MESSAGE FROM THE CHAIRMAN

On behalf of the organizing committee, it is a pleasure for me to welcome you to the IEEE International Conference on Communication and Electronics Systems (ICCES 2019). The overwhelming response to our call-for-papers indicates the popularity of this conference and confirms that IEEE has become the world-wide forum for all aspects of science and technology in the field of information and Communication related topics.

In the long history of IEEE Conferences, it has provided a venue for researchers to address the new technology and findings, as well as to exchange recent research results. I hope that the presentations and special sessions will be valuable resources in your professional, research and educational activities whether you are a researcher, or a practicing professional.

The conference is intended to involve various research areas, including Communication Systems, Computer and Networks, VLSI Design, Medical Imaging, Signal Processing and Image Processing.The conference theme focuses on the new innovative technology in the field of Communication, Electronics Systems.

Finally, I thank all conference participants for making ICCES 2019 success, and hope that you have an enjoyable and fruitful stay in Coimbatore.

Dr.L.P.Thangavelu, M.S., FAIS, FIAGES, FICS
Founder-Chairman,
PPG Group of Institutions.

MESSAGE FROM THE CORRESPONDENT

It is a great honor and pleasure to welcome you to the IEEE International Conference on Communication and Electronics Systems (ICCES 2019) organized on 17-19 July 2019. We sincerely thank all members of the Organizing Committee for their long term enthusiasm in organizing the conference and we are very grateful to all the authors who created the scientific program of the 4th International Conference on Communication and Electronics Systems (ICCES 2019).

Finally, I would like to extend our thanks to the sponsors, who decided to join us at this important event.

We heartily welcome professors, scientists, experts and students from all countries to 4th International Conference on Communication and Electronics Systems (ICCES 2019) and we wishyou a pleasant experience in Coimbatore.

Tat. Shanti Thangavelu
Correspondent
PPG Group of Institutions.

MESSAGE FROM THE PRINCIPAL

It is an immense pleasure to welcome you all to the 4th International Conference on Communication and Electronics Systems (ICCES 2019). I am sure that the participants of this conference will return immensely enriched with knowledge and gain more confidence.

With the evolution of new technology, there is a stiff competition in this challenging world. To meet these challenges, one has to constantly and updates oneself in a Particular field to survive and to become successful. It is necessary to be keen towards the latest technology in their related fields and conference is one such way that helps to meet different people across the country and exchange their ideas. These experiences create innovative ideas among budding engineers. We are amazed to see a great response from various institutions across the globe and I am sure that this will develop the team spirit and leadership qualities among our students.

Hearty congratulations to the organizing committee. Wishing the delegates a fruitful deliberations and happy stay during ICCES-2019.

Dr.R.Prakasam, B.E (Hons),
M.E., Ph.D., F.I.E. C.Engg, M.I.S.T.E., PRINCIPAL,
PPG Institute of Technology.

MESSAGE FROM THE CONFERENCE CHAIR

It is my great pleasure to welcome you to the IEEE International Conference Communication and Electronics Systems (ICCES 2019) which takes place in Coimbatore, Tamil Nadu on July 17-19, 2019. It has been a real honor and privilege to serve as the Conference Chair on the conference.

I am sure that his conference will provide a cross-disciplinary venue for researchers and practitioners to address the rich space of Communication and Electronics System. The Conference spans two days and includes two Keynote Address followed by two days of main conference. The presentations and planned social events will provide ample opportunities for discussions, debate, and exchange of ideas and information among conference participants.

I would like to express our appreciation to the Technical Program Chair, for his valuable contribution in assembling the high quality conference program. We also thank the Chairs. A conference of this size relies on the contributions of many volunteers, and we would like to acknowledge the efforts of our conference judges and their invaluable help in the review process. We are also grateful to all the authors who trusted the conference with their work.

Dr.V.Bindhu,
Professor and Head,
ECE, PPG Institute of Technology,
Coimbatore, India.

4th International Conference on Communication and Electronics Systems

(ICCES 2019)

Table of Contents

S.No	Title/ Authors Name	Page. No
1	Fog Computing: An Enhanced Performance Analysis Emulation Framework for IoT with Load Balancing Smart Gateway Architecture Bikash Sarma, Gajender Kumar, R. Kumar, Themrichon Tuithung	1
2	Energy Efficient Spectrum Access Design for Cognitive Radio Wireless Sensor Network Professor Ruksar Fatima, Shaik humera tauseef, Rohina khanam	6
3	Object Detection and Tracking using Zernike Moment Samidha Girish Vengurlekar, Dipti Jadhav, Swapnil Shinde	12
4	Design of a miniaturised and novel DGS-based UWB antenna Ria Benny, P. Mythili	18
5	Low Power Hardware Based Real Time Music System and Digital Data Transmission Using FPGA Sudip Mondal, R. K. Sharma	21
6	Design of GMII Transparent Interface Based on Ethernet IEEE 802.3 Standard Rajat Kumar Maheshwari, T. N. Sasamal	24
7	Design of Efficient 2-4 Modified Mixed Logic Design Decoder Rohit Kumar Arya, Sonali Agrawal	29
8	HYBRID KEY GENERATION FOR RSA AND ECC E.VIDHYA, S.SIVABALAN, R.RATHIPRIYA	35
9	An Efficient Trusted Graph Based Approach for Inferring Trust in Epinions Network Debdutta Dey, Awadhesh Kumar Singh	41
10	AES Arduino Handshake for Unattackable Data Processing Gourav Saini, Dr. R.K Sharma	46
11	To evolve a predictive model for Dengue incidence using meteorological and geo spatial data N V Ganapathi Raju, P Gopala Krishna, Katapally Manognya, G S S Raj Kiran, Palakodeti Rohit, K Likhith	51
12	Pedestrian Detection Using Deep Learning Ponugumati Pavani, Kodali Bhavana, Duvvaki Venkatesh, Suneetha Manne	60

S.No	Title/ Authors Name	Page. No
13	Fast Error Correction for Header Flit in NoC V.Taraka Sai Srinatha Reddy, G.Hema Sekhar Reddy, K.Jeshmitha Reddy, M.Vinodhini	66
14	RCSA scheme with Rayleigh Fading Effect in massive-MIMO system Umesha G B, Dr M N Shanmukha Swamy	71
15	Implementation and Analysis of Adaptive Odd-Even Routing in Booksim 2.0 Simulator Jaswanth Marri, Sunder Manishankar, D. Radha, Minal Moharir	77
16	Analysis of Load Balancing Algorithms in Software Defined Networking Himanshi Babbar, Shalli Rani	85
17	A Multicasting Approach for Path Establishment in Vehicular Ad hoc Networks Abhander Chaudhary, Rakesh Kumar	91
18	Developing Augmented Reality Application for All-in-one Interface Card Rashmi M, S.G Raghavendra Prasad	97
19	Design of low power SR-flip-flop with on/off (ONOFIC) implementation Masood Ahmad Malik, Vijay Kumar Sharma	102
20	Design of 6T FinFET SRAM cell at 7nm Umayia Mushtaq, Vijay Kumar Sharma	105
21	Evaluation of Data Efficacy in Privacy-aware Computing Geetha P, Dr. Chandrakant Naikodi, Dr. Suresh L.	110
22	Saturation Optimization and Extrinsic Timing Analysis for Optically Controlled GFET S.Chakraborty, K.Bhowmick, N.S. Murty	116
23	Advanced Military Helmet aided with Wireless Live Video Transmission, Sensor Integration and Augmented Reality Headset Sandeep Jalui, Tushar Hait , Tulika Hathi , Soumes Ghosh	124
24	A Comparative Analysis of 8-bit Novel Adder Architecture Design using Traditional CMOS and m-GDI technique Gautam Nayan	129
25	Threshold driven Dual Cluster Head clustering protocol Navajyoti Nath, Biswanath Dey	137
26	Change Detection in Land use-Land cover using Convolutional Neural Network Sahithi Samudrala, Suhail Mohammad, Mekala Pranvitha nand, Radhesyam Vaddi	142
27	Efficient Resource Allocation Model For D2D Communication Under Overlapping Area of Multiple Cellular Cell Professor Ruksar Fatima, Rohina khanam, Shaik humera tauseef	146
28	IoT Based Automatic Attendance System Dharani Devi, Devi.A, Piriyyadarisani.V	152

S.No	Title/ Authors Name	Page. No
29	Gesture and Speech Recognizing Helper Bot Kailash Gogineni, Akhil Chitreddy, Anirudh Vattikuti, Dr. Natarajan P	156
30	Cost Efficient Subtractor Designs in QCA Marshal Raj, Lakshminarayanan Gopalakrishnan	162
31	FLOOD FORECASTING BY USING MACHINE LEARNING Amitkumar Baburao Ranit, Dr. P. V. Durge	167
32	Performance analysis of Transformer – Less UPFC Shaikh Mohammed Tauseef, S. M. Kulkarni	171
33	The Decomposition methods in Synthetic Aperture Radar Polarimetry Plasin Francis Dias, R. M. Banakar	175
34	Energy Aware Virtual Machine Consolidation for Load Balancing in Virtualized Environment Bishwabara Panda, Suresh Chandra Moharana, Himansu Das, Manoj Kumar Mishra	181
35	Design and Verification of Analog Integrated Circuits Using Free or Open source EDA Tools Guruprasad, Kumara Shama	187
36	Weighted Pseudorandom Based Deterministic Bist for Fault Testing and Self-Healing G.Bhavani, K. Jamal, B.Veera Reddy	193
37	Road Crack Detection and Segmentation for Autonomous Driving Geetika Aggarwal, Sarika Jain	199
38	Enhanced Secrecy Capacity under Eavesdropping Attack in Multi-Traffic Industrial WSN A.Chandra Shaker	204
39	Hybrid Algorithms for Moving Vehicle Plate Recognition System Shreyas S Bagi, Harshith C H, Santosh Tuppad, Dinu V, Dr. R Srikantaswamy	210
40	DIGICERT: A Secured Digital Certificate Application using Blockchain through Smart Contracts Ms. R.Poorni, Mr. M.Lakshmanan, Ms. S. Bhuvaneswari	216
41	Semantic Segmentation of Satellite Images Using Deep Learning(Deep Learning Technique for Semantic Segmentation of Satellite Images) Mohammad Yousuf Saifi, Dr. Jimmy Singla, Nikita	222
42	Real Time Virtual Human Hand Using Leap Motion Controller R. Satheeshkumar, Dr. R. Arivoli	228
43	Wireless IoT based Solution for Women Safety in Rural Areas Rahul Paknikar, Shrey Shah, Dr. Prachi Gharpure	234
44	Implementation of Power Quality Enhancement using Hybrid Series Active Filter VANITA NAKADE, SANGITA PATIL	240

S.No	Title/ Authors Name	Page. No
45	Neural Differential Equations for Face Recognition Gadicherla Sameer, Gogineni Manasa	244
46	TWO-DIMENSIONAL ECG SIGNAL COMPRESSION BASED ON REGION OF INTEREST USING PCA ANEESH K N, DARSHAN SINGH S, M H ABHISHEK, Dr. SHREEKANTH T	250
47	Library - A Face Recognition and QR Code Technology based Smart Library System Dhaval Bagal, Pallavi Saindane	255
48	Image Representation based on quantum Computation and their Application : Milestone Ontogeny Sanjay Singh, Ashish Mani, Rashmi Jain	261
49	Translating Artificial Intelligence into Healthcare: Diabetic Retinopathy Detection Reaya Grewal, Avleen Kaur Malhi, Palika Chopra	269
50	Single Phase AC-DC Cascaded Boost-SEPIC (CBS) Converter for Improved Power Quality at High Duty Cycle Mohammad Dehan Rahman, Md Saif Kabir, Md Nazaf Rabbi, Mohammad Abir Hassan Sarker, Dr. Golam Sarowar	275
51	Saturable Absorbers for Mode-Locking of Lasers Operating at Ultraviolet Wavelengths Akshayaa Venkatesh, Janani MV, Arya M Hari, R.Kumar, Dhanalakshmi Samiappan, Venkatesh Chakravartula, Junaid M Laskar	281
52	Level management in connected water reservoirs employing curve fitting based PID control scheme Mohit kumar, Dr. Sathans	286
53	Nonlinear Model Predictive Controller for the Real-Time control of Fast Dynamic System Mrs. Supriya P. Diwan, Dr.(Mrs.)Shraddha S. Deshpande	290
54	PANCHENDRIYA: A Multi-sensing framework through Wireless Sensor Networks for Advanced Border Surveillance and Human Intruder Detection Arjun D, Indukala P K, K A Unnikrishna Menon	296
55	Disparity Map Estimation Using Combined Cost Measure Deepa, Jyothi K	300
56	Object Detection and Gesture Control of Four-Wheel Mobile Robot M. Jain, M. Sehgal, Y. Kalra, P. Jain , N. Aggarwal, R.Singh, D. Kumar, T. K. Bera	304
57	Robust Hybrid Image and Audio Watermarking Using Cyclic Codes and Arnold Transform Bhavneet Sharma, Mayank Dave	310

S.No	Title/ Authors Name	Page. No
58	ANALYSIS OF BOOST CONVERTERS FOR PV AND WIND IN A HYBRID MICROGRID RAJALAKSHMI MENON, GOMATHY S, Lakshmipriya K J	317
59	Various Data Deduplication Techniques of Primary Storage D.Viji, Dr.S.Revathy	323
60	LAND COVER CHANGE DETECTION BASED ON SATELLITE IMAGES USING DEEP STACKING NETWORKS Deepa Palanisamy, Radha Senthilkumar	329
61	Influence of trip complexity on optimal driving based Energy Management System of Electric Vehicle Mousumi Khanra, Arup Kr Nandi	335
62	Load Flow Analysis for Smart Grid With Renewable Energy Resources Shaikh Mohammad Aamir, Dr. P. M. Joshi	341
63	Mathematical analysis of RNN and LSTM for Malicious URL detection M. Arivukarasi, A. Antonidoss,	345
64	Performance Enhancement of OFDM System Using Modified PTS (MOPTS) PAPR Reduction Algorithm Prabal Gupta, H. Pal Thethi	350
65	Evaluating Visual Performance of Multi-object Scene Reconstruction using Triangulation from Airborne Geo-spatial Point Clouds Swati RajeshKumar Maurya, Ganesh M. Magar	358
66	Network Traffic Optimization in Hadoop MapReduce through Pre-shuffling D C VINUTHA, G T RAJU	364
67	Intelligent Edge Security with Dynamic Task Offloading in Fog Environment Albin Mathew, Namboodiri E I Deepu, Dr. Maya Mohan	368
68	Selection of Optimal Renewable Energy Resources in Uncertain Environment Using ARAS-Z Methodology Nisha Rathore, M.P.Singh	374
69	Secure Defense Mechanism against Data Leakage and Distributed Denial of Service Attacks in Software Defined Networks P. Mohana Priya	379
70	A Machine Learning Approach for URL Based Web Phishing Using Fuzzy Logic as Classifier Happy Chapla, Riddhi Kotak	384
71	Power Analysis of 2-bit Array Multiplier using Adiabatic Logic Jacob Savio, Rekha Bhandarkar	390
72	Safety and Driver Assistance in VANETs: An Experimental Approach for V2V C. Suganthi Evangeline, Vinoth Babu Kumaravelu, Atul Joshi	398

S.No	Title/ Authors Name	Page. No
73	Design and Implementation of Automatic Miniature Indoor Plant Cultivator Using Artificial Environment Akhila S, Shriya Nithyan, Sowmya C, Priya B. K	404
74	A Network Intrusion Detection Approach Using Variant of Convolution Neural Network Ashish Kumar Verma, Dr.Praveen Kaushik, Gourav Shrivastava	410
75	Analysis of Bi-directional DC-DC Buck-Boost Quadratic Converter for Energy Storage Devices Neeti Dubey, Ashok kumar Sharma	418
76	Building a Cloud Solution for Energy Management using Raspberry Pi Laxmi Khichadi, Siva Ganesh Kumar, Dr. Nagamani K.	423
77	Test Pattern Generation to Detect Single Stuck- at Faults for Combinational Circuits Using ZBDD Antony Thomas, J. P. Anita	428
78	Design and performance analysis of WDM optical Communication system with EDFA-DCF and FBG for dispersion compensation using 8x5 Gbps data rate Nirmala Mahawar, Ajay Khunteta	432
79	Collaborative Filtering based Recommender System using Regression and Grey Wolf Optimization Algorithm for Sparse Data Sneha V., Shrinidhi K.R., Sunitha R. S., Dr.Mydhili K. Nair.	437
80	Automatic Evaluation of Short Answers Using Deep Neural Networks Barsha Sharma , Chandni Agarwal , Deep Shikha , Udit Kr. Chakraborty	443
81	Performance Analysis Of Inter-satellite Optical Wireless Communication System Using WDM(Comparison of BER and Q-factor in an Is-OWC system using WDM with different modulation techniques) Shubhneet Kaur, Ameeta Seehra	449
82	A Metaheuristic-based Emotional ANN (EmNN) Approach for Rainfall-runoff Modeling Bishwajit Roy, Maheshwari Prasad Singh	455
83	Reconfigurable Warped Digital Filter Architecture for Hearing Aid Kaustubh Banninthaya K., Niranjan N., Risla Fathima P., Pranav Kumar M. P., Dr. Ipsita Biswas Mahapatra	460
84	SUPPRESSION OF CROSS POLARIZATION WITH VARIOUS GEOMETRIES OF DGS IN THE DESIGN OF MICROSTRIP PATCH ANTENNA B Naveen reddy,M Hema dharani,S Pavithra,A Sivapradhayni, Mekaladevi V	465

***Abstract*—** With the exponential progress of IoT applications in last few years, a huge amount of data is being collected and stored every day and thus an enhanced and mature solution is very much necessary to knob these data. Usually cloud is utilized as the processing and storing unit of an IoT system. Cloud is deliberated to be the best solution for emerging IoT solutions with its diversified facilities. To tackle the massy amount of data that is being pumped everyday throughout the network, Fog computing is an effective solution which can trim and pre-process the data before forwarding it to cloud where Fog resides near the IoT application. Unlike cloud, Fog may not have high computing facilities but it can perform better in case of time sensitive application with moderate processing. Based on the recent trend smart gateway-based Fog-Cloud solutions are gaining more popularities compared with the other related solutions. In this paper, we have extensively discussed about a load balancing based smart gateway with Fog and Cloud environment where an analysis of load balancing environment with regards to processing delay and network delay is performed. Subsequently we have compared different scenarios with and without load balancing algorithm in the projected architecture.

***Keywords*—**IoT; Fog Computing; Smart Gateway; Load balancing; Cloud Computing

I. INTRODUCTION

Technology is developing rapidly and devices are becoming smart in day to day culture due to which the trend of IoT has taken a high rise in the world of applications in recent times. Ordinarily IoT paradigm is considered as a group of interconnected real-world small things, with storage and process constraint, distributed in nature and delivers good performance. Usually in IoT, devices like home appliances, process automation, life saving devices, smart devices and other related types are connected with Cloud for processing and storing the data generated over the period of intervals. The average growth of the connected devices has reached much higher due to which in 2020, it might reach nearer to 6.58 devices per person [1]. As a result, the data traffic in the network will be amplified enormously which may shape problems for latency sensitive and real time applications. Latency sensitive applications are typically restricted with strict response time. Even if the client gets response beyond the bounded time, the response will be considered as null and void. There are many ways latency may occur but in case of IoT, processing and network latency is mostly contemplated. Though network latency typically depends on the size of the data, distance it has covered and the medium it has to travel which also depends on the number of devices it has to travel across as each one conceivably checks and alters the header of the packet. Similarly a processing latency depends on the processing capacity as well as on the number of jobs waiting to get processed in the server.

Until fog computing was popularized by CISCO in the year 2012[2], cloud was one of the traditional tools to support Internet of Things (IoT). Cloud has a representative part in today's growth of IoT though is not precisely a group of interconnected devices rather an information and knowledge providing mechanism from the data it collected by sensing the environment. The data collected via IoT devices are sent to the cloud for central access and processing. The characteristics such as ease of access and scalability of cloud make it more comprehensive with IoT. As devices in IoT are collecting bulk

amount of data every day and it is gradually increasing, a scalable storage along with processing is necessary that can further be extended as per demand. With the help of those collected data many business models are being designed and established mechanism are used to find out certain patterns while designing such business models which require extendable and high processing where cloud is trending. Apart from that, the concept of pay-as-used makes cloud convenient for the IoT users, in spite of such infrastructure and facilities of cloud, fog is getting acceptance but of course cannot be replaced as they complement each other [3].

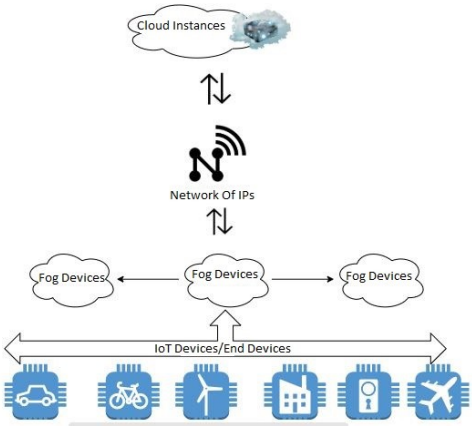

Fig 1: IoT with Fog and Cloud Environment

In this research work we have analyzed the Fog with smart gateway-based load balancing scenario in an emulation framework and in the remaining part of this paper we have discussed about the Fog computing in section II, related works in section III. In section IV and V, we have explained about the framework setup and output of the emulation. Finally, we conclude the paper in section VI with future work.

II. FOG COMPUTING

Fog computing is a platform that can compute, store and provide network services between the IoT nodes and the Cloud computing data centers, but it is not exactly positioned at the edge of the network [4]. It extends the typical Cloud environment providing better result in many applications where Fog is a type of distributed computing method that facilitates application of low latency services [5]. Fog Computing used to work on network ends instead of hosting and working from a centralized server or cloud and in most of the fog devices, computation is performed when necessary and also storage facilities is available for a while [6]. However, for the cloud, real-time interaction with IoT devices is such a task which is not possible because of its high latency [5], [7], [8]. Fog reside near the IoT devices due to that there is no latency issue but obviously it creates a problem of low processing power as it does not consist of any high computing configuration. Usually Fog nodes are available in the private network of the IoT system which exists in the local network makes Fog nodes and its communication much more secure than the Cloud. Fog and Edge computing are not only analogous with respect to their proximity with the source of the data but also both remain different paradigms at one point. In edge computing the processing power is in the device itself whereas in fog computing the processing power is in the network where the Fog nodes are interconnected. Moreover edge computing does not depend on the gateway but in Fog computing gateway is the key component which transmits the data from the edge nodes to the Fog. A typical IoT system architecture is shown in Figure 1 where all the IoT devices are connected with cloud through different IP networks crossing Fog layer.

III. RELATED WORK

Fog is trending towards the mainstream of Information technology. Many researchers are putting their effort for the nourishment of Fog and upbringing it to future level. In an automated system, Fog can be used in traffic light management system and with the help of image processing technique, emergency vehicle like ambulance can be identified. Further the conjugative smart traffic lights can change their status considering the current traffic as these smart traffic lights can communicate with each neighboring one and build a green corridor for emergency vehicle [4]. Smart meters are also a stimulating device which intelligently decide the other input power source which can be solar or wind, based on certain parameters like cost, availability as well as demand [9] and can also be implemented within the area of Fog. An intelligent home control system [10] is a type of intelligent system which works with the help of an android phone working as a special gateway instead of ordinary gateway that will observe and predict the behavior of the user and automatically power off the devices that will not be available for use due to which the wastage of energy can be minimized. In Smart e-Health Gateway [11], a health monitoring system has been elaborated and implemented with the help of Fog Computing where an immediate and automated medical instruction was derived on the basis of sensors data fitted on patient body. Further an implementation for an in-home EWS system was improvised to which patient may get different services and environment that is feasibly accepted medically. However to reduce the unnecessary data uploading to network, a smart gateway based communication was discussed in Fog Computing [12] where they suggest that the data can be pre-processed before uploading to the core network which may reduce the over burden to the cloud data centers. Here the gateway namely smart gateway, signifies a responsibility for data filtering and trimming as suggested in a design shown in Figure 2.

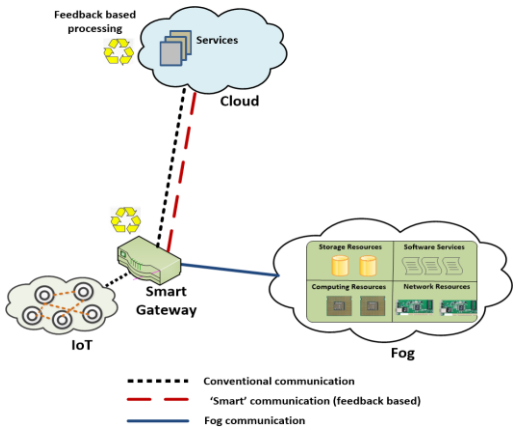

Fig 2: Smart Gateway with Fog computing/Smart network [11]

Many directions were discussed in most of the research papers of Fog and Cloud Computing but here we proposed the and verified the following approches appropriately to get better comparison with respect to network delay and processing delay.

1. IoT with Cloud alone situation
2. IoT with Fog alone Situation, Fog consisting of one node.
3. IoT with Fog alone Situation, Fog consists of multiple node.
4. IoT with Fog, Cloud and Smart Gateway based load balancing situation, Fog consists of multiple nodes.

In the last approach, a smart gateway will be used as load balancer between Fog and Cloud which usually perform the operation of data filtering before forwarding it to Cloud. A load balancing algorithm will be implemented in the same gateway which will route data to get executed. Sending all data to Cloud may increase the network latency and at the same time executing everything in Fog may overload the Fog servers. To achieve high computing (in Cloud) and less network latency (in Fog), launching a load balancer (smart gateway) between Cloud and Fog might be prolific direction. Hence in the following section a discussion about all the analysis with an emulation framework is mentioned systematically.

IV. INITIAL SETUP

Various simulators are available to simulate fog but since there was not much upgradation to those utilized in early stages, analyzing the Fog in a different scenario was equipped in this research work. A design implemented here is emulated framework where real gateway, real cloud, real fog nodes were adopted but simulated sensor data are utilized. Sensor nodes are contrived in such a way that it will send data in a continuous manner to the gateway.

For building the cloud environment, in this work the help of Google Cloud Computing Engine (VM instance) was availed. Creation of a cloud VM instance of 4 vCPUs, 15 GB Memory and on the other hand, for Fog environment Raspberry-Pi board with quad-core ARM Cortex A53 processor and 1 GB Memory were chosen accordingly. Raspberry-Pi was selected as a computing unit with less processing power and memory which matches the Fog server requirements. As gateway is a key part of the entire system and it has a lot of decision making along with pre-processing work with a chosen desktop machine as smart gateway with 8 GB RAM and core i7 processor. Secondly a system with i5 processor and 4 GB RAM was selected as a generator of sensor nodes from which N number of sensor nodes can be created and each of these can send the required amount of data as sensor data to the gateway. For the experimentation of the work the decision of using 10 sensor nodes was approximated which will send a constant data of 7kb size in every second of interval. Utilizing the concepts of multithreading, gateway will handle all 10 virtual sensor nodes in isolation along with the programming part carried out with the help of python programming language and python 2.17 compiler. To simulate the processing part in cloud and Fog, a mathematical calculation was put under a loop for certain number of iterations and the server was made busy as if they are busy with processing of the data sent via gateway. The processing time was calculated at the Fog/Cloud side and the calculated results are reverted back as reply and at the same time a round trip time is also been calculated in the gateway. By continuing the round trip time in this work a discussion about time constraint applications is carried out expecting the responses in real time and by subtracting the processing time from the round trip time the network delay was calculated.

V. RESULTS AND DISCUSSION

Once the execution of framework starts, sensor generator generates 10 sensor nodes and each of them will pump the file to the gateway. The gateway will forward the data to its destination with respect to the multiple scenarios. Whenever the framework is kept in run mode, it will record 10000 number of entries which can be increased or decreased as per the demand of the user.

A. IoT with Cloud alone situation(Case 1)

Here the gateway forwards the sensor data to the cloud server directly though gateway has no extra burden other than simply forwarding the received data to cloud server. Hence a simple gateway is enough to take care of this situation. Following are the results obtained after the execution.

Table 1: Delay details for Case 1

Network Delay	Processing Delay	Total Delay
0.674784167	0.015158118	0.689942285

B. IoT with Fog alone Situation, Fog consist of one node(Case 2)

Based on the scenario, replacement of the cloud server with one fog server has been executed. Usually Fog does not consist of only one node but to get more experimental results Fog was considered. Here also the gateway working is similar to cloud alone situation. Following are the results obtained after the execution.

Table 2: Delay details for Case 2

Network Delay	Processing Delay	Total Delay
0.539716318	0.559499568	1.099215885

C. IoT with Fog alone situation, Fog consist of multiple node (Case 3)

Considering multiple Fog nodes, the gateway used in this scenario should be smart enough to handle all the nodes simultaneously. Hence a smart gateway with a simple Round-robin load balancing algorithm was used which forwards the data to all the fog nodes periodically. Results obtained in this experiment are as follows.

Table 3: Delay details for Case 3

Network Delay	Processing Delay	Total Delay
0.172555609	0.441512057	0.614067666

D. IoT with Fog, Cloud and smart gateway based load balancing situation, Fog consist of multiple nodes (Case 4)

To experience the power of cloud processing and Fog proximity, this scenario is experimented. The same smart gateway with Round-robin load balancing algorithm is used to route the data. Results achieved for this experiment is as follows.

Table 4: Delay details for Case 4

Network Delay	Processing Delay	Total Delay
0.208520656	0.302323014	0.51084367

All the experimented results summary is as shown in Figure 3. With no doubt about the performance of cloud, overall response time was pushed back by the network delay (Case 1). If the network delay can be reduced, the system may work much better.

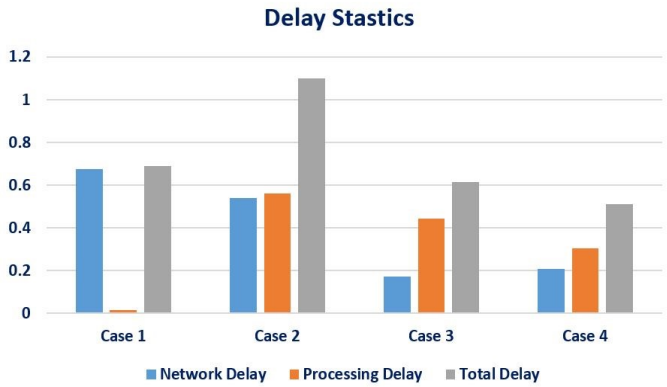

Fig 3: Delay statistics of all the Cases

Therefore by replacing the cloud server with a Fog node will decrease the network delay as the Fog node resides near the gateway. But as per the results obtained, replacing cloud server with one Fog node will not solve the issue because the processing time it takes is much higher than the cloud that increases the overall delay (Case 2). As Fog nodes do not possess high computing configuration it cannot handle more requests, because of which the overall network delay will not deliver much impressive output. With the addition of more Fog nodes in the Fog group can specify some exciting results i.e. as the number increase in Fog group, the load on the individual Fog nodes decreased which reduced the total delay (Case 3). Based on the work carried out, the smart gateway with load balancing mechanism plays an important role to balance the traffic and route all of those(data) carefully among Cloud and Fog servers. The achieved results after combining Cloud and Fog together has proved as the best one as per Case 4 mentioned above. All the Fog nodes and Cloud takes the load of individual request equally and yields more performance where Fog nodes contributes with less network delay and Cloud provide high computing. In figure 3, Case 4 shows less network delay then Case 1 where only Cloud is used and more processing delay as Fog is incorporated with less processing speed but still produced minimum total delay. During experiment the smart gateway is not used as a simple data trimmer or data forwarder instead it worked as a data traffic load balancing hardware. Even though a simple Round-robin load balancing algorithm is used in case 4 but still it has produce the best result among all the case considered in the experiment with minimum total delay. Hence the key part of the entire experiment is smart load balancer where a load balancing algorithm is used in a gateway which is connected to all the sensor nodes to intelligently route the traffic between Cloud and Fog.

VI. CONCLUSION AND FUTURE WORK

As per the research work conducted here many researchers introduced a smart gateway with the facility of pre-processing and data trimming before sending it to Cloud in literature. But here a conclusion has been drawn by which it is not necessary that smart gateway has to do data trimming and pre-processing every time instead this device can be used as smart load balancer. Thus data trimming and pre-processing shows an importance of work and it has a very good impact on overall performance though some file/data needs to be sent in its original size without trimming. In few multiple cases, smart gateway can be used as a smart load balancer. In future, researchers or scientists can introduce different load balancing algorithms to implement in the smart gateway which suite their respective applications and as the smart gateway is capable, the overall performance of Fog and Cloud can be improved with sophisticated and standard load balancing algorithms.

***Abstract*— Wireless sensor networks (WSN) considered to play an important part in Internet of Things (IoT). The increased wireless access device makes spectrum access challenging. Cognitive radio (CR) plays an eminent mechanism to address this issues by enabling sensor device to opportunistically access licensed spectrums. However, energy constraint of sensor device to provide cognitive capability such as channel switching, channel sensing and opportunistic access requires careful planning for enhancing energy efficiency of CR-WSN. For enabling WSN with cognitive capability to provision IOT requires efficient spectrum access and medium access control (MAC) design. The exiting spectrum access model incurs energy overhead and induces higher collision due to interference among contending user and very limited work is carried out considering multi-channel CR-WSN network. As a result, they are not efficient in utilizing spectrum. For overcoming research challenges, this work present an energy efficient spectrum access (EESA) model for multi-channel mobile CR-WSN. Experiment outcome shows EESA attain significant performance over exiting model in terms of throughput and energy efficiency. The EESA utilize spectrum more efficiently considering multi-channel mobile CR-WSN.**

Keywords*— Cognitive radio network, Dynamic spectrum access, energy efficiency, multi-channel.

I. INTRODUCTION

WSN device that are employed in perilous place where charging the sensor is highly improbable, at such places, these WSN are self -possessed and made up of the smallest sensor device available. Since the sensor device is less expensive, this property of the device has made the enormous growth in the IoT, where they are connected to the internet for various purpose and application [1], [2] such as IoT and Big-Data. These application needs the huge amount of data, LLS (Low Latency Service) delivery along with low energy dissipation, it also requires the availability of higher spectrum [3], hierarchical structure. Moreover, the frequency channel with 2.4GHZ is with the several application. These application includes Wi-Fi and Bluetooth, also the 5G network is expected to arrive in nearby future. The latest generation of the network needs the ESA (Efficient Spectrum Access) design.

For the future IoT technology which is based on the cognitive network, CRN (Cognitive Radio Network) [4] may be considered to address the accessing of spectrum. The model of CIoT provides enhanced intelligence to obtain the efficient DS (Data Sensing) and analysis [5] mainly for WSN. Improvised as well as the smartest version of MAC is used for absolute incorporation of CIoT in WSN. Moreover, also for the absolute incorporation cognition in the spectrum needs to be addressed. The spectrum utilizes the on and off scenario and they are intended to congested on the particular sections of spectrum. The several cases of real SS (Spectrum Scarcity) [6] and artificial makes it mandatory for needs of efficient spectrum uses. Fig1 shows the architectural design of CR-WSN (Cognitive Radio-WSN).

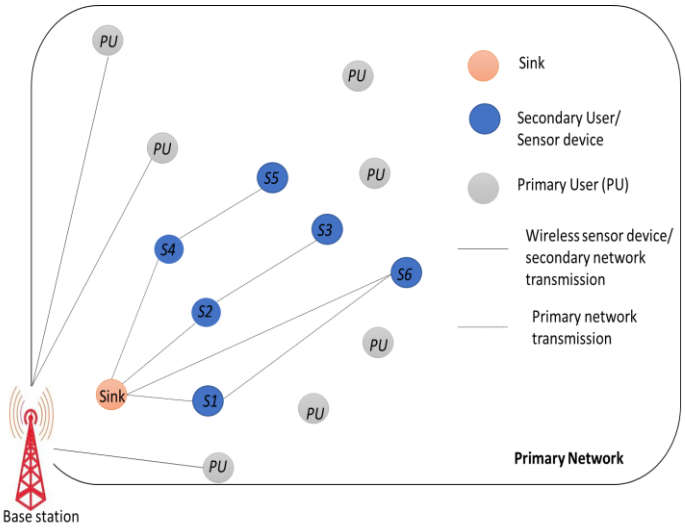

Fig. 1. Architecture of CR-WSN

Effective spectrum access design are required to attain efficient throughput for dynamic CIoT applications [7], [8], and [9]. The wireless network is getting more crowded and complicated. As a result, it is problematic in obtaining network information for cognitive user. Further, the fifth generation network is expected to offer ultra-low power and super-efficient spectrum access design to cater large density of users with low jitter, delay and restricted bandwidth which will be a challenging

task for existing crowded spectrum. Spectrum inefficiency can be overcome by using Opportunistic Spectrum Access (OSA) mechanism which is also denoted as Dynamic Spectrum Access (DSA) mechanism. Opportunistic spectrum access is considered to be key component of cognitive radio where wireless device can sense, learn and adapt. Though cognitive radio wireless sensor network aid in enhancing IoT network performance and user requirement. However, sensor devices incurs energy overhead to perform spectrum sensing and spectrum sharing [10] for attaining good QoS and high throughput requirement [11] of applications [8]. These real-time application [12] requires distributed channel access [13] considering unknown network information. Such methods was modelled for single cognitive radio user in [14] and for multi-user in [15]. However, considering multi-user scenario it induces collision in network due to interference [16] among user and some user are selfish in nature in CR-WSN. To reduce collision, priority access [17], random access [18], and fair resource allocation [19] model has been presented. However, these model are limited to provide only one channel at a time to a cognitive user. As a result, if a selected medium is busy then, that subscriber needs to wait another slot and if another channel is free at that time the spectrum is wasted.

For allocating and utilizing bandwidth or spectrum more efficiently game theory model is been adopted by various existing research [20], [21] and [22]. However, these model are designed considering single channel, static secondary network, and homogenous environment. In [23] presented a spectrum access model adopting game theory model and [24] presented a distributed spectrum access model adopting Markov model considering mobile secondary network and multi-channel environment. However, [23] failed to attain existence of Nash equilibrium and [23], [24] incurs channel switching overhead due to interference when mobility speed is increased. To overcome the research challenges, this paper presents an Energy efficient Spectrum Access (EESA) model for multi-channel mobile cognitive radio wireless sensor network.

The research contribution as follows

- This work presented a energy efficient spectrum access model considering both spatial and temporal information for multi-channel mobile CR-WSN. As per our knowledge no prior work as considered spectrum access model considering multi-channel mobile CR-WSN.
- EESA attain significant performance in terms of throughput and energy efficiency.
- EESA model brings good tradeoff between minimizing energy, maximizing throughput and utilizing spectrum efficiently.

The rest of the paper is organized as follows. In section II the Energy Efficient Spectrum Access (EESA) model for multi-channel mobile cognitive radio wireless sensor network is presented. In penultimate section experimental study is carried out. The conclusion and future work is described in last section.

II. ENERGY EFFICIENT SPECTRUM ACCESS DESIGN FOR COGNITIVE RADIO WIRELESS SENSOR NETWORK

This work present a novel Distributed and Efficient Channel Access (DECA) model for Multi-Channel Mobile Cognitive Radio Network. The DECA channel access model is designed considering both spatial distribution and temporal channel usage pattern of primary network considering mobile cognitive radio network. For attaining efficient spectrum/channel access model firstly, this work presents a system model for multi-channel mobile CR-WSN. Secondly, the channel accessibility model for multi-channel mobile CR-WSN is presented.

a) System network for CR-WSN:

Let considers there are set of primary network such as cellular network base station. Let consider set of secondary network as sensor node that has fitted with cognitive radio equipment which can resourcefully access the licensed band of primary network in an opportunistic manner. Let us assume that there are non-empty set of L licensed frequency slots that can be resourcefully accessed by sensor device in an opportunistic manner. Further, this work considers heterogeneous sensor i.e., the sensor device are mobile in nature. The channel accessibility for sensor device is affected due to mobility of sensor device and channel usage pattern of primary user. The channel accessibility status for sensor device can be described as the time period length in which channel is not accessible or accessible for a particular sensor device. The accessibility of channel j, $j \in L$, for a sensor device is described as temporal channel utilization behavior and spatial distribution of primary users that functions on j, as well as mobile nature of sensor device. Further, this work considers a grid-like topology where vertical segment M_W and horizontal segment M_I is identical.

Further, the **spatial distribution of primary user** that function on common channel j are generally distributed across topology segments. The distance among two adjacent primary users in vertical is depicted as $M_{QW,j}$and horizontal constructions is depicted as $M_{QI,j}$. The communication range of primary user on channel j is depicted as S_j. This work approximate the coverage area of primary user by a square area with side length $2S_j$, where $S_j < \min(M_{QW,j}, M_{QI,j})$ to evade overlapping coverage section of primary users (note: generally the approximated coverage area is greater than the actual coverage to avoid interference affecting primary communication).

Similarly, the **temporal channel utilizatio**n of primary users that functions on common channel j is designed as a discontinuous busy (i.e., the primary user is active in communication) and idle (i.e., the primary user does not communities) process. Further, to avoid interference among primary network during communication, this work does not permits sensor device in same coverage area to use same channel. The length of idle/busy session is designed as an exponential arbitrary functional with variables $\beta_{\mathbb{b}}/\beta_{\mathbb{i}}$,that is.,

$U_{\mathbb{b}} \sim e(\beta_{\mathbb{b}}, j)$ and $U_{\mathbb{i}} \sim e(\beta_{\mathbb{i}}, j)$	(1)

where $Y \sim U_{\mathbb{b},j} \sim e(\beta)$ depicts that functional Y follows exponential distribution with respect to variable β. The ideal condition likelihood that a primary transmitter on channel j is active is expressed as follows

$$\alpha_{\mathbb{i},j} = \beta_{\mathbb{b},j}/\beta_{\mathbb{i},j} + \beta_{\mathbb{b},j} \quad (2)$$

Similarly, the ideal condition likelihood that a primary transmitter on channel j is inactive is expressed as follows

$$\alpha_{\mathbb{b},j} = 1 - \alpha_{\mathbb{i},j} \quad (3)$$

Further, this work considers **mobile CR-WSN**. The sensor nodes moves at constant speed w and each sensor nodes can communicate with each other within its coverage region. The sensor can move in different direction such top, down, left, and right with different likelihood $\mathbb{L}_{\mathbb{t}}$, $\mathbb{L}_{\mathbb{d}}$, $\mathbb{L}_{\mathbb{l}}$, and $\mathbb{L}_{\mathbb{r}}$ respectively. It holds that $\mathbb{L}_{\mathbb{t}} + \mathbb{L}_{\mathbb{d}} + \mathbb{L}_{\mathbb{l}} + \mathbb{L}_{\mathbb{r}} = 1$. The sensor nodes changes its direction when it reaches end of region/network.

b) Energy model for data transmission in CR-WSN:

The energy dissipation of senor device in CR-WSN is mainly characterized by following things such as channel sensing, channel switching, packet transitions and packet reception. Let P_S denotes the energy dissipation of sensor devices for performing sensing on licensed channel, which is considered to be static and fixed across different available channels. Further, the sensor device consumes energy for configuring radio and switching to a new channel. Thus, we represent P_C as parameter to depict energy dissipation for performing channel switching. The spectrum sensing period S_k and for S_k, the packet communication energy dissipation $P_{k,u}$ is evaluated based on energy model [25] as follows

$$P_{k,u} = \left(E_k + E_{k,d}\right) * u_{k,y}, \quad (4)$$

where E_k is the communication power, $E_{k,d}$ is the circuit power at S_k and $u_{k,y}$ is the packet communication session period. Further, using model presented in [26], $E_{k,d}$ can be computed as follows

$$E_{k,d} = \beta_k + \left(\frac{1}{\delta} - 1\right) * E_k, \quad (5)$$

where β_k is a communication power coreponding elemnt with respt to power incurred by the circuit, and δ is described by drain efficiency the modulation scheme and radio frequency power amplifier [29], [30]. Therefore, the energy dissipation of packet transmission at S_k is computed as follows

$$E_{k,u} = \frac{1}{\delta} * E_k * u_{k,y} + \beta_k * u_{k,y} = \frac{1}{\delta}\left(E_k + \beta_{d,k}\right) * u_{k,y} \quad (6)$$

where $\beta_{d,k} = \delta * \beta_k$ is described as the identical circuit power dissipation for packet communication. the energy dissipation for packet reception is proportional tp the packet that a sensor device obtains [27]. If S_k obtains m bits packets, the energy dissipation is computed as

$$P_{k,o} = P_c * m \quad (7)$$

where P_c is the circuit power for packet reception.

c) Channel access model for CR-WSN:

This work consider channel information status to enhance the QoS performance and bandwidth utilization for secondary user considering mobile CR-WSN. Here we estimate the channel accessibility status of channel j considering both temporal channel utilization characteristic and spatial distribution. It is considered that primary network operates at same channel belongs to same class of network and possess same temporal channel utilization characteristics and spatial distribution. Therefore, he transition amount among the state in Markov model can be estimated by mean segment of the region of primary user coverage on channel j as follows

$$\varphi_j = \frac{4S_j^2}{M_{q,j}^2}. \quad (8)$$

Therefore, the mean segment of region where channel j is accessible at an instance of time is expressed as follows

$$\omega_j = \left(1 - \varphi_j\right) + \varphi_j \alpha_{\mathbb{i},j} = 1 - \varphi_j \alpha_{\mathbb{b},j}. \quad (9)$$

The proposed channel accessibility model for multi-channel bring good trade-off between maximizing energy efficiency, throughput and utilizing spectrum efficiently which is experimentally proven in next section below.

III. SIMULATION RESULT AND ANNALYSIS

This section present performance evaluation of proposed EESA over exiting model [20], [23], and [24]. The performance is evaluated in terms of throughput and energy efficiency considering varied sensor devices and mobility speed of sensor device. The proposed EESA and exiting model is implemented using C# programing language and Dot Net framework 4.5 and above. The experiment are conducted on windows 10 home single language edition, Intel Pentium I-5 class processor, 12 GB RAM with 4 GB dedicated CUDA enabled GPU. The parameter used for experiment analysis is described in Table I.

TABLE I. SIMULATION PARAMETER CONSIDERED

Network Parameter	Value
Wireless sensor network size	100m * 100m
Number of wireless sensor device	20, 30, 40 & 60
Initial energy of sensor device	1.0 joules
Energy consumption for data reception P_c	5 nj/bit
Circuit power $\beta_{d,k}$ [25]	5 mW
Power amplifier efficiency δ [25]	0.9
Per-device energy dissipation for channel Switching P_C [29]	10^{-5} J
Per-energy energy dissipation for sensing a licensed channel P_S [28]	$1.31*10^{-4}$ J
Modulation scheme	16-QAM
Mobility of devices	4, 6, 8 cycle per frame

Coding rate	3/4
Bandwidth	18 Mbps
Number of Frequency Channels	5
Time slots	12 µs
Message information size	27 bytes
MAC used	EESA

a) Throughput performance evaluation considering varied mobility speed of wireless sensor device and varied wireless sensor device:

This section presents throughput performance evaluation considering varied mobility speed of wireless sensor network and varied wireless sensor device. For varied sensor device case, the sensor device is varied as 20, 40 and 60 and is moving with fixed mobility speed of 3 cycle per frame, with one control channel and 4 data channel and experiment are conducted. The outcome of experimented is graphically represented in Fig. 2. Experiment outcome shows EESA improves throughout performance by 41.21%, 28.33%, and 28.45% over exiting model considering 20, 40, and 60 wireless sensor device, respectively. An average energy efficiency performance improvement of 32.62% is attained by EESA over existing model considering varied wireless sensor device. Further, for varied mobility speed of sensor device case, the senor device mobility speed is varied as 4 (highest mobility speed), 6 and 8 (least mobility speed) cycle per frame, senor device is fixed to 30, with one control channel and 4 data channel and experiment are conducted. The outcome of experiment is graphically represented in Fig. 3. Experiment outcome shows EESA improves energy efficiency performance by 65.11%, 52.22%, and 24.74% over exiting model considering 4, 6, and 8 cycle per frame, respectively. An average energy efficiency performance improvement of 47.35% is attained by EESA over existing model. From, Fig 4 and 5, it can be seen as sensor device and mobility speed of sensor device is increased the overall network performance is affected for both existing and proposed. However, the proposed model attain significant performance than exiting model considering varied sensor device and mobility speed of wireless sensor device shows adaptiveness of EESA considering multi-channel mobile CR-WSN.

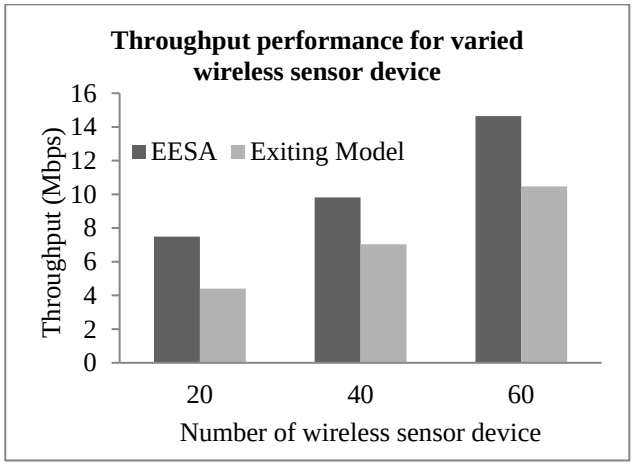

Fig. 2. Throughput performance considering varied wireless sensor device

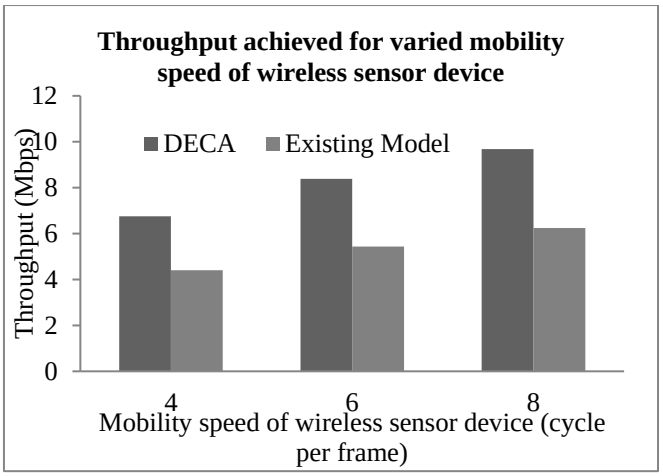

Fig. 3. Throughput performance considering varied mobility speed of wireless sensor device

b) Energy efficiency performance evaluation considering varied mobility speed of wireless sensor device and varied wireless sensor device:

This section presents energy efficiency performance evaluation considering varied mobility speed of wireless sensor network and varied wireless sensor device. For varied sensor device case, the sensor device is varied as 20, 40 and 60 and is moving with fixed mobility speed of 3 cycle per frame, with one control channel and 4 data channel and experiment are conducted. The outcome of experimented is graphically represented in Fig. 2. Experiment outcome shows EESA improves energy efficiency performance by 48.53%, 52.55%, and 54.513% over exiting model considering 20, 40, and 60 wireless sensor device, respectively. An average energy efficiency performance improvement of 51.86% is attained by EESA over existing model considering varied wireless sensor device. Further, for varied mobility speed of sensor device case, the senor device mobility speed is varied as 4 (highest mobility speed), 6 and 8 (least mobility speed) cycle per frame, senor device is fixed to 30, with one control channel and 4 data channel and experiment are conducted. The outcome of experiment is graphically represented in Fig. 3. Experiment outcome shows EESA improves throughout performance by 34.83%, 35.15%, and 35.52% over exiting model considering 4, 6, and 8 cycle per frame, respectively. An average throughput performance improvement of 35.96% is attained by EESA over existing model. From, Fig 2 and 3, it can be seen as sensor device and mobility speed of sensor device is increased the overall energy efficiency performance is affected for both existing and proposed. However, the proposed model attain significant performance than exiting model considering varied sensor device and mobility speed of wireless sensor device shows adaptiveness of EESA considering multi-channel mobile CR-WSN.

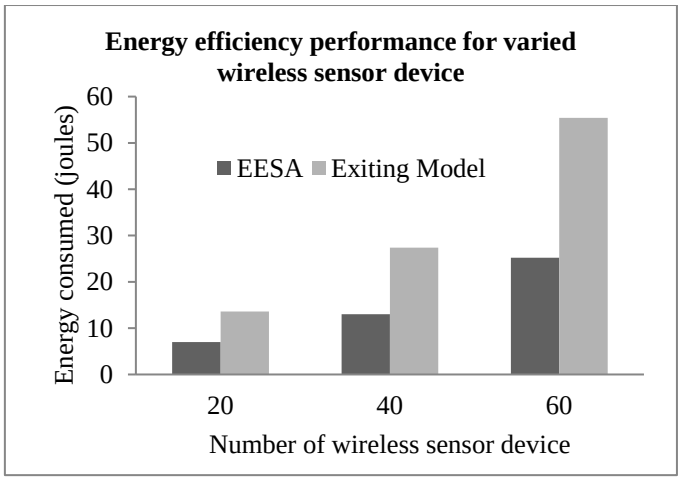

Fig. 3. Energy efficiency performance considering varied wireless sensor device

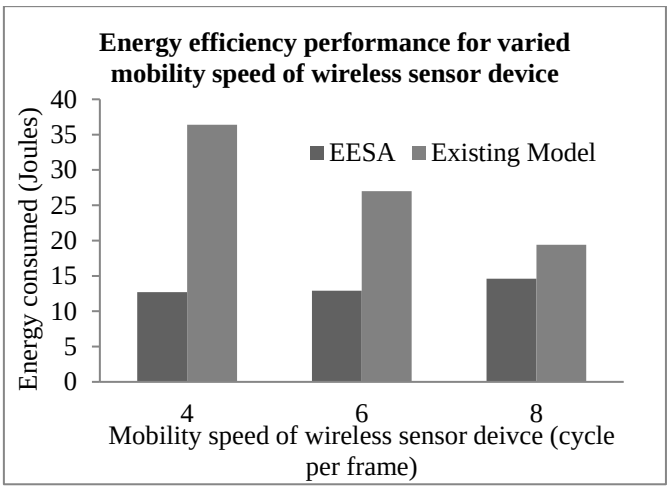

Fig. 5. Energy efficiency performance considering varied mobility speed of wireless sensor device

IV. CONCLUSION

This work conducted extensive survey and identified that the exiting spectrum access model suffers from energy overhead and spectrum utilization inefficiency issues. This paper overcome these issues and presented an energy efficient spectrum access model of multi-channel and mobile cognitive radio network. EESA used both temporal and spatial information for obtaining channel accessibility status for contending device. The EESA model addresses interference issues among contending device. Thus aided in maximizing throughput and minimizing energy overhead. Experiment are conducted to evaluate performance of EESA over exiting model. The result shows EESA attain significant performance over exiting model in terms of throughput and energy efficiency. The outcome shows EESA attain an average throughput performance improvement of 37.4% over existing model considering varied mobility speed of wireless sensor device and varied wireless sensor device. Further, EESA attain an average energy efficiency performance improvement of 48.8% over existing model considering varied mobility speed of wireless sensor device and varied wireless sensor device. The overall result attained shows, the EESA minimize energy consumption, maximize throughput and utilize spectrum more efficiently considering multi-channel mobile CR-WSN. The future work would consider performance evaluation considering varied network parameter and enhancing channel access model.

Abstract: **In this paper, the cameras capture lot of information that can be highly used in detecting and tracking objects in motion. Though it is challenging, object detection is used to detect object either in each frame or when it first comes in the video. Various methods like frame difference, background subtraction, optical flow can be used for detection. The highest objective of this is to contribute the human operators which help in detecting and tracking doubtful or uncommon actions in the video sequence. The visual observation system needs fast and strong approaches of detecting and tracking the moving objects. Moving objects were detected using canny edge method positively. Moments of different order were extracted using Zernike moments techniques. Analysis was done on all the Zernike moments from z00 to z88. The results show that the number of unique motion in the video and number of unique motion detected by the system is equal with accuracy of 100%.**

Keywords: Canny edge detection, Niblacks Algorithm, Object Tracking Sharpening filter, Zernike Moment.

I. INTRODUCTION

Image processing is amongst the peak explored fields. Surveillance systems are mainly utilized for safety purpose, and also many other necessities. Object tracking as well as object detection are the key phases. Various methods are being used for these phases. To automate the system and for reliability, researches are also done to a high extent. [1]. Object detecting and tracking are amongst the greatest jobs which are challenged which a surveillance system has to achieve so that important events and doubtful actions can be defined, and automatically explain and get the video data [2]. In an object tracking, an object is something which plays a vital role for the analysis done later. Objects are characterized based on shapes and forms [3]. Using a data in a single frame is a common approach to detect an object. To lesser the quantity of untrue detections, a temporary data is included from sequences of frames which are used by the approaches to detect an object [3]. Video Summarization generates the detailed information of the videos which covers extreme data that helps to understand the information in the video in an improved way. Video summarization techniques are of two types viz. Static Video summarization and Dynamic Video Summarization [4]. Summarization of static video basically includes selected key frames [5]. Also includes a group of key frames which is in the original video and there is no constraint with the sequence and time factors. Most methodologies contain the visual characteristics figured from video frames. A worth video abstraction helps the user to extract immense information regarding the aimed video sequence in a given time limit or sufficient data in less amount of time. The produced summarization can provide individuals in navigating big video files and in getting the judgments more powerfully related to selection consuming, sharing, or deleting information [4].

II. LITERATURE SURVEY

Authors have presented a system which is integrated for the abstraction of video which is object based [6]. Their contributions and features for the proposed methodology are as follows. • Effectiveness • Online processing• Open framework. Motion, color, special relationship, text and speech are certain features to describe an object. A research done for every feature should be led in order to discover important characteristics. Authors have proposed an algorithm which uses Kalman filters for segmentation as well as detecting an object [7]. For the purpose of prediction and filtering Algorithm, Kalman filter is used. Those extra situation is involved in this dynamic structure is to catch the error which are between the real and estimated position of the ball

which is done using filter. The model, the Authors have proposed is an Adaptive background subtraction [8]. For the purpose of object tracking and detection, this model is used to obtain best detection values using a stationary camera. In filtering process color and other characteristics are considered beneficial for both models viz.1. Generative Model 2. Discriminate Model. To improve the accuracy rate of the tracked objects, proposed model makes use of the tracking levels and reduce the computational difficulty for both indoor as well as outdoor dataset. It makes the use of illumination variant for dynamic variations tracking in the entire background. Authors have proposed a fast as well as accurate technique for detecting and tracking the objects which are moving [9]. The proposed technique has good performance of the detection amongst various objects present in the scenario and it is also non-sensitive to moving objects. In addition, the technique accurately evaluates the quantity of moving objects in each and every frame, which is appropriate for the scenarios where this data is unavailable or it is hard to get. The proposed technique works with feature points and also the time of execution is low than the others and its usage of memory is also very less, as all the frame doesn't go under the process. The Proposed method describes that as compared to 2 frames technique in which problem is regarding holes; there background subtraction gave the good results [10]. When comparison is done with existing and proposed, better estimation of the detected object is given by the background subtraction, proposed technique. The proposed system showed accurate and broader foreground as compared to existing background as well as 2 frame method and reduced the holes problem efficiently. In this paper, authors have discussed a widespread study of object detection as well as tracking approaches [11]. A detailed discussion over advantages and disadvantages of existing approaches of object detection, classification as well as tracking has been done. The method, background subtraction is determined to be the easiest technique which gave the detailed description about the object when comparison is done to frame difference along with the optical flow detecting approaches. Authors of [16] have proposed a video summarization technique based on SURF and its optimization. Video summarization technique based on color and texture features is proposed in [15].

III. COMPARATIVE ANALYSIS

The detailed comparison of different object detection and tracking techniques are given in the Table 3.1

Table 3.1: Comparative analysis of object detection and tracking techniques

Sr. No	Name of the Paper	Techniques Used	Advantages
1	Object-Based video Abstraction for video Surveillance system [6].	Canny edge detection method.	• Efficiency • Effectiveness • Online processing • Open framework.
2	Moving object tracking using Kalman filter [7].	Kalman Filter	• For security system , it is used for the navigation. • Best for prediction and filtering • Availability of high quality
3	A Novel approach on object detection and tracking using adaptive background subtraction method [8].	Gaussian, Adaptive Background Subtraction.	• Recognition rate for bending, running and walking is excellent.
4	Motion-based moving object detection and tracking using Automatic K-means [9].	Automatic K-means, Shi and Tomasi algorithm, Lucas-Kanade method, K-means algorithm.	• The performance for detection is good. • Accurately estimation of moving objects. • It has less execution time.
5	Optimized dynamic background subtraction technique for moving object detection and tracking [10].	Three Frame difference, Background subtraction	• Background subtraction technique is way much better when compared to two frames technique. • It gives the better estimation of the objects which are detected. • Shows accurate and wider foreground.

6	A survey on Moving Object Tracking Using Image Processing [11].	Frame Difference, Background Subtraction, Optical Flow	• Performs well in the static background. • Low memory requirement. • Produces complete movement information

IV. PROPOSED METHODOLOGY

The proposed system includes obtaining of videos of .avi and .mp4 formats. The video is full of information and can be used for the further processing. The bulk of data we get from the videos contains noise and redundant information so the images or the frames which are extracted need an enhancement.

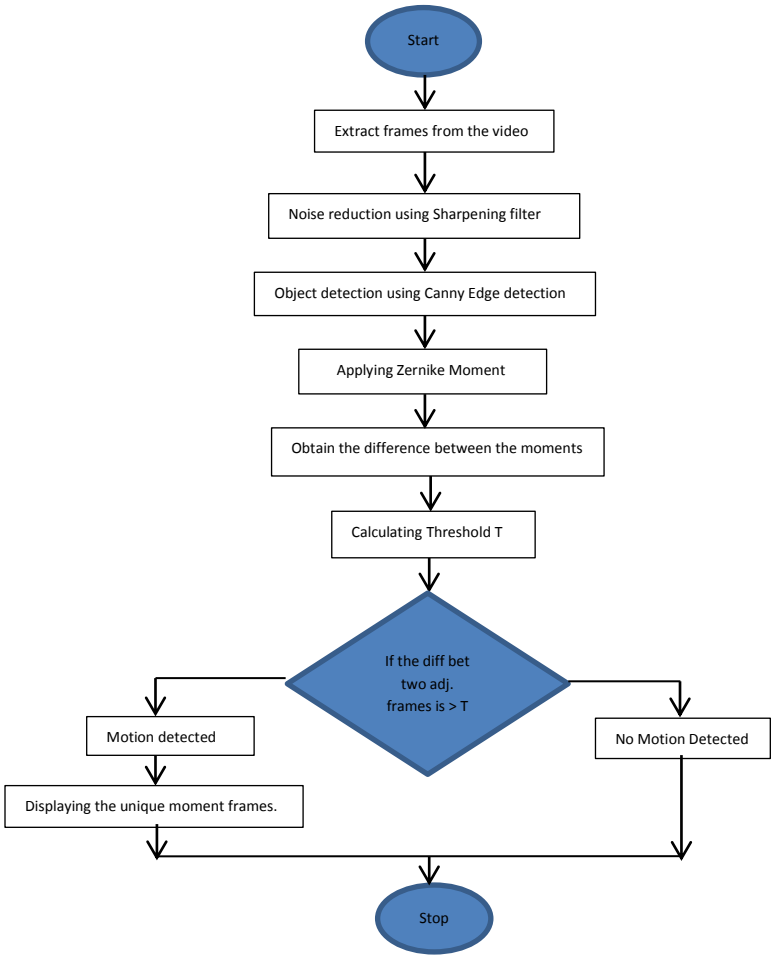

Fig 4.1. Proposed system diagram

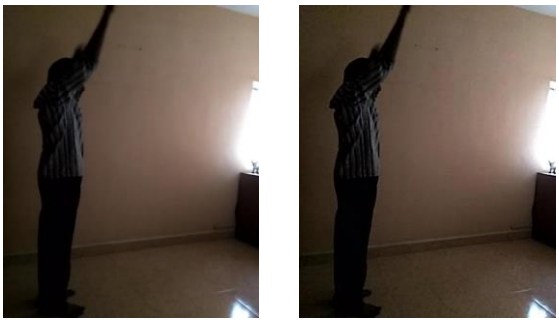
Enhancement can be done in various ways like color illumination, noise removing, removing blur from the blurred images etc. In the proposed system removal of noise and blur frames is performed using Sharpening filter to get the enhanced images or frames. After the noise removal the main aim is to detect the object on which we need to do the tracking of its movements. The canny edge detection method is used to identify the object from the frames which will just keep the object on focus. Then the next step is to track the object for which object features are extracted by using Zernike moments for better results. Once the object is tracked then the main focus is to track the unique moments of that tracked object. Figure 4.1 explains the proposed system. The detailed description about the proposed system is as follows:

Step1: Extract frames from the video: The proposed system includes obtaining of videos of .avi and .mp4 formats. Frames of the video are extracted and are stored for the further processing task.

Step 2: Noise reduction using sharpens filter: imsharp filter sharpens the image with the help of unsharp masking concept. Sharpness is essentially the distinct between various colors. A quick changeover from black to white appears sharp. A steady transition from black to gray to white appears blurry. Sharpening images growths the contrast along the edges where variety of colors meet. There is confusion with the name of this filter but an unsharp filter is an operator used to sharpen an image. Fig 4.2 shows the original and sharpen image.



Original Image Sharpen Image

Fig 4.2: Original image Sharpen image (For image no: 115)

Step 3: Object detection using Canny Edge detection: The performance criteria that the canny detector aims at are as follows:

1. Detection should be good
2. Good localization
3. Single edge should have only one response.

The steps of canny edge detection algorithm are as follows:

1. Gaussian filter helps to make the input image smooth.

2. Perform calculation of Gradient magnitude and phase of the filtered images.

3. Gradient Magnitude image is further used for applying non maxima suppression.

4. Apply two thresholds and perform connectivity to obtain the edges and link them. [12]
Fig 4.3 shows the original and canny edge detected image.

Original Image Canny Edge detected

Fig 4.3: Original image and canny edge detected image (For image no: 115)

Step 4: Applying Zernike moment: Moments defines the numeric amounts at certain distance from a reference point/axis. They are the scalar quantities which are used to describe a function and to obtain its features. It is broadly used for the description of shape. Hence, we can say that moments are used to extract the features [13] [14]. This concept was introduced in 1934 by Zernike. Zernike moments are representation of the image properties with negligible redundancy and information overlapping between them. Thus they can be utilized to extract features from the images. Zernike put forward a combination of complex polynomials which forms a complete orthogonal set over the interior of unit circle. For moment computation the origin is considered as the center of the given image and pixel co-ordinates mapping is done in the range of circle with unit distance. The pixels lying outside the unit distance circle are ignored at the time of computation. Hence Zernike moments are invariant under rotation. If all moments of a function f(x, y) up to order Nmax are known, then it is possible to reconstruct discrete function f(x, y) , whose moment matches to those of original function f(x, y) up to order Nmax [13].
Advantages of Zernike moments:
• Simple rotation invariance. • Higher accuracy for detailed shapes. • No redundancy. • Better at reconstruction.
Step 5: Obtain the difference between the moments: Initially the difference between two-two frames will be calculated. Assume there are 300 frames, so 299 differencing values will be calculated. Then the average of the same will be calculated. Sum of all the difference values will be divided by the total number. The result got is the mean.

Step 6: Calculating Threshold T:
Threshold is calculated with formula, niblack's algorithm:
$T(x, y) = m(x, y) + k^* \delta(x, y)$
Where $m(x, y)$ = local mean, $\delta(x, y)$ = standard deviation of the pixels which is inside the local window and K = bias. Default value of K is set as 0.5; $m(x, y)$ and $\delta(x, y)$ adjust the value of the threshold according to the contrast present in the local neighbourhood of the pixel. The k controls the adaptation levels by varying the value of threshold. Any value of frame differences higher than the threshold has unique motion in that frame. Then those frames are stored as uniquely detected motion.

V. EXPERIMENTAL RESULTS:

The Proposed method is implemented in MATLAB R2013a version.

Video details:
Name: walk3.flv
Size: 5310KB
Duration: 17 seconds
Total number of frames: 526

According to the analysis done on the video using all the Zernike moments right from z00 to z88, we have found that z75 and z55 are the two Zernike moments which gave the excellent results. These two moments have captured the small unique details from the extracted frames, which helps to find out what exactly happened in the entire video instead of going through the whole video.

The unique detected frames of Zernike moments Z55,Z60,Z75,Z77 and Z82 is shown in Fig 5.1, 5.2, 5.3, 5.4 and 5.5 respectively.

Z55

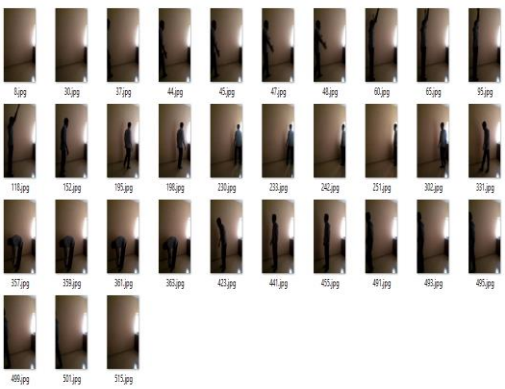


Fig 5.1: Uniquely Detected Frames of Zernike Moment z55

Z60

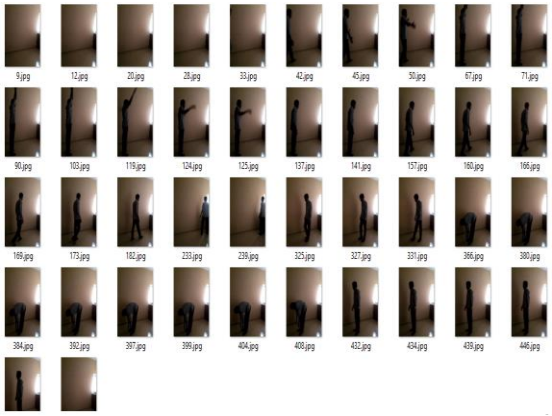

Fig 5.2: Uniquely Detected Frames of Zernike Moment z60

Z75

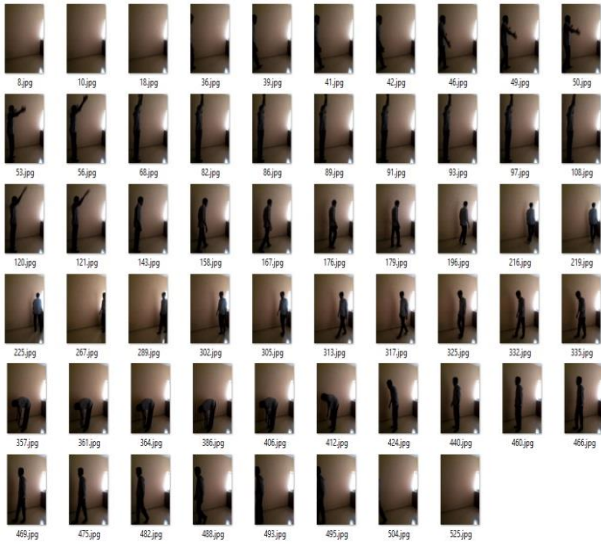

Fig 5.3: Uniquely Detected Frames of Zernike Moment z75

Z77

Fig 5.4: Uniquely Detected Frames of Zernike Moment z77

Z82

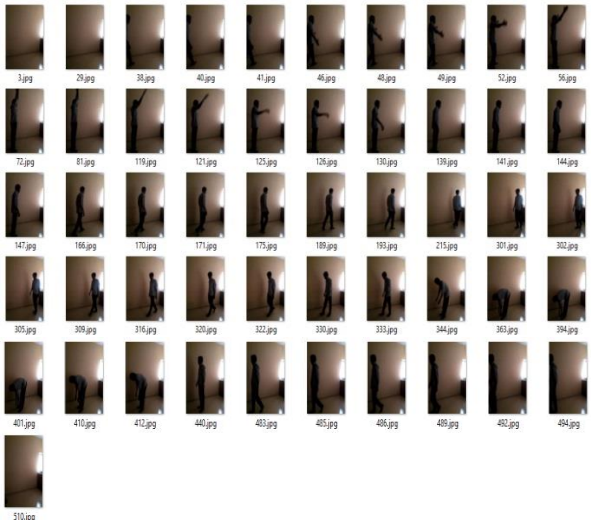

Fig 5.5: Uniquely Detected Frames of Zernike Moment z82

The total number of frames, unique frames detected and accuracy of the Zernike moments Z55,Z60,Z75,Z77 and Z82 is given in table 5.1

Table 5.1: Analysis of Zernike Moments, total number of frames, unique frames detected and accuracy.

Zernike Moment	Total no of frames	Unique frames	Accuracy
Z55	526	33	100
Z60	526	42	80
Z75	526	58	100
Z77	526	28	90
Z82	526	51	90

VI. PERFORMANCE ANALYSIS

6.1 Subjective Performance Analysis:

The Performance for the above mentioned Zernike moments were analysed by different types of audiences. The testing was done on it by different people and the analysis was done accordingly. As the audiences changes the way to the testing procedure changes. It was evaluated by other students, faculties, etc. The evaluator might rate the testing on each subjective criterion using a scale that ranges from poor to excellent. Subjective Performance Analysis for Zernike Moments is shown in Table 6.1.

Table 6.1: Subjective Performance Analysis

Zernike Moment	Poor	Good	Excellent
Z55	1	4	5
Z60	4	4	2
Z75	2	3	5
Z77	3	3	4
Z82	3	4	3

VII. CONCLUSION

The main idea of the work is to detect unique motion of the objects to trace any doubtful or unusual behavior. The study shows that the videos are taken by static cameras. That video is properly converted to the frames. As frames may contain some noise that is reduced using sharpen filter. Object detection plays an important role so the procedure should be done in such a manner that the object is properly extracted. This is done using canny edge detection algorithm successfully. Using Zernike moment the object tracking is done. Analysis was done with all the Zernike moments from z00 to z88. After the analysis, z55 and z75 gave the excellent results with 100% of accuracy.

Design of a miniaturised and novel DGS-based UWB antenna

***Abstract*—A novel and compact microstrip antenna with a slot designed in the shape of alphabet-I and a Defective Ground Structure (DGS) has been designed for UWB (Ultra Wide Band) and X-band applications. The dimensions of the designed antenna is 19 mm x 29 mm x 1.6 mm. The antenna was imprinted on FR4 material having relative permittivity of 4.4. Simulations were carried out using HFSS software and thereafter measurements of the fabricated prototype were done to validate the results. The reflection coefficient obtained covers both the UWB and X-bands extending upto 15.14 GHz. The radiation pattern is seen to be stable over the above mentioned band. This antenna with such a large band is designed with an aim to be put to use in microwave imaging experiments.**

***Index Terms*—antenna, ultrawideband, defected ground structure, microwave imaging.**

I. Introduction

In the year 2002, the Federal Communication commission (FCC) assigned the frequencies from 3.1 GHz to 10.6 Ghz as the UWB band for carrying out commercial communication. [1]. Since then active research efforts have been involved in developing more and more compact and low cost UWB antennas over time. The challenge faced by the designers is maintaining the large impedance bandwidth from 3.1-10.6 GHz along with a stable radiation pattern in the comptele frequency band [2].

Recently, UWB antennas are widely being applied in medical imaging using microwaves, such as in radar-based detection of bone anomolies, pulmonary edema, breast tumour, brain stroke etc. The antenna reported in this paper was designed to be integrated into a microwave imaging experimental setup. The antenna can act as transmitters to illuminate the model under study and also collect the scattered signals (occupying a large range of frequencies) coming from breast models to aid in a more accurate reconstruction [3].

Researchers across the globe have documented different (UWB) antennas which have microstrip feed or coplanar waveguide (printed) feed [4-7]. These antennas have various structures of the patch, have different shapes of slots, have complete ground on the bottom side or various levels of defected ground geometries; while others have been etched on substrates with varying ranges of dielectric constant (eg. Rogers substrate) [8-13].

In this article, a compact microstrip fed antenna with an I-shaped slot and a defected ground working in the UWB and X-bands (8-12 GHz) is presented. This DGS design with a semi-circular slot was instrumental in extending the bandwidth upto 15.14 GHz. This reported design was developed in HFSS software and was also verified using CST simulation studio. The fabricated antenna was placed in the anechoic chamber and tested with the Vector Network Analyzer (VNA) Agilent-PNAE8362B.

The paper has been arranged as follows. Section II explains in detail about the structure of the designed antenna complete with the dimensions of the cuts and slots made to the patch and ground planes.. Section III reports the results obtained during the testing of this antenna after fabrication against the simulated results. Finally, Section IV concludes the paper.

II. Antenna Design

The patch and ground schematic of the reported antenna has been depicted in Fig. 1 (a) and (b). The dimensions of the antenna and its slots have been listed in Table I. This novel structure was modeled using the HFSS platform to obtain the desired radiation characteristics. Thereafter, the antenna was etched on an FR4 substrate material which is prevalently employed in antenna fabrications. The FR4 material possesses dielectric constant of 4.4, loss tangent of 0.02 and comes with a height of 1.6mm.

Patch has an I-shaped slot to obtain the desired return loss in the UWB band. A hexagonal shaped patch of copper has been placed inside a circle of radius 5.7mm at the centre of the patch to attain better radiation patterns. The dimensions of the various cuts and slots of the patch at the top and near the feed end have been optimized through parametric analysis.

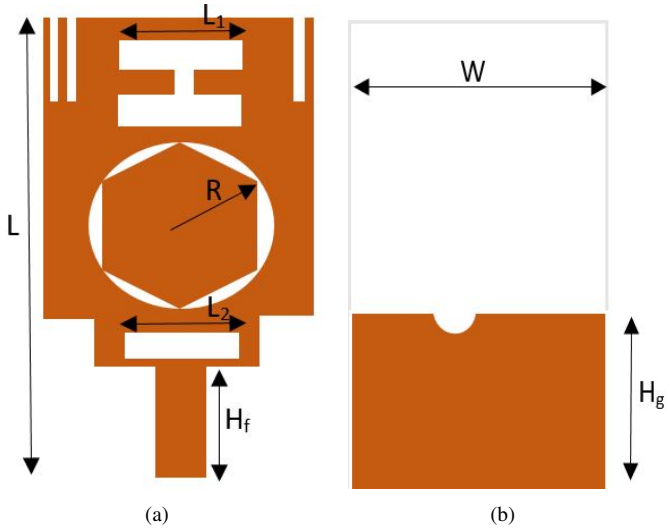

Fig. 1. Schematic diagram of the designed antenna showing the (a) top patch and (b) the ground.

The ground plane does not occupy the entire bottom side of this micro strip antenna. The ground plane has been modified to arrive at a DGS structure extending only upto a height of 5.8mm. A semicircular slot of radius 1.3mm has been etched out of this ground at the top. The DGS structure aided in attaining the large bandwidth as reported.

H_g	5.8

III. RESULTS AND DISCUSSION

The return loss simulations showed that the antenna had an impedence bandwidth extending from 3.05 to 14.5 GHz covering the UWB as well as the X-band and extending further. To verify the simulated results, the fabricated antenna was tested in the laboratory using the PNAE8362B network analyzer that could measure upto 20 GHZ. The measurements of return loss obtained validated the antenna's simulated results as clearly depicted in Fig. 2. It can be seen that the resonances of the fabricated antenna fall at 3.6 GHz, 4.9 GHz, 7.4 GHz, 8.3GHz, 9.6 GHz, 11.8 GHz and 13.9 GHz. The connector losses and fabrication errors may be the reason for this slight shift.

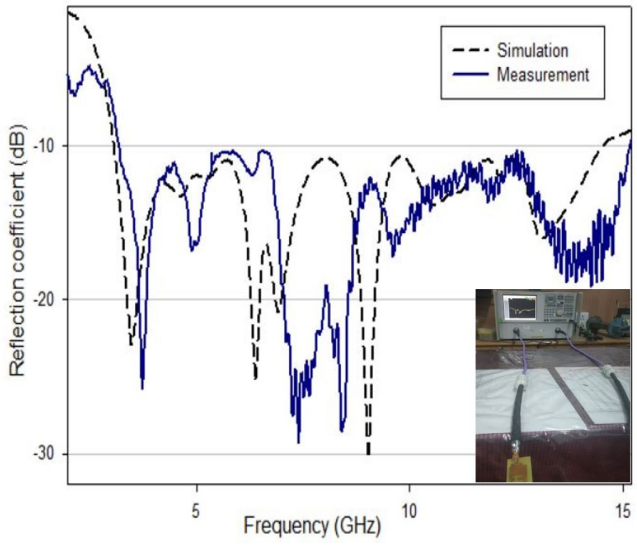

Fig. 2. The return loss of the antenna and the measurement setup in the inset

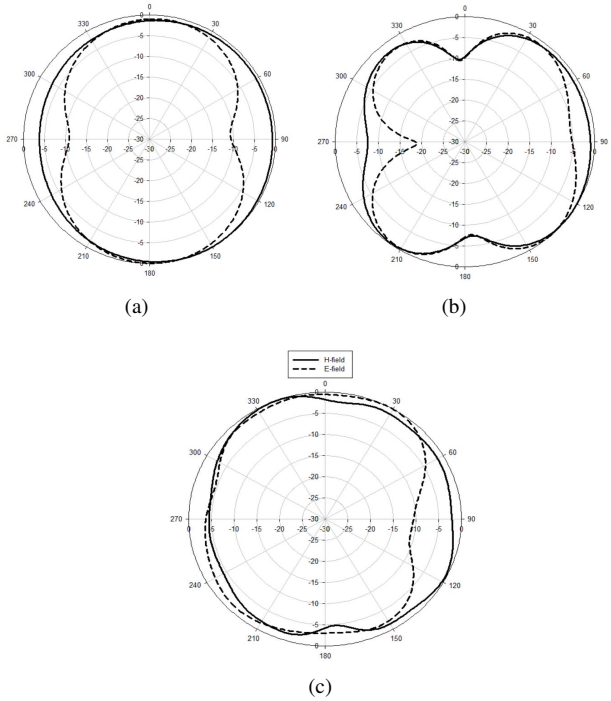
The return loss alone is not enough for judging the versatility of any antenna. Additionally, an omnidirectional radiation pattern that is stable throughout the proposed band is also required. Hence, the radiation pattern analysis was carried out for the antenna in the desired range of frequencies. The pattern is observed to have a desired nature in the entire band. The E-field and H-field radiation pattern plots have been shown in Fig. 3 (a-c) for 4GHz, 8GHz and 10GHz. It is observed that the pattern is more ideal at the lower frequencies and keep on taking more and more distorted shapes at higher frequencies.



(a) (b)

(c)

Fig. 3. E-field and H-field radiation pattern obtained at (a) 4GHz, (b) 8GHz and (c) 10GHz.

To know the advantage of the designed novel antenna reported in this paper over other state-of-art antennas present in the literature, a comparative analysis is carried out and illustrated in Table II below. Compactness in antenna size has been achieved with the dimensions of 19 x 29 sq.mm. Additionally, it may be noted that a very large bandwidth extending upto 15.14 GHz has been maintained with such compact antenna dimensions.

TABLE II
COMPARISON TABLE

Reference	***Size*** (mm^2)	***Band (GHz)***

Yeo et al. [13]	30 x 32	2.99-10.87
Proposed antenna	19 x 29	$3.1 - 15.14$

IV. Conclusion

A novel ultrawideband antenna capable of operating in the UWB and X-bands was designed and fabricated. The antenna has a compact size of 19mm x 29 mm x 1.6 mm operating over a band of 3.1 to 15.14 GHz. The antenna has been developed to be included in a microwave imaging setup to illuminate the object under study and to collect the signals scattered off this object for further reconstruction and analysis for breast tumour detection.

Acknowledgment

The authors express their gratitude to Professor P. Mohanan of Department of Electronics, Cochin University of Science and Technology, Cochin for his guidance and also for permitting to carry out the measurements of the fabricated antenna in Centre for Research in Electromagnetics and antennas (CREMA) lab.

Abstract—**This paper presents implementation of FPGA based low power music system and digital data transmission in real time environment. The proposed system consists of a music source, voltage divider, JXADC Pmod, Artix-7 Processor, DDR2 memory and Mono Audio Out. Music source provides analog input using auxiliary wire to the JXADC port. The music data is sampled at 44.1KHz using JXADC and output is taken from the headphone jack using PWM. JXADC port requires bias voltage of 0.5volt that is made available from on-board 1volt rail found on J14. A divider circuit is used to obtain 0.5volt out of 1.0volt input. Nexys4 DDR board is used for designing the algorithm of real time music system. Algorithm is designed using Verilog on Vivado 2018.3 Design Suite. In this process XADC's consumes 0.002W of total power 1.198W. The music system provides an excellent music data to the audio out pin J8 in real time.**

Keywords— FPGA (Field Programmable Gate Array), JXADC Pmod (Analog to Digital Converter Peripheral module), PWM (Pulse Width Modulation), DDR2 memory (Double Data Rate 2 RAM).

I. INTRODUCTION

Rapid progress of digital and multimedia technology, real time music data has been used in many remote locations like analog to digital transmission, Bluetooth transmission or by wired transmission [1]. In the recent days, digital audio data transmission is very important in digital electronics world [2]. The digital audio processing in real time made a vital role [3], where low power processing take place. The digital Audio data processing done in three steps [4], at first, the analog audio data process through the Pmod XADC port for converting the data in analog to digital format. Secondly, the digital formatted data can be transmitted in remote location from FPGA [5], that is very first process in terms of other devices. Thirdly, we can transmit the data by wires in digital format that's also been converted to analog formatted data by using of PWM on J8 pin on Nexys4 DDR board [6]. The basic advantages of Artix-7 processor is control. Artix-7 processor gives highest performance in per watt fabric, data processing and integration in a cost sensitive FPGA. Featuring the micro-blaze soft processor and 128MiB DDR2 support, the family is perfect for power-sensitive applications including low-end wireless communication, software-defined radio and machine vision cameras [7].

The goal of this paper is to introduce a novel low power-based music framework utilizing rough string-coordinating circuits for diminishing the computational time [8]. Field programmable gate arrays (FPGA) based design is appropriate instead of using application specific design. The FPGA procedures have similar computational speed to that of ASIC strategies. In addition, in light of their reconfigurable capacity, the FPGA gadgets give lower cost to changing circuits. This is very useful at the point of data transmission management. In the FPGA, signal processing is done by serially. So, minimum power management is also restored here.

This paper is separated in 5 Section and individual Section as follows, Introduction is discussed in section I and Section II describes the system design as block design format for real time music system. In the Section III low power-based design analyzed using proper implementation design and in Section IV the implementation design has been programmed on Nexys4 DDR FPGA board and simulation result has been discussed. In the last Section V result has been concluded and mentions the future scope.

II. SYSTEM DESIGN

Low power hardware-based music system is a data processing system in real time [9]. The music data processes from an external input sources and we can get the output at the mono audio output port. At the same time, this digital music data can be simultaneously sent through wired channel [10], Bluetooth or wireless transmission at any remote location [11]. The core design of music System block diagram is shown in Fig.1.The whole design act as an audio data processing system. The music or audio data fed to the JXADC by an auxiliary input cable and converted to the digital audio data. Which processed by the main process controller. Hence, digital data ready for transmission from FPGA to the remote location at the same time. Digital data transmission can be done by wire or wireless medium by using proper channel [12]. Digital data easily played at the mono audio output port through the head phone jack at J8 pin. Because of PWM the digital data converted to the analog format simultaneously. In this process the voice quality has been improved at the low power consumption level.

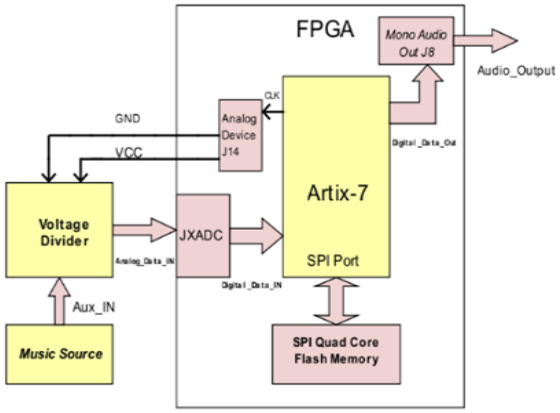

Fig.1. Block Diagram of Real Time Music System using FPGA

In the above block design in order to have a reliable transmission of data following blocks such as Music Source, Voltage Divider, JXADC and Mono audio output plays a crucial role. The analog data is transmitted at 0.5v after passing through the Voltage Divider from the Music Source. Analog to digital conversion is done by JXADC and after processing the data from Artix-7 processor the digital data out fed to the Audio out port. The Mono Audio Port plays a vital role for Noise cancellation and Pulse Width Modulation (PWM) and output is taken from the same port.

III. POWER ANALYSIS

The entire process is strongly able to manage a low power analysis. The implementation design is most effective in low power application [13]. In music system the maximum power is consumed up to 1.218 W. After implementing the design algorithm in Nexys4 DDR board, we have been analyzed the total on chip power is 1.198W shown in Fig.2. and the XADCs consumed the minimum power reason of using a voltage divider after the music source shown in Fig.3. The static and dynamic power is also derived from constraints files, simulation files or vector analysis. The static power of the device depends on the process, voltage and temperature. In this design the device static power is 9% of total on-chip power and the rest of the power is dynamic power i.e. 91% of total on-chip power, describes in fig.2.

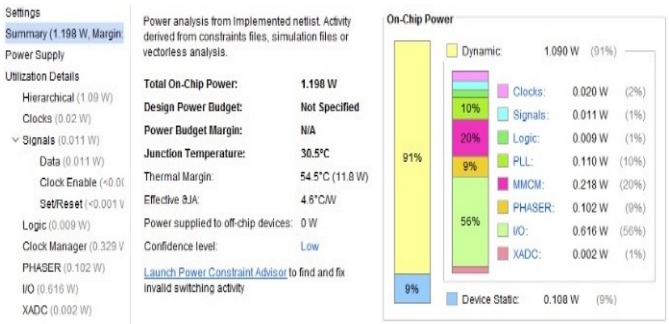

Fig.2. Power Analysis of Real Time Music System

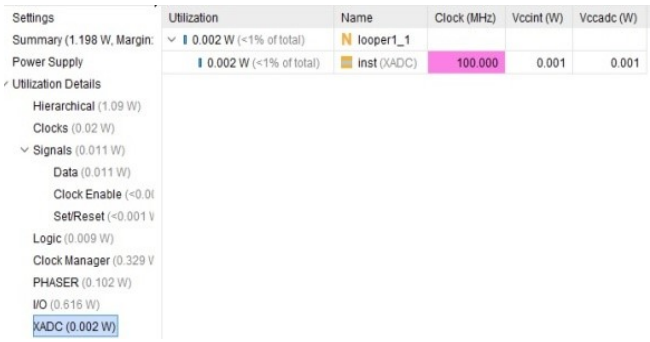

Fig.3. Minimum Power supply to the XADC Port of Real Time Music System

IV. RESULT

The prospective architecture is synthesized using VHDL in Vivado 2018.3 Design Suite. The design has been implemented on Nexys4 DDR (Xilinx part number XC7A100T-1CSG324C) FPGA kits. On board JXADC (Analog to Digital converter Pmod) that is next to the Pmod of JA. MIC is used to acquire the voice data from outsides and that data has been converted to the digital format by the on-board JXADC that is interfaces through the processor to the MONO AUDIO OUT (J8) pin. The real music system is implemented using FPGA at low power level. The RTL level schematic design and Simulation result of music system has been shown in Fig.4. and Fig.5. The hardware implementation design of low power based real time music system is depicted in Fig.6. where the music data is continuously playing in the audio port using a headphone jack at J8 pin.

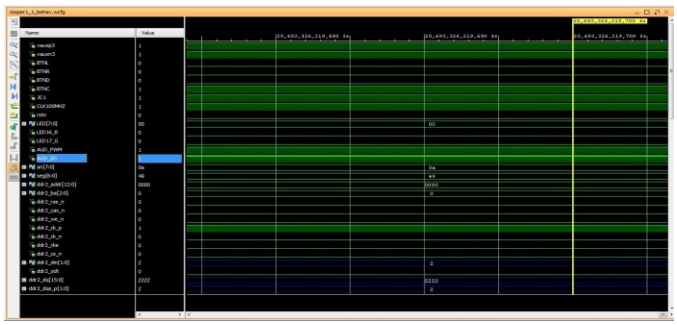

Fig.4. The simulation result of Real Time Music System

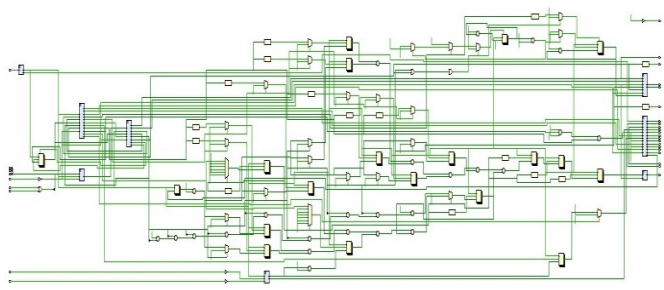

Fig.5. The RTL design of real time low power-based Real Time Music system

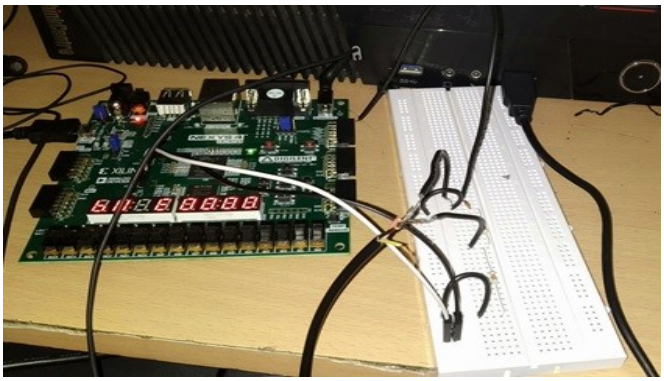

Fig.6. The hardware implemented design of low power based Real Time Music System

V. CONCLUSION

In this paper, low power level based real time music system hardware has been implemented on Nexys4 DDR board. First, the Auxiliary input analog data fed to XADC port by using a bias voltage with the help of voltage divider circuit shown in Fig.6. Then entire design has been synthesized on Vivado design suite 2018.3 and implemented on Nexys4 DDR board successfully and ensures superb voice quality on real time music system. Wherever low power is maintained in music system, we can use this type of approach and digital data transmission from the FPGA in real time produce a great advantage to manage the data at any remote location area where digital audio data is essential. In the future of work, the current approach and implementation design will improve by adding some extra interfaces for conventional real time music system.

ACKNOWLDGEMENT

This work is a part of SMDP-C2SD project under (Under MeitY). The authors acknowledge the technical and EAA tools support. Further optimization is required then it's may be possible to done on FPGA for sophisticated application. we are very thankful to the ministry for providing constant support.

***Abstract*—Today applications those work above Ethernet or Fast Ethernet will operate similarly well on Gigabit Ethernet. The redesigned system will convey undeniably more the application traffic. In this paper, Ethernet IEEE 802.3 Standard based interface design system in Verilog-HDL has been designed. This GMII interface recognizes Ethernet Frame Protocol and works at 1Gbps speed. The interface configuration has been simulated, later on it has been synthesized and implemented. The interface works on 125 MHz frequency. With the designing of this interface, Total On-Chip power as Static and Dynamic power, Slice logic, LUT as logic parameters are analysed. Furthermore, the implementation result is verified.**

Keywords—Ethernet, GMII interface, Ethernet MAC, OSI reference model.

I. INTRODUCTION

The development of data innovation including progression of data communications is quickly expanding. This open door impacts a significant improvement in other's life aspects. Without a doubt, the development of data innovation itself impacts likewise on innovation advancement of planning and executing hardware-based framework [1]. Usage of web, treated as one medium or arrangement of information correspondences, results numerous points of interest, for example, information security, far reaching network, fast of information transmission, and solid information trade component.

However, the execution of web arranges which will be utilized is unquestionably affected by gadgets or gear utilized inside the system [2]. The gear which will be utilized can be viewed as from the physical viewpoint, for example the equipment viewpoint. Conventions which will be utilized for information interchanges are additionally considered as imperative piece of executing the web organize.

Moreover, Advances in VLSI innovation have additionally pushed joining to the point where it is presently conceivable to structure and execution a system controller and microchip on single chip, which is known as SoC (System-on-chip) [3]. The Gigabit Ethernet innovation is an augmentation of the 10Mbps and 100Mbps Ethernet standard. Gigabit Ethernet gives an information data transfer capacity of 1000Mbps while keeping up full similarity with the introduced base of more than 70 million Ethernet hubs [4].

Gigabit Ethernet includes both full-duplex and half-duplex working modes. Gigabit Ethernet underpins arrange the board, existing applications, and the system working frameworks, which requires insignificant expectation to absorb information for Ethernet organize clients and directors [5]. These hazard minimization and speculation conservation angles are make Gigabit Ethernet excessively appealing.

The principle point of planning the Header and Trailer of Ethernet frame is isolated and remerged by the module which an interface module. The planning module will be an equipment based coordinated framework structured utilizing Verilog-HDL which may taking care of data relating correspondence conventions or principles which are utilized. The module interfacing procedure will be centred around the interfacing of Data-link-layer (Layer 2) and Physical Layer (Layer 1) in the view of the Ethernet convention IEEE 802.3 for picked the availability of Ethernet 1Gbps.

Fig. 1.1 gives an outline of IEEE 802.3 Gigabit Ethernet layer tends to the MAC and PHY layers of ISO model.

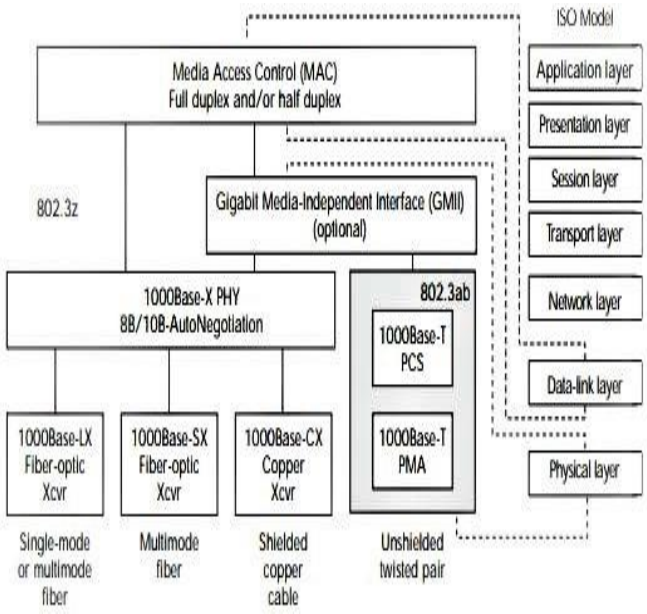

Fig. 1.1. Gigabit Ethernet layer graph tends to the MAC and PHY layers of the ISO model [7]

II. BACKGROUND

There are a few aspects or parts of communication conventions. These conventions are mainly centred to principal idea of Ethernet IEEE 802.3.

A. Introduction to OSI

A certain device manufactured by different manufactures need to follow consistent standards to able to communicate properly. This shows the development of certain reference models and network models, while network models set a standard as to how data communication or information transfer over a network.

The reference models divide the functions of network into layers. The two most popular reference models are OSI reference model and TCP/IP reference model. Open Systems Interconnection (OSI) provide standardization for protocols to be used in different seven layers [6]. The OSI reference model's every single layer act based on protocol of definitive type to communicate to peer layer of another node or system. Ethernet is perturbed with physical and data link layers of OSI reference model.

The Layer 1 (Physical layer) is responsible for converting the data from the form in which it is represented in data link layer to the form in which it is transmitted over the raw bits i.e. physical medium. Physical layer provides the hardware required to send and receive information over the physical medium [7]. This hardware contains clock synchronizer, signal encoders, line drivers, etc. It also defines the mechanical, electrical, and timing specifications for these devices that enable transfer of data over the communication channel. It also includes pin voltages, line impedances, cabling specifications like cabling distance, cabling type etc.

Data link layer is responsible for peer to peer or node to node communication within a network. The main function of data link layer is to convert the incoming data into frames, while other functions are include addressing, error control, control of access to shared medium and flow control [8]. Each frame contains its destination and source addresses which allows the identification of the sending and receiving stations respectively on the network. The corresponding OSI reference model and its Layer 2 architecture shown in below Fig. 2.1.

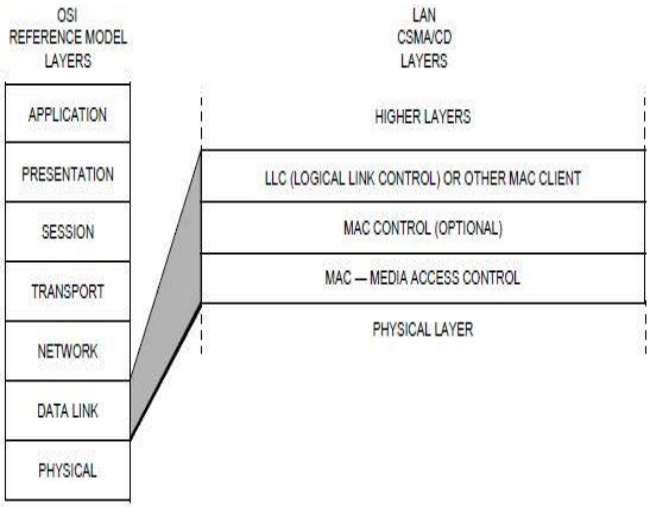

Fig. 2.1. OSI reference model and architectural positioning of Layer 2 [2]

B. Ethernet Frame Format

The heart of the Ethernet communication system is the Ethernet frame. The network hardware constitutes of the Ethernet interfaces, physical media cables move Ethernet frames between computers network or stations. In Ethernet frame the bits are formed up in specified fields. The basic Ethernet frame format is shown below Fig 2.2.

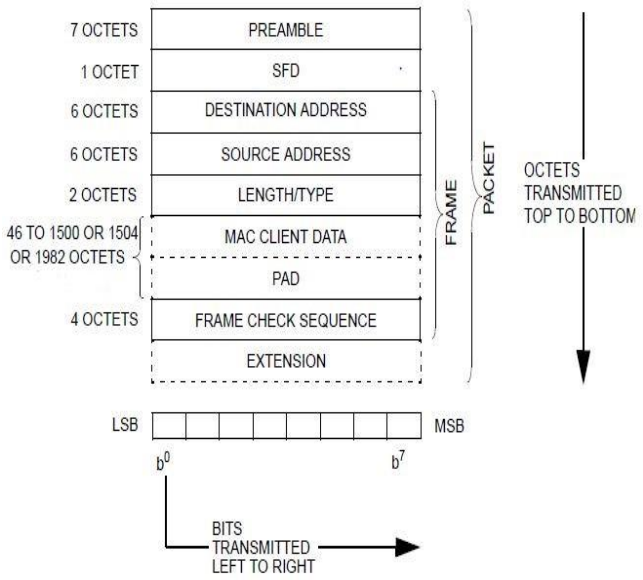

Fig. 2.2. Basic Ethernet Frame Format [5]

C. Ethernet Media Access Control

The Data link layer is partitioned into 2-Sub-layers namely the Logical Link Control sub-layer (LLC) and the Media Access Control sub-layer (MAC). The Logical Link Control sub-layer works as alliance between physical layer and the higher layer of protocol. The Media Access Control sub-layer adopts LLC to different media access technologies and physical medium. The main functions of the LLC sub-layer are flow control and multiplexing the protocol fields transmitted over the MAC sub-layer while transmitting and decoding them while receiving [9].

All Protocol signals are created which are required by the MAC module and its separate FIFO supportive buffers, according to the Host interface [10].

- The Transmitter control module, which originates frames is consisted by the Transmitter.
- The Destination address field, the Source address field and the Length/Type field of frame which is originate in transmit control module is included in the MAC address viper.
- A Cyclic Redundancy Code (CRC) generator is comprised in the transmitter to create the necessary CRC bits which is attached as the Frame Check Sequence (FCS).
- The Receiver control module, which decapsulates the protocol fields of frame is consisted by the Receiver.
- A checker of CRC is responsible to check lapses in frame transmission.

- The checker of MAC address is responsible for MAC address fields checking. It additionally checks for broadcast or multicast frames address.

The Ethernet Media Access Control (MAC) architecture shown in below Fig 2.3 consists of the Transmitter module and the Receiver module.

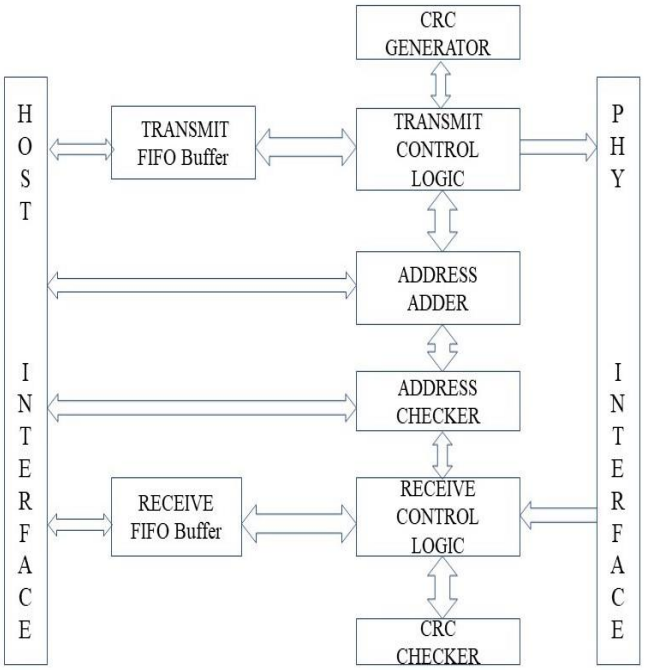

Fig. 2.3. MAC Implementation Block Diagram

III. THE DESIGN AND ITS SIMULATION

For the designing of this interface and advancement, the essential idea of configuration stream as following: the underlying advance of this reasonable structuring is started with characterizing the for the most part structure detail. The idea of configuration stream of this structured framework and advancement completed as the framework satisfied the significant criteria seen from its distinguishing identification process.

A. Design Specification

The initial step of design is started with characterizing about design specification. The plan worries on information interfacing which created from ethernet controller. Information unquestionably came about because of controller are 8-bit [11]. Information treatment of this plan isn't totally centred around the information originated from Ethernet PHY. The information is real information that complying with Ethernet frame protocol i.e. IEEE 802.3 Ethernet Standard.

Besides, this structure isn't totally executed for 10Mbps of Ethernet availability [12]. In any case, this structure is actualized dependent on strategy for 1Gbps of Ethernet connectivity.

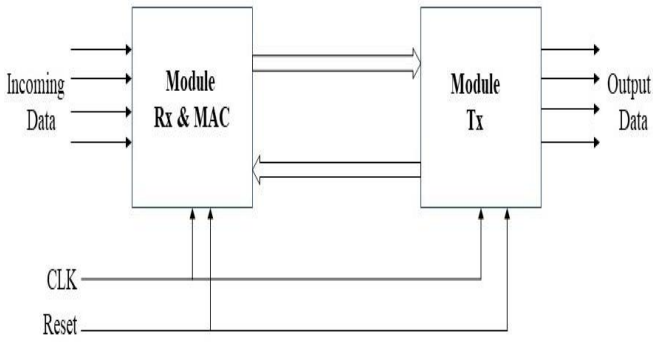

Fig. 3.1. Main Modules of Interfacing System

B. Functionality of the Designed Interface

The planned framework comprises of two primary modules to be specific, the Transmitter (Tx) and the Receiver (Rx). The Transmitter (Tx) as the primary module is arranged at host/PC, and the other module is arranged as the Receiver (Rx) at host/PC. However, the principal module and second module are capricious.

The interface framework outline is delineated in above Fig 3.1. Each unit has its own particular usefulness. The usefulness of every unit can be characterized as:

- **Module Rx-MAC,** which forms the approaching information, which will at that point recognize the Ethernet frame presence and complying with the MAC IEEE 802.3 convention inside the approaching information coursing through framework interface. In receive module the clock provided by PHY device (125MHz) is connected to MAC clock, rx_clk.
- **Module Tx,** which processes to control the gearbox information out from the interfacing framework. The gearbox information out is identified with MAC bits (Eight - bits). In transmit module standard programmable PHY devices operating in 1000Mbps mode generate a 125MHz clock.

Below Fig 3.2 shows the RTL view diagram of main module of interfacing design system, which consist of Rx and Tx-modules respectively.

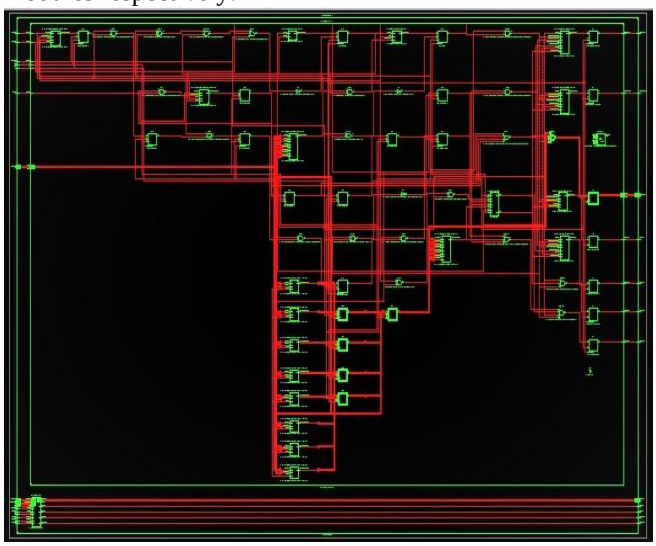

Fig. 3.2. RTL view diagram of design interfacing system

C. Design Simulation

The design system simulation was performed utilizing Xilinx ISE 14.7 and Vivado HLS 2016.2. The ISE Design Suite 14.7 was utilized to simulate the Verilog based interface plan framework. Inside the simulation, each module of incorporated plan framework will be gotten to dependent on usefulness and time imperative.

The PHY device expects a 125MHz clock from MAC system function in gigabit mode. Due to the MAC system function does not generate a clock output, an outside clock module is acquainted with drive the 125MHz clock to PHY devices and MAC system function. During the transmission MAC control signal selects GMII, which subsequently drives the MAC GMII to PHY interface.

In the Fig 3.3, recognition of substantial Ethernet frame is appeared, and yellow circle depicts the frame Preamble field which is responsible for clock synchronization. And red circle indicates the Payload or MAC client data field of Ethernet frame. MAC client data can be 46 to 1500 Bytes for Data frame, and those Ethernet frame contains Payload (> 1536 bytes) consider as Type frame. In indigo circle indicates the Inter Frame Gap (IFG) between the two consecutive frames. According to IEEE 802.3 Ethernet standard IFG should be 12 Bytes in normal communication transmission, most importantly IFG is decided by PHY device. As per IEEE 802.3 Ethernet standard minimum value of IFG can be 5 Bytes.

Fig. 3.3. Detection of different field of Ethernet Frame

Ethernet frame has dispatched to beneficiary module to one occasionally and analysed for recreation confirmation of casing. As indicated by Fig 3.4, at whatever point the FCS sent to beneficiary, the module RX-MAC looks at the FCS to other assertion FCS come about by checking the information section of Ethernet frame. In below Fig 3.4, red circle indicates FCS field match to receiver module side and transmitter module side. In Ethernet frame FCS field can be 4 bytes at before end of frame i.e. tx_en = 0.

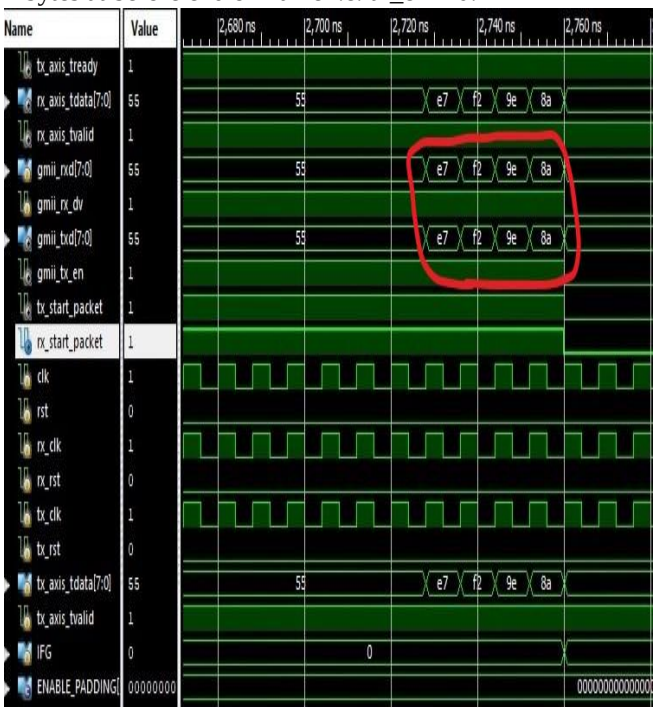

Fig. 3.4. Detection of FCS with no error

IV. VERIFICATION PROCESS

Verification procedure of our interface configuration is the procedure executed at whatever point the information embedded to interfacing plan framework. Verification process depends on a few stages which are characterized as pursues as:

- The first 7 bytes of Ethernet frame, will consider to Preamble field identification and to recognize next byte will consider as Start of Frame Delimiter (SFD).
- Address field identification, at any time the preamble field and SFD identifiaction process has been done, the next six bytes will occupy as Destination address field, and further next six bytes will consider as Source address field.
- The other stage is related to identification of the tagged frame, it will occupy next four bytes if frame is tagged and occupy next 2 bytes for Length/Type field. In case of untagged frame it will occupy 2 bytes only.
- After the identification of Length/Type field, MAC client data field starts, it can be 46 to 1500 bytes in case of Data frame. And in Jumbo Ethernet frame can carry up to 9000 bytes Payload.
- Last four bytes (before Inter frame gap) of Ethernet frame will consider as Frame Check Sequence (FCS).

Below Fig 4.1 shows the Verification process of Ethernet frame FSM. It shows the distinct fields detection of Ethernet frame.

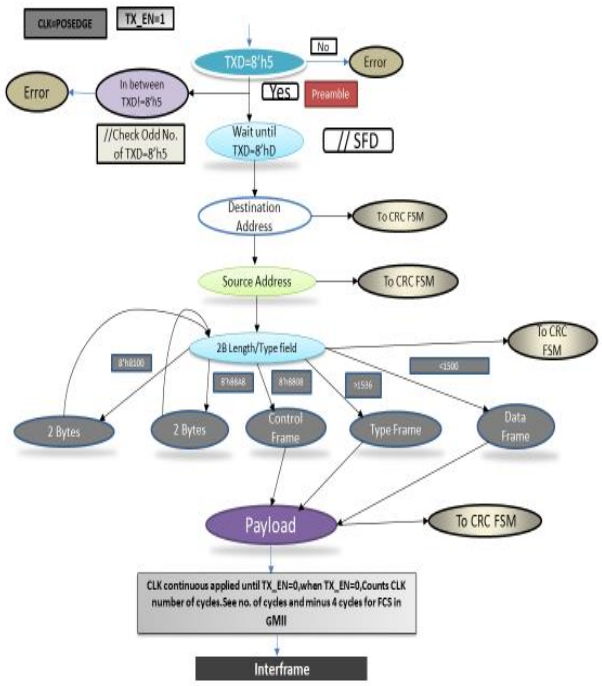

Fig. 4.1. Verification process FSM of Ethernet frame

V. CONCLUSION

In this report, a straightforward interface configuration dependent on Ethernet convention has been designed. The configuration of this interface is open or straightforward to physical media for information correspondence. To plan this interface, it is required 297 Slice logic, 136 LUT as logic and based on sysnthesis result, the Total On-Chip power 2.738W in which Dynamic 2.636W and rest Device static 0.102W is used. The Ethernet casing of IEEE 802.3 Protocol is recognized by this interface, which also comprises of Rx-module and Tx - module. The interface's design functionality has been verified by indicated its Verification process that it works appropriately as it also can recognize 802.3 Ethernet Frame.

India

***Abstract*— This paper proposes a Modified-Mixed Logic Design (MMLD) for the decoders, which comprises full swing Gate diffusion input (GDI) technique, conventional complementary metal oxide semiconductor (CMOS) and Dual value logic (DVL). Two modernized topologies: 14T and 15T decoders are designed for minimizing power dissipation and propagation delay respectively. Each traditional and inverting decoder is enforced in every case. Compared to the conventional CMOS logic, the proposed decoder gives full swing with reduced count of the transistors. The spread of Cadence (Virtuoso) simulation at 45nm is used for implementing this proposed mixed logic decoder at different frequencies with different various supply voltages, which shows reduction in power dissipation & propagation delay as compared to typical CMOS and existing mixed logic design.**

Keywords—Modified Mixed Logic Design (MMLD), Full swing GDI, DVL.

I. INTRODUCTION

The primary issue in modern technology world is power reduction. The low-power [1] designs are of great importance among all electronics domains like Integrated Circuits, System on Chip (SoC), DSPs, Digital Phase Locked Loop [2] and Very Large-Scale Integration (VLSI) and in many different domains [3].

The design of the systems is becoming increasingly compact in today's world as the technology is developing so rapidly. Even though the circuits are not compact in some systems; there is still a need for less power consumption. There is a huge demand of applications that consume less power and are smaller in area.

Static CMOS network consists of one pull-up and one pull-down network and it gives good output driving capabilities [4] together. There are different CMOS technologies to design any circuit like PTL, TGL etc.

Pass transistor logic (PTL) was initiated during late 20^{th} century, whose main motive was to deliver a good backup to conventional CMOS design in the sense of power, area and delay [5]-[7]. The major difference in the design is that, in PTL all the terminals that are presented can work as inputs.

Transmission gate logic (TGL) is a parallel bidirectional switch composed of NMOS and PMOS transistor. With the help of TG logic, implementation of complex designs can be easily done with a smaller number of transistors [8].

Further the paper is sectioned as follows: Brief understanding of Decoder circuit designed by using normal CMOS logic and mixed logic is given in section II. The modified mixed logic design is explained in section III. Relative simulation results and performance analysis among different designs is discussed in section IV. Section V provides application of proposed decoder and finally section VI tells about the conclusion and future scopes.

II. OVERVIEW OF DECODER CIRCUITS

Decoder is used to convert the data (which is available in coded format) from one format to another. So, we can say that a decoder translates a set of input data signals as their outputs into an equal decimal code. In other words, decoder is mainly a circuit that changes an obtained code into a group of signals. N-digit binary information is being translated into 2^n unique data lines in basic decoder circuit.

A. 2-4 Decoder using conventional CMOS logic

A decoder of size 2-4 produces four outputs from D0 to D3, where A & B are two inputs. Based on the combination of inputs, at a time only one output is set to one, while the remaining outputs are set to zero. On the other hand, an inverting decoder of size 2-4 also produces four complementary outputs from I0 to I3 in which based on the combination of inputs, one of the outputs is made to zero and all the remaining outputs are made to one.

The truth table of 2-4 Non-Inverting and inverting decoders are shown in Table I and II respectively.

TABLE I
TRUTH TABLE OF THE 2–4 DECODER

A	B	D_0	D_1	D_2	D_3
0	0	**1**	0	0	0
0	1	0	**1**	0	0
1	0	0	0	**1**	0
1	1	0	0	0	**1**

TABLE II
TRUTH TABLE OF THE INVERTING 2–4 DECODER

A	B	I_0	I_1	I_2	I_3
0	0	**0**	1	1	1
0	1	1	**0**	1	1
1	0	1	1	**0**	1
1	1	1	1	1	**0**

A 2-4 non-inverting decoder requires four NOR logic and two inverter logic as depicted in Fig. 1(a). On the other hand, a 2-4 inverting decoder is implemented with four Nand logic and two inverter logic as depicted in Fig. 1(b).

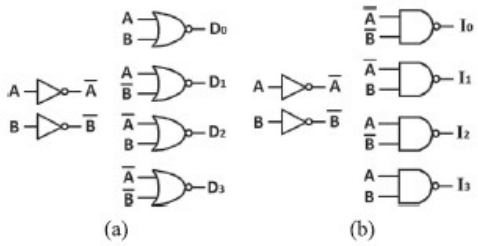

Fig. 1. 2-4 Decoder (a) Non-inverting decoder (b) Inverting decoder.

B. 2-4 Decoder using mixed logic design

Mixed logic [9] design comprises of transmission gate logic (TGL), conventional CMOS logic and dual value logic (DVL).

DVL is a type of Pass Transistor Logic (PTL). Actually, in PTL, two types of styles are present: Those using only NMOS transistors such as CPL and those using both NMOS & PMOS transistors, such as DPL and DVL [7]. But the logic which is taken here is DVL, because it eliminates the extra branches which are available in DPL and also it will sustain the full swing of DPL [10].

With the help of transmission gate logic and dual value logic AND & OR gates can be easily implemented [8], therefore it is used in decoders. To implement non-inverting decoder, take two inputs A and B. D0 & D2 outputs are designed with the help of DVL gates [7], where signal A is working as propagating signal. D1 & D3 outputs are done with TGL gates as shown in Fig. 2(a). Whereas to implement inverting decoder outputs I0 & I2 are done with TGL gates and outputs I1 & I3 are done with DVL gates as shown in Fig. 2(b).

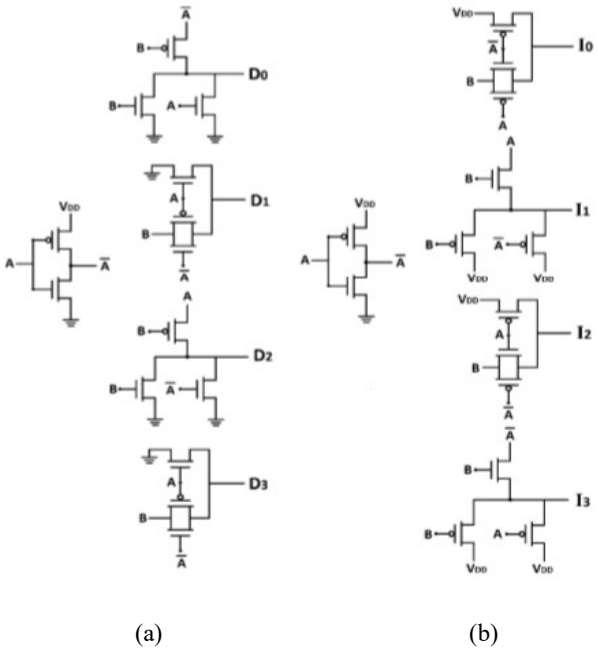

Fig. 2. 2-4 decoders. (a) Non-inverting. (b) Inverting.

