of autonomous streams with the specified direction and special frequency tuning [12] and it is a significant drawback. DWT's have a significant benefit by enhancing accuracy owing to multi-scale capacity and time-frequency localization relative to Gabor filter-based methods and TA Fourier transform [13], [14]. [15] and [16] uses two-dimensional wavelet extraction techniques for effective brain CT and MRI segmentation and texture analysis. These techniques are used alone in numerical methods.

Many DWT FPGA architectures were suggested to enhance time and resource consumption, primary focused on convolution [19], [20] and elating [21] schemes. Some of the parameters are not taken into account like group delay when calculating DWT and these delays have no effect in the processing of images or after the frame is processed by frame message, this architecture is considered. When the sample is processed by sample flow, the band errors of distinct filter routes cause the synchronization on problem s between the wavelet values at discrete scale concentrations, which is worsened by raising the scale value and therefore the structure of the image is modified by the wavelet numbers due to the accumulation of errors.

III.METHODOLOGY

The suggested scheme is implemented using the measures shown in Figure 6.

- Using MATLAB GUI feature, the registered MRI and CT scan images are converted into header files, where DWT and reverse DWT are going to apply on these images.
- Xilinx Platform Studio (XPS) is a tool used to select software and hardware components. In XPS all the header files, source codes etc. can be converted to bit stream and further going to download into FPGA
- Use Xilinx SDK and Xilinx Vivado to serially transfer the image matrix to FPGA through the JTAG cable.
- The input images. converted wavelet transform and reverse WT images are sent to the recipient facility via UART in FPGA. UART information was captured and seen through Visual Basic (VB) software in the monitor.

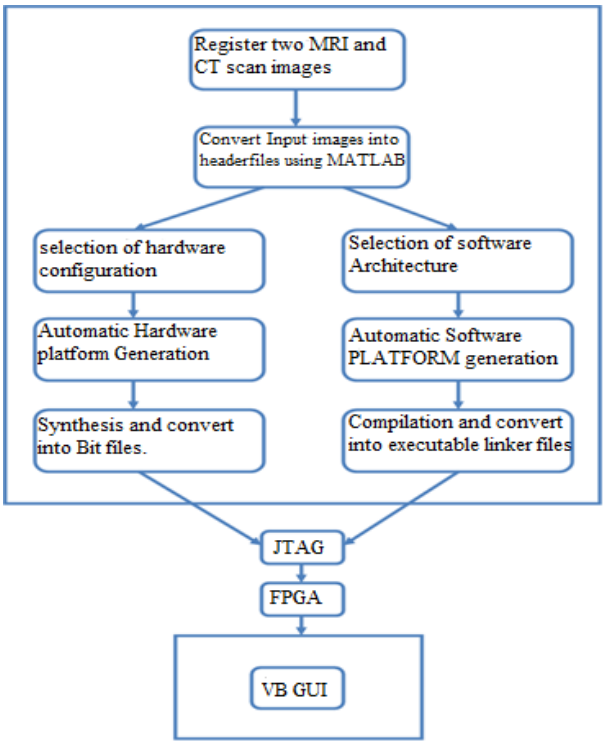

Figure 6: Proposed methodology

IV. RESULT AND DISCUSSION

Brain MRI and CT scan input images are registered for image fusion and converted into .h files using MATLAB. Hardware and software components for implementation are selected using Xilinx Platform Studio (XPS) tool which include RS232, MICOBLAZE software to access FPGA, SRAM, JTAG cable configuration, source codes, .h files etc. XPS converts all the source codes of DWT and inverse DWT and header files etc. into bitstreams. These source and .h files bit streams have .bit and .bmm extension, respectively. All these bit files are then exported to Software development kit (SDK) tool. SDK is part of Xilinx platform studio and it creates an Executable Linker File (ELF) to execute the program. Next step is to configure the JTAG settings with 500 kHz frequency and XILINX parallel IV cable type to LPT (Line Print Terminal) port. The bit stream codes are downloaded into a FPGA Spartan3 image processing Kit through JTAG serial transfer cable. Source codes, written in system c, contains DWT, Average approximation fusion rule and inverse DWT algorithms. The input, DWT's and inverse DWT images are stored in SRAM of the FPGA Spartan3 kit Board. The output from FPGA board can be configured through an UART cable into CPU COM port. All the input images, DWT MRI and CT scan images and output fused images are seen in Visual Basic GUI by executing ELF i.e. generated by XPS.