III. MODIFIED MIXED LOGIC DESIGNS

In modified mixed logic design the transmission gate part of decoder, used in existing mixed logic decoder, is replaced by full swing GDI technique. AND and OR gates can be accurately done by using full swing GDI logic technique and DVL. Hence a decoder can be designed by using GDI and DVL with conventional CMOS inverter. Full swings GDI based AND/OR gates [11]-[12] and DVL based two input AND/OR gates are shown in Fig. 3(a), (b), (c) and (d) respectively.

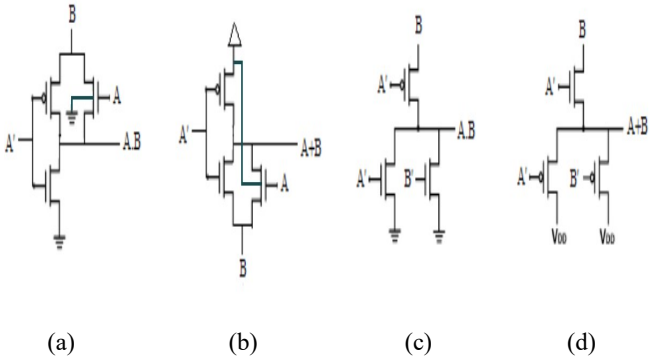

Fig. 3. AND/OR gates with three transistors (a) GDI based AND Logic. (b) GDI based OR logic. (c) DVL based AND logic. (d) DVL based OR logic.

As indicated in Fig. 3, two gate inputs A & B are labeled. In full swing GDI based AND/OR gates, input A is controlling all the three transistor's gate terminals, whereas in case of DVL based AND/OR gates input A is connected to the gate terminals of two transistors, while input B is controlling the gate terminal of one transistor and it is also working as propagating signal.

While designing any gates with the help of these techniques, always the concern is that never use complementary input signal as propagating signal because it adds inverter in the propagation path, which will contribute more in delay.

A. 2-4 Low-Power Decoder using 14-Transistor Topology

A 2-4 inverting decoder is designed with the proposed modified mixed logic design. Let us take two inputs A & B, where D0 & D2 outputs, of decoder, are designed with the help of DVL gates, where A is working as propagating signal. D1 & D3 outputs are done with the help of full swing GDI based AND gates and inverter is implemented with the help of conventional CMOS logic. Resulting in 2-4 non-inverting decoder using 14-transistors contains 9 NMOS and 5 PMOS as shown in Fig. 4.

Maintain the same procedure to design 2-4 inverting decoder with 14-transistor topology, where I0 & I2 outputs are designed with full swing GDI based OR gates and I1 & I3 outputs are done with DVL gates. This resulting 2-4 inverting decoder using 14-transistors contains 5 NMOS and 9 PMOS as shown in Fig.5.

The two introduced topologies are called "2-4 LP" and "2-4 LPI", with "LP" being "Low Power" and "I" being "Inverting".

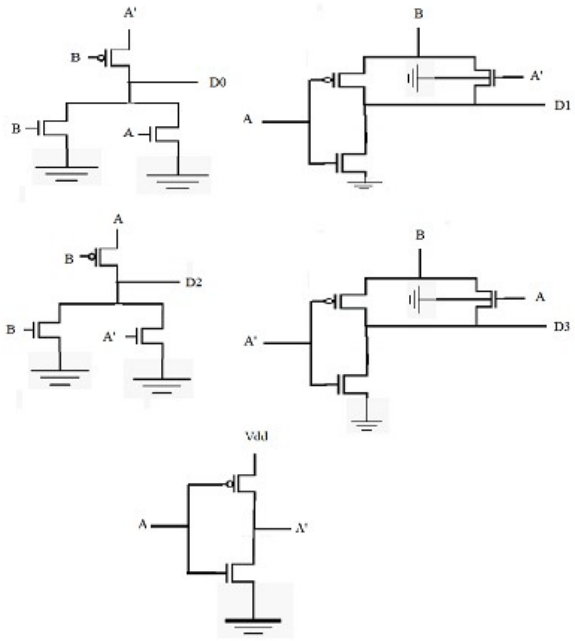

Fig. 4. 2-4 LP non-inverting decoder using 14-T.

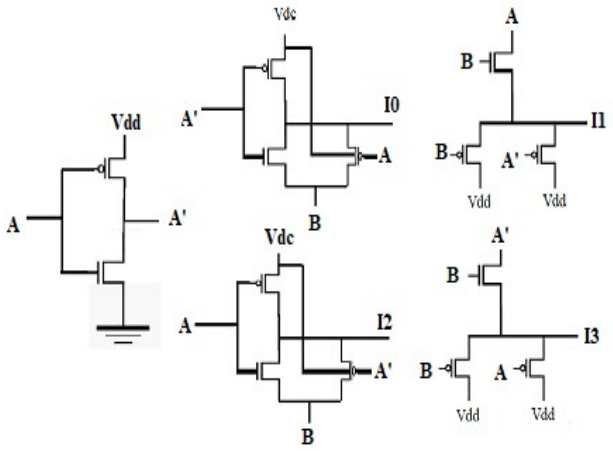

Fig. 5. 2-4 LP inverting decoders using 14-T.

B. *2-4 High-Performance Decoder using 15-Transistor Toplogy*

The low-power 14-T topologies have a disadvantage with respect to the delay, which is resulting by taking signal A (which is in complement form) in the act of propagating signal for D0 and I3 outputs. An inverter is used to complement the signal A which increases delay in that path.

In spite of that, D0 and I3 outputs can be accurately implemented with static CMOS. D0 output can be designed with CMOS based NOR gate and I3 output can be done with CMOS based NAND gate. Since, one extra transistor is added in both non-inverting and inverting cases, transistor count is increased by one. So, new 15-transistor topology reduces the delay, but power is increased little bit. A 2-4 non-inverting and inverting decoder using 15-T topology contain 9 NMOS & 6 PMOS and 6 NMOS & 9 PMOS respectively as shown in Fig. 6 and Fig. 7.

The two introduced topologies are called “2-4 HP” and “2-4 HPI”, with “HP” being “High-Performance” and “I” being “Inverting”.

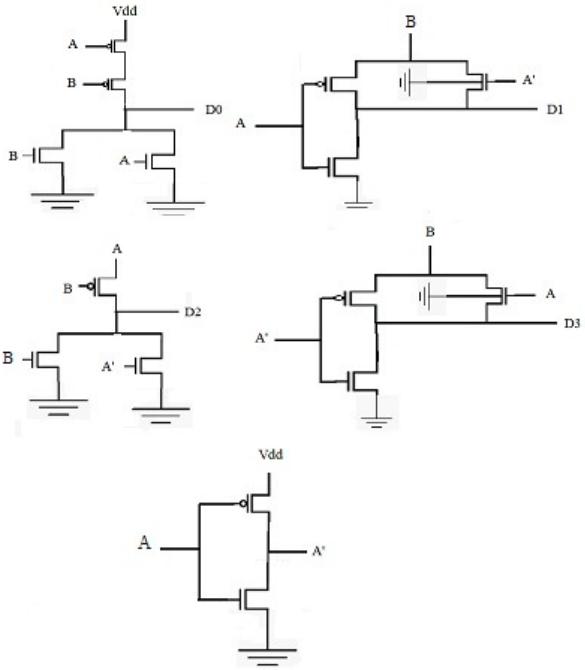

Fig. 6. 2-4 HP non-inverting decoders using 15-T.

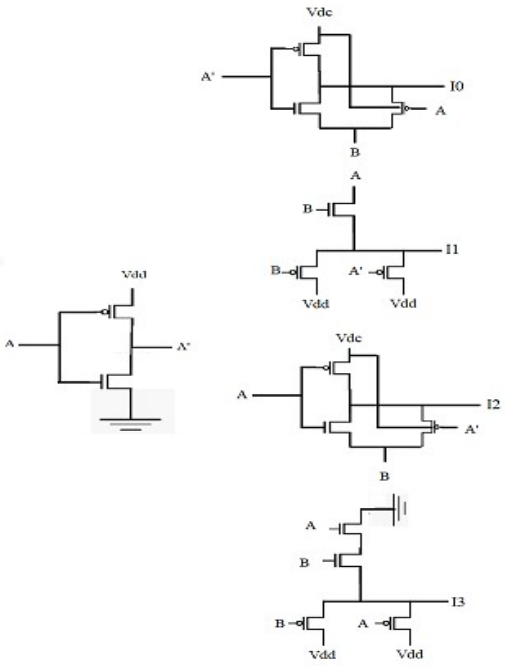

Fig. 7. 2-4 HPI inverting decoders using 15-T.

IV. Simulation Results & Performance Analysis

A. Simulation Results

A range of Cadence Virtuoso based simulation is performed for comparing modified mixed logic based 2-4 decoder with existing mixed logic and conventional CMOS based decoders. All circuits are designed in 45nm technology to get the reliable outputs. All designs are analyzed at different frequencies (0.5GHz, 1GHz, and 2GHz) and voltage (0.8V, 1V, 1.2 V). A capacitance of 0.2fF is connected to all outputs as a load. Input/output waveforms of non-inverting and inverting decoders using proposed method are depicted in Fig. 8 and Fig. 9 respectively.

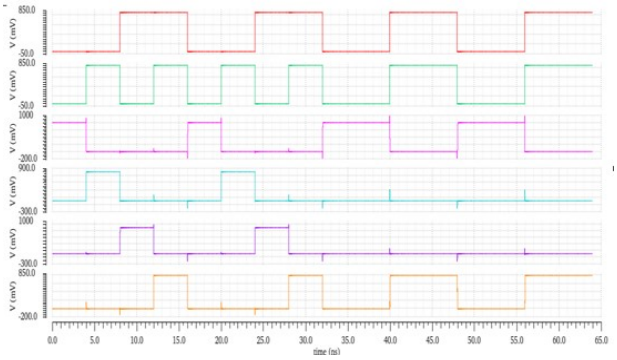

Fig. 8. I/O waveforms of proposed 2-4 non-inverting decoder.

B. Performance Analysis

The parameters taken for the analysis are: Power dissipation and Propagation delay. Various performance analyses are given in Table III, IV, V and VI for power dissipation and propagation delay. Each proposed design technique is compared with existing mixed logic technique [9] and conventional CMOS logic technique. Proper bit sequences are taken as input of the design to maintain all feasible transitions. In this analysis both power and delay are calculated by using Cadence Virtuoso tool. Power is obtained in Nanowatts. For the delay, maximum value that occurs from all input/output combinations is taken and measured in Picoseconds.

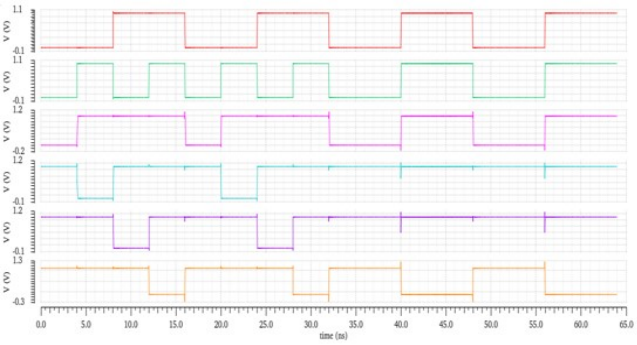

Fig. 9. I/O waveforms of proposed 2-4 inverting decoder.

MIXED LOGIC LPI [9]	13.58	6.834	5.035
PROPOSED LOGIC LPI	13.34	6.707	5.046
MIXED LOGIC HPI [9]	12.75	6.33	4.78
PROPOSED LOGIC HPI	12.73	6.30	4.75

The parameters considered in this analysis are: Power dissipation and Propagation delay. According to obtained results, for 2-4 non-inverting decoder, proposed modified mixed logic design (MMLD) 2-4 LP gives 62.41% and 18.18% reduced power dissipation compared to CMOS and mixed logic based 2-4 LP respectively. On the other hand, proposed MMLD 2-4 HP gives 62.88% and 18.16% reduced power dissipation compared to CMOS and mixed logic based 2-4 HP respectively.

For 2-4 inverting decoder, Proposed MMLD 2-4 LPI gives 57.39% and 16.41% reduced power dissipation compared to CMOS and mixed logic based 2-4 LPI respectively. On the other hand, proposed mixed logic 2-4 HPI gives 57.36% and 16.39% reduced power dissipation compared to CMOS and mixed logic based 2-4 HPI respectively.

Regarding delay, for 2-4 non-inverting decoders: proposed MMLD 2-4 LP gives 47.06% less delay than CMOS and gives almost same delay as mixed logic 2-4LP. Similarly proposed mixed logic 2-4 HP gives 53.3% less delay than CMOS and presents almost same delay as mixed logic 2-4 HP.

For 2-4 inverting decoder: Proposed MMLD 2-4 LPI gives 78.76% less delay than CMOS and presents almost same delay as mixed logic 2-4 LPI. On the other hand, proposed mixed logic 2-4 HPI gives 79.92% less delay than CMOS and presents almost same delay as mixed logic 2-4 HPI.

Percentage of power reduction for non-inverting and inverting decoder based on proposed mixed logic design and mixed logic design [9] with respect to conventional CMOS is shown in Fig. 10. It is indicating that as voltage increases percentage of reduction also increases but delay is almost same in both the cases.

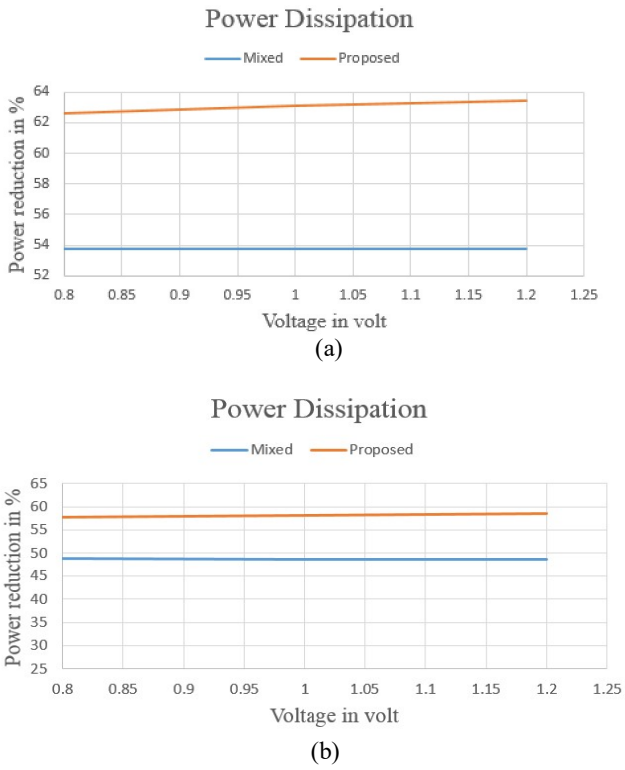

Fig. 10. Percentage of power reduction with respect to CMOS with different supply voltages (a) 2-4 non-inverting decoder. (b) 2-4 inverting decoder.

V. APPLICATION OF DECODERS

In digital systems full adder is a fundamental block [13], which adds three binary numbers of one bit, two operands and a bit of carry. Here, full adder contains two 2-4 decoder and three OR gates as shown in Fig. 11.

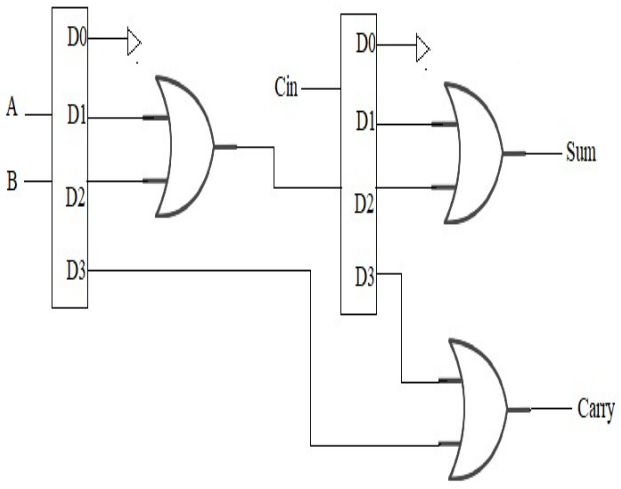

Fig. 11. Schematic of Full Adder.

Here full adder is designed with modified mixed logic decoder (MMLD) technique and compared with full adder using existing mixed logic-based decoder & conventional CMOS based full adder. The obtained results for power and delay are given in the table V and VI. Full adder based on MMLD taking less power and delay as compared to existing mixed logic and CMOS based full adder.

TABLE V

POWER DISSIPATION FOR FULL ADDER (IN NANOWATTS)

Full Adder (FA)	**0.8 V**	**1 V**	**1.2 V**
CMOS BASED FA	11300	30300	57000
MIXED LOGIC BASED FA	10930	29310	55210
PROPOSED MIXED LOGIC BASED FA	9793	26300	49560

TABLE VI

PROPAGARTION DELAY FOR FULL ADDER (IN PICOSENCODS)

Full Adder (FA)	**0.8 V**	**1 V**	**1.2 V**
CMOS BASED FA	193.3	94.11	77.82
MIXED LOGIC BASED FA	171.9	92.09	67.17
PROPOSED MIXED LOGIC BASED FA	101.5	81.37	64.62

For full adder, proposed full adder gives 13.29% and 10.33% less power dissipation than conventional CMOS and existing mixed logic based full adder respectively. Regarding delay proposed full adder gives 25.99% and 6.26% less delay than CMOS based full adder and mixed logic based full adder respectively.

VI. CONCLUSION AND FUTURE SCOPE

This paper proposed a modified mixed logic design for different styles of 2-4 decoders and implemented a full adder using proposed decoder. The analysis concludes that proposed 2-4 decoder (both non-inverting and inverting) consumes less power compared to existing mixed logic [9] and conventional CMOS based 2-4 decoders. On the other hand, proposed 2-4 decoders consumes less delay compared to conventional CMOS based 2-4 decoder but gives almost same delay as mixed logic based 2-4 decoders.

Full adder designed and implemented with modified mixed logic design consumes less power and delay compared to existing mixed logic decoder based and CMOS based full adders.

Decoders which are presented here deals only with binary number. Future research can design the decoders that will deal with BCD and Excess-3 codes.

***Abstract*--The Rivest, Shamir, and Adleman (RSA) is one of the most important types of the Asymmetric cryptography. In RSA the key size is bigger when compared to the algorithms in cryptography. The keys are generated with any two prime numbers. The unauthorized person can easily get the keys with a Greatest Common Divisor(GCD) Attack. This is one of the main drawbacks of RSA cryptography. The Elliptic Curve Cryptography (ECC) is also Asymmetric cryptography with a small key size. The proposed work is to overcome the drawback of the GCD Attack in RSA. The RSA private and public key can be combined with an ECC private and public key by using an Exclusive OR(XOR) and the new hybrid private and public key are generated. The RSA encryption can be done with a new hybrid public key. The RSA decryption can be done with a new hybrid private key. The advantages of the proposed work is the creation of three levels of key for cryptography to avoid the GCD attack in RSA. The key strength is higher when compared to the simple key generation of RSA algorithm.**

***Keywords--* RSA algorithm, ECC algorithm.**

I. INTRODUCTION

A. RSA Cryptography

The RSA algorithm is invented by Rivest, Shamir, and Adleman in 1977 [9], [10]. RSA is Public-Key cryptography. RSA has three phases first one is the key generation, Second is the Encryption and the third one is a Decryption. The key generation algorithm is to generate two keys that are private key and public key. The public key is used to encrypt the message and send to a public channel, this key is enabled anyone can access the public key. Another one is a private key, this is used to decrypt the message. This is only accessible by an authenticated person. The private key is also known as a secret key.[3]. Figure (1) shows the RSA encryption and decryption process.

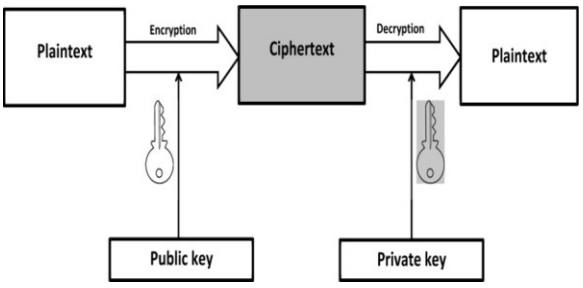

Figure 1. RSA Encryption and Decryption

B. Elliptic Curve Cryptography [ECC]

Elliptic Curve Cryptography is one of the public key encryption. ECC is difficult because it fully depends on the mathematical background. The problems of ECC can be solved using a discrete logarithm problem. [1]. The discrete logarithm problem is used to solve the problem of calculating the points which are moved from one point to another point in the ECC. In ECC, the process of encryption and decryption can be done by three processes. First one is an abelian group, the second one is an elliptic curve over the real numbers and the last one is the elliptic curve defined over a finite field.

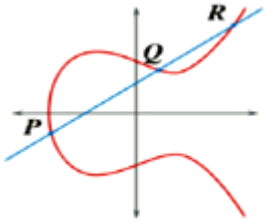

Figure 2. Basic Elliptic Curve Cryptography

The elliptic curve can be generated by using a binary curve. The Fig (2) is drawn based on the equation (1)[4] is

$$y^2 = x^3 + ax + b \qquad (1)$$

In equation (1), x and y are the standard variables which are used to define the function and 'a' and 'b' are the constant coefficient [5] which is used to define the curve. The discriminate form of elliptic curve is

$$\Delta = 4a^3 + 27b^2 \neq 0 \quad (2)$$

Equation (2), is used to assign the operation of elliptic curve. The operations are [2] point addition, point multiplication and point doubling.
The finite field is one of the important concepts in the ECC. Main use of the finite field is to define the limited points on the curve. The points are represented in x-axis which is defined as an 'p' which is also called as an modulo value. The point 'p' is defined the operation of ecc based on the discriminate form. [12]. The modulo value is also used to define the key size of ECC. The parameters are

P : finite field.
a,b : curve coefficients.
G : generator point based on operation of curve.
N : order of G.
H : divide the total points on the curve.

Table 1 : Key length of Different Algorithms

SYMMETRIC KEY LENGTH	RSA KEY LENGTH	ECC KEY LENGTH
80	1024	160
112	2048	224
128	3072	256
192	7680	384
256	15360	512

Table 1. represent the comparison of the key length of the symmetric, RSA and ECC. The symmetric key length is start from 80 bits and end with an 256 bits. The RSA key length is stratr from 1024 bits and end with an 15360 bits and the ECC key length is start from 160 bits and end with 512 bits.

II. RELATED WORK

This section is to provide the general overview of related works in the field of RSA and ECC cryptography. In particular, for those works are survey and received in detailed of RSA cryptography and ECC cryptography are listed below.

Author Name	Cryptography	Description	Remarks
Ansah Jeelani Zargar, Mehreen Manzoor, Taha Mukhtar	ECC cryptography	Making a essential relationship between the techniques explaining why ECC is better than any other cryptographic techniques recent to it.	Use of elliptical curve cryptography for given that the data security in high-level more or less all low power devices
F. Amounas and E. H. El Kinani	Elliptic Curve Cryptography, Discrete Logarithm, Cryptosystem	The ECC algorithm gives a strong point against crypto analysis and the work can be compared with standard algorithms like Rivest-Shamir-Adleman algorithm (RSA).	In the ECC the use of data sequence will given better result in this hold.
Anoop MS	Elliptic Curve Cryptography.	The basics of prime and binary field arithmetic	The polynomial reduction in binary field to run much faster than the modular reduction in prime field.
Avi Kak	Elliptic Curve Cryptography	The basics of Elliptic Curve Cryptography	Fully understand about the ECC in mathematical formate
Sriram Vajapeyam	Shannon's Entropy	Uses of Shannon entropy and how to measure the entropy value for text and image data.	Shannon's Entropy is used to calculate the lower-bound on number of actual bits required to store or transmit information
Joseph H. Silverman	Elliptic Curve Cryptography	Deatiled describtion on Elliptic curve cryptography	Fully describtion of ecc with an advantages and disadvantages

Joseph H. Silverman	Elliptic Curve Cryptography	Deatiled describtion on Elliptic curve cryptography	Fully describtion of ecc with an advantages and disadvantages
Ankush Sharma, Jyoti Attri, Aarti Devi & Pratibha Sharma	RSA, ElGamal cryptograaphy	comparison of the rsa and elgamal algorithms has been completed on the basis of security and time consumption for encryption and decryption.	ElGamal algorithm is more secure as compared to RSA algorithm
Fanyu Kong, Jia Yu, and Lei Wu	RSA, Key generation algorithm	The algorithm leak enough secret information and then everybody can recover the factorization of the RSA modulus *N* in polynomial time.	Generate the rsa key as strength.
M. Preetha, M. Nithya	RSA Algorithm	Public key algorithm RSA and enhanced RSA are compared analysis is made on time based on execution time.	It is used for encryption of long messages without employing the hybrid and symmetric encryption.
Wang	Information & Entropy.	How the entropy is worked and given with an simple example.	Calculate the entropy with an large data.
Kefa Rabah	RSA Algorithm	RSA Key generation are implementated in JCE provider	Compare to any other provider it gives some of the best result
H.J. Shiu, K.L. Ng, J.F. Fang, R.C.T. Lee, C.H. Huang.	Complementary pair, Data recovery	The data hiding methods crated based on the properties of DNA sequences. The three methods are: the Insertion Method, the Complementary Pair Method and the Substitution Method.	For all image media schemes and text message, the three methods are easy to implement and hard to detect
Mansi Rathi1, Shreyas Bhaskare, Tejas Kale, Niral Shah, Naveen Vaswani	DNA Cryptography, DNA Sequencing	This technique encrypt the data in a very complex and it prove it is very efficient algorithm with high accuracy	Implementing the DNA sequencing to the cipher text it will enable the cipher text to get strong encrypted and it can be also used for banking applications to encrypt the vital data of the customer such as the account number or pin or password.

From the above study, it has been observed that most of the work are carried out to compare the performance of RSA with ECC . But in this work, the hybridation of RSA key with ECC key a strong key with a less information gain and with an less execution time. Limitations in the above study, the GCD attack is to taken for the proposed work.

III. METHODS

Method 1: RSA Cryptography

Algorithm 1-1 RSA Key generation.
Input: Two Prime Numbers.   ***Output: Generate Public key and Private key.***
Step 1: Select the two large prime numbers as p and q where p is not equal q [bits are 512 bits].   **Step 2:** Calculate the modulo value represented as N , N=p*q   **Step 3:** Calculate the N with an phi value

$\phi(N)=(p-1)*(q-1)$.
Step 4: Select the integer of 'e'
'e' value must in small integer which is relatively prime to an $\phi(N)$ and not equal to 1.
Where $1<e<\phi(N)$.
Step 5: Compute Greatest Common Division[gcd]
$gcd(e, \phi(N))=1$.
Step 6: Calculate d, which is an multiplicative inverse of e modulo $\phi(N)$
$e*d=1 \bmod \phi(N)$, where $0 \le d \le N$.
Step 7: Return Public Key pair (e, N).
Step 8: Return Private Key pair (d, N).

In algorithm 1-1 [3] RSA Key generation, the public and the private key pairs are generated based on the large prime numbers which is given by users. The key bits are given as an 512 bits based on the bits the two prime numbers are generated the product of two primes 'p' and 'q' are stored in the variable ' N'. The phi value is find for an variable N. select an e which is lesser then the phi of N. find the GCD of e, phi of N. calculate the value of d . the private key is created with an two values 'e' and 'N'. The private key is created with an 'd' and 'N'.

Algorithm 1-2 RSA Encryption.
Input : Plaintext
Output : Cipher text
Step 1: Enter the plaintext as M.
Step 2: Encrypt the plaintext M with an public key pair (e, N).
$C=M^e \bmod N$, Where $0 \le M \le N$.
Step 3: Return the Cipher text C.

In algorithm 1-2 RSA Encryption, [6],[8] the plaintext is represented as 'M' which is encrypted with an public key pair (e,N) and stored in an variable 'C' which is represented an cipher text.

Algorithm 1-3 RSA Decryption
Input : *Cipher text*
Output : *Plaintext*
Step 1: Enter the cipher text as C.
Step 2: Decrypt the cipher text C with an private key pair (d, N).
$M=C^d \bmod N$, Where $0 \le M \le N$.
Step 3: Return the plaintext M.

In algorithm 1-2 RSA Decryption, [9],[10],[11] the cipher text 'C' is decrypted with an private key pair (d,N) and generate an plain text as 'M'. The original text is decrypted by the user.

Method 2: Elliptic Curve Cryptography

Algorithm 2-1 Elliptic Curve key generation
Input : Parameters
Output: User A And User B Public key
Step 1: Input the parameters as a, b and q,
Where q is a prime with an integer of the form 2^m.
Step 2: Compute the generator G as a point on the curve whose order is larger value as n.
Step 3: Select the Public key as n_A.
$n_A<n$, where A is an User A
Step 4 : select the Public key as n_B.
$n_B<n$, where B is an User B
Step 5: Calculate the Public key P_A
$P_A=n_A*G$, where A is an User A
Step 6: Calculate the Public key P_B
$P_B=n_B*G$, where B is an User B
Step 7: Return Public Key P_A.
Step 8: Return Public Key P_B.

In algorithm 2-1 Elliptic Curve Key Generation,[12] Input the parameters are 'a','b' and 'q' where 'q' is an prime number the points on the curve has been generated as 'G' which order is larger the n. [15] The public key of user A is selected and represented as n_A which less than 'n'. The public key of user B is selected which is represented as n_B which is less than 'n'. The public key of user B has been calculated with product of n_B and 'G'. which is stored in P_B. The public key of user A has been calculated with product of n_A and 'G' which is stored in P_B. The private key of user A is represented as P_A and the public key of user B has been represented as an P_B.

Algorithm 2-2 Elliptic Curve Secret key
Input : *Public key of User A and Public Key User B.*
Output: *Secret key k.*
Step 1: Calculate the Secret key of User A.
$K_A=n_{A*}P_B$.
Step 2: Calculate the Secret key of User B.
$K_B=n_{B*}P_A$.
Step 3 : Return Secret key of user A.
Step 4: Return Secret key of user B.

In algorithm 2-2 Elliptic curve Secret key, the input of user A and user B public key. Calculate the secret key of User A with the product of selected user A publick key n_A and with an user an calculated public key P_A. Calculate the secret key of User B with the product of selected user A public key n_B and with an user an calculated public key P_B.

A. Exclusive OR

Exclusive OR is one of the logical operation. The inputs of binary numbers are same the output is false(0). The inputs of the binary numbers are differ it returns true(1).

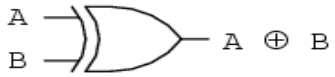

Figure 3. Exclusive OR

IV. PROPOSED WORK

In proposed work, the RSA public key and the private key are combined with an Elliptic Curve secret key and

public key using an exclusive OR and generate a new key pair based on the new key pair the data are encrypted and decrypted using an RSA encryption and decryption process. The proposed work is mainly concentrating on generating a strong key pair for the encryption and decryption.

A. Proposed Work Flow For Key Generation, Encrypt And Decrypt Process

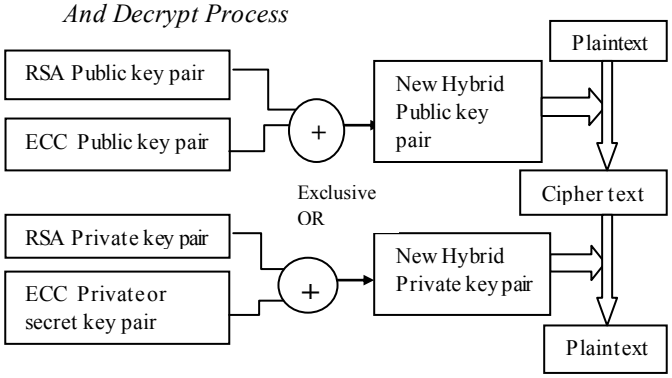

Figure 4. key generation, encryption and decryption process.

Figure 3. RSA public key is exclusiveOR with an ECC public key and generates a new public key. Like a RSA , private key is exclusive or with an ECC private key and generate a new private key. The plaintext is given for an encryption process the new public key is used to encrypt the plaintext and generate a cipher text. The cipher text is to decrypt by using a new private key and the plaintext is generated.

B. Proposed Algorithm For Key Generation, Encrypt And Decrypt Process.

Algorithm3-1: New Key generation
Input: RSA public and private key, ECC public and private key. *Output: New public and private key.*
Step1: Input an RSA public key pair as n and e. **Step 2 :**Input an ECC public key pair as P_A and P_B. **Step 3 :** ExclusiveOR with an Step1 and Step 2 and generate new hybrid public key pair. **Step 4 :** Input an RSA Private key pair as d and n. **Step 5:** Input an ECC private key pair as K_A and K_B. **Step 6:** ExclusiveOR with an Step4 and Step 5 and generate new hybrid private key pair. **Step 7:** Return New hybrid public key pair . **Step 8:** Return New hybrid private key pair.

In algorithm 3-1, The input parameters are RSA public key and private key, ECC public key and private key. The RSA public key can be XOR with an ECC public key and the new hybrid public key pair is created. the RSA private key can be XOR with an ECC private key and the new hybrid private key is created.

Algorithm3-2 Encryption
Input: RSA public and private key, ECC public and private key. *Output: New public and private key.*
Step1: Input an RSA public key pair as n and e. **Step 2 :**Input an ECC public key pair as P_A and P_B. **Step 3 :** ExclusiveOR with an Step1 and Step 2 and generate new hybrid public key pair. **Step 4 :** Input an RSA Private key pair as d and n. **Step 5:** Input an ECC private key pair as K_A and K_B. **Step 6:** ExclusiveOR with an Step4 and Step 5 and generate new hybrid private key pair. **Step 7:** Return New hybrid public key pair . **Step 8:** Return New hybrid private key pair.

In algorithm 3-2, the input parameters are plain text and the new hybrid public key. The plaintext can be encrypted with an new hybrid public key and return an cipher text which is represented as a variable 'cip'.

Algorithm 3-3 Decryption
Input : Cipher text as cip and New hybrid Private key *Output : Plaintext.*
Step 1: Enter the cipher text as cip. Step 2: Decrypt the cipher text cip with an new private key pair (d1, N1). $M1=C1^{d1} \bmod N1$, Where $0 \le M1 \le N1$ Step 3: Return the plaintext M1.

In algorithm 3-3, the input parameters are cipher text and the private key. The cipher ext can be decrypted with an new hybrid private key and return an plaintext as 'M'.

V. RESULT AND DISCUSSION

A. Information Entropy

Information entropy is defined as the amount of information in a variable, that variable has been providing the basic theory around the notation of information. It can be simply defined in terms of the probabilistic model. [13],[14]. It means that the modules which have many possible rearrangements then the system has high entropy, and the system has very few rearrangements, then the system has low entropy.

The Shannon entropy equation (3) is used to estimate the average minimum number of bits needed to encode a string of symbols, based on the frequency of the symbols.

$$H(X)= -\sum_{i=1}^{n} P(x_i)\log_b P(x_i) \qquad (3)$$

Where P is Probability of given symbol, b is the base of the logarithm.

Table 2 Information entropy values of cipher text.

FILE SIZE	INFORMATION ENTROPY	
	RSA	RSA-ECC
1kb	3.060	2.726
20kb	3.044	2.743
25kb	3.165	2.990
54kb	2.962	2.845
14mb	3.338	3.116

In table 2, the information entropy value for different file size is given. The first column is represented as file size. The file size is given as 1kb,20kb,25kb,54kb and 14 mb. The information entropy value are calculated for each of the file size separately for the algorithms RSA and RSA-ECC. Compare the entropy value of two algorithm. The proposed algorithm of RSA-ECC gives an better result compared to RSA algorithm. The figure 4, shows the graphical representation of the table 2 values.

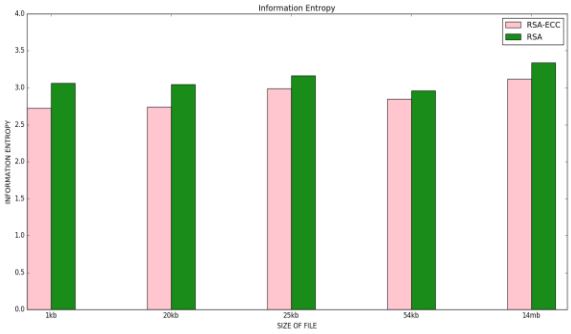

Figure 5. Information entropy values of cipher text.

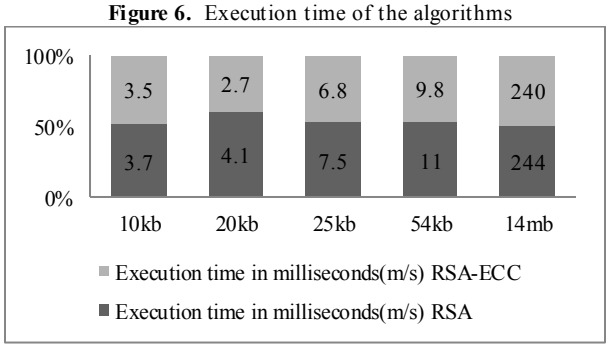
Table 3 Execution time of the algorithms.

File Size	Execution time in milliseconds(m/s)	
	RSA	RSA-ECC
10kb	3.7	3.5
20kb	4.1	2.7
25kb	7.5	6.8
54kb	11.0	9.8
14mb	244	240

In table 3 the execution time is calculated with an milliseconds. The first column is filesize from 10kb,20kb,25kb,54kb and 14 mb. The execution time is calculated and compared the two algorithms RSA and RSA-ECC with this comparison the ECC-RSA is given an less execution time when compared to RSA algorithm. The figure 5. represented the execution time values in graphical representation.

Figure 6. Execution time of the algorithms



VI. CONCLUSION

The GCD attack is one of the disadvantage in the RSA algorithm. To overcome this problem, the proposed work is to combine the RSA key and the ECC key using an Exclusive OR and create an new hybrid key. The encryption and decryption can be done with an new hybrid private key and new hybrid public key. The hybrid key giving an secured key. The key strength can be measured by using an information entropy. In the result the proposed algorithm giving an high entropy when compared to an RSA algorithm. The proposed work has been created with an three levels of key but in future to increases the key levels and give an high secured level.

***Abstract*—**The social network has acquired popularity due to cheap availability of wireless connectivity and portable devices. It links people with common interests and provides platform to share information. However, the information shared over social network demands high level of trust and privacy. The paper presents a trusted graph based trust inference approach for measuring trustworthiness of an user. The effectiveness of the proposed approach has been assessed on real online social network dataset, Epinions and the same has been contrasted with recently published algorithms.

Keywords—Epinions; Online social network; Trust Evaluation; Trusted Graph

I. INTRODUCTION

A social network can be represented as a connected graph. Each node of the connected graph represents entity which can be any individual, group, organization or government agency and edges represent interdependencies among nodes. Recently, the popularity of online social network is witnessing a rapid increase due to its user friendly characteristic. Moreover, SN provides a platform that allows users to share and exchange information.

In the last decade, the evolution of networking technology has boosted up the acceptance of social networks like Facebook, LinkedIn among common users. However, many challenges like community detection, spam detection, availability of dynamic dataset, security issues, trust evaluation of users, are putting a stop to its wider acceptance. Since a SN consists of large number of users, an user may not be familiar with many of them. As an outcome, information breaching may occur. Thus determining trustworthiness of an user becomes very frequent problem faced by every SN user. Hence, trust plays a significant role in social network. In this paper, we have proposed an efficient approach to evaluate trustworthiness of an user. Our motivation is to provide an environment where users can share their thoughts, opinions and experiences in a transparent path without worries about privacy and dread of being judged [12]. "Trust in a person is a commitment to an action, based on a belief that the future actions of that person will lead to a good outcome (Golbeck [1])". In our real life, trust is being calculated cumulatively. For an example, if a person A wants to know how much he should trust another person B, he will consult with his friends first. If they don't have any knowledge about B, they may ask their friends and so on.

Trust can be of two types, direct and indirect or transitive trust. In Fig 1, we can see that A trusts neighbor node P directly, as there is direct edge between A and P .On the other hand, A trusts B indirectly, via a trusted path (A,P,Q,B) or (A,R,B). Direct trust can be easily derived based on the direct communication experience of two users, while indirect trust is usually evaluated based on other relevant users' interaction experiences in the social network [2]. There are different approaches available to evaluate indirect trust like Subjective logic based, Traditional mathematics tools based, AI information learning based, Graph based [3]. We have focused on trusted graph based approach in this work. Trusted graph is a directed acyclic graph(DAG) which includes a trustor, a trustee, recommenders and trust relationship among them [4]. Fig 1. is an example of trusted graph. Trustor is a node having no edge pointing to itself like A here and a trustee implies a node having no edge pointing from itself, node B is an example. Each edge of the DAG let (i,j) is associated with a values, which signifies how much I trusts neighbor node j. A trusted graph may have multiple paths between a trustor and a trustee, each of the paths is called as trusted path.

Several attempts have been done on modeling trust inference system based on trusted graph. Golbeck [1] proposes TidalTrust to generate a recommendation about the trust degree of an user according to another one based on trusted paths. Breadth-first search from the trustor to the trustee generates the trusted paths and only the shortest and strongest paths are being considered in TidalTrust. Due to considering only shortest paths, many important information may be neglected.

RN-Trust algorithm has been proposed by Taherian et. al. [5] to evaluate trust value from a trustor to trustee by modeling trust network as a resistive network. Each trust relationship between two nodes in graph has been represented by a resistor, so that the trust value would be more for less resistance value of resistor. Multiple paths between two nodes are combined using parallel circuit rule. RN-Trust considered all paths rather than only shortest paths, for trust inference. Main drawbacks of RN-Trust includes that there are no maximum path length limit and no threshold for the trust values between intermediary nodes. However, the weakest trust values causes decrease in inferred trust value.

Most of the graph based trust models pre-assume that a small trusted graph already available. But generating small trusted graph from large social network is very challenging task. Jiang et. al. [6] first proposed SWTrust to overcome this challenge. Along with the theory of "weak ties" [7] , it uses user's active domain information to assign trust value, which is more objective than explicit trust ratings. SWTrust constructs a small trusted graph by considering all paths between trustor and trustee with path length constraint as well as trust threshold. In this work, authors have performed eight trust prediction strategies which comprise three key factors of trust propagation functions (Min and Multiply), trust aggregation functions (Max and Weighted Average), and if all paths or only shortest paths are considered. Experimental results show that Weighted average function performs best to measure most accurate trust value. But in some scenarios, taking average of inferred trust values for all paths decreases the quality of inferred trust value as it weighs up the opinions of malicious nodes.

Sana et. al.[8] modeled TISoN to evaluate trust in social network. They proposed two algorithms for this model, first one is TPS (Trust Path Searching) and second one is TIM (Trust Inference Measuring) . TPS prioritizes neighbors based on the direct trust degrees and chooses trusted paths with path length constraint. TIM measures trust by constructing a trust network. TISoN depends on direct trust matrix. Thus lacking the advantage of constructing trust value from user's domain knowledge like SWTrust [6].

GFTrust [9] is another latest trusted graph based trust inference algorithm that uses SWTrust algorithm for generating small trusted graph and then uses generalized network flow concept to evaluate trust rating between two indirectly connected nodes or users. In this work Jiang et. al. [9] overcomes trust aggregation issue of social network.

In this paper, we propose an efficient trusted graph based approach for inferring trust for Epinions network. Our work includes SWTrust [6] framework to generate small trusted graph using user's domain related information as well as trust inference scheme used by Sana et. al. [8] for evaluation of trust between two indirectly connected users. We incorporate SWTrust framework to overcome the challenge of generating small trusted graph from a large social network dataset like Epinions. Then, we have implemented the approach used by Sana et. al. to calculate trust for increasing quality of the trust value. Finally efficiency of the proposed scheme has been estimated on Epinions network data set and comparative analysis has been performed with SWTrust [6] and GFTrust [9].

The remainder of this paper is organized as follows: In Section II, we will review the SWTrust framework. In Section III, we go through trust inference scheme used by Sana et. al.[8]. In Section IV, we discuss in details about our proposed approach. In Section V, we conduct experiments on Epinions dataset and give experimental result. Lastly, In Section VI, we conclude this paper.

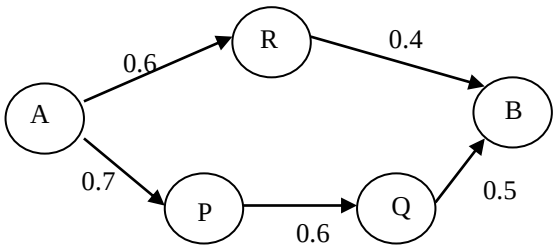

Fig 1: Trusted graph between A and B.

II. SWTrust Framework: Review

In this section we provide brief review of SWTrust framework. This framework has been architected with three key steps:

A. Preprocessing of an online social network (PSN):

The PSN starts with preprocessing of large online dataset to collect all domain related information related to every user and beside that domain information of topic (reason to know trustee by the trustor) has also noted. Jiang et. al. [6] Consider that every recommender or friend must be related to the topic and the target. Following that according to the theory of "weak ties" user domain based trusted acquaintance chain has been discovered. Thus Depending on social distance all the neighbors of an user has been categorized into three types e.g. local neighbors, longer neighbors and longest neighbors. Then neighbors in each category have been sorted conforming to their priority in descending order. Jiang uses referral trust to decide priority of a neighbor node with respect to a node.

"Referral trust" is ability to recommend a good target (i.e. trustee). If (i,j) is an edge in trusted graph, then referral trust is priority of selecting neighbor j as the next hop by i. Assuming that user i has full information of the active domains (domains in which user has participated) of his neighbor j, topic (reason to know trustee by the trustor) and target, below is the mathematical expression for calculating referral trust of neighbor j by user i.

$$p(i,j)=\frac{\lambda 1*x(j)+\lambda 2*y(j)}{^{\circ}D_{topic}+^{\circ}D_{target}}$$

$^{\circ}D_{topic}$: denotes total number of active domains of topic

$^{\circ}D_{target}$: denotes total number of active domains of target

λ1, λ2 belongs to [0,1]. x(j) denotes number of common domains between j and topic and y(j) denotes number of common domains between j and target.

Finally, next hop neighbors have been chosen uniformly from the three categories to build trust acquaintance chain.

B. Building the trust network (BTN):

Two methods of breadth-first search have been provided to construct a trust network from source to sink or trustor and trustee. First one is centralized BFS for small scale social networks and second one is distributed BFS, suitable for large scale online social networks. Max path length constraint has been used to maintain efficiency.

C. Generation of trusted graph (GTG):

GTG process includes deletion of paths in previously generated trust network having path length more than max path length constraint. Any path holding referral trust of any edge of it less than defined trust threshold has also been omitted. GTG has been performed in centralized server, resulting set of trusted paths. Thus a trusted graph between given trustor and trustee can be generated.

III. TRUST INFERENCE SCHEME

Sana et. al. [8] proposed trust inference between trustor and trustee using two interdependent methods:
i) trust propagation from trustor to the direct neighbor of trustee via a trusted path and ii) trust aggregation from trustor to trustee.

A. *Trust Propagation:*

A propagation function has been presented to calculate strength s_p of each trusted path p. Following function for s_p uses PathAverage, PathVariance and PathWeight as three factors:

$$s_p=\alpha t_p+\beta(1-\upsilon_p)+\gamma w_p$$

•PathAverage: t_p symbolizes average of direct trust values between n path nodes of a trusted path. They assumed that high trust rating values of mediator friends increase the quality of trust calculation.

$$t_p=\frac{1}{n}\sum_{i=1}^{n}t_i$$

•PathVariance: υ_p signifies path variance that is how much n trust values of a path is deviated from its average path trust. As per their assumption, friends with close trust ratings maintain accuracy of trust calculation.

$$\upsilon_p=\frac{1}{|n|}\sum_{i=1}^{|n|}(t_i-t_p)^2$$

•PathWeight: Path weight has been symbolized as w_p. It denotes fraction between shortest trusted path length, |n'| and current trusted path length, |n|. Any path having length tends to shortest one enhances accuracy of calculation.

$$w_p=\frac{|n'|}{|n|}$$

Let, p is a trusted path that having last intermediary node a_{pn}. a_{pn} has direct trust rating of trustee o, $t(a_{pn}->o)$. Then, multiplying path strength s_p of path p to $t(a_{pn}->o)$ gives inferred trust value of path p from trustor to trustee.

B. Trust Aggregation:

Sana et. al. have used four trust aggregation functions to aggregate trust values of all trusted paths from trustor to trustee. Those methods are as follows:

•Mean aggregation method: Assuming that a trustor s has n numbers of trusted paths between itself and trustee o, path strength of each path is s_{pi} and direct trust rating in the middle of last intermediary node of each path and o is $t(a_{pi}->o)$, where i varies from 1 to n, aggregated trust value of node o to trustor s can be calculated as:

$$t(s->o)=\frac{\sum_{i=1}^{|PATHS|}s_{pi}\times t\,(a_{pi}->o)}{|PATHS|}$$

•Mult aggregation method: Mult aggregation method calculates aggregated trust similarly. Following is the aggregation function:

$$t(s->o)=\prod_{i=1}^{|PATHS|}s_{pi}\times t(a_{pi}->o)$$

•Min aggregation method: This method chooses trusted path with minimum path strength and multiply its path strength with direct trust between corresponding last intermediary node and trustee o to get the final aggregated trust.

$$t(s->o)=s_{pk}\times t(a_{pk}->o)$$
$$s_{pk}=\min(s_{pi}),\ i\in[1,|PATHS|]$$

•Max aggregation method: Like min aggregation method, this method calculates aggregated trust considering trusted path max path strength.

$$t(s->o)=s_{pk}\times t(a_{pk}->o)$$

$$S_{pk} = \max\left(S_{pi}\right), i \in \left[1, |PATHS|\right]$$

In this paper, we have used max aggregation method as it performs best for the accurate result calculation.

IV. Proposed Approach

We have used SWTrust [6] framework to generate small trusted network from large social network dataset. Calculated referral trust values have been considered as trust values for the edges of the generated trusted graph. This helps transforming trust value of edge to be in continuous range of [0,1]. After that Sana et. al. Trust inference approach has been applied on the trusted graph to find the final trustworthiness of the trustee to the trustor.

Epinions [10] is a dataset where users can express their opinion about another users and also can rate any article written by another author. Epinions dataset consists of three files. First file contains user's trust or distrust relationships. Trust is marked as 1 and distrust as -1. We have not considered distrust for our approach. All information related to article like article Id, writer of the article, domain of the article are stored in second file. Third file caches ratings of articles and other additional details.

We have modeled our approach as following:

1. Preprocessing of Epinions dataset to gather domain information of users and articles.
2. Performing PSN step to build up user domain based trusted acquaintance chain.
3. Building trust network using max path length constraint.
4. Trusted graph generation of Epinions.
5. For each path of the generated trusted graph path strength has been calculated implementing method used by Sana et. al.[8].
6. Finally, max aggregation method has been applied to calculate aggregated trust value of all the trusted paths between the trustor and the trustee.

By following the above steps , the calculated final trust value can be directly taken as trust score of target or trustee according to the source or trustor without any normalization.

V. Experiment and Result

Published dataset of Epinions has been used for our experiment. As mentioned before, this network provides platform for users to rate opinion of another users as well as the articles written by another users in a scale of 1 to 10.

Our process starts with preprocessing of dataset to gather all domain related information of each user and article written by user. Then three key steps of SWTrust [6] have been applied on the dataset to generate the trusted graph. Referral trusts are used to assign trust rating of the edges of the generated trusted graph. After that trust aggregation of trusted graph has been performed as per the method used by Sana et. al. [8] to get final trust score of the trustee to the trustor.

We have used leave one out, a standard evaluation technique by Kohavi [11], for our experimental analysis. For this we have masked direct edge between two nodes lets s and o of the trusted graph, and calculated trust score implementing different algorithms using trusted graph. After that, a comparison has been performed between the masked trust value and the calculated trust value for performance evaluation.

We have consider trust prediction accuracy as evaluation metric. Accuracy has been measured by calculating mean absolute error (MAE). Let, there are T numbers of total test pairs of trustor s and trustee o and among these total numbers of predictable (at least one trusted path exists between s and o) trustor-trustee pairs is N. MAE can be calculated as: $MAE = \sum(t_r - t_p)/ N$, where t_r denotes masked trust value or real trust value and t_p denotes predicted trust value.

In Table I we have provided a comparative accuracy analysis of our proposed method, SWTrust [6] and GFTrust [9] . According to Jiang [9] GFTrust performs best with polynomial leakage function. Hence, we have used same leakage function for GFTrust in our experiment. We have assumed trust threshold value as 0.4.

From the comparative analysis it can be observed that our method produces less mean error in comparison with that of SWTrust and GFTrust. As mentioned above, comparative analysis has been performed by considering multiple numbers of test pairs of trustor and trustee. So, smaller value of mean absolute error indicates that in most of the test scenarios our method predicts most accurate trust value than both SWTrust and GFTrust. Hence, it can be concluded that our proposed method performs efficiently for inferring trust in Epinions network.

TABLE I. COMPARATIVE ANALYSIS OF ACCURACY

Method	Mean Absolute Error
SWTrust	0.14
GFTrust	0.49
Proposed method	0.02

VI. Conclusion and Future Scope

With rapid increase in acceptance of social network, trust related issues are becoming more important among online service provider and common users. In this paper, an effective trusted graph based trust inference approach has been proposed for Epinions . Our approach overcomes challenge of generating small trusted graph from large dataset. Thus helps to perform trust aggregation method more efficiently over a small trusted graph. It also does not depend on direct trust matrix rather uses domain knowledge to generate quality trust ratings. Experiments are carried out over Epinions dataset to justify its efficiency. As imminent work, trust calculation method can be dynamic and more powerful to reflect updated trust between nodes in online social network in real-time.

***Abstract*— Arduino are used worldwide in different hardware applications ranges from industrial applications to private uses. In, this application information could be scrutinized by unauthorized individual, which could progress into a security rupture and information burglary. From now on to set up a protected and dependable communication, the methodology ought to be to verify information utilizing explicit encryption methodology. Executing AES on programming isn't gainful, as the Arduino has less memory space, low handling rate and has more Power consumption and less utilization of AES libraries. These limitations can be overwhelmed by the utilization of AES-128-bit core as Hardware approach. This paper has tended to every one of these limitations and proposed a novel methodology of Data processing Model Using "AES-128" on Hardware core working on 200MHZ. The Arduino and AES-128 core handshake with one another utilizing the SPI protocol with max recurrence of 16Mbps. For the exhibit Purpose a ".txt" document is sent from PC to Arduino through AES core and this Encrypted information is shown on the LCD.**

Keywords—Advanced Encrypt Standard (AES), Serial Peripheral interface (SPI), Arduino

I. INTRODUCTION

Data communication done by Arduino UNO in Home automation [1] clarifies how Arduino implanted System can Communicate with another gadgets Device. Information sent from sender side to recipient side must be sufficiently secure so as to keep away from abuse. Min-KYU [2] Choi referenced one method for secure information correspondence by utilizing Encryption strategy.

With expanding tendency towards data security there was even more inclination as to security concern which goes as blockage between hackers and the critical data. Parcel of Encryption standard are being used beginning from Asymmetric model to Symmetric model incorporate AES which replaced older DES. Already AES was incorporating into Software approach. In these cutting-edge ERA, our objective is likewise concentrating on Low resources utilize Increase of Speed and Low Power utilization. To satisfy necessities, we move from AES on software approach to AES on hardware. To think about this, we are utilizing customized AES on Hardware Implemented on NEXYS 4 DDR Kit, their interface with Arduino through SPI protocol. The encrypted data further used in so many applications on Real time basics in industries.

Along these lines, this Paper concentrated on giving a novel methodology on Data Communication between Arduino and FPGA occurs and its interface with a Customized AES for the better speed and less resources use. The Paper separate into 5 sections and each Section is clarified as Section (I) An Introduction part, Section (II) Gives an Overview on different Issues in AES as Software library inside Arduino. In Section (III) AES execution on Hardware, at that point Section (IV) Highlights System Design and Implementation, Finally the Conclusion in section (V).

II AES AS S/W LIBRARIES ON ARDUINO

A noteworthy concern utilizing Arduino in Personal Security Device (PSD) is its restricted memory. The significant distinction between a broadly useful PC and the Arduino microcontroller is sheer measure of accessible memory. The Arduino UNO we are utilizing have just 32K bytes of Flash Memory, SRAM having size 2KBand 1K bytes of EEPROM. That is multiple times less physical memory than a Low-end PC. It prompts the issue of actualized any Encryption Library inside Arduino memory.

AES encryption for 128 bit requires 10 rounds of processing and for 192-bit keys require 12 rounds. For processing of each round include a single-byte based substitution step, a Row-wise permutation step, a column-wise mixing step, and

the addition of the round key. The encryption process will require some memory to store the temporary results and final encrypted results that goes in flash. Key will be in the EEPROM. If we reasonably add AES as software libraries it doesn't give enough room for other applications. Alternatively, if we use AES on Hardware, we diminish this problem to a certain extent.

Currently several hardware implementations of AES have been designed and published. There are, many design choices are encountered during hardware implementation of AES. In reality, these choices are limited to its application and budget. For performance point of view, major decision lies in trade-off between area and speed. To consider all these, we are Customized our AES that uses less resources and provide high speed. The complete AES-128-bit core is explained in section (III).

III. AES IMPLENTATION ON HARDWARE

AES 128-bit is written in Verilog language. The design is Complete 128-bit mode which is synthesized and verified. The design contain both encrypt/decrypt and key scheduler inside it and both the input and output are connected to SPI protocol for taking DATA through Arduino and Vice-versa.

The LUT put together usage of AES calculation with respect to FPGA is a customary methodology. It is basic and simple to execute the ideal usefulness. When it is integrated, it extensively possesses a less amount of area on FPGA. Inside our AES block, we have top level AES controller for control both encryption and decryption and with the help of MUX any one of between shift row, mix column and Plain text data is selected.

A. AES ARCHITECTURE FLOW

It's a 2-stage pipeline approach and takes 10 rounds to complete, the input data is 128 bits with each round requiring 1 cycle to complete. The AES architecture Flow is shown in Fig3.1.

A. Sub Byte

It is non-linear transformation where byte is replaced with a value in Sbox. The Sbox is predetermined for using it in the algorithm.

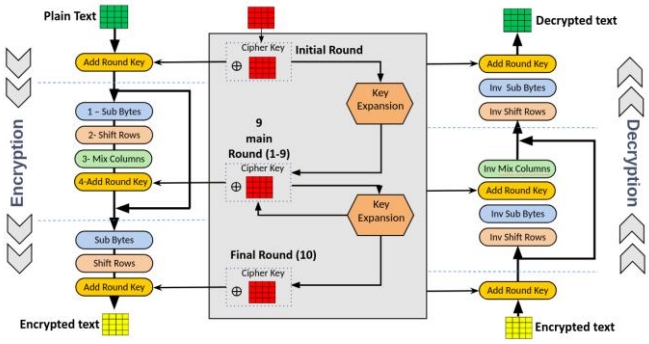

Fig 3.1. AES architecture Flow

B. Shift Rows

In shift Rows transformation, row of each state is cylindrically shifted left with different offset. First Rows is kept as it is and second row shifted by one byte and third row by two and finally the fourth row is shifted by three bytes left.

C. Mix Column Transformation

Mix column transformation is based on Galois field multiplication. Where each byte is replaced with particular value calculated. Each multiplication value is calculated using logic shown below.

$$S'(x) = a(x) \otimes S(x)$$
$$a(x) = \{03\} \times x3 \oplus \{01\} \times x2 \oplus \{01\} \times x \oplus \{02\}$$

Where x represents Galois field representation and xored gate for used.

D. Add Round key

The matrix of 16 bytes are consider as 128 bits and xored to 128 bits of the round key. If last round is this then output is 128 bits Encrypted output. Otherwise these 128 bits again going to the similar round considering 16 bytes.

The Data Flow path of both encryption and decryption is shown in Fig 3.2. Here in the 13 cycle's encryption completed and is obtained our data through 128-bit data out pins and Arduino for further processing.

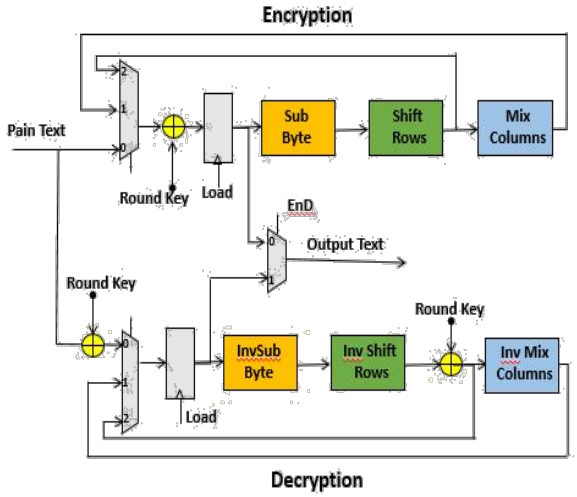

Fig 3.2. Data Flow path of AES 128-bit core

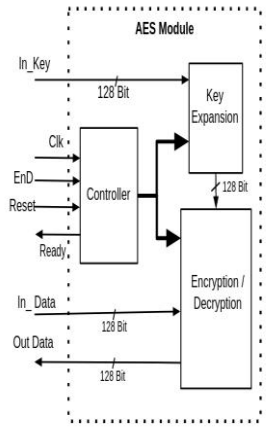
The complete block diagram and design hierarchy of AES block part at each level is shown in Fig 3.3 and fig 3.4



Interface signals of AES-128 core

S.No.	I/O Pin	Data Width	Direction	Description
1	Start	1 bit	Input	When it is true, Core will load input data and key, start encryption/decryption.
2	Reset	1 bit	Input	Reset the Core
3	EnD	1 bit	Input	Select mode, if it is false then Encryption , true then Decryption
4	In_Data	128 bit	Input	Input Data
5	In_key	128 bit	Input	Input Key
6	Clk	1 bit	Input	Clock
7	Out_data	128 bit	Output	Output Data
8	Ready	1 bit	Output	Encryption/Decryption is Over

Fig 3.3 Block Diagram of 128-bit AES core

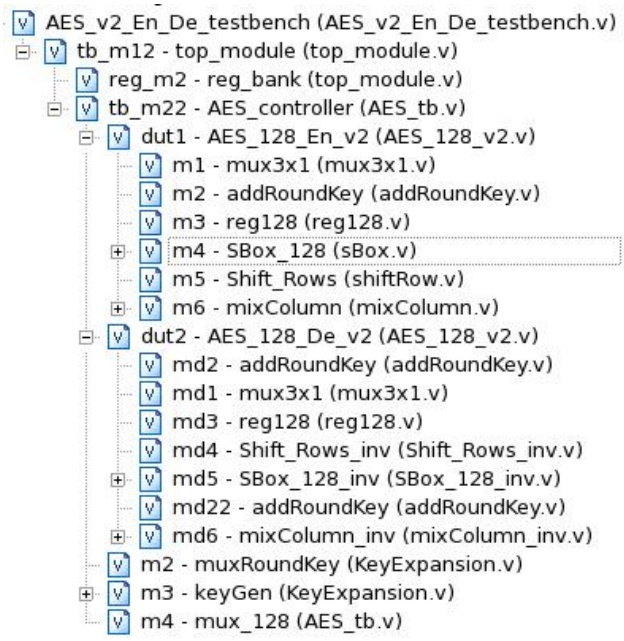


Fig 3. 4 Hierarchy view of AES Verilog code

IV. Proposed Appraoch and Experimental Setup

A. Proposed Approach

Firstly, we have taken data from PC in .txt format as input and then processed it through Arduino and converted it into bit format and then sending each bit data through SPI protocol working on 16MHZ to AES core implemented inside FPGA. After the Encryption is done data is send back to Arduino through SPI protocol. The communication of Data from PC to Arduino and FPGA to Arduino are monitored using Real Term serial analyser.

Arduino is programmed in Arduino IDE and the Pins declaration and EEROM to store the key value inside it first are shown below. Top level shows 5 main signals that are used for sending and receiving both data and clk.

```
#include <EEPROM.h>
#include <SPI.h>
int i = 0, j = 0;
int data_out = 17, data_in = 18, clk = 19, KEY = 12, SSEL =
16; int flag = 1;
//int time delay = 100;
int main_data[128];
void setup() {
Serial.begin(9600);
// start the SPI
 library: SPI.begin();
SPI.setBitOrder(MSBFIRST);
 //initalize the data ready and chip select
pins: pinMode(data_in,INPUT);
pinMode(data_out,OUTPUT);
pinMode(SSEL,OUTPUT);
pinMode(KEY,OUTPUT);
pinMode(clk,OUTPUT);
digitalWrite(SSEL,HIGH);
for (int i = 0; i < 128; i = i + 32) {
EEPROM.write(i,1);    //00000001
 EEPROM.write(i+8,2); //00000010
 EEPROM.write(i+16,3); //00000011
EEPROM.write(i+24,4); //00000100
}
}
```

B. SPI Protocol

The Serial peripheral interface, is a Synchronous Serial data communication protocol, used in sending data for short distance communication. It operates on frequency 16 MHz

provided by Arduino. The various signals used are described below.

1.) SCK: Clock signal
2.) MOSI: Master out slave in line
3.) MISO: Master In slave out line
4.) SS: Slave selection

C. *Experimental setup*

For realizing the design, we are using Arduino Uno and Nexys4DDR FPGA kit. It is a Digital circuit development platform based on Artix 7 FPGA from Xilinx having part no XC7A100T-1CSG324C.With its large, high capacity, it is suitable for Implementing AES.

In this implementation, for demonstration purpose we use "Hello_NITKKR" as input and encrypt data is shown on LCD as in Fig 4.1 AES as working on 200MHZ and it communicates with Arduino Through SPI working on 16MHZ, clock is provided by Arduino through Pin 19.

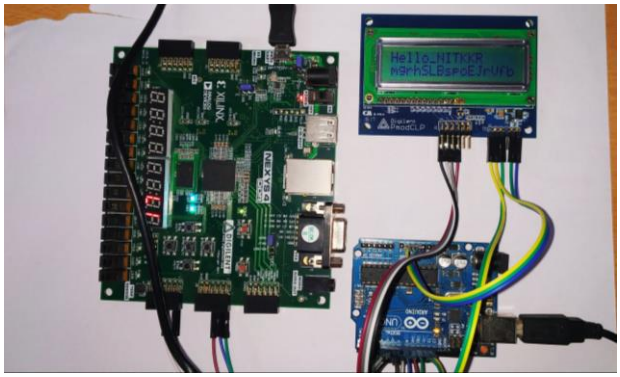

Fig 4.1. Experimental Setup

V.) EXPERIMENTAL RESULTS AND DISCUSSIONS

The AES utilize less resources and it provide high performance due to pipeline approach. The AES design utilize 389FF and 860 LUT. The top-level module of our project2 is shown below in Fig 5.1. It contains two SPI protocol modules, one for sending the data from Arduino to FPGA and second one for receiving the data back to Arduino from FPGA. Inside it we implemented our AES 128-bit core.

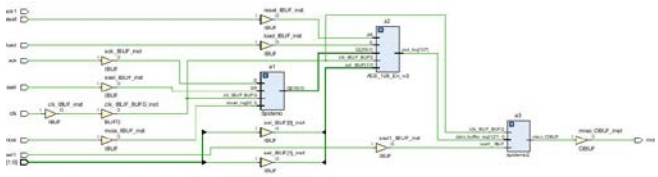

Fig 5.1. Top Level module

The Fig 5.2shows the resource utilization in our design which shows how less resources are used and how efficient that approach is.

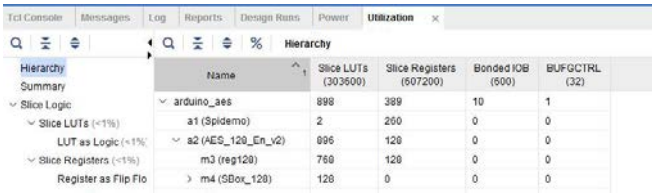

Fig 5.2. Resources utilization

The Fig 5.3 shows the Simulation result of design system i.e. AES output, here we are taking input from testbench and from the Encryption and Decryption Modules are instantiated inside our Top-level Module. The encryption module simulation results are verified.

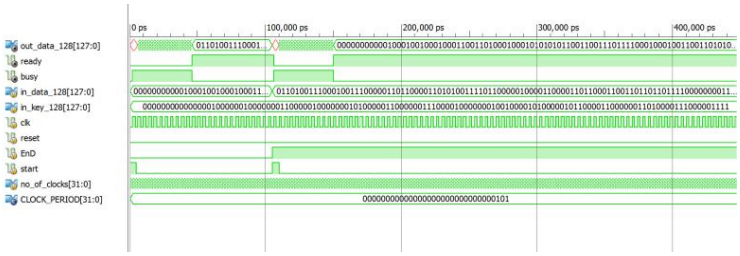

Fig 5.3 AES Encryption Module Waveform

VI.) CONCLUSION

This paper implemented the AES Core interface with Arduino as Hardware approach to provide sufficient space for Arduino to perform other functionality. While securing our data and dealing with data and control issues using SPI protocol, this interface provides an efficient speed performance and require least resources as 389 FF's and 860 LUTs used inside our FPGA. Further We can use this in Securable Arduino Applications where Security is also a major concern.

VII.) ACKNOLWLEDGMENT

This work is a part of SMDP-C2SD project under (Under MeitY). The authors acknowledge Dr. R.K Sharma and the technical and EDA tools provided in VLSI design lab.

Abstract: Dengue is a mosquito-borne, fatal viral disease expanding as a global problem. Three climate factors effect dengue fever namely temperature, rainfall, and humidity, they are critical to mosquito survival, reproduction, and development and can influence mosquito presence and abundance. A Predictive model for the dengue incidence and its prevalence has been proposed by considering Kerala state's Dengue data. In prediction module the algorithm predicts the number of dengue cases that might occur in that month. In meteorological analysis the relationship between humidity, temperature, rainfall and dengue cases was studied. The machine learning algorithms employed for the prediction were Linear Regression, SVR and Kernel Ridge. Comparative study been done on meteorological and geo spatial analysis on the data. The parameters taken into consideration for geo-spatial analysis were district's distance from the equator, shortest distance from the nearest seashore and percentage of forest cover in district, altitude of the district.

Keywords: dengue fever, regression algorithms, meteorological and geo spatial analysis

I. Introduction

Dengue has emerged as one of the most important mosquito-borne, fatal viral disease, apparently expanding as a global health problem [1]. Dengue is rampant in urban poor areas, suburbs and the countryside. It is also very common in more affluent neighborhoods in tropical and subtropical countries [2]. Dengue is transmitted through mosquitoes namely Aedes aegypti and Aedes albopictus. The primary vector of dengue, Aedes aegypti, is ordinarily found between 35°N and 35°S. The whole tropical area including America, Asia and Africa is prone to dengue, and highly populated countries like India, Indonesia, Brazil, and China have the greatest burden of share.

An estimated 3.6 billion people are at risk for dengue, with 50 million infections per year occurring across 100 countries globally [1]. India has also been witnessed an increase in the incident of dengue fever. Kerala state has been recording a greater number of Dengue fever cases over the years. Kerala has seen 1304 dengue cases in year 2011, 4056 in the year 2012, 7938 in the year 2013, 2548 in the year 2014, 4114 in the year 2015, 7218 in the year 2016, 21993 in the year 2017 and 4083 in the year 2018.

The algorithms which were used for classification are support vector classifier, logistic regression, naïve bayes, out of which support vector classifier performed best scoring an accuracy of 92.85% with precision, recall and f1-measure being 0.93,0.93 and 0.92 respectively.

For regression linear regression, support vector regressor were used. As our data was non-linear in nature linear regression didn't perform well by just scoring an accuracy of 48.49% with mean absolute error and mean percentage error being 190.04535 and -0.69568688 respectively. Support vector regressor performed extremely well by fitting a polynomial curve and scoring an accuracy of 90.63% with mean absolute error and mean percentage error being 103.48891 and -0.38543662.

In geo-spatial analysis the geographical parameters of the districts like distance from sea shore, distance from equator, altitude and percentage of forest cover were studied and conclusions were drawn in terms of how the variance of their parameters is affecting the dengue cases.

II. Background Study

In this study, the Author [3] adopted Naïve Bayes and Multi-regression to understand the relation between meteorological parameters and the occurrence of Dengue epidemic, also used k-means clustering to identify areas with similar spreading patterns.

In this study, the Author [4] focused on the extrinsic incubation period (EIP) and its changeability in different climatic zones of India. The results suggested that temperature is important for the virus to develop in different climatic regions and may be useful in understanding spatio-temporal variations in dengue risk.

In this study, the Author [5] collected the monthly mosquito larval survey data of Thailand from January to December 2010 and the results suggested that Aedes larvae were found more in rainy reasons compared to any other season.

In this study, the Author [6] used a methodology involving geospatial analysis. The Dengue cases from 2011 to 2014 were used as inputs for the analysis. The results suggested that a relationship exists between the climatic conditions and dengue occurrence.

III. Methodology

The methodology of the paper consists of the following steps:

A. Data Collection

1. Epidemiological data

From January 2011 to December 2018 except the year 2017 was obtained from the Directorate of Health Services, Government of Kerala [7]. The number of confirmed cases registered were taken into consideration and studied.

2. Metrological Data

The Barometrical data, of Kerala state from January 2011 to December 2018 was obtained from worldweatheronline website [8] as on 27th January 2018. The data included Behavior of monthly rainfall, temperature and relative humidity values.

B. Data Preprocessing

1. Data Normalization

Before applying the algorithms, various preprocessing techniques were applied to the data. The data was normalized using StandardScaler from sklearn.preprocessing package. The weather parameters such as humidity, rainfall and temperature were scaled in such a manner that their mean and standard deviation were -1 and 1 respectively [9].

2. Correlation Analysis

There is good amount of correlation between the rainfall and dengue cases occurring in a month. 0.63 was the correlation coefficient. Also, there was fair bit of correlation between humidity and dengue cases occurring in a month 0.52. And there is a negative correlation of -0.20 between the temperature and the dengue cases occurring per month. The pointbiserialr correlation between month and dengue cases is 0.12 [10].

3. Feature Selection

Temperature was dropped from the data-set before training the regression models for the reason being that average monthly temperature throughout the state of Kerala doesn't change drastically [11].

4. Cross-Validation

For regression the data-set was divided into training and testing data-sets. 80% (67 rows) of the data were given for training and the remaining data 20% (17 rows) were given for testing [12].

5. Choosing the best hyper parameters

Algorithm model ( )
{
$Param_1$ _combinations:= [val_1,..... val_n];
$Param_2$ _combinations:= [val_2,.....val_n];

```
.
.
Param_n _combinations:= [val_1,..... val_n];
error:=100000
for i_1 in param_1 _combinations do
{
for i_2 in param_2 _combinations do
{
.
.
for i_n in param_n_combinations do
{
model=algorithm(param_1=i_1, param_2= i_2,..... paramn=i_n);
model.fit(x_train,y_train);
if error>mean_squared_error(model.predict(x_test),y_test):do
{
error= mean_squared_error(model.predict(x_test),y_test);
print (i_1, i_2,....., i_n);
}
}
}
}
}
```

This logic was implemented in order to extract the ideal set of hyper parameters of each algorithm (except Linear Regression) which can extract maximum performance from the model and generate least mean_squared_error. In the above algorithm the $param_1$_combinations,$param_2$_combinations,…..,para m_n_combinations are the lists which contain the various values which when taken together generate a combination of hyper parameters with which the machine learning algorithm is trained.

In the above algorithm error which is initialized with 1000000 is later updated with latest maximum accuracy value. When the trained model is generating higher accuracy score then the till now highest acc then we are updating the existing error with new minimum error and printing the combination of parameters which are giving the best results. In this way the best parameters for SVR and Kernel Ridge were chosen.

6. *Model Generation*

Regression: To predict the number of dengue cases that might occur in a month from 2011 to 2018 except 2017 based on the weather parameters and data of Kerala

- Linear regression and Support vector regressor were used for this purpose.
- The parameters of support vector regressor were tweaked and adjusted in order to extract peak performance from the algorithm.

IV. Results and Discussion

The paper is implemented on Python programming on Anaconda 3.4 distribution. The dataset consists of humidity, rainfall, temperature and month. The paper uses supervised machine learning algorithms for predicting dengue cases of Kerala state of South India.

A. *As a predictive task*

Fig 1 to Fig 7 depicts index values of all records in dataset on x-axis and respective dengue cases on y-axis.

1. *Linear Regression:*

LinearRegression(copy_X=True, fit_intercept=True, n_jobs=1, normalize=False)

The Data was non-linear in nature and as a result Linear Regression algorithm didn't really fare well and gave us an accuracy of 47.49%.

The MAE (Mean-Absolute-Error) is 190.0453500344 8942.

The MSE (Mean-Squared-Error) is 87781.036833493 05.

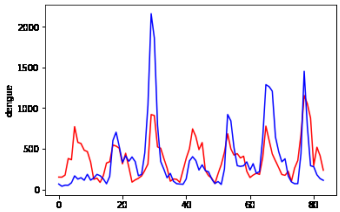

Fig 1 it is clearly visible that the model couldn't catch up to the sudden spikes during June and July in few cases.

The model is underestimating the values while testing. This is mainly accounted to the sudden spikes in the number of dengue cases in months of July and august which is the general trend in the state of Kerala as we have seen.

The coefficients of the features in linear regression decision curve- humidity, month, and rainfall were 62.60707993, -21.97886451, and 189.90310392. 376. 6528045066428 is the intercept of the fit equation.

Prediction = 62.60707993 (humidity) -21.97886451 (month) + 189.90310392 (rainfall) + 376.6528045066 428.

This clearly throws light on how different features ar e affecting the model. The dengue cases clearly depe nd on the amount of rainfall as it has the highest valu ed coefficient 182.90 followed by 62.60 of the feature humidity.

2. Support Vector Regressor:

support vector regressor with rbf kernel didn't really perform well as it is clearly visible in the below graph. The model specifically failed in fitting a curve which can take a sharp curve during the months of May, June and July. Accuracy of the model was 7%.

SVR(C=50.0, cache_size=200, coef0=0.0, degree=1. 0, epsilon=0.001, gamma=1.0, kernel='rbf', max_iter =-1, shrinking=True, tol=0.001, verbose=False)

MAE (Mean-Absolute-Error) is 180.6120357544998 9.
MSE (Mean-Squared-Error) is 153681.21744890077.

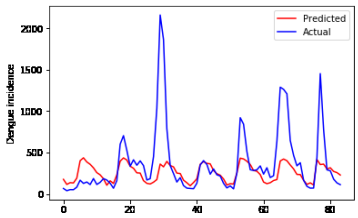

Fig 2 the model predicted very badly during the mont hs which had recorded very high dengue incidences.

SVR(C=50.0, cache_size=200, coef0=0.0, degree= 1.0, epsilon=10.0, gamma=1.0, kernel='linear', max_i ter=-1, shrinking=True, tol=0.001, verbose= F alse)

The model with linear kernel performed better than rbf kernel but when compared to polynomial kernel d idn't perform well. It scored an accuracy of 32.4%.

The MAE (Mean Absolute Error) is 177.9041777855 6534.
The MSE (Mean-Squared-Error) is 112893.94413108 726.

The linear kernel fitted a curve of decision curve with coefficients of the feature's humidity, month, and rai nfall being 3.20686362, 1.88293777, and 2.9 7340883. The intercept of the equation is 253.902288 14.

Prediction = 3.20686362 (humidity) + 1.88293777 (month) + 2.97340883(rainfall) + 253.90228814.

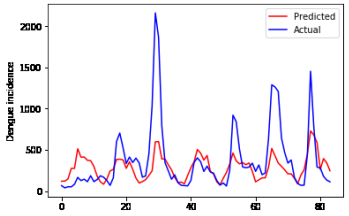

Fig 3 The model with linear kernel performed better when compared to rbf kernel but still is not the ideal kernel for prediction.

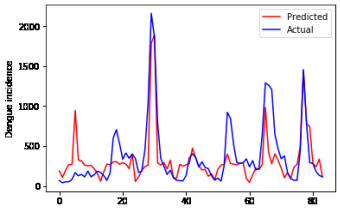
The Support vector regressor with polynomial kernel outperformed both rbf and linear kernels by a mile as it scored an accuracy of 90.63%.

SVR(C=50.0, cache_size=200, coef0=0.0, degree=4.0, epsilon=0.1, gamma=1.0, kernel='poly', max_iter=-1, shrinking=True, tol=0.001, verbose=False)

The MAE (Mean-Absolute-Error) is 103.4889107277 9048.
The MSE (Mean-Squared-Error) is 15635.611625347 123.



The model with polynomial kernel performed very w ell even during the sudden spikes in dengue incidence s during the months of June and July.

3. Kernel Ridge

3.1 Linear

The R^2 of the model on training with the model with linear kernel is -0.27. The negative value of the R^2 coefficient indicates that the model predicts values lesser than the mean of the target value distribution.

KernelRidge (alpha=1.0, coef0=1, degree=1, gamma =1e-06, kernel='linear',kernel_params=None)

The MSE (Mean-Squared-Error) of the model is 213211.95906435975
The MAE (Mean-Absolute-Error) of the model is 366.5700603704342

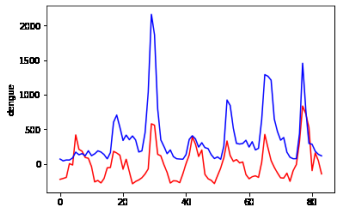


Fig 5 the linear kernel of Kernel Ridge performed the worst among all the kernels of SVR and Kernel Ridg e. It not only predicted way off the target during the J une and July but also during the non-monsoon month s during which the dengue incidences are very less.

3.2 poly

Kernel Ridge with polynomial kernel performed best among all the kernels of Kernel Ridge. The R^2 coefficient of the model is 0.87.

KernelRidge (alpha=100.0, coef0=1, degree=5, gam ma=1.0, kernel='poly',kernel_params=None)
The MSE (Mean-Squared-Error) of the model is 2008 9.045130779024
The MAE (Mean-Absolute-Error) of the model is 108 .96932376142536

The curve was well fit and when compared to the oth er two kernels of the Kernel Ridge.

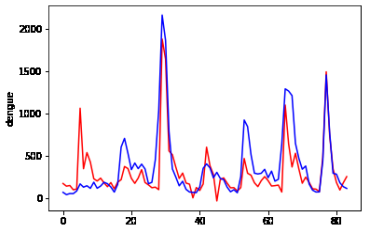

Fig 6 the polynomial kernel of Kernel Ridge performed second best among all the models. It performed decently during the sudden spikes in dengue incidences.

3.3 Rbf

Kernel Ridge with rbf performed better than the linear and rbf kernels of the SVR's rbf and linear kernels. The R^2 of 0.58.

KernelRidge (alpha=1e-05, coef0=1, degree=1, gam ma=0.001, kernel='rbf', kernel_params=None)

The MSE (Mean-Squared-Error) of the model is 6883 6.23541726012
The MAE (Mean-Absolute-Error) of the model is 158 .31175149670418

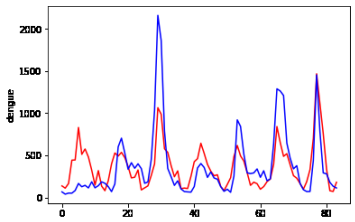

Fig 7 the rbf kernel of the Kernel Ridge performed better than the rbf kernel of the SVR but it is not the ideal model for predicting the dengue incidence.

B. Meteorological Analysis

Here humidity and rainfall refer to the monthly averages of the respective parameters. In fig 8 the red dots indicate the scenarios in which the dengue cases occurring in a month were more than 400. The blue dots indicate the scenarios in which the dengue cases occurring in a month were less than or equal to 400.

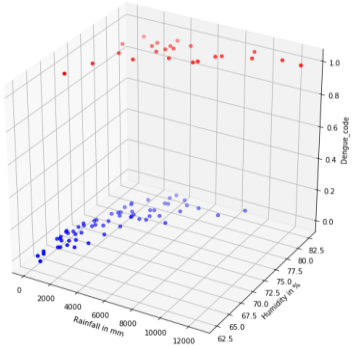

Fig 8 is a 3-Dimensional plot to understand the relationship between humidity, rainfall and the magnitude of dengue epidemic occurrence.

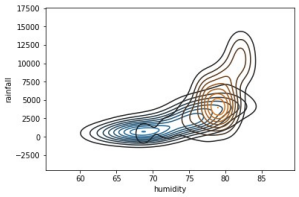

Fig 9 is KDE plot indicates the ranges of values in which majority of points belonging to a class label are existing. In this figure the blue spirals indicate the existence of scenarios with dengue cases less than 400 (n<=400) and the orange spirals indicate the existence of scenarios where the dengue cases are

greater than 400 (n>400). The more densely are the spirals indicates that a greater number of points of a particular class label are occurring in that particular region.

In the case of the blue points, they are generally occurring when humidity is varying between 66 % - 75%. At the same time the rainfall is varying in between as low as 63mm-8000mm. But the density of blue points decreases as both rainfall and humidity increase. More number of blue points can be observed when the humidity is in between 66% - 72% and rainfall is in between 63mm-2500mm.

In the case of red points, they are mostly occurring when the humidity is in the high 70's (77%-82%) or higher and when the rainfall is range 2500mm – 5500mm.

By this analysis it can be concluded that the ideal conditions for aedes aegypti to breed would be humidity 77% - 82% and rainfall 2500mm – 5500mm.

1. Study on effect on dengue cases changes in meteorological parameters throughout the time period from 2011-2018 (except 2017)

In the state of Kerala generally the dengue cases rapidly increase after the month April as Kerala experiences an early monsoon when compared to the rest of the India. Monsoon in Kerala starts right in the end of May. This is when things start to change.

The fig 10 and fig 11 depict the monthly variation of humidity, temperature, rainfall and dengue cases in terms of percentages with respect to previous month.

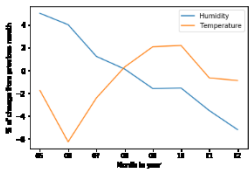

Fig 10

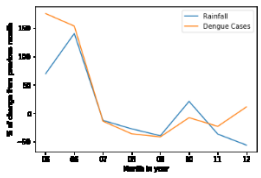

Fig 11

The mean-humidity increases by 5.02% and mean-rainfall increases by 69.49% and a -1.74 % decrease in mean-temperature from April to May and as a result dengue cases increase by 175%.

While going from May to June mean-humidity increases by 4.02% and mean-rainfall increases by 140.14% and mean-temperature falls by -6.26% which lead to an increase of 153% in dengue cases when compared to May.

And then going from June to July mean- humidity increases slightly by 1.23% and mean-rainfall decreases by -12.38% and mean- temperature decreases by -2.41% as a result dengue cases decrease -13.18%. This is expected as June in Kerala has highest mean rainfall and dengue cases.

This trend continues till September and from there on the dengue cases tend to decrease as time passes.

Figs 12 to 15 depict the variation of monthly mean values of humidity, temperature, rainfall and dengue cases with respect to their respective mean values.

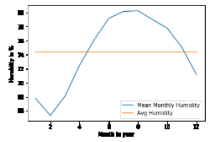

Fig 12

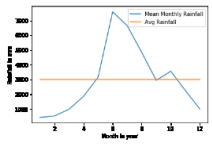

Fig 13

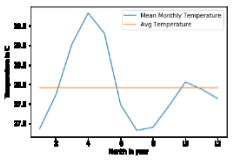

Fig 14

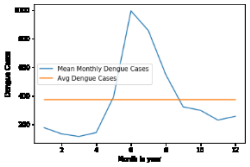

Fig 15

It is clearly visible that whenever there is a rise in dengue cases there is also rise in mean- humidity and mean-rainfall, while there is a descent in mean-temperature.

C. Geo Spatial Analysis:

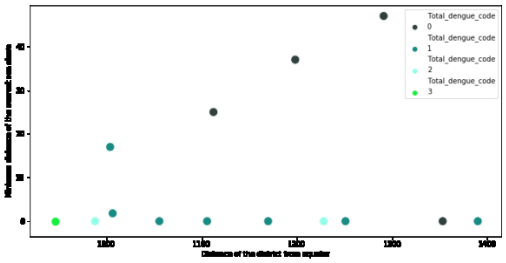
To study and understand the relationship between geospatial parameters and the dengue cases in the state of Kerala:

- The data considered for this study was the cumulative data of dengue cases district wise taken from the year 2011-2018(except 2017)

- Study was done on how the variation of geospatial parameter like distance from the seashore and distance from the equator of a district affected the dengue cases recorded in that particular district in the time period of 2011-2018(except 2017).
- Study was done on how the variation of geospatial parameters like percentage of forest cover and altitude of a particular district affected the number of dengue cases recorded in the time period of 2011-2018(except 2017).

In the fig 16 and fig 17 dark green points represent the districts which recorded total dengue cases in the range 0 – 1000, dark blue points represent districts which recorded total dengue cases in the range 1001 – 2000, light blue points represent districts which recorded total dengue cases in the range 2001 – 3000, light green points represent districts which recorded total dengue cases in range 3000 – and above from 2011 – 2018.

1. *Distance from nearest sea-shore vs distance from equator:*



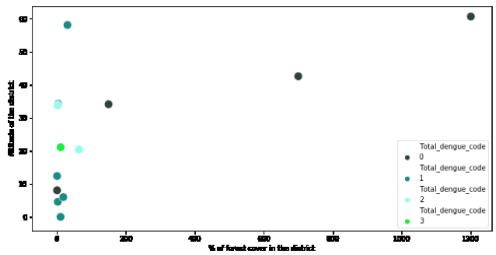
In the fig 16 Idukki (1112.3,25), Palakkad (1198.30,37), Wayanad (1291.23,47), Kannur (1353.30,0), Pahtanamthitta (1003.73,17), Kottayam (1006.35,1.8), Alappuzha (1055.45,0), Ernakulam (1105.61,0), Thrissur (1169.77,0), Kozhikode (1251.07,0), Kasargode (1390.19,0), Kollam (987.85,0), Malappuram (1228.20,0) and Thiruvananthapuram (945.86,0).

Fig 16 depicts the relationship between distance from equator and Minimum distance from the nearest seashore.

The general trend here is as both the distance from the coast and equator increase the dengue cases count is taking a hit. The only light green point which is Thiruvananthapuram is a coastal district and also it is the closest district to the equator of the earth 945.86 km and it recorded 12000+ dengue cases. The districts of Wayanad, Palakkad, and Idukki are 47.5 km, 37.5 km, 25 km away from their nearest sea shores. Also, their distances from equator of the earth are 1291.23 km, 1198.30 km, 1112.3 km respective. All the three districts are far ideal range from both the parameters as a result they recorded very a smaller number of dengue cases during 2011 – 2018 which are as low as 571, 893, 770 cases respectively.

There is one outlier in this graph which happens to be Malappuram. Though its distance from equator is as high as 1228.20 km it still was able to generate high number of dengue cases due to the following reasons, It is a coastal district, Also it is the most populated district of Kerala with 41,12,920 and also a high population density of 1158 people per sq. km. Due to high population and population density there is a good scope for the dengue epidemic to spread among more people as a single aedes mosquito carrying can inject the virus into many people.

2. *Altitude of district vs % area occupied by forest in district:*



In the fig 17 Idukki (1200,60.62), Palakkad (150,34.09), Wayanad (700,42.56), Kannur (1.02,8.06), Pahtanamthitta (31,58.05), Kottayam (3,4.57), Alappuzha (11,0.004), Ernakulam (4,34.41), Thrissur (2.83,33.73), Kozhikode (1,12.39), Kasargode (19,5.99), Kollam (3,33.74), Malappuram (64,20.39) and Thiruvananthapuram(10,21.16).

Fig 17 depicts the relationship between altitude of the district and percentage of forest cover in district.

The general trend here is as the altitude increases the dengue cases are decreasing. But when it comes to percentage of forest cover districts like Thiruvananthapuram, Kollam, and Malappuram

which recorded very high dengue cases are having forest cover in range of 20% - 33%. In the remaining scenarios where the forest cover is below 20% or above 33% the dengue cases took a hit. Districts like Alappuzha, Kottayam, Kasaragod, Kannur, Kozhikode which are having percentage of forest cover less than 20% as a result they have recorded lower number of dengue cases. Whereas the districts like Pahtanamthitta, Wayanad, and Idukki are having percentage of forest cover greater than 33% and even they recorded a smaller number of dengue cases.

Even though the district of Palakkad has the percentage of forest cover near to 33% it recorded a smaller number of dengue cases because it has higher altitude when compared to other districts in that range. The districts Ernakulum and Thrissur despite having very low altitude and forest cover percentage lying in the range of 20% - 33% failed to record higher number of dengue cases due to their distance from the equator of the earth being seemingly high.

The districts Wayanad and Idukki have recorded least number of dengue cases when compared with other districts of Kerala; this is due to them being at a higher altitude of 700m and 1200m respectively. Also their percentage 42.56% and 60.62% of forest cover respectively are above the ideal range which is 20% - 33%. As altitude increases the average temperature of the district decreases, this effect the survival of aedes aegypti as they are most likely to survive in high 20's which is around 28 to 30 degrees Celsius. The average temperatures of Wayanad and Idukki are 24.25 and 25.55 degrees Celsius respectively. Also, as the forest cover increases this generally leads to decrease in population of a particular district as people generally tend to live civilizations away from forests. If the forest is occupying the majority of the district's area, then it is most likely that the population and population density of the district decrease. Generally, when there is less population density the scope for dengue spreading decreases. It is observed that the districts Wayanad, Idukki and Pahtanamthitta are having forest covers of 42.56%, 60.62% and 58.05% having very low population of 817,420, 11,08,974 and 11,97,412 respectively , these are lower than the average population of a district of Kerala which is 23,86,147. Also, their population densities are lower 383, 254 and 453 respectively compared with the average population density of a district of Kerala which is 911.

V. Conclusion

The SVR algorithm with polynomial kernel performed the best among all the algorithms. But apart from the polynomial kernel of the SVR the remaining two kernels rbf and linear didn't perform as well as the rbf and linear kernel of Kernel Ridge algorithm. Both Kernel Ridge and SVR use l2 regularization but they use different loss function. The SVR uses epsilon intensive loss function whereas the Kernel Ridge uses squared loss function. Linear Regression didn't perform up to the mark. This is expected as the nature of the data is non-linear. In the meteorological analysis the findings suggest that the ideal conditions for occurring of high number of dengue incidences the average monthly humidity should be in range 77%-82% and average monthly rainfall should be in range 2500mm-5500mm. Also, the variation of average monthly humidity is affecting the occurrence of dengue incidences to higher extent when compared to what variation of average monthly rainfall. The findings found in geo-spatial analysis were that as the distance of the district from the equator increased the occurrence of dengue incidences decreased. Also as the distance from the nearest sea-shore increased the occurrence of dengue incidences decreased. The ideal amount of forest cover to be present in the district in order to record higher dengue incidences is 20%-33% area in total area of the district. As the altitude increased the prevalence of dengue incidences decreased in the state of Kerala.

***Abstract*— This paper makes a specialty of the utility of Convolutional Neural Networks for pedestrian detection. This is important for self riding vehicles. Work in this area become based on function based totally methods for a while earlier than convolutional neural networks have been implemented to it. On this work, a convolutional neural network based totally pedestrian detection pipeline become installation the use of the AlexNet and ResNet algorithms. Those had been trained on a subset of the Caltech Pedestrian Database and then tested on another subset of the database. It changed into determined that both the methodologies executed pretty nicely in detecting pedestrians from the specified photos. But the outcomes seemed a bit too constructive due to the small dataset used to check the consequences. Exams on the complete dataset is required to verify whether or not the methodology works well.**

Keywords*— *Convolutional Neural Networks; pedestrian detection; AlexNet; ResNet;

I. INTRODUCTION

Object detection has been an essential and challenging a part of laptop imaginative and prescient issues. It is a vital component of many regions which includes robotics, autonomous systems, protection systems, and unmanned aerial automobiles. Pedestrian detection, is a sub-part of item detection wherein the aim is to take both a frame (an picture) or video and stumble on the presence of human beings (human beings) in the picture. This has been a subject of studies over the last few years as it is an crucial factor of self sufficient/self- using vehicles. It can also be used as a protection feature for present motors to come across pedestrians and warn the driver, as well as in security structures like site visitors cameras. For this paintings we cognizance on detection in frames/pictures. Moreover even as sensible structures require real time detection, we do no longer attempt to speed up the test/detection mechanism. As a result the problem input reduces to a hard and fast of images containing or now not containing pedestrians, which are fed into the pedestrian detection pipeline (defined underneath) containing a convolutional neural community. The neural network is needed to offer a bounding container indicating the presence of a pedestrian. As a sliding window technique (defined below) is used for photo subsampling, the CNN gets a hard and fast of cropped images and the output is a class declaring whether the cropped photo contains a pedestrian or now not. The submit-processing strategies use this output to compute the bounding containers.

II. RELATED WORK

To start with function primarily based strategies were implemented to this hassle. With the resurgence of convolutional neural networks, those were carried out to the trouble as well. Function-based strategies Supervised and unsupervised studying techniques have been applied to this trouble. The paintings of Rowley[6] which carried out neural networks for facial detection become a first step on this course with the point of interest on function primarily based detection. The work via Viola and Jones[7] among 2001 and 2003 was a first-rate milestone in pedestrian/item detection. They used an crucial photograph representation and a new feature detection/mastering set of rules based on AdaBoost. This become accompanied by means of the work of Dalal and Triggs[5] on Histograms of oriented Gradients (HOG) for human detection which ended in addition enhancements to

feature primarily based prediction and pedestrian detection systems. Those have been followed by using improvements to the characteristic based methods with the intention to improve characteristic-based totally detection. However maximum of these techniques used function-based totally detection coupled with SVM regression methods to carry out pedestrian detection. The overview papers by using dollar et al. In 2009[2] and 2012[4] summarize the different function based techniques in detail and examine their performance on the Caltech pedestrian database[3].

III. Proposed Method

A. Convolutional Neural Networks

However since 2012, convolutional neural networks have revolutionized the sphere of laptop imaginative and prescient and photograph detection. Architectures like AlexNet[12] and GoogleNet[13] reduced the mistakes within the picture internet project by using report degrees. This has caused a sizable shift inside the method of the network with convolutional neural networks being applied effectively to a huge wide variety of vision and photograph classification issues. Due to the fact convolutional neural nets are a brand new idea, their software to pedestrian detection systems remains in its infancy. The paintings by means of Tome et al.[1] in 2015 applied CNNs to this problem. The work checked out the overall performance of different area concept and function extraction methods coupled with a CNN. Each the AlexNet and the GoogleNet architectures have been studied. Different paintings inside the same time frame consists of the work by using Fukui et al.[10], Sermanet et al.[8] and Angelova et al.[9] . Some of these procedures perform a feature extraction from the image and then use CNNs for classification. A distinctive approach turned into observed within the thesis of Molin, D [11] where the community takes within the complete photo as an enter (in preference to a characteristic) and generates the chance of a pedestrian at the photo pixels (at a place) as the output. The method whilst giving results just like present methods changed into a shift from present methods discovered. R-CNN based totally pipeline turned into recently correctly applied to this problem[17].

B. Methods

Solving the pedestrian detection problem requires the putting in place of a pedestrian detection pipeline as shown in parent 1. The pipeline contains a vicinity concept technique, a function extraction pipeline and a place classifier. In the case while an R-CNN method is used (no longer here), the vicinity concept and the feature extraction techniques are part of the R-CNN.

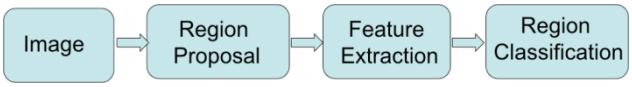

Fig.1 Pedestrian Detection Pipeline

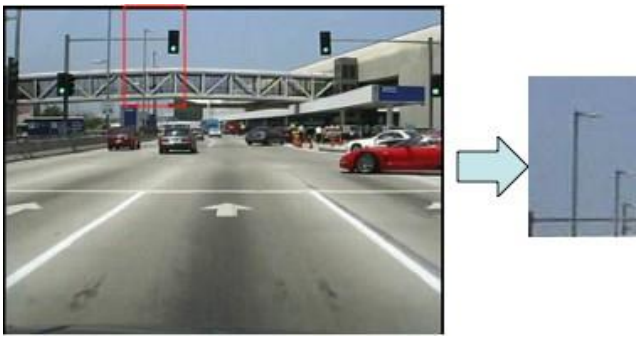

Fig.2 Sliding window approach

For area idea, a sliding window technique is followed right here. At some point of this technique, sections of the snap shots (sub pics) , which could have special sizes/component ratios are extracted from the picture. As shown in figure 2 where the purple phase/window is extracted as a feature. Those are then fed into characteristic extractor. The sliding window approach is used each at some point of schooling and take a look at runs within the same style. The characteristic extractor for earlier implementations turned into a simple HOG like function detector. For this technique the convolutional neural network (CNN) is used as a characteristic extractor. The cropped photo from the sliding window detector is surpassed directly to convolutional neural community. Inside the education runs, the photograph is preprocessed by first scaling the image (that is smaller). For maximum of the cases, the sliding window detector is ready to go back photographs of size 96x48. Those are scaled to required length of the CNN (224 x 224) inputs. The images are then normalized (subtracting a mean and scaling with the aid of a well known deviation). Education is then completed on those photographs in batches of 32. CNN architectures are attempted as characteristic extractors, AlexNet[12] and a 18 layer ResNet[14]. The AlexNet architecture has been applied to the trouble in present literature but no cases of the ResNet being implemented to the hassle were found via the author. As a consequence reading how well the ResNet performs at the hassle as compared to the other architectures changed into seen to be an interesting problem.

In education mode, once the set of the scaled and normalized photos are passed to the CNN (each architectures), it is skilled

in batch mode (32 photos/batch) the usage of a Nesterov momentum based SGD method. The presence of the bounding containers within the scaled photograph for the training snap shots is handed on to the CNN for training. At some point of the take a look at opinions, the photographs are handed to the CNN which classifies it as magnificence zero or magnificence 1 and those magnificence values are extracted out of the pipeline. These may be used to test the check accuracy of the CNN.

The AlexNet version is a 8 layer CNN containing five convolutional layers and 3 fully connected layers. It is a distinctly simple however pretty powerful version that turned into attempted for its simplicity and its effectiveness. The info of the version are defined in Reference.

The ResNet is a fairly complex CNN with many layers. An 18 layer network is used for this paintings although a good deal large layers were used for other packages. The simple concept of the ResNet (Residual network) is that unlike previous architectures, the community additionally has connections between neurons 2 layers aside. As a result the trade layers acquire statistics from neurons that aren't simply within the preceding layer permitting the features in that layer to be laid low with greater neurons and layer with feature sets. Information of the technique are described in Reference.

The closing step of the pipeline is a category pipeline is the classifier. For the contemporary examine, the classification hassle is stored simple with two training, man or woman detected (elegance zero), individual now not detected (class 1). But, a more complicated problem with lessons together with vehicles detected, and so on. Can be solved using the identical method with the aid of converting the final fully linked of the CNNs. The softmax classifier is used right here. The components for the loss is proven in Equation 1 (taken shape the CS231N notes)[18] wherein Li is the loss associated with sample i, and fyi is the elegance score of the magnificence y for pattern i

$$L_i = -\log\left(\frac{e^{f_{yi}}}{\sum_j e^{f_j}}\right) \quad \text{- Equation 1}$$

Furthermore, those can be used for in addition publish processing. The sub pics may be regrouped into their figure photos and based at the magnificence detected, the bounding container may be created inside the picture. Furthermore, these can be used to generate other evaluation/checking out metrics, which includes the ones distinctive inside the paper through dollar et al[2,4].

The pedestrian detection pipeline is setup in Torch7[19] the use of current implementation in torch which have been changed to in shape into the pipeline. Python scripts were used for pre and submit processing. The overall CNN testing and education framework was obtained by using modifying the ResNet implementation on github through facebook [15,16]. This implementation carries the resent along with and interface to load/preprocess pix, educate using sgd and run take a look at opinions. This framework turned into tailored to allow different networks (AlexNet obtained from the paintings of Soumith[20,who installation a fixed of ConvNet benchmarks on github) to be plugged in and incorporated with the pedestrian detection pipeline. Post-processing modules were introduced to permit extraction of the check/assessment results for further publish processing.

C. Dataset and Features

The Caltech Pedestrian Database[3] containing approximately 250,000 frames (60x480) with 350,000 bounding containers is used to attain education and take a look at statistics. This is a well known take a look at for the pedestrian detection hassle. The dataset is described in element in the paper by dollar et al[2,4]. Samples from the database are proven in parent 3. As shown some of the photograph incorporate a single pedestrian, some incorporate multiple pedestrians and some do now not incorporate any pedestrians. Moreover in some of the pix the pedestrians are clearly seen and are large in length(towards the digital camera) whilst in some of the snap shots, the pedestrians are occluded with the aid of items or very small(far faraway from the digital camera). The dataset consists of 11 periods of information amassed from video taken driving around busy streets. Periods 0 to five are assigned to the education set and the final are assigned to the check set. The pics are obtained as .Seq documents which have been preprocessed the use of matlab code received along aspect the database at the Caltech Pedestrian Database web site[3] and python code. The bounding boxes round the pedestrian is likewise Supplied as a set of text documents (again those want to be extracted from a compressed report using matlab code furnished). Each report corresponds to a body/picture inside the database and is empty if no pedestrian is gift or contains the coordinates of the bounding bins if someone/multiple humans are gift.

The dollar et al. Paper cautioned that each 0.33 frame inside the schooling set is taken as a schooling pattern and each 30th image inside the check units are used as take a look at samples. However the sliding technique resulted in the pix being in addition divided into approximately 50 sub images. This made the training and test pattern sizes intractable for this paintings because the schooling times had been becoming extraordinarily long and even trying out a assignment. Consequently the datasets were in addition sampled from. The

schooling dataset changed into sub sampled (randomly) to 2000 snap shots (around one hundred thousand pictures for the CNN) and the check set become also decreased to 1500 pictures through random sampling. The aim is to re- run the answer on larger datasets once basic pipeline is completed validated. The same old evaluation metrics for the accuracy of the detection system is described inside the paintings via greenback et al and additionally in Tome et al. For each set of rules/architecture, the pass over charge (MR) and the variety of false positives in keeping with image (FPPI) are measured. For each bounding container, if the bounding box distinctive by the set of rules and the actual bounding field (reality fee) do now not overlap by greater than 50% of their location, then it's miles considered as miss or a false negative. If the bounding field is particular by the set of rules in a region that does not contain a (fact)bounding container/pedestrian, then it is considered a false fantastic (FP). That is used to compute the quantity of fake positives according to image (FPPI) and averaged. The pass over charge (MR) is the ratio of the range of false Negatives to the variety of effectively diagnosed boxes (Positives). But as defined in the segment under, because the type effects seem unrealistic, the usual CNN metrics of check accuracy are used for the time being. Yet again realistic effects are received by using training/trying out on a larger dataset and making sure that the pipeline itself isn't always fallacious (in its implementation), those metrics could be used/defined.

D. Experiments/ Results/ Discussion

To teach the community, the photos are first handed thru the sliding window detector which generates a fixed of smaller sub snap shots for education. Those are then publish-processed and fed into the CNN for education. The Nesterov momentum method is used for education. Exceptional mastering costs are attempted for each the architectures and the first-class acting values are selected (0.1 for the Resnet and zero.01 for the AlexNet). The momentum value is set at 0.9 and the Weight decay is 1e-4. For both the networks, the training set is run for a couple of epochs (6 for AlexNet, three for ResNet) with a batch size of 32 picsan iteration.

Discern four suggests the evolution of the loss feature in the course of training for each the CNN architectures. Whilst training was performed for more than one epochs, we see that the loss is appreciably decreased inside the first 100 or so iterations after which doesn't alternate drastically. The loss for the ResNet comes down a lot faster than the AlexNet. The education became achieved for 2000 schooling pics that resulted in a complete of about

Fig.3 Samples from the Caltech Pedestrian Database

As hundred thousand photos. The take a look at accuracies for the skilled models had been proven to be extremely high (round five% for both the architectures). This regarded to be an exceedingly constructive measure of performance. A good way to determine the motives, the algorithm and the training and take a look at set changed into checked out in greater element. It turned into determined that the schooling images generated by the sliding window (as proven in figure 5 carries a couple of times of clear human beings (full line character inside the photo) and of sections of humans. Similarly there have been also samples containing just the road, simply the automobile, lampposts and many others (parent 6). The sliding window generator generated only some images throughout education that contained humans a long way away/combined with the background/trees and so on. Consequently the community overfitted for those instances.

Fig.4 Images with/without people that are not classified correctly

Throughout take a look at due to the incredibly small quantity of photographs, maximum of the photos had been dominated no person gift (discern 5) (automobiles, empty avenue) or someone without a doubt gift much like cases proven in figure 5.

The instances that the set of rules had trouble with (shown in figure 6) were smaller in number. Thus the overfitted version done properly on the test set as well. To triumph over this

trouble, using a larger pattern set containing extra check pictures is required. Other reasons are also being investigated.

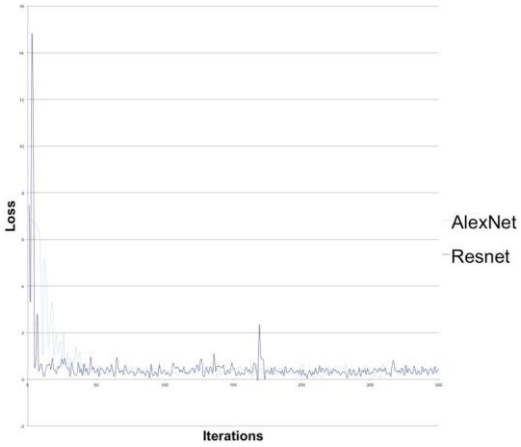

Fig.5 Training results of the CNNs

Fig.6 Images with people clearly defined (easily classified)

Fig.7 Images without people (only road etc) easily classified

It turned into also located that the use of a sliding window method for characteristic detection resulted inside the hassle becoming extremely big (in terms of statistics size) requiring down sampling. Moreover the sliding window carried out become no longer clever sufficient to tug out human beings successfully(with out reducing) especially in cases in which the humans had been a small part of the entire frame (a long way far from the digicam). This likely resulted inside the overfitting and wrong take a look at outcomes. Therefore for future paintings, transferring to an R-CNN primarily based approach in which the CNN acts as each the region inspiration and the feature detection techniques is recommended.

IV. Conclusion and Futurescope

As a part of the take a look at, a pedestrian detection pipeline became installation the use of the Torch7 framework leveraging present implementations [15,16,18,19,20]. A sliding window detector changed into used for area proposal and both the AlexNet and 18 layer ResNet had been used for function detection with the softmax feature serving as a classifier. The hassle turned into formulated as a binary category trouble (individual detected or character now not detected).

Regrettably the effects obtained indicated that the model become possibly overfit and because of the down sampling of the check set, test accuracies had been overoptimistic. The model works fairly nicely for cases wherein people are certainly present inside the frame or completely absent within the frame but doesn't in reality work well for instances of occluded pedestrians or for cases of small pedestrians (far from the digicam).

The subsequent steps to be performed involve schooling the picture on a much larger schooling set and testing the overall performance on a bigger test set, furthermore, which will put off the trouble of too many samples that occurs because of the sliding window technique, transferring to a R-CNN approach, which get rid of the sliding window detector could be attempted.

ACKNOWLEDGMENT

This work is supported by Dr.Sunnetha Manne, Professor and Head, Department of Information Technology from VR Siddhartha. We thank our colleagues who provided insight and expertise that greatly assisted the research.

Fast Error Correction for Header Flit in NoC

V.Taraka Sai Srinatha Reddy, G.Hema Sekhar Reddy, K.Jeshmitha Reddy, M.Vinodhini
Department of Electronics and Communication Engineering
Amrita School of Engineering, Bengaluru
Amrita Vishwa Vidyapeetham
India

***Abstract*—To improve data reliability in NoC, extensively adopted method is the deployment of error correction codes. Errors present in the data flit are corrected by these codes and this is not applicable for correcting errors present in the header flit. So, there is a need for an coding method which will correct errors in data and also the header flit. Further, it is important to have a coding method that will decode the header flit faster compared to data flit, as header flit is used for processing the data flits. Existing single error correction and double error detection code is improved and presented in this paper to support faster error correction in header flit with retaining the same number of redundant bits. This improved code is synthesised and results are compared with existing code. The results show that the header flit are decoded faster compared to data flits as the critical path delay is reduced.**

***Index Terms*—Error correction and detection codes, high-speed networking, Noc, single error correction and double error detection (SEC-DED).**

I. Introduction

In System on Chips (SoC), the reliability issues are increasing gradually when we move towards Deep Sub Micron (DSM) Technology [1]. In SoC's, the information is communicated through an inter communication architecture known as Network on Chip (NoC). Generally, the packets communicated in NoC are more vulnerable to soft errors due to various external and internal noise sources. To improve SoC reliability, Error Correcting Codes (ECCs) are used widely. Error Detection And Correction (EDAC) uses 3D parity check bits to detect and correct multiple errors [2]. This EDAC will correct upto 3 bits of errors. Single Error Correction and Double Error Detection (SEC-DED) code, detect and correct two and one error bits respectively [3]. Horizontal-Vertical Parity and Diagonal Hamming (HVPDH) code, detects 8 bit errors and one bit error is corrected [4]. The extended Hamming code which has similar error correction feature as SEC-DED is also very commonly used [5]. In all the ECC's proposed for Noc and as per the literature survey carried out, detection and correction of error bits are possible only in the corrupted data flit. All these codes are not designed to support error correction in header flit bits.

Various applications of SoC is drastically affected because of the reliability problems present in NoC [6]. In NoC, communication takes place in the form of packets. Packets consists of header and trailer flit each one and body flits between them as shown in Fig. 1. Two or more packets are grouped together to form a message. A packet is further processed in a router based on the information taken from the header flit. If this flit is corrupted, processing of the remaining part of the packet is effected and delayed. Therefore, an ECC which supports error correction in header flit is important. This paper proposes an enhanced SEC-DED Code which can correct and detect errors present in header flit and also in body flit parallelly.

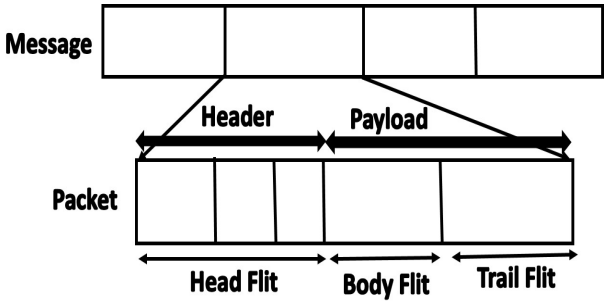

Fig. 1. Packet format of NoC

Further the paper is organised as follows. Survey on all the existing works are presented In Section II. Proposed enhanced SEC-DED code is explained in Section III. Evaluation of proposed work and the conclusion are discussed in Section IV and Section v respectively.

II. RELATED WORKS

There are methods available for constructing the single error correction codes of data bits only with low decoding delay [7].But those methods are not proposed for SEC-DED. In general, there are two methods for detection and correction of errors in the header flit and also in body flit [8]. In first method, two independent ECC's are used for header flit and also body flit, where it requires extra redundant bits. This requires extra storage for the redundant bits. In second method, only one ECC is used for correcting and detecting the errors in both body flit and also the header flit, where same number of redundant bits are used. Therefore, second method is preferred over first method. SEC-DED codes are also widely used in rapid memories [9]. If there are u number of bits in data block, then there will be k number of parity bits to support single error correction which can be specified as given in equation (1).

$$2^k > (u + k) + 1 \tag{1}$$

For example, for a 32 bit data block using equation (1) number of parity bits required is 6. Similarly, for 64 bit data

block, 7 parity bits are required. Further, to extend single error correction feature to single error correction double error detection one extra parity bit is used. So in Hsaio code, here 32 and 64 bit data block requires 7 and 8 parity bits respectively. There are two types of SEC-DED codes they are extended Hamming code and Hsaio code. Hsaio code uses H matrix where every column in this matrix has odd number of ones. Also, the other rules followed in this H matrix are every column should be unique and there should be no all-0 columns. The H matrix for SEC-DED code [10] for data block size of 32 and 64 bits is shown in Fig. 2 and Fig. 3.

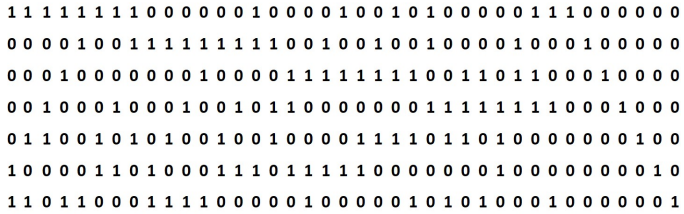

Fig. 2. H matrix for 32 bit data block

Fig. 3. H matrix for 64 bit data block

III. PROPOSED ENHANCED SEC-DED CODE

In this paper, by retaining same number of redundant bits used for SEC-DED code, a extended SEC-DED code is designed. This is designed to protect the entire packet. A fast decoding method is also proposed for header flit bits which reduces the decoding delay of those bits. The same traditional H matrix as shown in Fig. 2 and Fig. 3 are modified to support extended SEC-DED code in our work. To the H matrix of SEC-DED code, which is available for 32 and 64 data block sizes [4], 16 and 32 columns are added to the most significant side to support error correction in header flit bits as shown in Fig.4 and Fig.5.

This extra 16 columns corresponding to the header flit are unique. The bits corresponding to these columns are decoded faster in order to support faster processing of data bits. Faster decoding is performed by considering only fewer redundant bits. In the same way, 32 unique columns are added to facilitate the error correction in the header flit of 64 bit data. In general, the number of bits that can be protected by SEC-DED is always a power of 2. For 32 bit data, 7 parity bits are needed that means $2^7 = 128$ i.e 128 total number of possible bits which are protected by using same 7 parity bits. This is

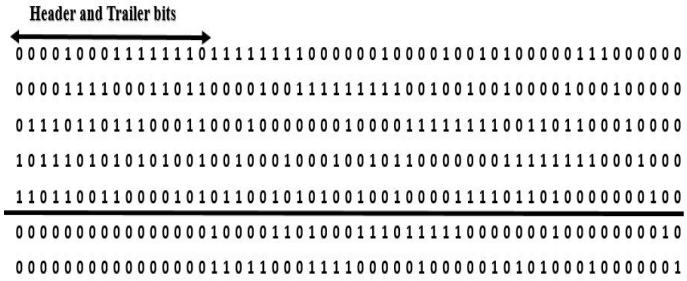

Fig. 4. H matrix for 32+16 bit data block

applicable for 64 bit data also. Therefore, few extra bits can also be protected by the same number of redundant bits.

A. Enhanced SEC-DED encoder

Let h, d, r represents the header flit bits, data bits and redundant bits respectively. In H matrix shown in fig. 4, first 16 columns at the MSB side belongs to headerflit bits (v[0], v[1], v[2],...., v[15]), last 7 columns at the LSB side belong to redundant bits (r[0], r[1], r[2],...., r[6]) and remaining all the 32 bits corresponds to data bits (g[0], g[1], g[2],....., g[31]).

The 48 bit data block (16+32) is given as input to the encoder and the output of the encoder is 55 bits (16+32+7). These 7 redundant bits are calculated by XORing the bits present in the bit position holding 1 in the H matrix [11] without considering the redundant bit columns as shown in equation (2) to equation (8)

$$r[0] = v[4] \oplus v[8] \oplus v[9] \oplus v[10] \oplus v[11] \oplus v[12] \oplus v[14] \oplus v[13] \oplus g[16] \oplus g[17] \oplus g[18] \oplus g[19] \oplus g[20] \oplus g[21] \oplus g[22] \oplus g[23] \oplus g[30] \oplus g[35] \oplus g[38] \oplus g[40] \oplus g[46] \oplus g[47] \tag{2}$$

$$r[1] = v[4] \oplus v[5] \oplus v[6] \oplus v[7] \oplus v[11] \oplus v[12] \oplus v[14] \oplus v[15] \oplus g[20] \oplus g[23] \oplus g[24] \oplus g[25] \oplus g[26] \oplus g[27] \oplus g[28] \oplus g[29] \oplus g[30] \oplus g[31] \oplus g[34] \oplus g[37] \oplus g[40] \oplus g[45] \tag{3}$$

$$r[2] = v[1] \oplus v[2] \oplus v[3] \oplus v[5] \oplus v[6] \oplus v[9] \oplus v[8] \oplus v[10] \oplus v[14] \oplus v[15] \oplus g[42] \oplus g[43] \oplus g[45] \oplus g[19] \oplus g[32] \oplus g[33] \oplus g[34] \oplus g[35] \oplus g[36] \oplus g[37] \oplus g[38] \oplus g[39] \oplus g[46] \oplus g[27] \tag{4}$$

$$r[3] = v[0] \oplus v[2] \oplus v[4] \oplus v[3] \oplus v[8] \oplus v[6] \oplus v[10] \oplus v[12] \oplus v[15] \oplus g[18] \oplus g[22] \oplus g[26] \oplus g[29] \oplus g[31] \oplus g[32] \oplus g[40] \oplus g[41] \oplus g[42] \oplus g[43] \oplus g[44] \oplus g[45] \oplus g[46] \oplus g[47] \tag{5}$$

$$\begin{aligned} r[5] = {} & g[32] \oplus g[33] \oplus g[34] \oplus g[35] \oplus g[36] \oplus g[44] \oplus \\ & g[16] \oplus g[21] \oplus g[22] \oplus g[24] \oplus g[28] \oplus g[29] \oplus \\ & g[30] \end{aligned} \tag{7}$$

$$\begin{aligned} r[6] = {} & g[16] \oplus g[17] \oplus g[19] \oplus g[20] \oplus g[24] \oplus g[25] \oplus \\ & g[26] \oplus g[27] \oplus g[33] \oplus g[39] \oplus g[41] \oplus g[43] \oplus \\ & g[47] \end{aligned} \tag{8}$$

B. Enhanced SEC-DED decoder

The encoder output is now input to the decoder. For 32+16 data block, the 55 encoded bits are decoded by calculating the syndrome bits. Syndrome bits detect single and double bit errors that are present in the entire packet assuming error free redundant bits. Let nr represents newly calculated redundant bits and r represents the received redundant bits. The syndrome bits (y[0], y[1], y[2]...., y[6]) are calculated by XORing the newly calculated redundant bits and received redundant bits. The calculation of syndrome bits are shown in equation(9) to equation(15). Similarly, for 64+32 data block the 8 syndrome bits are calculated in the same way.

$$y[0] = nr[0] \oplus r[0] \tag{9}$$

$$y[1] = nr[1] \oplus r[1] \tag{10}$$

$$y[2] = nr[2] \oplus r[2] \tag{11}$$

$$y[3] = nr[3] \oplus r[3] \tag{12}$$

$$y[4] = nr[4] \oplus r[4] \tag{13}$$

$$y[5] = nr[5] \oplus r[5] \tag{14}$$

$$y[6] = nr[6] \oplus r[6] \tag{15}$$

For decoding, the syndrome bits corresponding to the ones in the column of H matrix are taken into consideration. In this way the decoding for all the bits are done. In our proposed decoder, bits that are present on the critical time path are to be simplified for low delay. To achieve this, the redundant bits must be divided into two parts. Here, both header flit bits and data bits are shared by the first group and the second group is used only for decoding of data bits. The first group of redundant bits are to be re-computed for header flit bits decoding.

For 32 bit data block with 16 header flit bits, 7 redundant bits are required for protection. As discussed earlier these 7 redundant bits should be divided into two parts. First part is of 5 bits and the second part of 2 bits. First part is used for both header flit bits and data bits and the second part is only for data bits. In this code, for decoding the header flit bits, only the 5 syndrome bits with value ones and zeros are considered. Other 2 syndrome bits are not considered for the decoding of header flit bits. For decoding of data bits, all the 7 syndrome bits with value ones and zeros are considered. For the case of 32+16, in the first part 5 syndrome bits are used. With 5 syndrome bits, 2^5 combinations can be generated. This supports single bit error correction in 32 bits. This way by considering the 5 syndromes bits for evaluating the header flit bits we achieved faster decoding and also we can extend the number of header flit bits from 16 to 32.

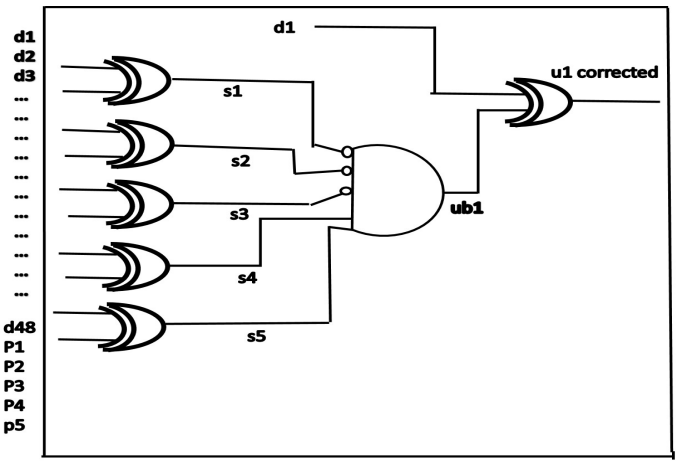

Fig. 6. One bit fast decoding of 32+16 data

Similarly, for 64 bit data block with 32 header flit bits, 8 redundant bits are used for protection. These 8 redundant bits will be divided into two parts. First part is of 6 bits and the second part is of 2 bits as done for 32 bit data block. The

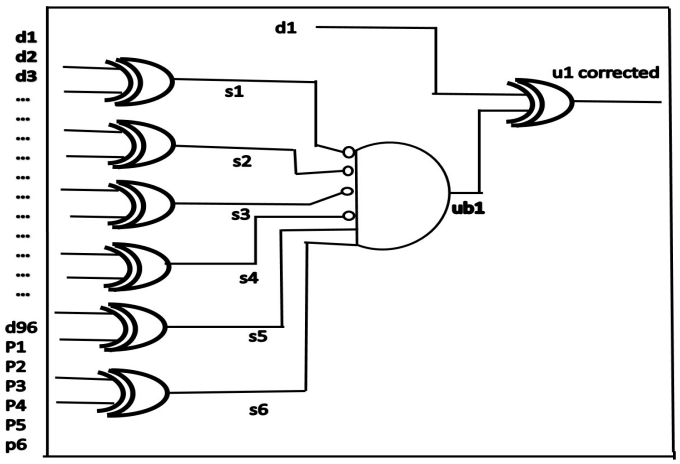

Fig. 7. One bit fast decoding of 64+32 data

first part will protect header flit bits and data bits and second part is only for data bits. In this code for decoding the header flit bits, only 6 syndrome bits with values ones and zeros are considered. Other 2 bits are not considered for the decoding of the header flit bits. For decoding the data bits all the 8 syndrome bits with value ones and zeros are considered. Fig. 6 and Fig. 7 shows Fast decoding hardware architecture for 32+16 and 64+32 data blocks respectively.

IV. EVALUATION

To evaluate the proposed code, this code is implemented for 32, and 64 data block sizes. considering 16 and 64 additional header flit bits respectively. The codec of these codes are compared to the original SEC-DED codes. To evaluate these codes, all these codes are designed in Verilog HDL. The designed codes are synthesized using Cadence RTL compiler for 45nm technology [12]. As per the main design goal, the synthesis for the decoders is to the minimize the delay on the header flit bits with same number of redundant bits. The same synthesis constraints are used for both proposed and original SEC-DED codes. The parameters that are evaluated in this paper are area, power and delay.

The results of the proposed codes are analysed in terms of area, power and delay and are compared to the original SEC-DED code. The encoder results for the case of 32+16 and 64+32 data block size are shown in TABLE I and TABLE II respectively. similarly decoder results for 32+16 data block, header flit bits and 64+32 data block, header flit bits and also the original SEC-DED decoding results are shown in the TABLE III. In this area, power and delay are calculated by separating data and header flit bits. The decoding delay of the header flit bits for 32+16 and original 32 bit is reduced by approximately 3%. In the same way for 64+32 and original 64 the decoding delay of header flit bits is also reduced by 3%. With this delay reduction, it is clear that bits on the critical path are decoded faster. There is a slight increase in circuit area when compared to original SEC-DED codes and there is marginal increase in the delay and power of encoders.

TABLE I
ENCODER RESULTS FOR 32 BIT DATA WITH 7 PARITY CHECK BITS

Number of bits	Area (μm^2)	power(mW)	Delay (pS)
32+16 encoder	410	0.064	1997
original 32 encoder	296	0.038	1295

It is observed that, there is slight impact on the data bits, that is decoding delay is slightly increased for the data bits. However, As discussed earlier,we are concerned only on the fast decoding of header flit bits that are on the critical path. As a result it is observed that AISC circuit area for encoders and decoders have slightest variations when compared to the original SEC-DED codes. Decoding delay of data bits is slower than minimum-weight codes and power consumption increased slightly. However, this proposed code will detect double errors and correct single errors in data and header flit bits with a marginal increase in overall delay and power.

TABLE II
ENCODER RESULTS FOR 64 BIT DATA WITH 8 PARITY CHECK BITS

Number of bits	Area(μm^2)	power(mW)	Delay(pS)
64+32 encoder	830	0.150	2631
original 64 encoder	589	0.090	1567

V. CONCLUSION

This proposed paper presents a code for the construction of SEC-DED code that has a capability to correct and detect the errors in both header flit bits and data bits. These codes are designed for NoC which in turn gives fast decoding of the header flit bits by using minimum number of parity bits that are required for decoding of those header and trailer flit bits. This will eliminate extra memory space that will account for redundant bits. It can also be extended by changing the H matrix which will correct and detect multiple errors. With marginal increase in the overall delay this proposed extended SEC-DED code is able to protect the errors in both header flit bits and data flits and with included advantage of fast decoding of the header flit.

TABLE III
DECODER RESULTS

Number of bits	Area(μm^2)	power(mW)	Delay(pS)
Decoder(32+16, data bits)	722	0.135	3630
Decoder(32+16, header flit bits)	582	0.114	3121
Decoder(original 32+16, data bits)	722	0.135	3630
Decoder(original 32+16, header flit bits)	584	0.104	3227
Decoder(64+32, bits)	1400	0.309	4364
Decoder(64+32, header flit bits)	1131	0.263	4234
Decoder(original 64+32, data bits)	1400	0.309	4364
Decoder(original 64+32, header flit bits)	1150	0.239	4364

***Abstract*— A multi-user MIMO network system with channel fading effect provide a multiple challenges such as pilot contamination, collision, model complexity, resource allocation and etc. In this paper, we provide minimal collision probability with the less model complexity under consideration of pilot contamination problem and resource allocation using RCSA approach. Here, the uncorrelated Rayleigh fading channels is considered in massive-MIMO network and focused on initial timing variation at urban organizations and proposed a random access process for UEs that want to communicate in the cellular network. In the result analysis, we shown the effectiveness of our proposed model in order to minimize the pilot collision, it also compared with the state-of-art technique to validate the performance of our model.**

Keywords— user equipment's (UEs); massive multiple-input-multiple-output (mMIMO); base station (BS); reactive channel state based allocation (RCSA)

I. INTRODUCTION

A recent enhancement in the field of wireless communication majorly focussed on the MIMO system, which able to provide more spectral efficiency by spatial diversity and multiplexing method at the transmitter side as well as at the receiver end. In paper [1] [2], shows the related research in order to increase the channel capacity with using minimal transmit and receive antennas in MIMO system. In [3], the channel capacity under channels fading effect are analysed using multiple transmission occurrences through emphasizing on the coding structures and multi-path fading equalization of channels. A hyper-geometric matrix is considered in [4] that generates a unique function for the propagation of several scenarios in MIMO correlation fading at receiver and transmitter side. Moreover, an upper bound sum capacity is examined in [5] in order to decentralize the multiple channels, which acknowledge all distributed CSI (channel state information) and receiver CSI.

The method of spectrum sharing is considered in [6] by using new receiver, which enhance the capacity process, minimize collision and decrease problem to obtain efficient optimal power at interference power and transmission scenarios. The power allocation and optimal bandwidth is obtained through frequency-division multiple access protocol in cognitive network [7]. In addition, the security of physical layer in wireless communication network has studied in [8], which compute secure connection probability to provide better secure connection and secrecy capacity process. In [9], effectiveness of several channel capacity and the outage capacity is studied, also it provide probable source distortion for the several outage probabilities under the Rayleigh fading channels. Though the simplified approach to analyse the collision in dual MIMO configuration is considered in [10], which is done by using normalized power distribution in a configured network system.

In [11], studied the spatial correlation through considering two channel models in order to get optimal MIMO capacity at different scenarios, moreover a closed-form appearance for maximizing the efficiency of MIMO channels under at Rayleigh fading is studied in [12] that approximate optimal allocation of antenna, where the transmitter has no acknowledge channel and side CSI. In study [13], the capacity of the several relay channels is investigated under shadowing and fading scenarios with considering constraints of spectrum sharing. Minimum mean square error (MMSE) for multi-cell that based upon the pre-coding method was considered in [14], for each BS the pre-coding matrix was designed to minimalize the sum squared errors of UEs in the cells, but it has some computational complexity because of its huge matrix inversion. In [15], the time-shifted pilot technique is proposed to overcome pilot contamination through distributing the complete system into some smaller groups, then by make use of asynchronous transmission at entire smaller groups. Moreover, the time-shifted method makes definite that the very less pilot contamination among at users in all smaller groups, whenever very large number of the BS antennas is considered this leads towards the communal interference in between transmitted data and the pilot sequences.

A multi-user MIMO network system with the orthogonal block coding was considered that tends to compute both spatial diversity gain and multi user gain under a low complexity of encoding and decoding, in paper [16] a channel fading distribution at several real time scenario is considered, where the behaviour of the channel is subjected to be independent and distributed non-identically such as Nakagami-m fading. Subsequently a relay node may be unable to serve simultaneously multiple source destination pairs, therefore the appropriate design of user scheduling approach is essential. So the drawback of this paper is to not have the opportunistic scheduling and one end-to-end pair under the optimal channel conditions for the transmission in given time period.

In [17], proposed a smart pilot allocation method through minimizing the SINR (signal-to-interference-plus-noise ratio) of users for individual cells in a consecutive manner, but it cannot fulfil the required convergence. Moreover, adaptive pilot allocation based method is proposed in [18] through dividing UEs in a system into the dual group, in according to the present inter-cell interference available number of pilot should be larger than the UEs in individual cell and, if the available number of pilot is limited and considered to be same to UEs in individual cell, then the adaptive pilot allocation based method work same as the random pilot allocation. However, a pilot contamination based elimination pre-coding method is proposed in [19], through exploiting the coefficients property of large-scale fading for channel vector of BSs and users. Figure I.1 shows the MIMO system model.

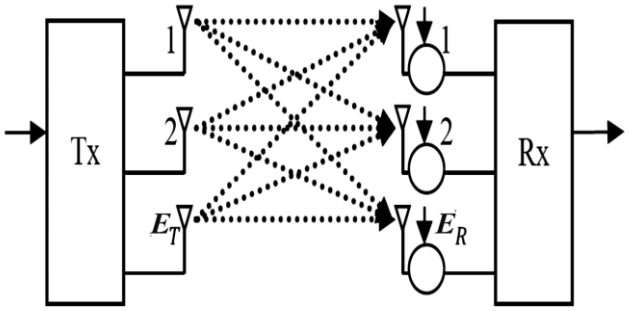

Figure I.1 MIMO system model

In [20], presented a novel approach for intra-cell interference to overcome the problem of pilot contamination in massive MIMO networks, this approach majorly relies on the channel powers stability and the orthogonality at user channels using the graph code method. A random access scheme is proposed in [21] in order to overcome the collision, power and channel estimation through utilizing the huge number of antennas planned in mMIMO network. In this paper, we proposed a RCSA approach with uncorrelated Rayleigh fading channels, the major aim of this is study is to minimize the intra-cell interference in between the UEs. Here we have considered the time-division duplexing (TDD) for the pilot contamination in m-MIMO [22], also we focused on initial timing variation at urban organizations and proposed a random access process for UEs that want to communicate in the cellular network. In addition, UE consigned a pilot sequence before transmitting the data to overcome the pilot collisions at intra-cell. To verify the performance of our proposed model with uncorrelated Rayleigh fading channels effects, in result analysis section we will consider huge number of inactive UEs as compared to active UEs with varying the number of BS antennas.

II. REACTIVE CHANNEL STATE BASED ALLOCATION (RCSA) SCHEME

In this section, we provide a brief of RCSA approach for Massive MIMO that we have proposed in earlier study [23], afterwards in next section we will provide RCSA approach with Rayleigh fading channels. The proposed RCSA approach consist of four major steps as given in fig 1, where the first step stands for queuing and system initialization, the second step provides the response queuing, the third step provides the resource contention and channel state analysis and, at last step stands for the resource allocation. Here, we consider the cellular network, where individual number of BS is having M antennas. The considered network system operates at TDD mode and time-frequency properties are sub-divided to some coherent blocks for the usage of T number of channels. Here, the channel responses at BS and its corresponding UEs are considered to be constant and the frequency remains same with in a same block and vary at different blocks. For this we have considered the OFDM (orthogonal frequency division multiplexing).

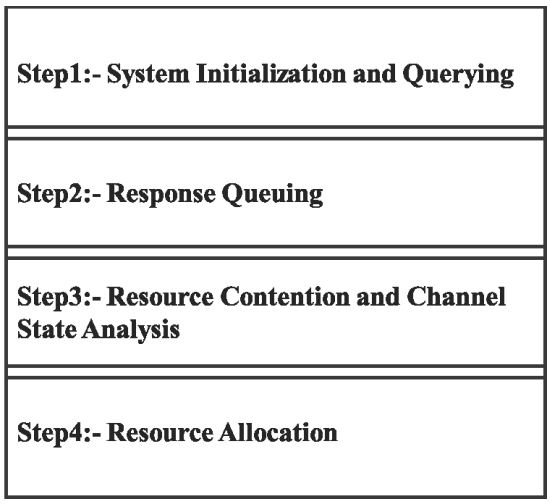

Figure II.1: A proposed RCSA Approach for the Massive MIMO

While assuming huge network of MIMO, the collisions are needed to resolve and recognize as earlier than the UE which is coming into the blocks of payload. Our proposed method can be distributed the approach to resolve a collision at the UEs via using the principle of enormous MIMO. Wherever, the vectors of channel at UE are denoted as $b \in B_0$ and $d_b \in \mathrm{C}^E$ can be denoted as BS, whereas we have though- about the model of generic propagation and also the channels are pre-expected to satisfy these 2 conditions:

$$\frac{\|\mathrm{d}_b\|^2}{E} \xrightarrow{E\to\infty} \beta_b, \forall b, \tag{1}$$

$$\frac{\mathrm{d}_b^{\mathrm{D}}\mathrm{d}_a}{E} \xrightarrow{E\to\infty} 0, \qquad \forall b, a, where\ b \neq a, \tag{2}$$

Here, β_b has much number of strictly values that is well-known to UE b, so that the channels are provided the propagation of asymptotic favorable and the channel hardening [24]. While assuming, the step 1 process for RAP, and the signal is received by the help of BS is known as $\mathbf{F} \in \mathrm{C}^{E\times g_k}$ from the pilot transmission.

$$\mathbf{F} = \sum_{b \in B_0} \sqrt{hb}\, \mathrm{d}_b * \psi_{c(b)}^{\mathrm{T}} + \mathbf{L} + \mathbf{M} \tag{3}$$

Where, $\mathbf{L}$ is represented by the help of inter-cell interference, $\mathbf{M} \in \mathrm{C}^{M \times \tau_p}$ is not dependent the receiver noise and every single distribution of the element is specified as $CZ(0, \sigma^2)$ and it is more complex as Gaussian distribution, where, $\mathrm{C}^{E \times g_k}$ metric represents the interference from various cells. The resources of time-frequency are separated the channel T of coherence block and E denotes the number of antennas. The transmit power is given by the help of h, complex value corresponds to C and the transmitted value is represented by ψ.

During queuing of the response, the BS replies at the side of RAP pilots via transmitting the pre-coded signals of downlink that leads to every single RAP pilots which were being utilized in the uplinks. The reaction towards (ψ_t) can be the sequence of channel $N_t \in \mathrm{C}^{g_k}$ and the sequences of downlink channel can be specified as $N_1, N_2, \ldots, N_{g_k} \in \mathrm{C}^{g_k}$ are the orthogonal to each and everyone and satisfy $\|N_t\|^2 = g_k$. If the BS is considered as the normalized conjugate then $\frac{p_t^*}{\|p_t\|}$ is pre-coded vector at the pilot sequence of N_t in downlink. Then the signal is directed towards MCMR (multi-cast-maximal-ratio) transmission t the UEs in Q_t. Hence, the complete pilot signal of pre- coded downlink $\mathbf{R}$ is specified as;

$$\mathbf{R} = \sqrt{s} \sum_{t=1}^{g_k} \frac{p_t^*}{\|p_t\|} N_t^{\mathrm{T}} \tag{4}$$

Where, down-link sends the power s and it has pre-defined value, the length of pilot channel is mentioned as g_k and it is not dependent from huge number of antennas. The received signal $(\mathbf{U}_b \in \mathrm{C}^{g_k})$ at UE $b \in Q_t$ is defined by;

$$\mathbf{U}_b^{\mathrm{T}} = r_b^{\mathrm{T}} + \eta_b^{\mathrm{T}} + \mathrm{d}_b^{\mathrm{T}} \mathbf{R} \tag{5}$$

Whereas, $\mathrm{h}_k^{\mathrm{T}}$ represented for the channel of reciprocal downlink, and r_b correspond to C^{g_k} which is interference of inter-cell, and η_b can be the receiver noise signal. Though the UE obtain the signal $U_b = \mathbf{U}_b^{\mathrm{T}} \frac{N_t^*}{\|N_t\|}$ by correlating receiver signal $\mathbf{U}_b$ with N_t normalized downlink pilot sequence.

$$U_b = \sqrt{s g_k}\, \mathrm{d}_b^{\mathrm{T}} + \eta_b + r_b^{\mathrm{T}} \frac{N_t^*}{\|N_t\|} \tag{6}$$

In step3, the mechanism of resource contention and analysis of channel state has been proposed to resolve the contention of channel at the distributed manner, so that every single channel can be reiterated only one by the one-UE. The UE $(b \in Q_t)$ can be considered as $h_b \beta_b g_k$ (signal gain) and estimate the signal gain $(\hat{V}_{t,b})$ of the sum of inter-cell interference and contending UEs. The BS (base station) receives the repeated pilot transmission of RAP that followed by the uplink message. The BS can be considered the tth level of pilot signal to estimate the channel UEs which is transmitted ψ_t and decode the corresponded messages. After successfully decoding, the BS can be recognized one-UEs in Q_t and give it to the coherent payload blocks via assigning the sequence of pilot channel. These types of allocation decision can be forwarded through the downlink in the step 4 and equally for step 2. The protocol of RCSA can be reiterated for the fixed number of time, if UEs were not recognized in the step 4, then it is instructed to send via the new RAP channels.

III. RCSA Approach with Rayleigh Fading Channels

Here, we going to consider the uncorrelated Rayleigh fading channels for all UEs, where $b \in B_0$ and d_b can be given as;

$$d_b \sim CZ(0, \beta_b \vartheta_E) \tag{7}$$

Moreover, the model of inter-cell interference can be given as $\mathrm{r}_b \sim CZ(0, \mu_b \vartheta_{g_h})$ which is independent from the other signals, this will allows for relative analysis of traceable performance at any value of E. While considering section II analysis on E for the property of asymptotic favorable propagation and channel hardening, the E value generally will be at larger amount. As per consideration of step 2 (6), the distribution of the random variable under considered uncorrelated Rayleigh fading channels for any UE received signal can be given as;

$$U_b = \mathcal{Y}_b + r_b \tag{8}$$

Where, the $\mathcal{Y}_b$ and r_b parameters are obtained from (9) and (10). The $\mathcal{Y}_b$ consist of scaled chi-distribution with the $2E$ degree of freedom.

$$\mathcal{Y}_b \sim \sqrt{\frac{0.5 h_b s \beta_b^2 g_k^2}{V_t + \sigma^2}}\, m, m \sim \mathfrak{M}_{2E} \tag{9}$$

Where, $\mathfrak{M}$ denotes for the independent chi-distribution and its corresponds lower value denotes the degree of freedom.

$$r_b \sim CZ\left(0, \sigma^2 + \mu_b + s\beta_b g_k - \frac{h_b s \beta_b^2 g_k^2}{V_t + \sigma^2}\right) \tag{10}$$

Through using the statistical property at (8), we will able to calculate the value of expectation and variance related to random variables for received downlink-signal $\frac{U_b}{\sqrt{E}}$, so the mean value can be computed as;

$$\mathbb{M}\left\{\frac{U_b}{\sqrt{E}}\right\} = \sqrt{\frac{h_b s \beta_b^2 g_k^2}{V_t + \sigma^2}} \frac{\mathfrak{D}(0.5 + E)}{\sqrt{E}\, \mathfrak{D}(E)} \tag{11}$$

Similarly, the variance can be computed as;

$$\mathbb{K}\left\{\frac{U_b}{\sqrt{E}}\right\} = \frac{h_b s\beta_b^2 g_k^2}{V_t + \sigma^2}\left(1 - \left(\frac{\mathfrak{D}(0.5+E)}{\sqrt{E}\mathfrak{D}(E)}\right)^2\right) + \frac{1}{E}\left(\sigma^2 + \mu_b + s\beta_b g_k - \frac{h_b s\beta_b^2 g_k^2}{V_t + \sigma^2}\right) \quad (12)$$

While, $\mathfrak{D}(.)$ denotes the gamma function, while considering the E value to infinity, the expected value of received downlink signal can be given as;

$$\mathbb{M}\left\{\frac{z_k}{\sqrt{M}}\right\} = \sqrt{\frac{h_b s\beta_b^2 g_k^2}{V_t + \sigma^2}}, where\ E \to \infty \quad (13)$$

Where, σ denotes the coherence blocks of T channel uses and consecutively, if the E value is tends to infinity, the variance of received downlink signal can be given as;

$$\mathbb{K}\left\{\frac{U_b}{\sqrt{E}}\right\} \to 0, where\ E \to \infty \quad (14)$$

The expected value of received signal with respect to random variables satisfied the considered condition and the variance value tends to zero that confirms the asymptotic satisfactory propagation from the uncorrelated Rayleigh channels fading effect.

IV. Simulation Result and Analysis

In this section, we illustrate the RCSA approach with uncorrelated Rayleigh fading channels (URFC), which is capable to resolve the collision and increase the capacity of network. The simulation of code has done using Matlab 2018a on a Windows operating system. Here, we considered a scenario, where 5000 number of inactive UEs are present in a network, active UEs at the neighboring cells is consider to be 10 and cell radius is 250m. UEs transmit power in the cell is 1 dB, the transmit power of BS is also consider to be 1 dB, the length of the random access pilot sequence is 30 and the noise variance is considered to be 1 dB. The maximum number of BS antennas E is 200, and it varies from 1 to 200, in addition the number of Monte-Carlo realizations is considered to be 1000 in an intra-channel interference module.

In order to make a decision on UE, whether it's a strongest user or not is very difficult, therefore in order to soften the decision we consider the random bias term. As per acknowledgment obtained by b to UEs, the bias term value can made and provide ability to UE to itself appoints the appropriate strongest user under the probability condition. Here, we are going to compared with the existing vertex graph-coloring-based pilot assignment (VGCPA) with URFC [25].

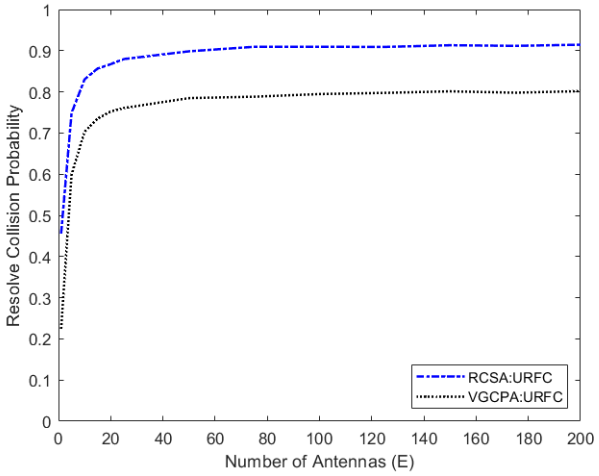

Figure IV.1 Resolved Collision Probability at Zero Bias Term

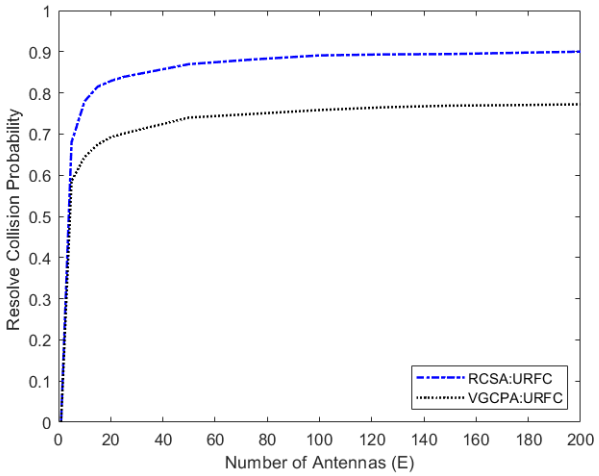

Figure IV.2 Resolved Collision Probability at 0.5 Bias Term

Figure IV.1 shows the resolved collision probability at zero bias term, where the x-axis represents the number of antennas that varies from 1 to 200 and y-axis represents probability at the resolved collision. Here, RCSA-URFC has got minimum and maximum probability score of 0.45 and 0.91, where the average at total number of BSs is 0.84. Whereas, VGCPA-URFC has got minimum and maximum probability score of 0.22 and 0.8, where the average at total number of BSs is 0.7, which is 15.4% less than our proposed approach. Similarly, fig IV.2 shows the resolved collision probability at 0.5 bias term, where our proposed model RCSA-URFC has got maximum probability score of 0.9, where the average at total number of BSs is 0.78. Whereas, VGCPA-URFC has got maximum probability score of 0.77, where the average at total number of BSs is 0.66, which is 15.3% less than our proposed approach.

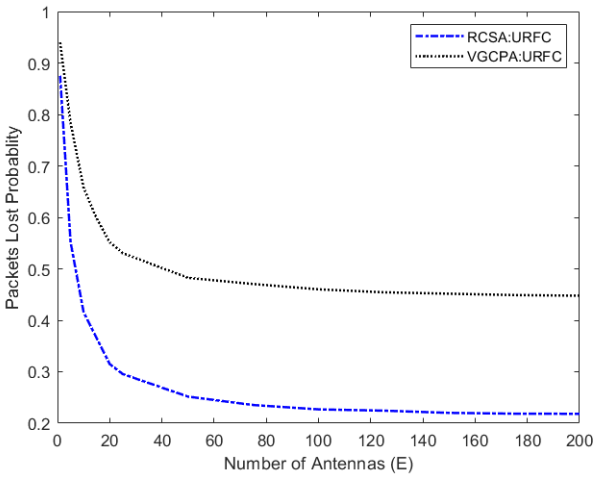

Figure IV.3: Probability at Packets Loss

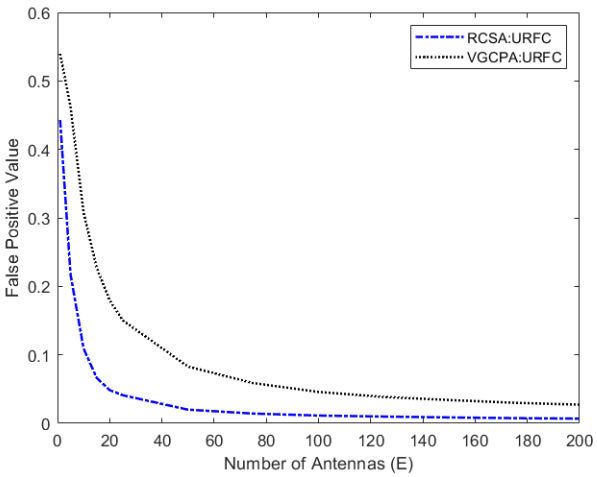

Figure IV.4: False Positive Value at Retransmission

IV.3 shows the probability of packets loss with respect to number of BS antennas, here the x-axis represents the number of antennas that varies from 1 to 200 and y-axis represents probability of packet loss. The minimum and maximum probability of packet loss is 0.44 and 0.94 from VGCPA-URFC approach, and from RCSA-URFC approach the minimum and maximum probability of packet loss is 0.21 and 0.87, in average it is 40% more than our proposed model. Figure IV.4 shows the false positive value with respect to number of BS antennas, where the average false positive value from VGCPA-URFC approach is 0.168 and from RCSA-URFC approach is 0.077, which 54% less than the existing approach.

V. CONCLUSION

The proposed RCSA approach consist of four major steps such as queuing and system initialization, response queuing, resource contention and channel state analysis and, at last resource allocation. The mechanism of resource contention and analysis of channel state has been proposed to resolve the contention of channel at the distributed manner, so that every single channel can be reiterated only one by one UE. From the result section IV, the average resolved collision probability by our proposed model at total number of BSs is 15.4% more than the existing approach. So we can say that the RCSA approach with uncorrelated Rayleigh fading channels is capable to resolve the collision and increase the capacity of network. In future-work, we are going to consider the inter-channel interference along with the intra-channel interference in m-MIMO system.

Abstract. With the speed in every move in life, the speed of processors is vital for the modern technology. As the single processor has its own limitations, multicore/many-core processor are introduced to compete for the speed. Communication among the cores in a network on Chip(NoC) needs to be expertly handled to avoid needless delay in processing speed. The proposed work presents a deadlock free adaptive odd even routing (OE) to route cache miss packets in the cores with less delay in a 2D mesh topology. The algorithm is implemented and tested in BookSim 2.0 simulator. In a multi-core architecture, as each core processes multiple applications in parallel which results in increase in the chip's overall processing capability. One of the major issue in this NoC is congestion management in the network. As this routing algorithm is adaptive it can change its route accordingly to the traffic present at nodes with help of credits. Simulation result shows the analysis of the routing algorithm in various synthetic traffic patterns such as uniform, tornado, bitrev, shuffle and transpose. It also gives a comparative analysis of performance in terms of latency in various routing algorithms such as XY, adaptive XY, shuffle, transpose.

I. INTRODUCTION

Most of the electronic products, such as mobile phones, smart devices, and so on, consists a lot of software and hardware blocks. Due to usage of several advanced techniques in the products, which results in several number of blocks in a chip. Simultaneously, the system complexity increases with the increase in number of blocks in a chip. With the increase in embedded systems complexity, it is essential to organize the SoCs design and architecture[1].

According to System on Chip (SoC), on a single chip different electronics or computing systems are embedded on to it. As the number of cores increases, which leads to increase in demand for bandwidth for inter core communication to facilitate high core utilization. An essential requirement for scalable interconnection fabrics such as on-chip networks(NoC) is required. The need for better performance is satisfied by increasing the processing cores count on the chip. To address these problems, a new type of interconnect is proposed which is NoC. In NoC context, cores communicate with packet-switching mechanism and all are connected to one another through a network of routers. Routing algorithm is an essential parameter in determining the NoC's performance. For mesh-based NoC, number of routing algorithms have been published and analysed [2].

Routing algorithm is mainly divided into two classes: deterministic and adaptive. In most of the purely deterministic routing algorithms, routing reserves only one path for each communication pair. An example for this type of routing is Dimension Order Routing (DOR) [2]. But this also takes large computational time as they route packets along the same route every time irrespective of the congestion state of the network. Deterministic algorithms are reliable and have low latency in congestion free networks. But the network won't be congestion free always and may need adaptive algorithms for better performance in terms of latency and throughput. On the other side, packets have a choice of multiple paths to reach its destination node in adaptive routing. An example for adaptive routing is Odd-Even (OE) turn model [2]. Network resource utilisation is very high for adaptive routing compared to deterministic routing[3]. The adaptiveness can be in terms of credits, virtual channel etc of the neighbouring cores. There are many simulators in which the algorithms can be analysed in terms of throughput and latency. The topology of the network can like mesh topology, torus topology, spidergon, hypercube etc[4]. In those topologies, variations can be applied for more cores and better connections like 3D connections in mesh topology [5].

The algorithms can be tested on different size of each topology. Performance of NoC can be analysed in terms of throughput, latency, area and power. Apart from these, communication errors are also to be addressed[6].

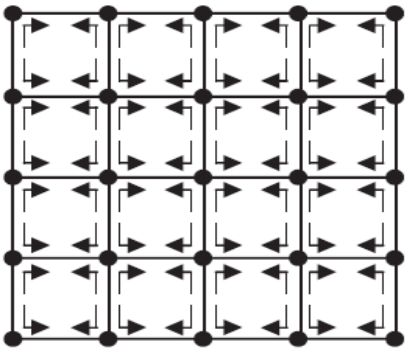

Fig. 1 Restricted turns in XY routing

II. RELATED WORKS

In the literature, most widely studied topic is 2D mesh[7]. In order to avoid deadlock in 2D mesh topology, some 90 degree turns are to be restricted. The system performance is influenced by the number and distribution of the restricted turns. In XY routing, packets are initially routed in X-direction and then in Y-direction. Fig. 1 depicts the restricted turns of XY routing algorithm. In column's perspective same turns are restricted in every column. similarly,same turns are restricted in every row[8].

There were many approaches towards optimizing the routing on different topologies using different routing algorithms and traffics. Some of them are repetitive turn model for adaptive routing [2] their "goal is to exploit the designing space for logic based routing algorithms, and proposed new logic-based routing algorithms that outperformed the state-of-the-art counterparts". The work on "The Odd-Even turn model for adaptive routing"[9] present a model without virtual channels for designing adaptive wormhole routing algorithms for mesh. When Minghua Tang, Chunhui Wu[1] conducted a case study of a adaptive routing algorithm for NoC, known as Odd-Even turn model, Simulation results conclude that in local region there is an high amount of congestion compared to outer regions. It suggests that this issue has to be taken into consideration while designing routing algorithm by researchers.

A model with preemptive approach was applied to odd even routing called PWOE[10].which postpones the saturation traffic rate of NoC by significant percentage compared to odd even under synthetic traffic loads.

Topologies are one of the most essential part of a NoC design, the constraint is performance factor. The parameters which influence the network's performance are latency, throughput, injection rate, hop count etc. Performances are studied and analyzed with the parameters of the topologies in the work "Performance Evaluation of Various Parameters of Network-On-Chip (NoC) for Different Topologies" [11]. Anil Kumar and other authors proposed a machine learning framework[12] that is used on mesh and torus architectures to analyze the performance factors. A comparison was made between the results obtained and the widely used cycle-accurate Booksim-2.0 simulator. Experiments were conducted with various injection rates, virtual channels, and traffic patterns on different topology size ranging from 2×2 to 30×30. The framework showed a prediction error ranging between 5% to 8% and overall minimum speedup ranging between 1500 times to 2000 times. So, considering their analysis, mesh topology is chosen for implementing odd-even routing and run the simulations on 8x8 mesh to analyse and to give out results which can be useful for further research and for development of other routing algorithms.

The proposed work emphasizes on the local region congestion and implemented a fully adaptive non-minimal odd-even routing where the traffic avoidance is the major focus on and the packets may take a longer route in order to avoid the traffic in the mesh.

III. FULLY ADAPTIVE NON-MINIMAL ODD-EVEN ROUTING ALGORITHM

In adaptive routing algorithm there are choices of multiple routing paths between source node and destination node and a single path will be chosen which has the least congestion while routing a packet in the network. According to the dynamic changes in the congestion condition of a network, the paths keep changing. Odd-Even Routing is based upon odd-even turn model [9]. It is classified under the class of distributed adaptive routing algorithm.

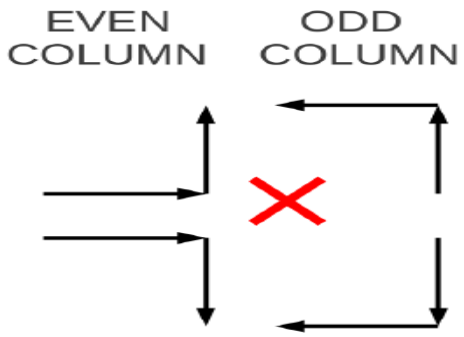

Fig. 2 Restricted turns in odd-even routing

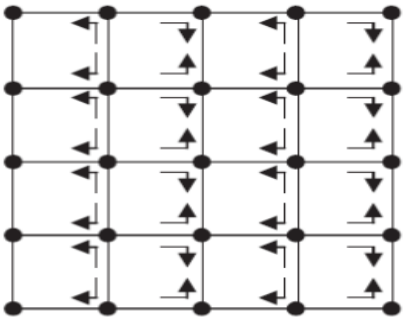

Fig. 3 Restricted turns in Odd-Even Routing at each column is 5x5 mesh.

It introduces various restrictions on taking turns which is depicted in Fig.2. As a result of restrictions in turns, it is deadlock free. Every node in a 2-D mesh has (x, y) co-ordinate. According to the turn model, a column is termed as even or odd based on the x coordinate if it is even then the column is regarded as even column and if it is an odd number then the column is termed as odd column. A turn is regarded as a change in travelling direction in 90- degree. As per these restrictions, there are eight combinations of turns that are possible as shown in the Fig.4. If the packet has 90 degree variation in direction from East to South then it is regarded a ES turn. Likewise if the packet has 90 degree variation in direction from West to South then the turn is termed as WS turn. Similarly, other six types of turns can be described namely EN, WN, SE, SW, NE, and NW turns, where N, S, E and W specify North, South, East and West respectively.

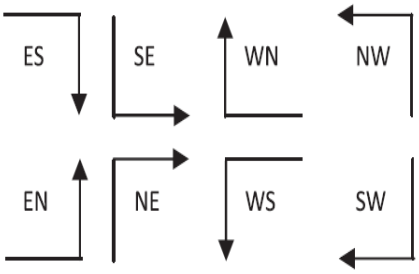

Fig. 4 Combination of turns possible in 90degree angle

The following conditions are necessary to avoid deadlock in OE routing algorithm.

The packets avoid EN and ES turns when present on a even column node. The packets avoid NW and SW turns when present on an odd column node.

ALGORITHM 1

```
//Source nodes are (S1,S2);Destination nodes are (D1,D2);Current nodes are(C1,C2).
Begin
Available_Set ← Ø;
E1 ← D1-C1;
E2 ← D2-C2;
If(E1=0 and E2=0)//current router is the destination router
the packet is delivered to the local node and exits:
If(E1=0)//currently the packet and destination are in same column.
  If (E2>0)
    Append North to Available_Set;
  Else
    Append South to Available_Set;
Else
  If(E1>0)// Eastbound messages
    If(E2=0)
      Append East to Available_Set;
    Else{
      If(C1 is Odd or C1=S1)
        If(E2>0)
          Append North to Available_Set;
        Else
          Append South to Available_Set;
       If (D1 is Odd or E1!=1)//Odd destination column or >= 2 columns to destination
          AppendEast to Available_Set;
          }
 Else{      //Westbound messages
    Append West to Available_Set;
    If(C1 is Even)
      Append North to Available_Set;
    Else
```

```
        Append South to Available_Set;
    }
```

A dimension is selected from the Available_Set for forwarding the packet;

End

****

The above Algorithm 1 is a Fully adaptive minimal OE routing algorithm, available dimensions for forwarding the packet are present in Available_Set.

Available_set is a list of boolean values which contains True or False for the directions North, South, East, West for a packet to route at the current node. This set represents all the available directions excluding the turns in Fig. 2. The congestion detection is implemented through the credit based system present in Booksim 2.0. The detection can be from the delay that is occurred in every core in transferring the packets[13]. The packet is forwarded to the router which has less credits, While routing a packet sometimes non-minimal paths are possible. However, non-minimal paths are not guaranteed to exist.

ALGORITHM 2 - CREDIT BASED

The Available_set in algorithm 1 is used in algorithm 2 to get a a set of available directions of a node and using getusedcredits() function we will save the respective credits for the directions available and find the most feasible or less congested path for the packet.

```
// Initializing the variables.
Counter,ref = 0;
store[2]=null
For  i = 0 to 3 : //  used for finding the no of available directions for a node when Available_set is true.
{
    If(Available_set[i]==true)
   {
      Counter++;//stores the directions
       Store[ref]=j;
       Ref++;
   }
}
If(counter>1)//multiple directions are available
 {  //Cred1 and Cred2 are the respective credits of the available directions.
   Cred1=getusedcredits(store[0]);
   Cred2=getusedcredits(store[1]);
   If(Cred1<Cred2)
   {
     Return store[1];
   Else if(Cred1>Cred2)
   {
     Return store[1];
   }
   Else
   {
     Return store[rand( )%2]
   }
Else  //if only 1 direction is available
  {
   For j =0 to 3
   {
     If(Available_set[j] == True)
     {
        Return  j;
     }
   }
}
**********
```

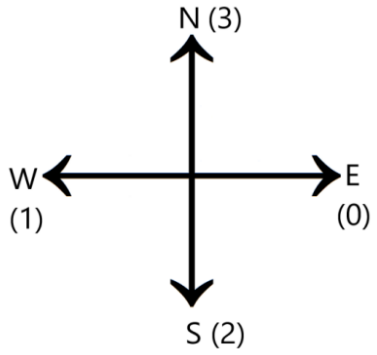

Fig. 5 Encoding of the 4 directions.

In Algorithm 2 we find the number of available directions at a node with help of Available_set and if they are more than 1 direction available then we will find the credits for each direction available and route the packet to that direction in which the credits are less and this will help in congestion avoidance. If both the directions have the same credits then with the help random function we randomly choose one path.

The directions are encoded as depicted in Fig. 5 .When there is only one direction, the algorithm will determine the encoded number for the available path and forwards the packet in that direction. While performing this process the resultant path can be a minimal path or can be non-minimal path depending on the direction.

Existence of non-minimal paths is not guaranteed. If there is only one direction is available, then that is the only direction that can be traversed. A sample selection of routes from source to destination is shown in the Fig. 6.

From Source and Current 49 to Destination 14 : the packet is generated on core 49 which is on odd column. Now using Algorithm 1 it will check the available paths which are East and South. By using Algorithm 2 it will check the credits for both directions and found south direction has less credits and forwards the packet to the router which is in south direction.

From Current 41 to Destination 14: the available directions are east and south from Algorithm 1 and it is still on the odd column. Finds the credits for available directions and chooses the feasible direction which is south and the packet is forwarded to 33, a next router in south direction.

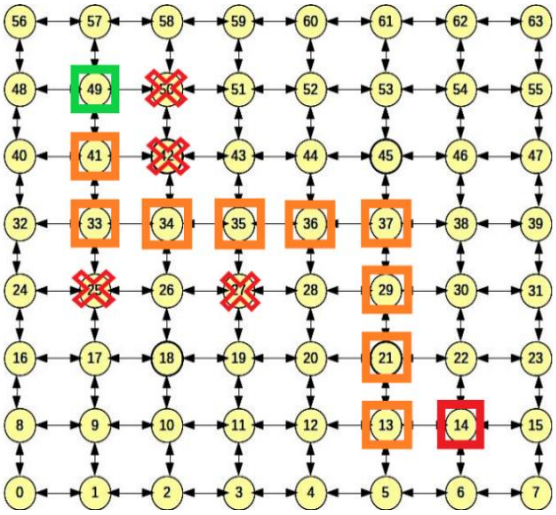

Fig. 6 Route of a packet for source to destination using OE routing and avoiding congested nodes.

From Current 33 to Destination 14 : The available directions are East and South from Algorithm 1.And this time the East direction is preferred over south based on Algorithm 2. So the packet is forwarded to 34.

From Current 34 to Destination 14 : The available direction is only a east direction as it is in even column. ES turn is prohibited and it restricts south direction. So the packet is forwarded to 35.

From Current 35 to Destination 14 : The available directions are east and south using Algorithm 1 . From Algorithm 2 east direction is preferred and is routed to 36.

From Current 36 to Destination 14 : The available directions are only east as the packet is in even column and restricted to take a ES turn. As the packet has only one possibility it is forwarded to the router on east which is 37.

From Current 37 to Destination 14 : The available direction is only south as it is in odd column and the difference between the destination and current is 1,So the east is not added to the Available_set. As the south is the only direction available the packet is forwarded to 29.

Form Current 29 to Destination 14: As its condition is same as the condition at node 37.even at this node it will have only south as the available direction and it will be forwarded to 21.

From Current 21 to Destination 14 : Even this node also has same state as node 37 it also has only south direction in the Available_set .and the packet is forwarded to the node 13.

From Current 13 to Destination 14 : As the vertical distance is zero and only horizontal distance is greater than zero, East direction is added to the Available_set and the packet is forwarded to node 14.

Although the packet had multiple available paths and had to take more turns than a deterministic XY routing algorithm. It avoids the congested routes by using the getusedcredits() function in Booksim 2.0 and routes the packet in the less congested path, thus improving the performance of routing.

V. RESULTS AND ANALYSIS

The simulation is run in Booksim 2.0 for various traffic patterns. The synthetic traffic patterns considered are bitrev, transpose, uniform, and shuffle. In bitrev the node number is converted into binary number and the destination will be the reverse of the source node's binary number. In Fig. 7 the results

show that the odd-even routing has the least packet latency which is till 0.065 injection rate and after 0.065 it saturates. Out of all the traffics the algorithm shows the best results in bitrev traffic when compared with standard deterministic and adaptive algorithms.

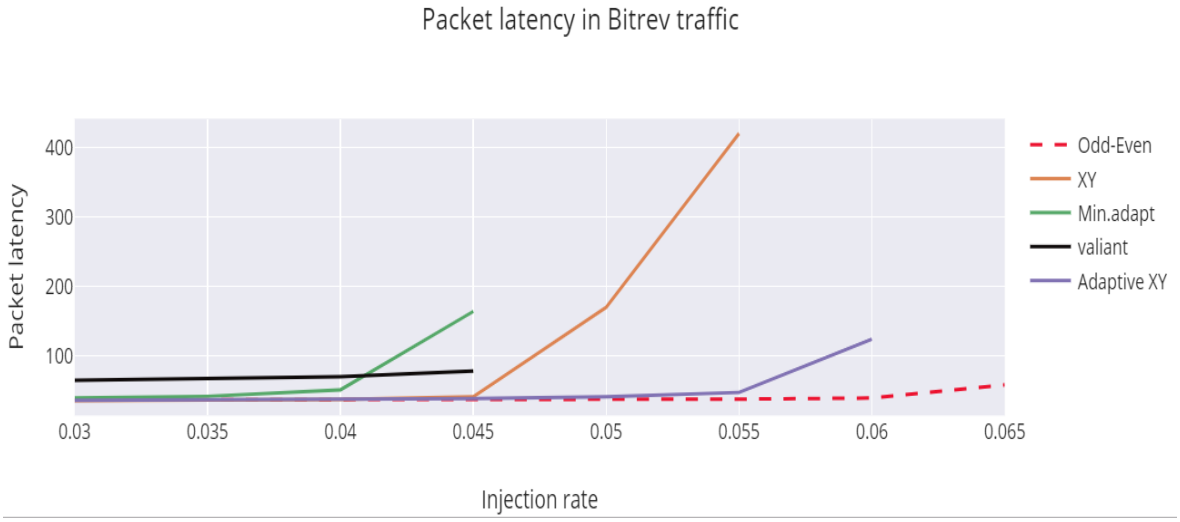

Fig. 7 Packet latency in Bitrev traffic in 8x8 mesh

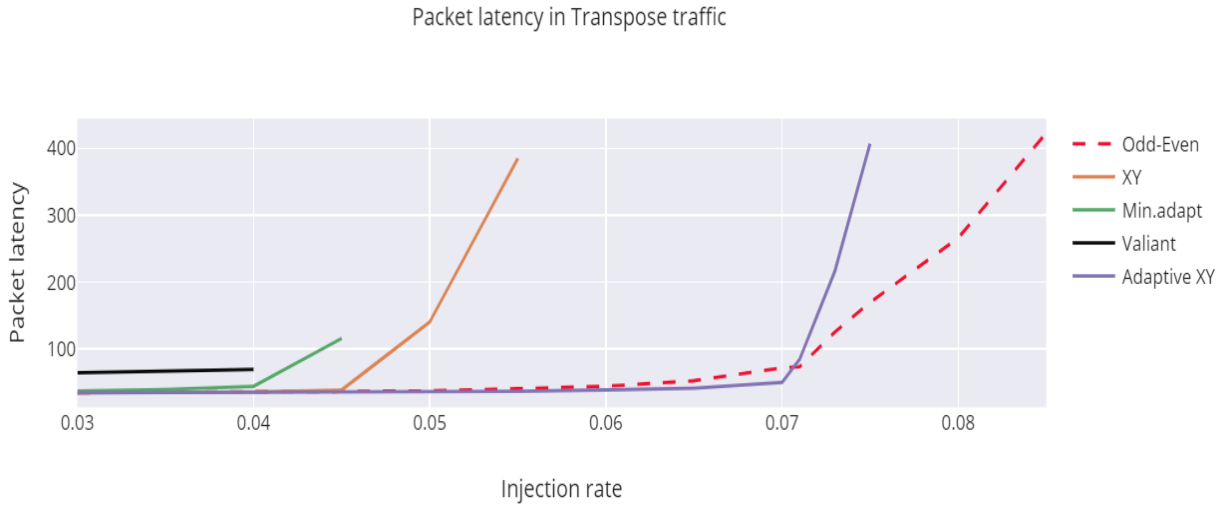

Fig. 8 Packet latency in Transpose traffic in 8x8 mesh

In Transpose traffic, the destination is the transpose of the row, column pair which means for example if the pair (row=1,column=7) is the source which is node 6 will have its destination as node 48 with row=7 and column=1. Fig. 8 shows packet latency for Transpose traffic, the packet latency for Odd-Even algorithm is almost equal to adaptive xy_yx which is the least upto an injection rate of 0.055 and the network latency is least among all other routing algorithms after the injection rate of 0.072. From the Fig. 8 we can conclude that the odd-even routing has the least packet latency or delay which means that it is able to transfer the packet faster than any other algorithms and other algorithms are saturating at low injections whereas saturation point of odd-even is high and saturates after 0.085.

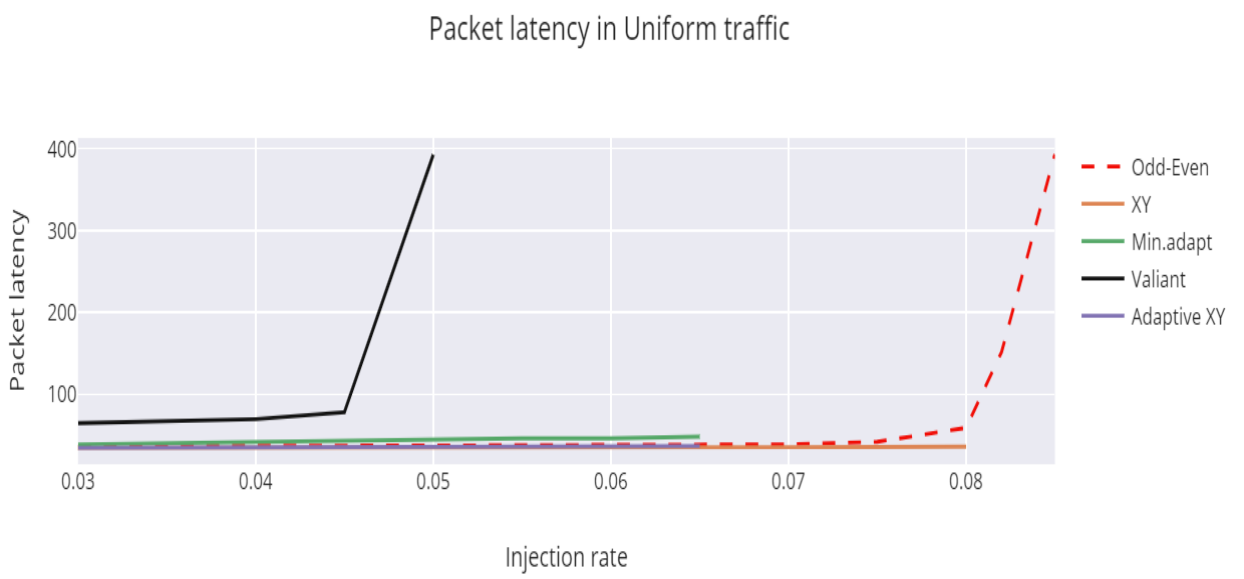

Fig. 9 Packet latency in Uniform traffic in 8x8 mesh

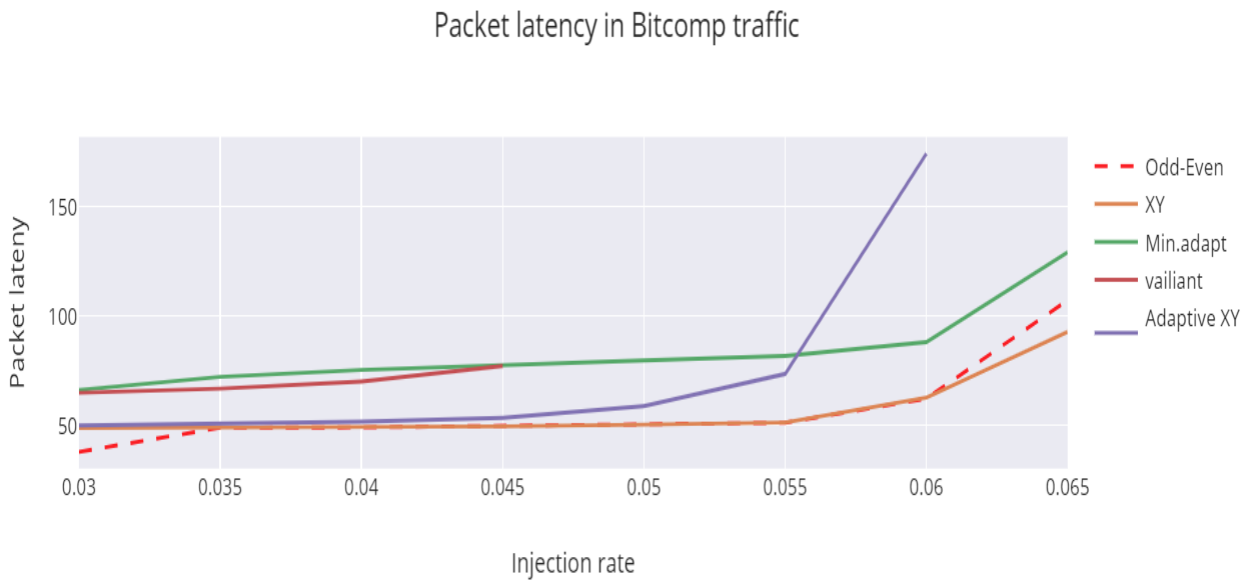

Fig. 10 Packet latency in Bitcomp traffic in 8x8 mesh

In uniform traffic the destination is random to which the packet is sent. From the Fig. 9 we can come to a conclusion that although the odd even routing algorithm's performance is almost same till 0.08 but the XY routing gets saturated at 0.08 and the odd-even still works beyond and saturates at point beyond 0.085 it means although it gives the same performance as the XY routing but it can handle the network with more number of packets than the XY routing.

In bitcomp traffic, the source node number is converted into binary number and negation of the source node number is the destination node. From the Fig. 10, the performance of odd-even routing is almost equal to the XY routing but it shows better performance between 0.03 and 0.035 where the odd even algorithm is able to route packets well by avoiding congestion and as the injection rate increases it is same as XY and at 0.06 it shows a little variation with XY routing. This is because of the vertical and

horizontal distance of the destination is always equal from the source. So, the routing the packets in XY is feasible at higher injection rates.

VI. CONCLUSION

Odd even routing algorithm is a deadlock free algorithm with its own advantages. Addition of adaptiveness results in better performance in routing the cache-miss packets in a dynamic network. Adaptiveness is implemented in terms of credits of each router. The implementation and result analysis are done in Booksim simulator for 8x8 mesh network. The analysis says that it outperforms most of the adaptive algorithms in terms of less latency and extension of saturated injection rates. Latency is better in bitrev type of traffic pattern for the implemented odd even routing compared to all algorithms shown in the graph. It shows better performance in most of the other patterns when compared with other routing algorithms and working of this on larger mesh topology and other topologies is an interesting subject for future work.

Abstract— With the increasing growth in the network and arising with the latest technologies including cloud and big data, to control and manage the traditional networks is quite tedious. Therefore, it's mandatory to transform conventional network architecture. In order to resolve this issue, Software Defined Networking (SDN) came into existence which makes the management of the network more conformable. To satisfy the fulfilments of Quality of Service (QoS) and with the limited network availability, one of the keynotes that have been taken into consideration is the load balancing issue. It is quite a tedious job to handle the massive amount of load for a single server. Therefore, we can use many servers with the load balancers that behaves as the front end. Although Load balancing is an important aspect in SDN. The basic motive of SDN is to separate the control plane (comprises of intelligent network and this is the area where the controller resides) from the data plane (comprises of routers, switches, and other networking devices that are used in networking). Networks are nowadays more programmable and thus the applications like load balancers don't rely on the dedicated hardware that can be executed with the association of controller and OpenFlow switches in the network can act as a load balancer for this we don't require dedicated hardware for such applications. This paper includes different techniques for SDN that are discussed with their related work and the tool used for load balancing.

Keywords— Software Defined Networking (SDN); Load Balancing; Mininet; OpenFlow; Load Balancing Algorithms.

I. INTRODUCTION

Software Defined Networking (SDN) emerges as one of the noteworthy forms of networking concepts. It helps in lubricating a convenient and efficient flow of network control that facilitates the cost of investment in the meantime which is availing the huge number of users [1]. SDN has transposed the way of managing the network and it is defined by two different tendencies: 1. SDN disassociates the control level (controllers) from the data level (forwarding plane). 2. Decoupling makes the control level programmable by the end users. In conventional networks, it is hardly possible to separate the control level from the data level [2]. Therefore, the end users had to rely on the merchants for the configurations of a software network and its users. In this traditional network data plane, informs your data where it is required to go and control plane, is situated inside a switch or router, in this one device could take the decision of progressing the packet and it also takes into charge of maintaining the routing table information and required to reserve the data and SDN was refined to design, build and manage the networks that decouple the network layer and forwarding layer and becomes directly programmable by the source automation tools [3]. The concept of SDN is explained in Fig. 1. Below:

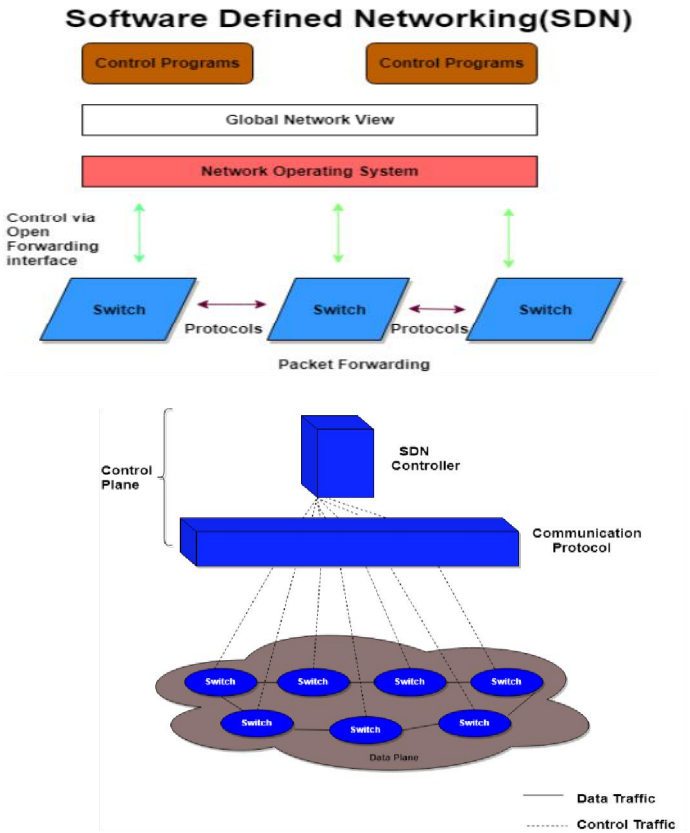

Fig. 1. Software Defined Networking

SDN consolidated the control layer so that the software programmer can have the control over the various data plane elements and SDN interacts the control plane elements with the data plane elements with respect to the defined Application Programming Interface (API).

i. Similarities of Software Defined Networking with Traditional/ Conventional Networking

a. Controllers of SDN has the northbound application programming interface which interacts with the tenders via the API's. It enhances the developers to directly program the network and traditional networks work by using the protocols [4].

b. The main difference between the traditional network and SDN is its virtualization and scalability, the comparison is shown in Table 1 below:

TABLE 1. SDN V/S CONVENTIONAL NETWORKING

Software Defined Networking	Conventional Networking
Forwarding devices and Controller level are disassociated by the API's.	Forwarding devices and Controller level are mingled on the same plane, for every service they require a new protocol.
Facilitates the entire view of the network which leads to consistent and effective policies.	Facilitates the limited information about the networks.

II. MOTIVATION OF RESEARCH

Software Defined Networking is examined to be one of the eminent of the telecom stages. This technology extracts the functions at a lower level of a network on the centralized control level which permits the administers to direct the flow of traffic to the centralized console.

i. The idea of SDN was based on the switch model. The switches process the packets with the system that includes OpenFlow which oppresses the behavior of the switch of the network. This facilitates the control point which coordinates how the switches can handle traffic of the network [5].

ii. The main purpose of choosing load balancing is to keep the network balance the load in SDN. The proposed action is adaptive to the traffic of the network and the flow that is dependent on the integrated path load that relies on the BP Artificial neural network [1]. The primary aim of this proposed action is to optimize the path load and choose the minimal loaded path for the upcoming flow of data.

III. RELATED WORK

Nikhil Handigol et al.,2009, accomplished the coherent technique of optimization algorithm that was developed known as LOBUS (LOad balancing UnStructured networks). We compared this with that of an oblivious or stateful outlook of load balancing.

Chao-Tung Yang et al., 2018, implemented the wildcard mask to execute balancing the load and they even assembled a predicted mechanism that is done in opinion to the traffic of the network.

Ashkan Ghaffarinejad et al., 2014, proposed SDN based load balancing scheme for ASU's Campus Network. In this, approximately 5000 CISCO scattered in unique locations that facilitate the redundant 8 Gbps connectivity to several ten regional 5000 routers.

Sukhveer Kaur et al., 2014, implemented the mininet emulator and compared this emulator with the testbeds which include GENI, VINI, and Emulab. It is accessible to run the real and candid code that are EstiNet, ns-3.

Tariq Emad Ali et al., 2018, proposed the scenario that comprises of fat tree topology SDN Data Center Networks. In this OpenFlow switches are being used. In this, they implemented the OpenDaylight SDN Controller.

Shavan K. Askar, 2016, proposed an adaptive load balancing technique uses the OpenFlow switches that was designed to work using the function it can be a switch, hub or router. OpenFlow switches operate in the charge of the controller that is interconnected to the entire switches and has the overview of the complete network and its corresponding resources.

IV. PROPOSED WORK

i. Data Centre Networks (DCN): The most challenge of SDN is Data Center Networks, which handles the massive number of networks which is not sustained by the changing requirements of the server virtualization. SDN DCN is developed and constructed from a large number of OpenFlow switches which is authoritative for the configuration of switches so to progress the traffic as a layer-2 switch and pertaining the balancing of the load in the DCN [6]. SDN modifies the wide area networks that are required to have the specific API's to provide the changing flow of traffic to degrade the latency and assured the Quality of Service (QoS) for the specific applications.

ii. Load Balancing: Load Balancing is defined as the distribution of load amongst the different servers in order to refinement of the resources, degrade the response time and maximize the throughput. In conventional load balancing networks, it facilitates the support of hardware which is very expensive and suffers from lack of flexibility with this it becomes a single point of failure easily [7]. Availability of Service is predominant in aligning the satisfaction of the end users, which has a higher level of significance on the achievement of balancing the load amongst the process clusters. Connection of most of the people with the internet affects the web traffic which causes the congestion of the network and the loss of packets. With this technique, load balancing refines the efficiency of the network [8].

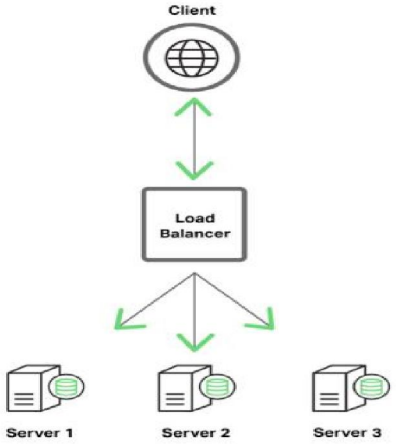

Fig. 2. Load Balancing Architecture

In the process of balancing the load as mentioned in Fig. 2., the traffic is integrated into the multiple servers and it refines the ongoing capacity of the servers [9]. Client's request is forwarded to the backend servers and servers give back the reply and which it then replies to the client. With this client's get directly connected to the backend servers through which the structure of the network is secured, and it inhibits from the attacks on the network.

iii. **Working with Mininet:** In order to work with the SDN, we require many hosts, OpenFlow switches and the wires for creating the connection separating the switches and controller of SDN. Therefore, Mininet is described as the software program that is used to permit the whole network that comprises of controllers, switches, virtual hosts and the links that are to be emulated on a single PC. Mininet has a simple and easy command line API and tools. It is said to be available free i.e. open source software that emulates the OpenFlow devices and the controllers of SDN. Without configuring the physical networks, mininet can generate a topology of the network for the purpose of testing. It reinforces the simplest and adjustable python API for the creation of network and testing.

iv. **Controllers in SDN:** SDN comprises of five topmost controllers that are: POX, Ryu, Floodlight, Open Daylight and Trema. It is considered as the brain of the network and used to facilitate the required information to the switches or routers via Southbound API's [10]. Acts as an intermediator between applications and networking devices. Any interaction between both will be done via the controllers. Controllers are explained briefly in below given Table 2.:

TABLE 2. CONTROLLERS IN SDN

BASICS	POX	RYU	TREMA	OpenDaylight	Floodlight
Language Supported	Python	Python and Message passing reference	Ruby and C	Java	Java and any language that uses REST API
Platform Supported	Linux, Mac OS, Windows	Linux	Linux only	Linux	Linux, Mac OS, Windows
Productivity	Medium	Medium	High	Medium	Medium
Developer	Nicira	NTT, OSRG group	NEC	Multiple Contributors	Big Switch
OpenFlow Version	1.0	1.0, 1.2, 1.3, 1.4		1.0, 1.3	1.0
Used for	Open source platform SDN controller	Used to give logically centralized control and API's of this develops new control	Used to create open flow controllers using C and Ruby programming		It is based on the implementation of Beacon that works with OVSDB.

v. **OpenFlow Protocol:** It is considered as one of the SDN standard protocol which is needed for the building of the solutions of SDN which was established by Stanford University and nowadays is transformed to Open Networking Foundation (ONF) [11]. The most preferable protocol that is required for interaction between the control logic and virtual data plane is OpenFlow. It is orthodox of SDN Southbound Interface Protocol. It is the de-facto interaction between the control plane and the infrastructure plane of the SDN architecture. It is mostly used in wider area networks such as GENI and JGN-X, also useful for ethernet networks.

vi. **SDN based on Load Balancing:** Load Balancing can be administered in either the software or the hardware equipment [12]. The main sole responsibility of load balancer is to distribute the workload requests into multiple servers of a similar type to reduce the burden on the single server. Load Balancer consists of OpenFlow Virtual Switches (OVS) with a controller and various servers that are intermingled to the ports of the OVS [13]. So, in this, each of the servers is assigned its unique IP address and controller has the authority to sustain a list of servers that are interconnected to the OVS. Web service is implemented on every server having a well-known port number as 80.

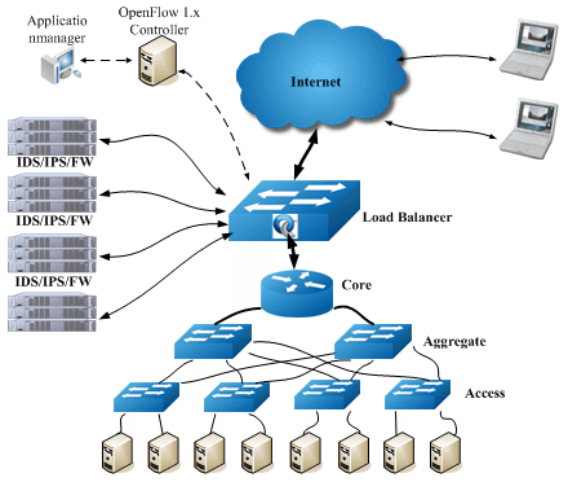

Fig. 3. SDN Based Load Balancer

The controller comprises of the physical location as explained in Fig. 3. All the requests are sent to the physical IP address from the customers [14]. So when the customer is sending the request packet to the physical IP address, then OVS uses the information that is put in the packet header and then later contrast it with the flow entries present in the switch, (1) If the customer's packet header information matches with the flow entry then the switch alters the goal IP address to the location of any one of the servers that are based on strategy of load balancing and forward the bundle of packet to that server. (2) [15] If the packet doesn't match with the flow entry then the switch will advance this packet to the controller. The controller will choose how to deal with the packet, and it embeds new flow entries to the switch by utilizing the OpenFlow [16].

V. Comparative Analysis of Load Balancing Algorithms

Load Balancing divides the workload amongst various links to optimize the efficiency of scheduling and allocation of resources so as to degrade the overloading [17]. We have analyzed the performance of load balancing with time and cost using the cloud analytical tool.

i. Round Robin Algorithm

This algorithm is used to determines the load randomly in the case only when some of the servers are loaded lightly or some of the servers are loaded heavily. This is based on random sampling [18]. The performance analysis is shown in Table 3. and Fig. 4.

Table 3.
Reconfiguration of Time and Cost

Round Robin Algorithm	Time	Cost
R1	40.37	6.09
R10	40.45	10.81
R20	68.9	18.36
R30	48.9	30.7
R40	57.47	39.91
R50	40.73	43.45

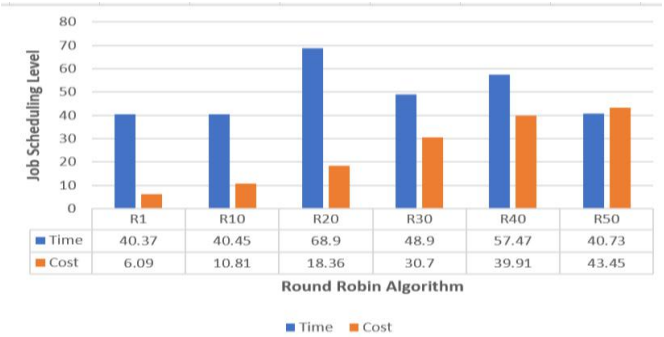

Fig. 4. Performance Analysis of Round Robin Algorithm

ii. Equally Spread Current Execution Algorithm

This algorithm is prepared to deal with priorities. It partitions the load arbitrarily by investigating the size and then later forward the load to only that virtual machine which is said to be loaded delicately and creates the maximum throughput [17]. The performance analysis is shown below in Table 4. And Fig. 5.

Table 4.
Reconfiguration of Time and Cost

ESCE Algorithm	Time	Cost
EC1	40.09	0.89
EC10	40.07	4.5
EC20	40.17	3.03
EC30	40.33	15.03
EC40	40.49	18.12
EC50	40.66	40.67

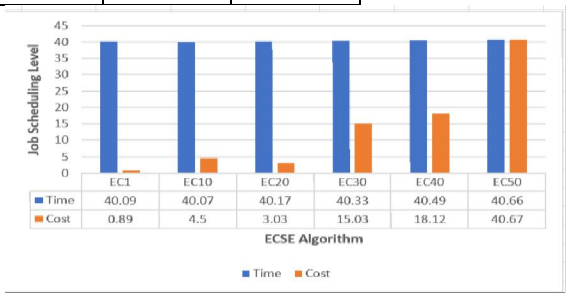

Fig. 5. Performance Analysis of ECSE Algorithm

iii. Throttled Algorithm

This algorithm is done based on the virtual machine and coordinator of cloud couldn't divide this task:

- The request is first sent to the virtual machine.
- The virtual machine has the sole duty to take the choice to move the work as indicated by its size and accessibility.
- Each measure is estimated with its index value.
- The index value is matched with the accessibility. If there is enough space available, then the section sends the response back to the virtual machine.
- After the task is completed the response is stored in the virtual machine allocation table [17].
- The analysis of this algorithm is done in the below Table 5. And Fig. 6.:

TABLE 5.
RECONFIGURATION OF TIME AND COST

Throttled Algorithm	Time	Cost
TH1	40.11	0.89
TH10	40.09	4.5
TH20	40.19	3.03
TH30	40.35	15.03
TH40	40.51	18.12
TH50	40.68	40.67

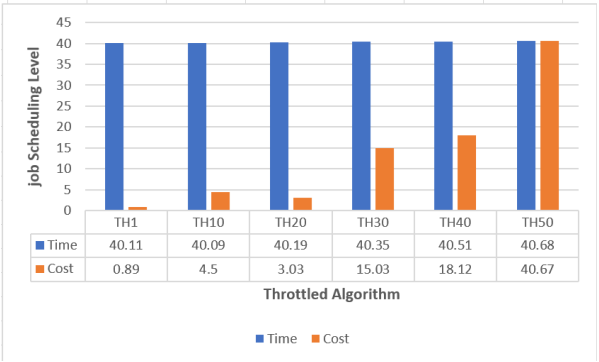

Fig. 6. Performance Analysis of Throttled Algorithm

VI. RESULT ANALYSIS OF LOAD BALANCING ALGORITHMS

We have concluded from the above algorithms that growth of increased strategies using improved jobs and load balancing techniques of allocation of resource. Equally Spread Current Execution (ESEC) algorithm and Throttled algorithm have dynamically allocated the resource to the job in a queue that leads to the cost reduction in the transfer of data and formation of the virtual machine. The result after simulation shows us the result of up to 60% reduction in time and cost.

VII. CONCLUSION

Software Defined Networking is a concept of networking that facilitates the increasing requirements of the network in today's era. As with traditional networks technology redundancy in the path in SDN has efficiently and effectively facilitated the robustness and stability for the whole network. This paper has proposed a domain area to be done in our research work. Load Balancing focusses on how to distribute the massive amount of data into the small portions. Data centers in load balancing handled the huge amount of the data. Load Balancing minimized response time, huge data transfer rate, and how to efficiently and effectively enhance the performance of the whole system are the major key challenges in our research area.

raakeshdhiman@gmail.com

***Abstract*— Vehicular ad hoc network is a decentralized type of network in which vehicles can join or leave the network when they want. Due to such type of the network, path establishment is the major issue of the vehicle ad hoc network. A broadcasting approach is an approach for the path establishment which increases routing over head in the network. In this research work, a multicasting approach is proposed for the path establishment which reduces routing overhead in the network. The proposed approach will be implemented in network simulator version 2. The results will be analyzed in terms of certain parameters.**

***Keywords*— Broadcasting, VANET, Multicasting, NS2**

I. INTRODUCTION

It is very important to ensure the safety, comfort, mobility and quality of huge traffic that is commonly seen within smart cities every day. The Intelligent Transport Systems (ITS) are introduced to provide such facilities within these applications. The Vehicular Ad-Hoc Network (VANET) plays a very important role in developing the ITS for all applications [1]. There are several researchers attracted towards this latest research field from all across the globe. VANETs mainly ensure the safety of vehicles travelling on road along with providing traffic efficiency and level of comfort to the individuals. One of the most important challenges being faced when designing the VANETs is the development of dynamic routing protocol [2]. Lately, in comparison to other traditional approaches, various changes have been made for routing in VANET because of the topology changes arising in highly dynamic and continuous manner. There are several protocols designed for MANETs previously, which are applied and tested within VANET scenarios as well.

The most important challenge here is to reduce the delay related to passing the information from one node to another. If these challenges from MANET protocols are overcome, these protocols can be applied within real time VANET applications. Examining the implications carefully is important [3]. Through the examination of dynamic properties of VANETs, it is possible to control the unpredicted and dynamic nature of vehicular network topologies with the help of routing protocol. The most difficult task to be performed in VANET routing is the identification and maintenance of optimal paths of communication. It is possible to connect the routing protocols of VANET depending upon the topology being used in the network architecture. Further, the performance is also affected whenever the topology of network is changed. With the help of this protocol, it is possible to perform communication amongst the source and destination node with the help of geographical position [4]. It is possible to provide communication amongst the neighboring nodes in such a manner that the beacons are transmitted at regular time interval by using the nodes' geographical positions. The three important components of this protocol are beaconing, location services and forwarding. This protocol also uses the GPS to help in deciding the location of several vehicular nodes. For minimizing the traffic and overhead of VANETs, the Cluster Based Routing (CBR) is applied. The major concern of this routing is generation of network architecture depending upon the clusters that are small groups of vehicles. One of the vehicles present in a cluster is represented as a cluster-head. The size of a cluster completely depends upon the designing of routing algorithm [5]. This design completely relies upon the number of vehicles present within a cluster or geographical positioning of the vehicles. The concept of CBR is also involved previously within ad hoc networks.

The performance of CBR is tested for MANETs that have rigid network conditions. In order to develop the cluster range in most of the routing protocols, a mechanism is generated here. In the next step, the optimal routes are searched to provide communication. Because of the scalability issue, it is not possible to directly apply the cluster formation techniques of MANET in case of VANETs [6]. Broadcast routing is known to be one of the traditional routing approaches of VANETs. The broadcast routing mechanism is applied so that the message that is outside the range of a vehicle can be forwarded. For transmitting the packets, flooding techniques are applied. This routing approach ensures the delivery of information across the network. This approach however, needs to include extensive resources of bandwidth. This approach is applicable in several well established routing protocols particularly within the route discovery process followed towards the destination [7].

Within BROADCOMM, it is possible to simulate the hierarchical structure of highway. The complete region is divided with the help of virtual cells. In case when Cell Reflector (CR) acts like a base station, it is possible to collect the messages from particular call and neighboring calls. CR is used to make judgments when the messages are to be forwarded to individual vehicles. Geocast routing is performed within specific regions that require the need to handle dissemination of information. Due to the increase in use of

VANETS, several geocast routing approaches have been proposed [8]. It is important to perform position based multicasting in several VANET applications in which the vehicles are moving in one similar direction. This routing is also applied for minimizing the search area for next hop to a specific Zone of Relevance (ZOR).

II. LITERATURE REVIEW

Following are the major research work done in the area of VANET:-

Zhiwei Yang et al. (2017) [9] proposed a novel technique for clustering which provides information about the vehicular navigation systems [9]. The author designed a residual route time function which evaluates the overlapping time among the vehicles according to route information. The researchers also designed a method that selects a new cluster head which helps to avoid the exchanging of messages at intersection and maintenance of cluster head is reduced. The comparison is made between the existing algorithms and proposed clustering algorithm, the results shows that the proposed methodology can improve the stability of cluster, in terms of various parameters like lifetime of clusters, number of changed status and so on. Therefore, the researcher draws conclusion from the simulations results that clustering algorithm achieves higher stability and in turn reduces the cost.

Yangyang Xia et al. (2018) [10] presents greedy traffic light and queue aware routing protocol. There are certain benefits provided by applying this approach by performing vehicle clustering at the time of intersection and balance the traffic load among the vehicles. The simulations performed provide results which prove that the designed approach provides better results in comparison to TLRC and GLSR-L. Therefore, the researcher concludes that the simulation performed provides effective results as compared to the other position-based routing protocols.

Abdul Kareem Basil et al. (2017) [11] proposed OSLR routing protocol in which AODV values are evaluated using NS3 simulator [11]. A common geographical topology is used within these applications. There are certain important properties provided within the congestion region. Hence, the researcher concludes that OSLR performs much better than other protocols in terms of the throughput values, PDR values and latency by 17.4%, 7%, and 5% respectively also reduces the density crossroad scenarios.

Wenxiao Dong et al. (2017) [12] proposed a routing protocol called cluster-based recursive broadcast (CRB) which is used to solve the issues and problems faced by other scientists in this field [12]. The re-broadcasting is performed only by the selected vehicles. By taking in consideration the traffic light signal, the CRB is able to achieve the broadcasting along with improvement in efficiency of the forwarded message. The simulations were performed which show that the proposed approach outperform flooding one at a time, in delivery time and delivery ratio. Therefore, the researcher concluded that the proposed approach avoids the storm related issues but outperforms the flooding at the time of high vehicular density and message rate.

Seung-Seok Kang et al. (2017) [13] proposed a simulator called SUMO which is a road traffic simulator and part of NS3 computer based simulator [13]. This proposed simulator is used in monitor the real time traffic of roads and vehicles. The result of this simulation proves that the DSDV routing protocol transfers the information to the network which affects the performance of the packet delivery ratio. Hence, the researcher concludes that the proposed simulator shows better performance and drives at very high speed.

Harinder Kaur et al. (2017) [14] presented two routing protocols called Anchor based street and traffic Aware routing (A-STAR) and Greedy Perimeter Stateless Routing (GPSR) which is used to analyze the real city map [14]. A simulation performed on real map scenario gives accurate results and helps in designing and deployment of VANET in real life. The performance of the proposed approach is evaluated in terms of certain parameters. Simulations were performed by using variable density nodes. Therefore, the simulations of GPSR and A-STAR provide better performance on city map of Bathinda which in turn also shows that A-STAR technique is better. Therefore, the author concludes that the proposed approach is better than the other conventional routing protocols and show effective and satisfactory results.

A. Malathi et al. (2017) [15] presented new multicast routing algorithm for VANET which meets the challenges of multicasting. The proposed approach focuses on the analyzed cluster based routing performance of VANET. The HSSABC optimized algorithm is used to make sure about the effective routing path. The researcher concludes that the proposed algorithm show much better performance in comparison to the already existed routing protocols of ACO, AODV and GA-ACO routing protocols. The experiments were performed which concludes that the proposed approach show effective results in terms of the delivery packet ratio, end-to-end delay, bandwidth and the consumption of energy.

Rajesh Kumar M et al. (2016) [16] proposed quantities like movement of vehicles, vehicular density, and velocity by implementing the Ant Colony Technique. This algorithm responds to the routing protocol having dynamic source routing and improves the working of the MANET. The combined form of algorithm shows much better results at least much better than the end to end delay and packet delivery ratio. In this paper the researcher focuses on the use of ACO technique and provides good routing adaptability at various VANET network. Also, the proposed approach characterizes the dynamic topology, calculation of link quality and so on.

Awos Kh. Ali et al. (2016) [17] proposed routing protocols like AODV, OSLR and GPSR and provides in-depth evaluation of the MANET. This performance is compared in terms of three parameters which are DEL, delay and PDR. The simulations were conducted on NS2 and SUMO and the platforms are configured with the real time situations. Hence, the researcher concluded that the proposed approach OSLR achieves less drop burst length and provides increased PDR results in comparison to the AODV and GPSR load of network. Also, GPSR shows much better results in terms of high node of network and delivers the packets through shortest path.

Arohi Gupta et al. (2016) [18] presented the study of VANET and their routing protocols. The paper also introduces the comparison of AODV, DSR, DYMO and OSLR routing protocols for VANETs along with their advantages and disadvantages [18]. The existing ad hoc routing protocol was also reviewed and elaborated in the respective paper. The paper also shows the comparison between the routing protocols. Every protocol has certain advantages and disadvantages. Therefore, the results of each protocol are compared with one another. Hence, the proposed algorithm is effective and provides much better results.

TABLE I. COMPARISON OF EXISTING ROUTING SCHEME IN VANET

Author's Names	Year	Description	Outcome	Advantages	Disadvantage
Yangyang Xia, Xiaoqi Qin, Baoling Liu, Ping Zhang,	2018	Presents greedy traffic light and queue aware routing protocol. Certain problems are caused due to vehicle clustering at the time of intersection and balance the traffic load among the vehicles.	The proposed approach shows much competitive performance as compared to the other routing algorithms.	It provides better results as compared t other protocols.	Large amount of bandwidth is wasted in this protocol.
Abdul Kareem Basil, Mahamod Ismail, Mohammed A. Altahrawi, Hussain Mahdi and Nordin Ramli,	2017	Presented an OLSR routing protocol and evaluates the value of AODV protocol in various traffic scenarios.	OSLR is effective than the AODV networks in terms of the network metrics.	This protocol is much better than the AODV networks during network blockage scenarios.	Delay in time.
Wenxiao Dong, Fei Lin, Hongling Zhang, Yuping Yin,	2017	Proposed a routing protocol called CRB which is used to solve the issues and problems faced by other scientists in this field	The researcher concluded that the proposed approach avoids the storm related issues but outperforms the flooding at the time of high vehicular density and message rate.	It avoids the storm problems and having high message rate	It increases network congestion.
Harinder Kaur and Meenakshi	2017	Presents two routing protocols called A-STAR and GPSR which are used to analyze the real city map.	The author concludes that the proposed approach is better than the other conventional routing protocols and show effective and satisfactory results.	It is much more effective than previously existed approach.	It shows bad performance for long distance between sources and destination.
A. Malathi , Dr. N. Sreenath,	2017	Presented new multicast routing algorithm for VANET which meets the challenges of multicasting.	The experiments were performed which concludes that the proposed approach show effective results in terms of several parameters.	Shows superior performance in terms of different parameters.	It has no fixed access point.
Rajesh Kumar M and Sudhir K.Routray,	2016	Proposed quantities like movement of vehicles, vehicular density, and velocity by implementing the Ant Colony Technique.	In this paper the researcher focuses on the use of ACO technique and provides good routing adaptability at various VANET network. Also, the proposed approach characterizes the dynamic topology, calculation of link quality and so on.	It provides excellent adaptability to routing protocol at VANET.	The hybrid approaches cannot be used and applied to the VANET environment.

Awos Kh. Ali, lain Phillips and Huanjia Yang	2016	Proposed routing protocols like AODV, OSLR and GPSR and provides in-depth evaluation of the MANET.	The researcher concluded that the proposed approach OSLR achieves less drop burst length and provides increased PDR results in comparison to the AODV and GPSR load of network.	The DEL reduces and PDR increases as per the performance results.	No protocol provides complete information about the path.
Arohi Gupta, Raghuraj Singh, Danish Ather and Ravi Shankar Shukla,	2016	Presents the study of VANET and their routing protocols. The paper also introduces the comparison of various protocols for VANETs along with their advantages and disadvantages.	The proposed algorithm is effective and provides much better results.	It is better and shows satisfactory results.	It requires longer latency for the establishment of the route.
Zhiwei Yang, Weigang Wu, Yishun Chen, Xiaola Lin, Xiang Chen	2016	A novel technique had been proposed for clustering which provides the information about the navigation of vehicles.	The proposed approach shows higher stability and is less expensive.	Higher stability is achieved and becomes less expensive.	The route discovery is floods during the initial phase.

III. INFERENCES DRAWN FROM LITERATURE REVIEW

Following are the various inferences drawn from the literature review:-

1. The vehicular ad hoc network has the self configuring nature and vehicles have high mobility due to which it is difficult to establish stable path. The techniques that are proposed in the previous years have problem of link failure which affect its efficiency.
2. Since the mobility of vehicles is high, road side units plays importance role for the path establishment. The techniques which are already proposed by the authors require extra hardware to deal with the issue of network mobility
3. To establish stable and secure path, clocks of vehicles must be synchronized. An approach needs to be proposed here which can synchronize clocks of the vehicles.

IV. WORK METHODOLOGY

A. Problem Formulation

Most popular amongst all is the reactive routing protocol which establishes the path due to its effective performance. The concept of broadcasting is used in the reactive routing protocol in order to establish the path from source to desired address. Route request packets are flood by the source node when broadcasting the data packets. Route reply packets are sent in response to those requests by the nodes closer to the source node. Hop count and sequence number are the two factors based on which the path for data transmission is chosen.

It had been found that by using broadcasting the nodes which are unable establish a path from source to destination will also receives a request packet which in turn enhances the delay within the network. In this research paper an innovative approach is proposed in which multicasting is used in order to establish a path from source to the desired address.

B. Methodology

In this research work, we will propose scheme for the path establishment using the concept of multicasting. The following are the various steps which are followed for the path establishment:-

1. The VANET is made up of large number of vehicles. In this the road side parameters are employed for the vehicle to vehicle and vehicle to infrastructure interactions.
2. In the second step, the road side units send the control message to each node in the network. The vehicle nodes receive that message and check number of nodes in their direct range.
3. In the third step, each node in the network which presents its number of nodes in their range with the other nodes. The vehicle node which has maximum number of nodes in their range is selected as the zonal head node.
4. The message is transmitted by the source node to its zonal head and verifies that whether it is in its zone or not. When the requesting node is in its zone then path will be directly established from source to the destination and when the requesting node is not in its zone, the zonal head passes the request to the next zonal head. The process is repeated unless the desired path is established.

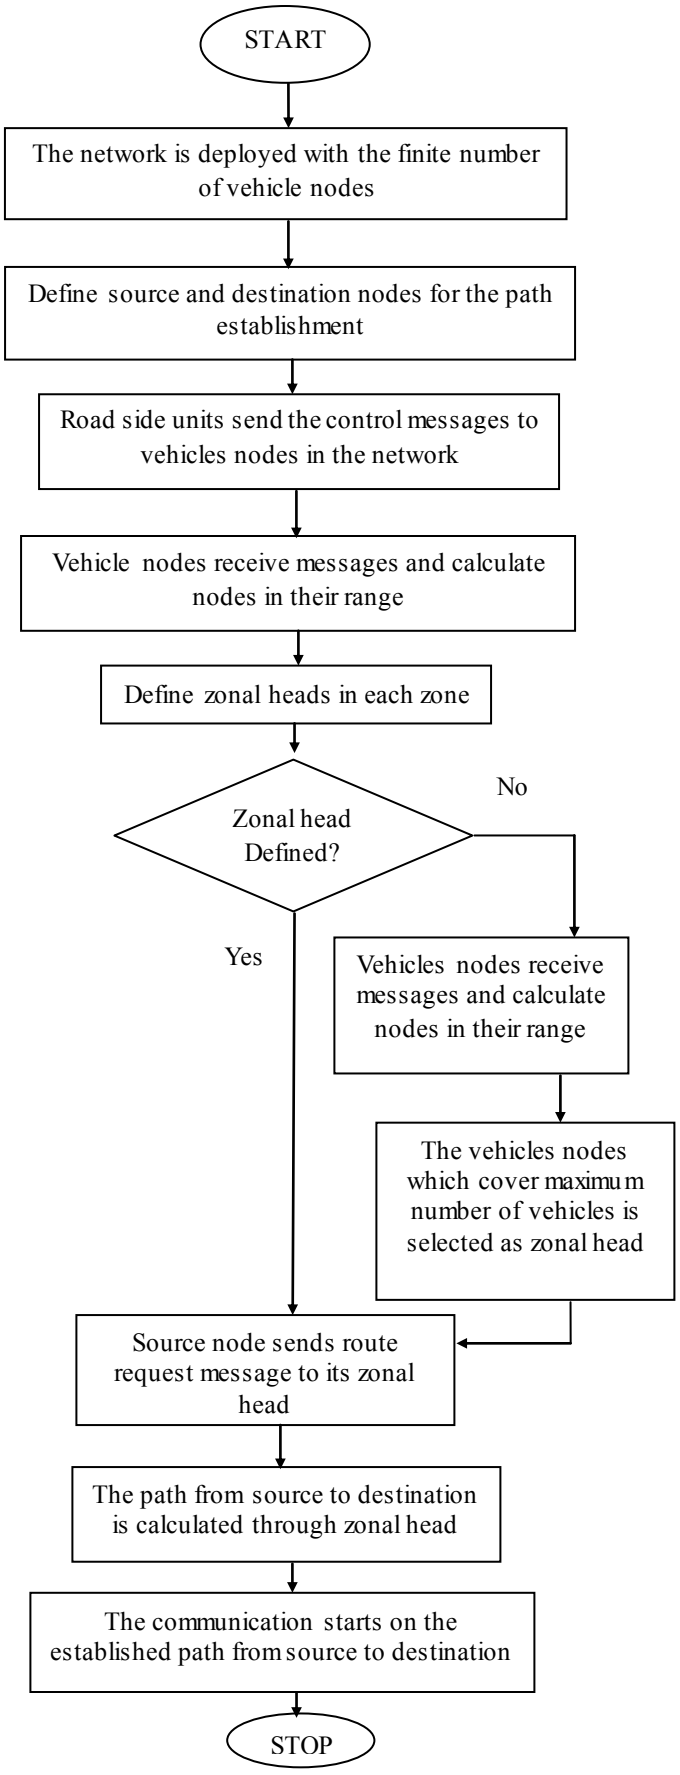

Fig 1: Proposed Flowchart

V. Implementation and Observation

Since VANETs are decentralized in nature, routing is one of the major concerns in these networks. For establishing a path from source to destination, several reactive and proactive types of routing protocols are applied. The reactive and proactive routing protocols are implemented in this research work in network simulator version 2. The table II describes various simulation parameters. The performance of the reactive and proactive routing protocols are compared in terms of throughput and packet loss

Table II. : Simulation Parameters

Parameters	Values
Number of nodes	34
Type of Propagation	Two-Ray Ground
Link layer	LL
Queue type	Priority queue
Queue Length	50
Antenna type	Omni directional

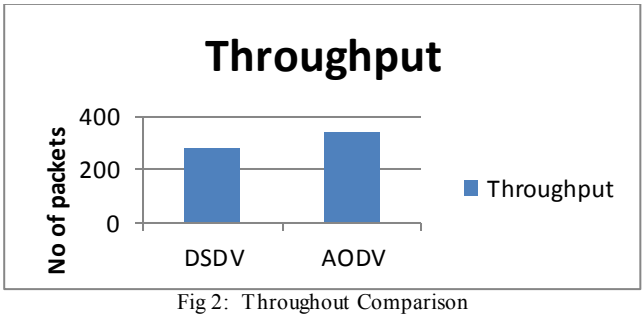

Fig 2: Throughout Comparison

Figure 2 shows a comparative analysis of AODV and DSDV routing protocols in terms of throughput. It is seen that in comparison to DSDV protocol, the throughput achieved when applying AODV protocol is high.

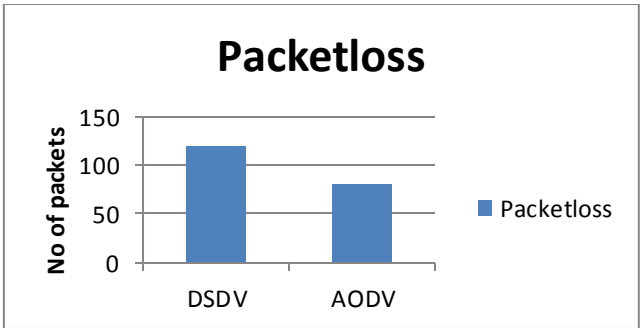

Fig 3: Packetloss Comparison

Figure 3 shows a comparative analysis of DSDV and AODV protocols in terms of packet loss. It is seen that in comparison to DSDV protocol, the packet loss achieved when applying AODV protocol is less.

VI. CONCLUSION AND FUTURE WORK

A decentralized type of network which allows the nodes to enter or leave the network freely is called VANET. VANETs face certain issues while routing is performed due to their dynamic nature. This research work proposes to use multicasting approach to establish paths in these networks. NS2 simulator is used to implement this proposed approach and with respect to certain performance parameters, analysis of outcomes is done at the end.

***Abstract*— Technologies like Augmented Reality (AR) and Virtual Reality (VR) have been advanced quickly in recent years. Many hardware devices and special techniques have been developed. AR is a technology which integrates the virtual objects with the real time environment. But the critical breakthrough came, when AR spread to the smart phones, this enabled mass spread of AR applications in the field of Education, Manufacturing industries, Military, Medical etc. providing the information about the specified targets to the users. It is also one of the key technologies used in Industry 4.0. AR systems have already reached some level of maturity in educational field and the effectiveness have been widely proven. This paper proposes the development of Marker-based mobile Augmented Reality application, which demonstrates the working of RVCE All-in-one Interface Card.**

Keywords—Augmented Reality, Virtual Reality, Industry 4.0, RVCE All-in-one Interface Card

I. INTRODUCTION

Interaction of Human Computer [1] is a field which is related to Design, Evaluation and implementation of interaction computing systems for use of humans and the study of surrounding phenomena. Augmented reality and Virtual reality are the technologies, which are under Human Computer Interaction. Augmented reality is a technology where virtual reality is combined with real world environments to make it look as if the virtual object is in real world [9]. Augmented Reality can be integrated into daily life and activity, and can be used for various purposes. Augmented Reality (AR) applications provide environment to the users, where they can immerse themselves in to the partially virtual world and interact with the virtual objects and user interface. A lot of Artificial Intelligence (AI) technologies [2] have been used in Augmented Reality. Computer vision is the one area, where AR meets with AI. Computer vision utilizes techniques for computer learning and pattern recognition, that is the reason why it is part of AI.

AR has increased its popularity in both industry and academia, the evolution to Industry 4.0 [3], where during manufacturing , using some of the new technologies in that even AR is also been included.

There are basically two types of Augmented reality,

Marker-Based AR which uses a camera and some type of visual marker from the real-world to produce the result, Virtual objects pop-up only when the marker is sensed by the camera.

Marker-less AR applications [4] have implemented most widely. This is also called as Location-based or GPS, position-based. Uses GPS, Velocity meter, or Accelerometer which is integrated in device to provide the data based on the user's location.

This paper proposes the work of developing a Marker-Based mobile Augmented reality application, which demonstrates RVCE *All-in-one* Interface Card by using AR technology. It gives the information about the Interface card in the form of buttons, videos and other virtual enhancements integrated with real world objects.

A. RVCE ALL-IN-ONE INTERFACE Card

Microprocessors / Microcontrollers is one the core courses studied by under graduate students of computer science, Information Science, Electronics & communication, Instrumentation, Electrical & Electronics Engineering in many universities. R&D Labs of CSE Department, RVCE has taken up the Design & Development of "All In One – Multipurpose Interfacing Card" for PC for X86 Programming and product developments, successfully manufactured and adopted.

RV All-In-One Interface Card can be used to convert PC to PC based product for number of applications and also to create interest and bring innovation among students by using the interface card to conduct different experiments and projects using their computer system.

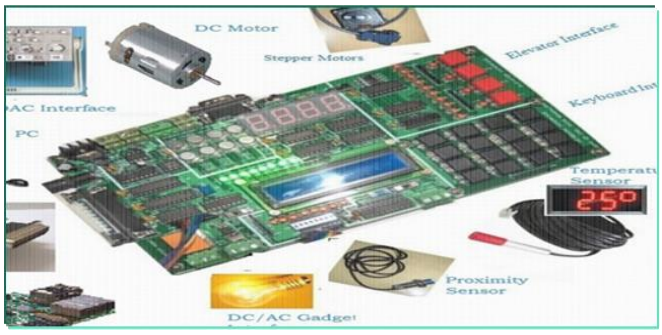

Figure 1: RVCE All-in-one Interface Card

The Different Interfacing Modules Integrated in RV ALL-IN-ONE Interface Board are Logic Controller, Seven Segment Display Module, LCD Interface ,Stepper Motor Interface, DAC Interface, ADC Interface, DC Motor Interface , DC Solenoid , Temperature Sensor Interface , Ac

Gadget Interface, Industrial Sensors Input Interface, Elevator Interface , Keyboard Interface.

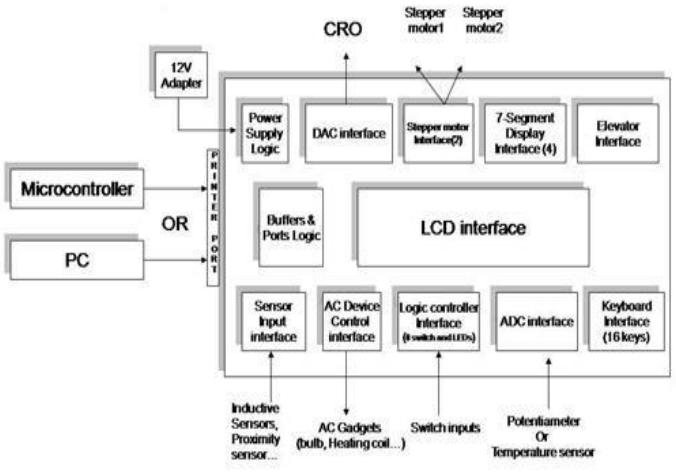

Figure 2 : Block Diagram of RVCE ALL-IN-ONE Interface Card

The application senses the Interface Card and mixes it with virtual objects (like text, graphics and audio) and gives back those information to the users.

II. Objectives and Scope

1. The main purpose of the work is to demonstrate the RVCE *All-in-one* Interface card using Augmented Reality by providing each module's internal working ,functionalities, architecture and code-snippet, and providing all the information at one place and making students understand the concept in easier way.

2. Idea of introducing the technology to the students and make learning as new and creative.

3. This application helps the student to understand about the basic information of Interface card independently.

4. One of the useful technology in the Industry 4.0, which helps engineers while manufacturing by guiding them the procedure.

III. Theory and Concepts

AR uses the device's camera of handheld mobile devices, such as a smart-phones or tablets to capture the video and place virtual objects on top of the real world. To run an AR app on a mobile device, point its camera to the target and application will recognize the target and render computer graphics which is registered for the target position and orientation.

Mobile devices [5] should have the following important features to run AR application

1. Flat panel graphic display touch-screen input. Rear-facing camera.
2. Motion sensors, rotational motion has been recognized by the gyroscope and linear motion has been detected by the accelerometer.
3. GPS and other position sensor for geo-location and wireless.
4. Untethered and battery powered.
5. GPU (Graphics processor), CPU(Main processor) and Memory.

The video frames of the real-world have been captured by the rear-facing camera and displays it in screen. Because the video data is digital, app will modify it and combine virtual graphics in real-time.

AR uses computer vision to recognize targets in the field of view. Whether natural feature tracking (NFT), specific coded markers or other techniques to recognize text or object. The application generates computer graphics that aligns with those real-world transform that overlaps on top of real world imagery when it recognizes the targets and orientation.

The key to the success of mobile AR, also includes sensors which measures orientation, motion and other conditions. A gyroscope for detecting rotational motion around the axes and an accelerometer used for detecting linear motion. The software estimates the device's position and orientation by using three data in real 3D space at any given time. The specific view of the device camera capturing is determined by this data. And uses this 3D transformation to register the computer generated graphics in 3D space as well.

A. Target Based AR

The device camera captures a frame of video [6]. The familiar target is analyzed from the frames by the software, such as a pre-programmed marker, by using the technique called Photogrammetry.

Deformation like size and skew is analyzed as part of target detection, is analyzed to determine its distance, orientation and position relation to the camera in a three-dimensional space. The 3D space is determined from that camera pose that is position and orientation. And these values are used in the computer graphics calculations to reduce virtual objects. Finally, the video frame and rendered graphics are merged and displayed it to the user.

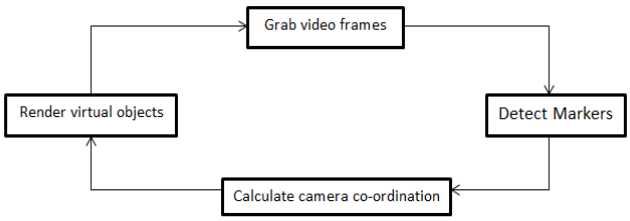

Figure 3: Explains the modules in which AR works

The ability to recognize and track complex 3D objects goes beyond the 2D image recognition [8]. A good marker is detected easily in all the conditions or circumstances. The brightness differences is easily detected than color differences using machine vision techniques. This is because of camera's automatic white balance are poor: it is incorrect color register. The object changes the color depending on the view in the image. The lightening also changes the colors of the objects, that's why color detection becomes challenging. The object detects easily, when there is more contrast in the luminance, that means there should be optimal black and white markers. By using the detected markers, the system also calculates the camera's pose.

B. Marker pose

The object's pose always refers to is location and orientation [6]. Around the three co-ordinate axes, the orientation is expressed with three rotational angles (α, β, γ) and with three translation co-ordinates (x, y, z) location can be expressed. Thus the pose has six degrees of freedom.

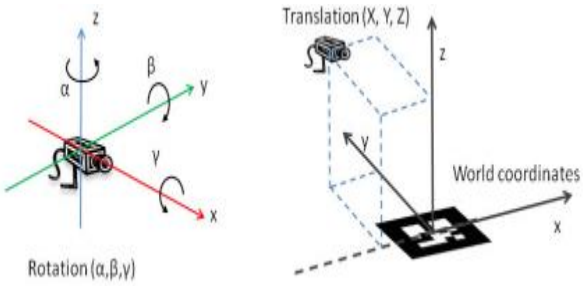

Figure 4: The pose of camera (Orientation and Location in the world co-ordinates)

From a minimum of four coplanar and non-collinear points, the camera's pose can be determined. Thus, calculation of marker's pose in 3D co-ordinate by the system using four corner points of the marker in image co-ordinates.

In digital cameras, co-ordination of elements and image registers on the image sensors differ from ideal co-ordinates. The camera image depends on the camera's physical characteristics such as size and orientation of Image sensor, focal length etc.

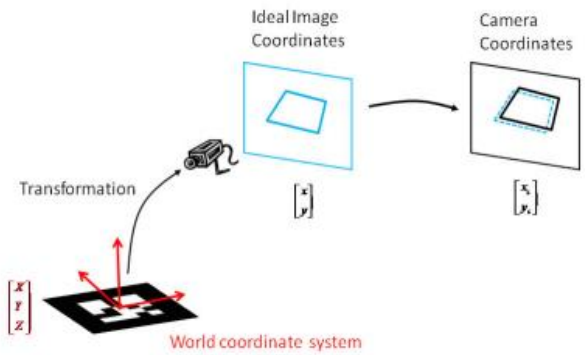

Figure 5: Additional conversion to the camera co-ordinate system is needed as ideal pinhole camera models does not hold for digital camera.

1. Camera transformation

Camera and marker's transformation T

$$x = TX,$$

where X is a point world co-ordinates, x is its projection in ideal image co-ordinates and T is the camera transformation matrix or pose matrix. Transformation T consists 3*3 rotation matrix R and translation vector t and can be expressed in the form of matrix.

x = [R | t] X , which is homogeneous co-ordination is

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} r_1 & r_2 & r_3 & t_x \\ r_4 & r_5 & r_6 & t_y \\ r_7 & r_8 & r_9 & t_z \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}.$$

There are only three parameters in rotation matrix (α, β, γ) which defines its nine elements. There are also three parameters in translation vector and six free parameters in pose matrix. When the marker is detected, the marker tracking system needs to solve this camera for each frame.

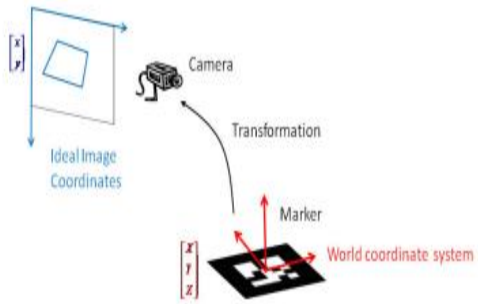

Figure 6: Conversion of worlds co-ordinate to ideal camera co-ordinates by transformation matrix.

2. Detection errors in pose calculation

It is more reliable to detect the x and y translation than z translation. The movement of image plane is smaller It is more reliable to detect the x and y translation than z translation. The movement of image plane is smaller when object moves the same distance in x or y direction than the object moves some distance in z direction.

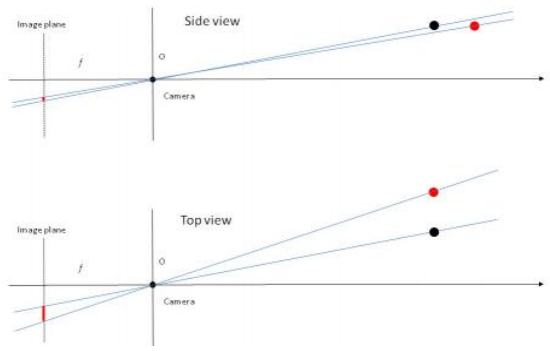

Figure 7: If the black dot (object) moves parallel to the optical axes (on the top) [12], the moment in the image plane is small than the movement of perpendicular to the bottom (optical axes). That's why detection of errors on the image plane have a great detection on the z dimension.

3. Rendering with the pose

The camera is moved to render the virtual object in the right scale and perspective, the camera should be moved to same pose as the real camera and on top of the real image, virtual objects are rendered.

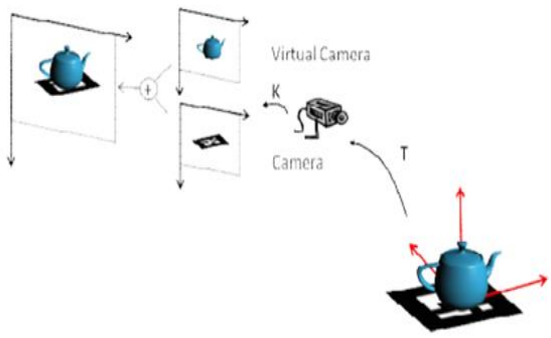

Figure 8: Augmentation in origin

IV. METHODOLOGY

The proposed methodology for the Marker based Augmented reality mobile application has six modules [7]. Below are the names of the following modules.

- Camera
- Capturing Image module
- Processing Image module
- Rendering Image module
- Tracking marker module
- Display the screen

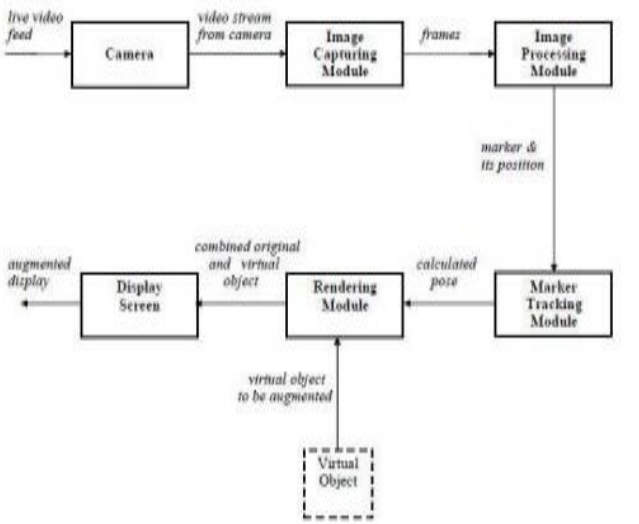

Figure 9: Methodology of the proposed application.

1. Camera module

Camera module takes the live video as an input from the Android smart phone. In Augmented reality displaying this live video is reality

2. Capturing Image module

The live video from the camera module is given as an input for the capturing image module. This module analyses each frames from the live video and generates binary images that has only two values for every pixel. Basically white and black are the only two colors that are used for the binary images.

3. Processing image module

Binary images from capturing module is given as an input to this module. Here binary images are processed by using techniques of image processing to detect the markers for Augmented reality, this is necessary to identify the position to place the virtual objects [10]. Once this is identified, then the location of AR marker is given as an input to the tracking module.

4. Marker Tracking module

The marker tracking module is like heart of AR systems. Calculations of the real-time camera's relative pose is done by this module. 3D orientation and 3D location is the meaning of the term pose, i.e. six degrees of freedom position.

5. Rendering module

Basically the inputs of rendering modules are two. One is tracking module's calculated pose and the

other is virtual objects that needs to be augmented. By using the calculated pose, the rendering module combines the virtual objects with the original image that has been capturing from the camera and displayed on the screen of android smart phone.

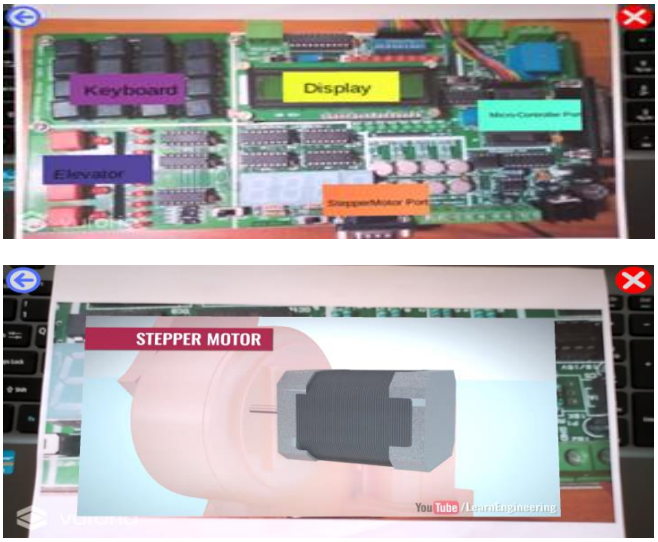

Figure 10: Screenshots of the application which demonstrated the virtual objects of RVCE All-in-one Interface Card.

V. CONCLUSION

This paper proposes the marker based augmented reality using Android, which helps the students to understand the working of RVCE All-in-one Interface card in better way by showing the virtual objects in the form of video (which explains the working of modules like Matrix keyboard, Elevator, Stepper motor) audio and virtual buttons and also provide the program of each module. So that students get all the materials in one place. Further, AR modules can be developed to enhance different electronic devices, machines motors, etc., to enhance the learning [11], in turn enabling the way to adopt and enhance ICT based learning techniques.

Design of low power SR-flip-flop with on/off (ONOFIC) implementation

Masood Ahmad Malik, Vijay Kumar Sharma

School of Electronics and Communication Engineering,
Shri Mata Vaishno Devi University, Kakryal-182320, Katra, (Jammu & Kashmir)

(Email id: malikmasood93@gmail.com ,vijay.sharma@smvdu.ac.in)

Abstract: Metal oxide semiconductor (MOS) devices are the basic building blocks for the logic circuits. Advancement in technology increases the expectation of customer in electronics. Various challenges face by IC designer during the uses of this Nano-scale technology because no one technology is completely satisfied all requirements. Better performance with minimum power dissipation and high stability is become basic need and low power dissipation is possible when power consumption of VLSI device is low. As the need of small electronics components and devices is increased day by day. There is a rapid growth in industry of electronics in few decades. World and technology are growing at the same speed. Day by day as the demand for small devices increases with high efficiency and result in flip-flop came into existence. These flip-flops have number of applications in electronics like used in communication, computers. As the size of the flip-flops decrease there is a problem of leakage current which prevents us to design a low power circuit. To decrease these leakage currents in the SR flip-flops and made it as a low power flip-flop an approach is used in this paper called as ON/OFF (ONOFIC). This ONOFIC implementation of SR flips decreases the leakage current and in this way our SR flip-flop is low power consuming

Keywords—Flip-Flop, ONOFIC, Power Dissipation, VLSI

I INTRODUCTION

World and technology are growing at the same speed. Day by day as the demand for small devices increases with high efficiency and result in flip-flop came into existence. Flip flops have a number of applications in electrons and nowadays these flip-flops are used for optical signal processing and transparent optical fiber processing [1]. Flip-flops is main hardware device that is highly used in synchronous finite state machines [2]. SR flip-flop have number of application one of the application is mechanical bounce and its elimination removal [3]. Flip-flops can be simple or clocked[4], they are positive edge triggered I.e. when clock is raising we are accepting the data from the input and also negative edge triggered which means when clock is falling down at the time data is sampled. There are two types of logic circuits combinational and sequential logic circuits. Combinational logic circuits are the function of current input values but sequential logic circuits are the function of current values of the inputs and also on the preceding input values. Set reset flip-flop is called SR flip-flop and is the simpler one among all the other flip-flops. SR flip-flop has a clock signal and two inputs called as set and reset. When the set input is high output is high and when reset is high output is low. When the set and reset input both are high output is this state is Invalid. NOR and NAND gates are used by simply cross coupling to each other. Due to tremendous use of small devices in electronics field the technology is also scaled down day by day. Scaling has lot of advantages like we are able to make small and small devices like in these days small iPods, tablets, pacemakers and hearing machines but on the other hand we are losing the property of low power. These small devices must be low power dissipation because low power devices are highly demanded in these days. Maximum power consumption of a chip depends on its implementation and technology [5]. Aggressive scaling of MOS devices requires use of ultra-thin gate oxides to maintain a reasonable short channel effect [6].When we are scaling the device parameters we have to scale the supply voltage, threshold voltage and oxide thickness. Supply voltage plays an important factor to reduce the power dissipation in portable devices [7]. Reducing the supply voltage increases the sub-threshold leakage current and decreasing the oxide thickness results in increase of junction tunneling of electrons. When the gate oxide is reduced to a large extent there is exponential increase in gate leakage current and reduction of transistor threshold voltage increases sub-threshold leakage currents [8]. The tunneling of electrons is directly proportional to scaling, new standard CMOS SOCS face major challenges because of leakage current. These leakage currents have a serious effect i.e. the device consumes large quantity of power and this is the main challenge in the VLSI technology.

These leakage currents pose a challenge to the low power devices and lead to the instability of logic circuits. These leakages currents needs to be reduced so that power dissipation of the CMOS devices is low and stability, speed should be improve. This high dissipation power is becoming a serious design concern as we towards the mobile computing world [9]. In this paper CMOS SR flip-flop is designed with ONOFIC implementation which reduces the leakage to a great extent. A comparison is made between the conventional SR flip-flop and our ONOFIC implementation of CMOS SR flip-flop in terms of power dissipation. This paper is divided into four sections. Section 2 explains the related work and ON/OFF (ONOFIC) approach for designing of CMOS SR

flip-flop, section 3 explains the conventional CMOS SR flip-flop and ONOFIC implementation and finally results and conclusion in section 4. All the simulations are done using cadence tool at 45nm.

II RELATED WORK

In [12] a SR flip-flop is designed by using CMOS 90nm technology. Two layout models I.e. semicustom and full-custom design technology are made. A comparison is made between these two in terms of power and fully customized layout is 39%better than semi-custom layout

In [3] SR flip-flop is designed by using 45nm CMOS technology. By using MOS transistors less energy is consumed than by using conventional gates.

ON/OFF (ONOFIC) APPROACH

In the ONOFIC approach design, a logic block consists of one PMOS and one NMOS is inserted between the pull-up and pull-down network. This logic block is known as ON/OFF logic block we usually use PMOS as pull-up and NMOS as pull-down because NMOS will let us go to zero and PMOS will let to go to VDD so we get maximum swing available in this case. If we change the position of the pull-up and pull-down we have to compromise on certain output parameters. This approach is less complex only one logic block is added between the pull-up and pull-down network.

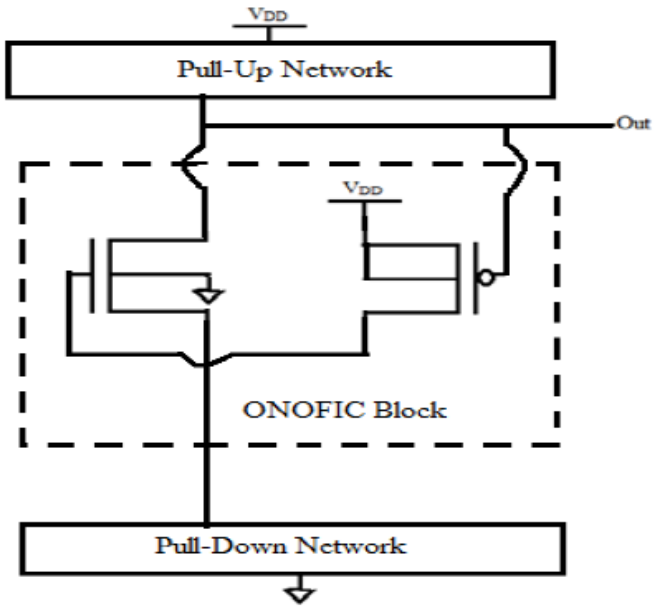

Figure 1.Schematic of ONOFIC approach [10]

This PMOS and NMOS block should work in ON/OFF condition for any logic output. This block works like as force stacking concept providing maximum resistance in OFF condition and minimum resistance in ON condition thus reduces the leakage current. These two transistors should be in cut-off or in linear state depending on the output logic. Figure below shows the schematic of ONOFIC approach. The ONOFIC transistors are connected in this way. The gate of NMOS is connected to the drain of PMOS and source of PMOS is connected to VDD and then the gate of PMOS with the output. The right turning of the ONOFIC transistors helps us in low propagation delay [10].

III CONVENTIONAL AND ONOFIC IMPLEMENTATION OF CMOS SR FLIP-FLOP

The below circuit diagram represents the SR flip-flop with a NOR based design this is the basic design. R and S are inputs and E is clock signal. In this section the SR flip-flop is designed by CMOS technology, designing the SR flip-flop with CMOS technology has number of advantages like low power dissipation, high noise immunity, lower propagation delay and high speed high frequency of operation [11]. The advantage of MOSFET'S is that they draw almost zero control current while idle [12].

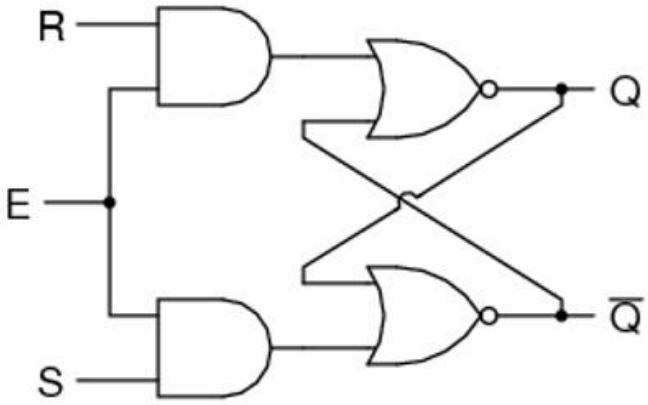

Figure 2 NOR based SR flip-flop

The conventional CMOS SR flip-flop consists of twelve transistors only. The status of the transistors in this design are when clock signal is low in N tree the two series terminals N are and open and also in P tree two parallel transistors are ON by this the state is retaining in the memory cell. When the clock signal is high the circuit is simple a CMOS NOR latch which will answer to inputs S and R.

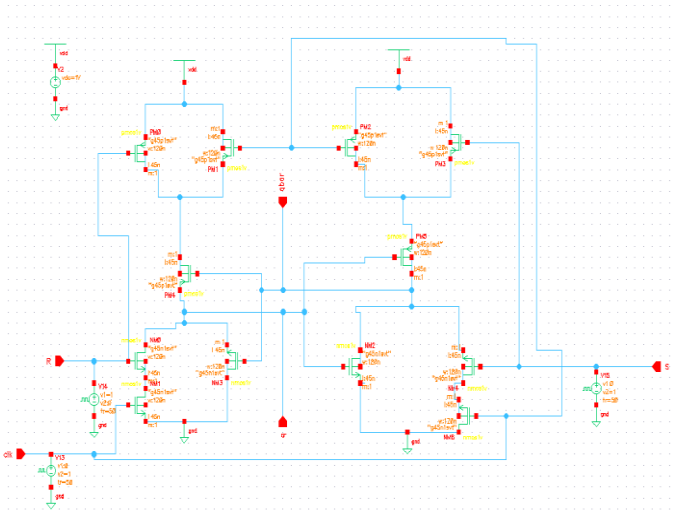

Figure 3.Conventional CMOS SR flip-flop

ONOFIC implementation of CMOS flip-flop

The below circuit represents the ONOFIC implementation of SR flip-flop. It consists of conventional CMOS SR flip-flop and further with addition of ONOFIC logic block. Two logic blocks are added in this implementation between the two pull-ups and pull-down networks. The total number of transistors in this implementation is sixteen. These four extra transistors help us to reduce the leakage current in the network. PMOS transistors control the operation of the NMOS transistors In the OFF state this block provides maximum resistance due to which the leakage currents are reduced because we know these leakage currents arises in OFF state when we go scaling to a to a large extent.

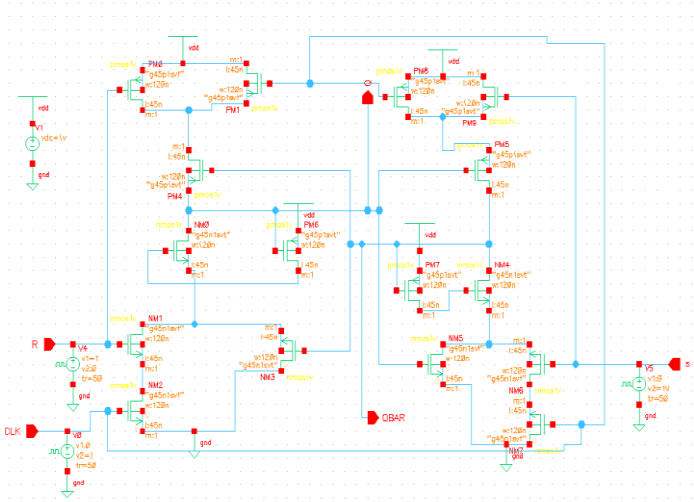

Figure 4.ONOFIC implementation of CMOS SR flip-flop

Static power is consumed even when chip is in quiescent (sleep mode). Static power can also be defined when device is in OFF state still current is flowing from VDD to ground. The main cause of static power consumption is scaling of transistor geometries which cause various leakage currents. Leakage power is about 20-50% today and increasing. The static power can be minimized by using various techniques like in this paper ONOFIC approach is used.

IV RESULT AND CONCLUSION

Table 1 comparison of power dissipation

POWER DISSIPATION OF CONVENTIONAL CMOS SR FLIP-FLOP	POWER DISSIPATION OF ONOFIC IMPLEMENTATION OF CMOS SR FLIP-FLOP
2.8µ	2.1µ

In this section a comparison is made between the conventional CMOS designs of SR with the ONOFIC implementation in terms of power dissipation. The results obtained in ONOFIC implementation are better than the conventional method.

CONCLUSION

In this paper we have discussed various leakage currents and their impact on low power devices. In VLSI technology low power is the main focus of IC designer. The above discussed ON/OFF (ONOFIC) method was used to design a SR flip-flop. ONOFIC technique is easy and only one threshold voltage is used for decreasing the leakage current. The main point of this technique is better ON/OFF property. ONOFIC implementation reduces leakage power and boosts the performance of the digital circuits which is need of the hour. Low power consumption is the outcome of this approach. the future scope of this approach is that if this logic block is turned ON/OFF in a better way it will help in reducing the propagation delay of logic circuits.

***Abstract*—Due to the tremendous increase in power dissipation in sub-micrometer region of operation, there arises a need to design low power circuits. The continuous scaling of CMOS logic circuits is not straight forward in the sense that when CMOS devices are scaled below 16nm, short channel effects are observed. These effects increase leakage power dissipation to large extent. The memory occupies about 90% of area in any logic design. The design of memory is of main concern as there occurs parameter variations in CMOS SRAM cells when designed below 16nm. This can be solved by the replacement of CMOS with FinFET in traditional SRAM cells. In this paper, design of 6T FinFET SRAM cell is presented at 7nm technology using ASAP7 PDK and Cadence virtuoso tool. Besides, parameters like power dissipation, delay, power delay products and static noise margins are also analyzed. The simulation results showed that design of SRAM cells using FinFET can be highly efficient in comparison to CMOS SRAM cells.**

Keywords—SRAMt; CMOS; ASAP7 PDK; Power dissipationg;Sub-threshold region; FinFET

I. INTRODUCTION

The parameters like performance, speed, propagation delay and energy per transition improves with continuous scaling. But scaling proves beneficial only upto certain level i.e. below 16nm in complementary metal oxide semi-conductor (CMOS) logic devices. Scaling is not straight forward as it results in degradation of performance. In addition to this, scaling of threshold voltage increases sub-threshold leakage as well [1]

Continuous scaling results in short channel effects. These effects include drain induced barrier lowering, velocity saturation, hot carrier effect, impact ionization, gate induced drain lowering etc. Many methods are devised from time to time to overcome these short channel effects. The methods include channel engineering techniques like retrograde doping, halo doping etc. [2]. Besides, circuit level techniques like INDEP, LECTOR and ON/OFFIC techniques are also suggested [3, 4, 5]. These techniques no doubt reduce leakage power but at the same time increase in propagation delay as well. The best method to reduce leakage in static random access memory cells is to replace CMOS with FinFET logic gates.

FinFETs are best for the design of SRAM cells in the sense that they improve electrostatic behavior of a device. FinFETs are the double gate devices and leakage power dissipation can be controlled by providing two gates instead of one gate which occurs in CMOS logic circuits. Increasing the gate control i.e. by using double gate reduces the leakage power dissipation to huge extent.

FinFETs consist of thin body of silicon and the gate electrodes are wrapped over it as shown in figure 1. There are many types are FinFETs and among them short gate and independent gate FinFET are the common types which are used in digital design [6].

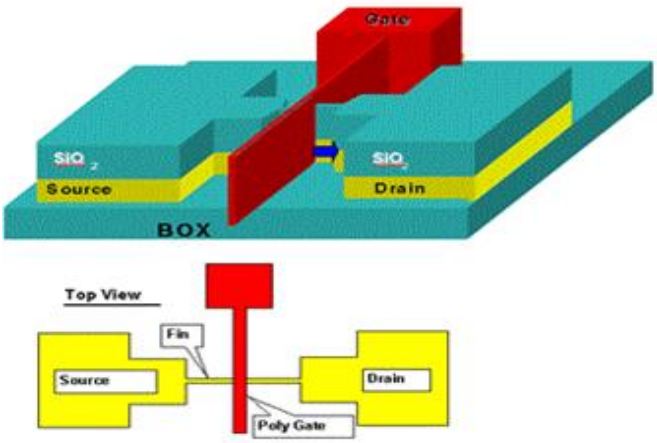

Figure 1: Fin type Field Effect Transistor (courtesy T.J King and C.Hu, UC BERKELEY)

In static random access memory design leakage power dissipation is of primary concern. This can be reduced by the use of FinFET in designing SRAM cells. There occurs increase in area overhead due to the use of FinFET in SRAM cells but this can be compensated by considering the trade-off between

various parameters [7]. The ease and compatibility to design static random access memory (SRAM) cells using FinFET [8] make us to design 6T FinFET SRAM cell.

The design of 6T FinFET static random access memory cell is done using cadence virtuoso tool. Moreover, ASAP7 PDK is used because cadence virtuoso tool does not have any inbuilt library to design FinFET logic circuits. The design of 6T FinFET SRAM cells is performed at 7nm technology.

The development of ASAP 7nm process design kit (PDK) was made at Arizona State university in association with ARM research .This is free PDK used at academic level by various researchers. The PDK has FinFET device models compatible with SPICE for cadence virtuoso tool. The PDK is helpful in designing six transistor (6T) FinFET static random access memory cell at 7nm using Cadence virtuoso tool. The section II describes how FinFET logic circuits are better in comparison to CMOS logic circuits. Section III discussed the modes of operation of FinFET SRAM cells and the section IV consists of simulation results and discussion. Finally the conclusion and future work is provided in the section V.

II. RELATED WORK

To minimize the leakage power many techniques are suggested from time to time for CMOS logic circuits but these techniques have many disadvantages like increase in propagation delay and area. Designing of logic circuits using FinFET is better in the sense because it reduces power dissipation by minimizing short channel effects and at the same time improves subthreshold slope and drive current capability of logic circuits as well. There are certain design challenges which should be taken in consideration i.e. quantized nature of the fin in case of FinFET static random access memory design [9].

The scaling in CMOS logic devices is limited to 16nm only due to scaling obstacles. In case of metal oxide semi-conductor (MOS) devices, high channel doping and moderate thickness of thermal oxide is required at lower dimensions. If these considerations are not satisfied it may lead to degraded performance and reduction in carrier mobility. Better channel control due to dual gate structure, straight process flow and improved on-current capability makes FinFET better in comparison to MOS devices [10, 11].

Due to larger on-current of FinFET devices, FinFET SRAM cells can be operated at higher speed in comparison to conventional CMOS SRAM cells. In addition to this FinFET SRAM cells have low propagation delay for read and write cycles as compared to CMOS SRAM cells [12].

III. PROPOSED SIX TRANSISTOR(6T) FINFET SRAM CELL

Modes of operation in FinFET SRAM cell

FinFET static random access memory (SRAM) cell has three modes of operation i.e. FinFET SRAM hold, FinFET SRAM read and FinFET SRAM write mode. The memory cells are designed at 7nm technology. These cells consist of two cross coupled FinFETs inverters and two access transistors (FinFETS). The access transistors are controlled by word lines. Besides, bit and bit bar voltages are also applied to access transistors.

A. FinFET SRAM HOLD

In hold mode FinFET static random access memory cell has to retain its data and for this word lines are kept at ground or low voltage. Due to this access transistors (FinFETs) are in off state and hence the data present in cross coupled FinFET inverters is retained and the FinFET SRAM cell acts as latch in that case. The circuit diagram for hold operation is given in figure 2. FinFET SRAM cell consists of six FinFETs. The FinFETs used in our design are short gate FinFETs. As shown in figure 2 the word lines are set to “0” or grounded. This suggests that in hold condition 6T SRAM cell acts as latch and latches the value at the output of cross coupled inverters.

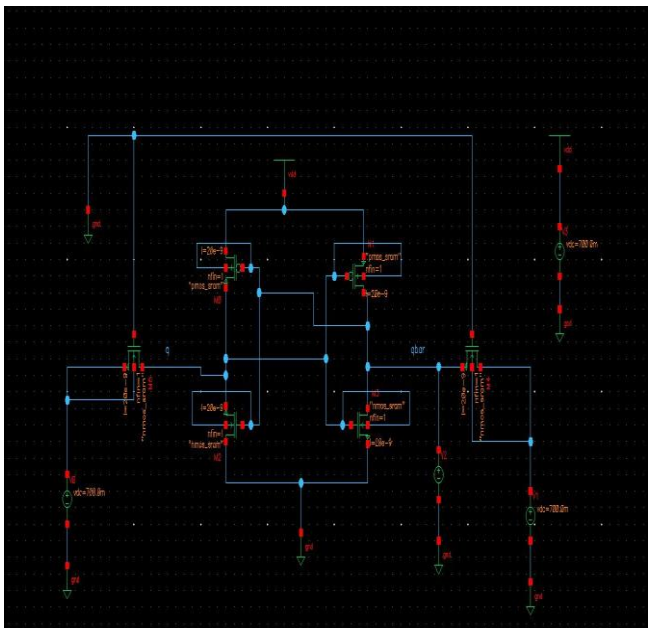

Figure 2: FinFET SRAM hold circuit

B. FinFET SRAM READ

In read mode, which is considered most vulnerable state to parameter variations [13] because both bit and bit bar are set to high voltages (Vdd). The voltage at word lines is also high equal to Vdd (0.7). The node which has "0" value is detected using sense amplifier because this node pulls the respective bit voltages to ground, hence detected by sense amplifier. The circuit diagram for read operation is given in figure 3.

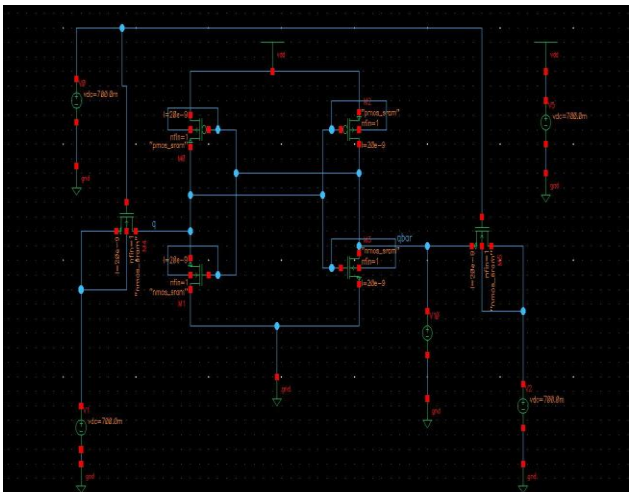

Figure 3: FinFET SRAM read circuit

C. FinFET SRAM WRITE

In write operation also word lines are set to high voltage i.e. equal to Vdd=0.7 in our design of 6T FinFET SRAM cell. For writing "0" at node q , the bit lines are set to "0" and Vdd respectively. To write "0" at qbar, bit and bit bar lines are set to Vdd and "0" respectively.

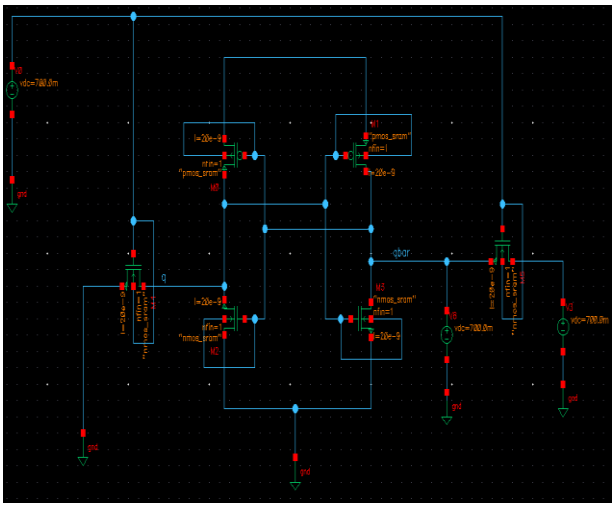

Figure 4: FinFET SRAM write circuit

IV. SIMULATION RESULTS AND DISSCUSSION

As we know power dissipation is one of the major issues which the modern electronic industry is facing these days. The density of chips is increasing day by day and simultaneously increasing power dissipation. Due to this cooling devices are inserted in chips which increase the cost. To overcome this problem FinFET devices can be used which reduce the power dissipation in digital logic circuits.

The parameters like power dissipation, propagation delay and power delay products are obtained for 6T FinFET static random access memory cell in hold, read and write condition.

The power dissipation has gained vital importance now a days due to the reason that as the technology is scaled, there occurs rise in leakage power dissipation to a large extent. The parameters of 6T FinFET SRAM cell at 7nm technology node obtained on cadence virtuoso tool using ASAP 7nm PDK are tabulated in table 1.

Table 1: Parameters of 6T FinFET SRAM cell at 7nm

Parameters of 6T FinFET SRAM cell	**HOLD condition**	**Read condition**	**Write condition**
Power dissipation (µW)	0.10	10.68	31.01
Propagation delay(pS)	11.02	12.8	13.98
Power delay product(aJ)	1.10	136.70	433.52

Besides other important parameter of FinFET SRAM cell i.e. static noise margins are also obtained as shown in figure 5.

The static noise margin curves for read and write are obtained. The static noise parameter is considered as one of the important parameters for FinFET memory design as well.

The static noise margin in 6T FinFET affects both write and read margins of FinFET memory and have a relation with threshold voltage of nfet (n type FinFET) and pfet (p type FinFET) as well, hence determines stability of SRAM cell. The static noise margin curves obtained are given in figure 5 and 6 for read and hold operation respectively.

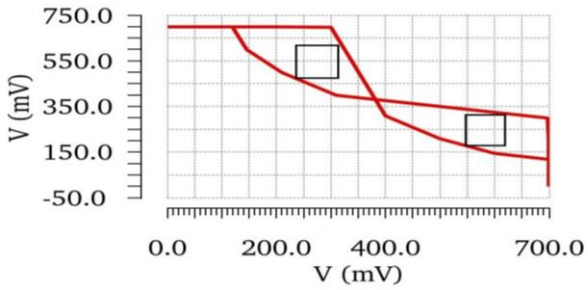

Figure 5: static noise margin for READ operation

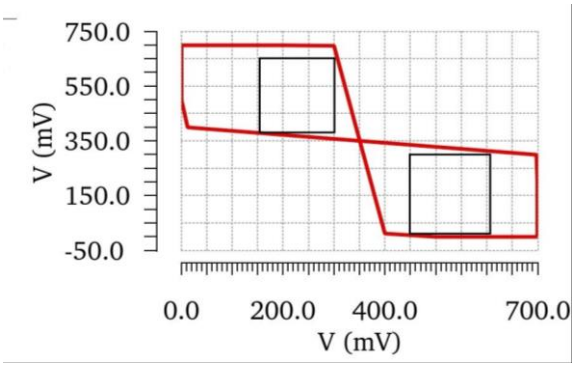

Figure 6: static noise margin for HOLD operation

The static noise margin obtained for hold condition of FinFET memory cell comes is obtained by taking the diagonal length of smallest square obtained from butterfly curves as shown in figure 5 and figure 6. For read and hold operation of 6T FinFET SRAM cell it comes out to be equal to 103mV and 205.06mV respectively.

V CONCLUSION & FUTURE SCOPE

For the minimum possible leakage power and better stability of static random access memory cell, it is preferred to design it with FinFET logic devices. The FinFET logic circuits have lower power dissipation and power delay products compared to complementary metal oxide semi-conductor devices. The various parameters for 6T FinFET SRAM cell are analyzed. In addition to this, stability in terms of static noise margin is analyzed which clearly depict better stability of 6T FinFET SRAM cells. This clearly make us understand that design of 6T FinFET SRAM cell at 7nm has better performance parameters in comparison to CMOS static random access memory cells.

Scaling down of FinFET less than 7nm is the new challenge for design engineers. The Fin height, length and with can be varied which also plays crucial role in determining functionality of logic design. Besides, parameter variation will be carried out to further improve performance of FinFET SRAM cells.

Abstract
The Digital era marked by the unparalleled growth of Internet and its services with day-to-day technological advancements has paved way for a data driven society. This digital explosion offers huge market value to organizations and business processes who gain valuable information from the collected data to promote futuristic decision making. The aftermath of this large scale analytics is the privacy breach of sensitive information of individuals. The confidential information of people is at a risk of disclosure when it is used for a purpose not intended. Not only should privacy techniques guard classified data, but also ensure that it does not weaken data value when considered for analytical purposes. The proposed work focuses on assessing the expediency of sanitized data for analytics, using a threshold based optimal strategy for improving anonymization with large data. Classification models are trained on the anonymized data using benchmark algorithms and its accuracy is determined. The work is extended to evaluate the performance aspects of the proposed technique on diverse parallel execution environments, Hadoop and Spark.

Keywords: Privacy Preserving, Spark, anonymization, MapReduce

I. INTRODUCTION

Security and Privacy are issues that are a cause of concern in the Digital era. With technological advancement being the norm of the day, data is divulged through many a source and used by organizations for economic benefit. Although regulations regarding privacy are being formulated within an organization's periphery, strict enforcement is a matter of debate, since there is no watchdog policy that ensures the correct use of the data collected. What appears as safe to an end-user may not be the case, in reality. Privacy preservation techniques have been a subject matter in the recent past, in the light of data proliferation from IoT devices and electronic media. These techniques throw light on the challenges that are required to be handled, to sustain quality of data while enforcing privacy. As a matter of fact, utility of data is an important aspect that needs to be considered if analytics should generate meaningful results. Achieving a trade-off between the two is demanding, given the fact that the scale of data is ever-increasing. There is a need for an all-encompassing solution that can handle scale, efficiency and usefulness, while upholding privacy.

The rest of the paper is organized as follows: Section II discusses the privacy scheme used in the paper, discussing the key characteristics of the technique to be considered for privacy enforcement. The section also highlights the processing framework, Spark, used for testing performance aspects of the privacy design in the context of Big Data. Section III defines the overview of the problem stating the objectives of the research. Section IV details the proposed methodology and workflow. Section V details the preparatory data groundwork, categorizing the privacy attributes. Section VI covers the results and discussion, Section VII discusses the related work and Section VIII concludes the paper.

II. BACKGROUND

A. Acronymns

AD	Anonymized Data
NAD	Non-Anonymized Data
AnonyOPT - k	Anonymized Optimal - k
LIL	Local Information Loss
GIL	Global Information Loss
s.t.	Subject to

B. Privacy Scheme

Anonymization is a technique of obscuring published data to prevent sensitive information from disclosure.[1] The parent of all anonymization privacy models, k-anonymity[1][2] is a group anonymization technique that tries to conceal confidential data by creating group of unidentifiable records that avoids the isolation of singular identity by grouping it with k other individuals. The algorithm categorizes the attributes in the dataset into three: sensitive attributes that are not public, but containing personal information of individuals such as salary, disease conditions etc.., quasi-identifying attributes which is a group of attributes that when collectively linked with publicly available data can identify an individual and identifying attributes that are uniquely associated with an individual. Although anonymization literature has shown that the technique fails to handle inference attacks [2] in poorly assorted data belonging to the same equivalence class [2], there are numerous works [2][3] which prove that it can be used as an efficient technique to handle high dimensional data in a context-aware premise.

C. Processing Engine

Spark is a fast in-memory cluster computing framework based on Hadoop MapReduce(MR)[4] capable of handling large workloads. While Spark uses the underlying HDFS[4] for storage, its clusters are utilized for parallel processing of data. Computing is done by creating Resilient Distributed Databases [4] that enables faster MR operations. Due to its in-memory computing it overcomes the slow data transfer associated with Hadoop's MR. The use of Spark data processing has been

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

found to be greatly efficient for processing large data streams, text, graph data and high dimensional tabular data. Spark can be integrated with many data querying and processing tools that can be integrated as a stand-alone environment or on a cluster based Hadoop platform.

III. PROBLEM OVERVIEW

A. Objectives

1. To evaluate the efficacy of optimized data anonymization on a data analytic functionality
2. To evaluate the performance improvement of the mining functionality on Apache Spark for Big Data

How does anonymization affect usefulness of data? Can it be used for an effective data analytic functionality in the context of Big Data? A clinical dataset has been used for the purpose. The clinical data is anonymized (AD), the data thus masked is then used for classification. The work evaluates the consequent variation that occurs in the accuracy of classification by comparing it with the classification accuracy on non-anonymized data.(NAD) In addition, the performance of the classification task on Hadoop and Spark is also determined. The parallelization of task on cluster based executing platform brings about significant rapidity in execution. Performance enhancement for large scale data processing is one of the key factors that can be exploited and leveraged in the context of Privacy Preserving Big Data processing. Data worth and performance with scale are challenging issues that have a wide scope of research in the Big Data era while not compromising privacy.

IV. PROPOSED METHODOLOGY

The proposed research goes through two phases of implementation as shown in Fig 1. In the first phase, the data is de-identified by applying the k-anonymity algorithm. This is a preliminary step in the preparation of the data for privacy preserving analytics. Although privacy literature [2] [3] cites a number of variations in the implementation of k-anonymity, the parent algorithm is still known to show convincing results [5] for privacy preservation in the context of Big Data. It is a group based strategy by which the algorithm creates group of anonymous records based on their similarity of certain attributes. The grouping is done by classifying attributes in the dataset into four types [1], sensitive, identifying, quasi-identifying and non-identifying. The identifying attributes are attributes that uniquely identify an individual and are generally removed before the data gets published for analysis. Quasi-attributes are a combination of one or more attributes, which in isolation may not cause privacy breach, but can be linked with publicly available data to identify a data subject. For instance, a voter database may have attributes such as zip code, which can be linked with personal information to zero in on an individual. Information such as disease condition, income etc...are sensitive attributes which are deemed personal and hence should not carry a risk of disclosure. k-anonymity groups data in such a way that the probability of an individual record being identified from the a set of k records is only 1/k. The value of k chosen depends upon the size of the dataset. Here the value of k is chosen optimally based on the general loss information obtained from anonymization. The privacy preserved data is used for classification task implemented using the classic benchmark algorithms such as ID3 and SVM. The results are found to be reasonable and of comparable accuracy with that of the non-anonymized counterpart. In the second phase, the classifiers' performance on Spark is assessed and the result is compared with that of Hadoop execution.

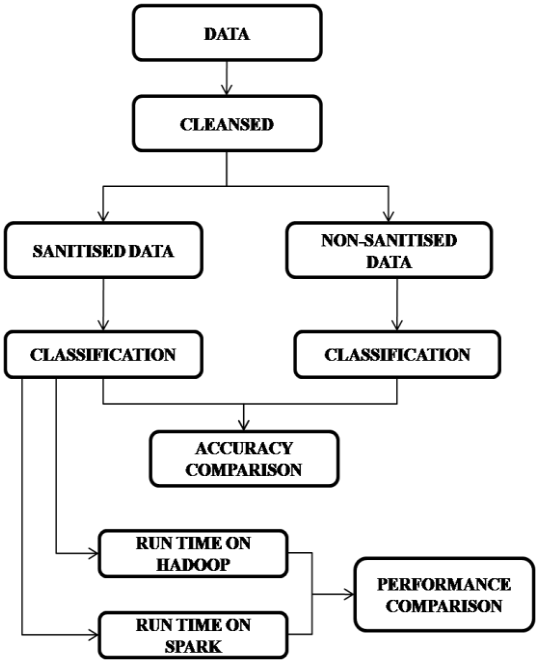

Fig 1 Proposed Workflow

A. Optimal Strategy for anonymity

a) Optimization Formulation

As literature reiterates[1], the choice of k greatly influences the trade-off between privacy and data worthiness. In this work, we propose an optimal algorithm for selecting k value based on the general information loss that occurs when data in a table T is divided into k-anonymous groups. The usefulness of data is prioritized in the formulation of the optimization problem. We call our proposed algorithm as AnonyOPT-k.

b) Definitions

1) Let S represent the total number of data subjects in the input set T, m represent the total number of attributes. The Generic Information Loss [3] is defined as follows:

$$GIL = \frac{1}{S * m} \sum_{i=1}^{S} \sum_{k=1}^{m} \frac{\beta_{ik}^{u} - \beta_{ik}^{l}}{\beta_{k}^{u} - \beta_{k}^{l}} \quad (1)$$

where β_{ik}^{u} and β_{ik}^{l} represent the limiting range of data, β_{k}^{u} and β_{k}^{l} represent the range value of any attribute k.

2) The selection of k is formulated as an optimization problem, considering the following objective function [6]

Maximize 'k' s. t. inequality constraint

$$GIL(T) <= \alpha \quad (2)$$

with range constraint

$$k_l \leq k \leq k_u \quad (3)$$

In Eq. 2, α is the predefined threshold, set for acceptable information loss prioritizing data worth over privacy. The algorithm is repeated for different random seed values of k limited by the range 100-500 as specified in Eq. 3

B. Algorithm AnonyOPT -k

2. Repeat until
   a. Generalize the quasi-group and suppress the sensitive attribute using k //Split T into k groups
   b. Calculate LIL for every group
   c. Calculate GIL for T
   d. Increment k

   GIL <= α
3. return k

V. DATA GROUNDWORK

A. Essential Requirements

A clinical dataset has been used for implementation. The data has more than one lakh instances with 24 attributes, containing both categorical as well as numerical attributes. As a preparatory step, data is first checked for missing values and inconsistencies. Numerical data is normalized in order to reduce noise, missing values in categorical data is filled with frequently occurring values. The categorical data are adaptively discretized to facilitate privacy quantification.

B. Privacy Qualifying Attributes

The identifying attribute in the data, patient-id is eliminated, and the disease condition is assumed sensitive. The race, gender, age, occupation, and zipcode attributes are categorized into quasi-group. Generalization is applied to the quasi-group and the data instances are grouped into k-anonymous groups. The disease condition is suppressed to protect sensitivity. Initially, the value of k is chosen randomly, limited by the range constraint of the problem formulation. The upper and lower bounds are assumed for the data under the assumption that the data size and k follow an inverse linear relationship. An optimal value of k is chosen using our proposed AnonyOPT – k, varied at each stage to experiment the change in the level of accuracy of classification task.

VI. RESULTS AND DISCUSSION

The results were considered from two perspectives. Firstly, the usefulness of sanitized data was quantified based on the accuracy of the classifiers on the anonymized data. Results indicate that anonymization technique can be used for privacy preservation, provided an optimal strategy is applied to choose k value. An arbitrary choice of k does not give good results for large data due to the diversity of attribute values. The optimal selection of k using our AnonyOPT – k was found to give reasonable accuracy. Secondly, the execution performance of the technique is evaluated on MapReduce based execution environments, Hadoop and Spark. Results clearly showed that significant performance enhancements are realizable with the in-memory computations of Spark in comparison to Hadoop, both of which are based on MapReduce.

A. Utility of data

The benchmark classification techniques such as Decision Tree and SVM were used to evaluate the usefulness of the transformed data. These results were then compared with the non-anonymized counterpart to assess the variation in the classification accuracies due to the privacy constraints. As shown in the figures [2][3][4][5], anonymization can be used for imposing privacy restrictions, albeit a degree of reduction could be observed in the classification accuracy. The accuracy of the classifiers were checked for differing and increasing sizes of data. The accuracy of classifier was found to reduce as the value of k was increased as shown in figure[6]. A larger value of k minimizes the possibility of an individual record being identified, but reduces the value of data, directly reflected in the reduced accuracy of the classifier. The choice of k is directly proportional to the level of privacy and hence the information loss, and affects data quality that is essential for analytical purposes. In order to bring a balance between the two, AnonyOPT-k followed a threshold based approach so that loss can be kept at check. A threshold of 0.3 for generic information loss was assumed, which helped maintain the usefulness of data. Further increase of k augmented loss. The algorithm was tested with different random seed values for k and experimented for classification accuracy. The data sizes were also gradually increased for testing the effectiveness of the classifiers on AD along with optimal selection for k.

B. Performance

The classification task on anonymized data was tested on Spark to measure speed of execution for increasing data sizes. The results showed that Spark's use of RDD speeded up execution through parallel MapReduce computing in contrast to its equivalent execution on Hadoop. The implementation was optimized using the Dataset API and hence improved the computation speed

of iterative processing required for most of the machine learning tasks. Figure [7] shows the execution time difference between the two environments. For the purpose of testing, initially the experiments were conducted on Hadoop with the cluster environment set in a pseudo-distributed mode. Next, the experiments were carried out on Spark with data on HDFS, and execution on Spark. The task was repeated with Spark set up in stand-alone mode. Stand-alone Spark execution and HDFS based Spark execution did not create much differences in the execution time. The partitioning and splitting of processing into stages was found to vary with expansion in data sizes.

VII. RELATED WORK

A vast history of research exists for privacy preserving analytics, primarily classifying work into privacy preserving data publishing [2][3] and privacy preserving data mining [2][3]. A number of privacy techniques have been studied in literature, k-anonymity[1], l-diversity[7], t-closeness[8] and differential privacy[9] being the major ones. Variations of k-anonymity [10] have been discussed, that detail the need to overcome linkage attacks, possible due to linking data with publicly available databases. Although k- anonymity is cited in literature as a poor handler of large data, causing high information loss, the large crowd effect [11] of Big Data is a strong reason to believe that this notion could be proved otherwise. The hindering fact is the optimal choice of k. The value of k chosen largely determines the level of privacy and hence the information loss. The work in [5] uses anonymity to mask large web logs and shows that analytics on such large data can produce acceptable level of correctness. The large crowd effect [11] of Big Data is a fact that can be considered in analyzing the effectiveness of anonymization algorithms for large-scale data. Numerous works has been carried out using k –anonymity as the basic algorithm for privacy preservation, along with MapReduce based computing. The MapReduce based parallel computing platform Hadoop has been used in a number of research innovations for splitting data and working in groups to speed up data execution. The distributed data processing of Big Data using MapReduce gives better performance in terms of scalability as well as speed. The data is uploaded to Cloud, and privacy techniques work on data in the presence of assumptions on the possible attacks on the Cloud Environment. Recent work in anonymization based privacy preservation has focused on improving its effectiveness, by testing heuristic techniques for k value selection. A greedy approach [12] has been used to make an optimized selection, without considering the performance factors. Various techniques of optimization have been tried in order to balance privacy-utility trade-off by using evolutionary [15] algorithms that works on the principle of genetic mutation [15] that works iteratively to arrive at a suitable value of k. Recent work by [16] splits data into homogenous groups, visualizing the data as graphs. It follows a heuristic algorithm [16] that is based on minimum cost flow algorithms. [13] has showed that Spark can be used to improve performance of anonymization due to the use of Resilient Distributed Databases [14]. Anonymization on Spark[13] has been tested on large data of varying sizes and its found that Spark scales well in performance over Hadoop. Algorithms can be fine tuned by using high performance computing techniques that can cater to the Big data technological demands. Spark can also be used with Hive[17] for large scale data querying over millions of instances, and it can be seamlessly integrated with any structured databases.

VIII. CONCLUSION

Large-scale analytics with the onset of Big Data and IoT paradigm is the norm of the day. Useful analytics on data has far-fetched benefits that can be put to advantage in a number of ways for futuristic decision making. But on the downside, lot of personal data is used in the bargain. Hence sensitive information of individuals is disclosed and used for unwarranted reasons. To keep privacy at check and still stride forward with useful analytics in the Big Data era, effective techniques are required that can handle scale and performance. The investigation in this paper firstly uses the classical anonymization algorithm for imposing privacy that is optimized for bounded information loss. Thus the technique prioritizes utility for privacy although reasonably. Secondly, benchmark algorithms are used to train and build classifiers, whose accuracy claim the quality of data. Lastly, the performance of the technique is experimented on parallel execution environments to handle speed of computation. In conclusion, the work suggests that ever growing data sizes require robust algorithms, associated with high performance computations to withstand the growing demands of the digital revolution.

***Abstract*—In the present work, we propose an optically controlled graphene field effect transistor (OC-GFET) structure where saturation can be attained at lower supply voltage of the order of 1 V. It is compared to present GFET structures using only electrical bias which reaches saturation by using higher supply voltages. The optically induced mobility for the OC-GFET, of the order of 10^5 cm^2/V-s on h-BN substrate allows it to achieve higher current at the aforesaid bias voltage level. An extrinsic timing analysis is carried out and the OC-GFET is found to have a response time of the order of 10 ps and a bandwidth of the order of 60 GHz.**

***Index Terms*—Field effect transistor (FET), mobility, response time, bandwidth**

I. Introduction

The growing need for increased data and process capability has led to the development of advanced electronic systems equipped with complex architectures. The operating frequency designed for the state-of-the-art ICs is in the order of 10^9 Hz. This is devised to cater to the requirement of the on-chip operation bandwidth for high-performance multiprocessor systems [1]. In pursuit of faster ICs a quest for a material with faster response time escalated the interests of researchers towards graphene [2].

Graphene is ideally a one atom thick 2D layer of carbon with a very high mobility, thermal conductivity, optical responsivity and ambipolar transfer characteristics [3]. These properties of graphene can enhance the applications of GFET devices in analog electronics and spintronics [4], [5]. Graphene has extraordinary electronic and optical characteristics and studies have suggested it to be a potential replacement for silicon-based optoelectronic devices [6]–[8].

GFETs are used in electronic sensing applications, non-volatile memory devices and analog RF circuits [9], [10]. Its excellent optical properties provide flexibility in designing highly sensitive photo-detectors [11], electromagnetic wave shields [12] and waveguide polarizers [13]. Graphene has been able to prove its significance in only a handful of digital logic circuit applications, although it has been envisaged for logic circuits for desirable GFET applications [14]. Due to negligible band gap, these devices show low on-off current ratio [15] which does not allow them to achieve saturation region, essential to determine logic '1' in a digital logic circuit [16], [17].

The intrinsic mobility of graphene at room temperature is of the order $2 \times 10^5 \mathrm{cm}^2/V - s$. The effect of scattering due to mismatch in lattice symmetry between graphene and silicon (Si) substrate on electrical biasing limits the mobility of GFET devices thus exhibiting a mobility of the order of $10^3 \mathrm{cm}^2/V - s$ [18]. This decrease in mobility enables GFETs to reach from cut-off region to linear region but fails to attain saturation region even with the industry standard input voltage ranges (1.8-3.3 V) [19], [21]. A perfect cut-off point is also not achieved in GFETs, because graphene has negligible bandgap, but in the present work the attainment of the saturation region is addressed.

In this theoretical work a laser beam of 1550 nm is modelled on the graphene channel of a dual-gated GFET. A comparative analysis is made between the proposed optically controlled GFET (OC-GFET) and conventional electrically biased GFETs (see figure 1(a), (b)) on the performance criteria like saturation velocity attainment voltage, bandwidth and response time. A drain-source voltage (V_{DS}) of around 1 V is required for OC-GFET (see device structure in figure 1(c)) to reach saturation region in contrast to 7 V for an electrically biased GFET [20]. In all the present work endeavours to test the applicability of graphene in FET structure for digital applications. A method of charged impurity scattering into the graphene layer to obtain saturation velocities is reported [22]. However in the present work, we report attainment of saturation around V_{DS} = 1 V by using 1550 nm light incident on intrinsic graphene channel which makes fabrication easy.

II. Device structure

We consider a dual-gated GFET of length (L) and width (W) $1\mu m$, respectively as shown in figure 1(a),1(b) [20]. The top-gate oxide and the back-gate oxide are both made of SiO_2. The thickness of the former (t_{oxt}) is 4 nm whereas that of the latter (t_{oxb}) is 300 nm. The substrate for both the devices as shown in figure 1(a), 1(b) is made of Si. The

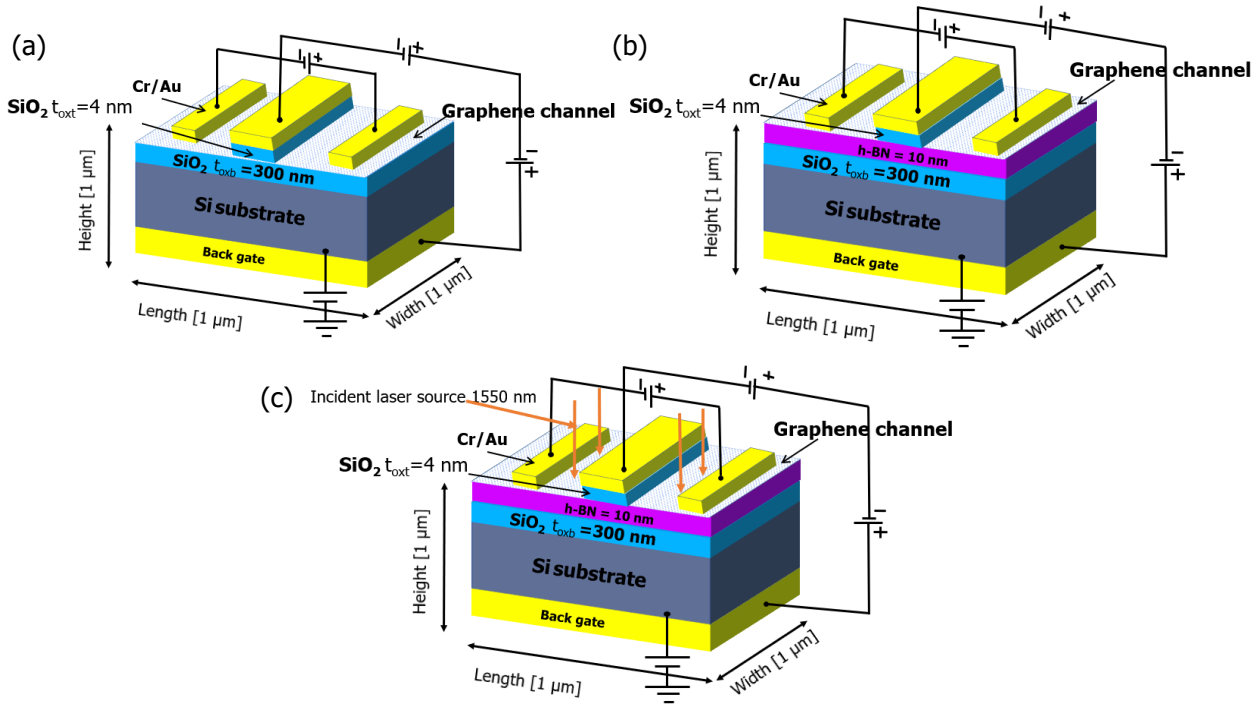

Fig. 1. (a) Schematic of $1\mu m$ electrically biased dual-gated G/SiO_2/Si FET (b) Schematic of $1\mu m$ electrically biased dual-gated G/h-BN/Si FET with graphene on $10nm$ h-BN sheet as channel (c) Schematic of $1\mu m$ dual-gated G/h-BN/Si FET with graphene on 10 nm h-BN sheet as channel and an incident laser source of 1550 nm is modelled on the channel

top-gate, back-gate, and the drain source electrodes are made of Cr/Au. Graphene channel is in direct contact with SiO_2 as shown in figure 1(a) for which it is named as G/SiO_2/Si FET. In figure 1(b) it is shown that graphene channel is in contact with h-BN of thickness 10 nm and is named as G/h-BN/Si FET. Both the FET devices are biased electrically.

1) Electrical characteristics for GFET modeling: A graphene channel has a net mobile sheet charge density (assuming hole conduction) responsible for generation of drain current (I_{DS}) [20] for both G/SiO_2/Si and G/h-BN/Si FETs. The expression for an electrically biased graphene channel potential (V_{ch}) (see equation (1)) is found using Kirchhoffs Laws [18].

$$V_{ch} = \frac{-(V_{GS} - V_{GS0} - V)C_t + (V_{BS} - V_{BS0} - V)C_b}{C_t + C_b + aC_q} \tag{1}$$

where V_{GS} and V_{BS} are top and back-gate source voltages. V_{GS0} and V_{BS0} are the top- and back gate voltages at which I_{DS} reaches minimum. V is the voltage across channel considered as 1 V. C_t and C_b are the top and back gate capacitances. The parameter a is defined as capacitance weighing factor which is 0.5 in this work. The value of quantum capacitance (C_q) is obtained by using V_{ch} value of 0.0034 V (found when V_{GS} and V_{BS} are biased at 0 V) [20] .

2) Drain-Current Model : The effective mobilities (μ_{eff}) at 300 K which is 1125 $cm^2/V-s$ [20] for G/SiO_2/Si/Si and 40000 $cm^2/V-s$ [23] for G/h-BN/Si/Si are substituted in the drain-diffusion model based current equation shown in expression (2) [13], [16] to estimate their respective transfer and output characteristics.

$$I_{DS} = \frac{W\int_0^{V_{DS}} \mu Q_{tot} dV}{L + |\int_0^{V_{DS}} \frac{\mu}{v_{sat_{opt}}}|} \tag{2}$$

where v_{sat} is equated and shown in equation (3) as:

$$v_{sat} = v_F(\frac{e}{1 + fV_{ch}^2} + g) \tag{3}$$

The fitting parameters e, f and g are used from the previously obtained calculations [20].

A. Transfer/Output characteristics for verification

The transfer characteristics (I_{DS} vs V_{GS}) for G/SiO_2/Si FET (refer figure 1(a)) are calculated by varying V_{GS} from -5 V to 5 V for every constant value of drain-source voltage V_{DS} (0.05 - 0.2) V as shown in figure 2(a). The carrier mobility for this device is 1125 $cm^2/V-s$ [20]. The I_{DS} calculated is of the order of $10^{-3}A$.

The output characteristics (I_{DS} vs V_{DS}) shown in figure 2(b) for G/SiO_2/Si FET are calculated by varying V_{DS} from (0-7) V for every V_{GS} (0-4) V. The obtained I_{DS} is of the order of $10^{-3}A$. The device reaches saturation region when V_{DS} applied is 7 V. The obtained I_{DS} is of the order of $10^{-3}A$. A detailed analysis of the I_{DS} vs V_{DS} characteristics for G/SiO_2/Si FET are explained and shown in figure 6(a).

The obtained I_{DS} vs V_{GS} characteristics for G/h-BN/Si FET

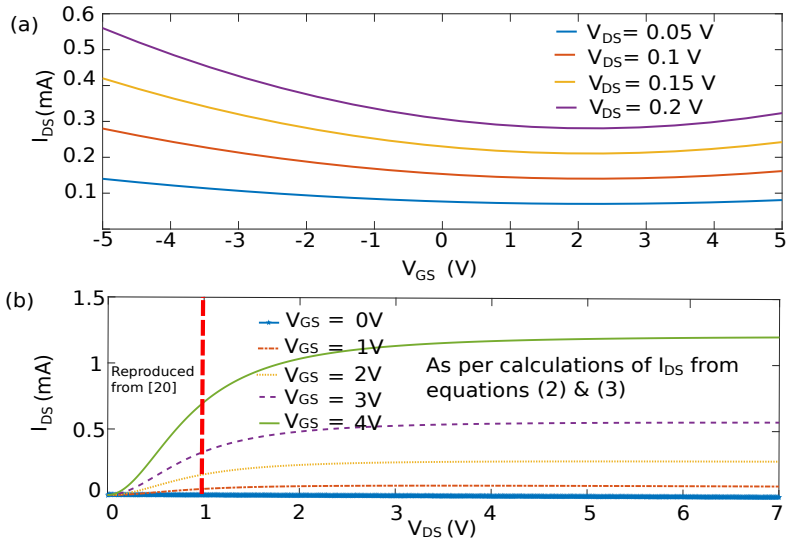

Fig. 2. (a) Transfer characteristics of 1 μm dual gated electrically biased G/SiO_2/Si FET for varying V_{GS} from -5 to 5 V for every V_{DS} ranging from (0.05 - 0.2) V, t_{oxt}= 4 nm, t_{oxb} = 300 nm, T = 300 K, V_{GS0} = 1.1 V, V_{BS0} = 11 V, V_{BS} = 5 V, V_{BS} = 5 V, V = 1 V, m = 0.1 V^2, Δ = 92 meV, μ_{eff} = 1125 cm^2/Vs. (b) Output characteristics of a 1 μm dual gated electrically biased G/SiO_2/Si FET exhibiting the saturation region it attains by applying V_{DS} of 7 V.

are estimated by the same method but the achieved I_{DS} is of the order of 20 mA at V_{GS} -5 V for V_{DS} at 0.2 V and is shown in figure 3(a). The I_{DS} is higher compared to the G/SiO_2/Si FET.

The I_{DS} vs V_{DS} characteristics calculated by the same method as described in sections II(1), II(2) are shown in figure 3(b). It is observed that the G/h-BN/Si FET reaches saturation state on applying V_{DS} of 2 V in contrast to V_{DS} of 7 V used by G/SiO_2/Si to attain saturation. The graphene channel on h-BN has μ_{eff} value 40000 $cm^2/V-s$ [23] which is far higher compared to graphene channel on SiO_2 which has μ_{eff} of 1125 $cm^2/V-s$. On applying V_{DS} of 1.3 V G/h-BN/Si FET can reach saturation region faster than G/SiO_2/Si FET.

III. Effect of Incident Light on Conductivity and Mobility

The optical conductance that occurs as a result of $\pi-\pi^*$ transitions for graphene are mathematically represented by equation(4) [24].

$$\sigma_{\pi-\pi^*} = \sigma_{r1} + i\sigma_{i1} \tag{4}$$

We approximate $\sigma_{\pi-\pi^*} \sim \sigma_0$ (for wavelengths of visible spectrum which doesn't influence the optical conductance [24]) and create universal optical conductance of graphene, identical to conductance of graphene that occurs due to $\pi-\pi^*$ transitions. The intrinsic conduction in graphene is represented by equation(5) [25].

$$\sigma_0 = (\frac{\pi}{2}).(\frac{e^2}{4\hbar}) = \frac{e^2}{4\hbar} \sim 6.08.10^{-5}\Omega^{-1} \tag{5}$$

The term σ_0 (see equation (5)) is the real part of the expression (10) and has minimum conductivity ($6.08.10^{-5}\Omega^{-1}$) at charge neutrality point and is neglected. The imaginary part of the conductivity as shown in equation (4) contributes to the electron transportation in graphene and is expressed in equation (6) [24], [26].

$$\sigma(\omega) = -i\epsilon_r(\omega)\epsilon_0\omega d \tag{6}$$

Here ϵ_0 is the permittivity of free space, ω is frequency of the incident light, d is the thickness of monolayer graphene which has a value of 0.34 nm. The relative permittivity is obtained from the expression (7) [24].

$$n + ik = \sqrt{\epsilon_r(\omega)} \tag{7}$$

The values of refractive indices (r.i.) of a monolayer graphene for the wavelength range (0.2 to 3.5) μm were reported in [24], and are used to calculate $\sigma(\omega)$. The μ_{eff} of a monolayer graphene for corresponding wavelengths $(0.2-3.5)\mu m$ is obtained from expression (8) and is shown in figure 4. The μ_{eff} at 1550 nm is found to be $1.06\times10^5 cm^2/V-s$ (marked by the red dotted line) and the r.i. is found to be 50+50.68i.

$$\mu_{eff} = \frac{\sigma(\omega)}{ne} \tag{8}$$

Here e is the elementary charge and n is the number of charge carriers in the monolayer graphene channel taken as $(6.2\times10^{11} cm^{-2})$.

1) Device structure of OC-GFET: A G/h-BN/Si device of the same device parameters as shown in figure 1(c) is chosen staying consistent with the electrically biased G/SiO_2/Si and G/h-BN/Si FET. It is named OC-GFET, where the graphene channel is on a 10 nm h-BN layer [23]. The choice of interacting layer is considered as h-BN, since it has reported to have achieved a higher μ_{eff} of the order of 60000 $cm^2/V-s$ at 2

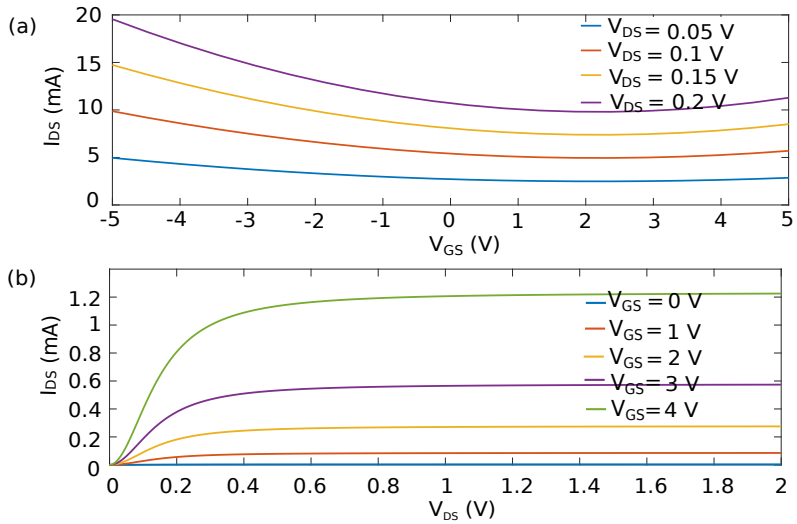

Fig. 3. (a) Transfer characteristics of 1 μm dual gated electrically biased G/h-BN/Si FET for varying V_{GS} from -5 to 5 V for every V_{DS} ranging from (0.05 - 0.2) V, t_{oxt} = 4 nm, t_{oxb} = 300 nm, T = 300 K, V_{GS0} = 1.1 V, V_{BS0} = 11 V, V_{BS} = 5 V, V_{BS} = 5 V, V = 1 V, m = 0.1 V^2, Δ = 92 meV, μ_{eff} = 40000 cm^2/Vs. (b) Output characteristics of a 1 μm dual gated electrically biased G/h-BN/Si FET exhibiting the saturation region it attains by applying V_{DS} of 2V.

K [23]. In this FET a laser source of 1550 nm is modelled on the graphene channel to generate a number of photogenerated carriers as shown in figure 1(c). Due to presence of modulated potential step throughout the graphene channel sheet, the incident laser source does not contribute to generation and transport of photocurrent equally in the channel. However photocurrent due to incident laser beam intensity shows linear dependence due to presence of electrostatic potential steps at the contacts. Such a situation is termed as contact edge effects in OC-GFET which generates a photovoltage of 2 mV [27]. The incident photons on the electrodes will generate less photocurrent compared to graphene channel due to higher resistance of Cr/Au. In this scenario incident photons due to input optical power (P_{opt} result) in a photovoltage (V_{ph}) on the channel as formulated in equation (9) [1].

$$V_{ph} = -0.021 \times ln(P_{opt} - 0.54) \tag{9}$$

As a consequence the μ_{eff} of the graphene channel is found to be $1.06 \times 10^5 cm^2/V - s$ as mentioned in the previous section. A question may arise that the graphene on h-BN interaction may cause scattering in the channel thus reducing the μ_{eff}. However the μ_{eff} is determined from r.i. of monolayer graphene, neglecting the effect of the substrate [24].

A. Channel Potential change due to modelling of Light on the Channel

On the basis of the effect of incident light according to the experimental work [1] on V_{ch} as in literature [27], in the present work it has been assumed that the V_{ph} has an additive effect on the V_{ch}. Hence V_{ph} affects the potential of

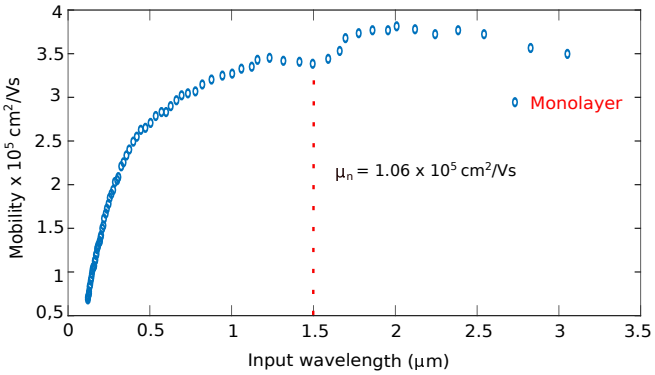

Fig. 4. Input wavelengths ranging from (0.2 to 3.5) μm vs effective carrier mobility μ_{eff} for a monolayer graphene channel.

the electrically biased graphene channel as shown in equation (10). It is a modification to equation (1) with the establishment of V_{ph}.

$$V_{ch_{opt}} = V_{ch} + V_{ph} \tag{10}$$

The effect of $V_{ch_{opt}}$ influences the v_{sat} and is expressed in equation (11):

$$v_{sat_{opt}} = v_F(\frac{e}{1 + fV_{ch_{opt}}^2} + g) \tag{11}$$

which is essential for calculating I_{DS} for OC-GFET.

B. Output characteristics of OC-GFET

The I_{DS} vs V_{DS} characteristics for OC-GFET are obtained by keeping a constant λ at 1550 m anda constant P_{opt} of 10 μW. V_{DS} is varied from (0-1) V for every V_{GS} ranging from (0-4) V. It is evident from figure 5(a) that the device achieves

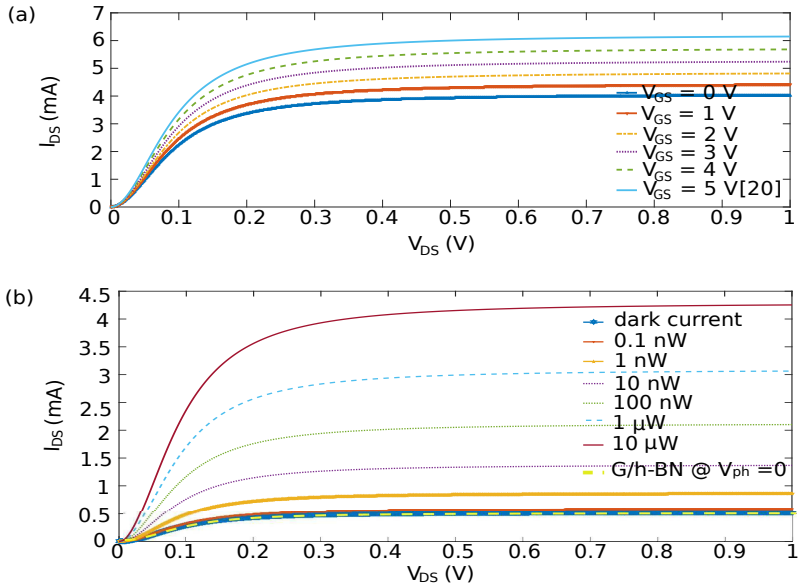

Fig. 5. (a) Output characteristics of 1 μm dual-gated OC-GFET for P_{opt} at 10 μW, t_{oxt} = 4 nm, t_{oxb} = 300 nm, T = 300 K, V_{GS0} = 1.1 V, V_{BS0} = 11 V, V_{BS} = 5 V, V_{BS} = 5 V, V = 1 V, m = 0.1 V^2, Δ = 92 meV, μ_{eff} = 1.06×$10^5 cm^2/V-s$ when light of wavelength λ = 1550 nm is modelled on the channel with V_{DS} varying from (0-1) V for every value of V_{GS} ranging from (0-4) V .(b) Output characteristics of a 1 μm dual-gated OC-GFET for V_{GS} at 0.6 V, t_{oxt} = 4 nm, t_{oxb} = 300 nm, T = 300 K, V_{GS0} = 1.1 V, V_{BS0} = 11 V, V_{BS} = 5 V, V = 1 V, m = 0.1 V^2, Δ = 92 meV, μ_{eff} = 1.06×$10^5 cm^2/V-s$ when light of wavelength λ = 1550 nm is modelled on the channel with P_{opt} as 0.1 nW, 1 nW, 10 nW, 100 nW, 1 μW, 10 μW.

saturation by applying V_{DS} of 1 V. The I_{DS} obtained is of the order of $10^{-3}A$. The achieved I_{DS} for V_{GS} = 5 V (see figure 5(a)) is in close agreement with the results as in [20] for a μ_{eff} value of $1.15 \times 10^5 cm^2/V-s$. Hence the output characteristics of OC-GFET are deemed to be sufficient.

In figure 5(b) the I_{DS} vs V_{DS} characteristics are presented by keeping V_{GS} constant at 0.6 V, λ at 1550 nm and P_{opt} is varied from dark current to 10μW. In this case also the saturation is reached within applied V_{DS} of 1 V. The calculated I_{DS} is of the order of $10^{-3}A$. The reason OC-GFET achieves saturation on applying 1 V is due to its achieved optically induced mobility which is $1.06 \times 10^5 cm^2/V-s$. The I_{DS} vs V_{DS} characteristics were recalculated in terms of G/h-BN/Si FET (see section 2(c)) with V_{GS} as 0.6 V and has been compared with V_{GS} = 0.6 V when V_{ph} = 0 V. Intuitively with no modelled light source on the graphene channel, the OC-GFET should behave like an electrically biased G/h-BN/Si FET. Therefore the output characteristics marked by the yellow dotted lines of G/h-BN/Si FET overlap with the blue line (dark current) of the OC-GFET as shown in figure 5(b).

IV. Comaprison of FETs

This section compares the 3 types of GFETs based on their requirement of V_{DS} values to attain saturation velocity. This also comprises of the comparison based on the response time and bandwidth for each of these devices.

A. Fast attainment of saturation velocity

It is evident from the sections II and III that OC-GFET has the μ_{eff} of 1.06×$10^5 cm^2/V-s$ whereas G/SiO_2/Si and G/h-BN/Si FETs have μ_{eff} values of 1125 $cm^2/V-s$ and 40000 $cm^2/V-s$ respectively. This proves that a FET device with higher μ_{eff} attains saturation velocity, and subsequently the saturation region with less drain-source supply voltage (V_{DS}). The G/SiO_2/Si continues to show a linear behaviour when the applied V_{DS} is 1 V (see figure 6(a)), but it reaches the saturation state on applying a V_{DS} of 7 V as shown in figure 2(b). On the other hand a G/h-BN/Si FET does not attain complete saturation state on applying V_{DS} of 1 V, it attains saturation for the V_{GS} values ranging from (0-3) V, on applying a V_{DS} of 0.73 V, shown by the red dotted lines in figure 6(b). It attains complete saturation on applying V_{DS} of 2 V as shown in figure 3(b). In the case for an optically induced mobility in a monolayer graphene channel, the OC-GFET attains the saturation region with a V_{DS} of 1 V as shown in figure 6(c). For all V_{GS} values ranging from (0-5) V it attains the saturation region on applying a V_{DS} of 0.62 V which is indicated by red dotted lines in figure 6(c). It is inferred from figure 6(c) that saturation has been attained (at V_{DS} = 0.62 V) by using light on pure graphene without any material alteration. However, it can be seen that perfect cut-off is not obtainable. Hence, GFET structures may not be advisable for switching, but for high power applications and RF circuits it shows outstanding performance. Heterostructure variations like graphene/MoS_2/h-BN (G/MoS_2/h-BN) [28] may be tried with light illumination for simultaneous fast saturation attainment and cut-off achievement.

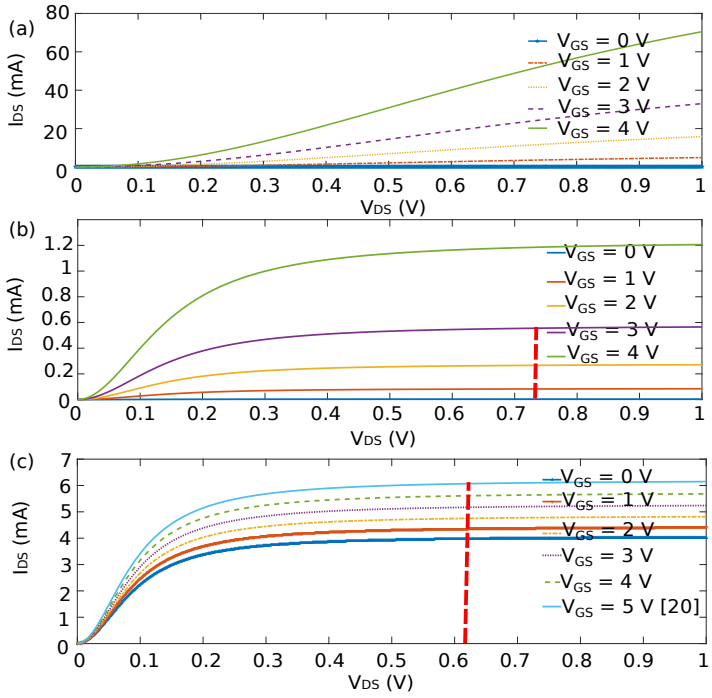

Fig. 6. (a) Output characteristics of a G/SiO_2/Si FET where V_{DS} ranges from (0-1) V for every value of V_{GS} ranging from (0-4) V, the FET exhibits linear behaviour on applying V_{DS} - 1 V (b) Output characteristics of a G/h-BN/Si FET where V_{DS} ranges from (0-1) V for every value of V_{GS} ranging from (0-4) V, the FET reaches saturation region for V_{GS} ranging from (0-3) V correspondingly marked by red dotted lines till V_{GS} of 3 V (c) Output characteristics of a OC-GFET where V_{DS} ranges from (0-1) V for every value of V_{GS} ranging from (0-4) V, the FET reaches saturation region at V_{DS} - 0.62 V marked by red dotted line

B. Extrinsic timing analysis of GFET, OC-GFET and OCFET

The timing analysis is fundamentally characterized by the response time of FET devices. Response time for FETs is measured by rise time (τ_r) and fall time (τ_f) of the output pulse with respect to the given input pulse [29]. It is inversely proportional to the average current (I_{mean}) during the transition of voltage. The power supply (V_{DD}) for all the devices is considered to be 2 V. It is inversely proportional to the average current (I_{mean}) during the transition of voltage. The power supply (V_{DD}) for all the devices is considered to be 2 V. The load capacitance (C_{load}) and load resistance (R_{load}) are connected to the drain electrode from where the output voltage V_{out} is measured. The external load added to all the devices and the output measured from the load at the drain electrode gives the extrinsic timing analysis for the devices. In this work to perform extrinsic timing analysis for the devices R_{load} of 10 $k\Omega$ and C_{load} of 1 pF [29] are chosen. The higher I_{mean} in a device will represent faster rise and fall time compared to a device with lower I_{mean}. It clearly suggests that I_{mean} for OC-GFET in this case has I_{mean} of the order of $10^{-3}A$ in contrast to an optically controlled MOSFET (OCFET) with Ge gate and Si channel [1] which has I_{mean} of the order of $10^{-6}A$. Carrying forward from intrinsic timing analysis of OCFET [1], an extrinsic timing analysis was performed on the same using R_{load} of 10 $k\Omega$ and C_{load} of 1 pF [29]. The τ_r of the OCFET is found to be 4.95 * 10^{-8}s.

While comparing the response time for all the four devices it is found that the OC-GFET has τ_r and τ_f of the order of 10^{-11} s, G/h-BN/Si FET shows τ_r of 1.4*10^{-10} s, G/SiO_2/Si FET bears τ_r of 5.2*10^{-10} s, whereas OCFET delivers τ_r in the order of 10^{-8} s.

When a V_{in} with τ_r and τ_f of 5 ps (see figure 7(a)) is applied to all the FETs, the output voltage V_{out} is observed with respect to time (ps). In figure 7(b), the V_{out} for an ideal inverter is observed at 0.1 ps, where it follows the V_{in} pulse exactly i.e. V_{out} is OFF when V_{in} is ON and vice-versa. In figure 7(c) an OC-GFET observed at 0.1 ps as marked by the red dotted line only shows one V_{out} pulse when already two V_{in} pulses have passed by. It has the τ_r of 6*10^{-11} s which is the fastest among all the other FETs but $\sim$ 10 times slower than input pulse. In figure 7(d,e) the G/h-BN/Si and G/SiO_2/Si FETs observed at the same time 0.1 ps display only the rising half of the V_{out} pulse. However G/h-BN/Si FET (τ_r - 1.4 * 10^{-11} s) is faster than G/SiO_2/Si (τ_r - 5.2 * 10^{-11} s) because of its higher current carrying capability. At 0.5 ps it is clearly demonstrated that G/SiO_2/Si FET is lagging behind the G/h-BN/Si FET (marked by blue dotted line). An OCFET inverter [1] (τ_r - 4.95 * 10^{-8} s) is illustrated in figure 7(f) and it is almost $\sim$ 10^3 times slower than the OC-GFET. At 1 ps the output pulse is very relaxed and only the rising half of the pulse is visible.

Faster response time in photodetectors lead to higher bandwidth (BW) capability which is expressed by the relation (12).

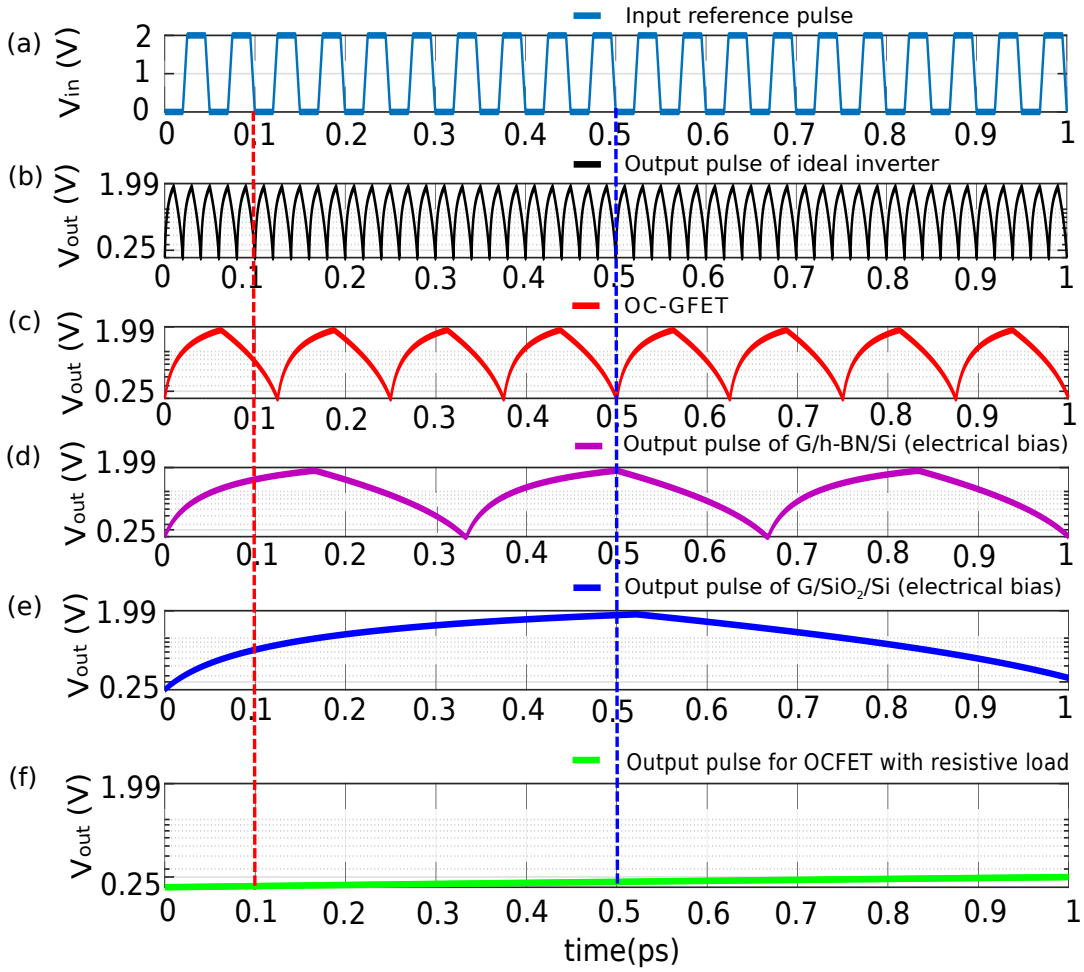

Fig. 7. Timing analysis of FET with devices respect to voltage with resistive load resistance $R_L = 10k\Omega$, load capacitance C_{load} = 1 pF (a) Input reference pulse in $picoseconds(ps)$ (b) Output reference pulse of an ideal inverter (c) Output pulse of OC-GFET with τ_r and τ_f as 60 ps, P_{opt} =10 μW (d) Output pulse of electrically biased G/h-BN/Si FET with τ_r and τ_f as 1.4 * $10^{-10}s$ (e) Output pulse of electrically biased G/SiO_2/Si FET with τ_r and τ_f as 5 * $10^{-10}s$ (f) Output pulse of OCFET [1] with τ_r and τ_f as 4.95 * $10^{-8}s$.

TABLE I
COMPARATIVE RESULTS OF FETS

Device Name(FET)	Supplied V_{DS}(V)	τ_r(s)	BW(Hz)
G/SiO_2	7	5.2*10^{-10}	1.4*10^9
G/h-BN/Si	2	1.4*10^{-10}	5*10^9
OC-GFET	1	6*10^{-11}	1.25*10^{10}
OCFET	-	4.95 * 10^{-8}	5.8*10^7

A high performance FET exhibits an enhanced BW due to its faster response time. A faster τ_r results in higher BW.

$$BW = \frac{0.35}{\tau_r} \tag{12}$$

The performance parameters for all the graphene based FET devices and OCFET are enumerated in table I.

Intuitively it may be argued that OCFET has similar attainment properties in terms of V_{DS} values in order to attain a saturation region faster. However a comparison of τ_r and BW between OC-GFET and OCFET as shown in table I suggests that OC-GFET may outperform an OCFET by an order of 10^3 in performances of both τ_r and BW. It may be noticed that experimental values of I_{DS} for an OCFET are in order of $10^{-6}A$ [1] while graphene based FETs show a possible range of $10^{-3}A$ at similar V_{DS} ranges.

V. CONCLUSION

In this work an OC-GFET with a drain-source supply voltage of 1 V and an incident laser source of 1550 nm reaches saturation in comparison to G/SiO_2/Si and G/h-BN/Si FETs which requires 7 V and 2 V respectively. The extrinsic timing analysis determined in this work establishes that the response time for OC-GFET is of the order of $10^{-11}s$ and bandwidth is in 10^9Hz range. The optically induced mobility is of the order of $10^5cm^2/V-s$ which achieves drain-current in the range of $10^{-3}A$. Light assisted GFET devices have the potential to be used in digital applications.

ACKNOWLEDGMENT

We would like to acknowledge the invaluable insights from Dr. Abhilash Ravikumar, Assistant Professor, Department of Electronics and Communication Engineering, Amrita School of Engineering, Bengaluru.

Abstract - Military and Army need weapons for military activities or operations to safeguard our country and its citizens. They already have exquisite weaponry and ammunition for ensuring our safety. But all these weapons are costly, exclusive and bulkier. Military people face many problems due to the difficult conditions in warfare. Therefore, we came up with an idea of integrating different technologies and implementing augmented reality in helmet to display battlefield information in one screen. This should help improving strategies in war and can get more insights during military operation.

Keywords - Augmented Reality, Wireless Video Transmission, Radar Motion Detection, GPS tracking, Strategic War Improvement.

I. INTRODUCTION

Our military & army are ought to do surveillance in regions of extreme weather and terrain conditions. Military people face problems during their operations like counter insurgency operations, Night operations or surveillance. Bad communication scenarios, surprise attacks by enemy are few of the problems faced. Soldier may be stranded or blinded in desert sand storms or cold winds in snow clad regions, problems such as low visibility might cause hindrance to their operations and might get isolated from their troops.

Indian Army is already provided with advanced machinery and ammunition. They work in extreme weather conditions while securing our nation's borders. They can perform their mission with high awareness if they get information of their surrounding, with enhanced safety, speed and be in close co-ordination with team members, if they get excess to this information by an augmented reality display. Artificial Intelligence, Encrypted Secured Networking, Dedicated Satellite Communication or WiMAX, Night Vision Camera & Radar Technology can be a helping aid to this system.

One of the Successful mission of US military was to catch UN declared Global Terrorist Osama Bin Laden; during this mission they acquainted with technology such that satellite linked camera feeds, wherein the President Barack Obama and several key advisors, saw the real time footage of the operation. High-Tech Drones were also been used with camera with hyper spectral sensor. [1]

It is also expected that in the coming few years, there will be a vast implementation of virtual reality & augmented reality system in military domain. Market of augmented reality is growing worldwide with advancement in technology.[2] If we integrate, all the battlefield parameters, with the augmented reality system, it could result to be a boon for Indian military.

According to 2018 report, use of Artificial neural Networks, Computer Vision, Advanced Computing Autonomous System, Machine Learning and Robotics will keep up with the technological advancements such as warfare platforms, cybersecurity, logistics & transportation, Target recognition, Battlefield healthcare, Combat simulation and Training, Threat Monitoring & situational awareness, thus improving the military intelligence. [3]

Therefore, our project aims to create a best solution by combining all the features into one application that gives output of varied modules on one screen altogether.

II. PROPOSED METHODOLOGY

Our proposed project prototype is attempting to provide a helping aid to the Indian military to strengthen their Defenses and Strategic attack on a whole new level. During the military operation, harsh weather conditions and long-range attacks, our soldiers don't get proper insight, so our main aim here is to provide a modified vision to the soldiers.

The proposed helmet will contain a head mounted display on which we will beam information such as environmental conditions, distance from an enemy/obstacle, motion detection of enshrouded person, to help out with the user's position by displaying GPS co-ordinate to the user if personnel is lost. The helmet will have live wireless encrypted video transmission between the user and the central system. The most important aspect of helmet is built in such a way that it doesn't provide hindrance to the soldier in close combat operations. The Helmet works on a portable power supply.

Here, for visibility problems the solution can be Thermal IR and night vision camera. But it is important to note that undoubtedly, the cost of this accuracy is high enough. There is possibility that the person is separated from his troop & is attacked by the enemy army. In such conditions there is need of personnel's update by location tracking, distance between personal and the attacking troops; so, they could get prepared with their plan of attack. A good communication via audio along with live transmission between his fellowmen can intensify their strategy.

In Military applications, Radar is highly used for its features like stealth, long range coverage, high speed and altitude, maneuvering targets while facing the issues of jamming and fluctuations of radar cross-section with a minute change in the aspect angle of targets. Since, its features are appealing and hence, it is the prime component of helmet. [4]

It is necessary to be equipped with handy devices and be ready for any kind of combat and emergency situations. So

there is a need of provision of real-time information from combat soldiers in battle to their commanders. Hence, we have integrated all sensors onto one headgear, and made a product out of these.

III. PROPOSED SYSTEM

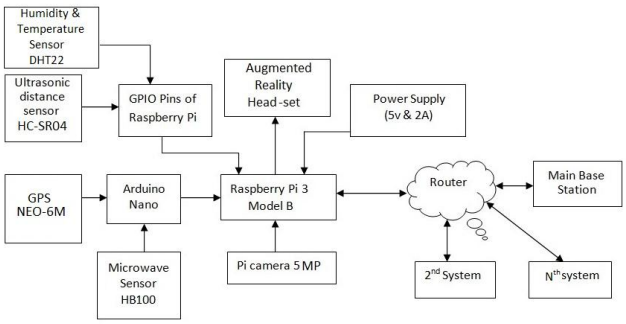

fig. 1 Block Diagram

The above block diagram shows the interconnection of all sensors and flow of data through different devices in a virtual network. The Temperature & Humidity sensor (DHT22) and Ultrasonic distance sensor (HC-SR04) is connected to Raspberry Pi. The GPS (NEO-6M) and Radar module (HB-100) is connected to Arduino. The Arduino is a micro-controller whose function is specific and gives output of sensors accordingly, while Raspberry Pi is microprocessor which integrates all the data coming from sensors and Arduino, combines them in a GUI and send to the display unit of augmented reality headset. Further detailed explanation of individual block is given below.

- **Distance Calculation using Ultrasonic Sensor HC-SR04:**

Ultrasonic sensor works on principle of reflection of sound waves i.e. short high frequency sound pulses which propagates at the velocity of sound. All materials reflect sound, regardless of colour, object shape and size. The time span between the emitting ultrasonic sound wave & receiving echo is termed as Time of flight. It is the measuring factor which determines the distance of the object from the wave source using kinematic formulae.

HC-SR04 Ultrasonic sensor sends 8, 40 KHz signal detecting the echo pulse. The measuring range being up to 400cm with a ranging accuracy of 3mm. High precision sensor can also be used to enhance the range. [5]

- **Motion detection using HB100 Radar module:**

When the Microwave of the Radar sensor are targeted to a particular object, there might be a chance of change in frequency of reflected signal. This change depends upon whether the target is stationary or not. When microwave signal falls on the moving object, the change in the frequency is determined based on that we can identify if there is any motion, this is Doppler effect. The output isn't affected by the presence of factors like temperature, humidity, light, dust or harsh environment.

HB100 uses a frequency of 10.525 GHz, and works up to the range of 20m. The signal detected by Sensor is in range of μV, hence further amplification is required using Operational-Amplifiers. This amplified signal is sent to the Main control unit. Radar systems can be configured in a number of different ways and across many different frequency bands.

- **Temperature and Humidity detection using DHT22:**

Temperature and Humidity are relative parameter when it comes to stating the environmental comfort for any living being. In DHT 22, measurement of temperature and humidity takes place simultaneously by 2 different independent sensors. For the measurement of humidity, capacitance as a principle is used. The moisture present in the atmosphere is adsorbed by the micro fiber material present between the two capacitive plates. The variation of capacitance helps sensor determines the humidity of the environment. A temperature compensation circuit is also taken into consideration for accurate humidity measurement. Also, an independent Thermistor is used for measurement of ambient temperature. Thermistor is a semiconductor device, which has a Negative Temperature Co-efficient (NTC).

Am2302 sensor has a humidity measuring range of 0 %RH to 100 %RH and temperature range of -40°C to 80°C with an accuracy of ± 2 %RH and ± 0.5°C respectively, with an average sensing time of 2 sec.

- **Location detection using GPS NEO-6M:**

GPS uses the method of trilateration to calculate the location. GPS satellites transmit information signal over radio frequency (1.1 to 1.5 GHz) to the receiver. Three GPS satellite revolving around Earth, this GPS module receives information from satellite and calculates the location. This is done by measuring the time required for signal transmission. The satellite transmits the pseudocode; which is received by the GPS receiver. These two signals are compared and the difference between the signals is the travel time.

Neo-6m GPS module has a ceramic antenna with strong satellite search capability. With a default baud rate of 9600 bps and interfaces with RS232 TTL.

- **Live video transmission:**

In this process, Pi-Camera module is connected to the CSI (Camera Serial Interface) port of raspberry pi via 15-pin ribbon cable. Then the camera option is enabled in interfacing options of raspberry pi. The video mp4 format carries huge data and hence for wireless transmission, we needed a device which will provide high speed and bandwidth.

Therefore, Raspberry pi is connected to the router, and transmits video data wirelessly at 15fps. Using python commands, video is uploaded to the virtual network having a specific IP address. Other users can access the data if they are connected to the same network.

Therefore, to access the live video, the end user has to put IP address of the video on the web browser. Also, many users can access this data by making this as one-to-many sharing features. Similarly, many-to-many transmission features is also possible. [6]

- **Virtual Networking:**

In many war zone regions, there is a problem of communication as there is no network available due to bad weather or geographical region constraints. Also there is a high change that the enemy can hack the network if the network is weak and can access our information which can

lead to losing of war. Hence, Military people uses dedicated satellites or transponders for encrypted and effective communication. [7]-[8]

Also in India, ISRO has launched its first military satellite i.e. GSAT-7 which is multi-band military communication satellite, revolves in geosynchronous orbit and connects ocean & land mass covering Indian Navy and Military forces.

In this prototype, we have created virtual network by using Wi-Fi router. As shown in the block diagram, this router is connected to base station i.e. in our case is computer which gets all data. We can connect multiple helmets as shown in fig 1 as nth number of systems. Wi-Fi router works on DHCP principle which connects multiple devices.

• **Augmented Reality:**

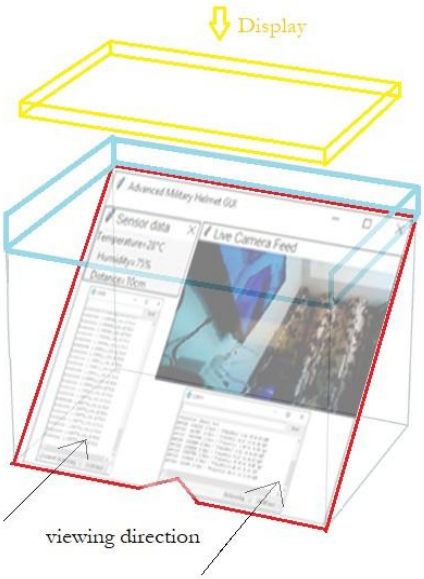

fig. 2 Augmented Reality

The Augmented Reality system is display unit for our Helmet, the data is been collected from the sensors via different modules by Raspberry Pi, is transmitted to a Smartphone with LCD display (6" diagonal length) via Wi-Fi. Augmented reality display is interactive experience with the real world, the normal insights of the ambience can be seen clearly through a transparent glass, also the interactive transparent display will show the LCD Display as shown in fig. 2, the display unit i.e. mobile screen (yellow zone) used as the display and kept on transparent rack (blue zone), the image on the screen from the rack is reflected on the 45° tilted transparent screen (red zone). Since the tilted screen is transparent the ambience can be clearly seen through it. The LCD display reflected on the 45° tilted glass can also be seen superimposed.

Hence, an interactive display could be seen on the transparent glass. This transparent display act as a High-Tech Display system helping the personnel to view the real world as well as the data provided by System. The data helps the personal to analyze the environment in a better way and could be a helping aid in areas with Low visibility. [9]-[10]

VNC server software is already available as android application package file (.apk) format. Hence the UI which we have created using Python Tkinter library is shown on mobile screen for Augmented reality Display. The combination of glass and mirror is structured in such a way that the superimposed image is formed in the glass structure. The augmented reality creates a superficial display of another data to a normal human vision.

IV. IMPLEMENTATION

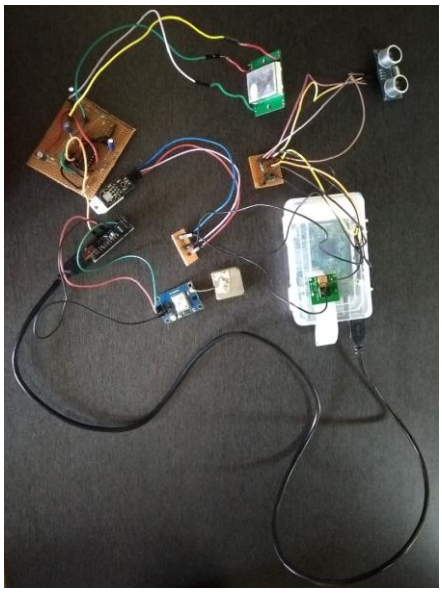

fig. 3 Connection of Components

- The Raspberry Pi is the CPU, the brain of the whole setup. All the modules are connected to it and interfaced via I/O ports and serial communication.
- Since Raspberry Pi is a micro-processor, it needs a screen to access the pi and give commands. We used VNC server software to access the Raspberry Pi User Interface wirelessly via router.
- The Arduino Nano is the microcontroller connected to pi and eases the interfacing of Radar and GPS module via analog and digital pins of Arduino.
- The Radar microwave sensor (HB100) is connected to Arduino Nano which is used for detection of motion of objects which are behind the solid obstacles using doppler principle of radar waves.
- GPS module (Neo-6m) is connected to the Arduino Nano which gives location in terms of longitude and latitude co-ordinates using trilateration methods.
- The DHT22 and Ultrasonic sensor are connected to the GPIO pins of the Raspberry Pi.
- The Temperature and Humidity Sensor DHT22 is connected to the Pi directly, giving the Temperature values in Centigrade and Humidity in percentage.
- The Ultrasonic Sensor HC-SR04 uses SONAR concepts to calculate distance effectively.
- The Raspberry Pi is provided with the power supply of 5 v & 2 amp. The Raspberry Pi Camera of 5 MP is connected the dedicated camera slot of the pi via serial communication. The camera frame rate is 15 fps.

- Raspberry Pi is connected to the router that acts like a satellite/transponder. Here router is an essential component to create a virtual network & imitate a satellite communication for transmission of data.

- The camera is for the live transmission following Master Slave communication protocol and all the 'N' number of systems are connected to the master via router, which had been allotted unique IP address to each device by DHCP.

- All these communications were possible because of the High-speed Router. Router allocates dynamic IP address to Raspberry Pi and other accessing devices as well. This is how we have achieved wireless communication and created a system of virtual network.

- The data of all the modules and video is combined in a GUI using Tkinter Library of python and is projected on mobile screen.

V. RESULT

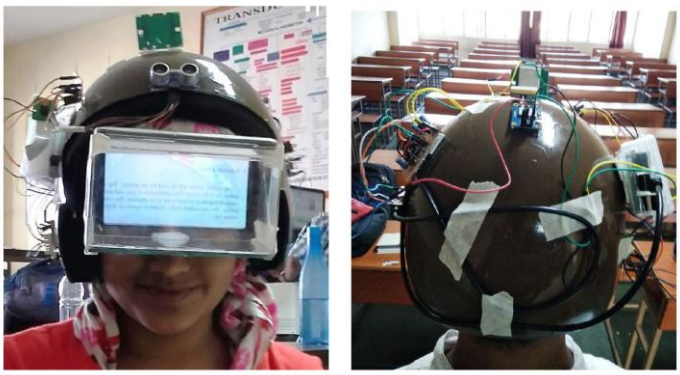

fig. 4 Prototype Model

The fig. 4 shows the prototype hardware model, with all components connected together. The front and rear view is shown on left and right image respectively. The AR is worn separately and then helmet over it. The sensors are kept in front and the processing unit towards sideway.

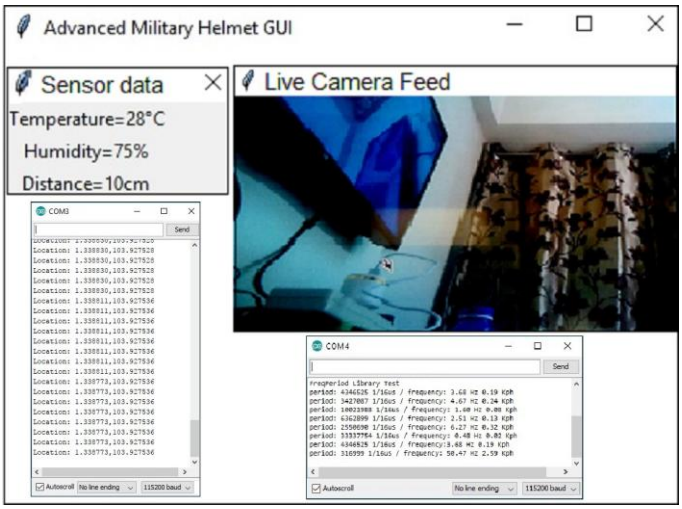

fig. 5 GUI Screen

The fig. 5 shows the GUI Screen. The Ultrasonic sensor shows the accurate distance of 10 cm. The distance shown had accuracy of 3 mm. This distance was also verified with scale. The DHT22 sensor gave us the accurate reading of surrounding temperature and humidity as 28°C and 75% respectively.

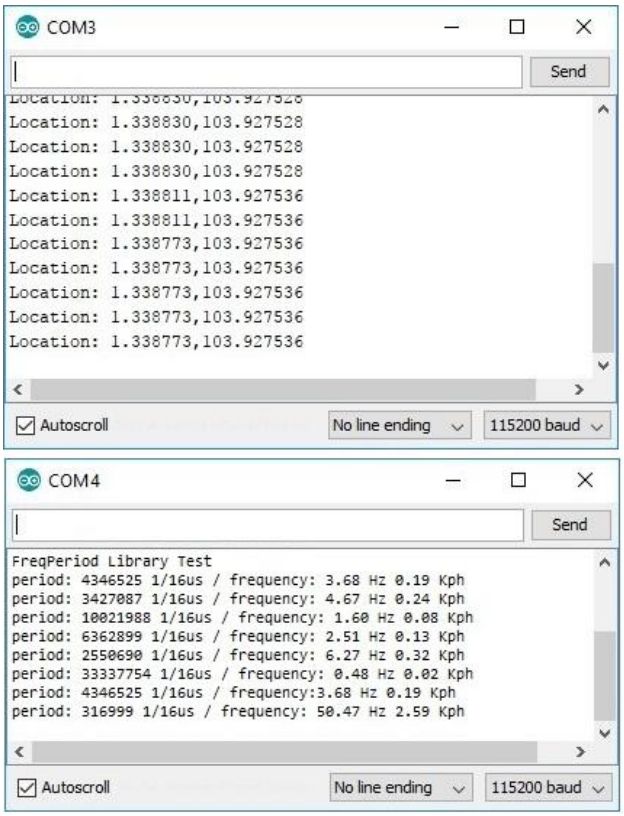

fig. 6 Output of GPS and Radar Module

The fig. 6 shows GPS Co-ordinates and Radar output. The GPS module Neo-6M gave us GPS co-ordinates in terms of latitude and longitude only in open space/ground. The radar module gives us the average frequency value as 3 Hz and velocity reading 0.2 Kph but it shows change in value when it detects the motion of the target. The value of frequency and velocity was 50.47 Hz and 2.59 Kph when we created dummy motion. This module shows motion detection for frequency value above 19.37Hz and velocity 1.0 kph.

In case of wireless transmission, router transmitted sensor and video data properly in a range of 20m radius. This video which was generated by the system was accessible to all the devices by putting the IP address on web browser. We can increase the number of devices if the bandwidth of the network is increased.

VI. CONCLUSION

This prototype project provides solution to all the problems which we discussed. It combines all possible features into one single unit and handles multiple devices simultaneously. The helmet is cost effective and accurate enough to spot the suspect and help making respective combat plans, while being updated about the live data feedback. The implementation of augmented reality in the field of military domain is a new idea and can be developed even more with the upgradation of technologies.

VII. FUTURE SCOPE

- Compact Design can be made using advanced VLSI, mini projector and smaller AR Headset.
- Use of bulletproof material makes it sturdier and more reliable.
- Voice communication between military personnel is an extension of our project. Addition of Voice control system to control all features of helmet with voice commands.
- Implementation of Artificial Intelligence and Advanced Image Computing will make these devices smarter and more reliable by scanning and determining any foreign material.
- Hologram projection of maps.

Tumakuru, Karnataka, India
gautamnayan02@gmail.com

***Abstract*– Addition is a standout amongst the most fundamental operations in VLSI frameworks such as microprocessors and digital signal processing systems. Therefore, the adders must render high speed operation. This paper proposes a novel implementation of 8-bit adder architecture using modified Gate Diffusion Input (m-GDI) approach. The primary blocks of adder are partial full adder, 1-bit full adder, 4-bit ripple carry adder (RCA), 4-bit carry look ahead adder (CLA). The proposed adder architecture devours 70% lesser area, 71% lesser delay and 35% lesser power dissipation w.r.t traditional CMOS design. The proposed adder is implemented utilizing Cadence Virtuoso Tool in 180nm technology.**

***Keywords*– Area, carry look ahead adder (CLA), m-GDI, Power, ripple carry adder (RCA), Speed**

I. INTRODUCTION

LOW-POWER design has turned into a basic concern in VLSI design, exceptionally for portable gadgets and high-density frameworks. As the integration density on the chip increments, fundamental concerns regarding the size and power dispersal of the components emerges. Therefore, the primary point is to lessen the power devoured by the digital circuits.

The design of digital circuits utilizing traditional CMOS technique requires large transistor counts and the circuit consumes larger area. As the technology reduces it results in high leakage power and dynamic power from the CMOS circuits. Digital circuit designed using m-GDI technique outcomes in high speed low power operation and devours lesser area. This approach permits the actualization of large variety of logic functions with a solitary m-GDI cell that's made up of two transistors. Thus, it expends lesser power, area and delay when contrasted with the circuits implemented using traditional CMOS technique [1-3]. Fig. 1 depicts the basic structure of m-GDI cell.

In the first view, the m-GDI cell looks alike to the CMOS NOT gate, but it consists of 3 inputs, one common input to the gate of both NMOS and PMOS, one input to the source/drain of PMOS and another to source/drain of NMOS [1,2].

Table I demonstrates the distinctive logic functions that can be actualized utilizing the single m-GDI cell [1].

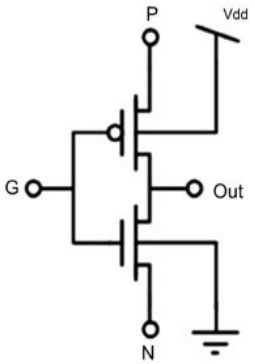

Fig. 1. Basic m-GDI cell

TABLE I. DIFFERENT LOGIC FUNCTIONS REALIZED USING m-GDI CELL

INPUTS			OUTPUT	LOGIC FUNCTION
N	P	G		
V_{SS}	V_{DD}	X	$\bar{X}$	NOT
V_{SS}	Y	X	$\bar{X}.Y$	F1
Y	V_{DD}	X	$\bar{X}+Y$	F2
V_{DD}	Y	X	X+Y	OR
Y	V_{SS}	X	XY	AND
Y	X	S	$\bar{S}X+SY$	MUX

Generally, the realization of basic logic gates utilizing static CMOS technique requires a transistor count varying from 6-12, whereas using a single m-GDI cell different logic functions can be actualized, as the transistor count lessons the circuit becomes compact and devours lesser area and intern offer high speed- low power operation [4].

Adders act as one of the fundamental building blocks of any higher subsystem design such as multiply accumulate units, arithmetic logic units, multipliers, microprocessors and so on [5].

The organization of the present paper is as per the following: Section II discusses the implementation of basic logic gates and full adder circuit. Section III aims at the design and implementation of Ripple Carry Adder and Carry Look Ahead Adder. Section IV aims at the design, implementation and performance analysis of 8-bit novel adder architecture and finally, Section V concludes the paper.

II. DESIGN AND IMPLEMENTATION OF VARIOUS LOGIC GATES AND FULL ADDER ARCHITECTURE.

It ought to be noticed that the producing of all logic gates, in basic m-GDI cell, can't be possible in CMOS process, so twin- well CMOS or Silicon oxide insulator (SOI) technology can be utilized for the cell fabrication [6].

Due to limitation of library in our Cadence simulator, there exists only single-well CMOS in the software, so maximum output voltage swing cannot be achieved. To reduce this disadvantage remarkably, we must use buffer at the output of basic gates to gain maximum output swing. Here, Cadence Schematic Editor was used for the front-end design and the layout was designed using the Cadence Layout XL. In order to carry out the performance analysis of various logic gates and proposed adder architectures Cadence spectre simulator was utilized.

A. AND gate

The realization of AND gate using traditional CMOS technique requires a transistor count of 6. Whereas the using a solitary m-GDI cell the AND operation can be realized. Fig. 2 depicts the traditional CMOS based AND gate. Fig. 3 depicts the m-GDI based AND logic. One input 'A' is applied to the source of NMOS i.e. N input of the m-GDI cell & another input 'B' is applied to the source of PMOS i.e. P input of m-GDI cell. Table II shows the different regions of operation of NMOS and PMOS of the m-GDI cell for the AND operation [3].

TABLE II. Different regions of operation of NMOS & PMOS for logic AND operation

Inputs		PMOS	NMOS	Output
a	b			
'0'	'0'	Linear $V_{in}-V_{tp}<V_{out}<V_{DD}$	Cut off $(V_{in}<V_{tn})$	'0'
'0'	'1'	Cut-off $V_{in}>V_{DD}+V_{tp}$	Linear $0<V_{out}<V_{in}-V_{tn}$	'0'
'1'	'0'	Linear $V_{in}-V_{tp}<V_{out}<V_{DD}$	Cut off $(V_{in}<V_{tn})$	'0'
'1'	'1'	Cut-off $V_{in}>V_{DD}+V_{tp}$	Linear $0<V_{out}<V_{in}-V_{tn}$	'1'

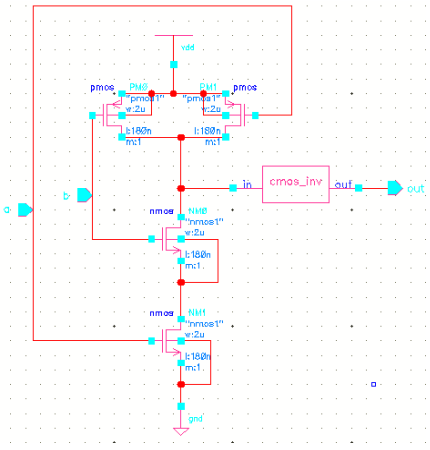

Fig. 2. CMOS AND logic

Fig. 4 depicts the layout of CMOS based AND gate. In order to achieve full swing output from the m-GDI based AND gate, the output of the logic gate is connected to a buffer. Fig. 5 depicts layout of m-GDI based AND gate with buffer.

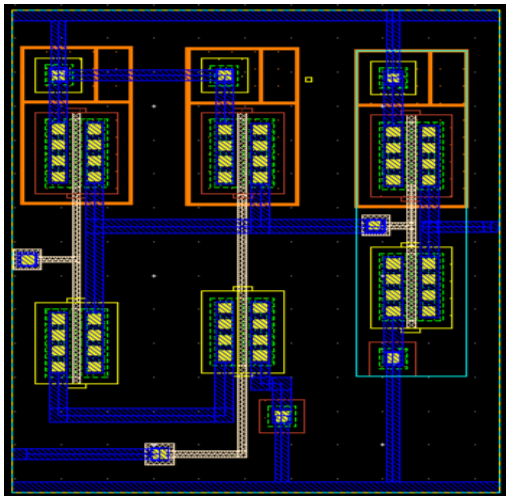

Fig. 4. CMOS AND layout

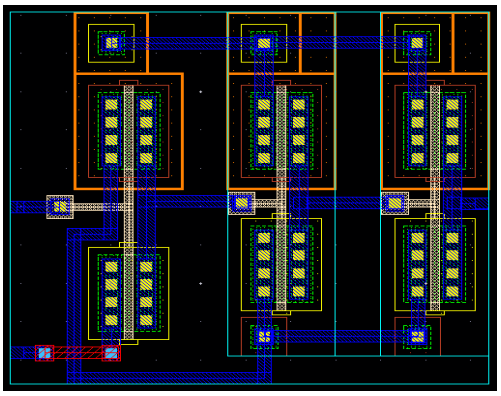

Fig. 5. m-GDI AND layout

B. *OR gate*

In order to actualize OR gate using traditional CMOS technique, it requires a 3 NMOS-PMOS transistor pair that counts to 6 no. of transistors, whereas actualization of basic OR gate using m-GDI technique can be done employing a solitary m-GDI cell.

Fig. 6 depicts the traditional CMOS OR logic and Fig. 7 depicts the m-GDI based OR logic.

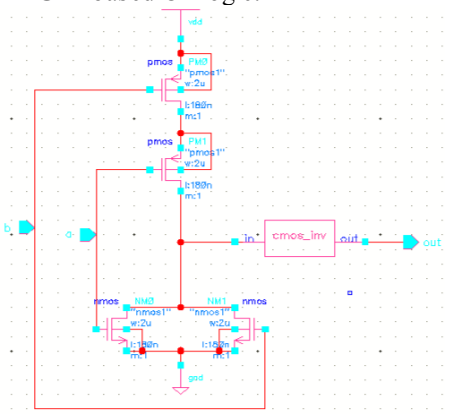

Fig. 6. CMOS based OR logic

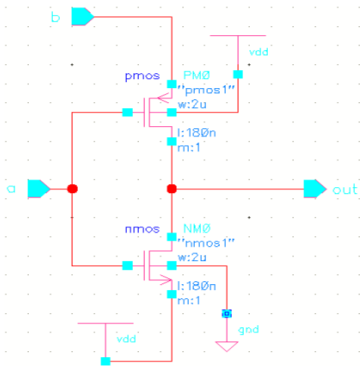

Fig. 7. m-GDI based OR logic

Fig. 8 shows the layout of CMOS based OR gate and Fig. 9 shows the layout of m-GDI based OR gate buffered to achieve full swing output.

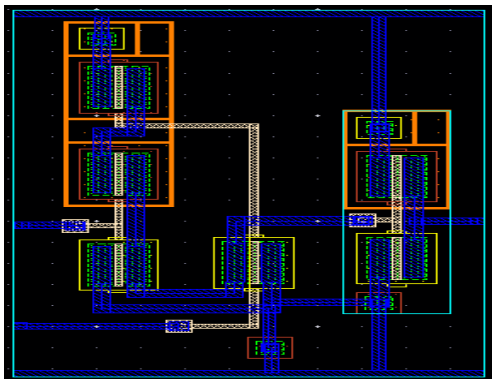

Fig. 8. CMOS OR layout

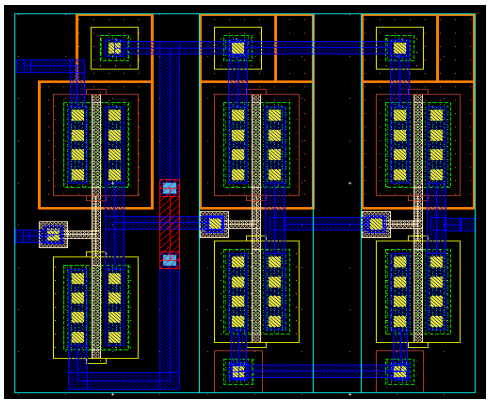

Fig. 9. m-GDI OR layout

C. *EX-OR gate*

The realization of EX-OR gate using traditional CMOS technique requires a transistor count of 12 whereas when realized using m-GDI technique the transistor count reduces to 4 nos.

Fig. 10 depicts the schematic of EX-OR gate realized utilizing traditional CMOS technique and Fig. 11 depicts the m-GDI based EX-OR gate.

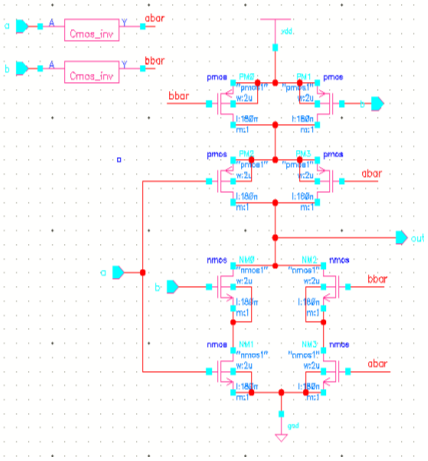

Fig. 10. CMOS based EX-OR logic

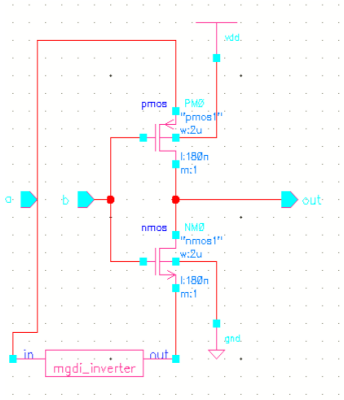

Fig. 11. m-GDI based EX-OR logic

Fig. 12 depicts the layout of the CMOS based EX-OR gate and Fig. 13 depicts the layout of m-GDI based EX-OR gate.

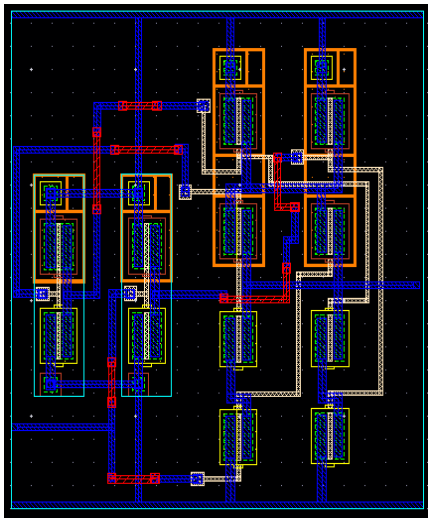

Fig. 12. CMOS EX-OR layout

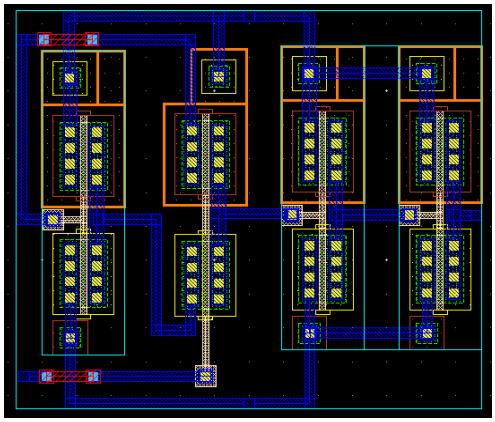

Fig. 13. m-GDI based EX-OR layout

D. Full Adder

A full adder circuits perform the addition of 3 one-bit numbers and often produces a sum and a carry output [5,7]. Table III shows the truth table of 1-bit full adder.

TABLE III. TRUTH TABLE FOR 1-BIT FULL ADDER

A	B	C_{in}	Sum	Carry
0	0	0	0	0
0	0	1	1	0
0	1	0	1	0
0	1	1	0	1
1	0	0	1	0
1	0	1	0	1
1	1	0	0	1
1	1	1	1	1

From the above table, the expressions for Sum can be given as:

$$Sum = A \oplus B \oplus C \quad (1)$$

In order to realize the expression for carry bit, let us examine the table.

When $A \oplus B = 0$;

$$Carry = B$$

Similarly, when $A \oplus B = 1$;

$$Carry = Cin$$

Therefore, this whole carry operation can be realized using a 2:1 MUX circuit. Where, $A \oplus B$ output can be given to the select line S of MUX B can be given to I_0 input and C_{in} can be given to I_1 input of 2:1 MUX.

2:1 MUX can be realized utilizing a single m-GDI cell, where the $A \oplus B$ output can be given to gate input of cell, B can be applied to P input of cell and C_{in} to the N input of the cell. Fig. 14 shows the schematic of m-GDI based Full Adder.

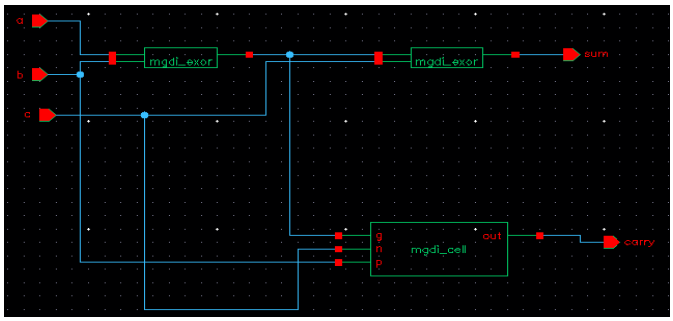

Fig. 14. m-GDI based Full Adder

Therefore, the no. transistors required to implement the full adder circuitry using the above equations employing conventional CMOS technique counts to 42, whereas when implemented using m-GDI the transistor count cut downs to 10 nos. only.

Fig. 15 depicts the layout of 42 transistor CMOS based full adder circuitry and Fig. 16 depicts the layout of m-GDI based Full adder circuitry which is buffered to get the full swing output.

Table IV shows the performance analysis of various logic gates and full adder circuitry. In order to carry out the performance analysis, cadence spectre simulator was utilized. Both the input to the logic gates where varied from 0-1.8V, with one input at 100ns time period and another at 50ns. For the full adder circuitry, the 3 inputs where varied from 0-1.8V and the time period were set to 150ns, 100ns & 50ns respectively.

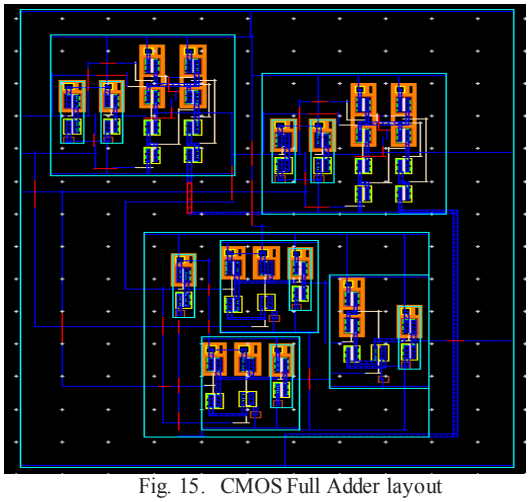

Fig. 15. CMOS Full Adder layout

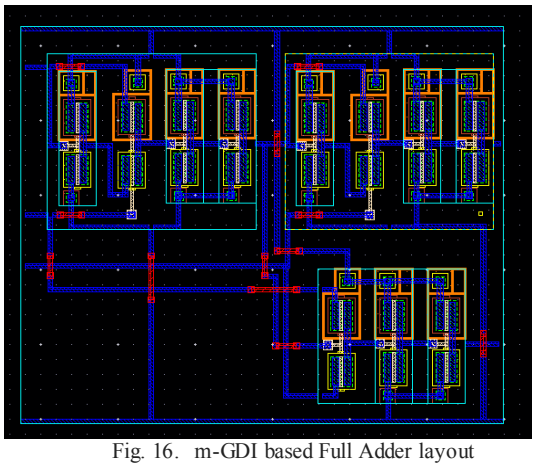

Fig. 16. m-GDI based Full Adder layout

TABLE IV. PERFORMANCE ANALYSIS OF VARIOUS LOGIC GATES AND FULL ADDER CIRCUITRY

Logic		Transistor count	Area (μm^2)	Delay (psec)	Peak power (mW)
NOT		2	21.59	88.46	0.242
Buffer		4	52.219	196.95	0.647
AND	CMOS	6	151.40	146.9	0.638
	mGDI	2	103.36	80.85	0.432
OR	CMOS	6	185.29	187.7	0.547
	mGDI	2	87.19	147.4	0.427
EXOR	CMOS	12	426.92	181.4	0.762
	mGDI	4	158.81	175.1	0.263
Full Adder	CMOS	42	3751.2	154.9	2.180
	mGDI	10	829.23	73.42	1.390

From the above table, it can be seen that the design of basic logic gates using m-GDI technique offers 30% lesser delay, 60% lesser area consumption and 30% lesser power dissipation w.r.t those designed using CMOS technique. Full adder design using m-GDI technique results in 50% lesser delay, 27% lesser power and 80% lesser area in contrast to CMOS based Full adder.

III. DESIGN AND IMPLEMENTATION OF RIPPLE CARRY ADDER AND CARRY LOOK AHEAD ADDER

A. Ripple Carry Adder

Here, a 4-bit Ripple Carry Adder (RCA) is designed by connecting 4 nos. of proposed full adder in cascade. In RCA, the carry bit ripples from each lower stage to the following higher stage and the final sum is only produced when the carry bit reaches the last MSB full adder [8,9].

CMOS based RCA design requires a transistor count of 168 whereas the RCA implementation through m-GDI technique requires a transistor count of 40 only. Fig. 17 depicts the m-GDI based schematic of 4-bit RCA design.

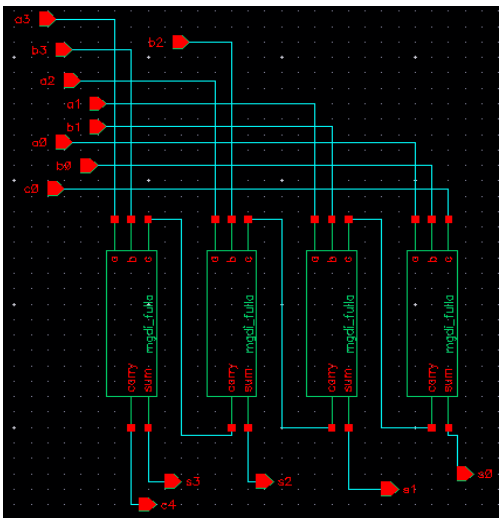

Fig. 17. m-GDI based 4-bit RCA

Fig. 18 depicts the layout of CMOS based 4-bit RCA design and Fig. 19 depicts the m-GDI based 4-bit RCA design employing buffers to obtain full swing outputs.

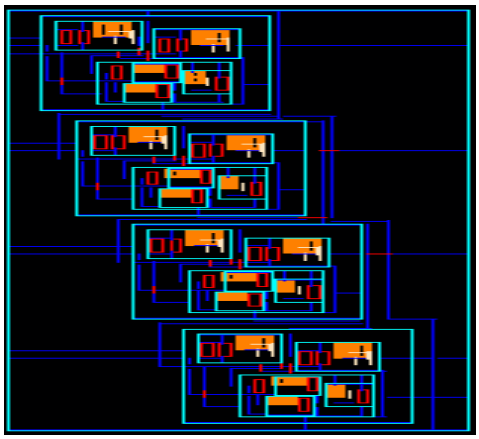

Fig. 18. CMOS based 4-bit RCA layout

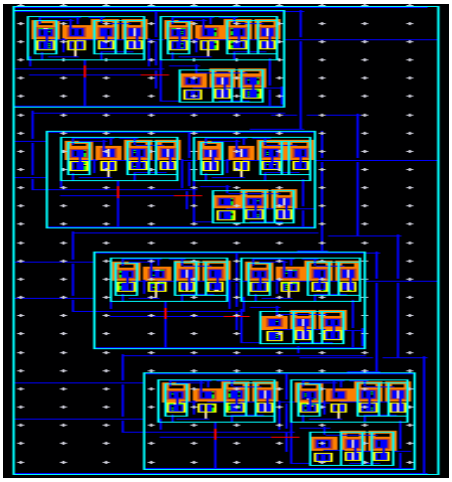

Fig. 19. m-GDI based 4-bit RCA layout

Fig. 20 depicts the simulation results for 4-bit RCA using m-GDI technique for input combination of $B_3B_2B_1B_0$= '1111' and $A_3A_2A_1A_0$ = '1111' & '0000'. Table V illustrates performance analysis of 4-bit Ripple Carry Adder.

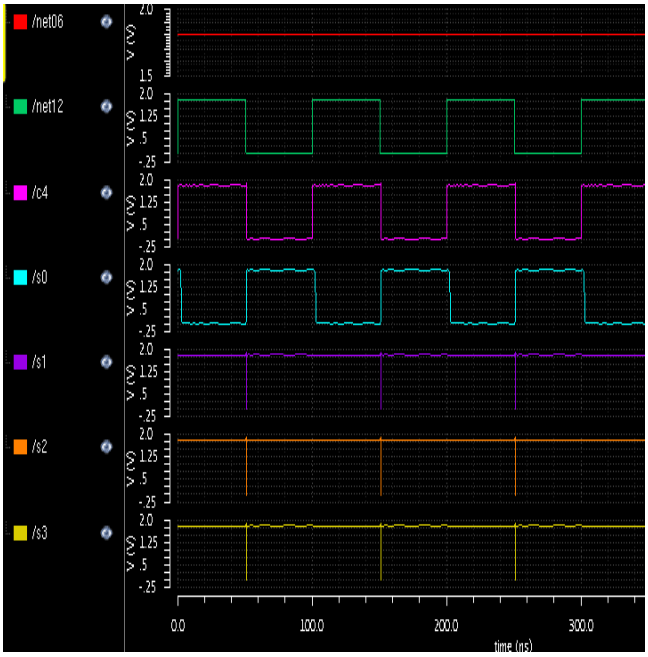

Fig. 20. Simulation result for 4-bit RCA employing m-GDI technique

TABLE V. PERFORMANCE ANALYSIS OF 4-BIT RCA

Design Approach	No. of Transistors	Area (μm^2)	Delay (psec)	Peak Power (μW)
CMOS	168	33767.1	381.50	5.19
m-GDI	40	6292.91	105.08	3.53

B. Carry Look Ahead Adder

This section proposes the implementation of 4-bit Carry Look Ahead Adder. A strategy for accelerating the addition process is by taking out inter stage carry delay. Such an addition operation is termed as look ahead-carry addition. The look ahead approach uses logic gates to look at he lower-order bits of augend and addend to check whether a higher order carry is to be generated. It makes use of two functions carry propagate (P_i) and carry generate (G_i) [10-12].

Where the equations for P_i and G_i can be expressed as:

$$P_i = A_i \oplus Bi \quad (2)$$

$$G_i = A_iB_i \quad (3)$$

For a 4-bit Carry look ahead adder (CLA) the carry output for each stage can be given as:

$$C_1=P_0C_0+G_0 \quad (4)$$

$$C_2=P_1C_1+G_1=P_1.(P_0C_0+G_0)+G_1 \quad (5)$$

$$C_3=P_2C_2+G_2=P_2.(P_1.(P_0C_0+G_0)+G_1)+G_2 \quad (6)$$

$$C_4=P_3C_3+G_3=P_3.(P_2.(P_1.(P_0C_0+G_0)+G_1)+G_2) +G_3 \quad (7)$$

The C_1 stage carry can be realized by using a m-GDI cell, by applying the P_0, the output of 1st partial full adder (PFA1) to the gate input of m-GDI cell, one input to the PFA i.e. C_0 as an input N of m-GDI cell and B_0 input of PFA as input P of m-GDI cell. The carry part of stage 1 i.e. C_1 is used for subsequent stage carry generation C_2, C_3 and C_4.

Fig. 21 stage shows the schematic of 1st partial full adder stage (PFA1) and Fig. 22 shows the schematic for C_1.

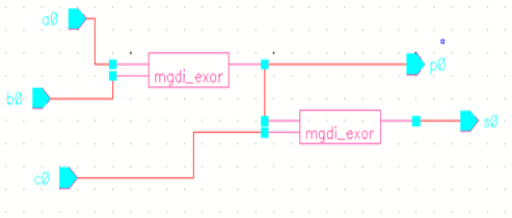

Fig. 21. 1st Partial Full Adder stage

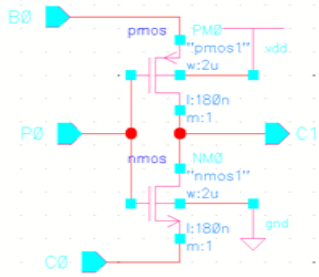

Fig. 22. Schematic of C_1 stage

To realize the sum for subsequent stages the partial full adder shown in the Fig. 23 is utilized.

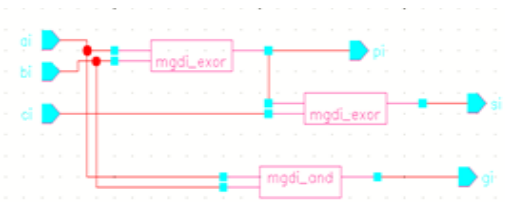

Fig. 23. Partial full adder for the S_1, S_2 & S_3 stage

Fig. 24 shows the schematic of m-GDI based 4-bit Carry Look Ahead Adder. Fig. 25 depicts the layout of 4-bit CMOS based CLA and Fig. 26 depicts the layout of m-GDI based 4-bit CLA. Table VI shows the performance analysis of 4-bit CLA.

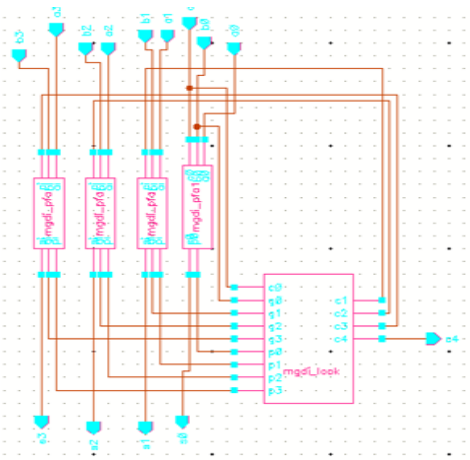

Fig. 24. Schematic of 4-bit m-GDI based CLA

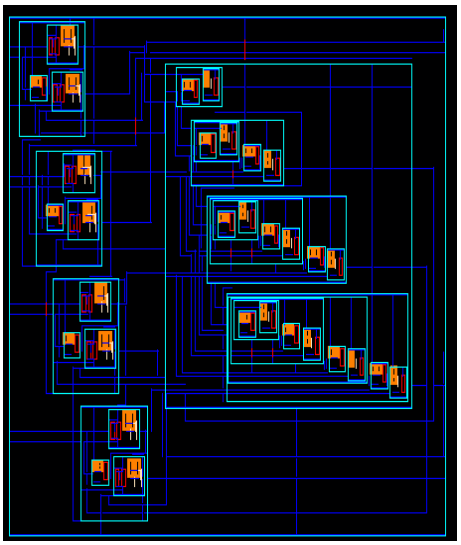

Fig. 25. Layout of CMOS based 4-bit CLA

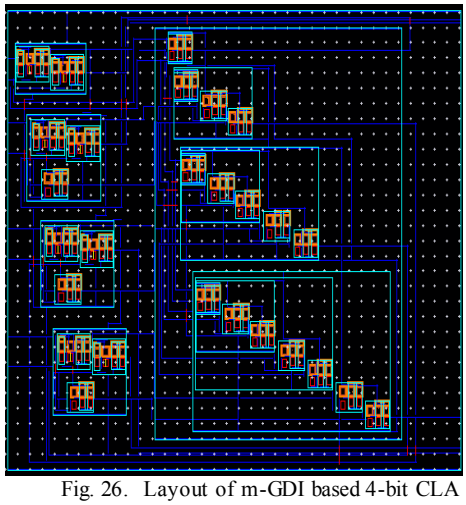

Fig. 26. Layout of m-GDI based 4-bit CLA

TABLE VI. PERFORMANCE ANALYSIS OF 4-BIT CLA

Design Approach	No. of Transistors	Area (μm^2)	Delay (psec)	Peak Power (μW)
CMOS	240	80350.7	261.60	6.38
m-GDI	70	27870.2	22.08	5.58

IV. DESIGN AND IMPLEMENTATION OF 8-BIT NOVEL ADDER ARCHITECTURE

The 8-bit hybrid adder is designed by cascading the two adder modules discussed in section III.

The lower 4-bits of the hybrid adder architecture uses 4-bit Carry Ripple Adder to carry out the summation of 4-LSB inputs to the adder. The carry output C_4 of the 4th stage of the CLA is applied as C_0 input to 1st stage of 4-bit Ripple Carry Adder. The 4-bit RCA calculates the sum of 4-MSB inputs to the adder. The final carry can be obtained at the carry output from the C_4 stage of the RCA.

Thus, the sum of lower 4-bits input $A_3A_2A_1A_0$ and $B_3B_2B_1B_0$ are calculated employing the 4-bit CLA and the higher 4-bits input $A_7A_6A_5A_4$ and $B_7B_6B_5B_4$ are calculated using 4-bit RCA.

Fig. 27 illustrates the schematic of m-GDI based 8-bit Hybrid Adder Architecture and Fig. 28 depicts the layout of proposed 8-bit adder architecture using m-GDI technique.

Fig. 29 depicts the simulation waveforms of 8-bit proposed adder architecture for input combination '11111111' for $A_7A_6A_5A_4A_3A_2A_1A_0$ and '00000000' & '11111111' as input to $B_7B_6B_5B_4B_3B_2B_1B_0$.

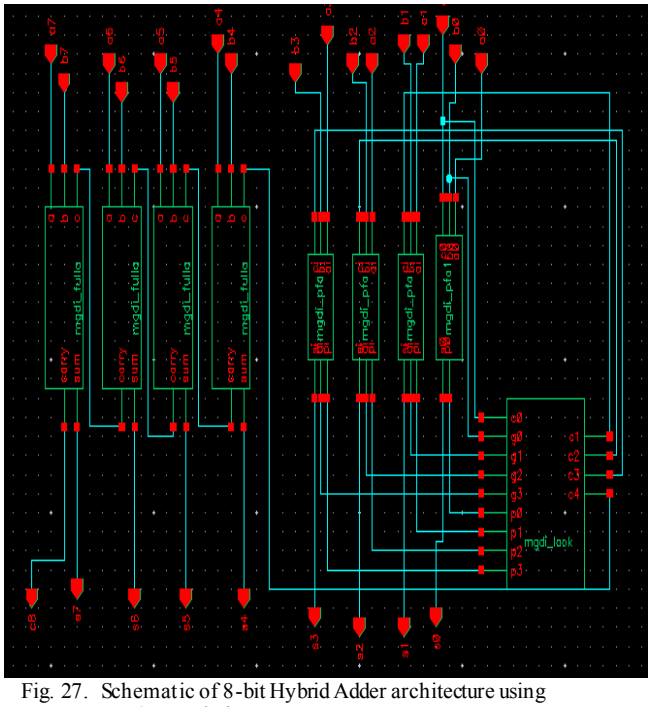

Fig. 27. Schematic of 8-bit Hybrid Adder architecture using m-GDI technique

Fig. 28. m-GDI based 8-bit adder layout

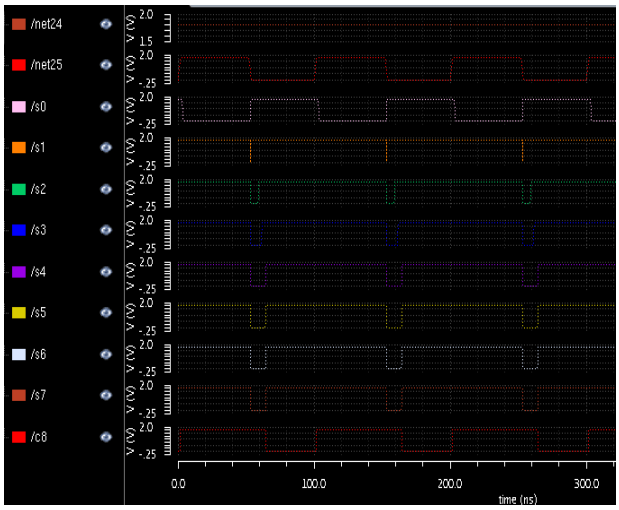

Fig. 29. m-GDI based 8-bit Adder simulation waveform

Table VII gives the performance analysis of 8-bit Hybrid Adder architecture.

TABLE VII. PERFORMANCE ANALYSIS OF 8-BIT NOVEL ADDER ARCHITECTURE.

Design Approach	No. of transistors	Area (μm^2)	Delay (psec)	Power (mW)
CMOS	408	191235.6	286.7	18.50
m-GDI	110	56638.3	82.58	12.05

V. CONCLUSION

This paper proposes a novel design of 4-bit Carry Look Ahead adder and 8-bit novel adder architecture. From the simulation result it was observed that the design of adder architectures using m-GDI technique results in high speed operation and consumes least no. of transistor. For ripple carry adder it was observed that the m-GDI based design consumes 81% lesser area, offers 72% lesser delay and the peak dynamic power reduced by 30% with respect to the traditional CMOS design.

Similarly, for the 4-bit carry look ahead adder it was observed that the m-GDI based design offered 91% lesser delay, a reduction in area by 65%, peak dynamic power reduced by 13% w.r.t the traditional CMOS design.

The proposed 8-bit hybrid adder architecture using m-GDI approach offered reduction in delay by 71%, the number of transistors reduced by a count of 298 when contrasted with the traditional CMOS design. The reduction in peak dynamic power was observed to be 35%. The reduction in area of the proposed adder architecture using m-GDI technique w.r.t the traditional CMOS implementation was found to be 70%.

Thus, from the above results it is clear that the design of 8-bit novel adder architecture using the mGDI technique results in lesser transistor count, dissipates lesser power and results in high speed operation.

Threshold driven Dual Cluster Head clustering protocol.

Navajyoti Nath, Biswanath Dey
National Institute of Technology Silchar
Silchar, India
navajyoti.cse@gmail.com

***Abstract*—In wireless sensor network, cluster based routing approach is a major step in the direction of energy efficiency. However, research shows that the energy dissipation in cluster based approach predominantly occurs in two cases; first during data transmission to the base station and second during data fusion, which foremost is the job of a Cluster Head (CH). Eventually this leads to sizable energy dissipation ,early death of CHs and lower network lifetime . Thus to address the problem, this paper proposes a new protocol which uses two cluster heads namely Primary CH (PCH) and Secondary CH(SCH).The Primary CH, which is deployed to collect information from sensor nodes and further performs data aggregation, and is elected based on the similar method used in LEACH protocol, but PCH also considers a threshold energy value while election whereas the Secondary Cluster Head (SCH) is selected considering the distance to the Sink and also considers a threshold energy value. Comparisons with LEACH protocol are shown in result area to substantiate the claim of this paper.**

***Index Terms*—LEACH, WSN, DUAL CLUSTER HEAD, Clustering Protocol.**

I. Introduction

Wireless sensor network is a group of huge numbers of sensor nodes which are randomly stationed in harsh conditions or difficult terrains to monitor and gather information of surrounding environment like temperature, humidity, forest fire, automobile movement, etc. Basically, the nodes deployed are limited on battery power and because of the area of deployment, replacing or replenishing of power source becomes very difficult. To overcome this issue, numerous studies [2][12] were brought out to look out for solutions to improve the network lifetime. In clustering based algorithms, the non-CH nodes forward the sensed data to respective CHs where the data aggregation/fusion is carried out and the output data signal is later transmitted to the sink for further processing by the CHs. The CH sends the data to the sink using either a single-hop or a multi-hop communication approach depending upon the distance to the sink [1]. If the distance between the two is greater than the prescribed distance (threshold) multi-hop approach is adopted, else single-hop communication is used. As for the single-hop communication for longer distance would require more energy which will lead to faster death of nodes. Thus, the nodes do not require any more to send data to the sink directly thereby lessening the individual power usage level, however the energy usage level of Cluster Heads (CHs) would increase exponentially, thus a rotation of role of CHs among other nodes is used after a certain interval (rounds) to reduce the burden of the CHs. Therefore, our approach primarily focuses on increasing the network lifetime of a given network. In our approach, we have contemplated the scenario by taking two cluster heads (CHs) in each cluster instead of one CH in LEACH protocol. The fundamental objective behind the election of dual cluster head is to bring down the burden of single cluster head and extent the lifetime. In the proposed approach, two roles of CH are separated and is designated to two different CHs i.e. one CH for data aggregation and other CH for data transmission, thus increasing the lifetime of CHs.

This article is divided into sections: Section II gives brief information about the related protocols, Section III is designed for the network assumptions containing the energy model and network model, in Section IV the proposed protocol is discussed, in Section V the proposed protocol is compared with LEACH protocol, and finally Section VI with a conclusion that concludes the paper.

II. Literature Review

A. Study on Low-Energy Adaptive Clustering Hierarchical Protocol

In LEACH protocol [1], sensor nodes in the WSN claims to be the cluster heads and based on that claim, few of the nodes get elected as CHs and the remaining nodes organize themselves to form clusters. The process of election of CHs, cluster formation and data transmission to the sink, are done in four separate parts: advertisement phase, cluster-setup phase, schedule-creation phase and data-transmission phase. Initially in advertisement phase, the nodes randomly generates any value within 0 to 1 and only if the number is less the value generated by the threshold function generator ($T(i)$), in equation (1) [1], then those nodes are said to be elected as

a CH for that round. The number of CHs in any given round in the network is decided a priori.

$$T(i) = \begin{cases} \frac{p}{1-p*mod(rd,\frac{1}{p})}, & if\ i \in Z \\ 0: & ,otherwise \end{cases} \quad (1)$$

where p = % of nodes being CH assigned a priori, rd = present round and Z = set of nodes that were not elected as cluster heads for the last $1/p^{th}$ rounds and $i = i^{th}$ node. Once the CHs are decided, the non CH nodes decides that to which cluster head it should select based on received signal strength indicator (RSSI)[3-5] to form a cluster. In cluster formation phase, after selecting the cluster heads to join, nodes now inform the cluster heads about the choices made via a control message for cluster formation. In schedule creation phase, the CH, based on the cluster information forms a TDMA schedule, directing the nodes when to send the data to the cluster head. In the final phase i.e. data transmission phase, the sensor nodes send the sensed data in their allotted transmission time to the respective CHs, and after receiving the information from all the non-CH, the CHs performs data aggregation to fuse the data into single data signal. This fused data is then finally forwarded to the sink for further processing.

B. Related Works

Hongjun Wang et al. in [6] proposed an algorithm to improve LEACH using double cluster heads and a mechanism for data fusion. In this algorithm, the clusters are formed on the basis of k-Medoids clustering algorithm, and after the completion of cluster formation the first and the second cluster heads are elected. As the algorithm follows k-medoids, where the value of k is selected based on the ratio of number of CHs required to number of nodes in the network. Election of CHs is same as in the LEACH [2], but with the probability which is based on the ratio between the number of CHs expected to number of nodes in cluster.

Jie Huang in [7], a double CH based algorithm is presented to minimize the effects of untimely death of cluster heads due to hefty energy dissipation. In this algorithm, two cluster heads are used, namely Master-CH, which is selected based on the LEACH protocol and Vice-CH, which is selected among the non-CH nodes in the cluster, based on the distance between other nodes and master node. In [7], the nodes within the cluster sends the data to any of the two cluster heads based on the distance. If the node is in proximity to the master cluster head it transmits the data to the master cluster and if near to the vice cluster head it sends it to the vice cluster head, on receiving the data both the master head as well as vice-CH performs data integration but only master cluster head sends the information to the base station whereas the vice cluster head sends the integrated data to the master-CH from where the data is further forwarded to the base station.

In [8], the clusters numbers are predefined and based on this criterion the network is partitioned into equal sized clusters which are static throughout. Based on the cluster information and the information imparted by the sensor nodes about their location, the sink assigns each node into a cluster. After the nodes are assigned to their clusters, two nodes in each clusters are selected as cluster heads , one being an Aggregating CH (ACH), used for data aggregation and the other being a Transmitting CH (TCH), used for transmitting data to the sink. The ACH is selected among other non-CH nodes in the cluster, based on a fitment factor which includes three weighted criterion residual energy, distance of nodes from sink, and distance of other nodes. The node with highest residual energy and being in the center is given the highest score and is finally selected as the ACH. On the other hand the TCH among other non-CH nodes in the cluster is also selected based on the same fitment factor used by the ACH, but the weightage is mainly focused on the residual energy and the distance between to the sink. Thus a node with highest residual energy and with least proximity to sink is given priority and hence is selected as a TCH. After the selection of cluster heads are completed, the sensor node send their data to the ACH where data aggregation is conducted and then the aggregated data is forwarded to the TCH and the TCH further transmits the data to the sink. This eventually reduces the energy consumption during communication within cluster and outside cluster, and results in overall increase in network lifetime.

III. Network Assumptions

The fundamental objective of this study is to propose a protocol that can improve the network lifetime of nodes with the same initial energy. By increase in network lifetime it is meant that the nodes will have prolonged lifetime or delayed death and to do so the following are the assumptions that are considered for the protocol:

A. Network Model

- Nodes are homogeneous having uniform energy and are energy constrained.
- Location of the sink is fixed and is far off from the nodes.
- Nodes are stationary.
- Every sensor nodes are in communication range with the base station.

B. Energy Model

The energy model for communication and data fusion used in proposed work is fundamentally based on that which was proposed by Heinzelman et al. [2] and are also being used by [1][6-11] . Here two channel models are used, free space channel and the multi-path space model. The option is dependent on the distance to the sink, if the distance is below the threshold distance (D_0), free space is adopted and if the distance is above than threshold distance (D_0), multi-path space model is selected, but in the protocol proposed only free-space communication is implemented. Thus the expression for the energy dissipation in transmitting a n-bit data to a distance d is as follows:

$$E_{tx}(n,d) = E_{tx-elec}(n) + E_{tx-amp}(n,d) = \begin{cases} n(E_{elec} + \varepsilon_{fs} d^2), & d < D_0 \\ n(E_{elec} + \varepsilon_{mp} d^4), & d > D_0 \end{cases} \quad (2)$$

where $E_{tx-elec}(n)$ is the energy required by the transmitter circuit which includes coding, modulation, filtering, and spreading of the signal, to transmit a m-bit message, whereas $E_{tx-amp}(n,d)$ is the amount of energy consumed by the transmitter for transmitting a n-bit message over a distance of d. E_{elec} is the energy consumed by the transmitting circuit to transmit a bit message and the ε_{fs} and ε_{mp} are the constant coefficients for free space and multipath communication respectively. The values of ε_{fs} and ε_{mp} are as per the values used in [2].In addition to the energy consumption on transmission, the expression for the energy consumption on receiving a m-bit message is:

$$E_{rx}(n) = n * E_{elec} \quad (3)$$

Further the expression for threshold value of distance used in our model is as proposed in [7], and is as given as:

$$D_0 = \sqrt{\frac{\varepsilon_{fs}}{\varepsilon_{mp}}} \quad (4)$$

Moreover, as discussed earlier, that for the Cluster Heads, huge amount of energy is dissipated in both the data transmission and data aggregation. Accordingly it becomes utmost importance that we include energy consumption in data aggregation along with the energy dissipation in data transmission. In this paper, therefore we take E_{DA} which represents energy consumption in data aggregation.

IV. Proposed Algorithm

This paper, proposes a new clustering protocol (threshold driven dual cluster head clustering), which surpasses the performance of LEACH protocol. The proposed algorithm is divided into four stages which are shown below:

A. Initialisation Stage:

The objective of this stage is to find the primary cluster heads. This stage follows similar process that is adopted in [2]. But as the LEACH does not consider the residual energy on individual energy, thus there may arise situations where the node elected as cluster head may die without performing its duties. Therefore, in this approach a threshold energy value is computed for primary cluster headE_{PO}, making sure that only that node would be elected as primary cluster head which as residual energy greater than the E_{PO}.

As known that the responsibility of a primary cluster head (PCH) is to collect all the information from all the member nodes and then after performing data fusion on the received data transmit the final data to the secondary cluster head(SCH). The following equation (1) is based on the energy dissipated during reception of m-bit message from the member nodes excluding the PCH ($\frac{1}{p} - 1$) in the cluster and then energy dissipation during data aggregation for all the member nodes and primary cluster head and finally energy consumption while the transmission of fused data to the SCH.

$$E_{P0} = E_{rx}(n) * ((N * p) - 1) + E_{DA}(n)(N * p) + E_{tx}(n,d)$$

$$E_{P0} = n*(E_{elec}*((N*p)-1)+E_{DA}*(N*p)+(E_{elec}+\varepsilon_{fs}*D_0^2)) \quad (5)$$

Where N is the total number of nodes,E_{rx} is the consumption of energy in reception of a $1 - bit$ message , and E_{DA} is the amount of energy that is consumed during aggregation of the nodes and is considered to be a constant and n is the n-bit message.

B. Cluster Formation:

After the election of primary cluster head is over, the primary cluster heads broadcast the information of being the cluster heads with their unique ids. On listening to the broadcast, the remaining nodes chooses to respond cluster heads with the highest signal strength. That is, the nodes selects a cluster head among other cluster heads when the received signal strength is higher than others, which implies that the communication cost with that cluster head would require less energy.

Once all the non cluster nodes selects their cluster heads, they respond with a message indicating their unique ids, residual energy, distance to the base station and the choice it has made. Thereby making the clusters in the network.

C. Secondary Cluster Head Selection:

In this stage, the main intent is to select a node which can act as secondary CH. The role of this very CH is to forward the aggregated data received from primary cluster head. The criterion for the election of SCH is principally based on the residual energy of the node and the distance to the sink. Thus among the member nodes in the cluster, the primary Ch elects a SCH which is at the boundary or near to the cluster boundary (proximity to the base station among other nodes) among the competitors on the information available. The residual energy is considered due the fact that, the node elected as SCH should be able to complete its role without being dead. Here also a threshold energy value for SCH (E_{SO}) is computed, so that only that node which has residual energy higher than the E_{SO} can participate in the election process. As the requirement of SCH is only to collect the aggregated data and later transmission of that data to the BS, therefore only those energy dissipation is considered in the equation (6).

$$E_{S0} = E_{rx}(n) + E_{tx}(n,d)$$

$$E_{S0} = n * (E_{elec} + (E_{elec} + \varepsilon_{fs} * D_0^2)) \quad (6)$$

Where $E_{tx}(n,d)$ is the consumption of energy while transmitting the data to the base station by the secondary CH, and $E_{rx}(n)$ is the energy dissipation while receiving the data from the primary CH.

D. Data Transmission:

After the selection of both the cluster heads and cluster formation, the primary CH broadcasts a TDMA schedule to all the non-CHs within the cluster to inform about when the nodes can transmit data to the primary CH and when to sleep. The primary and secondary cluster heads will always be in the listening mode. Once the schedule is notified, all the non-CH nodes within cluster, as per the schedule passes the data to the primary CH, where the data collection and aggregation is performed and the multiple data signals are transformed in to single signal and as the transmission is within the cluster the energy consumption is way lesser than the original protocol [2]. Further, the data signal is transmitted to the secondary CH for relaying it to the base station. As the secondary cluster head is at the cluster boundary, which enables it to transmit the data with comparatively lesser energy.

Therefore by using the dual CH approach in the proposed algorithm, energy consumption compared to LEACH protocol is reduced. As the role of one cluster head is divided into two and only optimal nodes are used for data transmission which minimizes the energy dissipation in the network, thereby enhancing the network lifetime.

V. Results and Analysis

In this section, the objective is to showcase the performance comparison of LEACH protocol with our proposed algorithm (Threshold driven Dual Cluster Head clustering protocol) in context of network lifetime. The simulation of the algorithm is performed on MATLAB. The network parameters and the network scenarios are given in Table 1 below.

Here for better comparison, two scenarios are implemented, where different combinations of initial energy of nodes(E_0) and the percentage of nodes being CH (p) equals to 10% is considered.

Parameters for Scenario	
Parameters	**Parameter values**
Network-Area	100 m X 100 m
BS position	(100m, 200m)
Total number of nodes	500 & 1000
Initial Energy (E_0)	0.5 J & 1 J
Percentage of clusters p	10%
Ee1ec	50nJ/bit
EDA	5nJ/bit
ε_{fs}	10 pJ/bit/m^2
ε_{mp}	0.0013 pJ/bit/m^4
D_O	87.7m
$E_{PO} - 500nodes$	$5.7 * 10^{-3}$ J
$E_{PO} - 1000nodes$	$1.12 * 10^{-2}$ J
E_{SO}	$3.538 * 10^{-4}$ J
Size of data frames	2000 bit

TABLE I
TABLE CONTAINING THE DETAILS OF PARAMETERS.

Here two network scenarios are being implemented, one of the scenarios consists of 500 nodes and in the another scenario 1000 nodes are deployed, whereas the base station location is same for both the scenarios. Different scenarios are

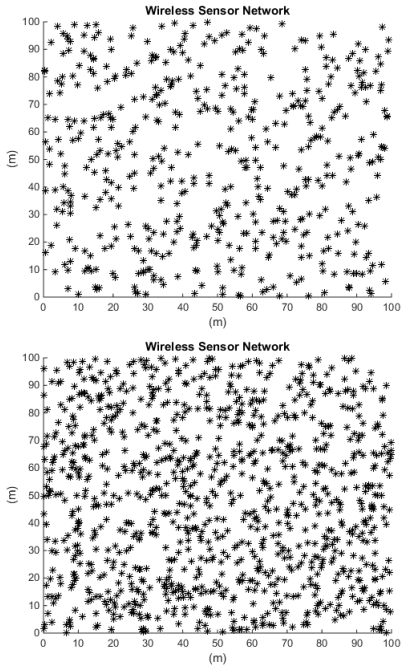

Fig. 1. Network Scenario with 500 and 1000 nodes respectively

As the network scenarios are known, the

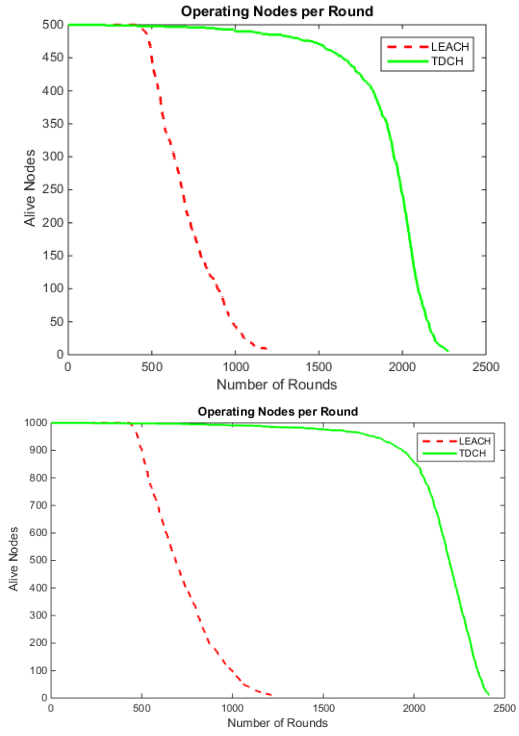

Fig. 2. Simulations comparing LEACH vs TDCH for 500 and 1000 nodes respectively with $E_0 = 0.5J$

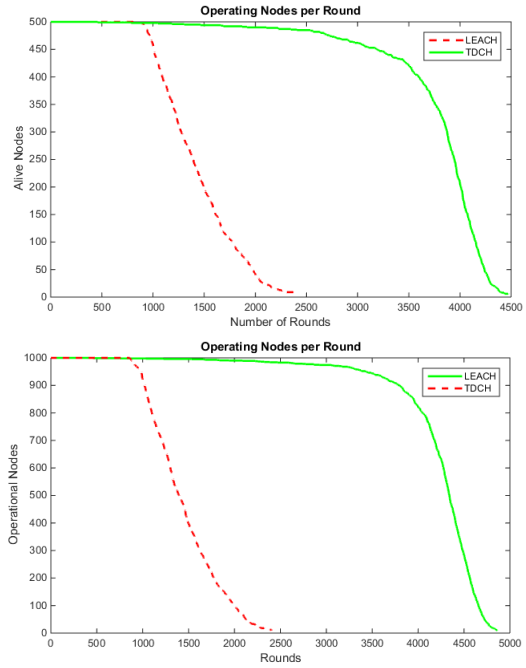

Fig. 3. Simulations comparing LEACH vs TDCH for 500 and 1000 nodes respectively with $E_0 = 1J$

After the comparison it is found that, the proposed algorithm is outperforming the LEACH protocol. In both the scenarios, TDCH is outperforming LEACH protocol by approximately 200%.

VI. Conclusion

The LEACH protocol is considered to be the benchmark of clustering protocols, thus comparison with LEACH protocol substantiate the performance of the proposed protocol. In the above experimental analysis it could be seen that, TDCH protocol has outperformed the LEACH protocol with a whooping difference of 200%. To substantiate the claims of the TDCH further, comparison of TDCH protocol with other well established protocols with few other network scenarios is required. Authors of this paper are working on this and would come with more results to validate the claims further.

***Abstract*— Change Detection in satellite imagery is a concerning topic for researchers and scientists. Studying changes in satellite images gives enormous amount of knowledge in studying the geography and ecosystem. The dataset used in this work is taken from AVIRIS sensor and normalized in order to reduce time of execution. This paper covers the important aspects of Classification of a satellite imagery using convolutional Neural Networks. Changes are detected basing on the classification maps in multi-temporal imagery. Experimental results show that proposed method got accuracy on par with state of art methods.**

Keywords*— *satellite imagery, Convolutional NN

I. INTRODUCTION

The changes on earth's surface from natural and human causes are rapid. Scientists and researchers are concerned on detecting the changes without knowing the scale of changes which is very hard and need to be addressed. There are many techniques which had been developed for detecting changes on land-cover which are optimal for both satellite imagery and also for digital imagery. Satellite images are different from normal images. They are not to be compared with each other. We can adapt the techniques or algorithms used for normal imagery on satellite imagery. Normal images are three or four channel and are speeded over the Visual Spectrum. Satellite images are multiple channels and are ranged from infrared to ultraviolet in the electromagnetic spectrum with minimal intervals. Digital images represent the intensity of the red-green-blue in the image whereas satellite images are reflection indexes for each interval.

This paper had considered only the push-broom passively scanned images. The spectral images can be collected in multiple ways from satellite to airborne imaging through more complex spectroscopes. Spectroscopes scan land cover in the spatial perspective in all the intervals of the Electromagnetic spectrum collecting the spectral data.

The spectral data collected for each spatial pixel is labeled manually by surveying onsite and respected ground truths of the spectral data are provided. But it is not possible to survey a land in a remote region manually so we are using a deep neural network to learn the patterns of the each spectral data in a remote region from the knowledge of spectral data which was provided with ground truths collected by manual surveys generate the classification maps aka Ground truths.

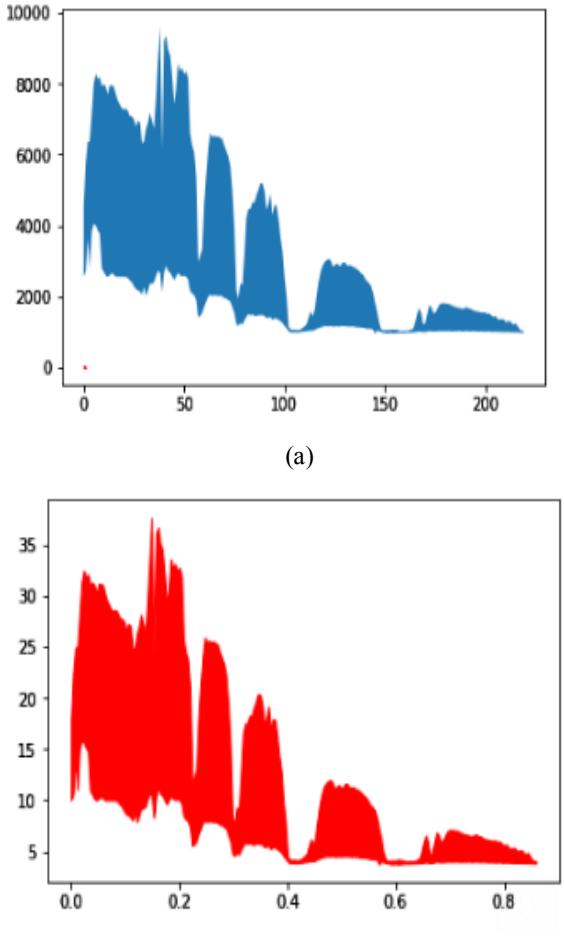

Fig. 1. Scale graph of the data (a) Before normalization (b) After normalization

The paper is organized as follows. This project need a change detection data set, description is shown in section-II. CNN algorithm and methodology is presented in sections III and IV. The complete analysis of results is presented in section V. The last section-VI describes conclusion and future work.

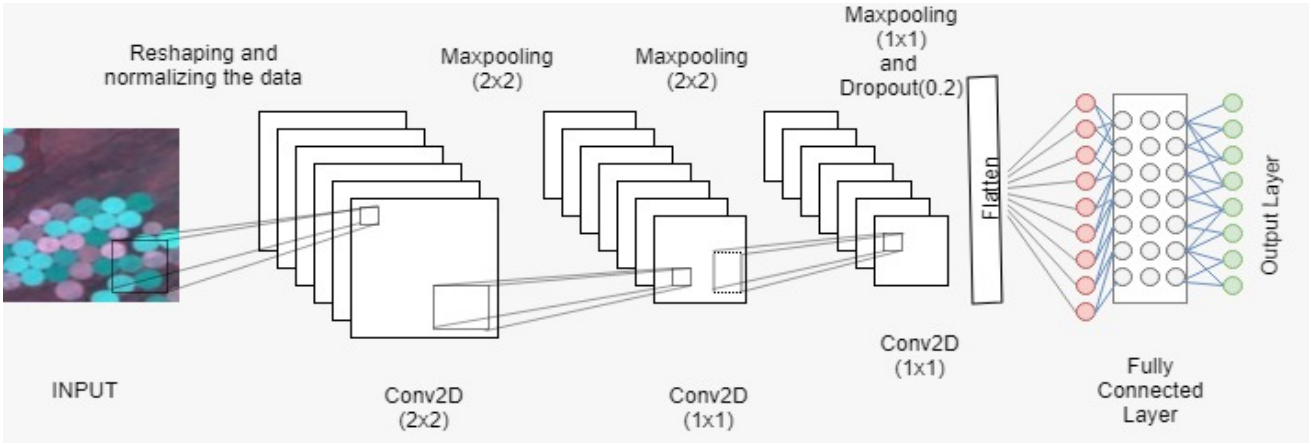

Fig. 2. Different layers of convolutional neural network

II. DATASET DESCRIPTION & NORMALIZATION

The data set used in this work is from AVIRIS sensor [5] with the following features.

- Each class is uniquely represented by an integer in the ground truth.
- They are 16 classes in the dataset
- The spatial resolution of the imagery is 145x145 pixels with spectral resolution of 220 channels for each pixel.

The data consists of a wide range of variables with very high numeric values. Cleaning the outliner values and normalizing the entire data was done for reducing the computation stress. Reducing the scale can fasten the computation and there is no loss in the pattern. The patterns are shown in figure-1.

III. ALGORITHM

There is a wide choice of selection in Deep Neural Networks for supervised learning. Our primary reason of choosing a convolutional neural network and its unique feature to detect new patterns. Recent studies prove that this is one of the best approaches in supervised learning mechanisms.

We used 12 layered CNN(Convolutional Neural Networks). With 3 Convolutional layers, 3 Max pooling layers followed by fully connected neural network layer. The Figure-1 explains the individual layers in detail.

A. Convolutional layer

We had used three Convolutional with relu as activation function and with filters of size (200,100,100). This is using with kernel size of (2,2) for first conv-layer and (1,1) for the next two layers.

B. Pooling layer

We had used Max Pooling layer with kernel size of (2,2). And each layer of pooling uses the Relu as activation function.

C. Fully connected layer

The Fully connected layer has four dense layers the input for the first fully connected layer was flatten and then give to the first layer each layer has RELU as the activation function except the last output layer which we had give activation as softmax, which returns the probability in the range of zero to one.

IV. METHODOLOGY

The change is detected in between two images which are taken from satellite image. Two land-cover images are taken from different time stamps 2013 and 2015. Methodology is represented in figure-3.

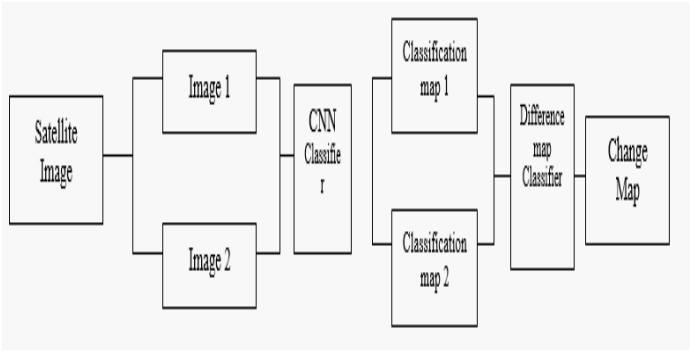

Fig. 3. Architecture diagram of the proposed change detection method

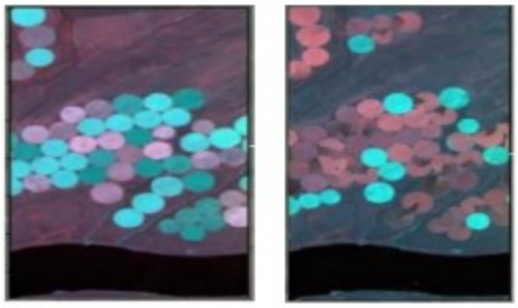

Fig. 4. Sattelite images used for change detection

Using CNN classifier we got two classification maps i.e classification map1 and classification map2.We applied simple difference operation on two classification maps then we got change map with accuracy 97%.

A. Training

Training was done on 8199 samples and test size was 2050. The model was trained for 20 epoches with a learning rate of 0.01. It took 14 seconds to complete the each iteration i.e., an average time of 5 minutes to get a training accuracy of 99% and a test accuracy of 99.66%. The learning curve is shown in figure 5 and the loss curve in figure6.

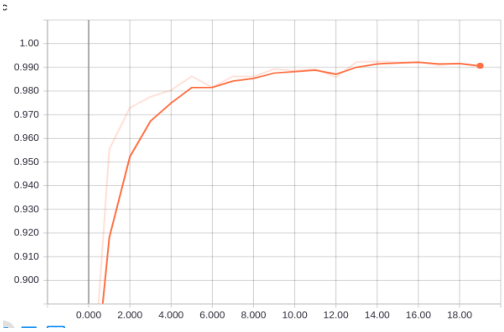

Fig. 5. Learning curve

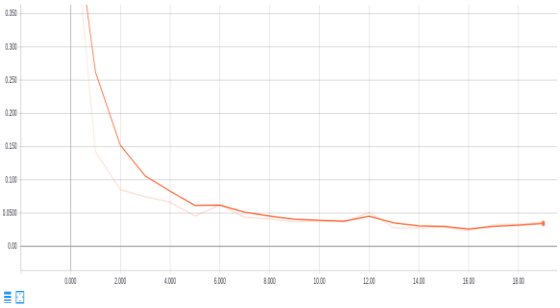

Fig. 6. Loss curve

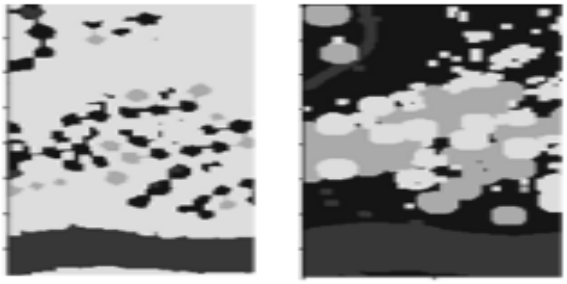
V. RESULTS

As we can see from the result that is Figure 8 describes about change map from two images that are shown in Figure 7. If we consider these two images they are inputs taken through satellite using AVIRIS (Airborne Visible/Infrared Imaging Spectrometer) sensor data which is temporally varied images that means considered in two different timestamps that are 2013 and 2015 from the area Hermiston located in oregon united states. As we see (390,240,242) these are the width,height and band channel (or) channel colour respectively.

Then both the images are classified using a classifier that is CNN (Convolutional Neural Networks Algorithm) then produces two classification maps by undergoing process of cnn they are conv-layer, batch-normalisation,max-pooling,dropout, flatten, dense. After undergoing cnn process then the two classification maps formed are shown in Figure-7 a and b which are shown below. The height and width of these images will be (390,200) no band channel is considered here.



(a) (b)

Fig. 7. Classification Maps (a) 2013 (b) 2015

To get the change map result we find the difference between the two classification maps which the figure is shown below that is Fig 7 change map. This figure shows the difference between two classification maps taken from two different timestamps. In the figure the yellow area indicates the changed area and purple indicates the unchanged area.

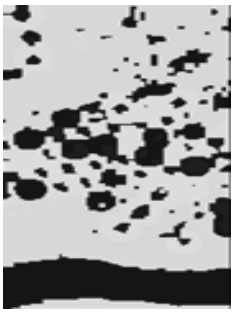


Fig. 8. Change map

The following table 1 illustrates the changes in the classes. The first Column specifies the classes. And remaining columns are the exact count of class labels with Difference in the last column.

TABLE I. CHANGES NOTIFIED WITH NUMBER OF PIXELS TABLE TYPE STYLES

Class	**Year 2013**	**Year 2015**	**Difference**
1	31456	8269	23187
2	14967	11122	3845
7	16239	2236	14003
9	15338	5373	-41035

VI. CONCLUSION AND FUTURE WORK

The technique of using a Deep Convnet model for generating classification maps is optimal for this use case. The generated classification maps for two temporal images are parsed for generating change maps. Using this kind of approach is best, if we need to detect changes in the known

classes. And this approach has wide applications in agriculture, forestry and mineralogy.

The Change Map obtained was well enough to identify the total changes in the complete spatial resolution. We can get the class wise changes from the Convolution Neural networks output layer. Further study can be made in developing a hybrid Convolutional Neural Network, which can classify two satellite imagery and identify the difference in the classification maps by using dual pipelines method.

***Abstract*— Device-to-Device (D2D) communications was originally projected in cellular networks as an innovative prototype for improving network performance. The rise of new applications such as location aware content distribution introduced new user scenarios for D2D communications in cellular networks. The preliminary studies exhibited that D2D communications has advantages such as reduced communication delay and increased spectral efficiency. However, D2D communication approach introduces problems in terms of interference control overhead and conventions that are still open research problems. Therefore, efficient interference modelling design are required. The existing model has focused on addressing interference considering D2D association operating on same cell and very limited work is carried out in addressing interference issues of D2D user operating on overlapping area of multiple cell. For overcoming research challenges, this work presented Efficient Resource Allocation (ERA) model for D2D under cellular network as a game theory model. Experiment are conducted to evaluate performance of ERA. The outcome shows ERA attained significant performance improvement over state-of-art models in terms of sum rate (utility), successful packet transmission, and revenue.**

I. INTRODUCTION

Recently, rapid growth of smart device has been seen resulting in increased traffic and is expected to grow at an annual traffic rate of 53% until 2020 [1]. Therefore, resulting in a requirement of spectrum in cellular network which is expected to go up exponentially in future [2]. However, achieving higher throughput within cellular network owes two challenges. Firstly, it is difficult to increase the physical layer capacity of wireless channel. Since physical layer technologies used in MIMO-OFDM ((Multiple Input Multiple Output-Orthogonal Frequency Division Multiplexing) and 4G/LTE (Long Term Evolution) with interference coordination and capacity-achieving codes, have reached their theoretical limits. Secondly, reducing the size of cell by using femtocell network is a realizable, yet costly, design for improving throughput, as it induces higher cost for offering backhaul connectivity of these small base stations.

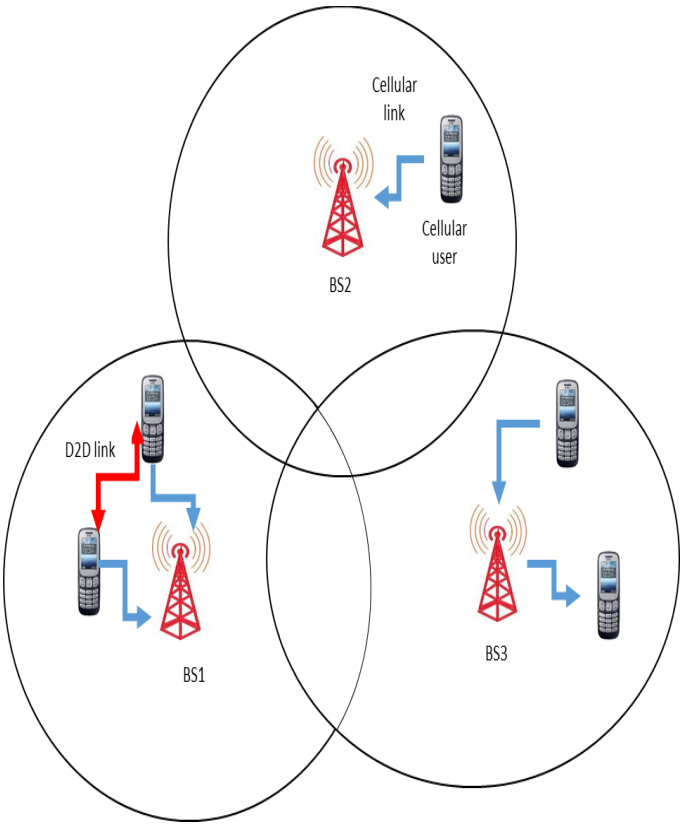

Fig. 1. Architecture of D2D communication under cellular network

Device-to-Device (D2D) communication has emerged has a new paradigm across academic and industries. The architecture of D2D communication is shown in Fig. 1. This is mainly due to unique advantages it offers, the cellular network can offload its traffic, attain higher energy proficiency, better throughput, and robustness to infrastructure failures. Recently, AllJoyn, Qualcomm has aimed at addressing many challenges for

enabling D2D communication. With the new Message Queue Telemetry Transport (MQTT) protocol is specifically designed only for device-to-device communication, the industry is well placed to its real-world deployment. The exiting model on D2D association [3] has still mainly focusing on how device-to-device communication can run proficiently as an underlay to cellular networks. Further, D2D is considered to be one of the promising technique in 5G communications. Here by sharing downlink or uplink resource blocks with cellular subscribers, device-to-device association attains a great potential of increasing network capacity and enhancing spectral efficiency [2]. D2D communication allows direct association among two subscribers which are geographically close to one another without being communicated by based station. This aid in attaining better spectrum utilization, lower delay, and less energy consumption, which can well adapt meet demand of higher transmission rate and larger network capacity [4], [5]. Although enhanced spectral efficiency can be attained by the reutilization of resources in device-device associations. However, it may result in severe cross-tier interference (among cellular subscribers and D2D links) and co-tier interference (among different D2D links transmitting on the same resource blocks) [6], [7].

The existing model [12], [13] has focused on addressing interference considering D2D association operating on same cell with the cellular association. As a result, it incurs interference to the cellular user located in the same cell. For reducing the interference among D2D and cellular subscribers, number of resource management technique adopting game theory [14], [15] approaches has been presented [16], [17], and [18]. However, most of the state-of-art resource allocation model has focused on addressing interference on the intra cell. However, inter cell scenario has be neglected. Therefore, there is need to remodel the game model to provision for inter cell condition. For overcoming the research issues, this work present efficient resource allocation method in intercell D2D association underlying cellular network. Further, this considers base stations as a contender looking for resource allocation of D2D requested load rather than D2D pair as a contender like state-of-art model.

The research contribution as follows

- The novelty of work is this work considers a case where device-to-device link is positioned in the overlapping segment of adjacent cells. Further, the game theory model for resource allocation is presented where base station is considered as contender for contending D2D pairs demand.
- The Efficient resource allocation model attain higher sum rate, successful packet transmission, and revenue.

The rest of the paper is organized as follows. Literature survey is presented in section II. In section III the proposed Efficient Resource Allocation (ERA) model for D2D under cellular network is presented. In penultimate section experimental study is carried out. The conclusion and future work is described in last section.

II. LITTERATURE SURVEY

This section conducted extensive survey on addressing interference issues of D2D association under cellular network for enhancing system performance. Recently, number of approaches is been presented to solve interference issues in device-to-device association underlying cellular networks [8], [9], [10] and, [11]. In [8], presented guard zone based interference modelling for providing QoS requirement of cellular user. For mitigating interference due to presence of D2D association, [9] pairing based interference coordinating model. Further, [10] transmission capacity region which aid in managing interference in D2D environment when both successive interference cancellation and power control were carried out. Limiting co-existence of D2D pairs and cellular user imposed serious interference to the cellular network affecting overall capacity, in [11] considered both uplink and downlink interferences through admission control and power allocation, which intended at maximizing the overall throughput of the D2D associations underlying cellular network. Further, for overcoming (reduce) the interference among D2D and cellular subscribers, number of resource management approaches has been presented [12], [13]. However, most of the state-of-art resource allocation model has focused on addressing interference on the intra cell. However, inter cell scenario has be neglected. In state-of-art D2D resource allocation model, game theory is widely used to obtain characteristics feature of competition between D2D associations. Game theory [14], [15] offers a mathematical solution for effective decision making, which offers a method to predict what may (or would) arise when rational contenders with varying interest. In state-of-art model [16], [17], and [18], D2D pairs is modelled as contender looking for the resources, where the utility of each contender is described as a function of generated interference and realizable data rate. The optimal solution (i.e., equilibrium) for resource allocation can be obtained by using utility function (i.e., contender's best response function). The state-of-art interference model can be used to address inter cell condition by using interference information from adjacent cells. However, it is not efficient when D2D tries to contend with the mutually shared channel of two adjacent cells and it also fails to determine resource configuration. From extensive survey it is clear that a new model is required for addressing interference and enabling D2D association operating in overlapping area of multiple cell in cellular network.

III. EFFICIENT RESOURCE ALLOCATION MODEL FOR D2D COMMUNICATION UNDER OVERLAPPING AREA OF MULTIPLE CELLULAR CELL

This work present efficient resource allocation model for D2D enabled under future high speed and crowded cellular network. Firstly, this work briefly discusses about interference model and architecture considered for resource allocation. Then, this model present a game theory model that maximize the sum rate (utility) of resource allocation considering different assumption. The architecture of interference assumption considered in this work is presented in Fig, 1.

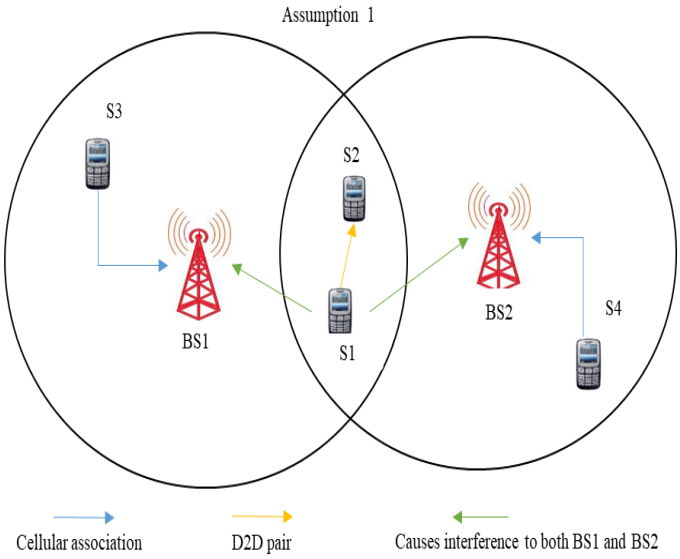

Fig. 1. Architecture of Assumption 1 of D2D communication under cellular network

a) System model for D2D network:

This section describes the D2D system model considered for efficient resource allocation among contending D2D subscribers. This work considers a case where two D2D subscribers are positioned in the overlying region of two adjacent cells using uplink resource for association. In each cell, there exits at least one cellular subscriber that associates with base station. This work further considers that D2D pair reutilize the uplink resources among cellular subscribers while cellular associations use either downlink or uplink resource, thus aid in synchronizing with base stations. The case can be expressed in to following three assumption, where subscriber 1 (source) and subscriber 2 (destination) are the D2D pair, subscriber 3 and subscriber 4 are the cellular subscriber.

Assumption 1: Cellular associations (blue line) in both cells utilize uplink resources. Here, D2D pair (yellow line) induces interference (red line) among base stations as shown in Fig. 1.

Let depict the rate allocation of base station of above assumptions. Let H_{jk} be the channel power gain among source j and destination k over a D2D channel or cellular channel, H_{3B_1} be the gain among subscriber 1 and base station 1, H_{3B_2} be the gain among subscriber 1 and base station 2.The source j power is denoted by q_j, the rate allocation of n^{th} base station in assumption o by S_n^o, the additive white Gaussian noise power at the destination is represented by O_0. Subsequently, for assumption 1, we obtains

$$S_1^1 = C_1 * \log_2\left(1 + \frac{H_{1B_1q_1}}{O_0 + H_{3B_1q_3}}\right), \quad (1)$$

$$S_2^1 = C_2 * \log_2\left(1 + \frac{H_{2B_2q_2}}{O_0 + H_{3B_2q_3}}\right). \quad (2)$$

where S_1 and S_2 are the data rate of base station 1 and base station 2, respectively.

The rate allocation of all base stations aid in obtaining their revenue attained from cellular associations. An important thig to be seen here is that the model to evaluate rate allocation considers interference induced among D2D channel, which aid in impacting revenue of the base station. For example, allocating more bandwidth resource to D2D user will result in reduced interference. As a result, careful planning is required in allocating resource to D2D subscriber in future high speed cellular network. This work present a game theory approach to estimate the amount of bandwidth to be assigned to D2D source subscriber by respective base stations. This work considers that the base station has all information regarding channel state information of each channel in the available cell with respect to base stations. So that overlapping base station can synchronize the radio resource.

b) System Resource allocation using game theory approach for D2D network:

This section describes the resource allocation using game theory approach. Let considers that the each service provider can charge its D2D subscriber. Since D2D channel reutilize the shared channel among two cell. Thus, service providers can maximize their revenue and possess incentive to assign resource to D2D subscriber. The race among service provider can be considered as cooperative game, in which base stations are modelled as contenders. This section present a game theory model where each base station can obtain information of policies and revenue of the base station. Let considers the utility of contender as the regulatory payoffs that composed of two phases. The first phase is obtained from charges obtained from cellular subscribers, and second phase is the charges obtained from D2D association. Therefore, the utility parameter of contenders are expressed as follows

$$V_1^o = \varphi * S_1^o + \omega * C_3^\tau - \mu * C_3^\tau, \quad (3)$$

$$V_2^o = \varphi * S_2^o + \omega * C_3^\rho - \mu * C_3^\rho, \quad (4)$$

where φ and ω are constant depicting the subscription charges of unite bandwidth and resource, respectively. The allocated bandwidth from base station 1 and base station 2 is represented by C_3^τ and C_3^ρ respectively and μ is the cost objective policies of resource. The pricing policies with respect to μ is used similar to [20], [21]. Therefore, it can be formulated as follows

$$\mu = y + z\left(C_3^\tau + C_3^\rho\right)^\alpha, \quad (5)$$

where y, z, and α are constant with non-negative parameter, and $\alpha \geq 1$ assures that the cost objective policies is convex. The Eq. (5), depicts that the cost of all base stations is directly proportional to resource attained by D2D subscriber. Then, the trade-off among data rate and power [22], can be obtained as follows

$$q_3 \propto \frac{1}{C_3^\tau + C_3^\rho}, \quad (6)$$

The proposed resource allocation model attains significant cost reduction and higher sum rate result which is experimentally proved in next section below.

IV. Simulation Result and Annalysis

This section present experiment evaluation of proposed efficient resource allocation (ERA) model for D2D pair under cellular network over state-of-art models. The performance of ERA model is evaluated over existing models in terms of Sum rate, successful packet transmission, and revenue generated to perform data transmission. This work consider a cell scenario, where D2D pairs and cellular users are uniform randomly distributed in a square area of 1000m×1000m with the base station in the center. Further, the D2D pairs and cellular subscribers are mobile in nature with uniform speed. For a fixed number of D2D pairs and cellular subscribers, we repeat the simulation by 2 times and mean of the result is taken. The simulation parameter considered for this work is similar to [17], and [18]. More detail of simulation parameter used for simulation study is described in TABLE I.

TABLE I. Simulation Parameter Considered

Network Parameter	Value
Number of cell	16
Cell width	1000m
Number of cellular and D2D users	200
Modulation scheme	QPSK
Mobility of devices	5 m/s
Maximum distance of D2D	100 m
Sub-carrier bandwidth	1 Hz (15 kHz)
Time slot duration	5 µs
Number of Frequency Channels	10, 20, 30, and 40
Path loss exponent	3.5

a) Sum rate performance evaluation considering varied channel:

This section evaluates sum rate as a utility performance of ERA over existing model [3], [16], [17]. The sum rate performance is evaluated by varying link/channel size and the outcome attained by ERA and exiting model is graphically shown in Fig. 3. The outcome shows that ERA improves sum rate performance by 4.19%, and 34.87%, over exiting model considering varied channel size of 10 and 20, respectively. An average sum rate performance improvement of 19.79% is attained by ERA over existing model.

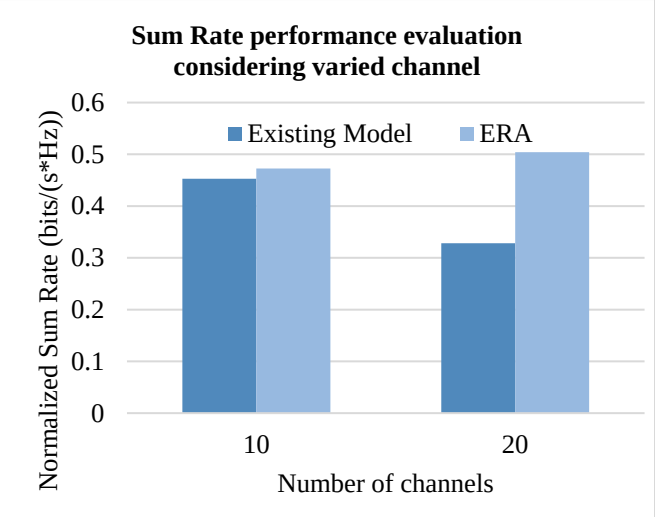

Fig. 3. Sum rate performance evaluation considering varied channel under assumption 1 (Fig. 1).

b) Successful packet transmission performance evaluation considering varied channel:

This section evaluates successful packet transmission performance of ERA over existing model [3], [16], [17]. The successful packet transmission performance is evaluated by varying link/channel size and the outcome attained by ERA and exiting model is graphically shown in Fig. 4. The outcome shows that ERA improves packet transmission performance by 4.87% and 37.18%, over exiting model considering varied channel size of 10 and 20 respectively. An average successful packet transmission performance improvement of 21.02% is attained by ERA over existing model. The overall result attained by ERA is scalable and robust.

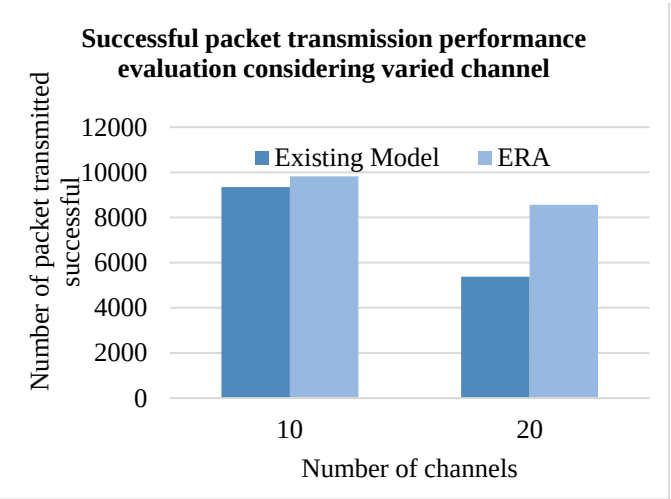

Fig. 4. Successful packet transmission performance evaluation considering varied channel.

c) Revenue performance evaluation considering varied channel:

This section evaluates revenue performance of ERA over existing model [3], [16], [17]. The revenue is computed similar to [13]. The revenue performance is evaluated by varying link/channel size and the outcome attained by ERA and exiting model is graphically shown in Fig. 5. The outcome shows that ERA increase revenue by 30.34% and 4.63%, over exiting model considering varied channel size of 10 and 20 respectively. An average revenue improvement of 17.48% is attained by ERA over existing model. The overall result attained by ERA is scalable and robust.

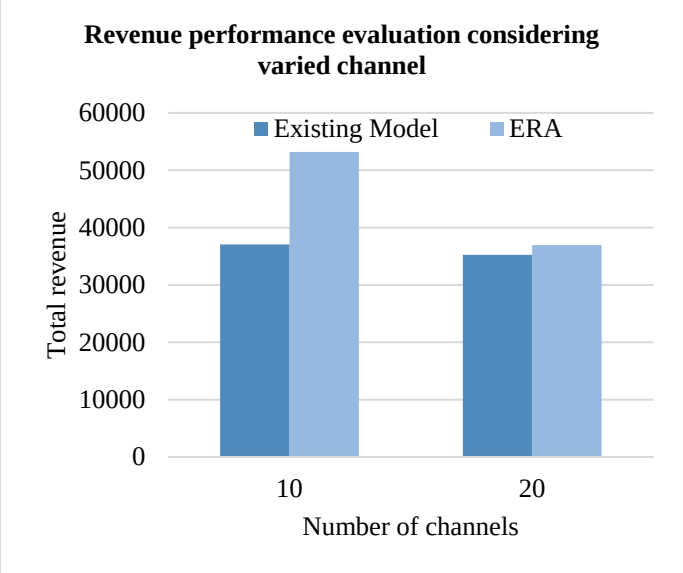

Fig. 5. Revenue performance evaluation considering varied channel.

V. CONCLUSION

For overcoming the interference issues D2D user operating in overlapping area of multiple adjacent cellular network. This work presented an Efficient Resource Allocation model for D2D under cellular network. The resource allocation model is designed as a game theory approach where base station is considered as a contender for meeting resource need of D2D pair presented in overlapping area of adjacent cells. Experiment are conducted to evaluate performance of ERA and outcome shows ERA attain superior performance improvement over state-of-art models in terms of sum rate (utility), successful packet transmission, and revenue. An average sum rate (utility) performance improvement of 19.79% is attained by ERA over existing models considering varied assumption. Further, an average successful packet transmission and revenue performance improvement of 21.02% and 17.48%, respectively is attained by ERA over existing models considering varied assumption. The overall result attained shows scalable and robust performance. In future, this work would consider performance evaluation considering other parameter such as delay and further enhance the resource allocation model.

***Abstract*—Now a days attendance plays a major role in classrooms. The attendance are taken and updated in the lectures logbook manually. Generally the manual work wastes the time for both students and staffs. This problem can be overcomed with the help of the proposed system. The unique characteristics of every human being are their face. In this proposed system, a face recognition technique is used for taking attendance automatically. The proposed system is initially trained with student's database which includes student name, photo and their personal details. The attendance will be taken automatically during every class hours using recognition technique and updated to the student's database. If any student is absent, the message will be automatically sent to their parents or guardian of the absentees using GSM module. The system will also update the everyday attendance database to the Head of department.**

Keywords— Face recognition, Face detection, Open CV, Raspberry pi, web camera

I. INTRODUCTION

IoT makes us to develop a system without human interference. This technology transfers data over the network. It allows objects to be sensed and controlled remotely. Now a day's attendance can be taken manually for every hour by the lectures in an educational institution. The lectures call the students name or their register number. So that, the minimal amount of time can be wasted. And also the lectures manually calculate and overall attendance of the students at the end of the semester. There is a possibility of wrong attendance while calculating overall attendance.

To avoid such problems, the proposed system is implemented on IoT for taking attendance. With the help of IoT, the attendance will be taken automatically which reduces the time and effort of the lecturer. Attendance will be taken for each and every hour in the classroom and it will be automatically updated to the student's database. The absentees are informed to the guardian through SMS. IoT based automatic attendance system will be more secure and efficient technique for taking attendance in the classroom. The login page is created for lecturer using IOT. The attendance database and attendance percentage can also be checked by the lecturer by using the IoT web page.

II. RELATED WORK

In **Face Recognition Attendance System using Raspberry Pi [1],** the attendance are taken using face recognition techniques. The main advantage of face recognition attendance system is to prevent the fake attendance system in the classrooms. The camera module is placed at the center of the classroom. The face recognition method recognizes the face and automatically verifies with the existing database present in Open CV and the attendance is taken.

In **Automatic Attendance system using Face Recognition[2],** the attendance is taken automatically with the help of the face recognition methods. This system is mainly designed to take attendance automatically during class hours. The camera captures the image of the classroom in the beginning of session. The face recognition and detection is performed. Again the image is captured at end of session. Images taken in both the sessions are compared and the attendance is updated in database.

In **Implementation of automated attendance system using face recognition[3],** proposes the attendance system using face recognition. This system can be mainly used in Employee management and Time attendance system. The camera is placed in the entry point of an organization. It can record only the entry time of a student and attendance is updated to the student's database.

In **Smart Attendance system using Face Detection on Raspberry pi[4],** proposes a face recognition attendance system with IOT. Using face recognition and detection algorithm the faces are detected and the attendance is updated to the student's database. The IOT device Raspberry pi use face recognition method for taking attendance automatically and communicates with cloud database.

In **Automated attendance using raspberry pi[5],** the camera is placed at the center of the classroom. Using the face recognition method, the system captures an image of the students in the classroom and compares it with a database already stored. If the image of a student matches it mark it as present otherwise as absent. The attendance will be automatically updated in an attendance database.

III. PROPOSED SYSTEM

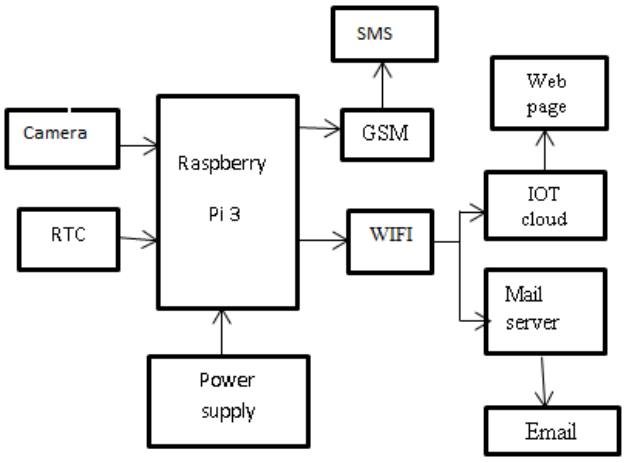

Fig. 1. Automatic Attendance system

The camera is connected with the Raspberry pi. Initially the camera captures images of students present in the classroom and detects the faces as a captured image. The detected faces are compared with the student's database stored in the IOT. When the detected faces matches with the already stored database, then the attendance is marked as present. If not, the absent is marked for the student's those who are not present inside the classroom. After a specified amount of time, the message will be sent to the parents or guardians of the absentees using GSM module. Thus the attendance is automatically updated to student's profile. The web page is created for attendance database using IOT Cloud. The attendance database can also be checked by the faculty advisor by using the web page created with their login id and password. The system will automatically update the attendance database to the Head of the Department. At the end of the semester the faculty advisor can export the student's attendance to calculate overall attendance.

IV. HARDWARE DETAILS

A. *RASBERRY PI 3*

Raspberry pi 3 is ARM based credit card sized single board computer can be used for many applications. Additionally it includes wireless LAN and Bluetooth connectivity for powerful connected designs. The speed of the Raspberry pi 3 is 10 times faster than first generation. Python language is a programming language used in Raspberry pi 3.

Here the Raspberry pi 3 can act major role. It gathers the captured image from the camera. Compare the captured image with the image stored in the database.

Fig. 2. Raspberry pi 3

B. *Camera*

A camera is a hardware device which is used for capturing a photographic images or recording a video which can be stored in a physical medium or photographic film. The image captured can be single image or a sequence of images such as videos or movies. Here the camera is used to capture the images of the students in all the directions. Send the information to the raspberry pi board.

Fig. 3. Camera

C. *RTC*

Real Time Clock (RTC) counts seconds, months, hours, date of the month, month, day of the week and year with leap year compensation up to 2100. RTC is a two wired interface. RTC is the computer clock that keeps tracks of current time.

C. *GSM (Global System for Mobile communication)*

Global System for Mobile communication (GSM) is widely used for mobile communication system. It is a mobile communication modem. GSM is an open and digital cellular technology used for transmitting mobile voice and data services at different frequency levels.

Here the GSM module is used to send the message to the parents or guardians if the student is not available in the class after specified duration of the time.

V. FLOW CHART OF THE PROPOSED SYSTEM

The flow diagram describes the entire operation carried out by the proposed system.

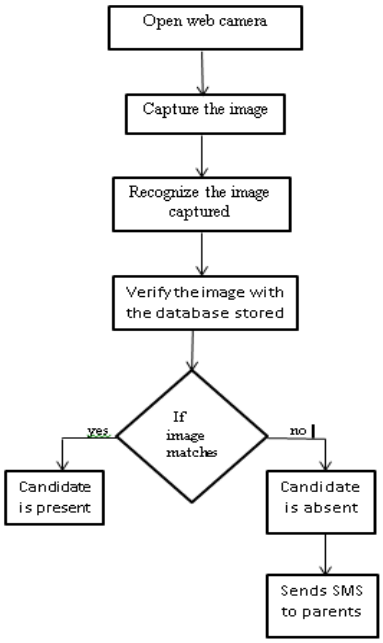

Fig. 4. Flow diagram of the proposed system

VI. EXPRIMENTAL SETUP

Fig. 5. Experimental setup of the proposed system

The different set of images of the students are trained and stored in a student's database. The captured images are compared with trained images and the attendance will be taken automatically using face recognition module.

Fig.6. Trained images

The absentees of the student's will be automatically informed to their's parents through SMS using GSM modem.

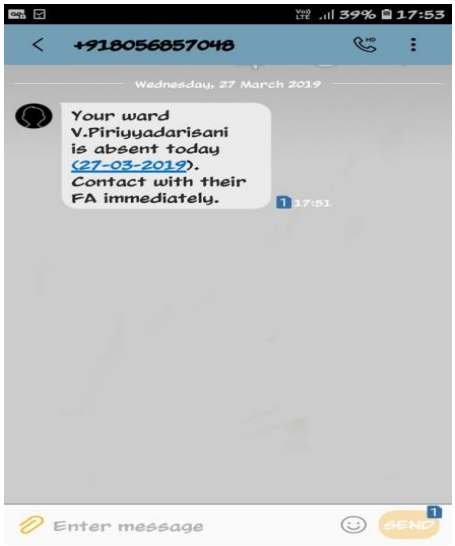

Fig.7. SMS to the parents

The updated attendance can be checked by the faculty advisor using the login page created.

VII. CONCLUSION

The automatic attendance system using face recognition technique has been developed for replacing a manual attendance system. The propsoed system can capable of working under numerous styles of lighting conditions, different seating arrangements and environments in various classrooms. Most of those conditions are tested on the system and system has shown 95% accuracy for many of the cases. There can also work for exist students depicting numerous facial expressions, varying hair styles, beard, spectacles etc. All of these cases are tested to get a high level of accuracy and efficiency. This proposed system will be enforced for higher results relating to the attendance management. So the proposed system is proved to be more secure, reliable, fast and efficient system. The system can save time, and reduce the quantity of work of the faculty in the administration and can replace the attendance sheets with electronic equipment and reduces the quantity of human resource required for the purpose.

VIII. FUTURE SCOPE

The proposed system can be further developed by improving the recognition rate and by using the Raspberry pi Infra Red camera module. So that the system can be uses as a security surveillance system.

***Abstract*—** In industries, difficult work is being decreased everywhere scale to expand effectiveness and exactness, and gain benefit by introducing robots that can do repetitive works at lesser expense of preparing. A onetime establishment of such a gadget may cost an enormous sum at first, yet in the more drawn out run, will end up being more beneficial than difficult work. Out of the part, a basic robotic arm is a standout amongst the most generally introduced machines. Robotic arm is one of the significant undertakings in the present computerization industry. Automated arm is a piece of the mechatronic industry which is quickly versatile and developing industry today. Distinctive changes and extra features are being associated with the first kind of straightforward robotic arm to upgrade its ease of use under various conditions. In this project we are building up a robotic arm which will have a free rotation around multiple axes and we are including the technology of Image Processing with it to make it a visual signal based working robotic arm. This project is a pick and place robot, you can take the desired article starting with one place and carry it with its gripper claw using Hand Gestures and, the movement of the whole robot from one place to another place takes place with the wheels attached to the robot using speech recognition. The operations will be constrained by a visual processing framework that read the gestures and will give directions to the Arm for performing various types of movements and tasks.

***Keywords*—** Robotic arm, Image Processing, DC motors, Machine Learning, Gestures, speech recognition.

I. INTRODUCTION

In this project, we will learn diverse parts of Mechatronics, Image Processing, sound processing Mechanics of Machines and their modern execution. We will have a hands-on involvement on working with Python, coding and execution. We will find out about the usage of Artificial Intelligence in the field of Image Processing. The proposed framework comprises of two modules .The first module is Robotic arm control utilizing static hand signals and the second module deals with Maneuverability control utilizing voice commands.

Raspberry Pi acts as a master in perceiving the signals and Arduino will go about as slave by moving the mechanical technology according to the direction issued by raspberry pi. The gestures are prepared utilizing Machine learning procedure utilizing Open CV and SKlearn (essential python libraries utilized for machine learning). At first the motion is distinguished utilizing background subtraction and after that skin segmentation is made and the hand portion is alone segmented and further the features are extracted using Histogram of Oriented gradients and further it is classified using Random Forest. The final model will deployed in the raspberryPi based on the detected gesture it will send command to Arduino to control servo/DC motors of the robotic to perform custom gestures using pulse width modulation.

Further utilizing Google API clients voice inputs are captured and prepared in such an approach to get the string of the specific command given by the client. The strings are further given to Arduino such that the mobility is controlled.

Utilizing Histogram of Oriented Gradients and Random Forests makes the venture increasingly exact in perceiving motions at any rate and parity of exchange off among speed and exactness is kept up.

II. LITERATURE SURVEY

Robots have turned into a substitute for people in unsafe and risky condition. They have turned out to be all the more socially intuitive and this clears path for improvement of algorithms to influence them to perform the tasks productively. Making machines progressively interactive with people and to improve the assignment execution of the robot with less human intervention are the principle goals of HRI. The robot must be equipped for translating, breaking down and understanding a few correspondence components engaged with human to human interaction. The past works in the field of HRI are talked about as for the region of utilization [1].

Sign language is a vital instance of open gestures. Since gesture based communications are exceptionally basic, they are truly reasonable as testbeds for vision calculations [2]. In the meantime, they can likewise be a decent method to assist the crippled with interacting with PCs. Communication via gestures for the deaf is a precedent that has got critical consideration in the gesture literature [3].

The applications like Telepresence and telerobot are regularly arranged inside the area of room investigation and military-based research ventures. The gestures used to connect with and control robots are like completely submerged computer generated experience collaborations, anyway the worlds are regularly genuine, giving the administrator video feed from cameras situated on the robot [4].Gestures can control a robots hand and arm developments to go after and control genuine articles, its development through the world.

Desktop and Tablet PC Applications: In work area figuring applications, gestures can give an elective cooperation to the mouse and console [5]. Numerous gestures for work area registering assignments include controlling illustrations, or clarifying and altering archives utilizing pen-based signals [6].

A player's hand or body position has been followed by Freeman et al. [7] to control development and introduction of intelligent amusement articles, for example, vehicles. Konrad et al. [8] utilized gestures to control the development of symbols in a virtual world, and Play Station 2 has presented a camera named Eye Toy, which tracks hand developments for intelligent amusements [9].

Gestures for virtual and augmented reality applications have encountered one of the best dimensions of take-up in registering. Augmented reality connections utilize signals to empower reasonable controls of virtual items utilizing ones hands, for 3D presentation communications [10] or 2D presentation that mimic 3D associations [11]

Needs for the senior individuals at home are being filled by social-interactive robots. One genuine model is HOBBIT which takes guidelines from the user as motions and facilitates the user with contact screen interface to make a call, stimulation, web, etc. Thus MOBILEROBOTS PeopleBot help the impaired and old individuals in family unit exercises. The association is through Phantom Omni, a haptic interface mounted over robot [12]. Kinect sensor goes about as interface to recognize arm signal for shopping in Mobile Shopping Cart (MSC) which executes the directions inside a large portion of a second time [13].

Recognition of the feelings being a piece of human robot association, where in physiological signals such as tension are registered and sustained through the bio-sensors mounted on human administrator. Moving nearer or casual banter with the user are the extra tasks performed by the robot alongside wall following, obstacle identification dependent on the data sources sustained to the robot. The Robot-based Basketball task (RBB) is an exploratory proving ground where consistent adjustment of its conduct happens as for the human physiological states [14].

Kinder-garten children were made to communicate with robots so as to advance the geometrical thinking while at the same time playing. Thus it improved their geometrical information and appreciated learning. Over the time, the robot is equipped for giving out execution insights of the kids. KindSAR [1], Kinder-garten social assistive robots gives entertainment to youngsters by narrating.

Recognition of the Hand Gesture was executed utilizing the parameters based on the shape [15]. The downside is most extreme parameters adopted in this approached are assumed.

III. *TECHNOLOGY STACK*

The paper deals with identifying the gestures and responding to the speech with the use of Google API and projecting the actions a bot can perform to lift an object. Technology stack includes Machine learning, Image processing and Robotics

- Machine Learning: It is the advanced technology in computer science, which helps the system to behave as human. The base of the Machine learning is pure Mathematics, which helps to perform wonderful tasks. Basically four algorithms such as SVM, logistic regression, Random forest and KNN are used and there accuracy, precision, recall, support are tested and the highest accuracy supported algorithm is used to embed into the Raspberry-pi and further process of loading the data set is done. Now, the machine is trained to recognize some actions. Recognized data is loaded into the program and test against the known and unknown fingers.

- Image Processing: Image processing, helps to do some processing techniques which help to improve the accuracy of recognition of the fingers through the mask. While taking the images of the gestures for dataset collection hog algorithm is used to extract features from the images.

- Robotics: To perform the actions of picking a block or an object a bot is needed which can walk and turn in different direction with respect to the gestures and speech, mostly in the form of a best method called Artificial Intelligence. The bot runs from calculating angles one by one, more likely they are powered by AI blocks that were trained to stand/walk/balance

IV. *ALGORITHMS*

A. Implementation of KNN

1. At the outset, we will generate the data set and send the data
2. Then the value of k is initialized (the nearest neighbor so that, we can make boundaries of each class).
3. Now, for obtaining the class of predicted output, the iteration is to be done from 1 to total number of training data arguments.

- Analyse the test data and each row of the training data and certainly compute the distance between them with the most popular method called Euclidean distance.
- The next step is, we will be using sorting method to the premeditated spaces in ascending order depending on their distance values.
- Now, obtain the top K rows from which the sorting is done.
- Now, just obtain the most recurrent class of the rows.
- Finally, the predicted class is returned and the subsequent output is given.

B. Random forest algorithm Procedure

The procedure consists of two phases which is **creation** and **perform the prediction** from the obtained random forest classifier.

Random forest Pseudocode:

- Arbitrarily pick “k” structures from a whole of “m” structures, only when k << m.
- Amid the different features of “k”, compute the node “d” using best split approach.
- Next, we need to separate the node into offspring nodes using the best split approach.

- Replicate the above 1 to 3 steps until "l" no.of nodes have been occurred and then construct forest by replicating all 1 to 4 steps for "n" no.of times to generate "n" no.of trees.

Prediction technique:
Prediction is performed using the trained random forest algorithm, the steps are:

1. Using the test features and the arbitrarily created decision tree perform the prediction and store it in the form of a target. Then the votes for each predicted target is computed.
2. Finally, the high voted target is the certainly fixed as final prediction.

Voting: Tree one and two would vote that she subsisted, but tree three votes that she expires. If we take a vote, it's 2 to 1 in favor of her existence, so we would classify this commuter as a stayer.

C. SVM: Given a data set containing of features set and tags set, an SVM classifier dimensions a prototype to predict classes for innovative occurrences. It allocates different data arguments to individual classes. If at all, there are only two classifiers means, then the classifier is called Binary SVM classifier.

In SVM algorithm, the plotting of each data element as unique identity in the "n"-dimensional space, where "n" is defined as the no.of features with every feature having a precise coordinate. Then, in the next step the classification is done by recognizing the hyper planes that categorizes the two classes. SVM's are briefly defined as the cutting edge which separates the two classes (hyperplane/ line).

D. Logistic Regression: For logistic regression, we can take any kind of data with wide range. It will run the algorithm on the training set and the model is used to decide the class of the test data.

Pseudocode

- The equation needed to predict the class of the test data is prepared and the data is supplied to the equation to get regression value.
- The regression value is used by the activation function to predict the class of the data. In the project sigma function is used as the activation function.

V. METHODOLOGY

The procedure starts by taking images of hand gestures and creating a dataset. The features from the images taken is extracted by using the HOG (histogram of oriented gradient) algorithm. The dataset is used to train various models such as KNN, SVM, random forest, logistic regression. The best among the algorithms is chosen to create an efficient prediction model using the test data. The model is then fed into raspberry pi module. When the program starts running the camera starts to detect hand gestures using the random forest model, as soon as the gesture has been identified the output is sent in the form binary numbers to the Arduino module. The Arduino module makes use of relays to increase the power voltage from 5 volts to 12 volts and it will be sent to the motors along with the signals from the Arduino board. As per the signals received the robotic arm performs actions in order to pick and place objects. The speech recognizing module includes a chassis which is controlled using the same Arduino module which has Bluetooth module connected to it. The Bluetooth module can be operated by using the google API which is already present in an app, then the signals are sent to Arduino for movement controlling. The movements include forward, reverse, right, left, stop. The power source for the robot is given through plug points and the movement is enabled till two meters.

VI. DESIGN OF THE SYSTEM

The helper bot is designed in such a way that the gesture and speech modules are independently implemented. The gesture recognition system uses machine learning techniques to identify gestures whereas the speech recognition system uses google API to pass the voice commands as signals to the Arduino board.

A. Gesture Recognition

There are two phases in the gesture recognition module. They are the training and the testing phase. From the above diagram, we can see that during the training phase, dataset is collected and then the edge detection algorithms start to act to identify the gestures from our hand. After completing these steps, training of images takes place to classify the gestures. Here we chose random forest algorithm to classify the gestures. Once the model is created we start to take video or an image input to predict the class of the image which will be sent to the raspberry pi for the robotic arm movement.

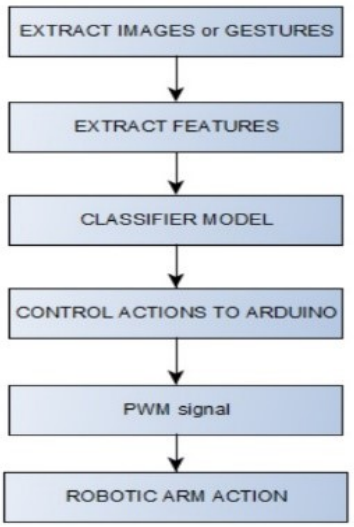

Fig. 1. Gesture Recognition Module flowchart

During the training phase, dataset is collected and then the edge detection algorithms start to act to identify the gestures from the hand. Training of images takes place to classify the gestures. Here we chose random forest algorithm to classify the gestures. Once the model is created we start to take video or an image input to predict the class of the image which will be sent to the raspberry pi for the robotic arm movement

B. Speech Recognition

The speech recognition module works by taking voice input through an android device. The voice commands are converted into signals by making use of a google API. When the Arduino microcontroller receives the signals, it controls the chassis of the robot by making it move front, back, left, right.

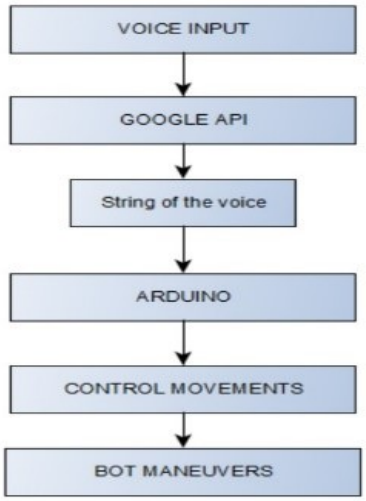

Fig. 2. Speech Recognition module flowchart

The speech recognition module works by taking voice input through an android device. The voice commands are converted into signals by making use of a google API. When the Arduino microcontroller receives the signals, it controls the chassis of the robot by making it move front, back, left, right.

VII. RESULTS

The dataset images of the hand gestures are collected and fed into all the algorithms and then training and tested parts are carried out for calculating the various parameters required to calculate the f1 score which will be helpful for finding accuracy. The results from the various algorithms are as follows:

Algorithms	Precision (avg)	Recall (avg)	F1-score (avg)	Support (avg)
Random Forest	1	1	1	1296
SVM	0.99	0.99	0.99	1296
KNN	0.88	0.88	0.88	1296
Logistic Regression	0.80	0.80	0.80	1296

Table 1. The performance analysis of KNN, LOGISTIC REGRESSION, RANDOM FOREST, SVM Algorithms is done to get the efficient output.

So, from the derived results we can say that, the algorithm of Random Forest and Support vector machine (SVM) gives us the highest values for the parameters precision, recall and f1-score. Among the top two it is obvious that random forest which is an ensemble learning classifier gives the best results. This will now be embedded into the raspberry pi module for recognizing gestures.

Fig. 3

Fig. 4

For the GESTURE 0 the task assingned for the ROBOT is to close its Claw and the Random forest algorithm classifying the gesture on the top left corner as shown in **Fig.3**. When the GESTURE 0 is shown the claw will be closed as shown in **Fig.4**.

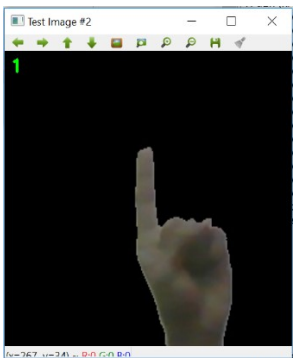

Fig. 5

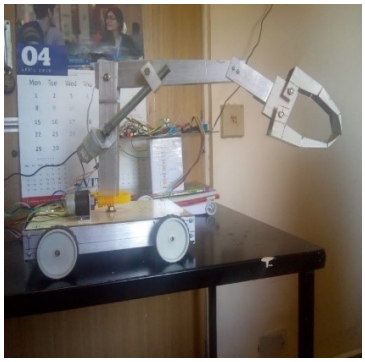

Fig. 6

For the GESTURE 1 the task assingned to the ROBOT is to move its Claw up and the Random forest algorithm classifying the gesture as shown in **Fig.5**. When the GESTURE 1 is shown the claw will move up as shown in **Fig.6**.

Fig. 7

Fig. 8

For the GESTURE 2 the task assingned to the ROBOT is to move its Claw down and the Random forest algorithm classifying the gesture as shown in **Fig.7**. When the GESTURE s is shown the claw will move its Claw down as shown in **Fig.8.**

Fig. 9

Fig. 10

For the GESTURE 3 the task assingned to the ROBOT is to move the Claw to its Left and the Random forest algorithm classifying the gesture as shown in **Fig**.9. When the GESTURE 3 is shown the claw will move to its Left as shown in **Fig.10.**

Fig. 11

Fig. 12

For the GESTURE 4 the task assingned to the ROBOT is to move the Claw to its Right and the Random forest algorithm classifying the gesture as shown in **Fig.11**. When the GESTURE 4 is shown the claw will move to its Right as shown in **Fig.12**.

Fig. 13

Fig. 14

For the GESTURE 5 the task assingned to the ROBOT is to Open its Claw and the Random forest algorithm classifying the gesture as shown in **Fig.13**. When the GESTURE 5 is shown the claw will be Opened as shown in **Fig.14**.

Fig. 15. Robotic arm picking up light objects such as paper balls etc.

After training the model with a dataset of 5000 images, we then test it on some random test data to classify the gesture. The gesture number appears on the top left corner.
The program successfully identifies the gestures when embedded in raspberry pi. The raspberry pi sends the signals to the robot to perform the corresponding action.

VIII. SCOPE

- Robotic devices combined with machine learning is the trending area for developing applications such as automatic plant cutting in a given period of time.
- These can also be used as assistant bots.
- When integrated with large scale equipment, which can send signals in a high range, it will be a great help for the military in detecting the mines.

IX. CONCLUSION

We can imply that the random forest performs better compared to the rest of the algorithms. Therefore, that will be fed into the raspberry pi module for recognizing gestures. When the data set is collected without noise, the gestures can be classified with higher accuracy. The robot picks light objects perfectly with a grip by following the gestures and voice commands.

***Abstract*- The increase in the number of challenges to CMOS technology at extreme Nano meter levels has pushed the research community to find alternative technologies to implement circuits at extremely smaller Nano meter levels. Quantum-dot Cellular Automata is considered to be one of the promising paradigm that can replace CMOS in extreme Nano meter circuit design. It is mainly due to the attractive features it promises to offer such as very high speed, compactness, and extreme low power consumption. Subtractor circuits are widely used in arithmetic and several signal processing applications. In this work, two cost efficient full subtractor designs are proposed using three input and five input majority logic gates. In order to design the circuits with more reliability, the circuits are implemented using clock zone based crossover. Simulation results show that the proposed designs are more cost efficient compared to the existing state-of-the-art designs. The proposed designs can be used to implement any kind of n-bit subtractor design. All the designs are validated and verified using simulation in QCADesigner 2.0.3.**

Keywords- Area, Cell count, Majority Logic, Quantum-dot Cellular Automata (QCA), Subtractor.

I. INTRODUCTION

The challenges in scaling down of CMOS devices to meet the demands of Moore's Law has ignited the research community to find alternatives to CMOS technology for circuit design at very low Nano meter levels. Researchers are trying to find several solutions to keep the CMOS technology relevant to Moore's Law. However, the existing solutions have many limitations and finding an alternative to CMOS has become inevitable [1]. Researchers have come with ideas of several beyond-CMOS technologies. Among the viable beyond-CMOS technologies, Quantum-dot Cellular Automata promises to replace CMOS due to its several promising features such as high speed, small area and low power consumption [2]. Subtractor circuits are used in almost every arithmetic and signal processing application. The existing subtractor designs in QCA have more cells and are vulnerable to fabrication defects due to the type of crossover employed in their implementation. In this paper, in order to reduce the complexity of the subtractor circuits, two cost efficient full subtractor designs are proposed using three input and five input majority logic gates. In addition to that, to increase the reliability of the proposed circuits, the proposed designs are implemented using clock zone based crossover. The proposed cost efficient designs perform better than the existing state-of-the-art designs and it can be used in the implementation of n-bit subtractor of any type. Design verification and validation of the proposed designs are done using QCADesigner 2.0.3 [3].

The authors thank the Visvesvaraya Ph.D. fellowship, Ministry of electronics and Technology (MeitY) for funding this research and DST-FIST, SMDP-C2SD for providing the lab facilities.

The remainder of the paper is organized as follows. Section II provides a crisp and short overview to QCA, Section III discusses the designs and techniques existing in the literature, Section IV presents the proposed subtractor designs and finally, Section V presents the conclusion.

II. QUANTUM-DOT CELLULAR AUTOMATA

A.QCA Cells and wire

QCA cells are the key components of circuit design in QCA. A QCA cell has two electrons and four quantum dots. The quantum dots are interconnected and the electrons can move between the dots but not outside the cell. The repulsion between the two electrons present inside the cell results in occupation of the electrons in one of the two diagonal positions. The cells are considered as binary '1' and '0' depending upon the position of the electrons. A wire is constructed by arranging the cells in an array. Information will be transmitted from one end of the wire and it will be received at the other end. QCA cells are classified into normal cells and rotated cells, based upon the position of quantum dots in the cell. A normal cell logic and a wire formed using normal cells is shown in Fig. 1(a), and Fig. 1(b), respectively. Binary logic transmitted using a normal wire will have the same logic received at the receiver end, irrespective of the number of cells between the transmitter and receiver cell. A rotated cell and rotated wire is shown in Fig. 2(a), Fig. 2 (b), respectively. Compared to a normal wire, the rotated cell wire will have an inverted or non-inverted logic of the transmitted logic, depending upon the even or odd number of cells, respectively, between the input and output cells.

Fig.1. Normal cell. (a) Logic. (b) Wire.

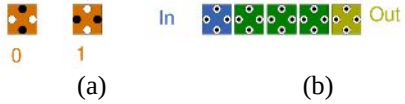

Fig.2. Rotated cell. (a) Logic. (b) Wire.

B. Majority gate and inverter

Majority logic is the key for circuit implementation in QCA. The Boolean logic of the digital circuits is converted to majority logic based expressions and they are implemented using majority gates and inverter. In QCA, three input and five input majority gates are widely used for implementation. The output

of the majority gate depends upon the logic of the inputs. A three input majority gate is shown in Fig. 3(a). To design circuits with optimum number of cells, the majority gate can also be implemented as shown in Fig. 3(b). The Boolean equivalent of a there input majority gate logic with inputs A, B, and C is given by (1).

$$M(A,B,C) = AB + BC + CA \qquad (1)$$

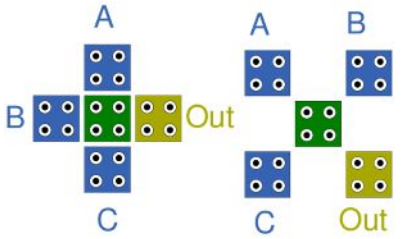

Fig.3. Three input majority gate. (a) Type-I. (b) Type-II.

Several structures of five input majority gates are proposed in the literature. Fig. 4(a) shows the widely used five input majority gate proposed in [4]. Fig. 4(b) shows another version of five input majority gate proposed in [5], which is used in circuits to reduce the complexity.

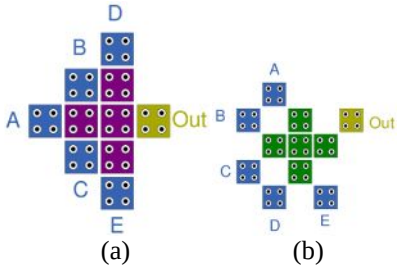

Fig.4. Five input majority gate. (a) Type-I. (b) Type-II.

Inverters are of two kinds in QCA, namely, double path inverter and simple inverter, respectively. Double path inverter is shown in Fig. 5(a) and a simple inverter is shown in Fig. 5(b). Simple inverter is less complex compared to double path inverter. Double path inverter has better fault resistance compared to simple inverter. However, it is achieved at the cost of increased cell count.

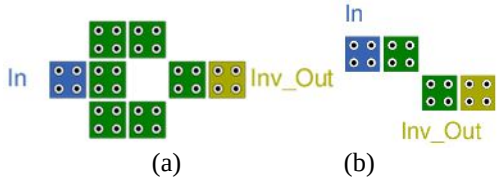

Fig.5. Inverter. (a) Double path. (b) Simple.

C. QCA Clocking

The cells in QCA are not connected to a single clock as done in conventional circuit designs. There are four clock signals (clock 0, 1, 2 or 3) and the cells are connected to any one of the clock. Connection is done in such a way that information flows from one clock zone to another in a pipelined fashion. All the clock signals are in distinct phase and the clock signals will have a 90° phase difference with its neighboring clock signals. Each clock signal follows a sequence of four states in a cyclic order, namely, Relax, Switch, Hold and Release [6]. To differentiate the cells in different clock zones, the cells are represented by different colors as shown in Fig. 6.

Fig.6. Clock zone representation.

D. QCA Crossovers

Wire crossings are the places where two wires cross each other. In QCA, the wire crossings are called as crossovers. QCA crossovers can be broadly categorized as coplanar crossover and multilayer crossover. Coplanar crossovers are the type of crossover where wire crossing is done in the same layer without adding any additional layer. The widely used coplanar crossovers are rotated cell coplanar crossover and clock zone based coplanar crossover. In a rotated cell coplanar crossover, one wire will be a normal wire and another wire will be a rotated cell wire as shown in Fig. 7 (a). In clock zone based crossover, wires which are not connected to the neighboring clock zones can cross each other. Fig. 7(b) shows a clock zone based crossover done between a clock 1 zone wire and clock 3 zone wire. Similarly, Fig. 7 (c) shows a clock zone based crossover done between a wire in clock 0 zone and a wire in clock 2 zone. Rotated cell crossover is more complex compared to clock zone based crossover due to the rotated cells and use of cells with displacement. Placing rotated cells and cells with displacement is very difficult and hence, they are vulnerable to faults that can arise during fabrication. Multilayer crossovers are crossovers where additional layers are introduced in the circuit to aid the wires to cross one another. In general, multilayer crossover is complicated due to the use of multiple layers. In addition to that, the spacing between the layers is also a major factor of concern. Hence, multilayer crossovers are very difficult to fabricate at smaller Nano meter levels. Fig. 7 (d) shows a multilayer crossover done between two clock 0 wires. Additional layers are added over the existing circuit layer and any one of the wire is made to jump the other wire using the additional layers added over the main circuit layer. Multilayer crossover is complex due to the additional layers added to the circuit. Multilayer crossovers are more vulnerable to fabrication faults compared to coplanar crossover.

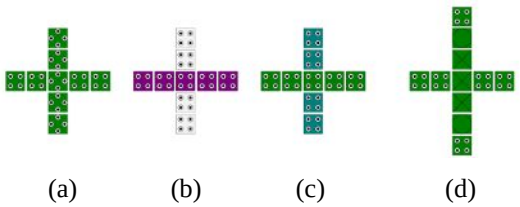

Fig.7. QCA Crossovers. (a) Rotated cell. (b) & (c) clock zone based. (d) Multilayer.

III. EXISTING SUBTRACTOR DESIGNS

In general, subtractor circuits are implemented by combining an adder with an exor gate which functions as a controllable inverter [7, 8]. It reduces the use of a separate hardware for adder and subtractor circuit. However, it is achieved at the cost of increased delay compared to separate implementation of adder and subtractor circuit. In QCA, several subtractor circuits are proposed in the literature. The subtractor circuit comprises of generation of two outputs, namely, Borrow and Difference. The conventional Boolean expression for borrow is given by (2).

$$Borrow = \overline{A}B + \overline{(A \oplus B)}.C \qquad (2)$$

Compared to Boolean logic implementation in CMOS technology, the implementation in QCA is complicated due to the implementation using majority logic. In QCA, only AND and OR gates can be implemented by using majority gates. Hence, implementation of exor operation will require more number of gates compared to CMOS implementation. Although there are dedicated structures proposed to implement exor gates in QCA [9], these structures are vulnerable to faults and it reduces the reliability of the circuit. Hence, to reduce the complexity of circuits, the Boolean expressions are optimized for majority logic based implementations using majority logic. The optimized borrow function using three input majority logic is given by (3). Compared to implementation of conventional Boolean expression using majority gates, (3) requires only one majority gate to implement the borrow function. The Boolean expression for difference given by (4).

$$Borrow = M(\overline{A}, B, C) \qquad (3)$$

$$Difference = A \oplus B \oplus C \qquad (4)$$

Similar to the optimization of Borrow expression, the Boolean expression for difference function is also optimized to reduce the complexity of implementation in QCA using majority logic. Most of the existing designs have used the Three Input ex-or (TIEO) structure proposed in [9], to implement the difference operation [10-12]. Since, the structure is built using the columbic repulsion and not on the conventional logic, the structure is more vulnerable to faults. Hence, it is preferable to implement the circuit using majority logic based expression.

Several subtractor structures are proposed using the optimized majority logic expressions. They have proposed optimized majority logic based expressions for implementation using three input majority gates. Among the proposed equations, the equation used in [13-15] has the least number of inverters and majority gates for its implementation. The optimized three input majority logic expression for difference generation is given by (5). The major advantage of the equation is its ability to generate as a part of its operation. It removes the use of a separate Borrow circuit.

$$Difference = M(M(\overline{A}, B, C), M(A, \overline{B}, C), \overline{C}) \quad (5)$$

Majority logic based expressions are also proposed using 5-input majority logic [16-18]. Among the optimized solutions proposed using 5-input majority logic, the majority logic expression in [17] requires minimum number of inverted inputs and also borrow is generated as a part of difference output generation. Hence, the circuit will be smaller and less complex. The expression used in [17] is given by (6).

$$Difference = M(A, \overline{B}, \overline{C}, Borr, Borr) \qquad (6)$$

IV. PROPOSED SUBTRACTOR

The existing subtractor designs are implemented mainly using rotated cell crossover and multilayer crossover. Hence, the existing designs are complex too implement and are vulnerable to fabrication defects. Hence, in this paper, two simple cost-efficient designs of subtractor are proposed using the three input majority gate and five input majority gate. To reduce the vulnerability to fabrication defects, clock zone based crossover is used for the implementation of the proposed designs. The proposed designs do not require rotated cells and cells with displacement. Hence, the proposed designs are better resistant to faults that can arise due to fabrication defects. The proposed designs are simulated and verified using the default simulation settings used in QCADesigner 2.0.3 as shown in Table I. The cost of QCA circuits is calculated by using (7).

$$Cost = Area * Clock\ phases * Cell\ type * No.of\ Layers \qquad (7)$$

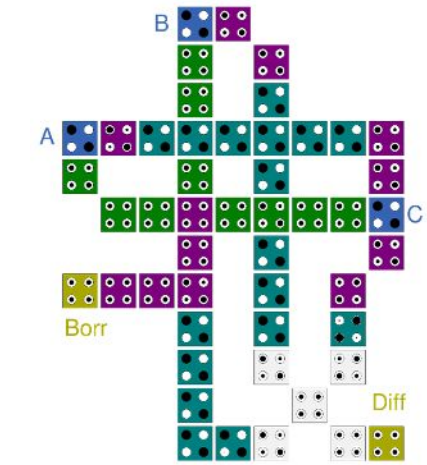
The area used by the circuit depends upon the number of cells used in the design. The speed of the circuit depends upon the number of clock phases needed by the circuit used to generate the output. In other words, the number of clock zones the input has to travel to reach the output. Cell type represents the type of cell used for implementation. For circuits using only normal cells, the value will be 1, for circuits with rotated cells, the value of cell type will be 2, due to its complexity. The number of layers will be 1 for coplanar designs. For multilayer designs, it will be more than 1, depending upon the number of layers used for its implementation.

TABLE.I. SIMULATION SETTINGS

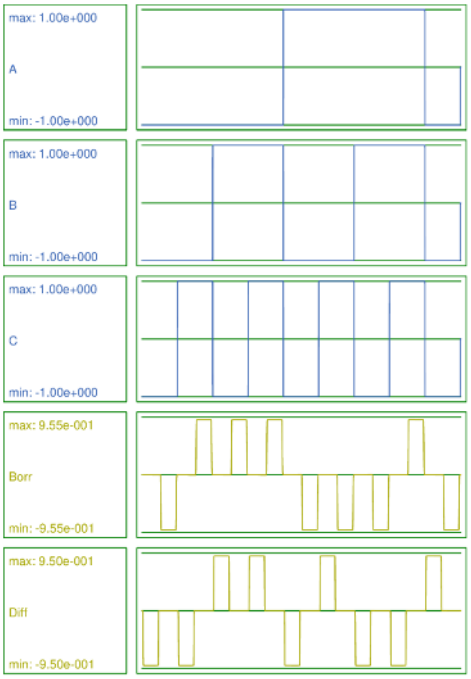
Parameter	Value
Cell dimension	18 nm x 18 nm
Dot diameter	5 nm
Distance between cells	2 nm
Distance between dots	4 nm
Radius of effect	80 nm
Relative permittivity	12.9
Clock High	9.8e-22
Clock Low	3.8e-23
Simulation engine	Coherence vector

A. Proposed Three input Majority Logic design

The first design is implemented using the three input majority logic expression in (5). In order to reduce the complexity of the circuit, the three input majority gate shown in Fig. 3(b) is used for the implementation of the proposed circuit. Fig. 8(a) shows the proposed design-I implemented using three input majority logic and its simulation results are shown in Fig. 8 (b). Table II compares the performance of the proposed design-I with the existing state-of-the-art designs implemented using three input majority logic.



(a)



(b)

Fig.8. Proposed Subtractor-I. (a) Circuit. (b) Simulation results.

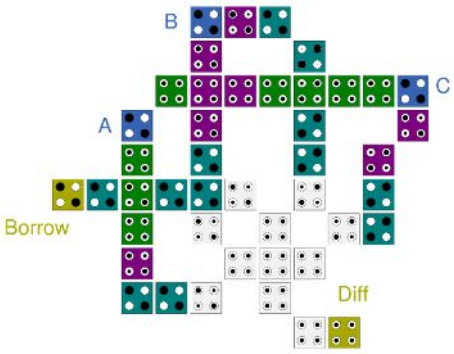
TABLE II
3-INPUT MAJORITY GATE BASED FULL SUBTRACTOR COMPARISON

Design	Cell count	Area in μm²	Borrow delay	Difference delay	Cost
[13]	233	0.13	2	8	3.12
[14]	272	0.44	5	9	7.92
[15]	90	0.11	4	4	0.88
Proposed-I	49	0.04	2	4	0.16

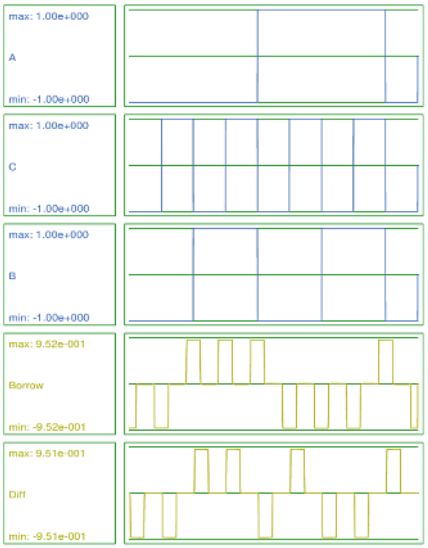
Table-II clearly shows that the proposed design-I is cost-efficient compared to the existing designs implemented using three input majority logic. The proposed design-I has the least cell count, area, delay, and cost among all the designs. The proposed design-I has the same delay even after implementation using clock zone based crossover.

B. Proposed Five Input Majority Logic design

The second proposed full subtractor is implemented using the five input majority logic expression given in (6). In order to reduce the complexity of the circuit, the five input majority gate shown in Fig. 4(b) is used for the implementation. Fig. 9(a) shows the proposed design-II implemented using five input majority logic and its simulation results are shown in Fig. 9(b). Table III compares the proposed deign-II with the existing designs implemented using five input majority logic expression.



(a)



(b)

Fig.9. Proposed Subtractor-II. (a) Circuit. (b) Simulation results.

TABLE III
5-INPUT MAJORITY GATE BASED FULL SUBTRACTOR COMPARISON

Design	Cell count	Area in μm²	Borrow delay	Difference delay	Cost
[17]	63	0.05	3	3	0.30
[18]	53	0.05	3	3	0.30
Proposed-II	44	0.04	3	4	0.16

Table III clearly shows that the proposed deign has the least cell count, area, and cost compared to the existing designs. The delay of the difference circuit is 33% larger than the existing designs due to the clock zone based crossover. However, the

proposed design-II is cost-efficient compared to other designs by more than 45%. In addition to that, both the proposed designs are better resistant to faults that can arise due to fabrication defects. It can be extended to implement any n-bit subtractor designs.

V. CONCLUSION

Quantum-dot cellular automata has the potential to design circuits at extreme Nano meter levels. Subtractor circuits are used predominantly in arithmetic and signal processing blocks. In this paper, two cost-efficient full subtractor designs are proposed using three input and five input majority logic gates. The simulation results show that the proposed designs have fewer cells, area, and cost compared to the existing state-of-the-art-designs. The proposed designs can be implemented in any application that requires a subtractor and also it can be extended to implement any n-nit subtractor design. The proposed designs are simulated and validated in QCADesigner 2.0.3.

***Abstract*— Flood is large amount of water passing an overflow on a land. Flood forecast (FF) system issue a warning corresponding to water level or discharges through hydraulic structures. Flood forecast (FF) increase the capability and advancement in hydrology to mitigate the hazards using machine leanings with ANN. Flood forecasting using machine learning algorithm (MLA) method understand to learn and improve system scale to mitigate flood hazards according to the climate change. This research is carrying out for flood forecasting on Upper Wardha project across Wardha river basin. Flood forecasting (FF) using real time estimation gives chances of flood value and by using the forecasted inflow, rate of inflow in reservoir can decide the time of operation i.e. opening and closing of gate in real time with ANN.**

Keywords—Flood; ANN; Machine Learning; Real Time;

Introduction

Flood Forecasting can be defined as a process of estimation of time and duration based on topographical characteristics of any river basin which reduced the hazards to human life and environment also. Flood Forecasting technique challenge to predict occurrence and magnitude with time of flash flood. Flood happened due to continue precipitation with respective time. Ordinary rainfall also contributes to transform with time into deadly flood.

Flood forecasting techniques play a vital and important role to mitigate the hazards for non-structural structures with cost-effective management. Flood forecasting stations cover the network of flood prone area to give flood warning to administration. Forecasting inflow also used for the operation of hydraulic structures such as dam on which opening and closing of gates on spillways.

Flood forecasting techniques and Flood warning system are required different type of architectures of flood. Flood may be reduced by constructing structures such as dams, weirs, dykes but cannot eliminate the risk. Flood forecasting techniques able to mitigate the hazards for population and environment in real time with an early warning [1].

Flood forecasting has been approach through rainfall – runoff and flood routing model. Flood forecast predict inflow at selected location with HFL value at selected locations of river with time depends on watershed or catchment area. Later, downstream side predicts the flood limited with travel time with an assessment of uncertainties to properly support the decision-makers activities [9].

Flood forecasting using machine learning algorithm (MLA) method understand to learn and improve system scale to mitigate flood hazards according to the climate change with the help of AI. Flood forecasting used for creating the machine learning algorithm with past and real records of flood with real time data using rain gauges for different coming back time.

The dataset sources are rainfall-runoff, water levels using automatic rain gauges with satellites technology, infiltration rate etc.

The present study carried out on Wardha River basin .The Upper Wardha project is one of the major irrigation project in Vidharbha region of Maharashtra state. This project is across Wardha River near village Simbhora Taluka Morshi of Amravati district. The Upper Wardha project consists of earthen dam on a both flanks with a centrally located gated spillway and canal on left and right flanks. The Upper Wardha dam has total grass irrigation (GI) of 11690 (ha) with gross capacity of 786 MCM in Godavari River Basin with annual rainfall in the catchment is 840 mm.

Literature Review

Muskingham equation is used for flood forecasting using combination of single and multi inflow model form on Tar River basin [11]. Real time flood forecast is used for Godavari River basin with improved time 12 hr as compared to conventional method with model accuracy improved by computing flood plain inundations [12]. ANN model tool used to forecast flood [13]. Stream flow estimation using multiple linear regression to generate Rainfall – Runoff data [14]. Overview on different methods for Flood Forecast and Early Warning with advanced development in England, Scotland [15]. A comparison between statistical and ANN method for flood forecasting in river Mahanadi, ANN methods are better beyond the calibration and efficient [16].

Different types and classification of floods are as follows.

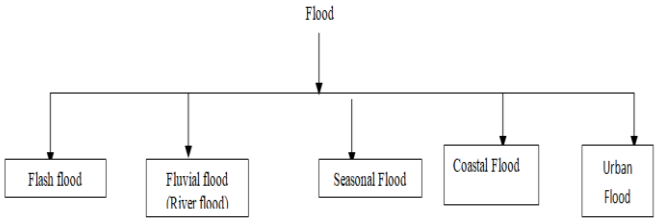

Fig.1:- Types and classification of flood

Methodology

A. Flood Forecasting Models:-

Flood forecasting models depends upon runoff-rainfall duration, intensity of rainfall-runoff, shape with characteristics of catchments and spatial extent. Time series analysis used in hydrology for stochastic model [17]. Flood forecasting is challenge for hydrological models. Different types of Hydrological modeling structure are as follows:

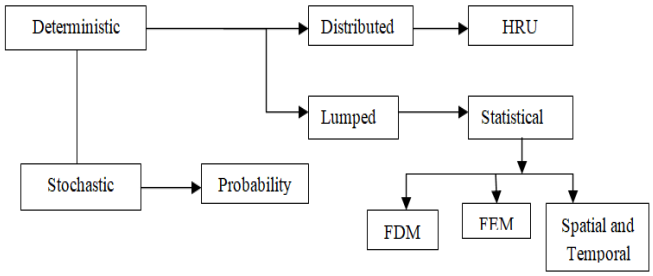

Fig. 2: Hydrological modeling Structures

B. ANN and Machine Learning Approach For Flood Forecasting:-

Neural Networks, which are simplified models of Biological Neuron System. ANN is used to process large data with simple elements [18]. ANN is classified into single layer, multilayer feed forward network and Back Propagation Network.

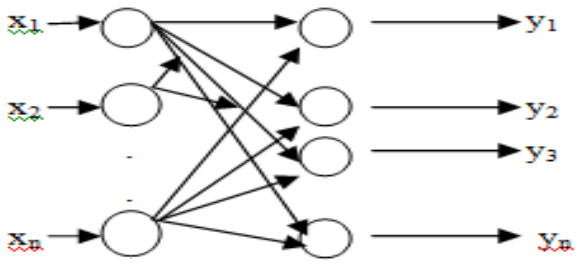

Fig.3. Neural Network Model

C. Machine Learning Method

Real time model is based on actual available and real rainfall and runoff data with time. The following flow chart will give you a concept of real time flood forecasting. Flood forecasting is the process off calculating water levels in reservoir, the storage quantities and outflow rates at particulars inflow hydrograph at various instant. Flood occurrence mainly depends upon various parameters like a rainfall intensity, runoff, evaporation, evapotranspiration, temperature and shape of catchment etc. By interpreting the data for flood routing the technique used i.e. Muskingum Equation which gives the value of inflow and outflow rate. The data obtained from reservoir routing is given to the machine learning, to learn and forecast by the real time data. The Muskingum method of stream flow routing is most frequently used because of its simplicity, as it works with known inflow hydrograph and some fitted parameters without seeking additional information. However, in order to get high degree of accuracy, this method should be for gradually varied flow and not in cases where reach is often affected by back water or unsteady flow condition.

The governing relation between inflow, outflow and change in storage is

Storage=inflow-outflow

$$\vec{I} - \overrightarrow{O} = \Delta S$$

Where,

· = Average outflow during given time period

· = Average outflow during given time period

Δ S= Volume of water stored in the reservoir.

$$\int_{S_j}^{S_{j+1}} S = \int_{j\Delta t}^{(j+1)} I(t)dt - \int_{j\Delta t}^{(j+1)\Delta t} Q\,(t)dt$$

The process of flowing in values at the starting time and end of the j^{th} time interval are I_j and I_{j+1} respectively and corresponding the value of outflow are Q_j and Q_{j+1}.

Machine learning able to learn and improve system in an explicit manner. Machine learning provides computer programs that can approach or obtain or retrieve access data with learning it.

Machine learning able with to calculate large data set. Artificial Intelligent system (AIS) used to train data in such way to improve flood forecasting system with occurring at an early stage development warning system

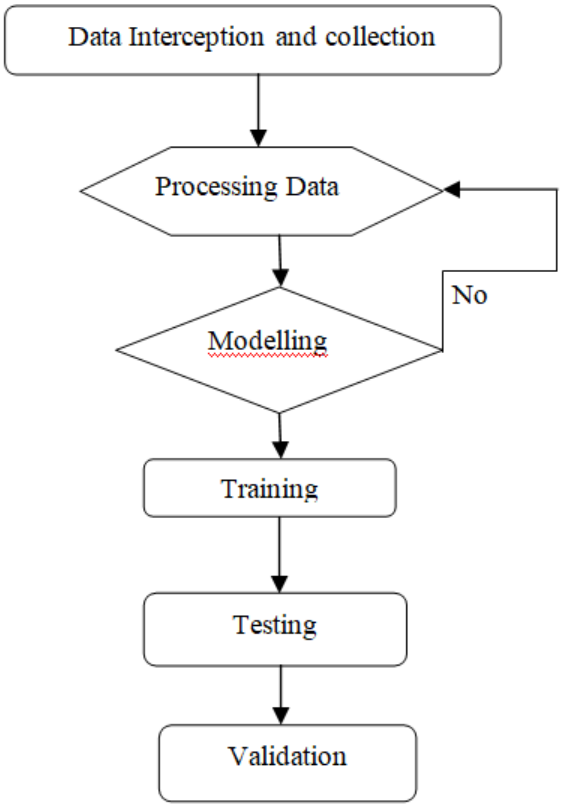

Fig. 4: Flow Chart for Modelling

Results and Conclusion

The Following results are obtained using ANN with machine learning and stochastic Method.

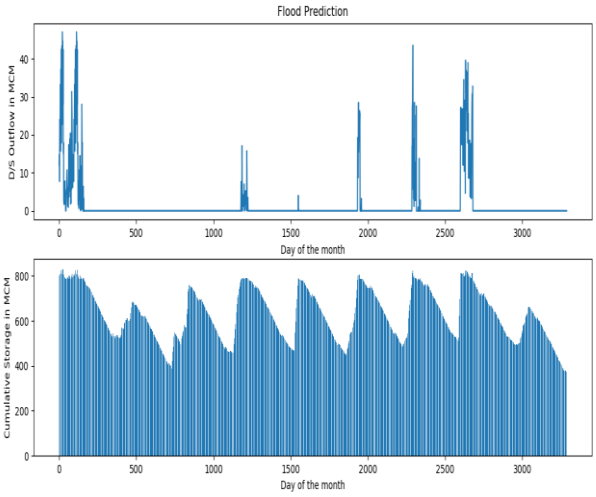

Fig.5: Cumulative Storage and days

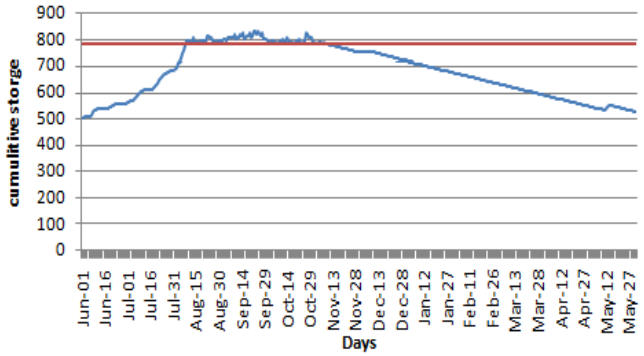

Fig.5: Cumulative Storage and days

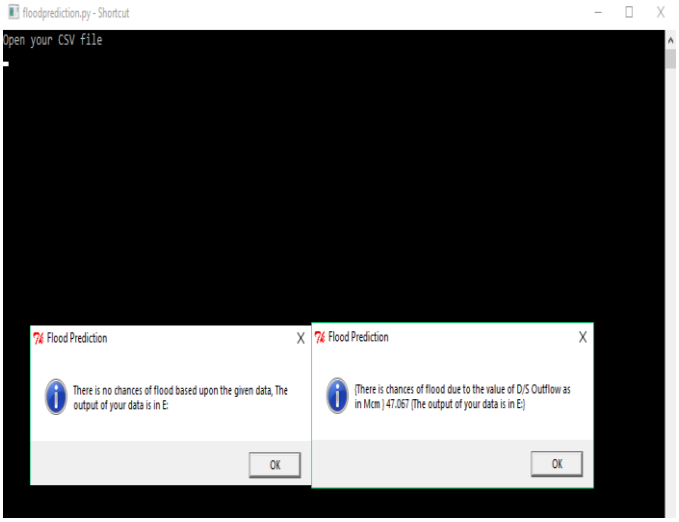

Fig.7:- Flood Forecasted value of outflow for opening of gates

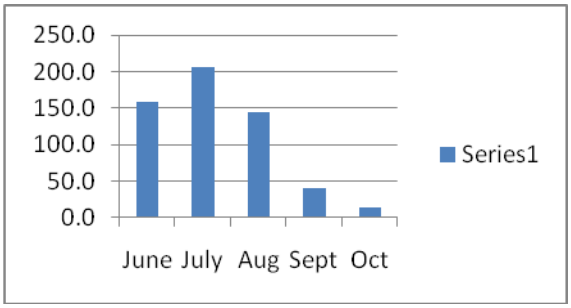

Fig.8:- Hyetograph

Flood forecasting technique organized method suitably based on available data and an appraisal of rating criteria with an inspired performance. Flood forecasting using real time estimation gives chances of flood value in GUI. Flood estimation using Machine Learning in real time can calculate large data instantly. Comparison between flood modelling by machine learning and stochastic method (i.e. Muskinghum method) gives machine learning is accurate, easy and can be applied for numbers of calculation. By using

the forecasted inflow, rate of inflow in reservoir can decide the time of operation i.e. opening and closing of gate.

Abstract — The paper presents the simulation of an pioneering and unique method of FACTS controller called Unified Power Flow Controller (UPFC) without transformer. Transformer-less Unified Power Flow Controller consist of two cascaded multi-level inverter, which lessen the complication and bulkiness of the circuit. Basically traditional UPFC controller consists of two inverters connected back to back. Conventional methods of UPFC involve complex and bulk circuit resulting in the problem for isolation of the transformers & achieve high power rating with desired output. The proposed Transformer less UPFC controller will be cost effective and acquire low space then the conventional UPFC. A multilevel cascade configuration system will reduce the harmonics of the system hence increases the efficiency of the model and reduce bulkiness.

Keywords — Cascaded Multilevel Inverter (CMI), FACTS, SSSC, STATCOM, UPFC.

I. INTRODUCTION

Power grid is a complicated meshed network which is overcrowded and is subjected to serve congestions. Thus several issues like voltage sag, imbalance of real and reactive power and demand of load supply are introduced. To tackle these issues there is need of introducing control devices which control power flow as per the need. Power electronics based FACTS controller are used for the said issues [1]. UPFC is a mostly used FACTS controller which control selectively or concurrently the parameters of power systems that are line and phase voltages, current, system impedance and etc, which influence power flow of the network. UPFC is a FACTS device which combines the function of SSSC and STATCOM via DC link. The Fig. 1 shows a traditional UPFC. Unified Power Flow Controller is a much flexible & multipurpose controller that can be used for following:

a) Phase Shifting
b) Voltage Regulation
c) Line Impedance Compensation
d) Oscillation Damping
e) Simultaneously control of system parameters.

Thus it provides a flexible controllability to completely control the Real and Reactive power flow over the transmission line. Due to the advantage of FACTS devices and independent control of real and reactive power, many researches is going on in the control, analysis and modeling of it [2].

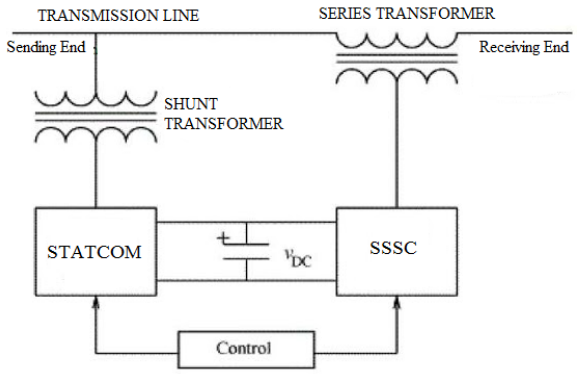

Fig.1. Transformer Unified Power Flow Controller (UPFC).

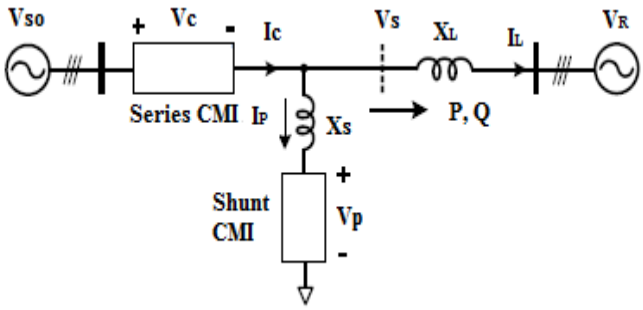
Though UPFC provides several advantages and controllability in the power system on the transmission line, but it suffers from several disadvantages like bulky size of controller since UPFC requires bulky zig-zag transformers which interface the controller with the high voltage transmission lines. Also these bulky transformers slow down the response of the controller to dynamic load changes. Along with the bulky zig-zag transformer, it also requires 48-pulse high voltage high power inverters to obtain desired high quality waveforms which makes it further complicated. Thus the conventional UPFC has many disadvantages like a) Bulky size, b) expensive and uneconomical (30% – 40% of the cost of the system), c) High Losses and d) Prone to failure [3]. The various disadvantages occurring in the conventional UPFC can be overcome by eliminating the transformer from controller. The innovative transformer-less UPFC provides better performance over existing UPFC due to its advantages such as light in weight, fast dynamic response, better efficiency, cost effective, high reliability and a highly modular structure of two CMIs.

II. SYSTEM MODELLING

The cascade multilevel inverter (CMI) can achieve the high-voltage level independent of using transformers, other semiconductor diodes, or number of coupling condensers. Thus to remove the transformer completely, a new transformer – less Unified Power Flow Controller which is based on an novel design of series and shunt cascaded multilevel inverters has been projected which is represented as shown in Fig. 2.



XXX-X-XXXX-XXXX-X/XX/$XX.00 ©2019 IEEE

Fig. 2. Transformerless UPFC using CMI.

The discussed transformer-less UPFC system has two CMIs which are connected in series and shunt. The Series Inverter is in series with transmission line and Shunt Inverter is connected parallel to transmission line just following the series CMI Inverter. Here are some features of the new configuration:

a) In this model there is no need of transformer distinct to the existing UPFC which uses coupling back-to-back dc links, hence, the proposed UPFC can accomplish advantages like economical, light in weight and compact, higher efficiency and reliability, & fast dynamic response to fault;
b) Shunt CMI inverter is connected following series CMI inverter. Also the series and shunt CMI have DC capacitor which supports the necessary dc voltage.
c) The series and shunt CMIs do not share real and reactive power among them and floating dc capacitors have been used;

The proposed UPFC has a modular series and shunt CMI which provides higher flexibility in the system model and high reliability of operation [4].

III. Principle of Operation

Phasor-diagram of the proposed UPFC is represented in the fig. 3. The V_{SO} is sending end voltage and V_R is receiving end voltage. As V_{SO} is along the rael axis thus it makes a phase angle zero. The series CMI can generate a controlled desired voltage to obtain a new sending end voltage V_S, that can control the P and Q of the transmission line. The active power of the system can be made zero by injecting a current through shunt CMI parallel to the voltage of CMIs at the sending end bus. The possibility of both series and shunt CMI using floating capacitors to control reactive power makes the transformer less UPFC a suitable device for the purpose.

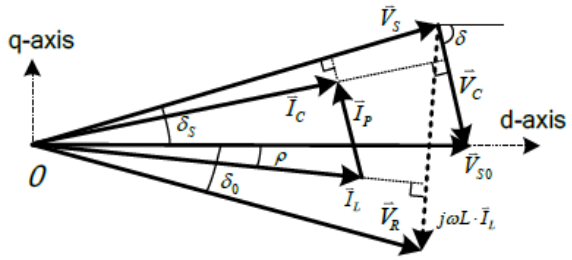


Fig. 3. Phasor diagram of the transformer-less UPFC

The principle of proposed UPFC is structured in detail as shown from Fig. 2 and Fig. 3. The Real Power and Reactive Power flowing on the transmission line can be given as

$$P + jQ = V_R \left(\frac{V_{so} - V_C - V_R}{jX_L}\right)^*$$
$$= \left(-\frac{V_{SO}V_R}{X_L} sin\delta_O + \frac{V_C V_R}{X_L} \sin(\delta_O - \delta)\right) +$$
$$j\left(\frac{V_{SO}V_R cos\delta_O - {V_R}^2}{X_L} - \frac{V_C V_R}{X_L} \cos(\delta_O - \delta)\right)$$

Where asterik (*) indicates complex conjugate of number.

δ_0 = Phase angle of receiving end voltage V_R
δ = Phase angle of series CMIs injected voltage V_C
X_L= Transmission line equivalent impedance.

The uncompensated real and reactive power is given as,

$$P_o = -\frac{V_{SO}V_R}{X_L} sin\delta_O$$
$$Q_O = \frac{V_{SO}V_R cos\delta_O - {V_R}^2}{X_L}$$

The controlled real power (P_C) and reactive power (Q_C) of the Transformer-less UPFC is given by,

$$P_C = \frac{V_C V_R}{X_L} \sin(\delta_O - \delta)$$
$$Q_C = -\frac{V_C V_R}{X_L} \cos(\delta_O - \delta)$$
$$P + jQ = (P_o + P_C) + j(Q_o - Q_C)$$

Since the amplitude and phase angle both of injected voltage V_C of UPFC can be adjusted thus it provide a controlled range of ($-V_C V_R/X_L$) to ($+V_C V_R/X_L$) for real power (P_C) as well as reactive Power (Q_C).

The injected voltage V_C from series CMI is given as,

$$V_C \angle\delta = \frac{X_L}{V_R}\sqrt{{P_C}^2 + {Q_C}^2}\angle\left(\delta_O - \arctan(\frac{P_C}{Q_C})\right)$$
$$V_S = V_S \angle\delta_S = V_{SO} - V_C$$

Where,

$$V_S = \sqrt{(V_{SO} - V_C cos\delta)^2 + (V_C sin\delta)^2}$$
$$\delta_S = \arctan\left(\frac{-V_C sin\delta}{V_{SO} - V_C cos\delta}\right)$$

where

$$I_L = \frac{\sqrt{(V_C sin\delta + V_R sin\delta_0)^2 + (V_{SO} - V_C cos\delta - V_R cos\delta_0)^2}}{X_L}$$
$$\rho = arctan\left(\frac{V_{SO} - V_C cos\delta - V_R cos\delta_0}{V_C sin\delta + V_R sin\delta_0}\right)$$

The new sending end voltage V_S and transmission line current can be controlled as the injected voltage V_C of series CMI is determined. The injected current I_P from the Shunt CMI decouple the Current I_C of series CMI from the line current I_L. Therefore, no real power is exchange between series CMI and shunt CMI which makes possibility to use CMIs with floating capacitors as proposed in the transformer-less UPFC.
Therefore, we have

$$P_{se} = V_c I_c = 0$$
$$P_{sh} = V_s I_p = 0$$

It means series CMI current I_C and Shunt CMI current I_P is to be perpendicular to their voltages V_C and V_S respectively.

$$I_p = I_p \angle \theta_{I_P}$$

Where

$$I_p = I_L \left(\frac{\cos(\rho - \delta_S)}{\tan(\delta - \delta_S)} - sin(\rho - \delta_S) \right)$$

$$\theta_{I_P} = 90 + \delta_S$$

IV. Simulation Model and Results

V. Conclusion

The proposed transformer-less UPFC uses a new configuration based on two CMIs. The Proposed UPFC can attain the same controllability as the existing UPFC. The proposed UPFC have two CMIs which offers numerous advantages over the existing UPFC, such as elimination of transformer compact structure & weight, great efficiency, high operation dependability, economical, and fast dynamic response against the fault.

Acknowledgment

I would like to thank Almighty Allah for his blessings and mercy. I would also like to thank my Guide Mr. S. M. Kulkarni for his support throughout and I also thank to all the staff of electrical department for encouraging me.

***Abstract*—Synthetic aperture radar is imaging radar to cover the wide range of earth surface with high resolution images. It captures images day and night in all type of weather conditions. The polarization data contains information, on scattering mechanism related to different objects. The objects are land, ocean, ice, snow and forest which are natural distributed targets. Using scattering mechanism different objects are categorized. Scattering mechanism is measured by scattering elements of the matrix. The full polarization of synthetic aperture radar data classifies the obtained image. This paper analyses the two different techniques of decomposition methods related to polarimetry. These are linear decomposition and Pauli decomposition methods. These two methods are helpful for system level design and scattering process considerations.**

Keywords—Synthetic Aperture Radar, Polarimetry, resolution, Decomposition, linear, Pauli

I. INTRODUCTION

To detect targets efficiently advanced airborne and space borne Synthetic Aperture Radars (SAR) are designed. In this radar the two platforms that is sensor and target region both are in relative motion. The SAR processing unit is mounted on a moving system basically aircraft or space craft. The target is covered by single beam by the radar antenna. The target area is continuously illuminated with pulses of radio waves, at wave lengths meters to mm. The obtained synthetic radar image can be classified by the full polarization information of the synthetic aperture radar data. The accessing of full polarization is the basic technique behind the SAR polarimetry. It is a method to obtain the target details which is basically based on amplitude and phase related information. The term full polarization refers to the four main channels used in quad (full) polarimetry. They are polarized in horizontal -horizontal (HH), horizontal -vertical (HV), vertical horizontal (VH) and vertical – vertical (VV) directions.

The scattering mechanism gives the physical details of the target. The physical details of the target are referenced to its dielectric constant and orientation. It is obtained through different scattering mechanisms. The radar SAR sensor transmits continuously the electromagnetic wave towards the target. In response to incident wave the various echo waveforms are received by the receiving antenna. At several different antenna positions, the target is detected with coherency. The received signals which are called as echo signals of polarimetric SAR is mathematically given by equation (1).

$$\begin{bmatrix} E^{r}_{H} \\ E^{r}_{V} \end{bmatrix} = [S] \begin{bmatrix} E^{t}_{H} \\ E^{t}_{V} \end{bmatrix} = \begin{bmatrix} S_{HH} & S_{HV} \\ S_{VH} & S_{VV} \end{bmatrix} \begin{bmatrix} E^{t}H \\ E^{t}V \end{bmatrix} \quad \ldots\ldots(1)$$

Here S is called as scattering matrix representing the four basic elements S_{HH}, S_{HV}, S_{VH}, S_{VV}[1]. The two angles namely ellipticity and orientation angle are the salient features. These parameters illustrate the mechanisms of polarization. The two angles related to field vector are represented in Fig. 1.

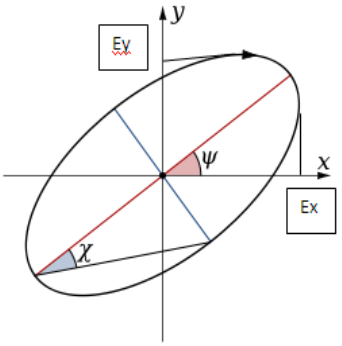

Fig. 1. Relation between ellipticity and orientation

Here ψ^{o} represents the orientation and χ^{o} represents ellipticity for the E vector of an electromagnetic wave. The properties of individual objects of the earth surface are characterized by their scattering nature. This is represented mathematically as the scattering matrix for each pixel of the target image. The received signal obtained by SAR sensor adds for criteria called resolution cell. It is basically the resultant criteria of many distributed targets. These targets are distributed in spatial manner. Every individual or target is represented by each different scattering type of mechanisms. The various scattering mechanisms involved are surface scattering also known as single bounce scattering. The other mechanisms are typically known as double bounce, volume and helix scattering. These are obtained by the natural targets and manmade targets. The physical property surface roughness and its materialistic property namely dielectric constant decide which type of scattering mechanisms occurs. The feature called coherent is basic element criteria of the scattering matrix. It means that the terms in off diagonal element of scattering matrix that is S_{HV} and S_{VH} are equal. Scattering matrix normally gives detail

idea of the working pattern of radar system, in hitting the particular target on the earth surface. It also describes the behavior of the targets on the earth surface for the feature called scatter. This represents the electromagnetic energy returned back towards the radar sensor.

The usual dimension of the S matrix is considered as 2*2. It is considered for every pixel of an image. This concept is illustrated by the authors Fawag Ulaby and Ehsrlon Elactic in contribution toward their paper radar polarimetry for geo science applications [2]. Resolution describes the minimal observable spacing between two same point responses. This is again applied to width of one more response other than previous two. A weaker response among them basically requires larger separation for the detection of the target. Each resolution cell is represented by two pixels. Pixel spacing in SAR imagery is considered for some standard scale. It is normally taken as multiple or division of 100 mts. For ex. ERS -1 data has resolution of 28 mts. In range and azimuth it is delivered with 12.5 mt pixel spacing. In SAR image, the direction of aircraft or space craft is called azimuth direction. The imaging direction is called range direction. SAR processing involves range focusing and azimuth focusing. Range focusing involves de-chirping of received echoes. Azimuth focusing relies on Doppler information produced by target. The difference in dimension of pixel of signal related to SAR image exists to the resolution cell during the data acquisition. It is due to variation of range resolution angle. So pixel resampling is carried out with uniform grid [23], [24].

The various angle related to the target and sensor are categorized as shown in Fig. 2.

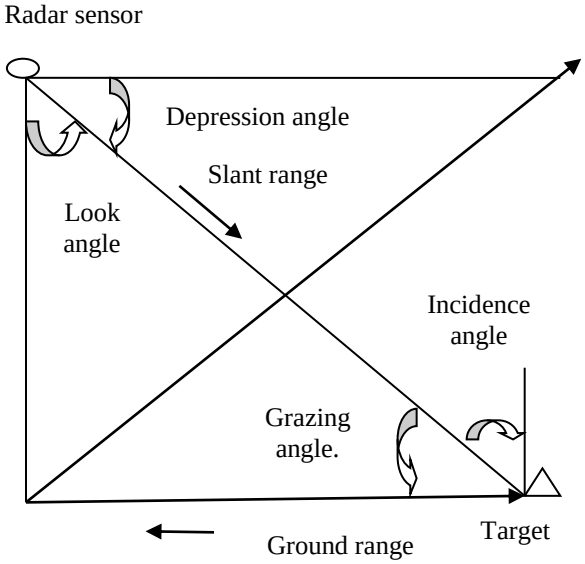

Fig. 2. Synthetic Aperture Radar angles

The slant range is the length representing the line connecting radar sensor and object being observed. The ground range is the range along the ground and target. It is measured from radar nadir track. There exists a line below the sensor base platform is termed as nadir track. The radar beam which hits the target creates a look angle with the orientation normal to ground range. The target also creates an angle with the beam with its normal which is called as incidence angle.

Case 1:

If the surface is smooth

Look angle =incidence angle

Case 2:

If the surface is having curvature

look angle < incidence angle

The depression angle is measured between radar beam by the sensor and horizontal direction of the radar platform. The look is related to depression angle with the difference of 90^{o} minus by each other. The depression angle increases if the look angle decreases. The grazing angle is measured between horizontal surface and incident wave by the sensor [8], [12], [17].

SAR polarimetry provides data about polarization state of received signals for every resolution element or pixel. The behavior of the target is a mathematical representation which is modeled in terms of scattering matrix. This basically gives information of electromagnetic wave by the objects. Current airborne systems have an azimuth resolution of 1m to 0.5m. The resolution of image gives the separation between closest surfaces, which is basically resolved in the final image. The authors in [14], [16] explain with illustrative figures the concept of SAR resolution.

. The recent advances in SAR polarimetry features the fundamentals of processing SAR data using mathematical model in an organized way [13], [7]. Polarimetry is the study of measuring and investigating the polarization pattern of transverse electromagnetic waves. These EM waves are also known as radio or light waves. Polarimetry is carried out on such electromagnetic waves, which are already are reflected or refracted or diffracted waves. These reflection or refraction or diffraction will occur through some material. This change in features will characterize the particular object. Depending on data acquisition method various processing techniques are followed [5], [6]. The processing of SAR data is limited to processing of intensity from target image acquired. The Interferometric processing involves intensity and interferometric phase processing. In interferometry phase and intensity are the main parameters. The target image is processed using various techniques. In interferometry only one image is acquired featuring phase and intensity. In polarimetry the data acquisition is done using different polarization techniques.

Polarimetric processing involves intensity and polarimetric phase processing. In [8], [9], [15] the authors illustrate the fundamental aspects of polarization. The EM wave orientation is discussed in detail. Polarization is method of alignment of electric and magnetic field. These fields are the elementary components of Electromagnetic waves. Although these two fields illustrate the characterization of EM waves, its behavior can be solely done by using the electric field. This is possible because the electric and magnetic field has distinct mathematical relationship. Hence the entire EM wave can be investigated only by knowing the electric field vector. The electric field is represented as a vector. This vector has a length which distinctly represents the amplitude of the electromagnetic wave. The vector rotation rate gives the frequency of the wave. The vector movement can be in different directions namely linear, elliptical and circular. Polarimetric interferometric processing involves intensity, interferometric and polarimetric phase processing which is a new technique.

The radar frequency or wavelength, polarization and incidence angles do affect the scattering mechanisms. If surface is found smooth there is no existence of depolarization. It implies HV or VH back scatter is not present. If the surface is rough there will be some depolarization. Hence HV or VH backscatter exists. For volume scattering such as forest and vegetation high depolarization is found. Thus one can categorize various objects based on the scattering mechanisms. There is peculiar relation exist between scattering mechanisms, scattering matrix and various decomposition techniques involved in the SAR polarimetry [10], [11]. The section II and III highlights the mechanisms related to decomposition techniques.

II. SYNTETIC APERTURE RADAR MATRICES

SAR image is identified with various matrices known as Stokes or Muller matrix or Scattering matrix parameters. The reflected wave from the target has different polarization in relation to incident wave of the radar sensor. The scattering matrix consists of 4 basic elements S_{hh}, S_{hv}, S_{vh} and S_{vv} which are complex numbers. The response of the target is function of incident electromagnetic wave as well as back scattered polarizations. The particular visualization is obtained by polarization signature of the target. The scattering power can be determined by 4 polarization variables HH, HV, VH and VV, the incident angle, elipticity angle, orientation and reflected angles. This variable possibly creates inconvenience in visualization. So backscattered polarizations are considered for two different techniques. The first one has similar polarization that is if the transmitted wave is H then received wave is also H. This is defined as co polarization. The second one has dissimilar polarization that is if transmitted wave is V then received wave is H. This is termed as cross polarization. It is considered for individual incident polarization. This is plotted in two surfaces called co polarization and cross polarization. These plots give proper visualization of proportion related to backscattered wave. The method usually called Back Scattering Alignment (BSA) is used to analyze polarization. When electromagnetic wave energy interacts with objects various scattering mechanism occurs with objects. Polarimetric information of given pixel is combination of scattering mechanisms. To interpret this scattering mechanism and objects properties polarimetric decomposition models are developed [18], [19], [20]. The section III describes the importance of Stokes matrix, along with Muller matrix.

III. SCATTERING AND STOKES MATRIX

A. Sattering matrix

The mechanism involved for the backscattering by the target depends on the wave polarization of incident wave. It may so happen that if the incident wave is horizontal the reflected wave may have either horizontal or vertical polarization. The vertical characterization of beam wave may be reflected by the target in vertical or horizontal directions. S matrix describes the backscattering properties of the target. The two basic component horizontal and vertical component forms the basis in illustrating the electromagnetic wave in terms of electric field. The scattering matrix being complex has both real and imaginary values. It is basically obtained from magnitude and phase measurement by the four channels of the polarimetric radar. To get such values normally a predefined calibration procedure is followed. If the calibration method is not followed then the four scattering matrix are directly measured by the relevant channels of the radar system. The measured scattering properties of the target are dependent on two parameters. These two parameters are nothing but the frequency and radar beam angle. The monostatic radar holds the reciprocity condition true. Here S_{hv} and S_{vh} are equal. Hence scattering matrix is called symmetrical matrix. It has only three independent elements. The two convention method used to describe electromagnetic wave is Forward scatter alignment (FSA) and Backward scatter alignment (BSA). In the FSA for incident and scattered wave the positive Z axis is in the same direction as the traveling of the wave. In BSA the direction of Z axis normally points to the target for two waves called as incident and reflected wave. In both cases the Z axis points in same direction for incident wave and opposite direction for scattered wave. In monostatic radar the coordinate system are same for incident and reflected wave. So in most of the imaging radars the BSA convention is given preference [15]. Therefore naming convention used in BSA for scattering matrix is Sinclair matrix. Similarly in FSA the scattering matrix is termed as Jones matrix.

B. Stokes matrix

The polarization state of electromagnetic wave is illustrated by three parameters. These are orientation, ellipticity and S_o. The parameter S_o is related to intensity of the incident wave. Gabriel Stoke has illustrated the polarization state of the EM wave by vector called Stoke vector. The vector parameters are S_o, Q, U and V

$$\begin{bmatrix} S_0 \\ Q \\ U \\ V \end{bmatrix} = \begin{bmatrix} |E_v|^2 + |E_h|^2 \\ |E_v|^2 - |E_h|^2 \\ 2\,\mathrm{Re}\{E_v E_h *\} \\ 2\,\mathrm{Im}\{E_v E_h *\} \end{bmatrix} = \begin{bmatrix} S_0 \\ S_0 \cos 2\psi \cos 2\chi \\ S_0 \sin 2\psi \cos 2\chi \\ S_0 \sin 2\chi \end{bmatrix} \text{.....(2)}$$

In equation 2 the |.| represents the absolute value. The character * represents the complex conjugate [15]. There are two cases of EM wave. The EM wave may be completely polarized or partially polarized or completely unpolarized. The three stokes parameter are independent in case of completely polarized wave. The total power is given by

$$S_o^{\,2} = Q^2 + U^2 + V^2 \text{.....(3)}$$

For the partially polarized wave, the total power is more than the polarized power.

$$S_o^{\,2} > Q^2 + U^2 + V^2 \text{.....(4)}$$

The polarization of the incident and reflected wave are related to backscattered power of scatterer with the equation (5).

$$P = 0.5(S^S)^T M S^i \text{.....(5)}$$

Here M represents the Stokes matrix. It is another way of transforming incident EM wave into backscattered wave. The Stokes matrix is also symmetric for reciprocity condition. In BSA the other version of Stokes matrix is used. It is called as Kennaugh matrix.

C . Muller matrix.

Muller matrix is mostly used in FSA convention. The various scatterers are distributed on the earth surface. So there is particular measurement to be followed for all N independent values. It is basically asymmetric in nature. The total numbers of pixels are considered as N values. The scattering behavior of the Muller matrix for individual pixel in the obtained image is feature of polarization criteria [21], [22]. All the three different scattering involved are odd, even number of reflections and diffuse scattering. The next section describes the two decomposition methods in scattering matrix called linear and Pauli decomposition methods.

IV. LINEAR AND PAULI DECOMPOSITIONS

The linear decomposition technique is considered as basic decomposition technique. Here information obtained from individual polarization channel is considered. The information obtained corresponds to cross polarized scatter. The three vectors are k_1, k_2, k_3. The k_1 represents the scatter of horizontal oriented target scattering. The second component is by cross polarized scatter. The third component is scatter of vertical oriented target scattering [3], [4]. The target vector for linear decomposition is given as

$$\bar{k}_l = \begin{bmatrix} k_1 \\ k_2 \\ k_3 \end{bmatrix} = \begin{bmatrix} S_{HH} \\ \sqrt{2}S_{HV} \\ S_{VV} \end{bmatrix} .....(6)$$

Pauli decomposition uses Pauli matrices for the extension of scattering matrix. It is basically applied to deterministic targets. It consists of four scattering mechanisms. The first is called single scattering from plane surface. The second and third parameter is called diplane scattering. It is also called as double or even bounce scattering. Such scattering will occur from corners with orientation of 0^o and 45^o. The fourth element is called anti symmetric component of S matrix. The monostatic radar this term leads to value zero [7]. The Pauli vector is given by

$$\bar{k}_p = \begin{bmatrix} k_1 \\ k_2 \\ k_3 \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} S_{HH} + S_{VV} \\ 2S_{HV} \\ S_{VV} - S_{HH} \end{bmatrix} .....(7)$$

V. DISCUSSIONS

The image characterization is basically obtained by polarization state of the electromagnetic wave. The various scattering mechanisms obtained through natural distributed targets basically depend on wavelength, dielectric constant and polarization of the EM wave. The mathematical modeling of the target identification is carried by different matrices. This basically depends on the scattering alignment technique involved such as BSA or FSA. Why and how different matrices can be used for the target detection is the valid information depicted in this paper. Identifying the target vector and evaluation of the target vector for linear and Pauli decomposition from the SAR image is the contribution of this paper.

The relation between ellipticity and orientation are analyzed using E vector analysis of electromagnetic wave. The component E and H are found to be orthogonal to each other.

Table 1. Comparison of target vectors in linear and Pauli decomposition

Decompositions	**Target Vector Significance**		
	k_1	**k_2**	**k_3**
Linear decomposition	Horizontal orientation	Cross polarized target	Vertical orientation
Pauli decomposition	Single bounce scattering	Double bounce scattering	Volume scattering
	Sphere, plate scatter	Diplane scatter	Dihedral scatter
	Single bounce scattering	Volume scattering	Double bounce scattering

Table 1 depicts the parameters of target vector related to the decomposition technique called as linear and Pauli decompositions. The information in the table reflects the scattering property of the target distributed on the earth surface. The backscattering information helps in identifying the target. SAR image is basically combination of energy present for individual image pixel. It depicts the combination of three images. The interpretation of polarization state change of the backscatter is obtained by target vector of these decomposition techniques.

Fig. 3 represents the overall analysis of decomposition method adopted for scattering matrix of polarimetry data. The two methods are evaluated through image analysis using Python system model.

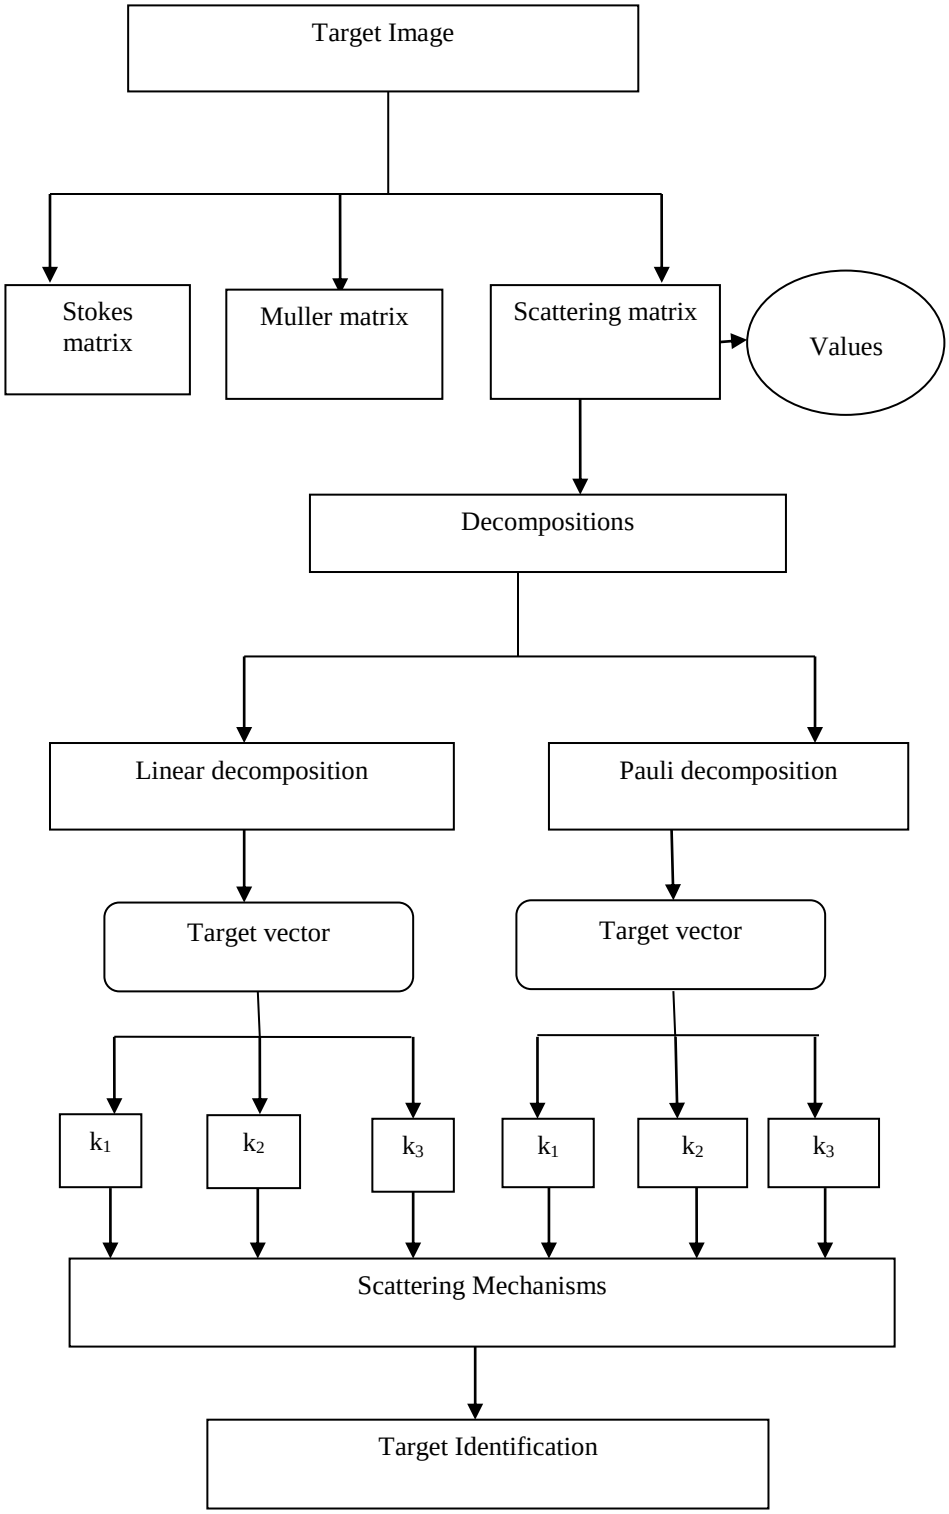

Fig. 3. Decomposition analysis for linear and Pauli decompositions

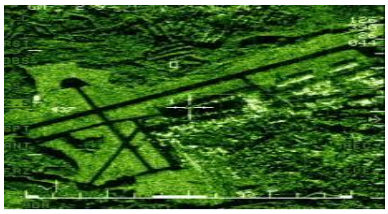

Fig. 4. Original Image

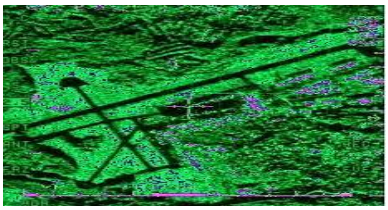

Fig. 5. Linear Decomposition Image

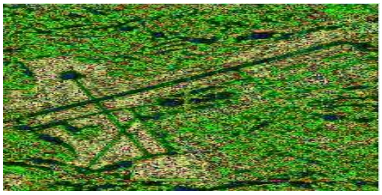

Fig.6. Pauli Decomposition Image

The Fig. 5. and Fig. 6. represents the cross polarization variation.

VI. CONCLUSION

This paper gives basic idea regarding the BSA and FSA conventions. The role of different matrices is highlighted in evaluating the target vector. The effect of polarization of the electromagnetic wave is studied for both conventional methods. System model for each method is developed. The involvement of linear and Pauli decomposition techniques for SAR polarimetry are realized. The target vector depicts the scattering property of the backscattering nature of the distributed targets.

***Abstract*— Cloud computing is one of the most prominent technology due to flexibility in distributing the resources. This technology enables the user to pay as per their requirement. In cloud computing virtualization is an essential technology. Reducing the load imbalance level across virtual machines in virtualized environment is of significant interest among researchers. In order to deal with the load balancing problem virtual machine migration is one of the popular technique being applicable. In this paper, we have devised a load balancing mechanism based on virtual machine migration for not only minimizes the load imbalance level but also utilizes the energy efficiently.**

Keywords— virtual machine; load imbalance level; virtual machine consolidation; energy usage

I. INTRODUCTION

Cloud computing is a modern computing model which has achieved the popularity for providing and managing services like software and applications online. Cloud-based services are basically on-demand, scalable, device independent and reliable [1,2]. Virtualization is an essential concept provided by cloud computing. It can control and share the available resources over the datacenters [3]. With the help of virtualization, we can create multiple operating systems like virtual machines and share the resources among these operating system. A virtual machine can be visualized as a software implementation in which an operating system can be installed. In other words a virtual machine work as a complete operating system. In the cloud, multiple numbers of virtual machines can run in a single physical machine by sharing its resources. Virtual machine placement is a process in which a physical machine is selected to host for a virtual machine with fulfilling all the requirements of the virtual machine. Virtual machine migration is an operation in which a virtual machine is a transfer from one host to another host according to its requirements.

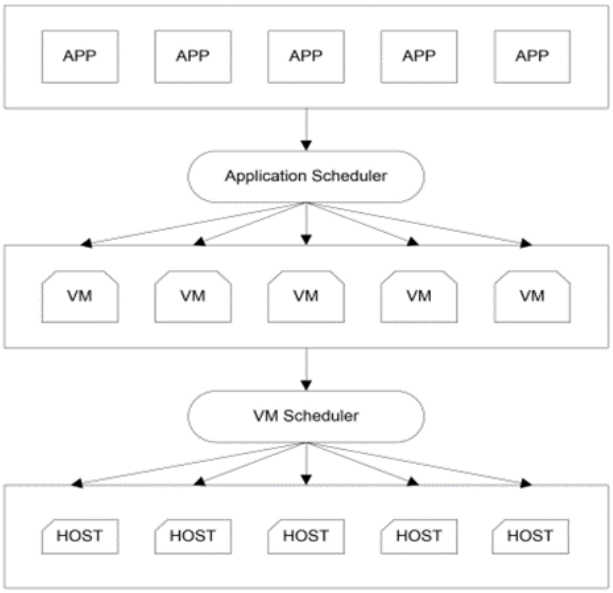

Fig. 1 Cloud System Architecture

In cloud datacenters load imbalance has always been a research subject. The result of load imbalance always leading to performance degradation, SLA violation, etc. To reduce this performance degradation, SLA violation the load balancing needs to be achieved not only across the virtual machines but also within the available host.

The cloud system can be represented as a three-layer architecture as shown in fig.1. According to the above figure the applications exist in the upper layer which is submitted by the user. The multiple numbers of the applications installed onto the virtual machines by the application scheduler. In the next layer, the virtual machines need to be scheduled in the physical machines with the help of virtual machine scheduler. In cloud the load can be possible at application level as well as virtual machine level.

In order achieve the load balancing at the host level there are many scheduling schemes are present. Virtual machine migration one of the popular technique in this direction [4,5,6]. Virtual machine migration is a technique in which a virtual machine is selected to transfer from one host to another host. In this paper, we have proposed a load balancing approach using virtual machine migration technique to achieving energy efficiently.

The next section provides a brief information about the related literature currently present. In Section 3 the proposed load balancing scheme is described. Section 4 highlights the experimental environment and obtained experimental results. Finally, the last section discusses the concluding remarks and future directions respectively.

II. RELATED LITERATURE

In cloud computing environment load imbalance is a well know problem. There are different types of approaches are available to deal with this load balancing problem. Virtual machine migration one of the popular technique in this direction. In this section we are going to discuss some migration based load balancing approaches proposed by different authors.

Zhu et al. [7] provide a heuristic based mechanism using only the CPU load to solve a dynamic virtual machine consolidation problem. For the evaluation, this technique uses historical data. In this technique, the overloaded host has decided by using 85% as an upper threshold value. If the CPU load of the host exceeds the above upper threshold value then that host is selected as overloaded host. Similarly, the lightly loaded host has decided by using 50% as a lower threshold value. If there is a host with the CPU load below the lower threshold value then that host selected as lightly loaded host. This static threshold heuristic doesn't lead to any workload changes as they are not acceptable for the system with the dynamic workload.

Beloglazov et al. [8] provide a consolidation approach which determines two types of threshold values to detect the overloaded and underloaded hosts. Like the previous technique, this technique also uses only the CPU load for the evaluation. The upper threshold value has decided using three types of policies that are MAD (median absolute deviation), local regression(LR) and interquartile range (IQR). If there is host having CPU load exceed the upper threshold value then that host is selected as overloaded host. After the completion of overloaded host detection , this technique selects the virtual machine from the overloaded host for the migration process to balance the load. For the virtual machine selection, this approach used three types of techniques that are MMT(Minimum migration time), Random choice policy(RC) and the maximum correlation(MC) policy. This approach provides a good result for energy consumption and SLA violation. In this approach, the author uses historical data.

TABLE 1 COMPARATIVE STUDY OF RELATED LITERATURE

Sing et al. [9] proposed a load balancing algorithm to manage the hierarchical and multi-dimensional resource constraint called vector dot. In this approach, the multi-dimensional resource demands are represented by the vectors. Such as the threshold vector of the node u is represented as *PathThresholdVec(u). sItemPathLoadFracVec(u)* captures the resource demand of virtual item on each node along *u*'s flow path. *PathLoadFracVec(u)* represent each node's resource usage fraction along the path. For the virtual machine migration process, this technique evaluates the dot product of *ItemFracLoadVec(u)* and *PathLoadFracVec(u)*. To reduce the highly loaded physical machines, this approach migrates the virtual machine from the overloaded host to the hostwhich has the lowest dot product of *ItemFracLoadVec(u)* and *PathLoadFracVec(u)*.

Wood et al. [10] design a system named sandpiper for hotspot detection and virtual machine migration. This approach also provides new scheduling of virtual machines and physical machines. This technique takes the CPU, network, and memory into the account. This approach predicts the load of the physical machines and compares it with the threshold value. If the load of the physical machine exceeds the threshold value then that host selected as overloaded host. In this approach, a volume is evaluated by multiplying the CPU, memory, and network to capture the multi-dimensional load. This volume represents the degree of a load of each physical

machine. After the overloaded detection, this approach proceeds for the virtual machine migration process. For the virtual machine migration, this approach calculates a VSR(Volume-to-Size Ratio) for each virtual machine, where size is the memory footprint of the virtual machine. The virtual machine with the highest VSR is selected from the physical machine having the highest volume for the migration process.

We have analyzed the surveyed literature in many aspects and provided a comparative study among the considered literature, as illustrated in table 1.

III. PROPOSED WORKING MODEL

The virtualized environment can be thought of virtual machines deployed over physical hosts in order to perform numerous computational tasks provided by various users. The said process of computation may result in uneven distribution of load across virtual machine and hence requires deployment of virtual machine consolidation schemes for achieving load balancing at virtual machine level. In this context, we have proposed a virtual machine consolidation scheme as given in algorithm 1 with an objective of not only minimizing the load imbalance level but also using energy efficiently.

Input: **vmList and hostList**
Output: **Virtual machine consolidation for load balancing**

Algorithm 1: **Energy aware load balancing**

1: Let total_ld = sum of load of all host
2: Let total_host = number of available hosts
3: Let avg_ld = total_ld/total_host
4: Store the host in lower_host_list having total_host_load <= avg_ld
5: Store the host in higher_host_list having total_host_load > avg_ld
6: Let vm_cnt = sum of vms mapped the host in higher_host_list
7: Calculate the curr_thr=100/vm_cnt
8: Let vm_ltt = virtual machine with lowest transfer time within lower_host_list
9: Repeat
10: for each host in higher_host_list
11: if avg_host_load > curr_thr then
12: migrate the current vm_ltt to the considered host
13: for each host in lower_host_list
14: if total_host_load < 10
15: poweroff the considered host
16: until the load among hosts in higher_host_list is balanced

The control flow of the proposed virtual machine consolidation scheme is shown in figure 2. In our proposed model, in the 1st stage we have planned to detect the lower loaded host by determining the average load among the available host. In case, the host having the load lower than the average load then that host will consider as underloaded host. In this situation, we are going to migrate all of the virtual machines from the underloaded host to non-underloaded hosts and keep all the underloaded host in sleep mode. In the next stage, we have selected a virtual machine from that underloaded host for the migration process using LTT (lowest transfer time) method. We have detected the higher-loaded hosts in 3rd stage by applying a current threshold value among the non-lower loaded hosts. Finally, in order to place those migrated virtual machines from the underloaded we have selected the destination host in the last stage.

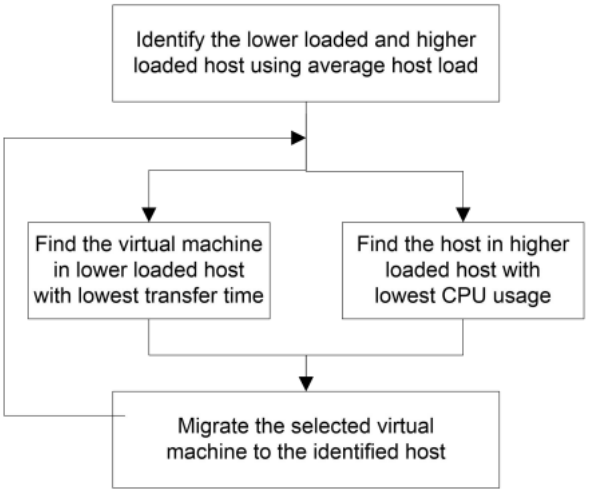

Fig. 2 Proposed Working Model

The proposed load balancing model takes virtual machine consolidation into consideration. Initially, it identifies the hosts with higher loaded as well as lower loaded hosts. Further, it selects appropriate virtual machines from lower loaded hosts and consolidates those virtual machines in the higher loaded ones. This approach looks for achieving load balancing within higher loaded hosts by intelligently consolidating virtual machines among them. The following sections explain the proposed model in detail.

A. Lowerloaded / Higherloaded Host Detection

In this work, we have used an average load to detect the lower loaded and higher loaded host by making use of only the CPU load. The average load can be defined as below,

$$avg_ld = total_ld/total_host \quad (1)$$

where *avg_ld*: average load of the available host.

total_ld: total load of the available host

total_host: the number of available host.

If the CPU load of a host is lower than the average load then that host is considered as lower loaded host and if there is a host having a load greater than this average load value then that host is considered as higher loaded host. In this situation, we are going to migrate all of its virtual machines from lower loaded hosts and keep them in sleep mode.

B. Virtual Machine Selection

Once the lower loaded host has been successfully decided for the migration, we will proceed to identify the virtual machine for the migration process. In order to select the virtual machine we have used the lowest transfer time(LTT) method. In this method, the virtual having that takes the lowest time to migrate will select for the migration process.

C. Destination Host Selection

After identifying the lower and higher loaded host and selecting the virtual machine from the lower loaded host for the migration process, we will move to select the destination hosts to place the migrated virtual machines from the lower loaded hosts. In order to identify the destination host to place the migrated virtual machines we are going to select the host having lowest CPU usage in higher loaded host. We have used a current threshold value to identify the destination host from higher loaded hosts [11,12].

This current threshold value can be determined as,

$$curr_thr = 100/vm_cnt \quad (2)$$

where *curr_thr*: current threshold value

vm_cnt: total number of virtual machines available in all the higherloaded hosts.

The host having CPU load lower than the current threshold value will be selected as the destination host to receive the migrated virtual machine from the lowerloaded hosts accordingly.

IV. EXPERIMENTAL EVALUATION

A. Experimental Parameters

For comparing the proposed model, we have taken *Load_Imbalance_Level* and *Energy_Usage_Sum* into consideration. The foremost parameter signifies the level of imbalance in-between the loads assigned to the available virtual machines, whereas the other parameter represents the total energy consumed by the available hosts in the cloud environment.

$$Load_Imbalance_Level = \frac{\sum_{i=1}^{k-1} |vmload_i - vmload_{i+1}|}{(k-1)} \quad (3)$$

where $vmload_i$ represents the load present in the *ith* virtual machine.

Further, the *Energy_Usage_Sum* can be defined as,

$$Energy_Usage_Sum = \sum_{j=1}^{n} hosteng_j \quad (4)$$

where $hosteng_j$ represents the total energy used by the *jth* physical host.

B. Experimental Environment and Results

We have used Cloudsim simulation environment [12] for implementing and validating the proposed virtual machine placement framework. The simulation environment is realized over Lenovo thinkstation with 4 GHZ processor, 8 GB of RAM and Ubuntu 18.04 operating system. For conducting the experiment, we have varied the number of hosts in the range of 2 to 20 with an interval of 2 over 10 datacenters. Further, we have considered different number of virtual machines over the range of 4 to 40 with a gap of 4 being mapped to the mentioned hosts and these virtual machines executes cloudlets over them. We have assumed that the hosts, virtual machines are homogeneous in nature. In this we have extended the existing VmAllocationPolicy() class of Cloudsim for implementing the proposed scheme. Further, we have computed the *Energy_Usage_Sum* and *Load_Imbalance_Level* upon observing lower level of variations among the loads over the virtual machine. We have used the said parameters to compare the proposed model with existing approaches.

After running the simulation, we have identified that, in terms of the *Load_Imbalance_Level* the proposed scheme outperforms the existing approach in most of the cases as shown in figure 3.

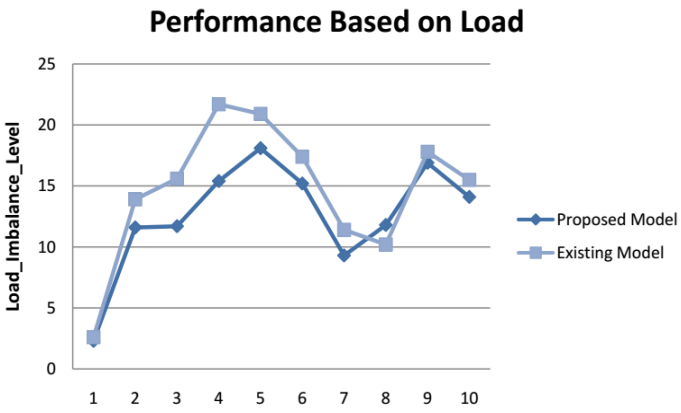

Fig. 3 Comparison based on Load_Imbalance_Level

The graph shown in figure 3 clearly mentions that apart from few iterations, the load_imbalance_level obtained in case of proposed model is less than the existing model. Hence, our proposed model provides a better load balance as compared with the existing model.

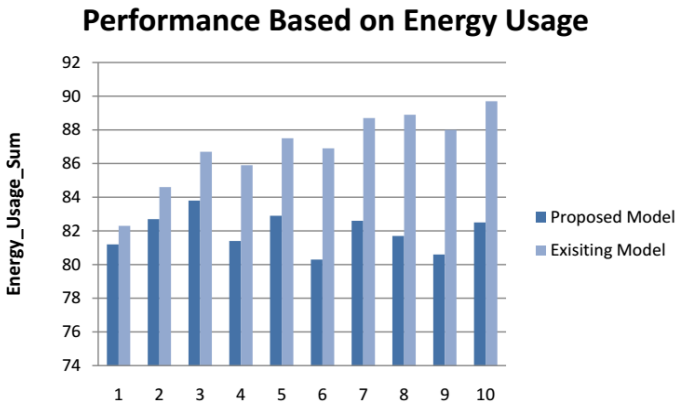

Fig. 4 Comparison based on Energy_Usage_Sum

Further, after comparing the proposed scheme in terms *Energy_Usage_Sum* with the existing model, we have also identified that the proposed consolidation scheme makes use of energy efficiently by suitably powering off the lower loaded physical hosts. It clearly visible in figure 4 that the energy usage in our proposed model is much lower than the existing model. Hence, our proposed model make use of the energy more efficiently as compared with the existing one.

V. CONCLUSION

In virtualized environment load balancing is a significant issue. In order to deal with this problem virtual machine migration is one of the popular technique to achieve load balancing. In our work we have proposed a migration based load balancing approach for the underloaded hosts. We have also compare our proposed approach with the existing technique by using the parameter load imbalance level and energy usage. After the comparison finally we conclude that our proposed approach provide less load imbalance than the existing approach and also the energy consumption of the proposed model is lower than the existing model. In future, our plan is to in-corporate multiple load parameters into the proposed consolidation scheme.

***Abstract*—In this paper, a design methodology for carrying out all the steps involved in a typical analog design flow, using free or open source electronic design automation [EDA] tools is proposed. Implementation of a three stage CMOS operational amplifier is chosen for demonstration. g*EDA-gschem* tool is utilized for schematic capture and SPICE net list generation. *Electric-VLSI* is a state of the art EDA tool which is used for laying out the op-amp, design rule checking [DRC], verifying layout versus schematic [LVS] and generating parasitic extracted SPICE net list. The SPICE net list are simulated with the help of versatile, electronics and electric circuit simulator, *Ngspice.* The scripting language provided by *Ngspice* is used for performing corner analysis and Monte-Carlo simulations. Simulation results reveal that the designed operational amplifier meets the desired specifications. Corner and Monte-Carlo analysis show that the op-amp is robust against process variations and mismatch.**

Keywords—CMOS op-amp; open source or Free EDA tools; Ng-spice; Electric-VLSI; gEDA-gschem.

I. INTRODUCTION

Analog electronics circuit design and verification heavily depend on Electronic Design Automation tools. The accuracy of the circuit simulation relies on how nonidealities and process variations are handled by EDA tools and model files. Unlike the digital circuits, the yield of analog circuits is poor. As technology is shrinking day by day, modeling and simulation are becoming extremely challenging. Cadence, Synopsis and Mentor graphics are the industries which are currently ruling EDA market. They charge millions of dollar for licensing and support which have to be paid periodically. For small scale industries, it is uneconomical and they can not afford. For academic institutions and research organizations, though above mentioned industries provide EDA tools at a concessional rate, still it is considered as costly, especially in developing countries. In this regard, open source and free EDA tools are becoming more and more popular. These tools can do almost all the tasks which are done by proprietary tools but they lack fancy graphic user interface [GUI] and hand-hold approach, hence user must have a fair knowledge in analog design flow to use them. In the present paper, an effort is made to introduce open source/Free EDA tools starting from schematic, layout, post-layout simulations to statistical analysis considering integrated CMOS operational amplifier as an example.

For undergraduate first and second year students, circuit schematic entry, net list creation and simulation tools are enough to understand and appreciate the concepts of basic circuit analysis and design. Instead of purchasing expensive *PSPICE* tool, a combination of schematic capture gEDA-gschem and *Ngspice* can be very effective in teaching and learning process. For higher semesters of undergraduate and post-graduation students can make use of Electric-VLSI along with *Ngspice* for the study and practice of analog circuits. These two tools can eliminate the need of costly softwares like *Cadence Spectre* and *Virtuoso*. One more added advantage is that the students will understand all the intermediate steps of circuit design. Even research scholars pursuing Ph. D program can efficiently use the above mentioned softwares for deeper analysis and design of integrated circuits. *Ngspice* has many builtin functions and scripting language, so that all the complicated analysis like corner analysis, Monte-Carlo statistical analysis can be conducted. Electric-VLSI comes with free MOSIS process design kit [PDK] which is very useful for layout.

Operational amplifiers [Op-amp] are the most common functional blocks found in any analog circuits, so performance metrics of Op-amp are critical. Many typologies like two stage, folded cascode, telescopic cascode, gain-boosted etc.[1-3] are available for implementing an Op-amp, depending on specifications and applications. Two stage Op-amp along with output buffer is the most basic and famous topology which van offer high gain and can drive capacitive loads. In the proposed paper, the design and verification of a two stage Op-amp followed by a source follower is presented. The paper is structured as follows. Section II describes the implementation of CMOS Op-amp. Simulation results and discussion are given in Section III. Conclusion is drawn in last section.

II. IMPLEMENTATION OF OP-AMP USING FREE OR OPEN SOURCE EDA TOOLS

Fig. 1 shows the typical analog design flow. It can be divided into two phases, one is the circuit level deign and other is physical level design [4]. In the first phase, design is validated at transistors level. Schematic capture, net list creation and SPICE simulation tools are required. If design meets the specifications, it will move to second phase else circuit has to be tweaked. In the second phase actual physical aspects of the

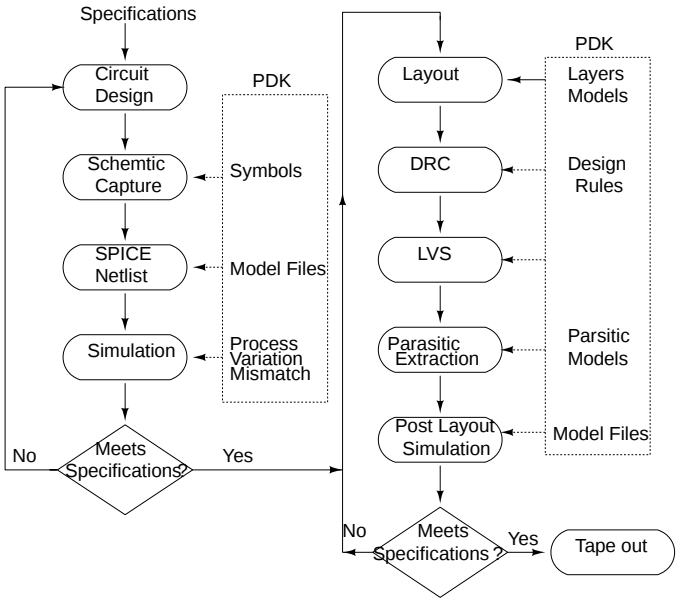

Fig. 1 A typical analog design flow

circuit on the chip is laid out and parasitic capacitance and resistance are extracted. Now again the function of the circuit in the presence of above mentioned parasitic elements is tested. The design flow is repeated till it meets the specifications. When it passes the test, the design is sent to fabrication in a prescribed file format. In this section, how each block can be implemented using open source or free EDA tool is elaborated.

A. Design of op-amp

First stage of op-amp is a differential amplifier which amplifies the only difference between the voltages at its inputs and rejects the common voltage. The second stage is a common source stage which further amplifies the signal received from differential amplifier. Last stage is a source follower which is a class A power amplifier, offers low output resistance. Fig. 2 shows the circuit diagram of op-amp and it is designed for the following specifications [5].

1. Slew rate=0.5 V/µs
2. Open loop gain > 60 dB
3. Phase Margin > 60°
4. Load capacitance=5 pF
5. Common mode rejection ratio [CMRR] > 45 dB
6. Power dissipation > 25 µW

Table I shows the W/L ratio of all the MOSFETs of op-amp.

B. gEDA-gschem

The schematic diagram of the designed op-amp was drawn using gEDA-gschem. gEDA-gschem is a part of General Public Licensed electronic design automation suite. This is used for electrical and electronic circuit schematic capture and producing SPICE net list [6]. It facilitates all SPICE modules, circuit hierarchy and custom symbol creation. Fig. 3 shows the screenshot of gEDA-gschem tool. 'gnetlist' command is used to generate SPICE net list from schematic circuit. The produced SPICE code is ready for the simulation.

TABLE I. TRANSISTORS SIZE

M_8	10
M_9	80
M_{10}	16

C. Ngspice

*Ngspic*e was used for simulating the designed op-amp. *Ngspice* is a mixed signal circuit simulator. It is derived from three open source software packages: Spice3f5, Cider1b1 and Xspice [7]. It handles the following circuit elements: integrated

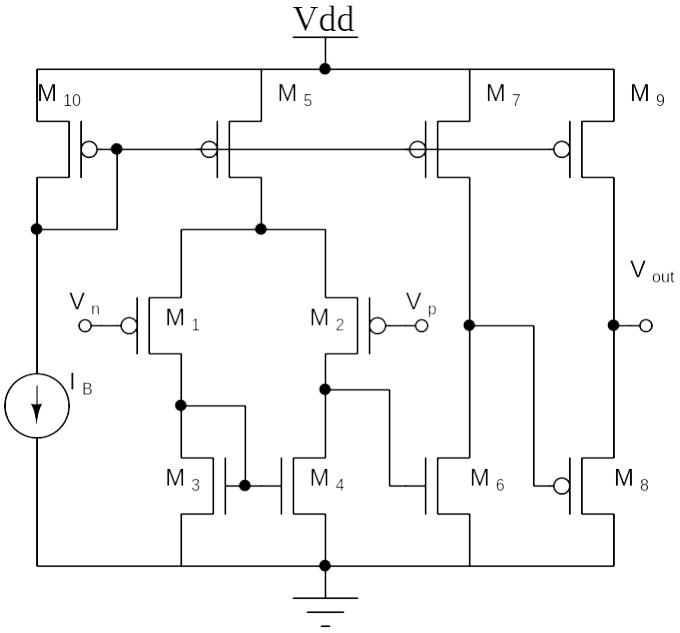

Fig. 2 Schematic diagram of the CMOS op-amp

and discrete resistors, capacitors and inductors, all types of diodes, BJTs, JFETs, MOSFETs, MESFETS, controlled sources, independent sources and many more. All the latest MOSFET device models like level-1 to level-4, Berkeley Short-channel IGFET Model [BSIM] 1 to 4 are supported by *Ngspice*. We can perform all the basic circuit analyses as listed below.

- Operating point analysis
- DC sweep
- Frequency response [phase and gain]
- Pole-zero analysis
- DC or small signal sensitivity analysis
- Transfer function analysis
- Transient analysis
- Noise and distortion analysis

Ngspice comes with *NUTMEG* scripting language which is very useful in plotting and saving the result data and writing the code for complicated circuit analysis like statistical analysis.

D. Electric-VLSI

The layout and parasitic extraction of the op-amp was carried out using *Electric-VLSI* tool. It is a state of the art computer aided design system for VLSI circuit design. Electric can design any type of electronic and electric components and has the capability of facilitating layout, schematics, artwork, and architectural specifications. Along with Ngspice, it can

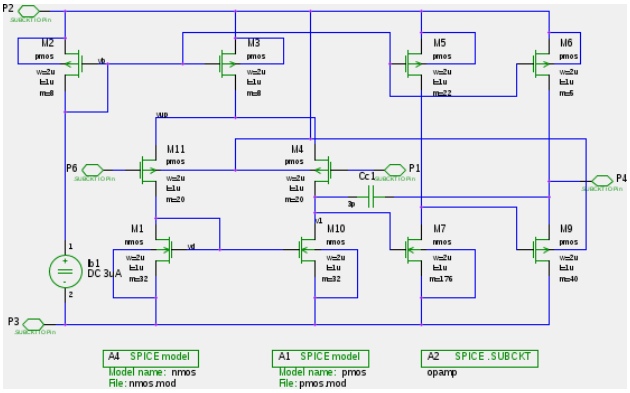

Fig. 3 Snapshot of gEDA-gschem

offer a complete analog design flow from design to fabrication. The salient features of Electric-VLSI are given below [8].

- It has built-in process design kits for different MOSIS technologies.
- Schematic capture
- Custom layout
- Design Rule Check and Electric rule check
- Parasitic extraction
- Layout versus Schematic verification
- It can generate net list for different SPICE engines
- Silicon compiler, placement and routing
- It can export the design to different formats required by the Fabrication units.

III. Results and Discussion

BSIM3v3 model [9] was used for modeling the transistors used in the op-amp circuit. First, stability of the op-amp was investigated by determining loop gain and phase margin [9]. The op-amp exhibited a loop gain of 60 dB with a phase margin of 70^0 as shown in Fig. 4. To determine the slew rate performance of the op-amp, a pulse voltage of 0.65 V with 1 µs rise and fall time was applied to it in voltage follower configuration. The op-amp displayed a slew rate of 0.4 V/µs as shown in Fig. 5. The common mode rejection ratio [CMRR] response of op-amp is shown in Fig. 6. The measured CMRR value was 85 dB.

Ngspice and *NUTMEG* [7,11] have many built-in functions, a few of them are listed in Table II. They are handy in performing statistical analysis and corner analysis. *NUTMEG* scripting language supports conditional statement 'if-else', loop statements 'while' and 'for'. We can run several simulation loops and change device model parameters with the help of 'alter' or 'altermod' commands. Corner analysis is one, which reveals the circuit behavior at different extreme process corners. Using the script, circuit can be analyzed with different process and model parameter values. Fig. 7 shows transient response of the op-amp for different process corners. It shows

that op-amp does not deviate much from nominal for all process corners.

TABLE II. A FEW BUILT-IN FUNCTIONS OF NGSPICE

Function	Notes
Gauss(nom, rvar, sigma)	Gaussian distribution with mean 0 and standard deviation rvar divided by sigma
agauss(nom, avar, sigma)	Gaussian distribution with mean 0 and standard deviation avar (absolute), divided by sigma
unif(nom, rvar)	Relative variation uniformly distributed between +/- rvar

Corner analysis determines the circuit behavior only at extreme process variation values where as local variations and mismatch are not considered. Monte-Carlo simulation is a statistical analysis in which process parameters are varied randomly assuming a distribution model (Gaussian) and also mismatch is considered among the components belong to same category [12]. Ngspice also provides many statistical functions, from which Monte-Carlo simulation can be run on the circuit with the help of scripting language. Table III shows a few statistical functions of Ngspice [6].

TABLE III. STATISTICAL FUNCTIONS OF NGSPICE

Function	Notes
rnd(vector)	A vector with each component a random integer between 0 and the absolute value of the input vector's corresponding integer element value.
sgauss(vector)	Returns a vector of random numbers drawn from a Gaussian distribution (real value, mean = 0,standard) deviation = 1).

The loop gain and phase response of designed op-amp under process variation and mismatch were tested using Monte-Carlo simulation [12]. The loop gain and phase margin of the op-amp for different samples are plotted in Fig. 8 and Fig. 9 respectively. It can be seen that the mean value of loop gain and phase margin matches with the nominal values. This proves the designed op-amp is robust. The layout of op-amp using *Electric-VLSI* is shown in Fig. 10. Op-amp occupies an area of 85 µm × 168 µm on the chip. Table IV shows the comparison between the desired and obtained performance values of the op-amp.

TABLE IV. PERFORMANCE SUMMARY

Parameters	Desired	Achieved
Loop Gain	60dB	60dB
Phase Margin	60^0	70^0
Slew rate	0.5V/µs	0.4V/µs
CMRR	>45dB	85dB

CONCLUSION

In the present work the entire analog design flow starting from schematic to post layout simulation and verification have been carried out using free or open source EDA tool considering integrated CMOS op-amp as an example. *Ngspice* and *Electric-VLSI* EDA tools have been used for simulation and laying out op-amp. The op-amp has been designed for a set of specifications and after post layout simulation the results are matched with the desired response. Corner analysis and Monte Carlo simulations have shown the designed op-amp is robust.

***Abstract*— The mechanism which involves evaluating design performance is known as Testing. The power dissipation for the circuit in evaluating process is more when compare to standard operation of the circuit. For constricting the power dissipation in testing form delay fault testing method is used in the proposed design. In the proposed design scan architecture with self-healing technique is introduced to enhance the fault coverage. It will be going to sort out number of scan flip flops into uniform group. This paper adds self-healing procedure of scan design that is functioned among two phase clocks for vital scan cell test procedure and faulty scan cell test procedure to pseudorandom pattern generation and deterministic BIST application to increase the fault coverage.**

Keywords— Scan Architecture, Deterministic BIST, LFSR, Pattern Generation, PRPG, CUT.

I.INTRODUCTION

The space at functional power along with test power dissipation is enlarging swiftly. The particulars to impart sufficient explicit power model would be getting within [9] and [17]. Ahead to, explained from Scan based Built in self test (BIST) power consumption is more when differentiated to Deterministic scan testing ascribable to extravagant activating actions originated with random patterns. A weighted pseudorandom test pattern generation and deterministic BIST using reseeding technique to give the low power consumption by disabling the scan chain weight signals while it is executing other application [18].

The procedures introduced in [13], [10], [12] are aimed to reduce functioning between different blocks during scan shift cycles, which has the test generation of allowing directing itself to their parameters. Weighted Pseudorandom testing schemes of [10], [5], [2], and [7] can effectually raise the fault coverage. Yet, which methods are usually resulting in more power consumption with persistent passage at the scan flip-flops in more instances [14].

A DFT method for launch on shift testing[12], [15] ,[16] , It was make sure that combinational circuit logic residues not disturbed among the interleaved capture phases, which was done using computer aided design tools have more search ability for reducing capture switching between scan flip flops. The stipulated operation went by test pattern ordering [20].

As from [13], PRESTO (preselected toggling generator) design which produces binary sequences using preselected toggling activity. The register which is of toggle controlled supervises the hold latches. It has data incorporates zeros and ones; here ones stipulate latches would go to the toggle action, hence recognizable for data attaining from the PRPG. Their portion finds a scan functioning format. Besides that two parameters put in 4-bit Hold along with Toggle registers to encapsulate how will extend whole PRESTO rest each of two in hold mode or toggle mode, respectively. To close either mode, a 1 must yield as T flip flop input. Toggle mode: defines data transferring from PRPG to Phase Shifter. Hold technique: It will encapsulate and reserve measure of clock cycles and equal piece of PRPG giving the phase Shifter with in regards to a eternal value. In absolute operational version of PRESTO , toggle and hold signals are sustain through T_ flip flop which organizes the switching activity, Test data can be done in the design with LBIST(low power built in self test).In which ATPG form of embedded test compression scheme was involved. In this, a pseudorandom pattern generator cascaded with phase shifter which feeds scan chain to form the test pattern. Scan forest design was arranged as individual scan tree it has in deterministic test vector phase. The prototype narrates the scan adopted BIST design for two phase BIST method. Scan forest model will be in active for pseudorandom testing in initial moment. This procedure was heavily diminishing the size of the Phase shifter contrasted with the several scan chain architecture, here individual stage of the Phase shifter directs a scan chain. It leads to area overhead caused by the phase shifter can be diminished significantly. The test response compactor was an included XOR gate network.[8].

As referred from [6], this tells us that test file compression model among hybrid approach and external testing. The designs shows that it has three assessed weights are involved. In reference to the design these signals 0, 1, U are applied to scan element to its represented weight. Here U shows that register takes value of 0 or 1. This Comparision does with three levels, i.e unique part differentiation; each weight set differentiation; and expanded set coalition.

In the extended block diagram of paper Scan Architecture is added to acquire high fault coverage in

pseudorandom pattern generation and Deterministic BIST approach. The Pseudorandom patterns Generation using clock enabling technique is done, Moreover in Deterministic BIST technique will be concealed deterministic patterns are generated. The scan Architecture will be allowing more scan chains to test the pattern generated in PRPG (Pseudorandom Pattern Generation) with respect to CUT (Circuit under Test).

II.BASIC ARCHITECTURE

The basic Architecture for existing design i.e weighted pseudorandom pattern generation and deterministic BIST is shown in Fig.1.The block diagram which is shown in Fig.1.[18]. is architecture for generation of test patterns randomly using weight enable signals and which enables the circuit under test (CUT) to test in Deterministic BIST case. This block diagram validate with scan chain testing. The weights w_0, w_1, w_2..... And w_k are disbursed among the weighted scan enable signals SE_1, SE_2, SE_3.....and SE_k successively. And the values for weight signal w_0, w_1, w_2....., w_k belongs to {0.5, 0.625, 0.75, 0.875}. Persistent values were instantiated by randomizing the output flip flops alongside its position will be explained by dispersing other scan chains. Drained size of sub circuits of discrete scan chain is incited by cutting the entire circuit into sub parts.

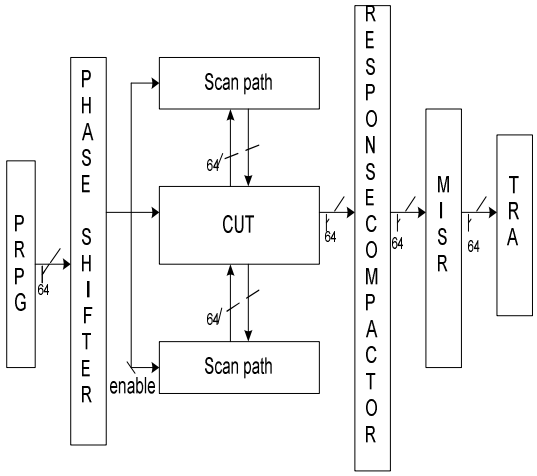

Fig.1. Weighted pseudorandom test pattern generation and deterministic BIST[18].

Where in degraded sub circuit total weight signals were selected. The Testability gain function determines the selection of weight signals. This is shown below:

$$g(f) = \sum_{l/i} \frac{|Co'_1(l) - Co'_0(l)|}{O'(l)}$$

Here, l/i =stuck at i fault at line i. 'f ' represents set of random pattern resistant fault , which accord to segregation of faults which has chance of finding is close to multiple times than thick fault. We aimed to moderate the testability gain function.

A Scan chain has weighted test enable signals which are shown in Fig2.[18]. In the figure test signal is test enable signal, SCin, SCo are Scan in and Scan out signals. Where every D flip flop is selected between Scan chain input and Pseudo primary inputs. Where it is known that each PI have a 0.5 Probability, and the observability calculation of the pseudo primary outputs PO's are declared to l/n. Then the Controllability is.

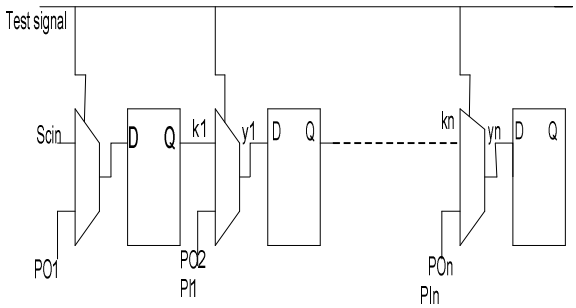

Fig.2. Scan chain with Test enables signals.

$$Co'(PI_i) = P.\ Co1'(x_{i-1}) + (1-P).\ Co1'(PO_i) \quad (1)$$

The Observability of PO_i (PO) can be determined as shown below:

$$O'(PI_i) = (1-P)\ .O'(x_i) \quad (2)$$
$$O'(x_i) = 1-(1-O'(y_i))\ .\ (1-O'(PI_i)) \quad (3)$$
$$O'(y_{i-1}) = P.\ O'(x_i) \quad (4)$$

From equation (1),(2) and(3) p is the chosen weight test enable control, x, y are nodes. Initially the observability coverage of scan out connection will be settled to 1. Yet to test response compactor was intended to course with yield of scan chain by attaching the output chain with XOR gates by perceptive we need to discover zero associating with least system evaluation. The controllability along with Observability measures help to calculate the PI's and PO's. A few iterations are covered to measurement of total nodes present in the benchmark circuits for more coverage.

The PI controllability for i^{th} iteration of scan flip flop is initially set to 0.5 and it has the Observability measurement of the PO is 1/d, where d represents length of the scan chain. It is observed that testing measurement of completely connected nodes become steady after few iterations of testability measure method.

As it is the design of weighted test enable signals separate sets of weights are charge with respect to the test enable control signals. The loads to the design are scan chain set, which are cleaved to sub circuits {SC_0,SC_1,.....SC_{k-1}}, given technique generates k degraded sub circuit formats .To keep down the gain function in the parent method selects the weights respective to initial scan chain. In order to keep down the cost function by specifying next to best among weight

signals, where in second scan chain a weight enable signal port will be chosen. Here in state it states that no weight is initialized for one of the scan chains, through returning the approach was conveyed their test enable control to the similar response as one of the value in standard test per scan BIST scan chains. The evaluation will be continued till the approximate weights should have to be chosen to every test enable signal of scan chains provided. Steps enclosed within existing method.

1. Primitive Polynomial Selection:

The given method includes single LFSR (Linear Feedback Shift Register) consideration to both pseudorandom pattern generation and deterministic states. The procedure gives a modern technique to choose the bits of LFSR and to fix the amount of extra variables to be injected. This will be done to diminish the quantity of deterministic test data. An effectively modeled phase shifter is sufficient for a minimum size of LFSR designed by primitive polynomial. In pseudorandom testing state a combined design of LFSR along with Phase shifter is retained to lend the test patterns. Weighted pseudorandom test patterns are generated from weighted test enable signal.

The amount of care bit length which does not give the maximum size of the LFSR, for every deterministic vector the same LFSR while doing both the phases. For encoding some deterministic test vectors having compute size of care bits, the seed which is kept in the LFSR and inserted control actions were added. It is not needed to provide length of an LFSR which is identical to extreme amount of care bits. At that time, pseudorandom testing state was extended moreover it is needed that effectively intended LFSR was utilized to initiate coded deterministic test vectors. Algorithm 2 referred to[18] , a procedure is explained to choose primitive polynomial that has least degree which is enhanced for the technique of coding of all deterministic test vectors to obtaining hard faults.

Ordinarily, The LFSR which was designed in architecture is shown below Fig.3.

Unlike the method in [8] , it is given that alternative use of an LFSR which has size i.e greater than quantity of care bits. The given procedure selects primitive polynomial with least degree. The commercial tool [5] used the same technique to limit the size of data to be reserved on chip ROM or ATE (Automatic Test Equipment). From Algorithm2 of [1], does choose the polynomial which has the degree should not be less than 20. There will be a rule which is to be provided that LFSR which does not have extra variables is considered first. When the encoding procedure of deterministic vectors cannot done based on LFSR based pseudorandom test generator, we will choose the case where separate extra variable is to be injected to the LFSR. If there is a case of deterministic vectors still cannot be coded in user needed format, the procedure then assessed the situation when two more variables are to be inserted. The process still is continued where given quantity of extra variables considered. If there status where LFSR as crucial portion of test generator cannot encode deterministic test pattern vectors there will be cast of considering second primitive polynomial [18]. The procedure is continued until we get the primitive polynomial which can code in test vector required composition of all deterministic vectors.

The example for LFSR with 64 –bit is presented in the Fig.3.The two extra variables are inserted at the 40 and 19^{th} d flip flop i.e XOR gate is inserted. This gives polynomial i.e to be applied for LFSR.

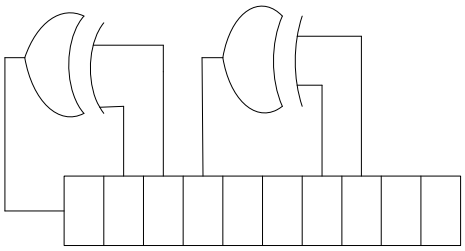

Fig.3. LFSR with variables.

2. Deterministic BIST:

There it is to impart with valuable seed encoding technique in order to cut down storage imperatives inside deterministic test patterns of which random pattern resistant faults. At first, conversion of another code format which gives error free element i.e initial test vector was introduced into LFSR. Every scan in standard in the circuit operates on driving numerical representation with scan trees. Respective scan in input is initialized where it has the equivalent scan tree. After receiving the test data of primary group it is defused and second group is activated then. LFSR prime input i.e seed will be reserved in auxiliary variable i.e shadow register [8]. The scan shift operations iterated till extra variables are placed into the LFSR. This procedure will be continued till scan trees in scan path got test data.. It gives more flexibility for test encoding technique. Minimum No. of clock cycles are basic to convey the entire test vector counter of past test vector, if there should arise an occurrence of scan chain design more clock cycles are assessed for completing the response. All the scan flip flops which were found at earlier level along with the scan chain amass the swearing off condition. i.e singular compound of scan flip flop would have no combinational successor. Process will be continued until the scan trees have been outlined. It has no need that same level scan tree should be kept aside.

The forgoing conditions are necessary to encode format of all deterministic vectors [3],[1].

This can be stated as:

i $L + i.v \geq s_{max}$

ii $\sum_{k=d-1}^{k=d-1-j} b_k \leq (L + V_j$

Where L is the size of LFSR, i represent Figure of sequential cycles to insert extra variables; V_j is the amount of extra variables among j shift cycles, S_{max} is quantity of care bits. b_k gives No. of care bits at scan level k. The previous technique provides reseeding process for LP deterministic BIST. This method partitions all of signals of scan chains to multiple subsets, condition to be remembered that one sub members of scan tree activated at one clock cycle. It will follow the gating logic. The logic was been helped by the shadow register which is of comparable length of LFSR. This register used to store seed values [6].

III. PROPOSED DESIGN

Before going to the proposed architecture, we need to know that what self-healing defines. Self-healing can be characterized that it is designed which has the quality of finding faults or failures and to debug their faults correctly. Essentially all self-healing strategies which were set up on repetition by cumulating spare cells they work same as scan chains in the BIST with executed methodology. The block diagram for proposed architecture is shown below:

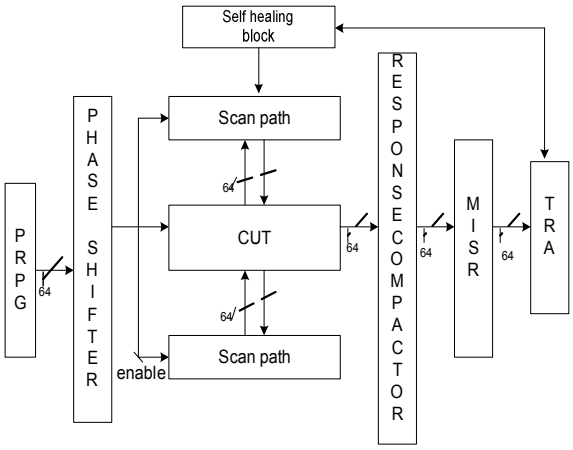

Fig4. Proposed architecture with self healing added block.[19].

As from Fig.4. i.e implementation of executed model, on that instance the defect have been delivered in particular scan cell, alongside the scan cell will condense the control flag which was started will have been assume responsibility for bist controller to bound this fault task was actualized initially. A dual edge triggered cell is introduced to divide the runtime with active scan cell, faulty cells. The primary half of the clock cycle is given switching to active scan cell and second half is given to faulty cell actions to be controlled. The scan cell circuit for self -healing technique is shown below:

In the block diagram, the foremost logic block gives the pattern generation i.e PRPG (pseudo Random pattern generation), these patterns are provided with LFSR and XOR network combination. Succeeding block is Phase shifter which shifts phase of produced patterns. Then other block Scan path will reserve the reference vectors as well as scan chain input is concatenated as input to bist controller. This is given from scan path. CUT shows that the circuit to be tested. Response compactor compresses the data which is under testing. MISR (Multiple Input Signature Register) is grouping of multiple XOR networks. It creates the compacted data to the indication level. This signature is the collection of multiple test data. TRA (Test Response Analyzer) checks the emulation between reference data and test pattern data. While, whether they are contrasted successfully the test will be pass otherwise it is fail. Here, Self-Healing block is joined to enlarge synchronize the clock phasing and test coverage.

The diagram shows the cell structure for DET (dual edge triggered circuit) in Fig.5.[19].There will be added two inputs I_0 and I_1 to the circuit. The control actions are representing that one is debug signal and another one is effective signal. When fault is detected the detection block will get to notice the faulty spot and control block sort the signal to go there location. When the clock rises to positive edge DET will accord normal result and for falling edge of the clock it will drive faulty value [19].

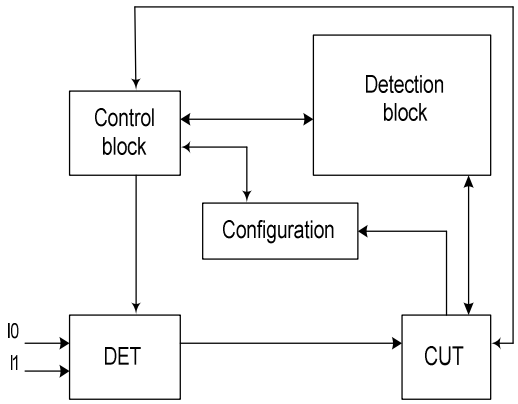

Fig.5. Scan cell structure[19].

IV. EXPERIMENTAL RESULTS

The existing method and propounded method are implemented as well analyzed on synopsys VCS (Verilog language simulation program for chip design) tool. It is quick simulator environment for functional verification. This compilation gives quality in functional verification. In the design truly small scan chain pins were introduced. In order to diminish the area over head a limited size of phase shifter was used. As from the existing design the supplying to the circuit of voltage and frequency are applied to 1.5v and 200MHz, independently. Simulation results from synopsys VCS is

shown in Fig.6. Bist out is the main response from the bist controller, it tells whether the test passing response or fail response.

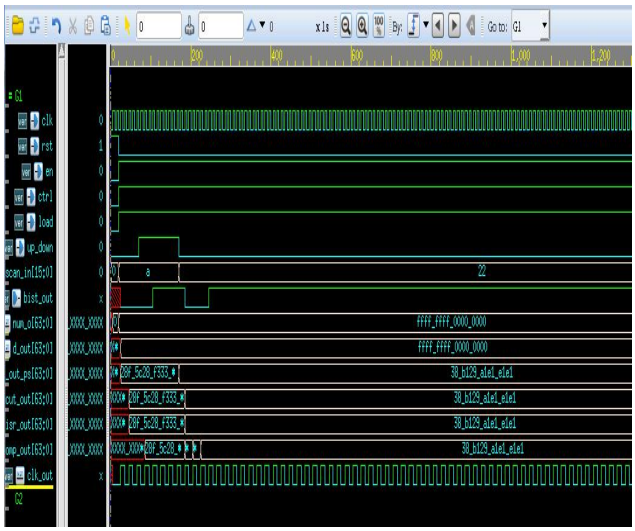

Fig.6. Simulation Results.

The comparison for LP deterministic BIST and low power Pseudorandom pattern generator and extended design is summarized in the below table. What's more, the proceeded is procured to expand the fault coverage. 10% when compared with the existing work. It will also increase fault coverage. For synthesis of both the work will be done by Xilinx vivado tool. Power dissipation calculation was taken from Xilinx vivado environment. This 10 % flip flops are in switching action gives to maximize in rate will give the reason to only switching version of flip flops are assisted in the operation of respective things.

TABLE.I

Comparision of previous work with proposed work(Power reduction)

	Deterministic BIST			**Scan based self healing technique**		
CUT	**Peak (mW)**	**Lppeak (mW)**	**Rate %**	**Peak (W)**	**Lppeak (mW)**	**Rate %**
S38417	6724	643	9.6	6700	620	9.9
b19	41933	5660	13.4	41000	5602	13.7
usb_funct	6261	610	9.7	6108	598	9.86
pci_bridge	8119	984	12.1	8075	978	12.7
74F569	5873	660	10.4	5704	624	10.9

The CUT is the design which is to be test. Contrast checking of deterministic Bist method and self healing technique are evaluated. Peak power and LP peak power are considerable to take the total Power dissipation in the CUT. CUT designs are taken that benchmark environment applications.

V.CONCLUSION

A new technique to raise the fault coverage and to decrease the power dissipation of the circuit is introduced in the proposed design. The proposed technique which has two clocking phases to synchronize error founded data with error corrected data. There it has more signals added, even the signals added it will keep down the power dissipation by using the two edges of clock are involved in the design. LP deterministic BIST is extended to self-healing method to increase power reduction rate.

Abstract – All things considered, the self-governing vehicle is the vehicles which are fit to detect tits condition and exploring without human contribution under various landscapes especially over pavements. The fact is, limit with regards to auto route for the most part relies upon the vehicle's capacity to screen and exactness so as to translate street surface condition. The improvement of powerful street surface checking instruments is extraordinarily improving the practicality of independent vehicles, while commitment in the decrease of related street mishaps on the planet. The toolbox, in the Mat lab condition, incorporates calculations to pre-process pictures, to identify breaks and describe them into sorts, in light of picture preparing and design acknowledgment procedures, just as modules committed to the execution assessment of irregularity location and portrayal arrangements. An example database of 84 asphalt surface pictures taken amid a conventional street review is furnished with the tool kit, since no asphalt picture databases are freely accessible for peculiarity identification and portrayal assessment purposes. Results accomplished applying the proposed tool kit to the example database are talked about, delineating the capability of the accessible calculations.

Keywords: Image Processing, Pre-processing technique, Image Segmentation, Post-processing technique, Road Surface, Road Anomaly Characterization

I. INTRODUCTION

As there are more improvements in the technology world, cars have become more advanced and thus the evolution of autonomous vehicles.

Self-governing vehicles will be vehicles fit for detecting their condition and exploring without human contribution under various territories, especially over black-top streets. The ability to auto explore to some degree relies upon the vehicle's capacity to screen and precisely decipher street surface conditions the extent that the streets are concerned crocodile part, furthermore called gator breaking and possibly misleadingly shortcoming breaking, is a regular sort of torment in dark top black-top. Cell sizes can fluctuate in size up to 11.80 inches (300 mm) over, yet are normally under 5.90 inches (150 mm) over. Debilitation breaking is commonly a stacking failure, yet various variables can add to it. Usually an indication of sub-base disappointment, poor seepage, or rehashed over-loading. It is vital to avert debilitation splitting, and fix as quickly as time permits, as cutting-edge cases can be all around expensive to fix and can prompt arrangement of potholes or untimely asphalt disappointment. The arbitrariness in increasing speed flags regularly makes street irregularity discovery a troublesome procedure, while rendering portrayal a significantly progressively troublesome and some of the time incomprehensible assignment. For this condition, we hint disclosure as the obvious confirmation of a peculiarity, while delineation is depicted as the certification of the sort of perceived variety from the standard (for this situation on the off chance that it is either a pothole or a pound). From this time forward, giving new frameworks to improving street.

Variety from the standard disclosure and delineation pushed the work revealed in this paper.

We have proposed a a RACA (Road Anomaly Characterization Algorithm) in context on the Wavelet Transformation Scale Space Filtering (SSF) figuring. The SSF figuring shapes the quickening signs by deteriorating them into different scales. It would continue by interfacing the debilitated wavelet coefficients of standard transversely over neighbouring scales and after that separating the loud models through an all around orchestrated spatial channel. The SSF calculation encourages a street irregularity location Algorithm (RADA) to distinguish street abnormalities by means of a fixed limit strategy, while nourishing RACA to describe street peculiarities. RACA accomplishes portrayal utilizing two one of a kind highlights to separate potholes from knocks. On the other end weakness breaking shows itself at first as longitudinal splitting (splits along the bearing of the stream of traffic) in the top layer of the

black-top. These splits are at first light and inadequate dispersed. In the event that further weakening is permitted, these longitudinal splits are associated by transverse breaks to shape sharp sided, kaleidoscopic pieces. This intertwist splitting example looks like the scales on the back of a crocodile or gator, consequently the epithet, crocodile breaking.

II. LITERATURE REVIEW

Yiyang et al. [1] have proposed a break location calculation dependent on computerized picture preparing innovation. By pre-preparing, picture division and highlight extraction [1], they have gotten the data about the break picture. In [4], Threshold strategy for division was utilized after the smoothening of the acknowledged info picture. Adhikari et al. [2] built up a model that numerically speaks to the deformities. Their reconciliation display comprises of split evaluation and recognition, neural system, and 3-D perception demonstrate individually. Alam et al. [3] have suggested an affirmation method at the mix about the pushed picture relationship and sound spread. The past approach permits a distinct estimation of surface re-territories, from now on part openings and break dissipating were settled. Iyer et al. [4] have sorted out a three-advance framework for the split distinctive verification from the high multifaceted nature pictures. The proposed methodology recognizes the split like model in the disorderly condition utilizing shape examination and numerical morphology system. Salman et al. [5] proposed a way to deal with oversee typically see parts in forefront pictures subject to the Gabor confining. Multi-directional break disclosure can be developed by expensive potential Gabor channel. Shan et al. [6] have appeared build part thickness unmistakable verification. In their technique, two cameras were utilized not run of the mill for different suggestion reviewed here. Sinha et al. [7] have researched the breaks by utilizing the two-advance methodology. They have built up a quantifiable channel structure for the break ID. After the limiting, they should the two-advance rationale at which the break incorporate extraction was done locally at the shrouded improvement of the pre-overseeing and some time later they have combined the photos. The second step is to delineate the part among the image zone by the route toward cleaning and accomplice. Talab et al. [8] have shown another system in picture managing for seeing parts in pictures of strong structures. Here the technique wires three phases: First; change the image to a light picture using the edge of the image and after that use Sobel's framework to develop an image using Sobel's channel for seeing parts. Yamaguchi et al. [9] have built up an immersion based break territory strategy. They have gotten their less check time by the modification of the end and avoid consolidate procedure. They have a snappy immersion tally which will utilize the neighboring pixels subject to the circularity of the pixel needs. Yang et al. [10] have proposed a picture examination framework to get slight parts and purpose of constrainment the requirement for pen venturing in invigorated security partner tests. Zou et al. [11] have built up a completely altered strategy to see split the dark top pictures. They utilized geodesic shadow discharge tally to expel the dark top shadows by protecting the break. After shadow clearing, utilizing the tensor tossing a ticket strategies break likelihood map was made. Oliveira et al. [12] have formed a structure for the changed break insistence. Here the break exposure relied on the model perspective. In the model perspective, a subset of the open picture database was usually picked and used for unsupervised getting ready of the structure pictures. Nguyen et al. [13] have proposed a system subject to the edge ID of strong parts from rambunctious 2D pictures of strong surfaces. They have watched the parts as tree-like topology. Lins et al. [14] have developed with the target to mechanize the split estimation process. In their system, they have used only a single camera for the getting ready of the social event of the photos for the split estimation. Li et al. [15] have solidified another structure for seeing the break in the mutilations with the dull shading and the low separation using the enthusiastic discrete curvelet waveform and surface examination.

III. RESULTS AND DISCUSSION

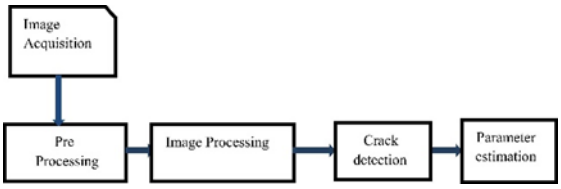

Fig1: The Stages of Image Processing to find road cracks

Picture Acquisition Toolbox gives capacities and squares to associating cameras and lidar sensors to MATLAB and Simulink. It incorporates a MATLAB application that lets you intelligently recognize and design equipment properties. You would then be able to create equal MATLAB code to mechanize your procurement in future sessions. The tool compartment empowers securing modes, for example, preparing tuned in, equipment activating, foundation procurement, and synchronizing obtaining over different gadgets. There are different image acquisition techniques which are used in image processing such as pre-processing technique, image processing technique, crack detection technique, parameter estimation.

I. Pre-processing Technique**:**

Informational indexes can require pre-processing methods to guarantee precise, effective, or significant investigation. Information cleaning alludes to strategies for discovering, expelling, and supplanting awful or missing information. Distinguishing neighbourhood extrema and sudden changes can recognize noteworthy information patterns. Smoothing and detrending are forms for expelling clamour and straight patterns from information, while scaling changes the limits of the information. Gathering and binning strategies are systems that recognize connections among the information factors.

II. Image processing Technique:

Picture examination includes preparing a picture into essential segments so as to extricate factual information. Picture examination can incorporate such undertakings as discovering shapes, recognizing edges, expelling commotion, tallying items, and estimating area and picture properties of an article.

Picture examination is an expansive term that covers a scope of strategies that for the most part fit into these subcategories:

i. Picture improvement to evacuate commotion.
ii. Picture division to seclude areas and objects of intrigue.
iii. Morphological sifting to evacuate more clamour.
iv. Locale investigation to remove measurable information.

III. Crack Detection technique:

Crack detection using computer vision toolbox (sobel edge detection algorithm).

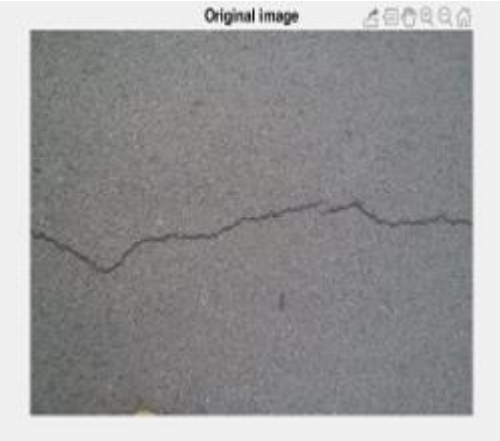

Fig2: Original Image

Fig 3: Contrast Stretched Image

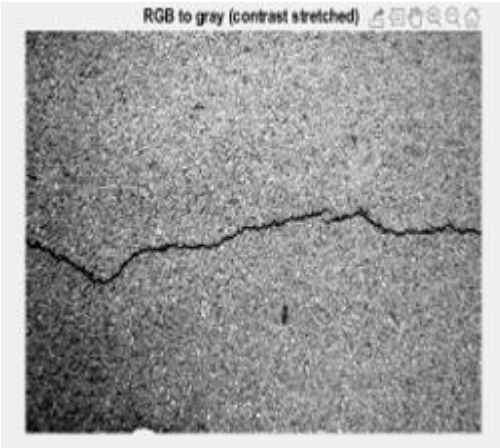

Fig 4: RGB to grey (Contrast Stretched Image)

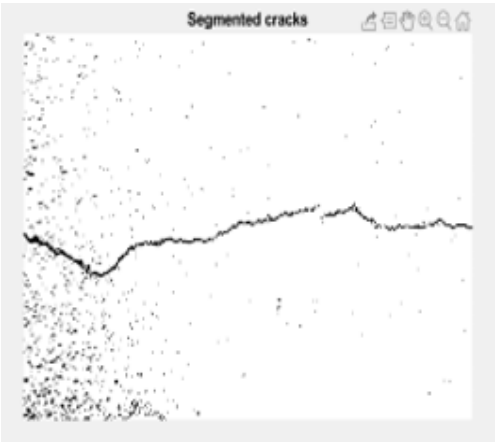

Fig 5: Segmented Cracks

IV. Parameter Estimation Technique

Parameter estimation assumes a basic job in precisely portraying framework conduct through scientific models, for example, likelihood dissemination capacities, parametric powerful models, and information-based Simulink models. Regular assignments for parameter estimation of Simulink models include: bringing in and preparing input-yield test information, for example, the voltage information and rotor speed yield of a DC engine and determining which demonstrate parameters and starting conditions to evaluate, for example, engine opposition and latency. Figure 7 shows genuine (green) and false (yellow) positives. Figure 7 shows in view of the sexually transmitted disease of cco's pixels organizes (level and vertical), indicating choice limits (dashed lines) and highlight space division (strong line).

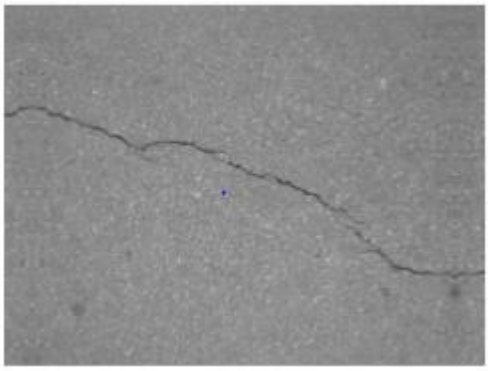

Fig 6: Original Image

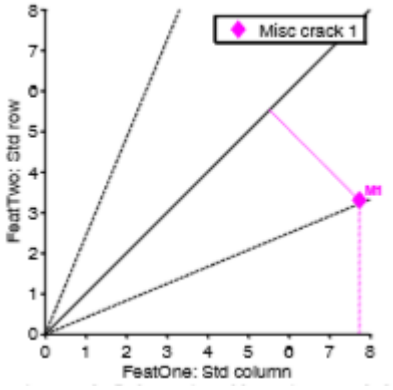

Fig 9: Crack type Assigned Pixels

V. CONCLUSION

The proposed tool compartment permits accomplishing great split location and portrayal results, however managing exceptionally flimsy breaks (of under 2 mm width) can be a troublesome assignment, the same number of false positives may show up, quite because of the trouble of recognize splitting from travelling upsets. There are no accessible conventions or institutionalized techniques for assessing the execution of the created frameworks and to think about the distributed methodologies, driving the creators to think about various conventions, in spite of some current harmonization endeavours. It is normal that this tool kit will be stretched out, for example to incorporate calculations to additionally decrease pixel power difference in non-split squares, or increment strength to picture splendour varieties.

The RACA Algorithm

Here, we depict the progress of our information confirming structure. The system of street surface recognizing is appeared in Fig 10. The three fundamental assignments in this stage combine the street surface information getting process utilizing an Accelerometer, the information parameter introduction, and information show up for visual examination/examination. We note that NI MyRio (1950) Accelerometer was altered utilizing LABVIEW for the information checking action.

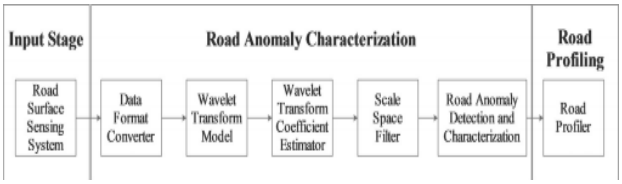

Fig 10: Block Diagram of the street oddity identification, portrayal and profiling framework

We joined a Global Positioning System (GPS) into our arrangement to discover road erraticisms. To do this, we balanced an Arduino microcontroller under the Arduino Integrated Development Environment (IDE). The GPS data getting process is showed up in Fig. 11. On an essential dimension, the system acquaints the GPS module with log the season of data get, and after that records the relating longitude and increase headings of the space where data was gotten. The GPS assessing rate was set at 1 Hz which was found acceptably appealing to give area server ranch in the midst of the drive test.

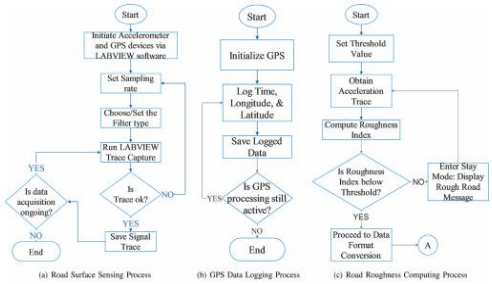

Fig. 10. Components of the Data Acquisition stage

We used the standard deviation of the enlivening flag got over a specific period as a deduced furiousness record to plot road quality. In case the offensiveness list regard is underneath a particular fixed point of confinement regard, RRAA picks that the road surface is smooth (prescribing that the vehicle is on a dull top road), and thusly starts the unusualness assertion and outline computation (delineated in the running with subsections). In any case, if the record regard is over the edge, the estimation enters a stay mode (seeing that the road being used may not be a diminish top road and thusly routinely imperfect). The program demonstrates a "Harsh Road" message in the midst of this stay period. The road abnormality confirmation and depiction check is perhaps established when RRAA measures a severity list underneath the most far off point regard.

Enhanced Secrecy Capacity under Eavesdropping Attack in Multi-Traffic Industrial WSN

A.Chandra Shaker
Department of Electronics and Telematics Engineering
G.Narayanamma Institute of Technology and Science
Hyderabad, Telangana, India
chandrashakerarrabotu@gmail.com

***Abstract*—Industrial networks are increasingly based on open protocols and platforms that are also employed in the IT industry and internet background. It is essential to secure the important information throughout transmission so highest secrecy capacity is chosen in Wireless Sensor Networks. The employment of sensing element to improve the physical layer security of industrial WSN can counter the eavesdropping attack and optimal sensor scheduling scheme targets to increase the secrecy capacity of wireless transmissions from the sensors to the sink. The system model with one eavesdropper and multiple sources with different data type is used. The scheduling theme satisfies the requirements in multiple traffics and achieves maximal secrecy capacity. Numerical results validate the proposed optimum scheduling theme in Nakagami fading environment. This system model performs better than the traditional Round Robin scheme in terms of the throughput, delay and packet delivery ratio and monitors the packet transmission according to the assigned priorities.**

Keywords—eavesdropping attacks, industrial wireless sensor networks, multi-traffic, secrecy capacity

I. INTRODUCTION

A wireless sensor network is a network which has many sensor devices that are connected with each other wirelessly. The sensor nodes can communicate the collected information from the physical monitored field or environment through the intermediate nodes to the destination. Using like Wireless Ethernet the data is passed to another network through interlinked nodes and gateways. A wireless sensor network are useful in applications where the physical environment like pressure, temperature, sound etc. can be monitored and transmitted to some other device it may be a mobile, laptop, computer or any other electronic device using wireless medium. The monitored information may help to control the application device or to take care of things to be done as per the requirement.

Every industry can have their own network, which is responsible for their own industry and also have a link with the global network. Using Bluetooth, WIFI, router communication one can develop their own personal network in industries by securing the network with passwords and can divide the access availability according to the level of authority in industry. For passing the internal communication the WSNs can be used in between labours and higher authorities.

II. LITERATURE SURVEY

Initial motivation of wireless sensor networks are done by the military [1], and now these are introduced in the industrial applications. These networks are used for line monitoring, automated manufacture of a product to improve the efficiency of factory, to have more productivity and very reliably work in industries [2][3], which can be called as industrial wireless sensor networks [4]-[6].

As the sensor networks are spatially distributed in a region, there is a need of maintaining strict security [7]. If a sensor failed to send exact sensed information to the destination then it is out of production line, or it may cause damage to the machine in factory or sometimes in critical work it may lead to loss of worker. The other aspect in the industrial environment is having machinery obstacles, engine vibrations and the noise generated by the machine.

The wireless sensor network has broadcast nature where the medium access is open to authorized and unauthorized users. So there are more chances of eavesdropper to attack the wireless network than wired networks. The eavesdropper hides within in the industry and the hidden attacker node can steal the information or tap the transmissions if there is no security for the information. Therefore finding the hidden attacker in industrial networks is main concern.

M. Mckay and X. Zhou [15] discussed about the secure transmission with help of generating external noise in the system at the transmitter end. By considering the multiple antennas, the transmitter starts transmitting original signal to the intended receiver and noise signal to the eavesdropper. It acquires systematic secrecy rate and target capacity to optimize the power allocations at the transmitter side for a single eavesdropper.

The specific considerations of industrial WSNs is the fading of channel due to the environmental constraints like machinery affects in the form of frictions and vibrations called as fading signals. Fading affects the signal loss or irrelevant additional signal to the main signal transmission in the channel.

III. PROBLEM FORMULATION

These days many industries are showing interest to implement the wireless networks in their work place for smart work. Sensor network has many advantages that attract industries to take step forward towards implementation of work. The security is the main concern of the industries; any way outside user cannot enter into the network. The intruder may hide within the network. As the technology is improving, intruder is also becoming more intelligent to crack the information. To secure the communication from the eavesdropper, many techniques came up, but still they have some limitations. Few cases how eavesdropper can attack the networks are explained below:

Case 1: Consider the communicational info is hacked by the intruder. In these days of developing technology, labour need not have the knowledge of protocol or algorithm implementation of the machine; it is automatically suggested by the predefined system updating software or new updating instructions may come from the higher technical authority to labour. If the intruder attacks on this information, the wrong updating of protocol installed in the machine damages the

machine functionality with the wrong guidelines of protocol. Sometimes, because of next versions it would not give immediate impact on machine.

Case 2: Consider the interloper has assaulted on the direct information where the human has to communicate with the machine. If a command is given to do an immediate action like switch on or off the machine at different modes according to the situation, that info may be hacked and gives some other mode selection to the machine. Due to this, there will be big loss; sometimes may cause loss of labour at work.

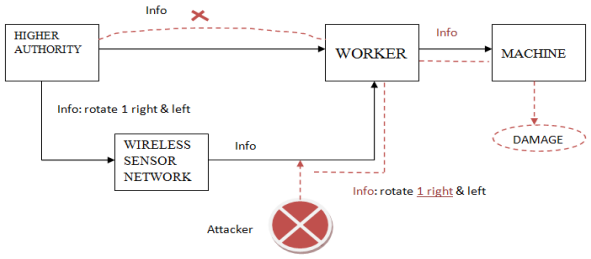

Figure 1: An example for industrial problem

The example in Figure 1 explains the real time problem and how it will damage or loss to the industries considering one higher authority node, worker node and machine with an eavesdropper node. As it is an autonomous network the only chance is having an interloper within the industry. The attack it is not a physical one, but the attacker also uses same nodal device like authority users.

The higher authority thinks to transmit the info 'rotate 1 right and left' to the worker through the wireless main channel link but the eavesdropper attacked on the channel and the info is misguided like 'rotate 1 right & left' to the worker, actual data has changed with the wrong info. If the machines are arranged in synchronous order, this misguided info will affect the machine and it damages the equipment.

Few key parameters are chosen to evaluate the security of the communication technically. By improving the main link channel capacity it shows the improvement of security level at physical layer without any additional power supply or additional relay nodes. As the transmission of data is in the form of packets, the key parameters are to be considered are:

Packet Delivery Ratio: The ratio is calculated in between the number of packets received at the receiver and transmitted from the source. The PDR factor should be at maximum level.

Throughput: The rate of successful packets reception at the receiver end from the transmission end calculates the throughput and this factor is important to see the performance of the introduced algorithm.

Delay: The difference between the estimated time to be reached and to the time when it has reached the destination. For any communication, this is also the main concern for delivering the packet within the time.

Consider the industrial WSN which includes a sink centre point and N sensors with an eavesdropper. Every node device uses a single antenna, the strong lines and dash lines address the main link and wiretap interface, exclusively. The eavesdropper in the Figure 2 could be either absurd user or genuine user who possesses the tapped data. The *N* sensors are indicated by $S = \{Si = 1,2,3 \dots N\}$. As appeared in the Figure 2, the proximity of hardware hindrances, metallic contacts and engine vibrations in mechanical conditions is undermining to the radio spread, which impacts the remote obscuring to change certainly.

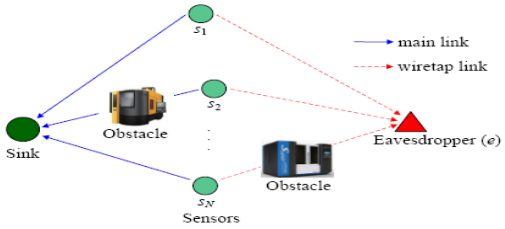

Figure 2: System model

Consider the Nakagami fading model for depicting both essential channel and wiretap channel. It is pointed that Nakagami model is more complex than the other obscuring models like Rayleigh fading model which is most used technique [18][19].

At the point when a sensor is planned to transmit its information to the sink node or destination over a channel, the attacker called eavesdropper attempts to catch the information, which is transmitted from the *Si*. This paper concentrates on the enhancement of wireless physical layer security with the guide of sensor scheduling plan keeping in mind the end goal to successfully shield against the eavesdropper.

IV. Existing Conventional Round Robin Scheme

The existing method conventional Round Robin is used for the reference purpose of this project, where the ***N*** sensors alternate in getting to a given channel and along these lines every sensor has equivalent opportunity to transmit its detected info to the sink without any loss of all inclusive data.

The detected data could be distinctive sorts of information from various sensors. For instance, the sensors might be utilized to identify and screen the distinctive part of the industrial plant conditions, including the movement of a machine, dampness, temperature, pressure and weight of the machine. Despite the fact that the sensors may create diverse sorts of information, their information streams are accepted with the same priority in transmission. The proposed work deals with the multiple data types with the individual priorities.

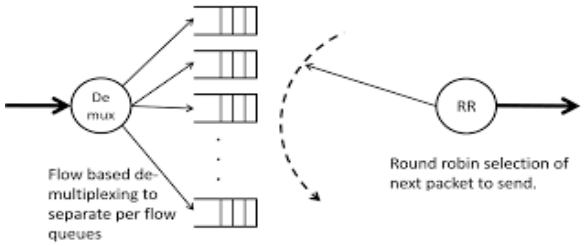

Figure 4: Conventional Round Robin scheme

The Round Robin schedule follows the time slots of a packet which is expressed as $T_{slice=}T_{cycle}/N$, the one circular round of the queue is T_{cycle} and the N defines the number of packets in the queue. The time slice will be changed from one process to other in the system, where the minimum time slice is allotted for the each packet to continue the process with system execution.

The Round Robin algorithm compares the burst time and the time quantum where packet is present in the ready state. If the condition is satisfied then it executes the program for the burst time and complete the process, if not it executes program for the time quantum. If the timer expires then it goes back to the ready state queue.

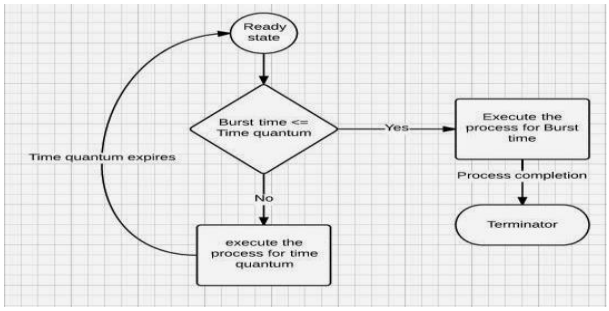

Figure 5: Flow chart for Round Robin method

As in Figure 5, all the packets are stored in the ready state then as per the commands the required program is executed to perform the action. It compares the timer allotted slots to each and every packet prior which packet has to be forwarded for the execution purpose and other packets has to wait till the execution process is done.

A. Secrecy Capacity Calculations for Round Robin Scheme

Considering the *Si* is processed to transmit the scheduled signal $xi(E|xi|^2 = 1)$ along with the power named as *Pi* and rate is termed as *Ri*. The expression for the collecting the signals at receiver, as the received signal is at sink side as:

$$y_s = \sqrt{P_i} h_{is} xi + n_s \quad (1)$$

where fading factor is termed as h_{is} of the original transmission channel or main channel, which transmits the info from *Si* to the intended receiver called sink. The factor n_s will show the additive Gaussian noise with the variances of the signal N_0. As per the Shannon capacity derived formula [9], the capacity of the primary channel can be expressed as:

$$c_s(i) = log_2\left(1 + \frac{|h_{is}|^2 Pi}{N0}\right) \quad (2)$$

where $i \in S$, as per the medium is open in air. The spy may attack on that open space when info is transmitting from the *Si*, as the *xi* is the main signal. In the equation (1), the spy tries to decode the *xi* signal from the transmitting signal.

As per the survey of physical layer [8]-[17], the spy is accepted to have the ideal learning of real transmissions, which includes the details like coding technique, the type of modulation and algorithm used for encryption and the secret key, only the original message signal *xi* is secret to the spy after the many trials also. So from the eavesdropper side *e* the signal is expressed as:

$$y_e = \sqrt{P_i h_{ie} x_i + n_e} \quad (3)$$

where h_{ie} is the factor of fading coefficient at the attacker channel can say wiretap link from *Si* to an eavesdropper and n_e represents the noise at spy link with variance N_0. Considering equation (3), the capacity of the channel at wiretap link is derived in terms of logarithmic expression along with the power *Pi*.

$$C_e(i) = log_2\left(1 + \frac{|h_{ie}|^2 Pi}{N_0}\right) \quad (4)$$

From the [10][11], the difference of channel capacities of the link is considered as the secrecy capacity. In presence of the spy or eavesdropper, we can derive the secrecy capacity as:

$$C_{secrecy}(i) = C_s(i) - C_e(i) \quad (5)$$

where $C_s(i)$ and $C_e(i)$ are expressed in the equations (2) and (4) in terms of capacity their channels respectively.

$$C_{secrecy}(i) = \left(log_2\left(1 + \frac{|h_{is}|^2 Pi}{N_0}\right) - log_2\left(1 + \frac{|h_{ie}|^2 Pi}{N_0}\right)\right) \quad (6)$$

The secrecy capacity is considered with the equation (6) but still the secrecy capacity of the channel is not maximized. So by keeping this as benchmark, an optimal sensor scheduling is proposed.

V. PROPOSED OPTIMAL SENSOR SCHEDULING

The optimal sensor scheduling is the proposed scheme of this paper along with changes in the system model, where the earlier system has only one source and one destination with one type of data traffic. In this proposed system model considering more than one source and one destination along with the different data types which has different priorities.

The optimal sensor scheduling deals with the secrecy capacity of the channel capacity of the spy link and the primary link, where exactly a path has to choose for transmission from source to the intended sink. Among the links it chooses optimally which has the highest secrecy capacity and according to the priority of the queue process it schedules the packets.

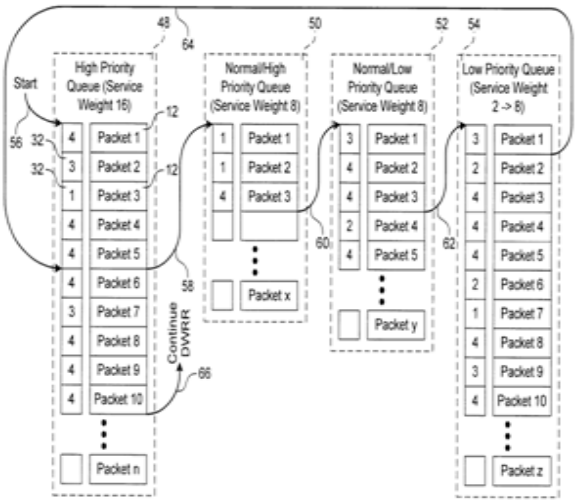

Figure 6: Scheduling queue with priorities

The above example shows the how scheduling process is done according to the priorities of the packets. The priorities levels are divided into four parts. First one is high priority queue with the service weight of 16. Second is normal/high priority of queue with the service weight of 8. Third is normal/low priority queue with the service weight of 8. Fourth is low priority queue with the service weight of 8.

The first queue stores the highest priority packets, remaining will be sent to the next priority queue. Similarly the remaining two priority queues are also filled up. In first queue, packets 1 to packet 10 are stored with their own special priority numbers in left column. It also divides the packets according to the bit size of a packet, compares the

mode of selection with the packet parameters then it sends packet to the schedule queue. It directly executes the packet as First-In-First-Out (FIFO) process.

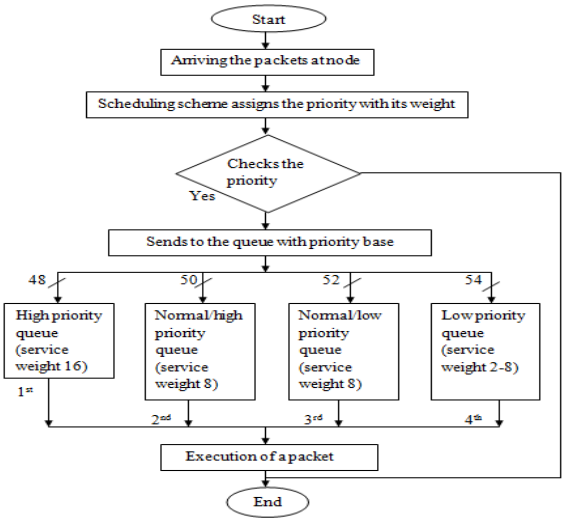

Figure 7: Flow chart for priority checking in queue

The flowchart shows the prioritising of packets according to the queue states. The scheduler divides the four queue states with respect to the prior number and the message weight. The main aim of prioritising the packets is to avoid the latency of emergency packets and to control the long time for low weight packets as the energy saving is the main constraint of WSN.

According to the weights and the priority numbers of packet, scheduler sends that packet into particular queue state then the execution process is started. The next in series of the high priority to the low priority queues will get into the process. The priority of the packets is done to avoid the overhead of the network, which helps to reduce the packet drop rate of the transmission without using any external buffers or memory devices. The flow chart in Figure 8 explains about the calculation of secrecy capacity and selects the optimal highest among the channel capacities by the reference of Round Robin schedule. The node allows transmitting the data by selecting the optimal secrecy capacity.

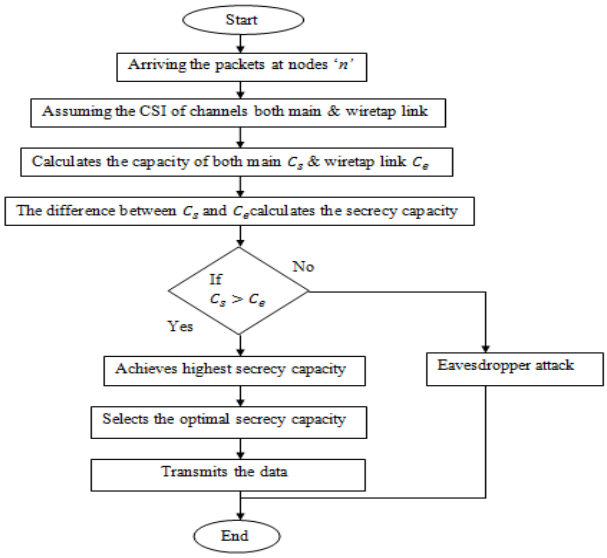

Figure 8: Flow chart for finding secrecy capacity

The system assumes the channel state information of the both main and wiretap link. After arrival of the packet, algorithm calculates the capacity of the channel main and wiretap links as C_s and C_e respectively. The difference of the channel main and wiretap link is called secrecy capacity, $S_c = C_s - C_e$. If $C_s > C_e$, when the channel capacity of the wiretap transmission channel is less than the main channel means a secured connection. S_c will increase with the increase of C_s and decrease of C_e. If $C_s < C_e$, then eavesdropper attacks the network.

Secrecy Capacity Calculations for Optimal Sensor Scheduling

The proposed scheme main objective is to enhance the secrecy capacity factor. Optimal selection of the secrecy capacity is done. Normally, a sensor which acquires the most highest $C_{secrecy}$ is chosen and scheduled in queue for transmitting its data from that sensor node to the destination called sink. Subsequently from the equation (5), the optimal sensor process of scheduling is:

$$\text{Optimal Sensor} = \arg \max_{i \in S} C_{\text{secrecy}} \text{ (i)}$$

$$= \arg \max_{i \in S} \frac{1+\frac{|h_{is}|^2 P_i}{N_0}}{1+\frac{|h_{ie}|^2 P_i}{N_0}} \quad (7)$$

where *S* denotes the arrangement of set of *N* sensor nodes in the scenario. From the above equation (7), the CSI (i.e., $|h_{is}|^2$ and $|h_{ie}|^2$) for every sensor node helps to define or choose the optimal node.

Using channel estimation methods from survey [10], every sensor may evaluate its own CSI with the estimation of a channel and transmits the accessed CSI to the intended receiver. In the wake of gathering all the sensor nodes CSI, the sink can promptly decide the optimal sensor, furthermore the entire network about the CSI of each sensor. When the eavesdropper appeared in the transmission, the secrecy capacity of the proposed system can be derived from (7) as:

$$C_{secrecy}^{Proposed} = \max_{i \in S} log_2 \left(\frac{1+\frac{|h_{is}|^2 P_i}{N_0}}{1+\frac{|h_{ie}|^2 P_i}{N_0}} \right) \quad (8)$$

For the remote connection between any two sensor nodes in system model, the system environment is considered with complex fading coefficients called Nakagami fading channel. The medium is getting very difficult with many signals and interferences that can affect the main signal. Other than eavesdropper effect, there is a need to take interference signals also that lead to the loss of packets or corrupt with interrupt signal.

In this $|h_{is}|$and$|h_{ie}|$ are the random variable coefficients of the channel which represents the fading effects in the transmission medium along with the shaping factors m_i and the k_i, tends to the gamma distributed factors as $|h_{is}|^2$ and the $|h_{ie}|^2$ of the main channel link and the wiretap link respectively.

In terms of the gamma distribution, the source to sink link is $|h_{is}|^2 \sim \gamma \left(m_i, \frac{\sigma_{is}^2}{m_i} \right)$ and for the wiretap to the sink link is $|h_{ie}|^2 \sim \gamma \left(k_i, \frac{\sigma_{ie}^2}{k_i} \right)$, where the expected values of coefficient variables are σ_{is}^2 and σ_{ie}^2 for $|h_{is}|^2$ and $|h_{ie}|^2$

respectively. For the notation convenience, $X_{is} = |h_{is}|^2$, $X_{ie} = |h_{ie}|^2$ for main and wiretap channel respectively.

As the wireless sensor network is the spatial distributed environment, the probability of the density functions of X_{is} and X_{ie} is derived as:

$$fx_{is}(x_{is}) = \frac{1}{\gamma(m_i)}\left(\frac{m_i}{\sigma_{is}^2}\right)^{m_i} x_{is}^{m_i-1} exp\left(-\frac{m_i x_{is}}{\sigma_{is}^2}\right) \quad (9)$$

$$fx_{ie}(x_{ie}) = \frac{1}{\gamma(k_i)}\left(\frac{k_i}{\sigma_{ie}^2}\right)^{k_i} x_{ie}^{k_i-1} exp\left(-\frac{k_i x_{ie}}{\sigma_{ie}^2}\right) \quad (10)$$

The $\gamma(.)$ denotes the gamma function for the density functions of main link X_{is} and the wiretap link X_{ie}. The probability density function of main channel is represented as $fx_{is}(x_{is})$ and for the wiretap channel is $fx_{ie}(x_{ie})$.

VI. Results

The main objective of this proposed system is to achieve the high secrecy capacity than existing scheduled scheme with the system model of one eavesdropper and multiple sources with different types of traffic with different priorities in the scenario. All the results of proposed scheme are simulated and compared with the existing scheme using NS2 software.

A. Secrecy Capacity

The secrecy capacity of a channel is technically measured in terms of the throughput, the speed of the communication in terms of delay factor and the priority rate of the traffic flow. The green portion shows the proposed optimal sensor scheduling scheme and the red portion shows the existing scheme.

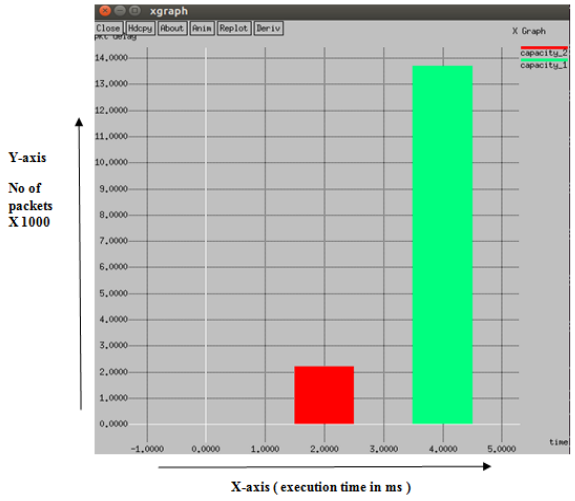

Figure 9: Throughput of existing vs proposed scheme

The optimal sensor scheduling has more throughput level. The secrecy capacity is achieved with the maximised capacity of the main channel. As per the theory it should achieve the more capacity, to have a high security. It is calculated with the successful transmission rate of packets. Hence it has improved the security of the physical layer.

B. Delay

The latency in terms of delay from the Figure 10, the optimal sensor scheduling has less delay compared to the existing model. With less delay it can achieve the fairness of communication without compromising in the speed.

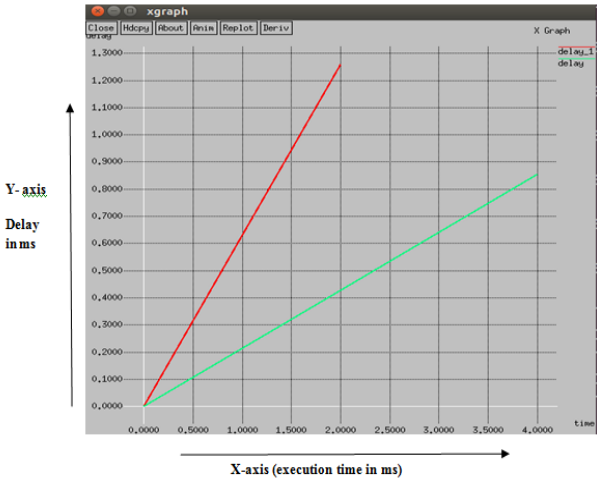

Figure 10: Latency of existing vs proposed scheme

The delay factor is more important in the wireless communication to achieve the QoS requirements. The proposed system has less latency. It also saves the energy of the node.

C. Packet Delivery Ratio

The packet delivery ratio is measured to know the ratio of number of packets received by the number of packets transmitted. The one which achieves maximum rate of PDR will have a secured communication. As per the Figure 11, the proposed optimal sensor scheduling achieved maximum packet delivery ratio than the existing method. This is also a factor which represents the achievement of the maximal secrecy capacity and improved security of physical layer communication.

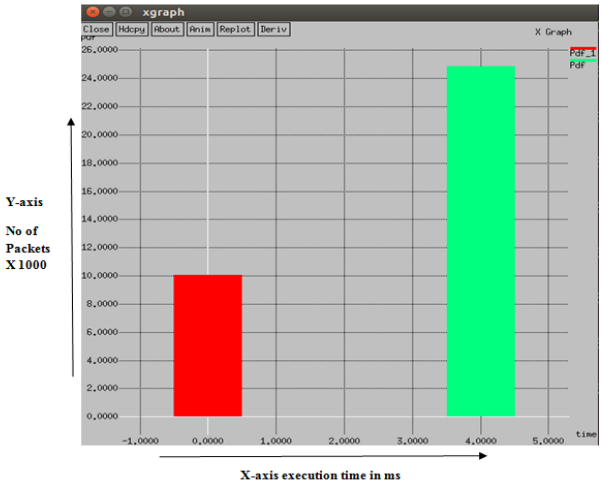

Figure 11: PDR of existing vs proposed scheme

The packet delivery ratio will show the ratio of the number of packets transmitted and the number of packets received. The maximal packet delivery ratio shows the enhancement of the packets that are received successfully at the end. Hence the factor shows the improved delivery ratio.

D. Priorities of Different Data Types

The system model considers the different data types according to their priorities; the graph monitors the priority wise transmission in the network with the same scheduling model. Even though the traffic is increased, the proposed

scheme successfully achieved the requirements of the communication with maximal secrecy capacity.

Considering X-axis as the run time and Y-axis is time taken to complete the transmission, the below graph shows the transmission of different data types with their own priorities, the red colour indicates the high priority traffic with priority0, priority1 is in green colour and priority2 is in blue colour. According to the assigned priority, the data types are forwarding through the nodes.

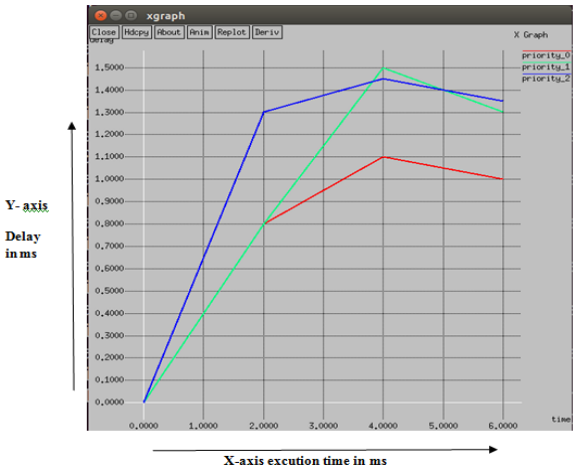

Figure 12: Priorities of different data types

As per the theory, priority0 should take less time to reach the destination which can be observed in the graph with red colour which completed its transmission before the other priority levels.

VII. Conclusion

The employment of sensing element improved the physical layer security of an industrial WSN to counter the eavesdropping attack and the optimal sensor scheduling scheme increased the secrecy capacity of wireless transmissions from the sensors to the sink. The system model with one eavesdropper and multiple sources with different data types in the scenario along with their own priority allocations for successful transmission of emergency data is used.

The scheduling scheme satisfied the requirements of multiple traffics and achieved successfully. The achieved maximal secrecy capacity shows the improved security levels of the physical layer. Numerical results validated the projected optimum scheduling theme in Nakagami fading environment. It performed better than the traditional Round Robin scheme in terms of the throughput, delay and packet delivery ratio and monitored the packets transmission according to the assigned priorities.

The security of the physical layer enhanced with multiple sensor nodes with different data types is only considered. The concept of QoS factor not taken into account and CSI of each sensor is assumed. Also the intercept probability of an eavesdropper in multiple transmissions and multiple eavesdroppers in the scenario for sensor scheduling is not considered. Thus, it is important to investigate the QoS ensured sensor scheduling, endeavouring to enhance the remote security while ensuring every sensor particular QoS necessity. Furthermore, because of the channel estimation mistakes, it is difficult to acquire the ideal CSI for the sensor scheduling. It is of enthusiasm to research the effect of CSI estimation errors with the arrival of intercepts and finding the intercept probability of this sensor scheduling scheme with explained system model. Further idea can be checking the sensor scheduling performance along with the QoS requirement if the multiple eavesdroppers attacked the network.

***Abstract*—The Automatic Number Plate Recognition (ANPR) is a Image Processing innovation that utilizes the vehicle number (permit) plate for vehicle identification. The goal is to utilize the vehicle number plate to plan a productive programmed approved vehicle distinguishing proof framework. The framework is executed in the college entrance for security control.This paper highlights the license plate extraction algorithm where number plate is extracted using Sobel filter, morphological operations and Connected Component Analysis (CCA). Then character segmentation based on CCA and Spectral Analysis, then character recognition based on Support Vector Machine (SVM) technique. In OpenCV-Python, the proposed model is simulated and implemented and its performance is evaluated on the actual image.**

***Index Terms*—Segmentation, Recognition, Sobel filter, Morphological, Connected Component Analysis, Spectral analysis, Support Vector Machine, Python, OpenCV.**

I. INTRODUCTION

ANPR is an technology in image processing that can be used without direct human intervention to peruse vehicle license plate. It is an imperative area of research, because of its numerous applications, for example, traffic observing and law implementation, tracking of automobile, robotizing of vehicle leaving, electronic toll accumulation, Entry and Exit time etc[1]. ANPR framework is still in advancement so as to distinguish and perceive vehicle number plates with different organizations under various natural conditions. Because of variety in the plate models, this undertaking turns out to be extremely troublesome in India. There are various factors that should be considered to increase high precision in the recognition of the number plate, for example, time of day, climate and angles between the cameras and the tags.

The work of ANPR is usually framed in the following steps: Image acquisition, Image pre-processing, Number plate extraction, character segmentation and the last is character recognition[2]. Number plate extraction is most difficult task, mainly because number plate generally occupies a small portion of the entire image and difference in number plate formats.

The proposed ALPR system consists a algorithm for number plate extraction applicable to various standard formats of lic penselate. Figure 1 shows the Block diagram of ALPR system. Character segmentation based on CCA and Spectral analysis and finally, character recognition based on SVM feature extraction that generally applies to different character fonts. . The remaining part of the paper is composed as follows:Section II describes the moving vehicle segmentation , Section IIIdescribes License plate extraction , Section IV explains Character Segmentation,Section V Feature Extraction, Section VI Character Recognition, Experimental results are demonstrated in Section VII. Section VIII concludes the paper.

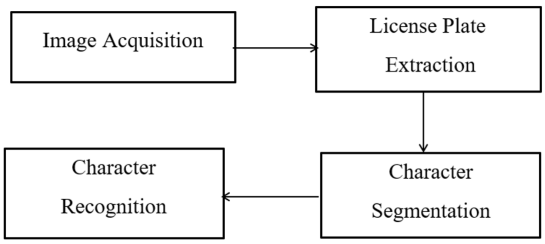

Fig. 1: Process flow diagram of ANPR system.

II. MOVING VEHICLE DETECTION AND SEGMENTATION

The main processing phase of the number plate identification model is the selection of footage frames led by detection and retrieval from a wider scene image of the plate number area to reduce subsequent mathematical calculations and sophistication of the algorithms. A moving object must be recognized & followed by a persistent video arrangement depending on it's essential data, such as visual characteristics, shading, surface, shape and movement characteristics.[3].In video, the car is tracked as it changes its position in each and every frame as it moves from one frame to another. The car throughout the footage is classified as a positive picture and with the Haar Cascade Classifier the entire background is identified as a negative picture. In the proposed model the car region is marked with rectangular box with help of Haar cascade classifier. The car region is extracted based on the

area region for example in the figure 2 the area region of the car is 332 X 332. Based on the x and y values and setting the criteria for the area then we have extracted the car region. Thus, in the overall video, only the car region is extracted as shown in Figure 2.

Fig. 2: Car identified and obtained from video.

A. Extracting the Frames from the video

Depending on the length of the video , the video is divided into six frames. The frames are further processed for plate extraction which recognize the license plate elements. As shown in the figure 3, frames are extracted from the sample video.

Fig. 3: Extracted car images from footage.

III. License Plate Extraction

The extraction of the license plate directly affects the system's accuracy, and is subsequently the most critical stage in the ANPR system. In this phase, a set of possible areas from the input image are produced and a real license plate is selected.

A. Image Acquisition and Preprocessing:

A high- resolution digital camera is utilized in this framework to capture an image. Pictures may be taken in various backgrounds, brightening situations or at different distances between the camera and the vehicle. Pictures are resized to (1000 X 700). Figure 4 demonstrates the preprocessing steps included. Picture will be changed over from RGB to Gray scale.The pre-preprocessing step is utilized for denoising and upgrading picture differentiate. Bilateral filtering is used on the vehicle's gray scale to obtain a smooth, better quality picture with less obscuring effect[4]. With the utilization of histogram leveling on gray scale picture, pictures are upgraded to lessen the issue of low quality and low difference in vehicle images[5]. Figure 5 demonstrates a case of an info picture and Figure 6 demonstrates a case of pre-processed picture with potential number plate region.

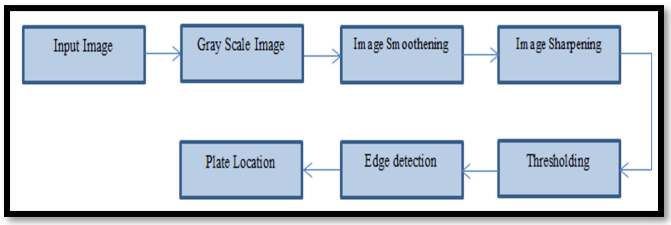

Fig. 4: The Preprocessing flow chart

B. Edge analysis and Morphology

To detect edges, the sobel operation is performed on the threshold image[6]. We mark the pixel as a 1 wherever an edge is presented, otherwise as a 0. Usually the edge pixels are affluent and evenly distributed in the true region of the license plate[7]. In the true license plate region, there are only 2 dominant colors: one for alpha numeric characters and another for the background of license plate. This component is utilized to nd the region of the applicant plate from the picture input. Dilation is connected to fortify the edges extracted by Sobel operation, hole lling is done to ll gaps in the expanded picture, morphological opening is connected to evacuate the undesirable regions in the hole - lled picture, lastly erosion is connected to distinguish hopeful tag districts. Figure 7 indicates consequence of impact of utilizing Sobel operator and Figure 8 shows an example of candidate license plate regions.

C. Candidate Plate Area Detection

Dilation and erosion are used for the entire image to extract candidate plate areas. Figure 9 shows an example of

Fig. 5: Input Image.

Fig. 6: Preprocessed Image.

Fig. 7: Edge analysed Image.

Fig. 8: Morphological analyzed image.

connected component analyzed image with candidate license plate regions[8].Background areas can also be declared as the candidate plate sometimes. This results in plate conrmation using the ratio of width to height, area of region and global image features such as geometrical features, colour and textual features of the number plate to removal of the fake candidates and extract the true license plate region.

D. Spectral Analysis

Characters have the same color and are aligned horizontally. The best way to process such data is to carry out spectral analysis through the Fourier transformation.[9]. In the segmentation of text areas, spectral analysis was normally used. Each row's intensity (gray scale) values are calculated through a periodogram(Equation 1). The periodogram provides a per frequency band energy distribution.

$$\prod_{f}^{Z} F(y) = 1/Z|\sum_{j=0}^{Z-1} f(j)e^{-i2\Pi\eta j}|^2 \quad (1)$$

Fig. 9: Connected Component Analyzed image

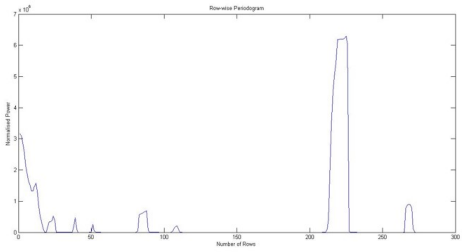

Fig. 10: Effect of spectral analysis on the connected component analyzed image.

1) True Number Plate Extraction: After detecting the area of the potential number plate, the corresponding Column and Row plate area indices will be finally discovered. In the Figure 10 the peak values are corresponding to the license plate rows. So, as soon as the Number Plate indices are known, the number plate is retrieved from the actual gray scale image. The resulting region of the License Plate is as shown in Figure 11.

Fig. 11: Extracted License Number Plate region.

IV. Character Segmentation

The objective of this stage is to segment every one of the characters, without losing character highlights from the given number plate picture.As shown in Figure 12, the segregation of the number plate picture is scaled down to 100 * 100 pixels.Then license plate is morphological opened as shown in Figure 13 and closed as shown in Figure 14 in order to eliminate the background noise on the License Plate. Each labeled 4-connectivity pixel matrix is evaluated based on the area threshold and parts that don't meet predefined zone, height to width ratio and column-row length are required to be non - character areas and are disposed of from the whole picture.The result of connected component analysis is as shown in Figure 15. The connected component are extracted individually which contains the only characters[10] as shown in Figure16

Fig. 12: Segmented License plate Image

Fig. 13: Morphological closing

Fig. 14: Morphological opening

Fig. 15: Connected Component Analysis(CCA)

Fig. 16: Segmented characters

V. Feature Extraction

A feature descriptor is a picture depiction which enhances input image through isolating valuable information and discarding of incidental data.Histogram of Oriented Gradients(HOG) is a feature descriptor.

A. Histogram of Oriented Gradients (HOG)

A technique introduced by Dalal et al[11] is the idea of dense and local gradient-oriented histograms (HOG). The objective of this method is to describe a picture through a set of local histograms. In a local part of the image, these histograms count occurrences of gradient orientation. The model uses the HOG descriptor to obtain character set features (0-9 and A-Z) and incorporate them into a single feature vector. The model is then categorized using the SVM classifier.

Step 1: The image character from the set of characters is resized to 27 X 36.

Step 2: The gradients are calculated horizontally and vertically using the Sobel operator.The sobel operator application on Character M is shown in Figure 17.

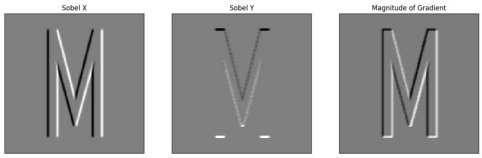

Fig. 17: Character image M

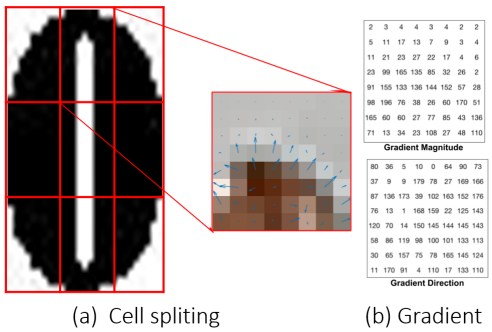
Step 3: Split the Character image into small units, in our case the small unit comprises of 9 rows and 12 columns. In Figure 18(a) The character-0 is of size 27 X 36 and total small units possible are nine units. Then calculate the direction and orientation of the pixels in small unit as the Figure 18(a) shows. The Figure 18(b) provides cell's Magnitude and Angle.

Step 4: Depending on the orientation of the gradient, the



(a) Cell spliting (b) Gradient

Fig. 18: Cell Splitting and Gradient of magnitude and orientation

individual cells will be transformed into symmetrical bins.

Step 5: The adjacent cell grouping is considered to be blocks. The blocks are standardized and represent the histogram of the block.The Figure19 shows how blocks are grouped.

The last step of HOG descriptor is normalization that can

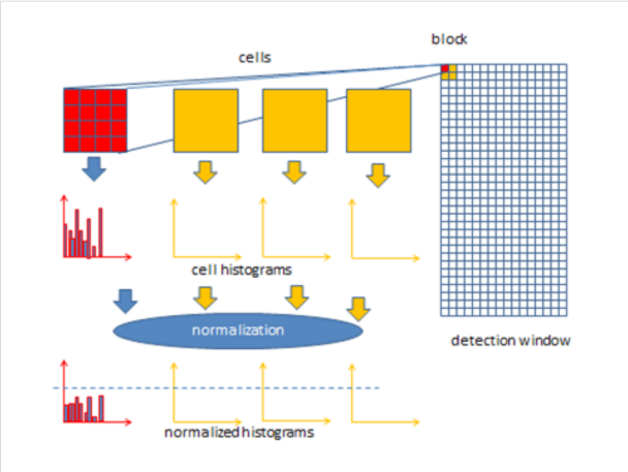


Fig. 19: Histogram computation and normalization

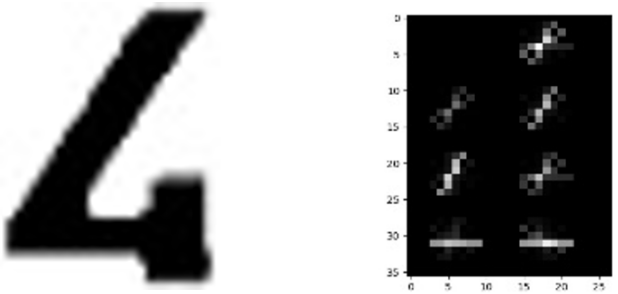
minimize the variability in illumination. By combining all standardized histograms into a single vector, the final feature vector is obtained.

Step 6: Flattening into a feature vector.

Figure 20 (a) is the Dimensional Vector-972(27 X 36 = 972) of character-4 image and Figure 20(b) shows the Dimensional Vector-144 of character-4 image.Their is dimensional reduction from 972 feature to 144 feature.



(a) (b)

Fig. 20: (a) input image character-4 (b) HOG image character-4

VI. Character Recognition

After element segmentation, the final interface becomes the phase of recognizing plate numbers and character, i.e. convert segmented Alphanumeric Characters into Text Format readable by machine. Character Recognition model depends on a classifier i.e., Support Vector Machine(SVM)[12].

A. Support Vector Machine (SVM)

SVM belongs to the maximum margin classification hyperplane or binary classifier. Support Vector Machines idea is to map the data input into a high-dimensional feature space. The SVM classifier is utilized to recognize the groups by finding an ideal Hyperplane which are having the most extraordinary partition from the closest dots in the group of preparations called Support Vectors[13]. The preparation set of points $m_j \epsilon R^n$, j=1,2,...,N where each point m_j has a place with the label $n_j \epsilon -1, 1$ as among two classes. The ultimate goal of the SVM classifier is to separate groups by means of a Hyperplane with increasing unification from the support vectors. The formed hyperplane known as Optimal Separating Hyperplane (OSH). The following equation 2 is expression of OSH:

$$f(a) = u \cdot m + z, whereu = \sum_{j=1}^{N} m_i n_i \beta_j \tag{2}$$

Classification is performed on current data point m by calculating sign on the right side of equation 3

$$Q(m) = \frac{u \cdot m + z}{||u||} \tag{3}$$

In Equation 3 the Q sign is used for data point m classification. The $|Q|$ is the perpendicular distance between Q and Hyperplane. The greater Q value the dot is more distant from the decision surface.The result of the classification is therefore more reliable. The system is trained with the number of classes set at 36 with 10 numerals and 26 letters of the English alphabet. The model is programmed with total count of classes set at 36 with 10 Numerals and 26 english characters.

VII. Results

The developed ALPR system automatically extracts the License Plate and segments the elements of the number plate through Connected Component Analysis(CCA). The classification of the Characters through SVM has been implemented. Accuracy of 85% is achieved using One against One SVM classifier. The segmented number plate characters are recognized as shown in Figure 21. A Graphical User Interface (GUI)

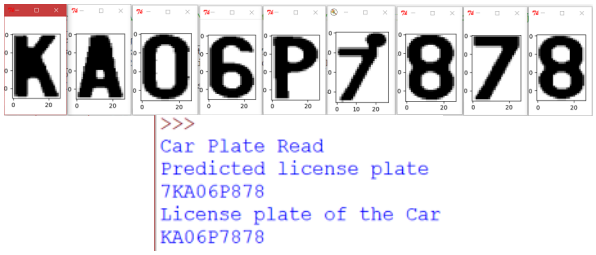


Fig. 21: Segmented Character Image and Recognized license plate number.

is developed. The client can connect with the LPR framework by utilizing the Menu options. Now select the button called Select Image from the GUI then dropdownlist arrives now select the car image and for video analysis select the button called Select Video for video analysis. The execution of the program for still images takes one-second whereas for video it takes around 40 seconds and for HD video it takes around 2-3

minutes.The results of the proposed ALPR system for car, two - wheeler and Taxi, are as illustrated in Figure 22, Figure 23 and Figure 24 correspondingly. The entry time time and exit time of the vehicle is stored in a file as a vehicle log entry to college. The Figure 25 shows the database results stored in file.

Fig. 22: GUI window showing Car image, Segmented license number plate, Segmented characters and Recognized characters of the vehicle license plate.

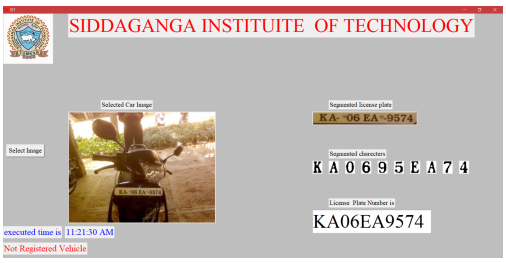

Fig. 23: GUI window showing Scooty image, Segmented license number plate, Segmented characters and Recognized characters of the vehicle license plate.

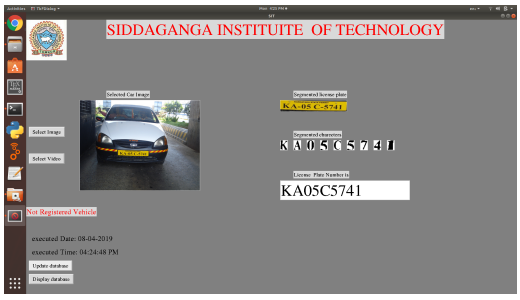

Fig. 24: GUI window showing Taxi image, Segmented license number plate, Segmented characters and Recognized characters of the vehicle license plate.

VIII. Conclusion

License Plate Recognition System has been developed and tested for a video sequence. The selection algorithm for frames is adopted to quickly locate the place of a License Plate and the License Plate is recognized in each frame.Spectral Analysis approach and Connected Component Analysis approach are used for license plate extraction.Connected Component Analysis improves the performance of number plate character segmentation over the technique of projections. The feature extraction based on HOG and followed SVM classifier to recognize the characters gives better recognition accuracy.

***Abstract*— Deception of Certificates is the major issue that is faced by the educational sector. In order to prevent forgery of certificates and to provide a secure certificate verification environment an authenticated system application is developed using blockchain with smart contracts. The immutability property of blockchain prevents the data stored from being manipulated and helps in implementing a verification system. The system generates a new block for every user in the blockchain. These blockchain are replicated across all the nodes involved in a Peer-to-Peer network and thus it improves the reliability of the system. Whenever a user is validated, their certificates are digitally provided by the system to the user along with a Quick Response code. This helps in sharing of certificates between the employers. The authenticity of certificates is improved by embedding the certificates with imperceptible watermark using the alpha blending process. This helps to avoid various attacks at different phases of certificate distribution.**

Keywords*— *Alpha blending process, Blockchain, Quick Response Code, Smart Contracts.

I. INTRODUCTION

In these modern days a large number of certificates are being duplicated where a large number of these cases go unnoticed. According to a statistical report there have been around 72% of the candidates were pertaining fake credentials. There are various stringent laws and penalties for the forgery of documents yet there are no systems for the prevention on certificate duplication. This system helps to avoid falsification of documents by using blockchain technology. Blockchain is a decentralized technology which utilizes distributed ledger essentially an asset database that can be shared across a network of multiple sites, geographies or institutions. Any changes made in one block can be replicated to all copies of a ledger quickly, ensuring that no participant is left working on outdated information.

The users in the distributed network are non-anonymous that is users need permission to access the blockchain or to get involved in the transactions happening in the blockchain. The applications of a distributed ledger enables information to become almost simultaneous on the blockchain and can be used for keeping records which cannot be manipulated but can be shared among various fields.

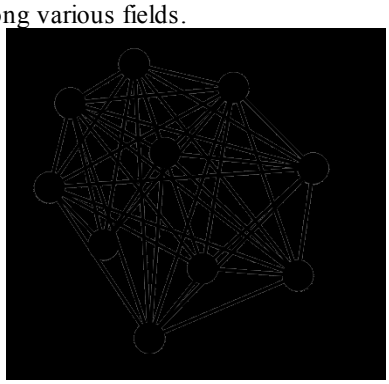

Fig 1.1: Distributed Network

Blockchain is a growing list of records called blocks which are linked through cryptography. Each block contains a cryptographic hash value of the previous block, a timestamp and transaction data generally most often represented as merkle tree root hash. By storing data across its network blockchain eliminates the risk of data getting help up centrally. The blockchain network lacks in a centralized point of contact and hence it avoids the vulnerability of getting hacked.

Smart contracts are protocols enforced to blockchain on which the blocks agree to interact with each other words smart contracts are set of rules which control the nodes in the peer-to-peer based on events taking places in the application. It ensures that the rules are met. Protocols such as Geth are used to develop smart contracts in blockchain. Ethereum is an open source blockchain project that was specifically built to realize the possibility of smart contracts getting executed only when the specific conditions are met.

Smart contracts are capable of implementing compliance

and control on the fly and need information which feed smart contracts with external information. Smart contracts are self verifying, self executing and are tamper resistant. They can turn legal obligations into an automated process and guarantee greater degree of security and reduce reliance on trusted intermediaries.

Fig 1.2: System Structure

The Figure 1.2 shows the structure of the system application. The smart contract establishes all the terms given by the parties included in the system such as the issuing authority i.e., university, the students and the employer. Once the smart contracts are enabled between the parties the events trigger the contract and start the transactions between the users. Based on the contract the execution takes place and the digital certificates will be provided by or to the authorized person.

The system is implemented through a public blockchain ethereum which prevent certificates from being duplicated and helps employers by eliminating the process of physical verification of certificates. It also enables users to have only the digital certificates which can even be shared by holding the security features that avoids certificate duplication.

II. RELATED WORK

EduCTX: A BLOCKCHAIN-BASED HIGHER EDUCATION CREDIT PLATFORM: The need for securely storing digital certificates in blockchain was first determined by Muhamed Turkanovic et al [8]. The idea was to develop distributed application on ARK chain blockchain platform, to securely store digital certificate and transcripts. This helps the user by making their certificates counterfeit proof and lets them carry certificates verified by the issuing authority in a digital wallet. The certificates were successfully stored in a blockchain and therefore protecting the certificates from counterfeiting, accidental damage, etc. Though the idea was broadminded the implementation of the application was narrowminded. The application was developed using ARK blockchain platform which is a private blockchain platform and is an invite only platform. The notion of central authority exists to a certain extent defeating the purpose of the application. The application does not have wide reach to a large audience due these reasons. The non-existence of smart contracts and automation hampers the distributed application from being future proof and also consumes significant amount of resources.

EXPLORING BLOCKCHAIN TECHNOLOGY AND ITS POTENTIAL APPLICATIONS FOR EDUCATION: Guang Chen et al [4] proposed the idea of utilizing a blockchain based application in everyday school activities in order to prevent plagiarism in every day schoolwork such as assignment, homework, project report .The proposed system was developed on the blockchain platform and also suggested to reward students through cryptocurrencies on completion of their work. The idea of incentivizing students on successful completion of their work is not sustainable. The downsides of the proposed idea are teachers need to verify their work only from the blockchain application and it is difficult to perform a perfect assessment through the digital platform. The transaction costs generated will skyrocket due to the amount of transactions taking place due to the a large number of students using the application. They also suggested the use of private blockchain platforms hosted by each school independently in order to reduce transaction cost and make the idea viable for implementation.

EDUCATION-INDUSTRY COOPERATIVE SYSTEM BASED ON BLOCKCHAIN: For any technology or ecosystemto develop it needs the cooperation of the users and the industry providing the technology for the development of tools, one such cooperation was devised by Honming Zhu et al [15]. The proposed idea bought together the education industry and the technology provider IBM to develop frameworks which assist user for developing blockchain applications. The Hyperledger framework and Hyper ledger Peer-Peer network developed by IBM is used to develop distributed application at a faster rate. Though the applications are easy to develop using the framework the applications developed using the framework lack robustness since they have a single point of failure.

UNTWIST BLOCKCHAIN: A DATA HANDLING PROCESS OF BLOCKCHAIN SYSTEMS

Sachin M. Kolekar and et al [10] have discussed the data handling process in blockchain systems. The authors have described how blockchain has grown immensely in the past few years. They eliminate the need for trust among different parties involved in a transaction. They have also eliminated the need for a central authority by using a distributed ledger and hence by doing so the tampering of data is highly difficult. They then present BLOCKBENCH, a criterion skeleton for understanding performance of private block chains and public Blockchain. In this paper they have discussed the circumscriptions of Blockchain. In section 1 they have discussed the workings of blockchain from creation of the genesis node to using clever cryptography in order to hash the nodes present in the network. Section 3 describes the types of blockchains ie private and public blockchains. Section 4 portrays the concepts of blockchain such as the distributed ledger, consensus algorithms and mining. The Intrusion detection systems in detail such as HIDS and NIDS. Their limitations are discussed ranging from updation management to their inability to avoid denial of service attacks. They have conducted comprehensive survey on Blockchain Technology. It is a budding solution for decentralized communication and data management without the need of a trusted third party. It is an open and spread ledger, enabling the recording of contact among various parties in a provable way. Basic clarity and justification of Blockchain is seen and working of the Blockchain in decentralized network has been understood. Also, Combination of Blockchain Technology with Internet of

Things has been studied. Few Advantages and Disadvantages have been seen and various applications of Blockchain Technology are stated. Most Importantly, Future of the Blockchain has been predicted if few of the assumption comes true, then what are the possible technologies which can be created by blockchain technology. Concepts like consensus, distributed ledger, proof of labor, proof of stake, etc. have been explained in short.

LITERATURE SURVEY ON UNTANGLING BLOCKCHAIN: A DATA PROCESSING VIEW OF BLOCKCHAIN SYSTEMS: Tien Tuan Anh Dinh et al [12] discuss about the blockchain systems that are gaining massive momentum in the last few years. The blockchain systems are useful for parties that do not trust each other amidst a transaction. Due to their usage of distributed ledgers parties do not need to depend on a central authority. The authors have focused their discussion on private blockchains and as a result the parties are authenticated. This paper has also discussed about BLOCKBENCH, a benchmarking framework for understanding performance of private blockchains against data processing workloads. They have provided information about the software such as Ethereum, Parity and Hyperledger fabric. The tradeoffs between blockchain and traditional database systems have been discussed in order to evaluate the differences between the former and the latter. They have discussed how a blockchain network is created. The genesis block is initially created whose hash value is stored in the next block and so on until it forms a chain. Consensus algorithms also play a major role in the addition and removal of new nodes in the system which also deals with Byzantine related problems. Blockchain has its advantages over tradition databases in providing robustness and decentralization.

III. PROPOSED SYSTEM

The system proposed is built over a public blockchain based on ethereum platform. The ethereum blockchain platform enables user to develop smart contracts which increases the level of automation and reduces the cost and the number of transactions. Fig 3.1 shows the architecture diagram of Digital Certificate System.

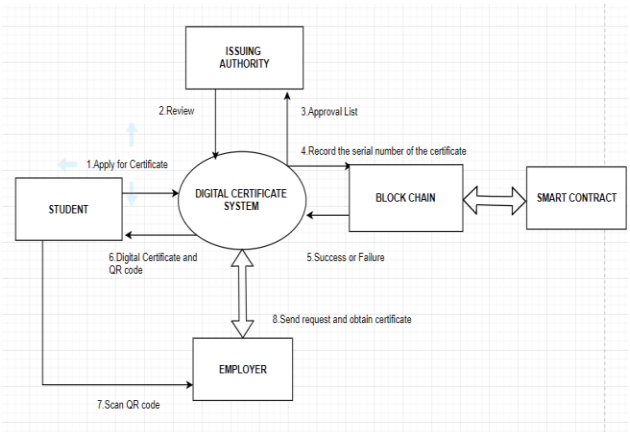

FIG 3.1: Architecture diagram of Digital Certificate System

The students are provided with an application interface through which the students upload their information. The issuing authority provides the authenticated students list to the distributed system which can be verified with the student details that are uploaded through the application interface. The verification list contains the serial number of the certificates that is stored to the blockchain with smart contracts by the Digital Certificate system. When the student request for the digital certificate, only when it is successfully stored in the blockchain they are provided with their digital certificate which is embedded with a data for security and a Quick Response (QR) code for further sharing of certificates. During certificate verification process the QR code is shared by the student to the employer and the certificate is verified.

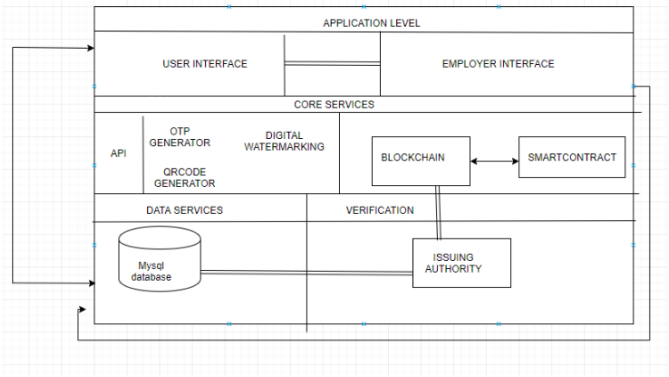

FIG 3.2: Functional Diagram of Digital Certificate System

Fig 3.2 describes the functional architecture of digital certificate system. The application level gives the interface among different users who access the application. The application gets the certificates from the issuing authority which holds the certificates in the database and stores the certificate number in the blockchain through smart contract with the help of hash functions. When the user requests for the certificate the application programming interface embeds the certificate with an imperceptible watermark for authentication and sends an OTP to the user whenever the certificates are shared.

The Digital Certificate System consists of four modules namely

a. Users Validation
b. Hash Generation
c. Securing digital certificates
d. QR code Sharing

The following are the essential components of the system.

a. USERS VALIDATION

Users in the specific module register their details in a form containing various fields in the application. The data collected is stored in a dropbox cloud platform using the dropbox library. Architecture of the dropbox database is of a tree structure which enables easy manipulation of data. Once registered, users are provided with an OTP (one time password) for

authentication. Upon authenticating the users details get uploaded in the concerned issuing authority.

b. HASH GENERATION

The module is the core of the application containing the blockchain system. For every new registered user a new block is created in the blockchain. The data of the user i.e the serial number of the certificate is stored in the block. Hashes are generated using hash function such as SHA-512.

SHA-512 is a cryptographic hash function that is built using Merkle-Damgard structure [3]. It consists of an 80 round module which generates the hashes. The hashes generated use the data stored in the blocks, hence if data changes the hash value will also get change.

The hash of the previous block is stored in the next block and thereby creating a chain of blocks. This is responsible for the property of immutability and any changes can be notified to the user.

c. SECURING DIGITAL CERTIFICATES

Once serial numbers are securely stored in the blockchain they generate a success signal to the system. Upon obtaining the signal and request from the user digital certificates are sent to the user along with a QR code.

The certificates from the digital certification system contain an indistinguishable imprint by using alpha blending process. It is used to display a bitmap which as has transparent and semitransparent pixels. In addition to red, green, blue color channel each channel in alpha bitmap has a transparency component known as alpha channel. An open source API is used for this purpose which imprints the digital certificates through the alpha bending process. This safeguards the digital certificates from being misused after sharing the certificates.

To make the imprint visible the color scale of the digital certificate is changed to a specified value.

The property of the imprint being indistinguishable is that when an unauthorized person tries to duplicate the certificate, they will be unaware of the imprint which can be identified on duplication. This safeguards the digital certificates from being misused after sharing the certificates

d. SHARING QR CODE

In an android interface the users receive the digitally imprinted certificates and are tagged along with a unique QR code. The QR codes are generated through an API (application programming interface). The generated QR codes are shared to the employers on their account. When the QR code is scanned the employer receives the digital certificate of the student after authenticating the user with an OTP.

IV. RESULTS AND DISCUSSION

The results of the above components end up in the system application with login for different users and their specified operation and the sample of user registration is shown below. Similarly the employer will register with their company details so that they can share the documents in a common platform.

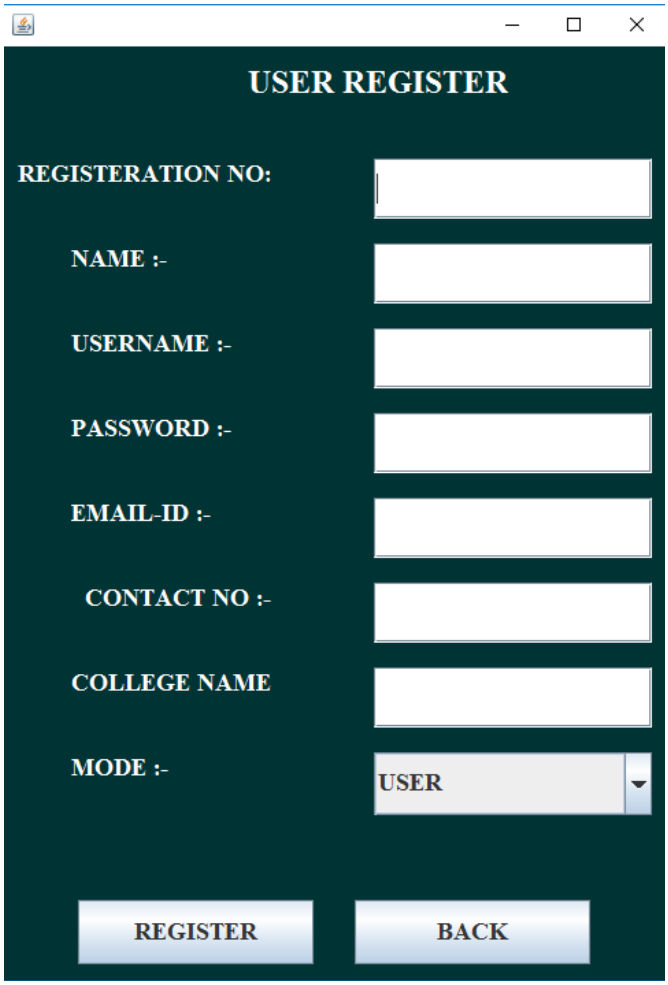

FIG 4.1: Form for Acquiring User Details

The documents are stored in the blockchain. Ethereum is a decentralized platform that runs smart contracts. The Ethereum wallet is installed in the host system and a temporary private test network is executed in order to reduce the cost of development. Genesis block is created and the blockchain is replicated across all the nodes in the Peer-to-Peer network successfully. The ethereum wallet is initialized in the command prompt. The blockchain is implemented on Ethereum blockchain platform. The blockchain is accessed through a command line interface.

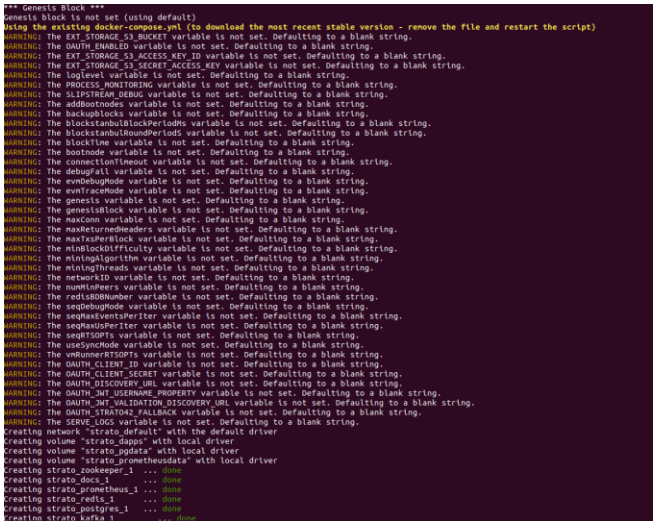

Fig 4.2: Initiating the Genesis block in the blockchain

Once the students register to the application they can request for the mark sheet in the application through blockchain.

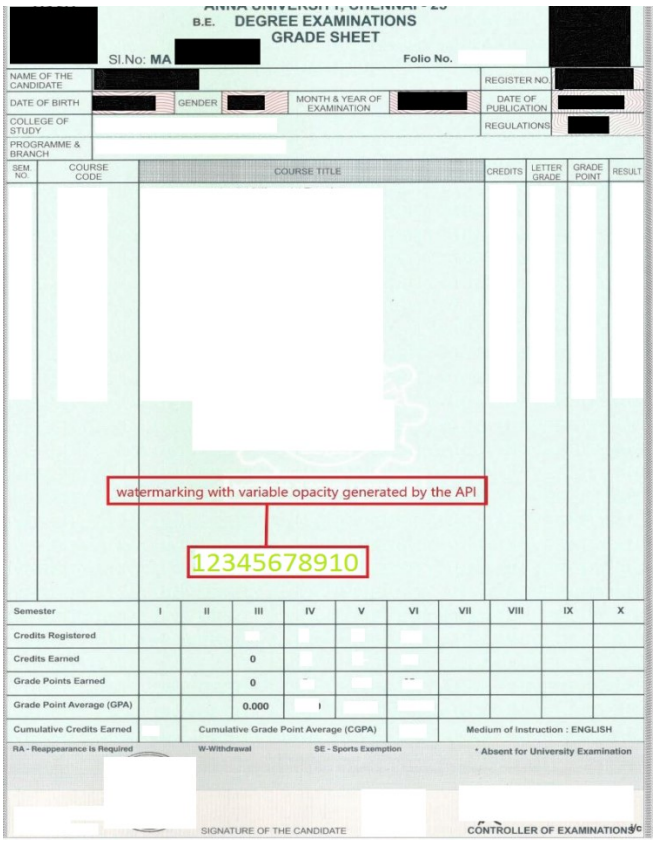

Fig 4.3: Sample watermarked Certificate

The mark sheet is embedded with a watermark for security purpose and can be shared among the employer and the user with the onetime password provided by the application to the user to avoid unauthorized access.

V. CONCLUSION AND FUTURE WORKS

The proposed system demonstrates the effective use of blockchain technology to develop a distributed application and it provides a certified method for preventing duplication of digital certificates. The core of the application is to generate hashes in order to effectively create a blockchain which stores data which cannot be manipulated. As a future work Hyperledger [13] fabric can be used to implement blockchains for effective access. Biometrics of the user can be stored to the application in order to generate highly unique hashes which cannot be decrypted easily.

Abstract— A sharp increase in the availability of satellite imagery data sets available in the past few years and nowadays made the explanation of all those data a challenging problem. Retrieving useful information and insights from images taken by satellite or any other aerial imagery system requires a good understanding of the information which is present in the images itself. This work searches and studies problem mentioned above by studying, designing and implementation of an automated model to extract semantic maps of waterways, roadways, buildings to track urban cities growth of satellite imagery. As it is a machine learning problem, a deep neural network is implemented and evaluated experimentally. Open source, publicly available frameworks and datasets are used in this work, the result of this work is a pre-processing image model which enables the user to take an input image with different quality and resolution and apply the semantic segmentation on it. U-Net is used as the underlying architecture for this project, because of many advantages and functionalities it provides as an example, we can name less computation time which can help starters in the field of AI and Computer Vision to build their prototype and models fast without the need of too much hardware (GPU, Processor, and RAM). To get a better result and decrease the amount of pressure on machine FCN (Fully Connected Neural Network) is used along with U-Net. As FCN has skip layer function and it also makes the network to learn faster and give more accurate results than CNN due to normalizing the pooling layers which in CNN it makes the network to lose lots of information about the data. The primary purpose of this work is to implement Semantic Segmentation on satellite images taken from Urban areas, SpaceNet dataset provides such a data. The data selected for this project is from Khartoum (Capital of Sudan), it is a developing and deserted city. The result of this work will help in managing resources such as agriculture, natural energy, and water, checking on natural disasters and responding to it, like floods, earthquakes, and tsunamis checking on environmental use such as deforestation and Monitoring Urban Development

Keywords- Satellite, Deep learning, Image, Segmentation

I. INTRODUCTION

Semantic Segmentation is the process of labeling images on pixel level or analyzing all details of an image in pixel level [6]. Segmentation is a process or method of dividing an image into multiple parts and section which can be sets or category of pixels, the main point of segmentation is to make the input image understandable for machines, robots, pc and other purposes. So we can say segmentation helps a computer to analyze and understand images and vides as input and detect boundaries, curves etc. While images given to a segmentation application it subdivides the taken image and classify every pixel available in the mentioned image and label it, after labeling done! There will be certain pixels which can contain same or almost same label, then we can say those pixels share some common characteristic or can be part of same object in the input image.

Fig. 1. Semantic Segmentation

There are 3 types of data sets available: RGB Data sets, RGB Depth and pure volumetric or 3D.

RGB Datasets:

Most of the time and through the years, semantic segmentation focus was on RGB images or data, for the reason RGB or 2D data sets are most widely available and the biggest and can be found easily. In RBB data sets any kind of two-dimensional like as gray measure or RGB images can be contained.

PASCAL Visual Object Classes

There are 5 sub classes available in this data set, which is: Dataset for sorting, appointing, segmentation, action classification and people lareadert. From the mentioned dataset, data for segmentation is interesting since the main objective is to identify objects there above 19 different classes of pictures with objects like: Cow, cat, birds, horse, sheep, person, car, boat, bus, tables…etc.

SBD (Semantic Boundaries Dataset)

This data set is extended version of Pascal Visual Object Classes dataset, the data set (SBD) provide semantic segmentation land fact for the picture which not mentioned in Pascal VOC (Visual Object Classes) which contains annotations for almost 11000 images from Pascal VOC and more than 8000 training images from it is own.

Microsoft COCO (Common Objects in Context)

This is another large scale dataset which is very suitable for image recognition, segmentation and capturing. The part of this data set which is focused on segmentation has more than 80 classes which includes more than 80000 images.

SYNTHetic set of imagery and annotations

It is a big set of photo-realistic renderings of virtual cities, semantically segmented which the main target is context of driving. This data set provides pixel-level annotations for more than 10 classes like river, nature, airplane, highway, house, pole, car…etc. It features more than 13000 training images which is taken from video streams.

Cityscapes

It is a large scale database which is the main focuses of this data set is on semantic understanding of civil road scenes? This dataset supply material in over 30 groups which have flat surfaces, people, cars, buildings, boats, nature and river. This dataset has been captured in over 40 cities during months, during the day when the weather was clear and good.

ReaderTube-Objects

The data available in this dataset mainly prepared from ReaderTube videos which contains objects from ten PASCAL VOC classes: Airplane, animals, different kinds of vehicles and train.

CamVid

It is a driving section, which eventually taken as a film by a camera attached on the dashboard of a car? The dataset covers 32 classes of objects and some of them are

- building
- wall
- tree
- vegetation
- fence
- sidewalk
- parking block

KITTI

It is a famous dataset to be used in mobile robotics and autonomous cars, which is contain couple of hours of traffic conditions filmed with mixture of sensor situations covering high: - Clearness RGB

- grayscale
- 3D scanners

it doesn't contain any data for semantic segmentation but lots of researchers manually marked parts of the database to fit their needs.

II. BACKGROUND WORK

Before deep learning become popular in field of semantic segmentation and computer vision, there were other approaches that we can name TextonForest and Random Forest Based Classifiers and in image classification convolutional neural networks (CNN) were able to be a good answer for most of segmentation problems.

Joao Carreira et.al (2012) In every object recognition or segmentation methods coding, pooling, feature extractions are always included an is basic part of procedure. This paper researched and proposed a method based on pooling, which encodes the second order of local characteristics within a region, to achieve this the multiplicative second order analogue is being introduced and together with good non linearities can give a great result on free form boundry detection and recognition, this can be done without any feature coding.
By researchers of this method it is been found that elevating local descriptors with image information addon can have a huge performance discoveries and gains, even better result can be reached by including the proposed method. In this paper it is been showed that pooling based on second-order technique and free form region has superiority over the other winning systems in Pascal VOC 2011 challenge, sometimes even 20000 time faster. [9]

Alexander Vezhnevets et.al (2012) this paper tried to address problem related to weakly supervised semantic segmentation. In the process the images labeling process only by the classes which is available in them, not regarding their location. On the test input this technique must predict label class for each pixel. The goal of this method is to enable segmentation so make them to use few visual cues in the setting of weakly supervised setting, similar to result which is achieved by full supervised method. Somehow it is difficult to measure the usefulness of different visual cues from data of the purposed method which is Weakly supervised. A group of parametric structured model is defined where each one of the models do the weight process in different way. The maximum expected Agreement is proposed which assesses the quality of model from the group without checking the Supperpixels levels. The process for searching the best and fittest model is a hard process for optimization problem. This problem is looked as Bayesian Optimization and proposed algorithm is based on Gaussian processes to perfectly solve it. The second contribution by this paper is "Extremely Randomized Hashing Forest" which represents varied Supperpixels feature like saparse binary. [10]

Alexander Vezhnevets et.al (2012) the main problem which is addressed by this paper is to solve classifying every pixel in the image related to their semantic class which they belong to for example buildings, water way, cars. Most of methods which exists train from a full supervised image, where every pixel is marked by a group or class label. To reduce the efforts for the process of annotation, recently weakly supervised methods appeared. The weakly supervised method only requires only image labels representing which groups are available or present. While the performance of these methods reaches a acceptable level, there is a huge gap between accuracy of this method and fully supervised method. Which in this paper it is been tried to reduce this gap or even remove it by proposing active learning method with is well suited for this technique. The problem is modeled as a pair-wise CRF along with cast active learning to check for findings it of as most useful node. Which these nodes made the biggest changes in CRF model after revealed the true label of them. After doing test on two different data sets, the proposed methods achieved 97% of accuracy.

Jonathan Long et.al (2015): proposed When in 2010 Deep learning become feasible and made programmers able to integrate it with many widely used software and applications, researchers tried to start their research to find how Deep Learning can contribute more and more in AI field, and one of the areas that Deep learning had a good impact on them is Segmentation. Patch classification is a semantic segmentation using deep

learning that we can name after deep learning invented. What exactly a patch classification does is classifying each pixel into different classes using a method called patch of image around it, the main reason using patches was fully connected layers in classification network and because of this reason the image needed to be of a fixe size. To solve this issue in 2014 Jonathan Long, Evan Shelhamer, Trevor Darrell tried to popularize Convolution Neural Network for dense predictions without any connected layers, and it worked and they named the method FCN Fully Convolution Networks. By using this method in segmentation, users of neural network are able to generate segmentation map of any size image and less time or faster. After this discovery all semantic segmentation start using this paradigm. Beside fully connected layers, we can name pooling layers that semantic segmentation method faced with, what exactly pooling layer is? A pooling layer or pooling tool that CNN using for taking a large image and shrinking them down and preserving important information of image, increase the field of view and ignoring the (where) information, while semantic segmentation needs the alignment of class maps and (where) information as well, different research and work has been done to resolve this issue which semantic segmentation faced with. the encoder and decoder architecture for resolving mentioned problem is introduced, the work process of encoder and decoder is: encoder grade by grade causing the dimension to reduces along with pooling layer after that decoder step recovers grade by grade details of object and spatial elements. One of popular architecture of this method can be named U-Net.

Suarabh Gupta et.al (2016) RGB-D images segmentation sometimes can be tricky; in this paper it is been tried to address that problem and propose a possible solution. The proposed method is "geocentric embedding for depth images" which encodes above the ground, angle with using taking notes on gravity for every and each pixel along with horizontal differences. The geocentric embedding has given better results in most cases than raw depth images for representation of learning features with CNN, which has been demonstrated specifically. The final product achieved average of 37.5% which is almost 56% more precise and accurate than existing methods. Along with other points, the focus on task of segmentation on instance based where the label pixels which belongs to object instances are found by the detector. For mentioned task (instance-based segmentation) the Decision forest technique is proposed which classifies pixels of the input in the detection windows which can be either foreground or background using Unary and Binary tests. Then the output of object detector is taken and given to a Supperpixels classification model for semantic segmentation purpose which had 24% improvement over existing methods that has been studied by this paper. .

Vijay Badrinaryanan et.al (2015) The SegNet which developed and worked on by Cambridge University of United Kingdom is a deep encoder and decoder technique for semantic segmentation. The SegNet architecture is contain structure of non-linear processing layers and set of decoders with pixel wise classifying method, and each encoder has a convolutional layer with batch standardization and ReLU procedure non linearity. One of the main characteristic which makes SegNet special is the use of max pooling indices in the decoders to perform the up sampling process of low resolution functionality maps.

Pedro pinherio et.al (2015) This research has been done by Pedro Pinheiro (and friends) which the main title of the paper is (Learning to Segment Objects), how it works: Given an image, at first outputs a segmentation mask, at the second step outputs the probability that the patch is centred on full object (the mentioned process is being applied on image so it could identify all objects available in the image) and all these process is done in one round or through one CNN. As Deep Mask uses simple feed forward network which is good and successful in creating (coarse object masks) but not for pixel accurate segmentations (or semantic segmentation).

Liang-Chieh Chen et.al (2016) proposed is a method which is using Deep convolutional networks and fully connected CRFs for semantic segmentation, made bellow important contributions in field of semantic segmentation:

- Using of atrous/dilated convolutions
- Propose atrous spatial pyramid pooling
- Use fully connected CRF

It tries to bring together method form DCNNs along with graphical probabilistic framework for solving task of classification on pixel-level, and displaying that responses at the last layer of DCNNs are not Enough local for precise object classification or segmentation, to solve this problem localization characteristic of deep networks by integrating the results at the last DCNN layer with CRF.

III. MATERIAL AND METHODS

Data Set Review

One of few publicly available datasets which provide most complete data for both training and testing purposes is SpaceNet, which contains commercial satellite images. Companies like GosmiQ, NVIDIA along with Radiant Solution partnered to make a possible public release of the data set to make innovation faster in the field of Computer Vision and machine learning and help build algorithms for feature detection from satellite images like buildings, roads, and other man-made structures.

AOI	Satellite	Location	Resolution	Area of Raster	Building Label	Road Labels
1	World View 2	Rio de Janerio	50 cm	2544	4082529	NULL
2	World View 3	Vegas	30 cm	216	151367	3685 km
3	World View 3	Paris	30 cm	1030	23816	425 km
4	World View 3	Shanghai	30 cm	1000	92015	3537 km
5	World View 3	Khartoum	30 cm	765	710960	1030 km

SpaceNet Datset

For a better understanding of the dataset, knowing the main source of the dataset will be helpful. Digital Globe is an American vendor which is main services is providing space imagery and geospatial data, is the main provider of the SpaceNet data as well. The mentioned company has few satellites which some of them can:

- WorldView -1, 2, 3 and 4
- GeoEye 1
- World View
- QuickBird

Each dataset generated from mentioned satellites has different features like geolocational accuracy and resolution.

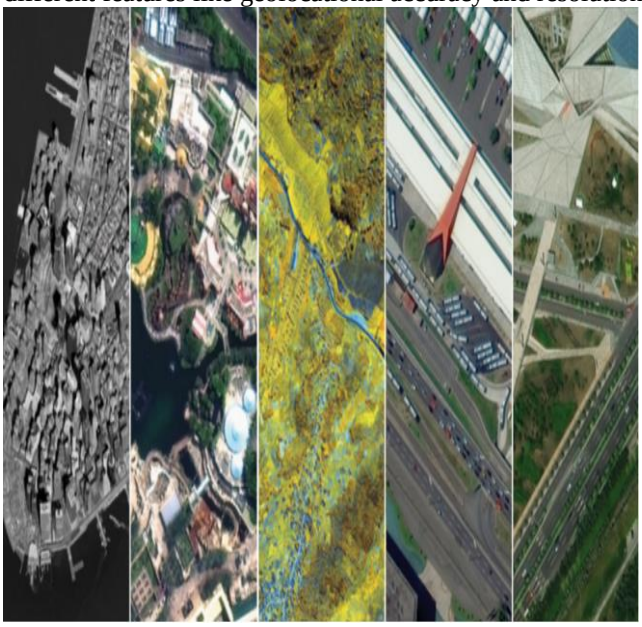

Fig. 2. Data Samples from SpaceNet Data set

Table 1. Different Features of Digital Glove Satellite

Feature	World View 1	World View 2	World View 3	World View 4	Geo Eye Serie
Altitude	495 km	680 km	760 km	615 km	615 km
Characteristics	Pan	Pan + 4 MS	Pan + 8 MS	Pan + 8 MS + 8 SWIR	Pan + 4 MS
Resolution	.50m	0.41m	0.46m	0.31m	0.31m
Multispectral Resolution	NULL	1.64M	1.85M	1.24M	1.24M
40 N Latitude	1.4 Days	< 3 days	1.1 days	1.0 day	1.0 day

Locations covered by SpaceNet Datset

SpaceNet provide satellite data for 5 main areas, which below table is summarizing them

Table 2. SpaceNet AOI (Areas of Interest)

From 2016 SpaceNet organizers started some competitions for the primary purpose of making innovations in the field of computer vision and help to create such algorithm to extract detailed features from satellite images.

The first round of such competition was organized in November 2016, and the target data set was Rio De Janeiro. In the first round, almost 40 developers competed in this challenge which hosted by Top Coder to create such an algorithm to extract building footprints from the input data. The Second competition of SpaceNet main target was from World View 3 satellite which had multiple formats of images like RGB, panchromatic and multispectral.

Raster in SpaceNet

SpaceNet raster is presented in the form of .tiff images. The GeoTiff images are a unique format of images which can be used for georeferencing and pixel in the picture is as real-world distances

Sensor Band of SpaceNet Data Set

Table 3. Sensor Bands of SpaceNet Data Set

Costal	400 – 450 nm	Red	630 – 690 nm
Blue	450 – 510 nm	Red Edge	705 – 745 nm
Green	510 – 580 nm	Near-IR1	770-895 nm
Yellow	585 – 625 nm	Near-IR2	860 – 1040 nm
SWIR-1	1195 – 1225 nm	SWIR-5	2185 – 2225 nm
SWIR-2	1640 – 1680 nm	SWIR-6	2235 – 2285 nm
SWIR-3	1640 – 1680 nm	SWIR-7	2235 – 2285 nm
SWIR-4	1710-1750 nm	SWIR-8	2295 – 2365 nm

Fully Connected Neural Network

Doing Segmentation is far different from classification because the primary purpose of segmentation is required to relate each pixel to a class of the input data, in place of only one class for all the input. To understand what is in the input for each pixel segmentation task is to predict what are contents of the data and to specify the location of the detected object as well.

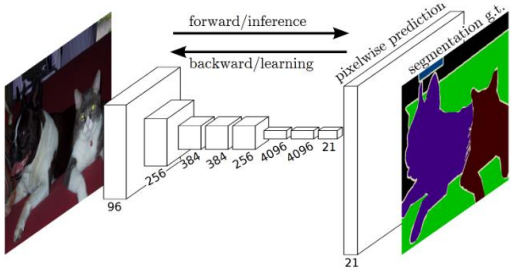

Fig. 3. FCNN

FCN (Fully Convolutional Network)

This model has got its name from the way in which architecture is built which is group of connected layers locally, and the layers are Upsampling, Convolution, and Pooling. This architecture is hugely affecting the number of parameters and computation time. The working method of this model is straightforward where it can work regardless

of the image size, does not require a fixed amount at any of the working stages, because all the layers and connections are local.

To acquire a segmentation result (in our case Map) all segmentation architectures having two main steps:

- Downsampling: which takes contextual information
- Upsampling: which recovers the information

The primary objective of Downsampling is to retrieve the information which is related to WHAT, and the upsampling job is to enable the network to detect exact localization of the detected object WHERE — followed by the recovery phase, to recover the spatial information lost during the pooling or downsampling stage.

Model

There are many FCN architectures available, which the main difference is in their output. the figure shows different types of FCN Architectures like:

FCN 8
FCN 32
FCN 16

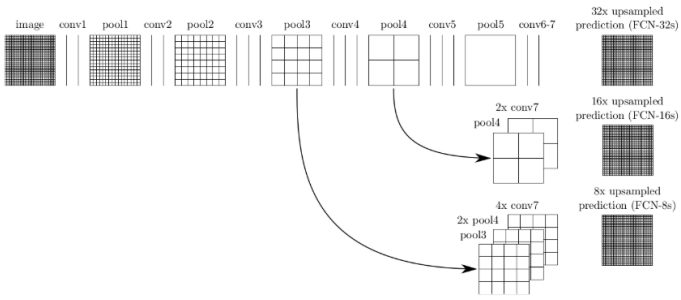

Fig. 4. Different Models

The mentioned FCN models (FCN 8, FCN 16 and FCN 32) differ from each other in the last convolution layer and skip connection. And another main difference between them is that all three mentioned models are using the same downsampling path, but an upsampling path.

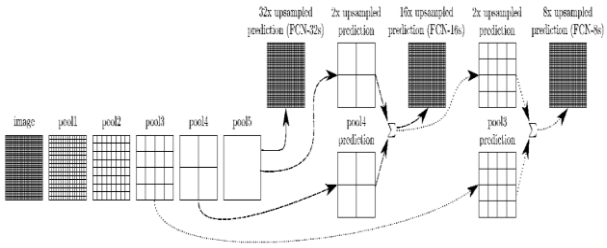

Fig. 5. FCN Models

U-Net Model

This model is built on the base of FCN (Fully Convolutional Network) and then customized which gives better result if used on the medical field and imagining. If we compare this to FCN 8, the main differences between these two models are:

(U-Net is symmetric) and (The skip between upsampling and downsampling uses concatenation instead of a sum operator). The skip connection provides information taken from local to the global during the upsampling stage, and because of it is symmetry characteristics it has a significant number of feature maps in the upsampling stage which enables to transfer information. They named U-Net because of its the symmetric shape which makes it different from other models of FCN Network. The interior architecture of U-Net is separated into three parts.

- Downsampling
- Bottleneck
- Upsampling

Downsampling Section

The downsampling stage is consist of 4 subsections, each section is consisting of

- 3x3 Convolution Layer + activation function
- 3x3 Convolution Layer + Activation Function
- 2x2 Pooling (Max Pooling)

First two layers contain Batch normalization too.

At each pooling block, feature maps double for example if it starts from 64, it will get to 128 at the second and so on. The task of the contracting is to retrieve the context of the input data to do the segmentation job and the result will be transferred to upsampling layer.

Bottleneck Stage

This section locates between the downsampling and upsampling which is built from 2 simple convolutional layers along with batch normalization followed by dropout.

Upsampling Stage

This stage contains the same number of blocks as downsampling, which is 4:

- Deconvolution layer
- Concatenation which contains the cropped feature mask from the downsampling stage
- 3x3 convolution layer + activation function
- 3x3 convolution layer + activation function

Keras

Keras is open source built for neural network library based on Python programming language, which runs by the help of TensorFlow and other technologies like Cognitive Toolkit (Microsoft), Theano. The primary purpose for building the Keras was to enable researchers who work in the field of AI especially Neural Network (Deep Learning) to do very fast experimentation. It helps researchers with the user-friendly environment and modular, the researchers in ONEIROS made some great efforts in building and developing this good platform, Francois Chollet (who is an engineer in Google) is the primary and author of this platform.

This model contains few functionalities which are most commonly used by neural network researchers in the field of deep neural network and can be used for neural network building blocks, optimizers and few useful data toolboxes to make dealing with images and text data a lot easier. The main code used for developing this platform is being hosted in Github and has lots of community support in different forums. Besides supporting the standard neural network, keras support convolutional and RCN (Recurrent Neural Network) as well, along with these it supports other utilities like batch normalization and pooling. The incredible feature of Keras is that let users implement deep models on Smartphones as well (iOS on iPhone and Android), web-based or on JVM.

Basic Approach

The first model which was developed as a single layer consists of 4 layers, with the primary purpose to understand

and implement a neural network model. Then this model firstly used on a small set of data set which mostly included roads and highways and then trained the model on a data set which had over 5000 labelled and ready for training purpose. It is usual to make the number of produced feature map available in each layer as we progress more and more. Our network model is consisting of four convolutional layers with 32 and 64 feature map each, which followed by 0.5 dropouts. The ReLU activation is also used in all function to the wanted probability heat map. All the pooling filter follow a simple 3x3 structure at each layer.

IV. RESULTS

The input data of our model has 712287 pixels in total, from the total number of available pixels about 28.79% are pointed as background and 71.21% segmented as our target points (Buildings, Roads, Water and Corps). Obtained performance parameters are shown in the following table-

Precision	Recall	FPR (False Positive)	TPR (True Positive)	IOU	F1
0.911	0.68	0.16	0.68	0.644	0.778

V. CONCLUSION

Deep Neural Network is studied to find out latest inventions and implodents in the field and possibility to help us out in this work. Segmentation and Semantic Segmentation is studied along with latest literatures to find our improvements in the field. Data sets available for this purpose has been studied and analyzed, and being tried to find the best data set which is suitable for this work and Then by using FCN as main architecture, U Net as pre trained model and python programming language is used to implement the work researched on. At the end in Results, all the output and result of the works have been shown along with training data set.

***Abstract*— The research of robotics needs a good and accurate control. The proposed concept is touch less and non-verbal communication with the use of Leap Motion Controller. The concept has two major parts : first one is "device perceive hand finger moments and send signal", Second one is Robotic hand interfaced with PIC microcontroller which receives signal and controls robotic hand. The paper aims to link virtual environment with real time environment. Here virtual environment consist of leap motion controller and laptop, real time environment consist robotic hand. In real time environment parodist is converts into virtual environment.**

Keywords— ***Leap Motion Controller, Zigbee, Pic16f877a and Robotic Arm.***

I. INTRODUCTION

The development of Advanced Gesture recognition sensors habitually used in robotic hand control. In wide and variety of areas Robotics substitutes human work [1].

Leap motion controller creates virtual screen to visualize hand gesture information and the same information send to robotic hand through wireless device support [2].

For hand gesture recognition many sensors used like MEMS accelerometer, EMG, Gyroscope, flex sensor, pressure sensor…etc [3]

LMC used to achieve hand of human intension by interaction of Robotics. Leap motion controlled good to recognize the intension of human by gesture of human hand and fingers [4].

LMC supports to complete virtual task like virtual game, virtual selection, virtual control, and all virtual environment based applications [5].

Gesture recognition of LMC used to control vehicles, Robotics, drones with the decision of human . at some kind of hazardous situation human brain takes the good decision [7].

LMC creates virtual reality environment for virtual game, virtual pen, virtual instruments performs simulated operations [8]. In this, leap motion controlled can be used like mouse, and joystick. By using LMC gesture recognition, user can interact with virtual reality (VR) environment. This method is a touch less interaction to communicate Robotics [11] [12].

II. RELATED WORK

Leap motion controller finds the touch less Human computer interface. LMC creates virtual environment in computer for various task handling on virtual environment. Interaction of objects By using LMC is an unique way of hand gesture recognition.

It supports various compilers and IDEs such as Visual Studio, Xcode3.0+, Mono version 2.10, Unity Pro and personal version 5.0, java versions 6and 7, python version 2.7.3, and UnrealEngine 4.9. All header files and library files, DLL files provided by leap SDK required to develop leap motion controller enabled application.

Hand gesture recognition is done by LMC on both hands dynamicaly and simultaniously. It can be used in virtual game, virtual air brush, virtual desktop application, virtual mouse and keyboard.

LMC consist of three IR(Infra Red) LEDs and two IR camera which visualize the skeletal point in computer similar to human finger moments. It uses specialized software to visualize skeletal point of finger. Many devices are used for motion capture but leap motion controller has built-in IR sensor to detect human hand and two cameras to capture the gesture of human hand which processed by software.

Distance between the above the Leap Motion Controller and Human hand should be approximately 20 centimeters.

Distance between around the Leap Motion Controller and Human hand should be approximately 45 centimete [6].

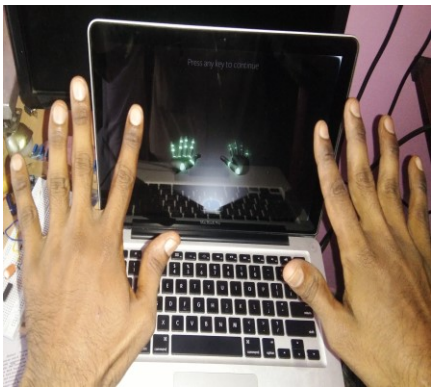

Fig. 1. Leap Motion Controller interface with virtual environment

III. PROPOSED WORK

The main motivation of this paper to is convert virtual hand into real time Robotic hand. LMC generates 3D skeleton image while the information of that virtual image is sent to robotic hand. The following three steps operates Real-Virtual-Robotic hand [9].

1. **Real hand -** Camera of LMC captures the real hand and finger gesture fed into the laptop/PC.
2. **Virtual hand** - Laptop/ PC visualize 3D image(Virtual Hand) and its related information send via wireless.
3. **Robotic hand -** Information of 3D image receive by robotic hand and behave like real and virtual hand.

The proposed design is to convert the HCI (Human Computer Interface) into HCRI (Human Computer Robotic Interface)

A. Schematic of LMC

Fig. 2 shows schematic diagram of leap motion controller. Gesture recognition using leap motion controller provide virtual and robotic hand grip. Each IR Camera is placed between IR LEDs [10].

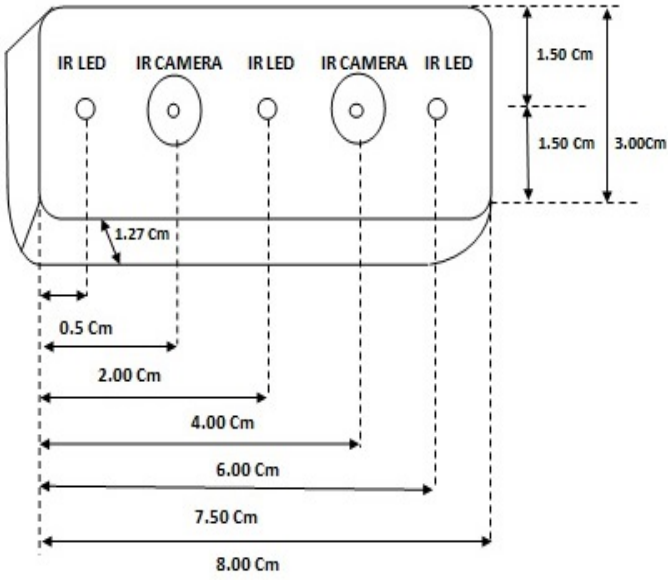

Fig. 2. Schematic of LMC

In Fig. 2 Camera and IR LEDs are placed in unit of Centimeter(Cm). Form the left side of schematic first IR led is placed at a distance of 0.5Cms, first Camera is placed at a distance of 2Cm, second IR led is placed at a distance of 4Cms, second Camera is placed at a distance of 6Cms, third IR led is placed at a distance of 7.50Cms.

Total length, width, and height of Leap Motion Controller is 8Cm, 3Cm and 1.27Cm respectively. The wave length of IR LEDs are 850 nanometers.

B. Software for leap motion controller

Special software program required to use leap motion controller for tracking human hand. Leap motion controller SDK(software development kit) is written in C++, Java, Java Script, Objective C, C#, Python. It support Windows, Linux & MAC operating system. The advantage of this is to make any software program to track human hand. Since for tracking of human hand can make own software.

C. Robotic Hand Design

This Robotic hand has palm and five fingers such as human and it is interfaced with servo motor to control. In this the structure of hand is nearly the same as human hand.

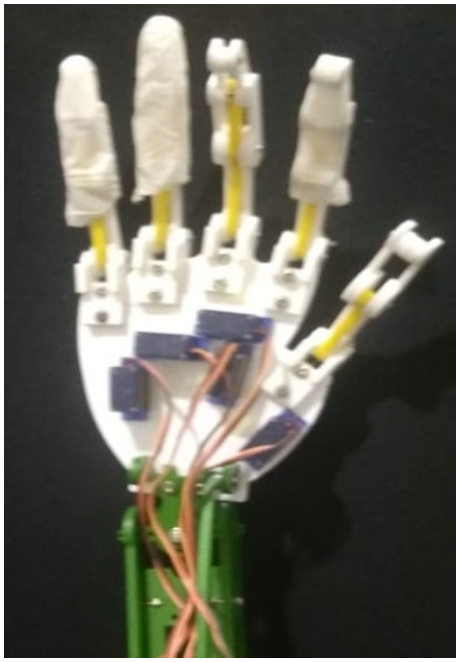

Fig. 3. Robotic Hand Internal View

Fig. 3 shows the internal view of robotic hand with five servo motors to control the five fingers. Each finger has separate control by servo motor [4].

D. Hand Skeletal

Fig. 4 shows the skeletal view of hand fingers. The distal phalanges , intermediate phalanges, proximal phalanges, metacarpals and carpals forms finger of human hand.

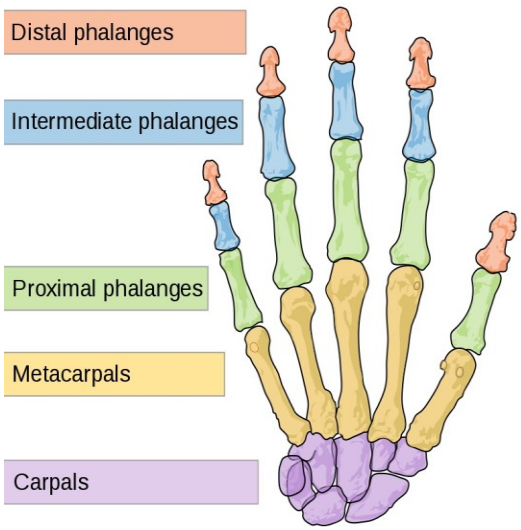

Fig. 4. Skeletal View Of Hand fingers

Fig. 4 Leap motion controller takes standard skeletal model for tracking human hand. Two row of four carpal bones(8 bones) forms wrist of the hand . The area between carpals and distal phalanges called hand. Metacarpals (5 bones), phalanges (14 bones) totally 27 distinct bones forms human hand.

E. Convert Human Hand Gesture into Virtual hand

Gesture of human hand is an input of this leap motion controller. IR sensor built in leap motion controller detects human hand motion and the two cameras built in leap motion controller capture the gesture of hand detected by IR sensors .

Hand gesture of LMC fed to the computer via USB communication port[13]. SDK present on the computer to manipulate the data of hand gesture for virtual simulation by visual C++ language and simulate the hand gesture in virtual environment. This virtual hand information from the computer transfer to robot hand via zigbee wireless device [7].

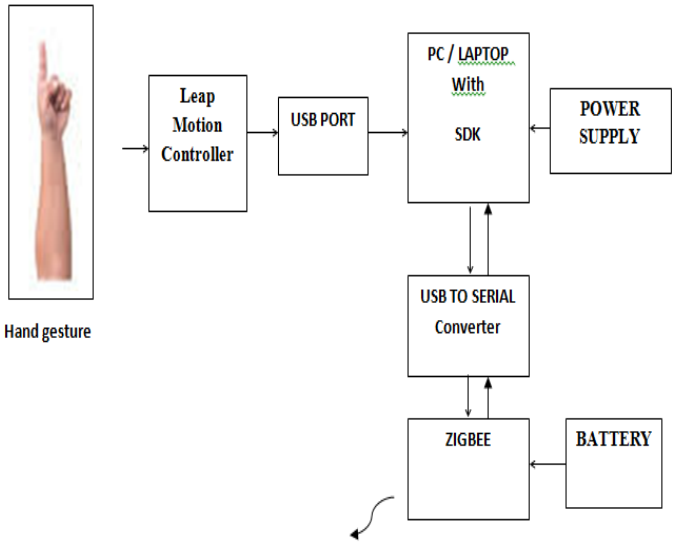

Fig. 5. Hand Tracking Using Leap Motion Controller

Fig. 5 shows the connection of Leap motion controller connected via USB communication port and the wireless device (zigbee) connected via USB communication port with the help of RS232 to USB converter cable which transfers hand gesture information. It operates with a speed of 9600 baud rate.

F. Image acquired by the LMC

Leap motion controller acquires image by camera in the structure of inverted pyramid shape [14]. The frame rate of leap motion controller is 120 frames per second. It has a field view of 135º.

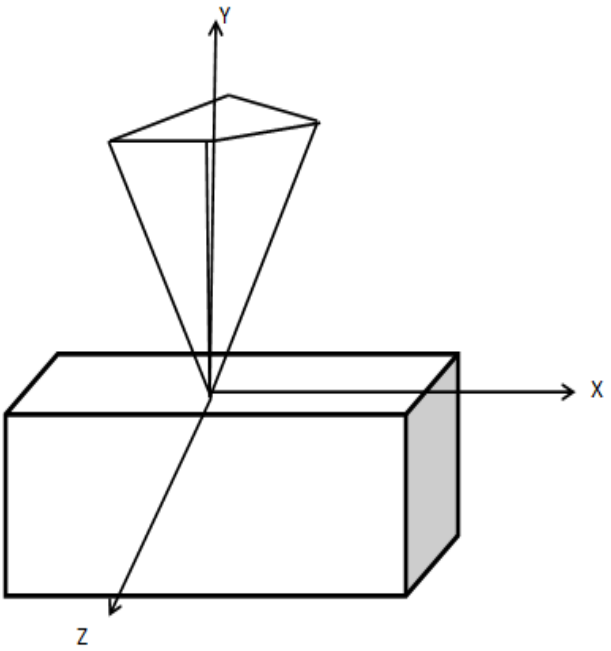

Fig. 6. LMC and Coordinates

Fig. 6 Leap motion controller gets images in inverted pyramid shape and its coordinate value of LMC consist of LMC_X, LMC_Y, LMC_Z in equation is denoted by R.

$$R = \begin{pmatrix} LMC_X \\ LMC_Y \\ LMC_Z \end{pmatrix} \quad \text{----------} (1)$$

$$R' = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} LMC_X \\ LMC_Y \\ LMC_Z \end{pmatrix} + \begin{pmatrix} dx \\ dy \\ dz \end{pmatrix} = \begin{pmatrix} LMC_X + dx \\ -LMC_Z + dz \\ LMC_Y + dy \end{pmatrix} \quad \text{-------} (2)$$

Where dx, dy, and dz are the constants of the distance between origin of the coordinate system of LMC.

G. Convert Virtual hand into Robotic Hand

Virtual hand information is received from remote computer by zigbee transceiver interfaced with pic16f877a microcontroller through UART communication with the speed of 9600 baud rate. It has the same speed as transmitter zigbee connected in computer for real hand tracking.

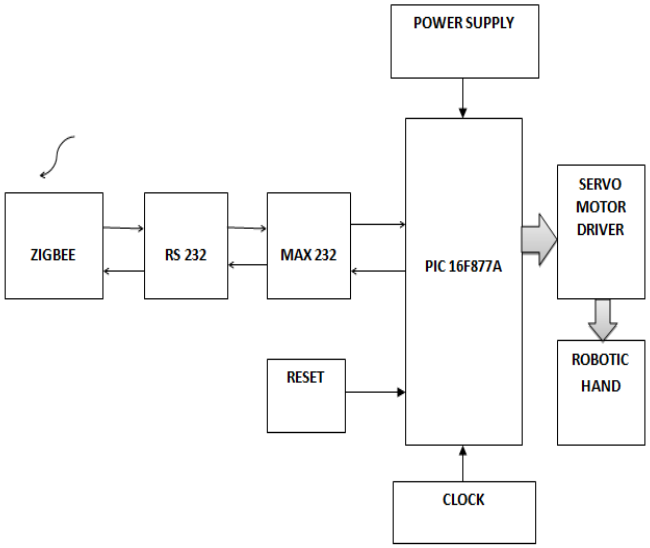

Fig. 7. Robotic Arm Control by LMC

Fig. 7 shows Robotic Arm connected with pic16f877a microcontroller. The robotic Arm receive the commands from real hand via Zigbee wireless communication. This Robotic Arm uses SG 90 servo motor to control fingers of Robotic Arm. Each finger in Robotic Arm has separate SG 90 servo motor our five fingered structure has five SG 90 servo motors.

IV. DATA SET

The Table 1 shows gesture image information analyzed by the Leap Motion SDK. Gesture image information is coded as text for wireless communication to transfer data to the robotic Arm.

Hand Gesture	Code
Swipe	'A'
Grab	'B'
Pinch	'C'
Close	'D'
Release	'E'

Table 1. Gesture Code

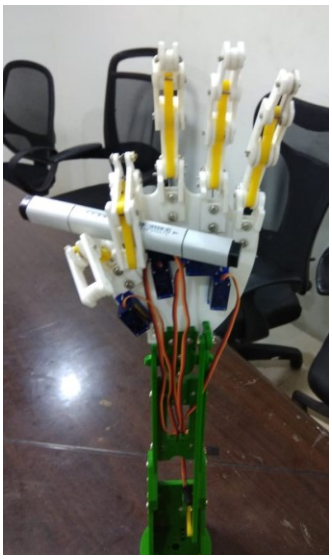
Hand gesture recognized by the leap motion controller is coded in Table 1. This text code is sent through zigbee wireless communication.

V. RESULT ANALYSIS

Robotic hand mimics similar to the hand of human controlled from remote area. Fig. 8 shows comparison of Human hand , Virtual hand and Robotic hand.

(a) Real Hand

(b) Virtual Hand



(c) Robotic Hand

Fig. 8. Comparison of hand gesture (a).human hand , (b)Virtual hand and (c) Robotic hand.

Fig. 8(a) shows human hand in front of leap motion controller, Fig. 8(b) shows virtual hand in PC/ Laptop and the Fig. 8(c) shows Robotic hand performs as per human activities. Fig. 9 shows different gesture result of Robotic hand.

The hand gesture method recognized by Leap Motion Controller which transfers the same information to virtual environment of PC/Laptop while same information is transferred to robotic hand through wireless communication [15].

Fig. 9. Gesture Result

Table 2. gives the accuracy of experimental prototype tested under various hand gestures from 4 different person with performance of Swipe, Grab, Pinch, Close, and Release gesture of the hand.

Gesture	Test	Accuracy
Swipe	4 Times	80%
Grab	4 Times	98%
Pinch	4 Times	65%
Close	4 Times	98%
Release	4 Times	98%

Table 2. Gesture Test

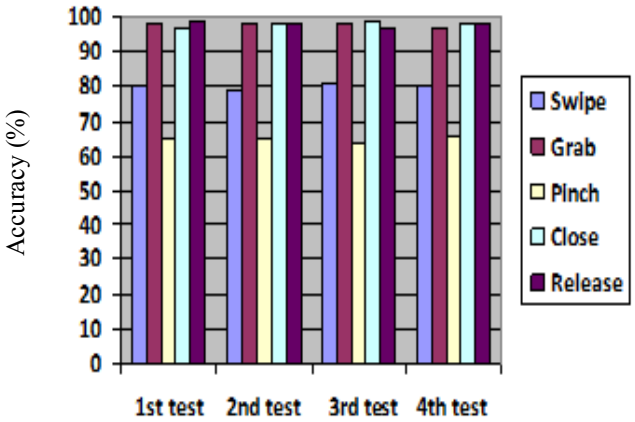


Fig. 10. Gesture Test Under Different Person

Fig. 10. Shows the bar chart of the accuracy obtained under different test conditions.

VI. CONCLUSION

In this research work, hand gesture and its interaction are used to control robotic arm. LMC observes hand and finger gestures. It displays a three dimensional image of hand and mimics Robotic hand like human hand activities. The proposed concept of linked virtual environment with real time environment is found to perform better.

This Robotic hand can perform operations in space research center , satellite, drone control, and places beyond human reach.

VII. FUTURE SCOPE

In future , latency of leap motion controller can be reduced by the new version of SDK.. Speed of wireless communication might be improved by the new types of wireless communication. The proposed concept can be implemented in tele operated Robotic application.

VIII. ACKNOWLEDGEMENT

Author would like to thank SusiRam Educational and Social Service Trust for the financial support and encouragement of this research.

Wireless IoT based Solution for Women Safety in Rural Areas

Rahul Paknikar, Shrey Shah, Dr. Prachi Gharpure
Department of Computer Engineering
Sardar Patel Institute of Technology
Mumbai, India
{rahul.paknikar, shrey.shah, prachi_gharpure}@spit.ac.in

***Abstract*—In today's era, women still feel scared to step out of their homes at late nights due to the fear of sexual harassment. This problem is compounded when one shifts the focus from urban to rural sector and interior areas of villages where there is erratic electric supply and poor cellular network connectivity. There are many smartphone based solutions, but the availability of smartphone and cellular network in rural areas is unreliable. This paper proposes a system, by creating a wireless network using IoT technology with a portable device for alerting the concerned authorities to prevent any mishap. Women will be provided with a beacon device consisting of a help button. In case of any emergency, the beacon information will reach the central stations and an alarm will be triggered at the prominent places of the village. One can find out the location of the victim based on her proximity to the nearest access point.**

***Index Terms*—Bluetooth Low Energy, Global Positioning System, Beacon device, Internet of Things, Solar Panels, Access Point, Central Station**

I. Introduction

Even though we live in the 21st century with much technological advancement and social awareness, women face the problem of harassment of any form and get abused physically or mentally. Areas like streets and public spaces have been the territory of such violence. This issue worsens for women living in remote and rural areas, where they might not be aware about these crimes or hesitate to report these crimes to the concerned authorities. There are many existing applications and devices for women security through smartphones. Though the smartphones have increased rapidly, it is not possible that the smartphones and cellular network will be available all the times in rural areas. Also, many people in the village do not have smartphones which can assist them in contacting the concerned authorities, otherwise. Literacy rate of villages is low and parents do not send girls to schools due to the fear of sexual harassment.

The proposed system for women safety is based on BLE (Bluetooth Low Energy) Beacon device due to their low cost, ease of deployment, ease of accessibility to the users and superior interior localization as described in [2], [3]. Kang Eun Jeon, James She, Perm Soonsawad, and Pai Chet Ng [2] specify that BLE has low energy requirements and battery life of BLE Beacon devices can be extended upto 2-3 years on a single coin cell battery if broadcast intervals are set appropriately based on the application. BLE is 60 - 80% cheaper than traditional Bluetooth and is compatible with a wide range of IoT (Internet of Things) boards, mobile phones, tablets and computers. It is ideal for the proposed system which requires small periodic broadcast of data at regular interval of 1 - 1.5 seconds.

The paper has been organized as follows - Section II describes the existing women safety systems and their demerits. An insight into the system that we proposed in Section III includes the overview of system, mathematical model, various components and the working model. The implementation of the system is described in Section IV which consists of a simulation experiment. Section V provides the results of the simulation and its analysis. Lastly, Section VI includes the conclusion and further improvements possible to the system.

II. Related Work

Majority of the approaches for providing women safety concentrate on urban areas where it becomes possible to provide immediate help for women in distress. Additionally, these systems [4], [5], [6] use smartphone and GPS (Global Positioning System) technologies which are difficult to support in undeveloped rural areas.

Implementation of Women Safety based on IoT approach by D. G. Monisha, M. Monisha, G. Pavithra and R. Subhashini [5] involves ARM Controller along with a smartphone, synchronized using Bluetooth to call the preset contacts and record audio for further investigation. It also include components like GPS Module, audio and video recorder in hardware based solution. However, using these components make the device bulky and not feasible to carry it all the time. A reliable GSM network is also required for the smartphone to alert the preset contacts. Noise can be present in the audio recording which can be misinterpreted, making it unreliable.

Another solution by G C Harikiran, Karthik Menasinkai, Suhas Shirol [6] comprises of a wearable Smart Band which continuously communicates with smartphone that has access to the GPS and Internet. The Smart Band sends emergency signal to the smartphone through Bluetooth 4.0 BLE which uses GSM messages and Internet to post on social platform provided by the mobile application. However, many remote areas in the country are difficult to be connected using Internet facilities due to latent requirements and location concerns. Also in distributed housing layout of rural areas, the cost of

providing Internet connectivity is not viable as the subscription fee will exceed the affordability of villagers and it is not feasible to provide reduced subscription rates.

The implementation proposed by Ms. Deepali M. Bhavale, Ms. Priyanka S. Bhawale, Ms. Tejal Sasane, Mr. Atul S. Bhawale [4] provides a unified approach by designing a safety kit for women using Arduino. It consists of a handheld device for alerting and GPS component for tracking the location of victim. But GPS depends heavily on cellular network. Also it is power exhaustive and does not support indoor localization due to its inability to penetrate through the solid rock structures.

III. Proposed System

A. Methodology

Multiple solar powered street light poles are arranged in an optimized formation of triangular geometry such that each pole is within the range of its adjacent poles on either side of it. IoT boards [1] will be positioned on these street poles and will be powered using the solar energy taking into account the unpredictable electricity supply to the rural areas. It will act as an Access Point (AP) of the local wireless network through which the communication between a Beacon device and an AP will occur.

Women will be provided with the Beacon device which will consist of a help button. Based on Beacon device's UUID (Universally Unique Identifier), the user will be identified uniquely and the Transmission (Tx) Power parameter will enable us to estimate the location of the victim. The AP which sense the maximum Tx Power from the Beacon device will give us the accurate location of the victim.

For this, the street poles will be identified by a unique identifier and its pre-defined GPS coordinates in the village area. Beacon communication consists primarily of advertisement broadcast at a regular interval by Beacon device via radio waves. The communication between a Beacon device and an AP, between any two APs and between an AP and a server at central station is governed by BLE Multi-Hop routing protocol [7].

Features of the System:

- Independent of Electricity: Rural areas face the problem of frequent power cuts. To power the APs, our system makes use of solar panels mounted on the street poles. This provides dual benefit by providing power supply to both the AP and street poles. So the system will continue to function even in the absence of electricity.
- Independent of real-time GPS: For accurate tracking of the victim's location, we store pre-defined GPS coordinates of street poles in a database. Also, an offline map of the entire village is stored at the central station to accurately track these GPS coordinates on the map along with the landmark.
- Tracking victim using preset GPS coordinates of APs: Once the victim triggers the help button on the Beacon device, the message is broadcasted and routed to the central station. Based on the information stored in the central station, the concerned authorities can be sure of the victim's location based on the pre-stored latitudinal and longitudinal details of APs.
- Independent of Smartphones and GSM system: The system takes care of Internet issues based on GSM network and smartphones which are not available all the time to make a call or be in range of GSM network.
- Multiple central stations: If multiple help requests are received simultaneously, a single station will not be able to handle and process all the load efficiently. Hence, we introduced multiple stations so that help requests can be routed to the stations and alarm be triggered. This also solves the issue of single point of failure of a station.

B. Mathematical Model

The arrangement of street poles on roads or highway follow 4-in-a-rectangle placement as seen in Fig. 1 indicating that 2 poles face each other in exact opposite direction. To provide adequate visibility for the same area, we optimize the number of poles by placing them in a 3-in-a-triangle placement with each pole placed at the vertex of a triangle as seen in Fig 2. This optimizes the number of APs which need to be mounted on these street poles. Further, we place the poles at some viable distance in the transmission range of APs.

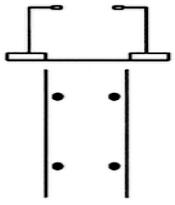

Fig. 1: Rectangular arrangement of poles

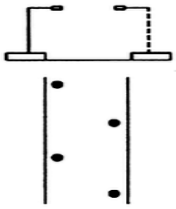

Fig. 2: Triangular arrangement of poles

The maximum transmission range of BLE Protocol is 100 meters. Taking into consideration the attenuation in signals that is caused normally due to interference or fading phenomenon, we restrict the maximum range of transmission to 80 meters. While considering the triangular arrangement, we need to take into account the blind spot, here a centroid, of triangle which is a point outside the normal range of an AP where there is unusually weak signal reception. The centroid is I as seen in Fig 3. To cover it within 3 APs, the distance of the AP to the centroid must be 80 meters which means KI is 80 meters. Based on an equilateral triangle's property, centroid bisects the median KB in the ratio 2:1. So the ratio of segment KI to IB is 2:1 and hence the distance IB is 40 meters. The height $KB = (KI + IB)$ turns out to be 80 + 40 = 120 meters.

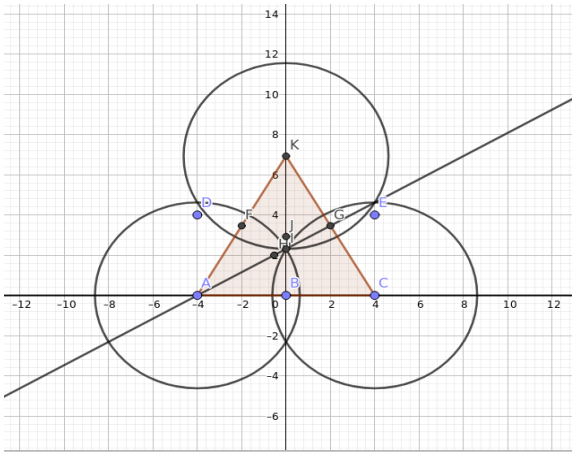

Fig. 3: Calculation of distance between 2 APs

Consider $\triangle KAB$.
Let the distances *AB, BC, CG, KG, FK* and *AF* be *r* meters.
$\implies$ The distance *AK* will be *2r* meters.

Using Pythagoras Theorem,
$(AK)^2 = (KB)^2 + (BA)^2$
$\therefore (2r)^2 = (120)^2 + (r)^2$
$\therefore 4r^2 = 14400 + r^2$
$\therefore r^2 = 4800$
$\therefore r$ = 69.28 meters

Hence, any 2 APs can be placed within a range of 130-140 meters. Thus, an area of 10^6 square meters would require 60 APs to cover the entire region without any blind spot. We can ensure that even if any victim is present at the blind spot and the help button is pressed, the help request will be received by atleast one of the three APs.

C. Hardware Description

Our system consists of five hardware components:

- Beacon device: It is a wearable and portable device [8] which is BLE enabled via radio waves [3], for alerting the concerned authorities in the village and is associated with 4 components - UUID, Major, Minor and Tx Power to uniquely identify the user. It consists of a help button that facilitates the trigger of emergency broadcast.
- AP: We performed a comprehensive review of the IoT boards [1] such as UDOO x86, Intel Galileo, Beagle-BoneBlack, Edison Arduino Kit, Tessel 2 and Raspberry Pi Zero W. All of these boards are BLE enabled, have low energy requirements and can be interfaced with the solar panels. They provide efficient and a reliable platform for development of the IoT boards as an AP.
- Central Station: At each central station, a server is setup by a computer which can be powered by solar panels. It consists of a database that stores the unique mapping of AP identifiers and its corresponding colloquial village region naming. These identifiers and landmarks is plotted on a preset map stored in the server for faster tracking of victim's location.
- Solar Panel: These panels supply power to both street light poles as well as AP. The voltage supply and the electric current drawn from the source are specific to the IoT boards that will be used for APs.
- Buzzer: It is an emergency alarm device interfaced with the server at central station. For effective audibility, the loudness depends on the surrounding environment and the distance from the source. However, the recommended loudness [11] should be 80 - 90 decibels with a region coverage of 60 meters.

D. Working Model

Each woman is provided with a Beacon device. If any woman feels threatened by any perpetrator, she will press the help button on the Beacon device provided. Beacon device will send the information about its unique identifier encapsulated in a broadcast message to APs 1, 2, 3, 4 in its range as shown in Fig 4. Even though AP 4 is down, message will be broadcasted to it, but it will not be able to forward any message to other APs. The APs will route these broadcast messages amongst themselves until they reach the central station. Multiple routes are possible for the message transmission, which will guarantee the delivery of message even in case of losses.

As shown in Fig. 4, the possible paths are as follows:

AP 1 $\rightarrow$ *AP 3* $\rightarrow$ *AP 5* $\rightarrow$ *Central Station*
AP 1 $\rightarrow$ *AP 3* $\rightarrow$ *AP 5* $\rightarrow$ *AP 6* $\rightarrow$ *Central Station*
AP 3 $\rightarrow$ *AP 5* $\rightarrow$ *Central Station*
AP 3 $\rightarrow$ *AP 5* $\rightarrow$ *AP 6* $\rightarrow$ *Central Station*

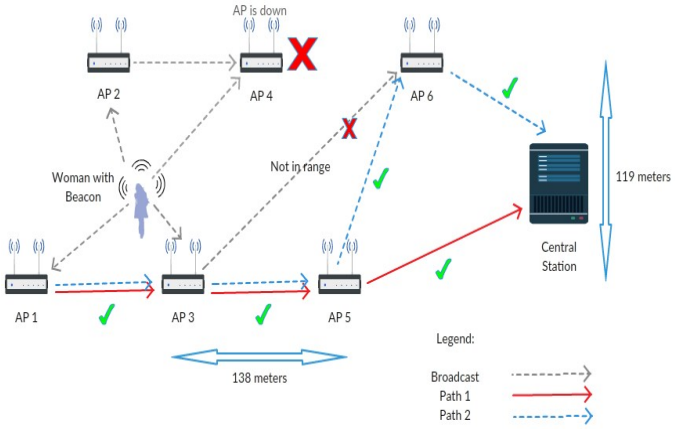

Fig. 4: Working Model of Proposed System

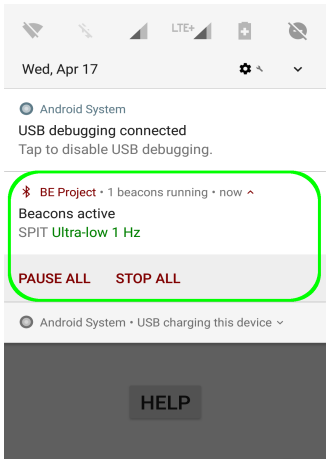
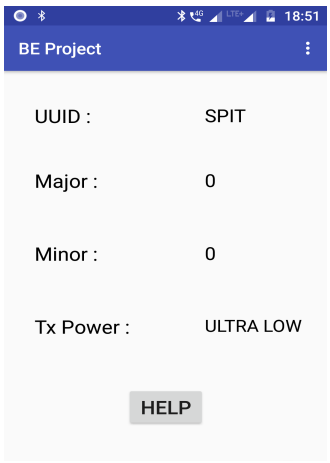
All these paths will route the message to the central station. As soon as the first message reaches the central station, the alarm will be triggered.

IV. Implementation

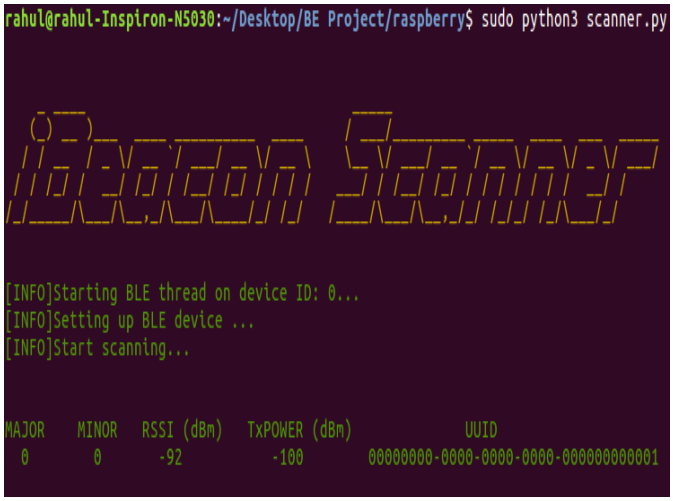
The proposed system consists of 2 aspects of implementation which are as follows:



(a) Beacon Configuration



(b) Interface at Beacon device (send regular broadcast)

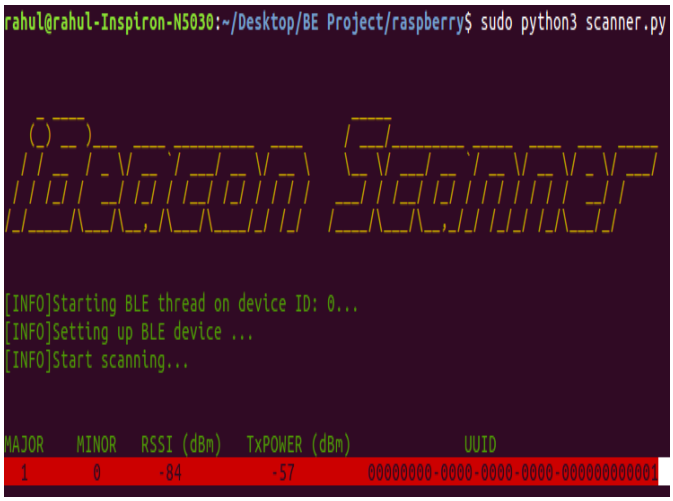


(c) Interface at AP - captured regular broadcast

Fig. 5: Regular Broadcast

(a) Beacon Configuration

(b) Interface at Beacon device (send emergency broadcast)



(c) Interface at AP - captured emergency broadcast

Fig. 6: Emergency Broadcast

A. *Beacon Device - AP Communication*

Communication between a Beacon device and an AP was tested by simulating the Beacon device as an Android Application and an AP device with Raspberry Pi Zero W, a single-board computer. The broadcast messages by an AP from the Beacon device is captured with the help of modules specified in [14].

Fig. 5 depicts a simulation of Beacon device, that the user will carry, for a regular use-case. Fig. 5(a) is a screenshot that shows the specification of Beacon device when it is broadcasting BLE packets at Ultra-low frequency as supported by the Android architecture. These packets are regular/normal broadcast packets that contain 4 parameters in its header frame as shown in Fig. 5(b) screenshot. The UUID name ”SPIT” is set at application layer, but at physical layer this parameter will be converted into 16 byte UUID along with Major as 0, Minor as 0 and Tx Power as integer indicating the advertisement mode. Fig. 5(c) is a screenshot that shows the regular broadcast packet captured by an AP device in the range of BLE Beacon device. Since the frequency is Ultra-low, the RSSI (Received Signal Strength Indicator) value and Tx Power are too low for any AP to capture these packets from farther distances and the calculated distance [13] gets restricted to a certain broadcast range. Thus, these packets may not even reach the AP and hence get filtered out. This benefits the system as such packets are regular broadcasts and not emergency broadcast; thus saving energy, increasing lifetime of Beacon devices, reducing load and traffic on APs.

Fig. 6 depicts a scenario for an emergency broadcast by the Beacon device that is triggered by the user. Fig. 6(a) is a screenshot that shows the specification of Beacon device when it is broadcasting an emergency BLE packet at High frequency as supported by the Android architecture. When user clicks

on help button, the Beacon device increases its frequency to transmit the emergency broadcast to a larger distance.

To differentiate between a regular and an emergency broadcast, a flag or some metadata is required in the packet. As shown in Fig. 6(b), the parameter "Major" serves this purpose without increasing the size of the packet. Fig. 6(c) is a screenshot of the extracted information from the packet in a readable format with extra parameter of RSSI sensed by the AP. The broadcast at High frequency facilitates AP to capture the packet with accurate reading of Tx Power and RSSI value, determining the distance with high accuracy [13]. This information from the received packet will then be routed to the central station for further processing.

B. AP - AP Communication and Routing

For testing the efficiency and scalability of our proposed system, we designed a network simulation using ***ns3*** Network Simulator [9], [10] for the scenario described in Working Model.

1) Initial Configuration:

In accordance with the Mathematical model, the horizontal distances between 2 APs is set to 138 meters and vertical distance as 119 meters approximately. As seen in Fig. 7, it depicts the initial state of the system simulating a scenario of 12 APs (red) of which 2 constitute the central stations (black) at prominent places in the region, 3 beacon users (blue) distributed in an approximate area of 261.085×10^3 square meters. Communication between the APs is simulated based on the underlying Multi-Hop routing protocol [7].

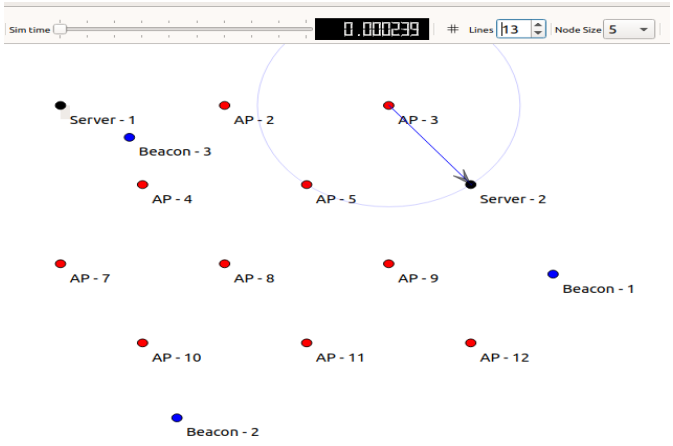


Fig. 7: Initial Configuration of Access Points and Beacons

2) Simulation of Dysfunctional AP:

If certain APs become dysfunctional the system is able to route packets to the central station. To reduce the response time for triggering the alarm, multiple stations have been incorporated so that if packets are unable to reach a particular central station, they are routed to some other central station. As shown in Fig. 8, AP-8 is labelled as 'Down' indicating that it is not in proper working condition. So packets from Beacon devices

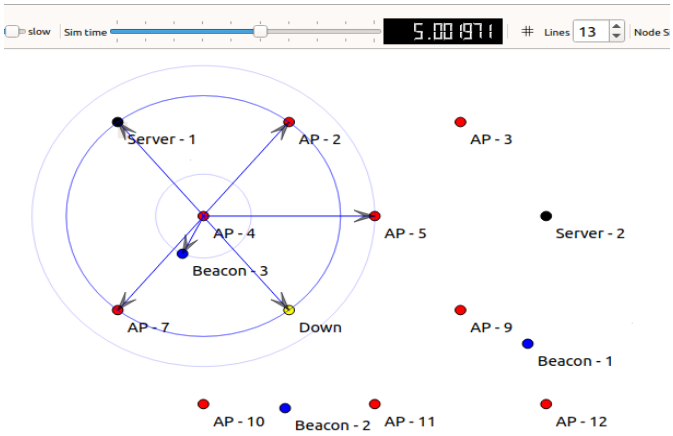

Fig. 8: Considering any random AP as dysfunctional

will be broadcasted to AP-8, but it will not be able to forward any packets.

Tx Power helps to estimate the victim location using RSSI. Fig. 9 shows each distress message packet reaching the central stations and each parameter of BLE header with its value. The message packets from all 3 Beacon devices are received indicating that system efficiently routes the packet even in case of AP failure. It also shows the warning alert - the Beacon device from which it originated and the central station where it is captured along with the time at which the message is received.

```

```

Fig. 9: Distress messages received by the Central Stations

V. Result Analysis

We tested the system for response time to trigger the alarm, scalability and efficiency of the system with the observations as shown in Table I.

Table I: Scalability of the system with increase in the APs, Users and Central Stations

Number of APs	12	50	150	450
Number of Users	3	6	15	30
Number of Central Stations	2	3	7	15
Response Time (in seconds)	0.419	1.019	2.039	4.551

As seen in Fig. 10, we infer that the response time, being a critical parameter, for triggering the alarm varies in an approximate linear fashion with respect to the number of APs, but is within the acceptable range of 0.1 - 15 seconds with the increase in number of APs as described in [12] indicating that first minute during an ongoing violence is most critical and hence the response time should be within 60 seconds. It may be due to the losses and buffer limitations that the time to hear alarm increases due to queuing and processing of packets at central station. Introduction of multiple stations is able to handle the load and packet losses by routing packets to all the stations and alarm be heard. If a station is down, still packets are broadcasted to other stations and alarm is heard. The routing algorithm is able to handle the routing of packets even if multiple Beacon devices are triggered simultaneously.

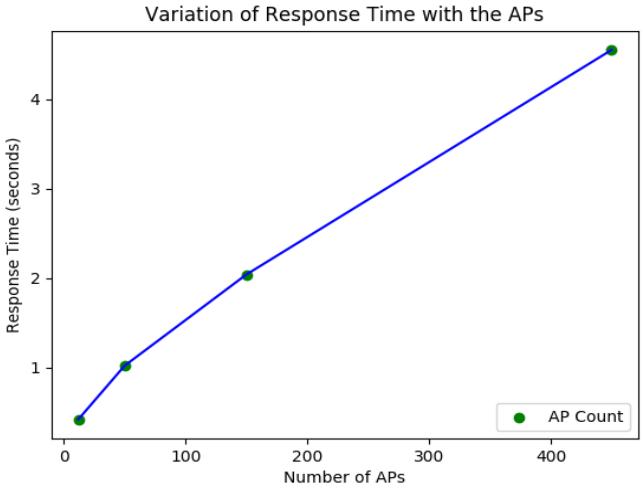

Fig. 10: Variation of Response time (seconds) with APs

VI. Conclusion and Future Scope

In this paper, we have proposed a wireless IoT based solution for women safety in rural areas by taking into account two most critical issues of erratic electricity supply and unreliable cellular network which are common in rural areas. To achieve this, solar panels on the street poles power the APs and an independent local network is created based on BLE routing protocol. Based on the Beacon signal received by an AP, location of the victim is traced out through the RSSI value and supported with a plot on preset map of the village. We introduced multiple central stations so that even if a station fails, the distress message can reach other stations to prevent any mishap.

As for future work to be done, the proposed system can be integrated with Machine Learning to identify most vulnerable and unsafe regions in the village. Thus, security in such regions can be increased by making the local network coverage more stringent. However, such computations need to be done when the system remains idle for long enough, without compromising the safety of women or else it can be done on remote systems. Also, APs can be combined with a surveillance system comprising of audio/video recorder or a camera to record the harassment incident as an evidence and to avoid false accusations. The proposed system can be extended to various emergency situations like fire breakdown, human accident, child abuse, robbery and senior citizen harassment.

***Abstract*- The quality of the power supply is an important concern over the years. The quality of the power can be considered with the factors like current, voltage, and power factor etc. The parameters like the stability and reliability of the power plays an important role in deciding the quality of supply. The end user always faces the economic losses if the quality of the supply is inadequate. The main cause of degradation in power supply is the harmonics. The voltage and current harmonics are the issues to be addresses to enrich the power quality. The active filters are helpful to improve the quality of power by means of mitigating the harmonics. Authors have implemented the hybrid active power filter to improve the quality of the power supply. The sliding mode of the controller is implemented to assure the better performance of the system.**

Keywords- filter, active power filter, power quality, harmonics, hybrid filters, sliding mode controller, etc.

I. INTRODUCTION

The variations in the type of loads connected, moreover the increase in the non-linear loads have caused the power quality degradation. The harmonics are inserted in the grid due to these loads. The protection devices although are smart now a days, experiences the adverse effects of the distorted power. The passive filter provides popular low cost solution over the problem. The problems with the passive filters are mistuning and dependency of impedance on the power supply. [1]

Improving the power quality is on the priority of the researchers since last two decades. The various configurations of filters are presented by the researchers. The reduction of the harmonics is effectively possible with the active power filters. The active filters become more effective with the various configurations. [2-3]

The harmonics present in the source current can be eliminated with the transformer-less hybrid filter. The system can be implemented for the single phase consumers who are really large in numbers. [4]

The harmonics injection at different consumer end or at different non-linear load is going to affect severely at common coupling point. The active filter with proper current selection method can control the impact of harmonics on the power supply. [5]

The inverters (voltage source) are very popular since last few years in micro grids. It provides the reliable conversion of the voltage. It is suitable from the point of view of improving the quality of the power supply as it is capable of handling the power and converting it to the reliable form. It helps in reducing cost also as the complete operations of power control and the conversion is done by the same circuit. [6]

The analysis shows that the power quality issues are increasing in recent years the generation of the electricity is done remotely at different places in small amount. The grid connection of such sources causes the severe effect on the power quality. The smart grid has achieved the performance enhancement to some extent while there is still a huge scope to enhance the grid performance. [7]

Medium distribution systems can work effectively with the unified power control method. The filers are added as per the need in the supply. The circuit is capable of balancing the power. [8]

The reactive power sometimes becomes beyond control of the generalized active filters. The system becomes challenging to control such high distortion in the supply. The selective harmonic reduction becomes an effective strategy to control the power for such situations. The discrete time filtering is another approach to overcome the quality issues. These can be useful in three-phase systems. [9-10]

The non-conventional sources are becoming effective with the enhancement in the technology. When these sources are inter-connected to the grid, there are several issues with the quality of power. It results in low quality of the grid supply and consumers may also be affected. [11]

The closed loop system for the insertion of the current in order to reduce the harmonics is another approach to be used for the micro-grids. It is flexible system to control the harmonic distortion in the power supply. [12]

With enhancement in the technology and number of the energy sources, it becomes more challenging to control the power. The power is generated with different capacities, different strategies and inserted to the grid hence it is very difficult to apply a single solution to control the power. Improving the quality of the supply needs the controlling circuits to be connected at different stages.

II. IMPLEMENTED SYSTEM

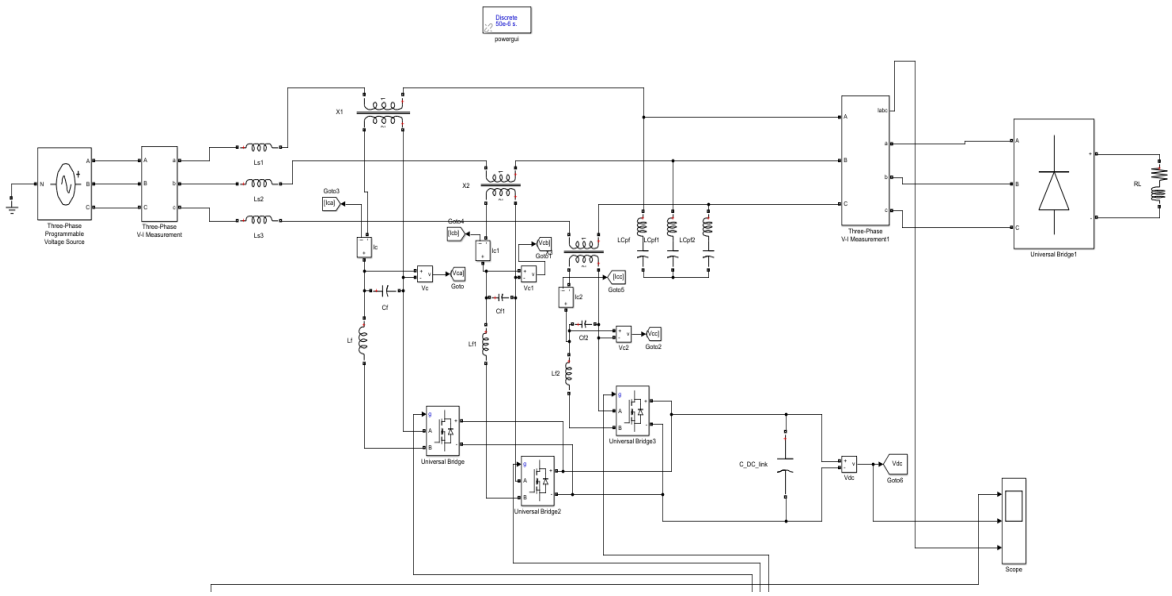

Fig.1. Implemented system for the harmonic control using hybrid active power filter

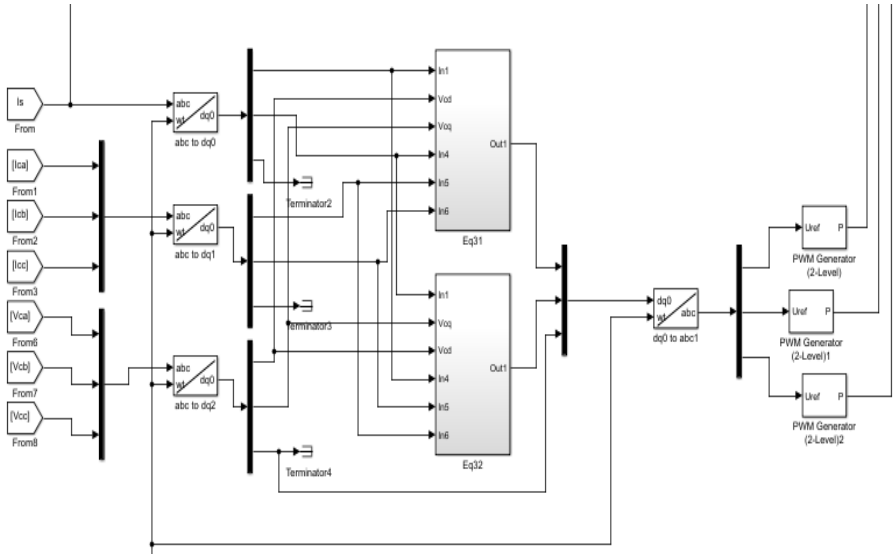

Fig.2. Implemented system –Sliding mode control circuit

Figure 1&2 shows the complete system implemented in MATLAB for controlling quality of power supply. The sliding mode helps in controlling the non-linear power. As it is a closed loop control method, it assures the auto setting of the desire parameters to be set in order to improve the power. The sliding mode control generally operates by comparing the actual quantities with the reference values.

The control scheme for the sliding mode operation is shown in the figure 2 above. The control is developed with the logic diagram controlling the various parameters for the operations. The logic is developed with reference to the following equations:

$$U_d = (\dot{V}^*_{cd} + \alpha \ddot{V}^*_{cd}) + \frac{L_f}{V_{dc}}(C_f\ \omega\ V_{cq} - i_{cd} + i_{sd}) + \frac{\alpha L_f}{V_{dc}}(-C_f\omega^2 V_{cd} - \omega i_{cq} + \omega i_{sq} - \frac{V_{cd}}{L_f} - \omega i_{cq} + i_{sd}) - K_{11}\text{sign}(S_d) - K_{12}\text{sign}(S_d)$$

----------Eq-1

$$U_q = (\dot{V}^*_{cq} + \alpha \ddot{V}^*_{cq}) + \frac{L_f}{V_{dc}}(C_f\ \omega\ V_{cd} - i_{cq} + i_{sq}) + \frac{\alpha L_f}{V_{dc}}(-C_f\omega^2 V_{cq} - \omega i_{cd} + \omega i_{sd} - \frac{V_{cq}}{L_f} - \omega i_{cd} + i_{sq}) - K_{21}\text{sign}(S_q) - K_{22}\text{sign}(S_q)$$

----------Eq-2 [1]

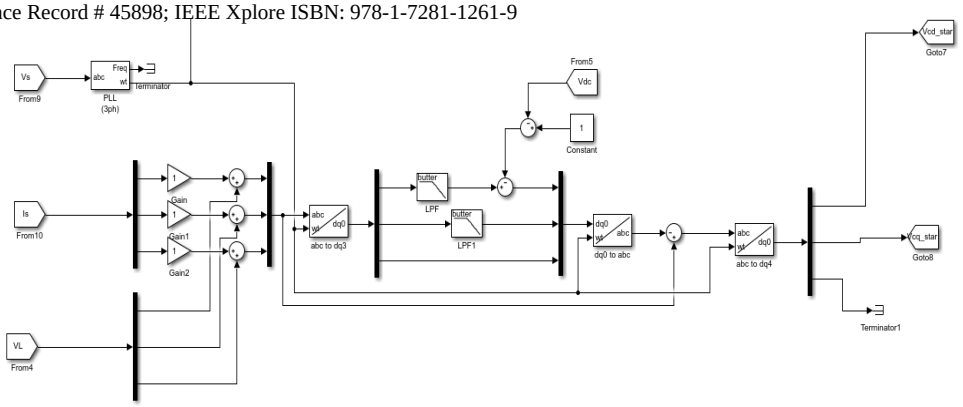

Fig.3. Reference signal generating scheme

Figure 3 shows the reference signal generating scheme. It is very important to have the reference signal in order to compare the real time quantities with the reference values. It helps in identifying the need for the control signal to be generated in order to mitigate the harmonics. The hybrid system detects the source and load parameters at a time.

III. RESULTS AND DISCUSSION

The simulation is implemented and the results are presented in this section. The non-linear load is considered for the experimentation. It leads to the harmonic distortion in supply and load side.

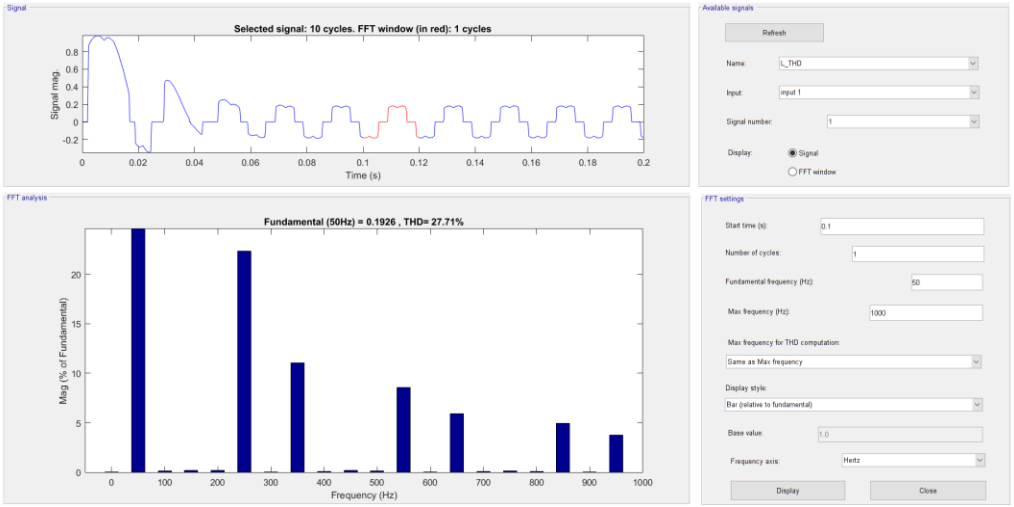

Fig.4 Total harmonic distortion of Supply side

The harmonic distortion of the supply is shown in the diagram 4. The above graph represents the harmonic distortion of the input side. When the input is provided, it is observed that the harmonic distortion of current is 27.71%. This value of the distortion is very high and if the same supply is given to the load, it again creates the problems as the performance of the system deteriorates.

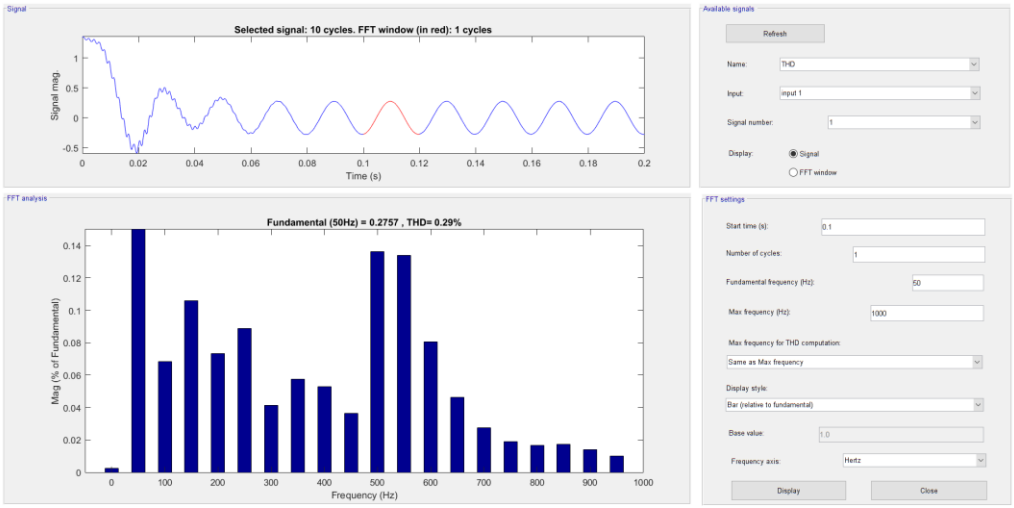

Fig.5 Total harmonic distortion on load side

The harmonic distortion of the load side is represented in the graph above. The hybrid active filter reduces the impact of harmonic distortion satisfactorily. It is observed that the total distortion is 0.29% after implementation of the scheme whereas on load side it was 27.71%. It is observed that distortion is compensated by the implemented hybrid filter scheme.

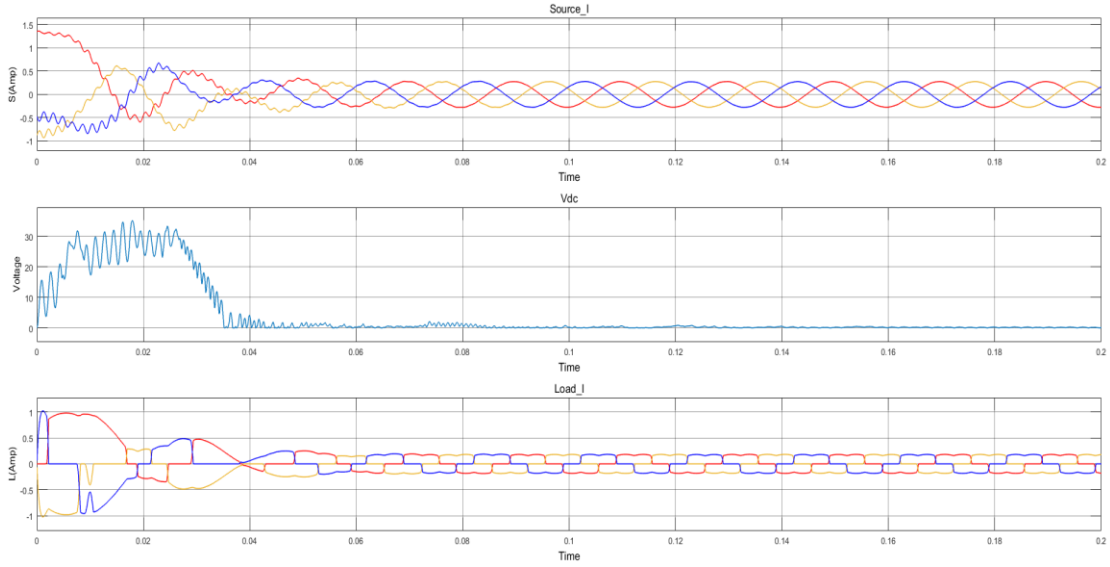

Fig.6. Source current, inverter voltage and load current of the implemented system

The results of the implemented scheme are shown in the waveforms above. It is observed from the above waveforms that, the distortion is reduced in output voltage and current as compared to the input current.

IV. CONCLUSION

The harmonics in the power supply are the severe cause of deterioration of the power quality. As the number of the sources increased and the nature of load is also changed over the years, the harmonic distortion becomes a serious issue to be addressed. Over the wide range of the filters available, it was challenging to select the proper filter to be implemented. The active hybrid filter with sliding mode control is implemented and presented in this paper. Authors have implemented the hybrid active filter scheme for the unbalanced load condition. Authors have achieved the reduction in harmonic distortion from 27.71% to 0.29% from supply to load side. The results achieved in MATLAB are satisfactory. The scheme presented in this paper, is useful for the micro-grid.

***Abstract*—Recently, Convolutional Neural Networks(CNNs) have been very efficient in many computer vision areas, especially in facial recognition where most CNN models showed near-perfect performance on standard benchmarks.One of the main problems faced by these CNN architectures today is that they need a large amount of processing power and memory to deliver their exceptional performance. This paper aims on comparing and contrasting these CNNs with a new advancement in deep learning called neural differential equations, where the whole architecture is thought of as a differential equation to be solved. This paper aims to show that this method can achieve comparable performance to a residual network with much less parameters. As a part of this project we will show that the models trained over the ODENet, that is neural net using the ordinary differential equations, takes very less memory and time to train when compared to that of CNNs. As to run these models on the benchmark datasets, these models have been run on the standard face datasets named Faces95 and Faces96 respectively.**

Keywords- Face Recognition, Activation Function, Minimum Barrier Detection (MBD), Ordinary Differential Equation network (ODENet), Scaled Exponential Linear Unit (SELU)

I. INTRODUCTION

Face recognition is a task of identifying or recognising a person from an image or a video frame. This involves a lot of training to be undergone for any model to do the prediction. One such methods is the Convolutional neural network(CNN). Recent advances in these networks have made the tasks of tracking[1],recognition[2] and detection[3] pretty much very easy to solve.Deep models have been so influential in this field that almost all the architectures designed have achieved the near perfect results. One of the main challenges faced by CNNs today is that the requirement of heavy processing power hinders the implementation of CNN based solutions on less powerful but ubiquitous devices like embedded systems and mobile phones without diminished performance with wellknown benchmarks[4].

To overcome the existing problem, we have chosen the unique approach from [5] where the whole network being trained is visualised as a differential equation. This neural differential equation is implemented as an ODEBlock in our paper which is a custom keras layer consisting of the differential equation along with weights and the dopri5 method for solving the differnetial equations. This method mainly takes out the very big process of deciding the architecture for training. Any architecture defined with this one block in between will try to learn with shared weights among all the layers which further form the differential equation.

The most interesting part of this network is that it supports supervised learning very effectively. As said in [5], they applied it over the task of classification of written digits by MNIST. The aim in this paper was to show that the ODESolve method written can achieve a comparable performance with the standard residual networks[6]with very less number of parameters. As a result it did perform very well and reduced the parameters from 0.6M in residual network to 0.22M in ODESolve method.Thereby reducing the processing power requirements and the time taken to train the model.

The popularly known datasets Faces95 and Faces96 were used here by pre-processing with Minimum Barrier Detection(MBD) for saliency detection. Upon this we have used the SELU activation function. The motivation behind using this was to avoid overfitting in learning due to less number of parameters being trained using the ODENetwork and the MBD for saliency detection. So as to allow for many levels of abstract representation of the output feeded as input to a neuron, SELU activation function was written, created the Self-Normalizing Neural Networks[7] via inducing the properties for self-normalisation in Feed Forward neural networks(FNNs)[8].

II. RELATED WORK

Neural Ordinary Differential Equations[5] paper introduces a new concept in deep neural network models. It uses a black-box differential equation solver to compute the output. It is a continuous-depth model as it does not use discrete hidden layers. It shows back-propagating through ODE solvers without changing its internal operations. They used this black-box ODE solver for developing new models for time-series modeling, density estimation and supervised learning. These models are evaluated based on computation speed and accuracy. They derived an instantaneous version of the change of variables formula and developed continuous time normalizing flows, which can scale to large layer sizes.

Residual Attention Network[9] is a Convolutional Neural Network with attention mechanism. It incorporates state-of-art feed-forward network architecture. Within each attention module bottom-up top-down structure is used. This architecture is tested on CIFAR-10, CIFAR-100 and ImageNet data sets. It also shows that this network architecture is not affected by noisy channels. This Residual Attention Network outperformed state-of-art image classification methods.

Face Recognition: EigenFace, Elastic Matching and Neural Nets[10] is a relative study between the three face recognition algorithms. EigenFace algorithm works well only when there is very less lighting variations. Elastic Matching algorithm is more adaptable to lighting variations, face positions and expression variations.

Convolutional Neural Networks[11] for Image Classification paper showed image classification using Convolutional Neural Networks. It used traffic signals dataset and classified it.

Face recognition/detection by probabilistic decision-based neural network[12] paper divides face recognition into three parts: Face detection, position of eyes and face recognizer.

Deep Face Recognition[13] paper does face recognition in photos with single face or with multiple faces. It uses very large data sets that are available like LFW, YTF, FaceBook, etc.

III. PROPOSED WORK

A. Overview

Every image from the dataset was pre-processed using two steps. First step was resizing the image into smaller scale, second is "Minimum Barrier Detection (MBD) Transform". MBD Transform is well known for salient object detection. After the MBD Transform is done the image is passed to the neural network with the ODEBlock and trained over the datasets.

B. Minimum Barrier Detection

The aim of salient object detection[14] is to create a prominence map which highlights the face(object) and overcomes the background[15] in the scene. This transform is being widely used in research due to its vast use in computer vision applications. This method is prominently used in mobile devices as they require high quality salient maps using lesser space and is fast in computing it. For this method we used FastMBD Transform Algorithm[16]. Let m be a pixel value in Inverse Raster Scan or Raster Scan. The following distance map can be used to minimize the cost of path m using each n in the neighbourhood of m:

$$DM(m) \leftarrow min\{DM(m), P(I(n).\langle n, m\rangle)\} \quad (1)$$

In this equation,

(1).β_P is used in Image Distance Transform, which is a cost function that is defined as:

$$\beta_P(\pi) = max_{i=0}^{k} P(\pi(i)) - min_{i=0}^{k} P(\pi(i)) \quad (2)$$

where P is the value of a Pixel.

(2).$I(n)$ denotes the assigned path to a pixel n and $\langle n, m\rangle$ is an edge joining pixel m to pixel n. Thus $I(n).\langle n, m\rangle$ is a path for m that appends edge $\langle n, m\rangle$ to $I(n)$ Therefore, the cost function becomes:

$$\beta_P(I_n(m)) = max\{H(n), P(m)\} - min\{L(n), P(m)\} \quad (3)$$

where $H(n)$ and $L(n)$ are the highest and lowest pixel values in $I(n)$ respectively. The value of H and L is updated accordingly when the path assignment changes in each iteration in the algorithm.

To perform the MBD transform following algorithm was used, it is based on [16].

Result: A list DM which is the distance map
Input: Number of Iterations : $iter$ for the Image $Img = (i, V)$;
Algo:$H, L \leftarrow Img, Img$;
set $DM(x)$ to 0 or to inf;
for *m from* 0 *to iter* **do**
  if *m is even* **then**
    InvRasterScan(Img,H,L,DM);
  else
    RasterScan(Img,H,L,DM);
  end
end

Algorithm 1: MBD transform

Result: A list DM which is the distance map
Input: Img, H, L, DM from MBD transform algorithm.; number of rows and columns are set to $rows$ and $cols$ in image Img;
for *m from* $rows - 2$ *to 1* **do**
  for *n from* $cols - 2$ *to 1* **do**
    imx,dist = Img[m][n],DM[m][n];
    high1,high2 = H[m+1][n],H[m][n+1];
    low1,low2 = L[m+1][n],L[m][n+1];
    u1 = max(high1,imx) - min(low1,imx);
    u2 = max(high2,imx) - min(low2,imx);
    if *b1<dist and b1<=b2* **then**
      DM[m][n] = u1;
      H[m][n] = max(high1,imx);
      L[m][n] = min(low1,imx);
    else
      DM[m][n] = u2;
      H[m][n] = max(high2,imx);
      L[m][n] = min(low2,imx);
    end
  end
end

Algorithm 2: Inverse Raster Scan

A sample of how salient object is detected using MBD is shown in Fig 1.

Fig. 1. An example of highlighting salient objects in an image using MBD transform.

C. ODENet

ODENet refers to Ordinary DIfferential Equation Network. In normal neural networks, the previous state vector V_n produces the new state vector V_{n+1} using the formula $V_{n+1} = F(V_n)$. Here function F is $F(x) = \sigma(\sum_i \theta_i x_i)$, where θ is a vector of parameters and σ is an activation function. Whereas in Deep Residual Learning[5], the new state vector is calculated using $V_{n+1} = F(V_n) + V_n$. Using Euler's Method in Residual Networks: Consider a constant $\triangle t \in R$, now the new state in neural network becomes,

$$V_{t+1} = F(V_t) + V_t = \frac{\triangle t}{\triangle t} F(V_t) + V_t = \triangle t G(V_t) + V_t \quad (4)$$

where $G(V_t) = \frac{F(V_t)}{\triangle t}$. If we consider every step of the neural network to be doing Euler's method, then our system can be modeled as

$$\frac{dV(t)}{dt} = G(V(t), t, \theta) \quad (5)$$

Here G is dependent on t and θ. The output of network at some time t_1 is $V(t_1)$. Hence, if we know G, we can use ODE Solvers to evaluate the neural network.

$$V(t_1) = ODE_S(V(t_0), G, t_0, t_1, \theta) \quad (6)$$

If this is substituted in Euler's Method we get something like the residual network state as above.

$$ODE_S(V(t_0), G, t_0, t_1, \theta) = V(t_0) + (t_1 - t_0) G(V(t_0), t_0, \theta) \quad (7)$$

D. Training approach used in ODENet

Train a neural network with ODEBlock as a layer with combination of few other layers, and thereby run as a normal artificial neural network.

The inputs start with preprocessed data, then it is forwarded through the neural network's layers.

In the layers, a function if applied on inputs and weights (inputs and weights are matrices) and then the activation function is applied(SELU). Further in experiment and results section, the exact parameters used will be shown.

The neural network used for ODENet is:

- 1-Conv2D,1-Activation(selu)
- 1-MaxPooling2D
- 1-Conv2D,1-Activation(selu)
- 1-MaxPooling2D
- 1-ODEBlock , 1-Flattening
- 1-DenseLayer , 1-Activation(softmax)

The exact neural network used for CNN for comaparision purpose is

- 1-Conv2D,1-BatchNormalization,1-Activation
- 1-Conv2D,1-MaxPooling2D,1-BatchNormalization,1-Activation
- 1-Conv2D,1-BatchNormalization,1-Activation
- 1-Conv2D,1-MaxPooling2D,1-BatchNormalization,1-Activation
- 1-Flatten,1-XnorDense,1-BatchNormalization,1-Activation
- 1-Dense,1-BatchNormalization

E. Activation Function - SeLU

SeLU is basically useful because it does normalization. Basically there are three types of normalization: input normalization, batch normalization and internal normalization. This function falls in the third category. This activation function needs negative and positive values for y to shift the mean.The gradients are used to adjust the variance. The formula for SeLU is

$$f(x) = \lambda \begin{cases} \alpha(e^x - 1), & for x < 0 \\ x, & for x \geq 0 \end{cases}$$

where λ = 1.05070 and α = 1.67326

This is similar to ReLU for positive values, except the λ. This is the reason for the S(caled). When λ is larger than 1, so is the gradient and the variance can be increased. Normalized outputs are very useful in stabilizing the training process. Additionally, SeLUs learn faster and better on their own compared to other activation functions, even when they are combined with batch normalization. The graph of SeLU looks like Fig. 2.

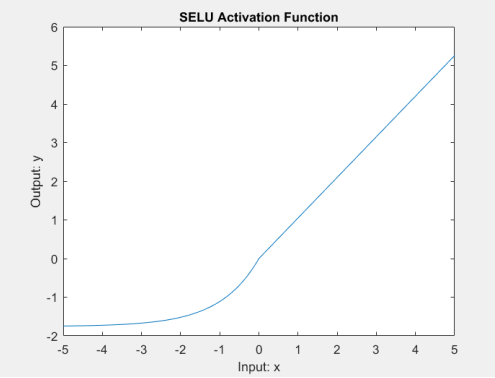

Fig. 2. Graph of SeLU activation function.

IV. EXPERIMENTAL SETUP

For the experimentation, the Faces95 and Faces96 publicly available datasets have been used to compare with current work and do further research.

A. Faces95 Dataset

The Faces95 [17] dataset contains 1440 images, 20 images each of 72 individuals both male and female. The resolution of the images is 180 by 200 pixels taken in portrait format. The subject moves towards the camera as the images are captured introducing head scale substantial variations between the images. Red curtains have been used in the background. Significant head scale variations and background changes were caused by the shadows as the subject moves towards the camera. Major changes in illumination of the face are

seen due to the use of artificial lighting. Minor variations in the facial expressions of the subject and their head tilt, slant and turn were also seen.

Fig. 3. Samples from the Faces95 dataset.

B. Faces96 Dataset

The Faces96 [18] dataset contains 3040 images, 20 images each of 152 individuals. The resolution of the images is 196 by 196 pixels taken in square format. Just like the Face95 dataset, the subject moves towards the camera as the images are captured introducing similar head scale variations in images.Glossy posters have been used for the background increasing the complexity and noise. The hairstyle and age remain same as all images were captured in a single session. Major changes consist illumination of the face are seen due to the use of artificial lighting. Minor variations have the facial expressions of the subject and their head tilt, slant and turn.

Fig. 4. Samples from the Faces96 dataset.

V. EXPERIMENT AND RESULT ANALYSIS

System description in which tests are conducted:

- CPU: Intel core i7 7th generation.
- GPU: NVIDIA GeForce 940MX.

Approach used:

- Images were pre-processed with Minimum Barrier Detection transform and then the processed image was passed as input into the neural network.
- The pre-processed dataset was then split into 80% training and 20% testing images.
- The neural network (training algorithm and architecture described in Subsection 4 of Approach Section) is then used to train upon the training data and tested with the testing data. The network was trained with SeLU for 30 epochs, with 10 as batch size for ODENet and 50 epochs with same batch size for CNN.
- The results are shown as an accuracy table in table I.
- The size consumed by models are described in table II.
- The time consumed for training by models are shown in Fig.10
- The time consumed for loading the models are described in table III.

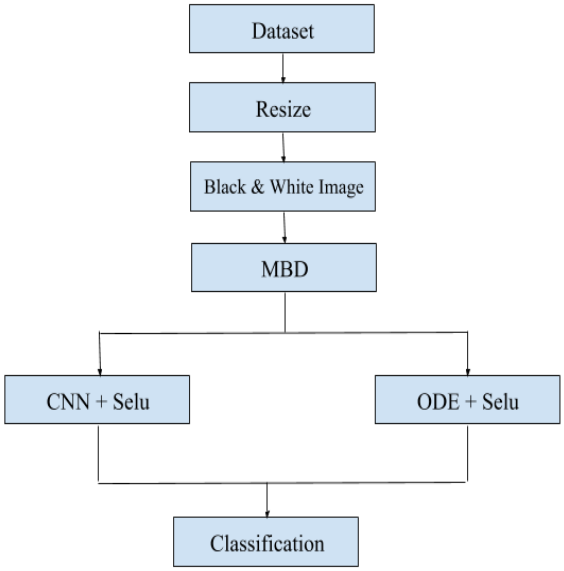

Fig. 5. Block Diagram of the experiment.

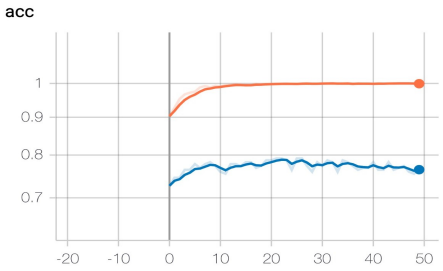

Fig. 6. Accuracy Vs Epochs for CNN over Faces95.

The accuracy for each epoch (50 epochs) for CNN over Faces95 is shown in Fig. 6.

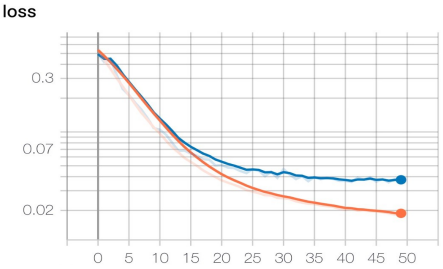

Fig. 7. Loss Vs Epochs for CNN over Faces95.

The loss for each epoch (50 epochs) for CNN over Faces95 is shown in Fig. 7. After training for 50 epochs, the loss of this model in terms or training and testing has reached very much near to zero, which says that the model has avoided overfitting.

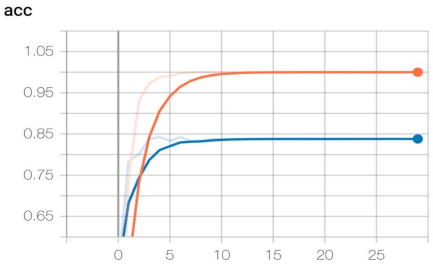

Fig. 8. Accuracy Vs Epochs for ODE over Faces95.

The accuracy for each epoch (30 epochs) for ODENet over Faces95 is shown in Fig. 8.

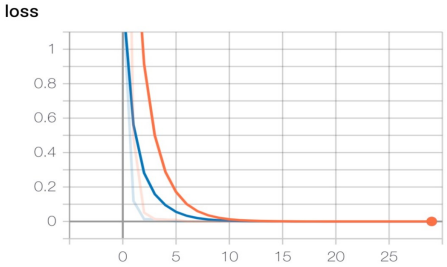

Fig. 9. Loss Vs Epochs for ODE over Faces95.

The loss for each epoch (30 epochs) for ODENet over Faces95 is shown in Fig. 9. Even here the losses have reached near to zero.

* Orange Line - Training Parameters

** Blue Line - Testing Parameters

TABLE I
AVERAGE VALIDATION ACCURACY

	CNN	ODE
Faces95	77.5%	83.46%
Faces96	96.24%	98.79%

From TABLE I, we observe that both the CNN and the ODENet on Faces95 performed poor than that over Faces96 in terms of accuracy. But if we see in Faces96, ODENet performed approximately same as CNN but in Faces95 it performed better than CNN. And all the models have a test loss approximately close to zero.

TABLE II
SIZE OF THE MODEL

	CNN	ODE
Faces95	3.52 GB (3605MB)	29.3 MB
Faces96	3.03 GB (3103MB)	50 MB

In TABLE II, we can see that over Faces95, model on ODENet is 123 times less size of that using CNN. Similarly over Faces96, model on ODENet is 62 times less size of that using CNN.

TABLE III
TIME TAKEN TO LOAD THE MODEL (IN SEC)

	CNN	ODE
Faces95	40	9
Faces96	37	10

TABLE III clearly shows that over Faces95, ODENet loads four times faster and over Faces96 also around four times faster than that over CNN on both the datasets.

Fig. 10. Training Times for each Epoch.

Apart from having less model size, we can also see that ODENet has taken very less time to train as shown in Fig.10. CNN has taken 255 and 235 seconds to train per epoch on the given system specifications. Where are ODENet has taken 45 and 83 seconds for Faces95 and Faces96 respectively. By this we can say that we have reduced the training time per epoch by almost greater than five times.

VI. CONCLUSION AND FUTURE WORK

We can see that the ODENet has outperformed the CNNs in face recognition tasks completely in terms of performance. They have consumed 123 and 62 times lesser the memory on both the datasets Faces95 and Faces96 respectively and also very less training time as shown in results section than the CNNs. Both the architectures performed very well in the recognition tasks,but we know that the ODENet needed less epochs than CNNs to achieve a test loss less than ten percent of 1. The model loading times of the ODENet is one third of CNNs which says that ODENets can be extremely fast to even train and test on devices with lesser computational resources. Thereby we can say that neural differential equations will be a very good advancement in the field of recognition tasks mainly avoiding the task of designing a neural network architecture and giving outperforming results.

Applying these networks over time series is a very good application to be done. We will be using this approach over different tasks like stock prediction and also try to refine the architecture based on the application.Training these networks with different differential equation solvers would be a very good step for doing analysis and getting the most effective one will help us with better training. Training these kinds of networks on small devices like mobiles phones is what our end goal is and will be proceeding with that as the next step.

VII. ACKNOWLEDGMENT

We would like to thank Prof.Shetty Mamatha Gopal for guiding us to carry out this research. Department of Computer Science of PES University has always been very encouraging for us to work on interesting topics like this. Finally our parents and friends have always been motivating and supporting in carrying forward our research, and we are very grateful to them.

***Abstract*—Several cardiac disorders can be diagnosed by meticulous analysis of ECG signals. The quality of signal determines the accuracy of diagnosis. Usually the size of ECG signals is huge and they are associated with noise. By compressing the ECG signals, they can be stored and transmitted easily. Hence, it is important to pre-process (de-noise) and compress it to a maximum extent. In the recent past many works have been done on ECG compression. Compression techniques have been done using time-domain as well transform domain techniques. In this work an approach through Principal Component Analysis (PCA) has been proposed to compress the pre-processed ECG signal and de-compress it efficiently, such that maximum amount of variance is retained. This algorithm has been tested for 28 ECG signals from the MIT-BIH database. In order to analyze the performance of the algorithm, CR (compression ratio) and PRD (Percent Root Mean Square Difference) have been considered as performance parameters and are calculated. The proposed method achieves a good CR along with small PRD in comparison with algorithms that has been proposed by other researchers.**

Keywords—ECG Signal Compression, Cut align beat, QRS detection, PCA Compression, PRD, CR, Singular Value Decomposition (SVD).

I. INTRODUCTION

Electrocardiography (ECG) is the process in which electrodes are used to record the electrical activity of the heart over a span of time. An ECG signal is used for various diagnostic purposes. They are obtained by placing the electrodes in different parts of body. The ECG signals can be classified as P, Q, R, S, T waveforms. The combination of Q, R, S wave forms the QRS complex wave and represent ventricular depolarization.

The first algorithm for QRS complex detection of ECG signals was developed by Pan and Tompkins (1985) using a band-pass filter of range 5 Hz to 25 Hz which had correctly detected 99.3% of QRS complexes, for the standard 24 h MIT/BIH arrhythmia database [1].

There are various approaches used for compressing the pre-processed ECG signals. Many methods have been proposed [2, 11] to compress the pre-processed ECG signal using jpeg2000 compression technique. Wavelet based approaches to compress ECG signals has also been demonstrated by Suresh Patel et al., and Oliveira et al., [3, 4]. An application of 2-D discrete cosine transforms for coding and compression of ECG signals has been shown by Hanwoo Lee et al., [5].

In this work Principal Component Analysis (PCA) is used to compress and de-compress the ECG signals.

PCA is an approach for obtaining important features from a large set of variables which are of smaller dimensions. PCA has become an important tool in modern data analysis. It is a powerful statistical technique that has found application in fields such as machine learning (such as dimensionality reduction), image compression, and is a common technique for finding patterns in data of high dimension [6]. It is the method of identifying patterns in data, and expressing the data so as to highlight their similarities and differences.

An equivalent 2-D representation (image) of ECG signal is first obtained. This includes various steps like QRS detection and Cut Align and Beat approach to map ECG signal into grayscale. The obtained 2-D representation of ECG signal can be compressed by the PCA image compression algorithm.

II. METHODOLOGY

The proposed methodology is an extension of the previous work done by Shreekanth et al., which uses JPEG2000 compression technique [2]. Since ECG signals are susceptible to various interferences and noises, it is important to de-noise them in the initial stage before compressing, which is done using wavelet de-noising. Two dimensional ECG signal is constructed using Pan-

* = Equal Contribution

Tompkins and Cut-Align-Beat approach. Region of interest is compressed in a way to achieve faithful reconstruction

The following are the sequences of steps which are performed on a raw ECG signal.

A. Baseline drift elimination and wavelet de-noising

The process of removing the noise from a signal is called de-noising and the process of removing baseline drift is called de-trending. The baseline shift is caused by low frequency components and hence such components must be deducted from the signal [9, 13]. A wavelet based approach [2] has been adopted in this work to eliminate baseline drift and noise as shown in Fig 1.

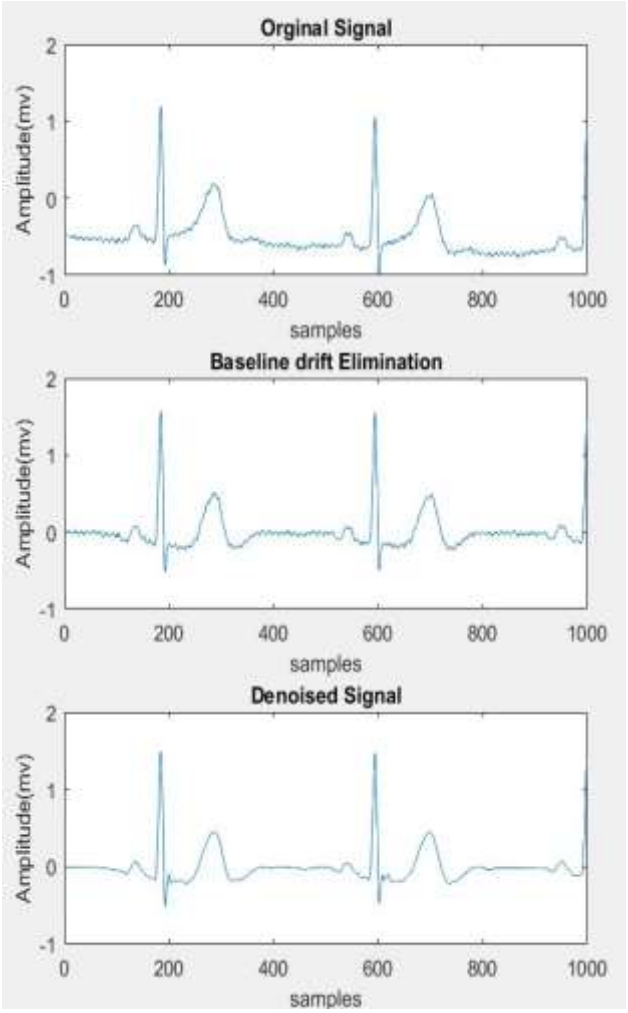

Fig. 1. ECG signal after applying baseline drift elimination and wavelet de-noising.

B. Pan Tompkins QRS detection

This algorithm is used to detect QRS complexes of ECG signal. It recognises QRS complexes based on digital analysis of slope, width and amplitude. Various interferences are removed by a digital bandpass filter which causes false detection of QRS complexes. This algorithm periodically sets parameters and thresholds so as to adapt to the heart rate and QRS morphology [1]. The detection of QRS complexes is as in Fig 2.

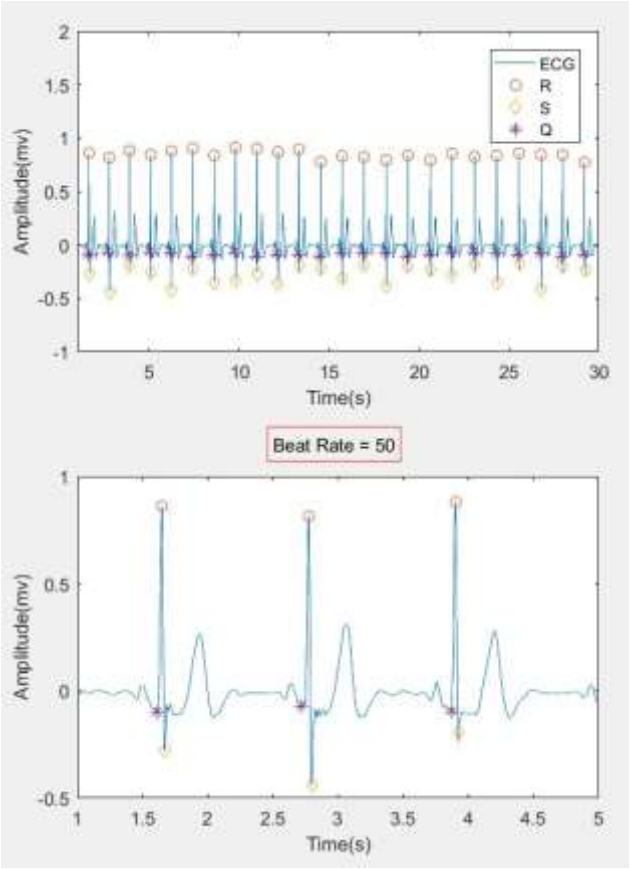

Fig. 2. ECG signal with QRS complexes detected

C. Cut align beat approach

Conversion of 1-D signal to 2-D ECG signal is done by Cut align beat approach. The QRS complexes of the ECG signal detected using Pan-Tompkins method, and the corresponding 2-D data array is obtained by cutting into segments and aligning it with other segments. Since the length of heart beat signal is different, appropriate numbers of zeros are padded [2].

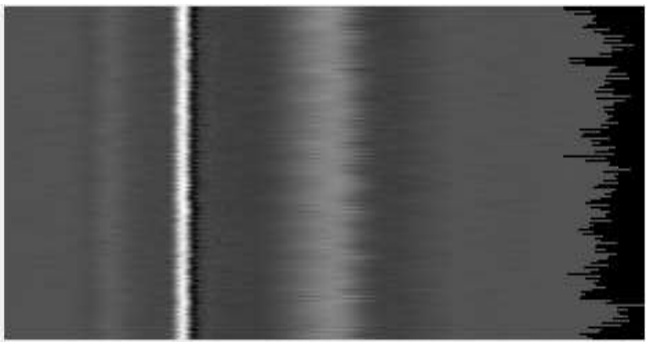

Fig. 3. ECG signal after applying cut and align beat approach

D. Mean extension for equalization of length

An acceptable 2D array can be obtained by the process of equalisation of length of each heartbeat. The period sorting is done first which sorts the beats from longer segments to shorter segments. The mean extension is done by replacing the zeros with the last value of the corresponding segments [2]. Period sorting with

descending order is employed. This improves interbeat correlation and decreases period differences.

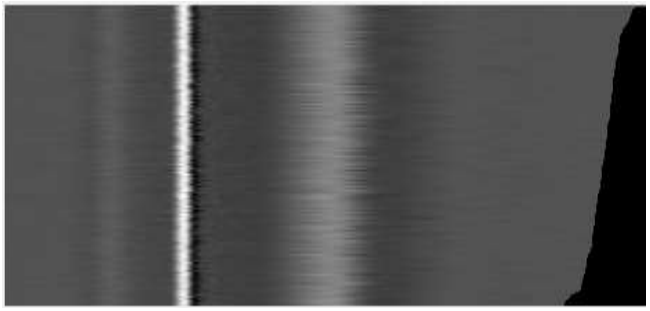

Fig. 4. ECG signal after Period Sorting

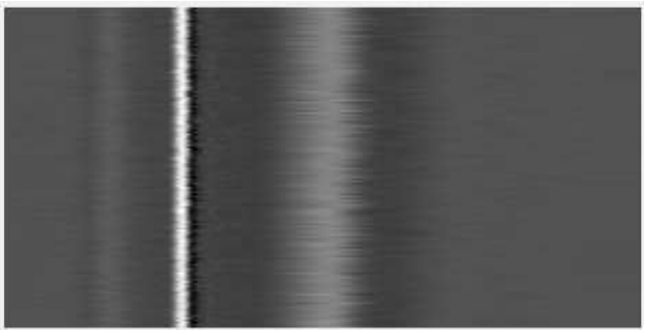

Fig. 5. ECG signal after Period Equalization

E. Period normalization

Each heart-beat has different periods and hence the data points of the 2D array are variable. The data points are normalized in order to ensure that the data occupies fixed number of columns in each row [14]. Within the beat, each sample value is divided with the highest sample value, to achieve amplitude normalization so that each beat will have a maximum amplitude value as unity.

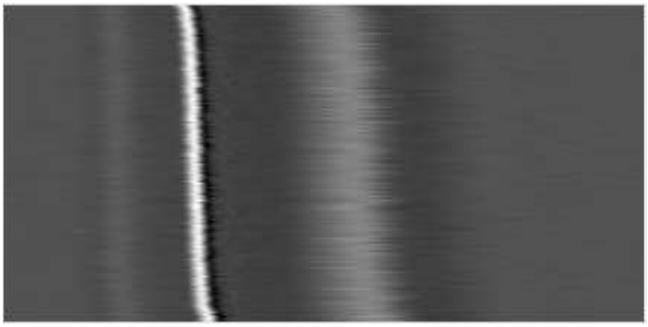

Fig. 6. ECG signal after period normalization

F. Region of Interest (ROI) mapping

Otsu thresholding is applied on the 2D ECG data, and ROI is formed by choosing the data in the QRS region. Then the vertical projection profile of the thresholding image is also found. Vertical projection profile is summation of all the pixel values in vertical direction and its width locates the ROI [2]. The QRS region obtained is compressed at a lower compression rate compared as shown in Fig 7 (a) to that of the Non-QRS region as shown Fig 7 (b). Hence, this results less PRD.

G. Principal Component Analysis (PCA)

In PCA the directions in which the data varies significantly is found. In the covariance matrix, eigenvectors that corresponds to the largest eigenvalues are found and the data is projected onto these directions. This is done because these directions contain most of the second order information.

The following algorithm for PCA is adopted for compression.

Let the data be of n dimensions. The goal is to reduce it to k dimensions where k is less than n.

Step 1: Computing the covariance matrix

For any two variables the degree of linear relationship can be measured by covariance. Positively correlated data is indicated by large positive value. Similarly, negatively correlated data denoted by large negative value. The degree of redundancy is nothing but the absolute magnitude of covariance [6].

$$\Sigma = \frac{1}{m} \sum_{i=`1}^{m} \left(x^{(i)}\right) . (x^{i})^{T} \qquad (1)$$

The resulting matrix Σ will be a $n \times n$ matrix.

Step 2: Computing the Eigen Vectors

The Eigen Vectors of the matrix Σ has to be computed. This can be done using Singular Value Decomposition (SVD).

$$[\, U, S, V \,] = svd\ (\Sigma) \qquad (2)$$

The resulting matrix U will be as follows:

$$U = \begin{pmatrix} | & | & & | \\ u^{(1)} & u^{(2)} & \dots & u^{(n)} \\ | & | & & | \end{pmatrix} \in \mathbb{R}^{n \times n} \quad (3)$$

Step 3: Projecting the data on to the matrix U

Before projecting, a suitable k value has to be chosen. Then only the first k columns of the above matrix U must be selected. Now the matrix U will be of $n \times k$ dimensions. The compressed data is obtained by multiplying the transpose of this new matrix U with the data.

H. Choosing the number of principal components

The number of principal components is chosen such that the average squared projection error should be minimized. It is given as follows:

$$\frac{1}{m} \sum_{i=1}^{m} || \ x^{(i)} - x^{(i)}_{approx} \ ||^2 \qquad (4)$$

Where, $x^{(i)}_{approx}$ is the reconstructed data.
The total variation of the original data is:

$$\frac{1}{m}\ \sum_{i=1}^{m} ||\ x^{(i)}\ ||^2 \qquad (5)$$

Typically, k has to be chosen such that the following value(c) has to be minimized

$$\frac{\frac{1}{m}\ \sum_{i=1}^{m} ||\ x^{(i)} - x^{(i)}_{approx}\ ||^2}{\frac{1}{m}\ \sum_{i=1}^{m} ||\ x^{(i)}\ ||^2} \leq c \qquad (6)$$

The smallest value of k has to be picked such that

‘

$$\frac{\sum_{i=1}^{k} S_{ii}}{\sum_{i=1}^{n} S_{ii}}\ \geq\ 1 - c \qquad (7)$$

Hence, this implies $100 \times (1 - c)\%$ of the variance is retained.

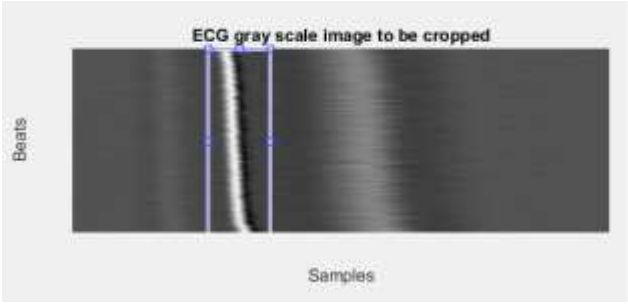

Fig 7. ECG signal with QRS cropped

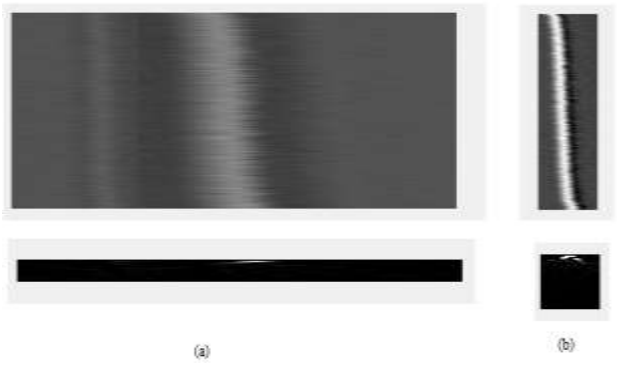

Fig. 8. Image after PCA compression. (a) Non QRS compression. (b) QRS compression.

I. Reconstruction of 1D ECG signal

The decompressed data can be obtained by multiplying the matrix U with the compressed data. The original data is then obtained from decompressed data by applying period denormalization. From the known heart-beat length, a number of samples are picked up. Then they are multiplied to their corresponding mean and amplitude values. Original ECG signal can be obtained by appending all the heart beat’s data to form a sequence [2].

III. RESULTS AND DISCUSSIONS

The algorithm was tested for ECG records obtained of the MIT/BIH dataset. It was sampled at the rate of 360 Hz, 11 bits/s [2]. The ECG signals were considered such that, the patterns were different. The corresponding record the patterns were different. The corresponding record numbers of the considered ECG signals are 102, 111, 114, 124 and 117. These records consisted of ECG signals with different rhythms. The results obtained are compared with other algorithms on the same dataset and are recorded in Table 1. The performance parameters obtained on the proposed algorithm is recorded in Table 2. Figure 8 shows 1000 samples of original signal along with the reconstructed signal and error signal corresponding to the record 117.

The performance of the proposed technique is measured using two parameters namely Compression Ratio (CR) and Percentage Root-mean-square Difference (PRD).

CR is used to quantify the amount of reduction in the size of representation of data due to a data compression algorithm. Compression ratio is defined as follows:

$$CR = \frac{Size\ of\ original\ signal}{Size\ of\ compressed\ data} \qquad (9)$$

Compressed signal quality is evaluated by PRD. It is defined as the square root of the ratio of square of error signal and the square of the original signal.

$$PRD = 100 \times \sqrt{\frac{\sum_{i=1}^{L}(x_{org}(i) - x_{recon}(i))^2}{\sum_{i=1}^{L}(x_{org}(i))^2}} \qquad (10)$$

where x_{org} represents the original signal, x_{recon} represents the reconstructed signal and L is the number of samples in the data.

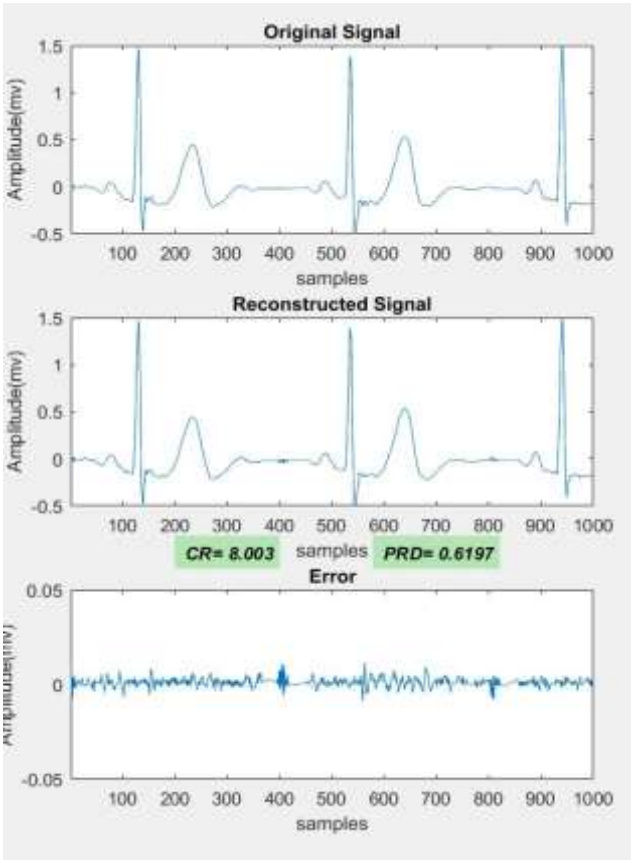

Fig. 8. Reconstructed signal for record 117 and its corresponding error.

Table I. Performance parameters comparison with different algorithm with sampling frequency 360Hz and resolutions 11 bits/sample

Algorithm	Record Number	CR	PRD
Hilton	117	8:1	2.6
Lu et al.	117	8:1	1.18
Djohan	117	8:1	3.9
SPHIT	117	8:1	1.8
Proposed	117	8:1	0.6

Table II. PRD and CR comparison with different data using proposed methodology

Record number	CR	PRD (%)	Sampling Frequency (Hz)	Resolution (bits/sample)
102	8	0.55	360	11
114	10	0.49	360	11
117	8	0.6	360	11
111	8.5	0.9	360	11
124	10	0.5	360	11

IV. CONCLUSION AND FUTURE SCOPE

The compression of ECG signal using PCA based on ROI has been demonstrated. The algorithm has been tested for the ECG signals obtained from MIT/BIH dataset. The performance of the presented algorithm depends on the record which is being used for compression and its signal length. The proposed algorithm outperforms many of the standard algorithms as demonstrated in Table I. The main drawback of this algorithm is the increased computational complexity. The only room for improvement of this work is to reduce error by keeping CR as high as possible. This can be achieved by using superior coding techniques.

***Abstract*—Libraries play the most important role when it comes to books and reading. Today, libraries have become a great source of information. If we look upon the procedure that most of the conventional libraries in the world follow, we see a great amount of drudgery involved. In this paper, we propose a smart library system, which eliminates most of this drudgery in the conventional library management systems. Using face recognition and QR code based technology, the system automates and eases the tasks of Book Issue, Book Return and Book Search. It resembles 'Just walk out technology' implemented by Amazon in the Amazon Go stores. The proposed system enjoins self-issue and self-return procedures along with the dynamic search feature which provides the real-time location of the books. The proposed system significantly expedites the process of issue, return and search thus avoiding long queues at the reception counter/librarian's desk.**

Keywords—smart libraries; face recognition; QR code technology; dynamic libraries; real time book tracking

I. INTRODUCTION

Traditional library management systems require a great amount of labor, starting from the person at the issue/return counter to the person who puts all the books at their correct locations when they are returned. When the user needs to issue a book, he has to physically visit the library and then carry out the required formalities in order to get the book issued. At peak times, there are long queues at the counter for the issuance of the books. Even for reissuing the book, the user has to physically visit the library and get the formalities done. Apart from all of this, the librarian is largely responsible for the entire library management. He has to properly place the books at the correct location when they are returned. In a conventional library management system, there is no provision to get the real-time location of the books. Also, paperwork is needed to some extent and the library staff must be qualified.

In the proposed system, for issuing a book, the user has to stand in front of a camera and show his face and the book's QR code to the camera to get it issued. This camera is not the usual CCTV camera. It is placed such that only one person can stand in front of it at a time. For returning the book, the user has to drop the book in the drop box such that the book's QR code faces upwards. The camera located at the top of the drop box scans the QR code on the book and updates the database accordingly. Thus, the book is returned. The system also proposes a dynamic search feature. The module for this feature updates the location of the books in the database continuously. Thus if a book is moved from shelf 1 to shelf 2, the location of that book is immediately updated to shelf 2. For this, each shelf has an associated camera which continuously detects the QR codes of the books present on that shelf. If a new book is added to that shelf, the camera for that shelf detects it. It decodes the book's QR code and updates its location to that particular shelf number.

For security purposes, the only labor that needs to be involved includes the person who sits at the exit gate to check whether each user exiting the library doesn't leave the library without issuing the books taken by him.

II. RELATED WORK

A. Smart Library System

Some of the related work in this area includes RFID based smart library systems [2]. They make use of RFID tags. The patron has to scan his ID card and then scan the tags present on the books in order to get them issued. The book drops can be located anywhere in the library and the patron has to simply place the books on the trays available for book drop. The reader reads the tags and notifies the patron of the successful return.

Face recognition based smart library system [1] employs face recognition in combination with RFID technology. The patron needs to stand in the line of sight of the camera until his face is detected and recognized. Once his face is recognized, the patron is logged in to the system after which he can scan the RFID tags of the books in order to get them issued.

The system proposed in [15] uses Near Field Communication based Book Tracking. Each book has an NFC tag attached to it. At the entrance, the user places his/her NFC enabled phone on the NFC reader. If fingerprint and user ID of the user exists in the database, the user is connected to the LAN. For searching a book, the user queries the system through his phone and gets the rack details as a reply from the server. This request is forwarded by the user to the Local Positioning System which further guides him to reach the desired rack. When a new book arrives, it is first registered in a

rack by scanning the book's tag against that particular rack's monitor. For issue procedure, the exit and entrance have NFC scanners. For returning a book, the user drops it in the drop box provided.

The system proposed in [16] focuses on security aspects majorly. When the book is returned by the patron, the librarian scans the book's RFID tag against the RFID reader and retrieves its location. For entering the library, the patron has to verify himself by scanning his tag against the door lock. On successful verification, the door is opened. The book security module checks for outgoing books continuously. If the outgoing book is not issued, then an alarm is activated.

Passive RFID tags at UHF frequencies are used by the system proposed in [17]. The system mainly focuses on smart bookshelves. Antennas are placed on the bookshelves which read RFID tags of the books within the shelf. The system uses microstrip antennas to minimize the spill-over electric field and the radiations emitted by them.

In the approach proposed in [3], the skin area is detected in the image and the facial features are searched in the skin area. The proposed approach considers the nose to be present for a partially occluded face since it does not change much with facial expression. Non-face objects are removed by using morphological operations. The HSV color model is used to avoid illumination variance effect and finally, a bounding box is drawn for the most probable face region.

B. Face Detection

1) Skin Segmentation based face detection: In this approach [3], the skin area is detected in the image and the facial features are searched in the skin area. The proposed approach considers the nose to be present for a partially occluded face since it does not change much with facial expression. Non-face objects are removed by using morphological operations. The HSV color model is used to avoid illumination variance effect and finally, a bounding box is drawn for the most probable face region.

2) Haar cascade combined with other classifiers: In this approach [4], three classifiers are combined with the haar cascade classifier. A face detected by the haar cascade classifier is only accepted when it passes the skin hue histogram test, eye, and mouth detection test.

3) Viola Jones Algorithm: This algorithm [5], [6] involves haar feature selection, creating an integral image, ADA-boost training and cascading classifiers.

C. Face Recognition

1) Support Vector Machines: The approach proposed in [7] uses the eigenfaces algorithm [8] to extract features from the input images. The features are then learned by the SVM. Since SVM is a binary classifier, this approach uses one against one strategy that is it classifies between each pair. A bottom-up binary tree is used for this classification.

2) Radial Basis Networks: In this approach [9], an n-sized input vector is given as input to the hidden unit which gives an m-sized output vector, where m is the number of faces registered. After the training, on feeding the test image we get an output vector. The given face image is recognized as that of a registered person if the maximum value of the output vector is larger than the threshold value. If it is not, the face is rejected as that of an unknown person.

3) EigenFaces Algorithm: This algorithm [8] is based on PCA (Principal Component Analysis). It extracts the variations in the collection of face images and uses this information to encode the face images and compare them individually.

4) LBPH Algorithm: In this approach [11], the central pixels for each window is substituted with a decimal number that is obtained from the binary pattern formed by the surrounding pixels. The LBPH (Local Binary Pattern Histogram) algorithm processes the image and forms binary patterns. It then stores these features into the histogram for later comparison. The histogram to which the test image's histogram is near to is assigned that particular class label.

D. QR Code decoding

Ref. [13] describes the structure of the QR code and its encoding and decoding process.

The approach of [12] uses image processing algorithms for detection of QR code. The grayscale image containing the QR code is binarized based on a threshold value. The alignment patterns and the timing pattern help locate the QR code in the image. The orientation of the QR code and width of one module is a representative of the timing pattern. Once the QR code is detected, a grid is constructed by joining the centers of the three alignment patterns detected. Error correction and decoding are then applied to retrieve the actual message.

The approach in [14] makes use of run length coding for QR code detection. The histogram of the grayscale image is equalized to increase its contrast followed by binarization. Run length coding is then applied to the resultant binary image.

III. Proposed System

A. Book Issue

According to the proposed system, the library can have multiple ATM-like machines for issuing/reissuing the book. The patron has to just stand holding the books in front of one such machine. The camera in it detects the user's face. If the patron is not a registered user, the system does nothing. However, if the patron is a registered member of the library, then upon recognizing his face, the system detects the QR codes present on those books which are held upfront by the patron. On decoding those QR codes, the book ID's of those books are retrieved and the system issues them against the patron whose face was recognized. The patron receives an

email as an acknowledgment for the successful issuance of the books.

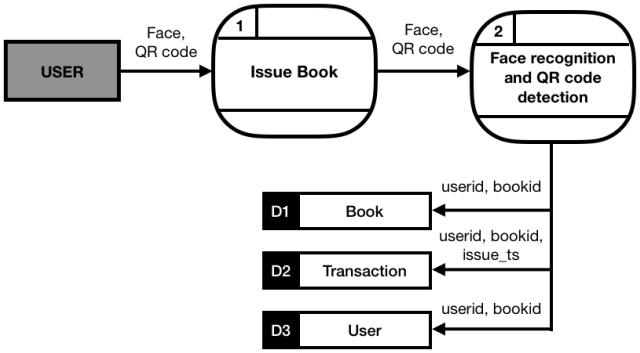

Fig 1. Data Flow Diagram for Book Issue

In Fig. 1, the face and the QR code data are supplied to the issue book module which involves Face recognition and QR code detection and decoding module. In the 'Book' table, the record with ID as 'bookid' is searched and the 'userid' of the patron who has issued that book is added to that book's record. The transaction containing the 'userid', 'bookid' and the 'issue_ts' (timestamp) is added to the 'Transaction table'. The 'User' table is then updated to store the 'bookid' in the details of the patron with ID as 'userid'.

B. Book Return

According to the proposed system, the library can have multiple drop-boxes with each drop-box having a camera situated above it. When the patron drops the books in these drop-boxes, the camera above them detects and decodes the QR code to fetch the book ID of that book. It then updates the database and the book is returned. The patron receives an email as an acknowledgment for the successful return of the book.

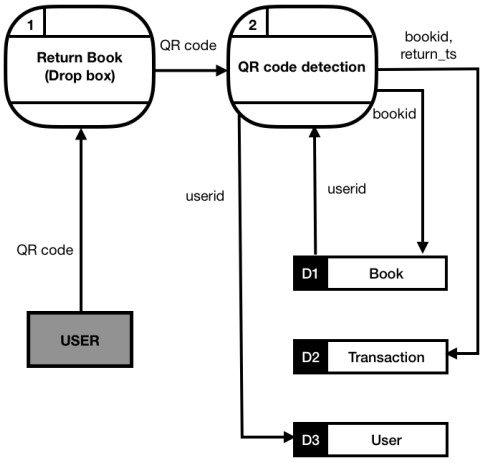

Fig 2. Data Flow Diagram for Book Return

In Fig. 2, the 'bookid' is retrieved from the QR code that is passed to the Return Book module. The 'Book' Table is then queried using 'bookid' to get the 'userid' of the patron who has issued that particular book. The 'return_ts' (return timestamp) which was initially empty is now updated in the 'Transaction' table. The retrieved 'userid' is then used to search for the patron in the 'User' Table and the returned book is removed from the list of his borrowed books.

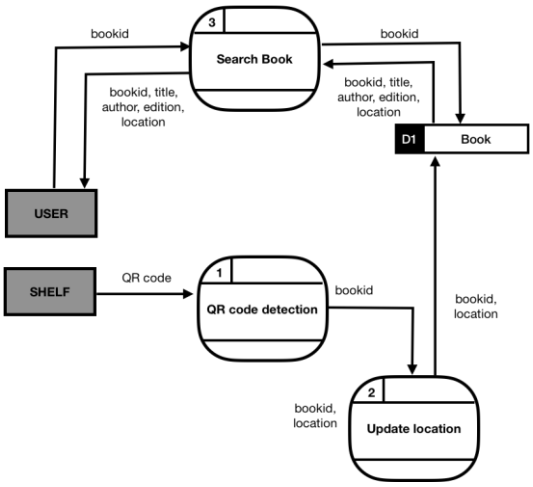

Fig 3. Data Flow Diagram for Dynamic Book Location Updation

C. Dynamic Book Location Updation

The system requires that each shelf has a designated camera which is associated with that particular shelf only. The camera detects all the QR codes found in its associated shelf. It decodes them all to get the book IDs and updates the location of those books to that particular shelf number.

Consider that a book is on shelf 1. The camera associated with shelf 1 will detect this and update the location of that book to Shelf 1. Now if the same book is moved to shelf 2, then the camera associated with shelf 2 will detect this additional QR code and will update the location of the same book to shelf 2. In this manner, the location of the book is updated dynamically in real-time.

The QR codes of the books present on a particular shelf are continuously decoded in real-time and their location is updated in the 'Book' table as shown in Fig. 3.

IV. Technology Used

A. Face Detection

The system uses the Viola-Jones Algorithm (haar cascades) in OpenCV [5], [6] to detect faces in the video frames. Haar cascade classifiers make use of kernels of a given size. Consider the size of the kernel as 3x3. The kernel moves across the image and does matrix multiplication with every 3x3 part of the image, emphasizing some features and smoothing others. Haar-features are good at detecting edges and lines. However, there are certain constraints to the objects that the haar cascade classifier can detect.

The algorithm is so chosen due to its high precision and recall value with respect to the other popular methods of face detection as proved in [6].

B. *Face Recognition*

The system uses the Local Binary Pattern Histogram (LBPH) [11] algorithm for face recognition. Local Binary Patterns are texture descriptors. They compute a local representation of the textures by comparing each pixel value with the surrounding pixel values. If the surrounding pixel value is greater than or equal to the central pixel value, then a zero is assigned at that position, else a one is assigned. The binary matrix (without considering the central pixel) formed is then read in either clockwise or anticlockwise direction and a binary number is generated. This binary number is then converted into a decimal value in the range of 0 to 255. The central pixel value is then replaced by this decimal value.

The above process is repeated for each pixel in the grayscale image and a new image is generated. The histogram for this newly generated image is calculated and is stored. The procedure is repeated for all training images and the histogram values for all the training images are stored. For testing purpose, the test image is processed in the same way and its histogram is calculated. This histogram can be compared with the stored histograms of the training images using distance metrics like Euclidian distance to determine the class label.

C. *QR Code Detection and Decoding*

The system uses the pyzbar library in python along with zbar dependencies to detect and decode QR codes. The advantage of this library is that the QR codes in any decent orientation can be detected and decoded using this library.

V. Experimental Results and Analysis

The system was tested on three datasets for face detection and face recognition viz. Cambridge Olivetti Research Laboratory face dataset, Caltech face dataset and our own manual dataset.

TABLE I. Face Detection Accuracy for Viola Jones Algorithm

Dataset	Total Images	True positives	Accuracy (%)
Cambridge ORL Face Dataset	400	265	66.25
Caltech Face dataset	445	435	97.53
Manual Dataset	200	50	25

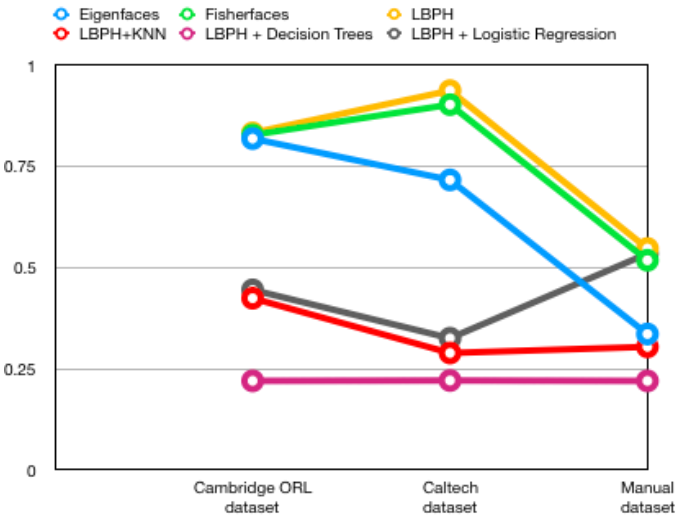

Fig 6. 2D Line plot for F1 scores of algorithms with respect to the three datasets considered

Table I displays the results of the tests performed on the three datasets for Viola-Jones algorithm. It displays the size of each dataset in terms of number of images and the true positives i.e the number of images in which face was detected accurately. The number of true positives divided by the total number of images gives the accuracy of the Viola-Jones algorithm for that particular dataset.

Table II, Table III, Table IV, sum up the results of various algorithms considered for each of the dataset. Since the number of test images for each face in the test dataset was variable, F1 score became significant comparison factor over accuracy. The

recall value is given by the ratio of the number of true positives and the sum of the true positives and false negatives. The precision value is given by the ratio of the number of true positives and the sum of the true and false positives. F1 score is given by the ratio of twice the product of precision and recall values and the sum of the precision and recall values. The empirically obtained F1 scores of LBPH with respect to the ORL, Caltech, and the Manual dataset in Table II, Table III, and Table IV, are 0.83, 0.94 and 0.55 respectively.

Three major algorithms viz. EigenFaces, FisherFaces and LBPH were tested. Other than these, the other three algorithms considered for testing were the combinations with the LBPH. In these algorithms, the histogram of the local binary patterns was extracted for all the training images to create a dataset and then the model was trained on this dataset using KNN, Decision trees, and Logistic Regression.

Fig. 6 justifies the use of LBPH algorithm for face recognition in the proposed system. The 2D line points for the LBPH algorithm in Fig. 6 are maximum with respect to all the three datasets.

VI. Conclusion and Future Work

Owing to the use of software to a great extent in the system, the wear out rate of the system is negligible. If the accuracy of face recognition is improved profusely, then the system would be self-sufficient and can be deployed in the actual libraries which can help reduce the significant amount of load on the librarians. With Librany, all the books in the library can be tracked in real-time. It needs no involvement with the librarian. The system enjoins self-issue and self-return procedures which avoids long queues at the counter.

The system can be extended to detect faces in any orientation. Also, the system can be tuned such that even if multiple faces are detected in the video frame, the book should be only issued to the patron holding it instead of the other detected faces. Buzzers can be deployed at the exit gate which can ensure security and alert the person in charge in case of larceny. Modules which provide business intelligence can be incorporated into the system for knowledge extraction.

Abstract — Image processing is relevant in our day to day life as it is helpful to solve important problems in real world. Recent progress in quantum information and computation led to the birth of a new field called Quantum Image Processing. This new field of image processing in quantum domain focuses on the development of the quantum image processing algorithms, which can run more efficiently on quantum computer. These quantum algorithms are better in terms of Image storage and retrieval with reduced computational complexity. In this article we present recent advancements in quantum image representation with different mathematical models and with their corresponding computational complexity.

Keywords — Quantum computation; Quantum image processing; quantum image depiction; Quantum measurement; Quantum information

I. INTRODUCTION

The field of digital image processing refers to processing of digital images by means of a digital computer. Image processing is well known in our day to day life as the need of extraction of crucial data is also increasing in real world. Computational complexity of an algorithm and visual information are the popular area of research for existing real world problems. Extracting right information from available digital data and removing associated noise in the images are two major problems in this field. Because of the limited architecture of classical computers and the often overwhelming computing complexity of state-of-art algorithms, better ways of storing, processing and retrieving digital images are required. The images of 3D scenes in 2D spaces, visual information and algorithm complexity are all major research areas.

In different fields of computer science, for example information theory, cryptography, emotional depiction and image processing, quantum computation and quantum information have appeared because inefficient tasks on conventional computers can be improved by exploiting the power of quantum computing. The first step in the processing of quantum images involved proposals for capturing and storage of the images on quantum computers. Quantum Computers enables different image illustrations like qubit lattice, Flexible Representation for Quantum Images (FRQI-Model), Multichannel Quantum Image (MCQI Model), Novel enhanced quantum representation model (NEQR), CQIR (Colored Quantum image representation) representation model, Three Channel Representation for quantum color images model (QMCR).

This paper tries to investigate basic of quantum computation, the different quantum image representation, comparison and application of investigated Quantum image representation. Sequence of paper is as follows: In Section 2, the fundamental learning of classical image processing and need of quantum image processing is discussed. In section 3, Basic knowledge of quantum image processing and associated operation used in quantum computation is presented. In section 4, detailed investigation of different quantum image representation, their features and comparison are analyzed. In section 5, Conclusions are drawn and direction for future work is discussed.

II. CLASSICAL IMAGE PROCESSING

Image processing is a technique of enhancement of the raw images received from various sensors or cameras which are placed on the sources like satellites, aircrafts and space probes or the pictures taken during the normal day to day life activities. Different techniques have been developed for improving raw images over the last five to six decades. Image process could be a method where an image is converted into a digital form using some operation to obtain an improved image and to extract a number of useful information. Image processing is used in various applications like: printing industry, film industry, military purpose, graphics arts, forensic studies, material science, medical imaging.

In traditional memory device, memory cells are available in the form of the hardware, i.e., each memory vicinity may be attributed to a truth that is independent of all other reminiscence places. Better ways of storing, processing and retrieving digital images are required because of the limited architecture of classical computers.

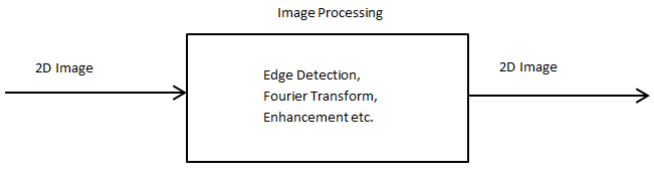

Fig. 1. 2 D Block of Image Processing

III. QUANTUM IMAGE PROCESSING

Image processing is prevalent in our day to day life as it is helpful to extract important information from real world. A new field called quantum image processing emerged after certain major research tasks. Research in this sector has experienced problems owing to its emerging phase. However, efforts continue to identify the diversity of its applicability in different fields of image processing. Most of the work done so far refers to fundamental aspects such as representing and storing an image on quantum computer and the basic processing. The portrayal of 3D scenes in 2D spaces, behaviour of visual information and algorithm complexity are all emerging research area. Quantum image processing is an important and emerging sub-domain in quantum theory.

A. Quantum Image Processing Operation

If we compare the quantum image with the classical image, there is an enormous benefit of the depiction of the quantum image. Let's take X pixel sized quantum image. The general mathematical equation of quantum image is represented as:

$$|\mathrm{QI}\rangle = {}^{1}/_{\sqrt{X}} \sum_{a=0}^{x-1} |\mathrm{Sa}\rangle \otimes |\mathrm{Z}\rangle \qquad (1)$$

Where $|\mathrm{Sa}\rangle$ is color information of quantum image, $|\mathrm{Z}\rangle$ Position of quantum image, $\otimes$ Tensor product.

The bits used to represent information are known as qubits in a quantum computer. These qubits lie in superposition of two basis states in a quantum computing system. As compared to classical bits these quantum bits can store more information because of the quantum-ness like superposition and entanglement. Quantum computer follows the rule of linear superposition principle. A quantum computer can be defined as the computing machine which is used to perform computation based on the laws of quantum mechanics.

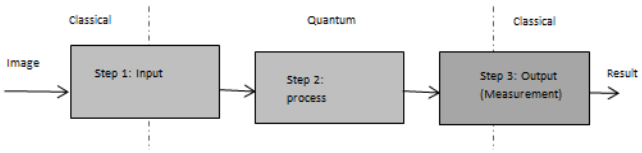

Fig. 2. Basic procedure for Quantum Image Processing

B. Quantum Bits

In the case of Classical Computation, storage and processing of the information used to take place in the form of the bits. As a mathematical structure it involves the processing of the classical bit. It works to represent two 'logical' values, commonly referred to as {0, 1}, and to link these obtained values to two different classical measurement solutions. So, that's why classical bit used to 'live' in the scalar space. Qubit is a real-world entity which is based on Quantum Mechanics law. Simple instances of qubits use two orthonormal polarization of a photon, alignment of a nuclear spin (spin-1/2) in a magnetic area or electron states orbiting an atom. The classical image uses bits that can be either 0 or 1 at a specific location and time.

C. Quantum Gates

Quantum gates are used to perform the manipulation of qubits. A qubit enters a gate of the quantum circuit and exits as another state, so quantum gates represent the time evolution of a state which is required to describe the qubits. The quantum gate satisfies the following criteria:

- Must uphold the norm i.e. norm squared probability amplitudes sum to one after gate application.
- It must be reversible in nature i.e. evolution of every non measured quantum state must be reversible.

The above conditions are equivalent to a restriction that quantum gates must be unitary matrices. In quantum computation most common used quantum gates are Hadamard, NOT and CNOT gates. There are several facts about quantum circuits which can be used in order to express more complex unitary transformations, write circuits more concisely, or adapt circuits to experimental constraints. The gates used to apply on the K qubits are usually represented by 2^k X 2^k unitary matrix; the qubit number in the gate input must be equal to the output end.

D. Quantum Measurement

Quantum physical systems are very susceptible to interference from outside of the scheme compared to conventional physical structures. One sort of external interference mentioned is the quantum measurement that tests a qubit status for the observable state in which it is. A set A_a of non-unitary measurement operators can mathematically describe quantum measurement [19]. Here, a is an index of the base state being evaluated. For instance, if there are two basis states pertaining to $|0\rangle$ and $|1\rangle$, there would be two indices, $a = 0$ and $a = 1$. The probability of the measurement producing the observable state a is given by

$$A(a) = \langle\psi|\, \bar{A}_a A_a\, |\psi\rangle \qquad (2)$$

Where $\bar{A}$ denotes the conjugate transpose of a matrix, $\langle\psi|$ represents the conjugate transpose of $|\psi\rangle$, and the state of the quantum system after measurement is

$$\frac{A_a|\psi\rangle}{\sqrt{\langle\psi|\bar{A}_a A_a|\psi\rangle}} \qquad (3)$$

Applying quantum measurement makes the system "collapse" to one of the basis states [19]. For example, consider the qubit state

$$|\psi\rangle = \alpha\,|0\rangle + \beta\,|1\rangle = \begin{pmatrix}\alpha\\ \beta\end{pmatrix} \qquad (4)$$

So that $\langle\psi| = (\alpha^*, \beta^*)$ (5)

The measurement operator

$$A_0 = \begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix} \qquad (6)$$

Projects $|\psi\rangle$ onto the observable state $|0\rangle$ with probability

$$\frac{A_0|\psi\rangle}{\sqrt{\langle\psi|\bar{A}_a A_a|\psi\rangle}} = \frac{\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}\begin{pmatrix}\alpha\\ \beta\end{pmatrix}}{\sqrt{\alpha^*\alpha}} = \frac{\alpha|0\rangle}{\sqrt{|\alpha|^2}} = |0\rangle \qquad (7)$$

With the coefficient $\frac{\alpha}{\sqrt{|\alpha|^2}}$ being a phase term, the effect of which on the measurement outcome is negligible and typically ignored. On repeated measurements, one gets a probability distribution over the observable states. The physical, meaningful outcome of quantum measurement can be estimated using quantum state tomography (QuST) [20]—that is, estimation by maximum likelihood. One of the most common tools for this estimation is the Kalman filter approach, as it is the one that is most robust against noise. Therefore, in the field of QuIP, most algorithms created use it to assess the outcomes of quantum measurements

E. Quantum Entanglement

Concept of quantum entanglement occupies the position of primary importance in quantum computing as well as in quantum image processing. Fundamentally entanglement is relationship between two particles. As we know in today's scenario images are being used for communication because they carry information in detail. So by taking advantage of quantum entanglement in images we can improve communication methods.

IV. Representation of an Image in Quantum context

Prof. Salvador E. Venegas-Andraca [2], proposed the quantum image representation, based on qubit lattice. Prof. Jose.I. Labtorre Sentis [4], by using the real ket, proposed the quantum image portrayal. Prof. Kaoru Hirota [3] proposed flexible way of representing the quantum images with a purpose to provide a portrayal of picture at the quantum computers which can be in the shape of a normalized state required to store the information regarding colors and the position associated with them in the given images.

A. Storing and Retrieving an Image in Quantum System using Qubit Lattice

Storing an Image: Let's define ourselves L as a lattice of qubits, that is L= $\{|q\rangle_{i,j}\}$, $I \in \{1,2,...,n_1\}$, $j \in \{1,2,...,n_2\}$ A set of qubit lattices S may be defined as S= $\{L_k\}$, k ∈ {1, 2,...,n_3} Thus, S = $\{\{|q\rangle_{i,j,k}\}$ is a set of n_1 x n_2 x n_3 qubits. Our motive here is to store or accumulate the visual information in S and each lattice, say $L_k \in S$ is used to save the copy of the given image. The process of storing an image using the set of qubit lattices S is described in the algorithm. During the execution of the algorithm, an assumption is made that the lattice L is made up of machine A. On the completion of algorithm, entire set S is initialized; n_3 is used to prepare the same qubit lattices, each of which contains the same image [2].

B. Flexible Representation for Quantum Images(FRQI model)

Le *et al.* [3] proposed the FRQI, which has begun to grow into most widely used quantum image representation (QIR). In this model, the required records i.e. the colors and position of all factors in an image get captured and then integrate with the tensor product to achieve a normalized quantum state. The below equation shows the vector of angles to encode color information in the form:

$$|\mathrm{I}\rangle = \frac{1}{2^n} \sum_{y=0}^{2^{n-1}} |Q_f\rangle \; |i\rangle \qquad (8)$$

$$|Q_f\rangle = \mathrm{Cos}\,\theta\,\mathrm{f}\,|0\rangle + \mathrm{Sin}\,\theta\mathrm{f}|1\rangle \qquad (9)$$

$|0\rangle$ and $|1\rangle$ are 2 Dimension computational basis quantum states, $Q_f \in [0, \pi/2]$ and f = 0, 1, 2.....2^n-1. The equation developed is an integral part of FRQI preparation process and its implementation. By this, the whole preparation of the computational complexity of FRQI image state requires o (2^{4n}). The normalized state of FRQI, i.e., $\| |Q_f\rangle \| = 1$ as follow:

$$\| |Q_f\rangle \| = \frac{1}{2^n}\sqrt{\sum_{f=0}^{2^{2n-1}} (\cos 2\,\theta\mathrm{f} + \sin 2\,\theta\mathrm{f}) = 1} \qquad (10)$$

FRQI illustration and transformation focus on the spatial and geometric data. FRQI has interesting application in quantum watermarking, quantum moves, quantum image data searching and quantum image frameworks and so on [4].

C. Multichannel Quantum Image(MCQI model)

While FRQI can be used in many application of quantum images but still, the concept of "full" color cannot be captured in the images. Sun *et al* [5] proposed the new model of color images processing in quantum computers. The proposed version simultaneously captures the records from R, G, B channels and store the information in quantum state. MCQI model is used to capture and store color information and position at the amplitudes of each image pixel. Thus model supports 2^n x2^n image and can be mathematically expressed as:

$$|QI\rangle = \frac{1}{2^{n+1}} \sum_{f=0}^{2^{2n-1}} |A_{RGB\alpha}^f\rangle \otimes |f\rangle \qquad (11)$$

$$|A_{RGB\alpha}^f\rangle = \mathrm{Cos}\,\theta_R^f|000\rangle + \mathrm{Cos}\,\theta_G^f\,|001\rangle + \mathrm{Cos}\,\theta_B^f|010\rangle + \mathrm{Cos}\,\theta_\alpha^f\,|011\rangle + \mathrm{Sin}\,\theta_R^f|100\rangle + \mathrm{Sin}\,\theta_G^f\,|101\rangle + \mathrm{Sin}\,\theta_B^f|110\rangle + \mathrm{Sin}\,\theta_\alpha^f\,|111\rangle \qquad (12)$$

$|000\rangle, |001\rangle \ldots |111\rangle$ is used to represent the computational premise conditions of the required three qubits. θ_R^f, θ_G^f, θ_B^f, θ_α^f represents the four angles that are used for encoding the data of color channels of the f-th pixel , $|f\rangle$ for f = 0, 1, . . . ,2^{2n}-1 are 2^{2n}-Dimension represents computational premise condition states. The main difference between the FRQI and MCQI is that FRQI require only one qubit to encode an

image color but MCQI uses three qubits to carry multichannel color information. Computational complexity of both MCQI quantum image and FRQI's is same i.e., O (2^{4n}) [5].

D. Novel Enhanced Quantum representation model (NEQR model)

Model representation of NEQR was put forward by Zhang *et al*. [6-7]. Under this model digital image, the basis sate of a qubit collection is used to keep the gray scale cost of each pixel instead of using encoding in a qubit in FRQI. Whereas in NEQR encoded qubit sequences are required to capture the entire image. NEQR requires only pixel's gray-scale and position information. Let us take into account that the value of grey range of the given picture is 2q with given binary collection $c_{ab}^{0} \ldots c_{ab}^{q-2} c_{ab}^{q-1}$ and the required encoding of the gray-scale value *f (a, b) is obtained by:*

$$f\ (a,b) = \ c_{ab}^{0} \ldots c_{ab}^{q-2} c_{ab}^{q-1} \quad (13)$$

Where $c_{ab}^{k} \in [0, 1]$ and *f (a, b)* $\in [1, 2^{q} - 1]$

In NQER quantum image model, first step is quite similar to FRQI. Second step involves the setting of the greyscale value of each pixel. This step is further divided into the 2^{2n} part-operation which is required for the storage of the grayscale information of each and every pixel. Time complexity concerned in preparation of NEQR quantum image shows typically a quadratic decrease, i.e., O($qn.2^{2n}$) whilst in comparison to FRQI. NEQR representation model requires a q +2n qubits for the construction of the quantum image model for the image of size 2^{n} x 2^{n} with gray scale range 2^{q}.

E. CQIR Representation model

CQIR model was proposed by Caraiman and Manta in 2014[8]. CQIR is similar to NEQR. A qubit sequence was used in encoding the colored information required in quantum images. CQIR facilitates histogram equalization of the quantum image. This model requires $m=log_2 L$ qubits to encode all the L grey levels which are available in the picture [8-9]. This model may find potential application in the processing of the images related to medical, radar and astronomy. This may result in enhancement of the contrast of the image for obtaining better details related to the image. The formulation of CQIR illustration is shown:

$$|\mathrm{I}\rangle = \ |C\rangle \mathrm{mx} |P\rangle 2\mathrm{n} \ = \frac{1}{2^{n}} \sum_{i=0}^{2^{2n}-1} \ \sum_{j=0}^{2^{m}-1} \propto i\ j\ |j\rangle\ |i\rangle \quad (14)$$

$$|\mathrm{I}\rangle = \frac{1}{2}(|01\rangle\ \otimes |00\rangle + |10\rangle\ \otimes |01\rangle + |11\rangle \otimes\ |10\rangle + |00\rangle \otimes 11)) \quad (15)$$

$|P\rangle$ is a register in which pixel positions are encoded by using the 2*n* qubits and the information of color pixel is denoted by using $m=log_2 L$ qubits required to encode the L grey level colors. Coefficients $\propto_{i\ j}$ represents the color associated with the pixel whose position is I by using the concept of a superposition of all possible colors with $0 \leq i \leq 2^{2n}$. In this for I, coefficients $\propto_{i\,j}$ holds the value 1 only when the color associated with the pixel is j, otherwise holds 0.

F. Three channel Representation for Quantum Colored images model (QMCR)

RGB three channel representations for quantum colored images model was suggested by Abdolmalekya *et al.* [10]. It is based on the NEQR. The formulation of QMCR representation is shown:

$$|\mathrm{I}\rangle = \frac{1}{2^{n}} \sum_{y=0}^{2^{n-1}} \ \sum_{x=0}^{2^{n-1}} |C_{RGByx}\rangle \otimes\ y\ x\rangle \quad (16)$$

Where the state $|C_{RGByx}\rangle$ is used to encode the information of the R, G and B channels (2^{q} range of each channel) of the pixel. The state $|C_{RGByx}\rangle$ is defined as follows:

$$|C_{RGByx}\rangle = |R_{yx}\rangle||G_{yx}\rangle|B_{yx}\rangle \quad (17)$$

$$|R_{yx}\rangle = \ |\mathrm{r}_{yx}^{q-1}\ \mathrm{r}_{yx}^{q-2} \ldots \mathrm{r}_{yx}^{q-0}\rangle \quad (18)$$

$$|G_{yx}\rangle = |\mathrm{g}_{yx}^{q-1}\ \mathrm{g}_{yx}^{q-2} \ldots \mathrm{g}_{yx}^{q-0}\rangle \quad (19)$$

$$|B_{yx}\rangle = |\mathrm{b}_{yx}^{q-1}\ \mathrm{b}_{yx}^{q-2} \ldots \mathrm{b}_{yx}^{q-0}\rangle \quad (20)$$

Where $\mathrm{r}_{yx}^{k}, \mathrm{g}_{yx}^{k}, \mathrm{b}_{yx}^{k} \in \{0,1\}$ and $R_{yx}, G_{yx}, B_{yx} \in \{0, 1, \ldots 2^{q}-1\}$.

G. Quantum Image representation for log-polar images (QUALPI)

Y. Zhang *et al*. [11-12] proposed the model of QUALPI. For Classical preparing of pictures, idea of log-polar is broadly utilized as an inspecting technique here on account of log-polar picture of size 2^{m} x 2^{n}, examining goals pursuing of the log-range and that of precise introduction are relied upon to be 2^{m} and 2^{n} respectively. This model was investigated for the purpose of processing and storage of the sampled images in log-polar coordinates. Existing quantum computing based image processing models can only present the image sampled in Cartesian coordinates, due to which rotation and scaling operation is not possible to be performed in the existing model. QUALPI utilizes three entangled qubit. In which first one is used for storing the gray scale information, second one is used for log-radius position and the last one is used to retrieve the information for the angular position of all the pixel in case of log-polar image. Estimation of every pixel is to be recorded on the premise condition of a standardized superposition which comprises of qubit groupings, in order to operate on them simultaneously. In the QUALPI model, further geometric transformation can be performed in a simple manner. It also includes the complex one named as symmetric transformation and rotation. The Mathematical formulation of QUALPI representation is shown:

$$|\mathrm{I}\rangle = \frac{1}{\sqrt{2^{m+n}}} \sum_{\rho=0}^{2^{m}-1} \ \sum_{\theta=0}^{2^{n}-1} \sum_{\theta=0}^{2^{n}-1} \ (|g(\rho,\theta)\rangle \otimes |\rho\rangle \otimes |\theta\rangle\ ) \quad (21)$$

Where $g(\rho,\theta)$ used to represent the gray - scale value of each pixels. Gray range of the image is expected to be 2^{q}, so that this can be encoded as:

$$g(\rho,\theta) = \mathrm{C0C1}\ \ldots \mathrm{Cq} - 2\mathrm{Cq} - 1, g(\rho,\theta)\ \in [0, 2\mathrm{q} - 1] \quad (22)$$

It is easy to understand that the pixels lying in different quadrant have different grey scale. *m + n + q qubits are* needed for the storage of information into a QUALPI state for a 2^{m} x 2^{n} log - polar image with gray range 2^{q}. The entire

procedure of arrangement of quantum picture will not cost more than O(q(m+n). 2^{m+n}) for the 2^m x 2^n log-polar quantum image whose grey range value is 2^q . QUALPI is, out of the blue, intended for the pictures tested in log-polar directions.

H. *Simple Quantum (SQR) representation model of infrared images.*

Suzhen *et al*. [13] proposed SQR model. This model was proposed to limit the drawbacks associated with the Qubit lattice and FRQI model. This model depends on qualities of the infrared pictures. SQR model involves the replacement of the color information with the radiation values as the coefficient values. The mathematical formulation of SQR representation is shown:

$$|\mathrm{I}\rangle = |\psi_{ij}\rangle \quad (23)$$

i = 1, 2,…, n_1, *j = 1,2,…,*n_2 *are real numbers. Where* $|\psi_{ij}\rangle$ = = $\cos\theta_{ij}\,|0\rangle + \sin\theta_{ij}|1\rangle$, we can view $|\psi_{ij}\rangle$ in the form of Bloch sphere as a great circle.

SQR model offers the following advantages in comparison to the Quantum Lattice model and latest suggested FRQI model:

1. SQR model requires two n-qubit states so as to keep the extraordinary values. It additionally requires a 2n straightforward quantum gate so as to define the quantum infrared picture in comparison with the Quantum Lattice model. While, n may be neglected because it is a very small number.
2. Simple quantum gate is required to setup the SQR quantum image, which also shows a quadratic decrease compared to the FRQI.
3. It also allows to perform more number of image operations conveniently which are based on SQR in comparison to the original Qubit Lattice representation.

SQR also has the ability to hold more information which includes image information as well as marked information. Here marked information used refers to that kind of information which requires emphasizing, on infrared target or some other vital geographical locations etc.

I. *Quantum states for M Colors and Quantum states for N coordinate (QSMC & QSNC)*

This model requires two sets of quantum states one for *M colors* and the other for *N coordinates*, so that both gray scale and information related to the color of an image can be represented efficiently. This model provides a lossless compression and quantum search enabled image segmentation technique which is universally applicable for both the gray scale and the color images. QSMC & QSNC both require two set of quantum states in order to capture the image, where QSMC is used to represent the M colors while QSNC is required to denote the coordinates of N pixels of an image [14]. Two bijective functions are developed for the purpose of storing the information regarding the coordinate and color of an image with the help of quantum states, *One from M's different colors to M's different angles and the second from N's to N's various angles.* Expression of mathematics associated with QSMC & QSNC Quantum image is shown under:

$$|\mathrm{I}\rangle = \frac{1}{2^n}\sum_{i=0}^{2^{2n}-1} |QSMC_i\rangle \otimes |QSNC_i\rangle \quad (24)$$

Where

$$|QSMC_i\rangle = \cos\phi\,\mathrm{i}\,|0\rangle + \sin\phi\,\mathrm{j}|1\rangle \quad (25)$$

$$|QSNC_i\rangle = \cos\theta\,\mathrm{i}|0\rangle + \sin\theta\,\mathrm{i}\,|1\rangle \quad (26)$$

ϕ_i , $\theta_i \in [0, \pi/2]$, i = 1, 2, ... 2^{2n}-1.

This model is designed in such a way that in a quantum system only 2N + m qubits is stored an image of N pixels and M different colors.

J. *Normal arbitrary Quantum Superposition State (NAQSS)*

This model is designed for multi-dimensional image representation. Li *et al*. [15] proposed this model. Also known as the normal arbitrary quantum superposition state (n+1) qubit. In this model n qubits represents 2n pixel colors and coordinates and the remaining 1 qubit represents information about image segmentation. In this a bijective function is established with the goal that each pixels can locate a relating value for an interval of [0, π/2] by making up a one to one correlation for angle and color. Function is shown as: *g: A→R where A* represents the data regarding the position of the picture in a k- dimensional Euclidean space. The mathematical representation of NAQSS image is shown:

$$|\mathrm{I}\rangle = \sum_{i=0}^{2^n-1} \theta_i\,|v_1\rangle\,|v_2\rangle \ldots |v_k\rangle \otimes |x_i\rangle \quad (27)$$

Where $|x_i\rangle = \cos\propto_0 |0\rangle + \sin\propto_0 |1\rangle$

Represents the information related to the segmentation, where $\propto_0$ is corresponding to the m in order to establish a bijective function. If we divide the image into m sub - images so that it will contains the pixels corresponding to the $|v_1\rangle\,|v_2\rangle \ldots |v_k\rangle$ coordinates.

K. *(2 –D QSNA) Two Dimensional Quantum states and Normalized Amplitude*

Above model for quantum image representation was proposed by *Madhur Srivastava et al. [16]*. The proposed method, two-dimensional quantum state and normalized amplitude, only requires ($[\log_2 \mathrm{N}] + [\log_2 \mathrm{N}]$) qubits. As compared to the previous model like FRQI and NEQR, they are only designed for only square images. Square quantum image needs ($[\log_2 \mathrm{N}] + [\log_2 \mathrm{N}] + l$) qubits. As we see here *l* is the additional qubits representing pixel's amplitude or intensity value, which leads to the increase in storage and reduces the efficiency of representation. For overcoming the above drawbacks Madhur Srivastava *et al. [*16] proposed the 2.D QSNA model, in which square as well as

rectangular images are processed which represent amplitude/intensity without using additional qubits. The formulation of 2-D QSNA representation is shown:

$$Y = \sum_{p=1}^{M} \sum_{q=1}^{N} \propto p,q \; Lp,q \tag{28}$$

Where Y represent the 2-D quantum image,

$$\propto p,q = \sqrt{\frac{A_{p,q}}{\sum_{p=1}^{M} \sum_{q=1}^{N} A_{p,q}}} \tag{29}$$

$$Lp,q = |I\rangle p \otimes \langle J|q \tag{30}$$

By substituting the values of $\propto_{p,q}$ *and* $L_{p,q}$ in equation no. We get,

$$Y = \frac{1}{\sqrt{A_T^{M\,X\,N}}} \sum_{p=1}^{M} \sum_{q=1}^{N} \sqrt{A_{p,q}} \, (|I\rangle \, p \otimes \langle J|_q) \tag{31}$$

L. Quantum representation of Multi Wavelength Images (QRMW)

In Today's scenario, at different wavelength image processing is very important with respect to the hyperspectral imaging, satellite based/airborne remote sending and detection of military target. So according to the application and importance of image processing at different wavelength, we need a model which represent quantum image at different wavelength. QRMW [17] model uses basic states of qubit sequence to store the values at different wavelength of each pixel of the image. This model uses three separate qubit register sequences to hold each pixel's position, wavelength, and color values. The first qubit sequence contains the color value for the pixel wavelength channel in the image, the second qubit sequence encodes the information for the wavelength channel and the last third qubit encodes position information.

The formulation of QRMW representation is shown:

$$|I\rangle = \frac{1}{\sqrt{2^{b+n+m}}} \sum_{\lambda=0}^{2^b-1} \sum_{y=0}^{2^n-1} \sum_{x=0}^{2^m-1} |f(\lambda,y,x)\rangle \otimes |\lambda\rangle \, p \otimes |yx\rangle \tag{32}$$

Where $f(\lambda,y,x) = C_{\lambda_{yx}}^{0} C_{\lambda_{yx}}^{1} \ldots C_{\lambda_{yx}}^{q-2} C_{\lambda_{yx}}^{q-1}$, $C_{\lambda_{yx}}^{0} \in [0,1]$, $f(\lambda,y,x) \in [0, 2^q - 1]$, λ is a channel information and yx is a position information.

QRMW model uses lesser qubits than the QMCR model for all channels.

M. Infra -Red Color Model

Infra-red color model reveals the lucid representation of a quantum infra-red image with respective pixel positions. We use 2x2 dimensional quantum images represented by infra-red model of quantum image. It is given as:

$$|I\rangle = \{|\psi_{ij}\rangle\} \tag{33}$$

Where (I,j) is the pixel position in the image and

$$|\psi_{ij}\rangle = \cos\theta \, ij \, |0\rangle + \sin\theta j|1\rangle \tag{34}$$

Getting quantum image in (2x2) dimensions, we get

$$|I\rangle = \{|\psi_{11}\rangle, \{|\psi_{12}\rangle, \{|\psi_{21}\rangle, \{|\psi_{22}\rangle \tag{35}$$

With,

$$|\psi_{11}\rangle = \cos\theta \, 11|0\rangle + \sin\theta \, 11|1\rangle \tag{36}$$

$$|\psi_{12}\rangle = \cos\theta \, 12|0\rangle + \sin\theta \, 12|1\rangle \tag{37}$$

$$|\psi_{21}\rangle = \cos\theta \, 21|0\rangle + \sin\theta \, 21|1\rangle \tag{38}$$

$$|\psi_{22}\rangle = \cos\theta \, 22|0\rangle + \sin\theta \, 22|1\rangle \tag{39}$$

($|\psi_{ij}\rangle$) these are the pixels represented in the form of qubits. The simplest case without color is assumed here. It is calculated as:

$$P(0) = |\psi_{11}\rangle \otimes |\psi_{12}\rangle \otimes |\psi_{21}\rangle \otimes |\psi_{22}\rangle \tag{40}$$

Simplifying,

$$P(0) = \begin{bmatrix} \cos\theta 11 \\ \sin\theta 11 \end{bmatrix} 2x2 \otimes \begin{bmatrix} \cos\theta 12 \\ \sin\theta 12 \end{bmatrix} 2x2 \otimes \begin{bmatrix} \cos\theta 21 \\ \sin\theta 21 \end{bmatrix} 2x2 \otimes \begin{bmatrix} \cos\theta 22 \\ \sin\theta 22 \end{bmatrix} 2x2 \tag{41}$$

P (0) is the whole initial state of quantum image. Assuming that each pixel faces the de-coherence in the quantum image, we use the following de-coherence channels:

a. Bit Flip Channel
b. Phase Flip
c. Bit Phase Flip

The Kraus operator of Bit Flip channel is given as

$$bo = \begin{bmatrix} \sqrt{p} & 0 \\ 0 & \sqrt{p} \end{bmatrix} \tag{42}$$

and

$$b1 = \begin{bmatrix} \sqrt{p} & 0 \\ 0 & \sqrt{p} \end{bmatrix} \tag{43}$$

Since there are 4 qubits in $[2\,X\,2]$ quantum image, we have to write the Kraus operator for 4 qubits. Let's consider that all qubits are subjected to independent environment. Let's i start with two qubits. On applying the de-coherence channel in the 1st pixel the result will be:

$$P^1(t) = (E_0 \otimes I)\, P(0)\, (E^t_0 \otimes I) + (E_1 \otimes I)\, P(0)\, ((E^t_1 \otimes I) \tag{44}$$

Now with the result obtained above, we evolve the second pixel. So we take p^1 (t) and evolve under the de-coherence noise under the 2nd

$$P(t) = (I \otimes E_0)\, P^1(t)\, (I \otimes E^t_0) + (I \otimes E_1)\, P^1(t)\, (I \otimes E^t_1) \tag{45}$$

$$= (I \otimes E_0)\, [(E_0 \otimes I)\, P(0)\, ((E^t_0 \otimes I) + (E_1 \otimes I)\, P(0)\, ((E^t_1 \otimes I)] \, (I \otimes E^t_0) + (I \otimes E_1)\, [(E_0 \otimes I)\, P(0)\, ((E^t_0 \otimes I) + (E_1 \otimes I)\, P(0)\, ((E^t_1 \otimes I)] \, (I \otimes E^t_1) \tag{46}$$

$$= (I \otimes E_0)\, (E_0 \otimes I)\, P(0)\, ((E^t_0 \otimes I)\, (I \otimes E^t_0) + (I \otimes E_0)\, (E_1 \otimes I)\, P(0)\, ((E^t_1 \otimes I)\, (I \otimes E^t_0) + (I \otimes E_1)\, (E_0 \otimes I)\, P(0)\, ((E^t_0 \otimes I)\, (I \otimes E^t_1) + (I \otimes E_1)\, (E_1 \otimes I)\, P(0)\, ((E^t_1 \otimes I)\, (I \otimes E^t_1) \tag{47}$$

$$= (E_0 \otimes E_0)\, P(0)\, (E^t_0 \otimes E^t_0) + (E_1 \otimes E_0)\, P(0)\, (E^t_1 \otimes E^t_0) + (E_0 \otimes E_1)\, P(0) (E^t_0 \otimes E^t_1) + (E_1 \otimes E_1)\, P(0)\, (E^t_1 \otimes E^t_1) \tag{48}$$

So we get

$$M_1 = (E_0 \otimes E_0) \quad (49)$$

$$M_2 = (E_0 \otimes E_1) \quad (50)$$

$$M_3 = (E_1 \otimes E_0) \quad (51)$$

$$M_4 = (E_1 \otimes E_1) \quad (52)$$

So the two pixels quantum image can be written after passing the quantum image, the Decoherence is as below:

$$P(t) = \sum_{i=1}^{4} Mi\, P(0)\, M_i^t \quad (53)$$

Here it is noted that, for 2 qubits, 2^2=4 kraus operator is needed, so for 4 qubits quantum image, the number of Kraus operator needed will be $2^4 = 16$.

Table: 1 Comparison of Different Image Representation Model

Image	Representation	Qubits Required	Complexity	Color Encoding	Comments
FRQI [3]	$\|I\rangle = \frac{1}{2^n}\sum_{y=0}^{2^{n-1}} \|Q_f\rangle\|i\rangle$	*2m+1*	*O(2^{4n})*	1 angle vector, gray scale	FRQI encodes an image color using one qubit.
MCQI [5]	$\|QI\rangle = \frac{1}{2^{n+1}}\sum_{f=0}^{2^{2n-1}} \|A_{RGB\alpha}^{f}\rangle \otimes \|f\rangle$	*2m+3*	*O(2^{4n})*	3 angle vector, RGB	MCQI uses three qubits to carry color information from multichannel.
NEQR [6,7]	$\|I\rangle = \frac{1}{2^n}\sum_{y=0}^{2^{n-1}}\sum_{x=0}^{2^{n-1}} \otimes_{i-0}^{q-1} \|c_{yx}^{i}\rangle \quad \|y,x\rangle$	*q +2n*	*O(qn.2^{2n})*	Qubit sequence, gray scale	NEQR requires a q +2n qubits for the construction of the quantum image
CQIR [8,9]	$\|I\rangle = \frac{1}{2^n}\sum_{i=0}^{2^{2n-1}}\sum_{j=0}^{2^{2n-1}} \propto_{ij} \|j\rangle \|i\rangle$	*2n, m=log_2L*	*O(log_2L.n. 2^{2n})*	Qubit sequence, gray scale	CQIR image representation is used for better preparing operation for example computing negative, binarization and histograms
QMCR [10]	$I\rangle = \frac{1}{2^n}\sum_{y=0}^{2^{n-1}}\sum_{x=0}^{2^{n-1}} \|C_{RGByx}\rangle \otimes \|y\,x\rangle$	*4q +2n*	*O* (qn x $2^{(2+2n)}$)	RGB	QMCR uses NEQR model to represent RGB-three channel representation
QUALP [11,12]	$I\rangle = \frac{1}{\sqrt{2^{m+n}}}\sum_{\rho=0}^{2^m-1}\sum_{\theta=0}^{2^n-1}$ ($\|g(\rho,\theta)\rangle \otimes \|\rho\rangle \otimes \|\theta\rangle$)	*Gray range 2^q*	*O(q(m+n). 2^{m+n})*	Qubit sequence, gray scale	For the log polar images, QUALPI uses three entangled qubit.
SQR [13]	$\|I\rangle$=Cos $\theta_{ij}\|0\rangle$ + Sin $\theta_{ij}\|1\rangle$	two n-qubit	O(2^{2n})	1 angle vector, infrared	SQR uses to represent the infrared quantum images
NAQSS [14]	$\|I\rangle = \sum_{i=0}^{2^n-1} \theta_i \|v_1\rangle\|v_2\rangle \ldots \|v_k\rangle \otimes \|x_i\rangle$,	(n+1)-qubit	O($\log 2^n.2^{2n}$)	1 angle vector/ gray scale	This model also known as (n+1)-qubit normal arbitrary quantum superposition state. use to store color, coordinate of 2^n pixels and one qubit for picture segmentation information
QSMC & QSNC [15]	$\|I\rangle = \frac{1}{2^n}\sum_{i=0}^{2^{2n}-1} \|QSMC_i\rangle \otimes \|QSNC_i\rangle$	2N + m qubits	O(2^{4n})	I angle vector, gray scale/RGB	QSMC & QSNC both require two set of quantum states in order to capture the image
2-D QSNA [16]	$Y = \frac{1}{\sqrt{A_I^{M\,X\,N}}}\sum_{p=1}^{M}\sum_{q=1}^{N}\sqrt{A_{p,q}}\,(\|I\rangle_p \otimes \langle J\|_q)$	m+n	Pure state	Gray scale/ different color channels	only requires ([Log_2 N] + [Log_2 N]) qubits
QRMW [17]	$\|I\rangle = \frac{1}{\sqrt{2^{b+n+m}}}$ $\sum_{\lambda=0}^{2^b-1}\sum_{y=0}^{2^n-1}\sum_{x=0}^{2^m-1} \|f(\lambda,y,x)\rangle \otimes \|\lambda\rangle_p \otimes \|yx\rangle$	q + 2 + 2n	O(q x $2^{(2+2n)}$)	4 channels and 2^q color scale	QRMW model uses less qubits as compare to MCQI model

V. Conclusion

FRQI illustration utilizes the fundamental quantum gates e.g NOT, CNOT and Toffoli gates. FRQI encodes an image color using one qubit. The representation of CQIR images is used for preparing, negative computing, binarization and histograms. QMCR uses NEQR model to represent RGB-three channel representation. QMCR and MCQI will have more time complexity. Blending operator in MCQI, α is used to mix an image. MCQI uses three qubits to carry color information from multichannel.

It uses quantum image color information R, G, and B. Its color transformation includes the Col operator which is used to shift the gray-scale value to the color channel preselected. CS operator is also used in MCQI which work as swap operator (swap grayscale values between two channels). Numerous mind boggling relative changes, for example, revolution and scaling can't be performed with Qubit Lattice, Entangled Image, Real ket and FRQI models in light of the fact that a great deal of irreversible insertions are required. Only images sampled in Cartesian coordinates can be stored and processed by existing models. For the log polar images, novel quantum representation model QUALPI

Suggested to overcome the disadvantages of current quantum image models. SQR uses infrared quantum images to represent color information from infrared radiation energy that could improve visual capacity in nearly any environment. It uses both qubit Lattice as well as FRQI methods. NAQSS is used to store color, coordinate of 2^n pixels and one qubit for image segmentation information. QSMC and QSNC are used to store image color and coordinate image information by quantum states. QRMW model uses less qubits as compared to MCQI model. QRMW model, 2^n x2^m rectangular images and 2^n x$2^{n \text{ square}}$ images can be represented in other models. In QRMW U_{cc} operator is used. $U_{cc} = x^{\otimes q} \otimes I^{\otimes b+n+m}$. It applies quantum X gate to each qubit of the qubit sequence in the first register. QRMW uses 4 channels 2^q color scale which is more than the earlier discussed image model.

Most of the quantum representation techniques are highly dependent on FRQI. This field's future is to find a way to represent better - performing images than FRQI. In this investigation we have shown some of quantum image representation which is better than FRQI.

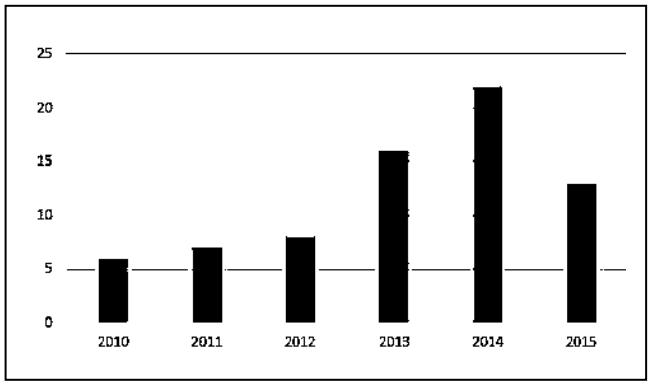

Fig. 3. Bar graph of the number of published works between 2010 and 2015 for Quantum image representation. The number of works has increased, indicating that more attention is being paid to the field of quantum image representation.

It very well may be seen that the consideration around Quantum Image representation has been an expanding pattern, with an especially sharp increment in 2014. In spite of the shortage in 2015 the quantity of concentrates in 2015 has outperformed the number contrasted with years before 2013[18]. Besides, driving diaries have been giving more regard for quantum image representation.

***Abstract*—Diabetes is a lifelong disease that has the capability to badly hinder the health and damages the retina causing Diabetic Retinopathy. Diabetic retinopathy is majorly identified by exudates.In this paper the coloured fundus images from datasets DIARETDB, MESSIDOR and E-OPTHA are considered.Initially image pre-processing is done for better detection of exudates (bright lesions)in the retina.Gray Level Co-occurrence Matrix (GLCM) is used for extracting the features. Finally, the classification for normal and abnormal retinal images is done by using various machine learning models like decision tree, logistic regression, SVM, kNN, ensemble classifier and analyzing their performances.Ensemble classifier (subspace discriminant), SVM and kNN give better accuracy than the other learners.This automated process will save the manual work and time of the ophthalmologists.Early detection of the exudates in the eyes is crucial for preventing the vision loss in diabetic patients.**

Keywords: **Diabetic retinopathy, exudates, GLCM, Classification**

I. Introduction

Diabetes is a chronic, lifelong condition that affects one's body ability to capitalize the energy found in food. This happens when either the pancreas can't produce enough insulin or the cells in the body become resistant to insulin. Diabetes can cause long term systematic complications that affect heart, nerves, blood vessels, kidneys and eyes.A patient might suffer from serious health problems if diabetes is not treated on time.The people who have suffered diabetes for a long time are affected by Diabetic Retinopathy. It is a micro vascular complication that damages blood vessels supplying the retina.It results in vision loss if care is not taken on medication and treatment. Diabetic Retinopathy is indicated by various features like micro aneurysms, haemorrhages, hard exudates and soft exudates or cotton-wool spots as shown in figure 1.Initially micro aneurysms which are small, dark red spots are the primary abnormality found in the eye and it further results in haemorrhages, that appear alone or in clusters in the compact middle layers of the retina .Micro aneurysms have circular shape and their sizes vary from 10-100 microns.Retinal nerve fibre layer is the location of flame shaped haemorrhages.The most important symptoms of diabetic retinopathy are hard exudates, that have varying sizes and are bright yellow colored lesions.Cotton wool spots which are light yellowish white lesions and also called soft exudates are found in severe stages of diabetic retinopathy.Cotton wool spots are created when the retinal pre-capillary arterioles that supply blood to the nerve fiber layer get blocked and the local nerve fiber axons get swollen.Detection of diabetic retinopathy is very tedious and tough in the initial stages.The earliest visible signs of diabetic retinopathy are exudates. So our focus is early diagnosis of diabetic retinopathy by discovering exudates and protection of the diabetic patients from loss of vision.Drusens are yellow deposits under the retina and made up of lipids (fatty protein) called Bruch's membrane. They shows a sign of dry age-related macular degeneration and can be often confused with exudates.

II. Literature Review

The developing predominance of diabetes overall expands the quantity of cases that should be surveyed by doctors. Furthermore, the cost involving the regular check ups and examination are very high and absence of expert specialists keep many people away from accepting a sufficient and effective medication. It will give the chance to analyze huge datasets of retinal images. Average examination expenses can be lessened as a result of decreasing the workload of prepared classifiers. Clara I. Sánchez et al.[11] focused on the fact that the early symptoms of diabetic retinopathy are hard exudates and used edge detection to differentiate the hard exudates from the other bright lesions. The method was implemented on the dataset of 80 images.Harry Pratta et al. [7] recently approached the problem of detecting the diabetic retinopathy by applying deep learning over a relatively very large dataset of the retinal images. They worked on detection of exudates and drusens with help of colour normalisation and applied CNN attaining accuracy of 75% . Morium Akter et al .[1] performed morphology based exudates detection from colored fundus images.Only morphological operations are used and no machine learning algorithms were used. Enrique V. Carrera et al [2] discovered diabetic retinopathy with the help of SVM and just performed image processing and no features extraction . Vaishali Suryawanshi et al.[4] performed only grayscale preprocessing and only neural network model for classification. Jayant Yadav et al.[5] also worked on fundus images using feed forward neural network. Handayani Tjandrasa et al.[6] did image preprocessing,features extractiona and just used a single model which is SVM for classification of hard exudates.Daniel Welfera et al.[12] worked on detection of exudates using morphological operations only and no machine learning algos were used.Huan Wang et al.[13] worked on detection of exudates using statistical classification and managed to attain accuracy of 70%.Sidra Rashid et al. [14] did detection of exudates by using CLAHE and then applying edge detection algorithm and fuzzy C-means clustering.Dynamic threshold and median filter techniques are used for detecting the hard exudates in [15].

retina which is the major cause of diabetic retinopathy. The figure 2 depicts the methodology used for diabetic retinopathy detection.

A. Image Pre-Processing

Digital image processing is needed for upgrading the visual appearance of an image by extracting important features such as edges , to give more sharpness etc. minor errors can be rectified, image sizes can be increased or decreased , unrecognisable features can be made prominent

etc. thus helping us all to have better vision and adding meaningfulness to the images.The various sub steps used in image processing are :

1) RGB to Grayscale Conversion: The process of converting the RGB image to a grey scale image helps to make the image more uniform as shown in figure 3. The grey scale image uses all the three values of red, green and blue by taking into account only a factor of these three channel values as follows: I = 0.299*R + 0.587*G + 0.114*B; Where I is the resulting grey scale image, R is the pixel colour value of red channel, G is the pixel colour value of green channel and B is the pixel colour value of blue channel.

The major reason to convert the images to grey scale is to reduce the complexities that occur due to colour.

2) Thresholding: Thresholding is an elementary methodology of image segmentation.Thresholding can be used to create binary images with grayscale images as the input. Thresholding segments an image by changing values of all pixels whose intensity values are above a threshold to a foreground value and all the remaining pixels to a background value.A global threshold is used in the conventional thresholding method for all pixels with threshold value T as shown in figure 4a.The gray level values below T are background and those above T are foreground objects.We have used a more sophisticated version of thresholding which is called as adaptive thresholding that varies the threshold dynamically over the image.It assists in the changing lighting conditions in the image, e.g. those occurring due to strong illumination gradient or shadows as shown in figure 4b

3) Median Filtering: It is a highly used nonlinear method for removing noises from images and is very successful at removing noise while maintaining the edges. It is particularly used for removing 'salt and pepper' type noise as displayed in figure 5b .For calculating the median ,all the pixel values are sorted in numerical order from the window and then the pixel being considered is replaced with the middle (median) pixel value as shown in figure 5a .

4) Morphological Operation: These operations depend on the elative ordering of pixel values and are associated with the shape or morphology of features present in an image.An opening operation is composed of an erosion operation which is followed by a dilation operation with the help of the same structuring element that is a disc of radius 3 in our case. The erosion of a binary image f by a structuring element s gives a new binary image g with ones in all locations (x,y) of a structuring element's origin at which that structuring element s fits the input image f, i.e. g(x,y) = 1 is s fits f and 0 otherwise, repeating for all pixel coordinates (x,y) as shown in figure 6a. The dilation of a binary image f by a structuring element s produces a new binary image g with ones in all locations (x,y) of a structuring element's origin at which that structuring element s hits the the input image f, i.e. g(x,y) = 1 if s hits f and 0 otherwise, repeating for all pixel coordinates (x,y) as shown in figure 6b.In erosion the outer boundary of pixels are stripped off whereas in dilation boundary of image is increased .It helps in further removing noise from the image as shown in figure 7.

5) Optic Disc Removal: Optic Disc is extracted using another morphological operation on the binary images using bwareafilt in MATLAB which extracts particular objects from the images . The Optic disc was extracted and subtracted from the images and hence making them free from optic disc which has similar texture to that of exudates.bwareafilt also helps in removal of the boundary of the fundus images of retina as shown in figure 8

B. Features Extraction

Feature Extraction is vital as huge amount of details and information lessens the effectiveness and meaning of data. There can be few data attributes which are collected together for creating and testing a model may not provide meaningful information to the model. Some may actually deviate from the quality and accuracy of the model.In our proposed methodology gray-level co-occurrence matrix (GLCM) is used which is a statistical technique to inspect the texture which takes into consideration the spatial relationship of pixels.The texture of an image is characterized by calculating how often pairs of pixel with specific values and in a specified spatial relationship occur in an image, thus forming a GLCM matrix and then extraction of statistical measures from this matrix are considered which are shown in the table 2.

GLCM is basically second order statistics therefore GLCM collected information regarding pixel of pairs. For creating GLCM, graycomatrix function is used.

C. Classification using machine learning models

The final phase is about application of The Machine Learning Models on the features extracted using GLCM and perform comparative analysis of them .Various models like Decision Trees ,Discriminant Analysis ,Logistic Regression ,Support Vector Machines , Nearest Neighbour and Ensemble Classifiers are trained and tested on the dataset provided with the binary target class as whether exudates are present i.e. class 1 or they are absent i.e class 0.The Models' Accuracy , Confusion matrices and ROC curves are also analyzed.The Ensemble Classifier of subspace discriminant improves the accuracy of discriminant analysis which assumes that different classes generate data based on different Gaussian distributions .Subspace ensemble is better as it makes use of lesser memory as compared to other ensembles with all predictors, and can handle and manage missing values (NaNs).

The basic random subspace algorithm makes use of the following parameters.

1) m, where m is the number of variables or dimensions which have to be sampled in each learner.
2) d, where d is the number of dimensions possessed by the data, that is the number of predictors or columns in the data matrix.
3) n, where n denotes the number of models or learners are present in the ensemble.

The basic random subspace algorithm performs the following steps:

1) A random set of m predictors has to be chosen from the d possible values without replacement.
2) With the help of the m chosen predictors, weak learners are trained.
3) Steps 1 and 2 are repeated until there are n weak learners.
4) Predict by averaging the score prediction of the weak learners, and classify the category with the highest average score.

IV. Results and Discussions

A. Dataset Description

The dataset used for detection of exudates is a combination of three datasets namely MESSIDOR,DIARETDB1 and E-OPTHA .

1) MESSIDOR : This dataset consists of 1200 colored fundus eye images of the rear view of retina which has been acquired by 3 ophthalmologic departments with the assistance of a colored video 3CCD camera on a Topcon TRC NW6 non-mydriatic retinograph with a 45 degree field of view.800 fundus images are obtained by diluting the pupil using a drop of Tropicamide at 0.5% and 400 fundus images are obtained without dilation.
2) DIARETDB1 : This dataset is a collection of 89 colored fundus images.The experts who took part in evaluation of the images confirmed that 84 fundus images display signs of diabetic retinopathy, and 5 images are normal that is they don't show any of the characteristics of diabetic retinopathy. A 50 degree field-of-view digital fundus camera is used for capturing the images which, also has

(a) Original Colored Fundus Image (b) Grayscale Fundus Image

TABLE II: Statistics Of Textural Features Extraction using GLCM

Statistics	Details
Contrast	The local variations in the gray-level co-occurrence matrix are measured
Correlation	The joint probability occurrence of the specified pixel pairs is calculated
Energy	The sum of squared elements in the GLCM is provided.also called as uniformity
Homogeneity	The closeness of the distribution of elements in the GLCM to the GLCM diagonal is measured.

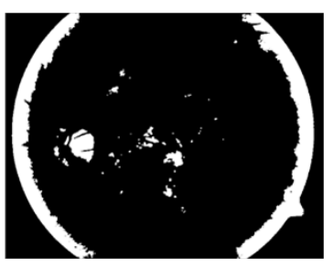

Fig. 7: Fundus image after opening operation to remove objects causing noise.

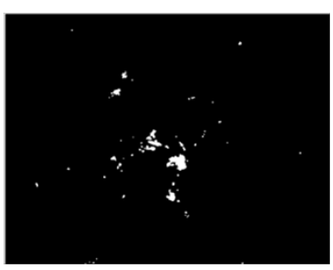

Fig. 8: Removal of optic disc

an advanced imaging settings. This data set is also known as ”calibration level 1 fundus images”.

3) E-OPTHA : This dataset of colored fundus images having 47 images with exudates and 35 images with no signs of exudates or any other lesions is drafted for scientific researches in the field of Diabetic Retinopathy (DR).OPHDIAT© Telemedical network has been used for the generation of the images for screening of DR in a project which has been funded by the French Research Agency (ANR).

TABLE III: Comparison of performance of various models

Model	Accuracy	Sensitivity	Specificity
Proposed ensemble of discriminant analysis	0.760	0.76	0.77
Decision Tree (Fine)	0.700	0.77	0.72
Decision Tree(Medium)	0.750	0.77	0.70
Decision Tree(Coarse)	0.755	0.76	0.66
Logistic Regression	0.765	0.77	1.00
SVM(Linear)	0.746	0.76	0.80
SVM(Quadratic)	0.746	0.76	0.70
SVM(Cubic)	0.633	0.76	0.79
KNN(Fine)	0.659	0.77	0.72
KNN(Medium)	0.757	0.76	0.71
KNN(Coarse)	0.766	0.75	0.70
Ensemble(Bagged Trees)	0.725	0.66	0.78
Ensemble(Sub-space KNN)	0.711	0.78	0.75
Ensemble(RUSBoosted Trees)	0.514	0.77	0.71

B. *Performance Analysis*

The images have a large variation in colour and illumination with in and between the images. Every image can be classified as exudates or not exudates. Hence, the four outcomes of the analysis are two classifications and two misclassifications. The quality measures used in binary classification are sensitivity(SN), specificity(SP) and accuracy(Acc) and these metrics.

The efficiency and authenticity is evaluated by using the formulas and defining necessary terms as follows.

$$Accuracy = \frac{(Correctlyidentifiedimages)}{(TotalNumberOfImages)}\% \qquad (1)$$

or

$$Accuracy = \frac{(T_N + T_P)}{(T_N + F_P + F_N + T_P)}\% \qquad (2)$$

An approach that combines the image processing tools with the machine learning for the discovering diabetic retinopathy by examining the coloured retinal images is followed. It was observed that the detection of the regions that contains the bright lesions(exudates) was achieved effectively by use of normalizing various factors such as conversion of the RGB retinal image into grayscale and binarising them. Morphological operators were used to clarify the candidate regions and remove all unwanted elements. The classification is done with training and testing ratio as 70:30 and also cross validation method of K-Folds is applied with number of folds set as 5 so as to avoid the overfitting problem by dividing the data sets into folds and estimating the accuracy on each fold. Also sensitivity and specificity are measured for various models.Sensitivity, also known as true positive rate, is the ability to correctly measure the proportion of actual positives which have been identified correctly and specificity, also named as true negative rate is the ability to correctly measure the proportion of actual negatives which have been identified correctly.The useful textural features shown in figure **??** are extracted by the GLCM feature extraction technique and further this detailed information is provided to the machine learning models which proved that subspace discriminant ensemble achieved a better accuracy of 76.6% as compared to other models.The overall methodology was effective and robust. The accuracy,sensitivity and specificity of different models are shown in table III and scatterplot, confusion matrix and ROC-AUC curve of ensemble model using subspace discriminant are displayed in figure 9.

V. Conclusion

The prposed approach combines the image processing tools with the machine learning for the recognizing the diabetic retinopathy via exudates in the coloured retinal images. It is achieved effectively by use of normalizing various factors such as conversion of the RGB retinal image into grayscale and binarising them. Morphological operators were used to remove all unwanted elements.The GLCM feature extraction technique is used and the classification of the images proved that ensemble (subspace discriminant), SVM, KNN achieved a better accuracy of 76.6% than the other models. Finally an efficacious automated system for the early detection of diabetic retinopathy based on the identification of exudates can be made based on the methodology carried out.

Abstract: **Modern day devices often use an AC source as input even though they are operated with DC voltage. In order to have a suitable and flexible DC output, an AC-DC converter is used. However the conventional converters are not suited for high voltage output without sacrificing conversion efficiency. A new topology of Cascaded Boost-SEPIC (CBS) converter is proposed in this paper. This converter is capable of delivering output voltage as high as 1255V at high conversion efficiency. Maximum power factor of 0.97 and minimum THD of 9.94% is ensured by current mode PI controller.**

Keywords—AC-DC converters; High voltage gain; Conversion efficiency; THD; power factor improvement

I. INTRODUCTION

In day to day life electronic devices are used in grid-connected systems, communication systems, power supply systems etc. Devices also operate in variable voltage levels. A converter that facilitates the capability of different level of operating voltage is essential for versatile use. But not all converters are able to make conversion properly without compromising performance. It is almost always the case that a tradeoff has to be made between necessity and performance. High voltage gain will cause for a deterioration of signal shape (high THD). Tradeoff is also visible among performance parameters of the converters. For example, improving power factor tends to decrease the efficiency. [14] These limitations can be addressed introducing cascaded converter topologies. [2 - 7]

The overall efficiency goes down slightly as the duty cycle rises in conventional converter. [1][8] Again increasing duty cycle causes conduction losses and serious reverse-recovery problem in diodes. [9][10] Also Boost converter can operate with lower voltage level of MOSFET. Boost converter also gives output with lower distortion which makes the circuit manage the THD level as low as possible. [11 - 13]

In this paper a new topology is introduced – Cascaded Boost SEPIC (CBS), which is used to avail different voltage level in accordance the duty cycle. Higher voltage conversion can be achieved using cascaded Boost-SEPIC converter. The proposed circuit will provide higher average voltage up to 80% duty cycle. The converter is designed to obtain higher average voltage levels at different duty cycles with appreciable low THD. To further improve the power factor and input current THD, a closed loop implementation is applied using a PI controller.

II. CONVENTIONAL CONVERTERS

A. CONVENTIONAL BOOST CONVERTER

Most commonly used AC-DC converter are boost converters which consisting of a full-wave rectifier and a DC-DC Boost converter following it. The converter is capable of supplying high voltage.

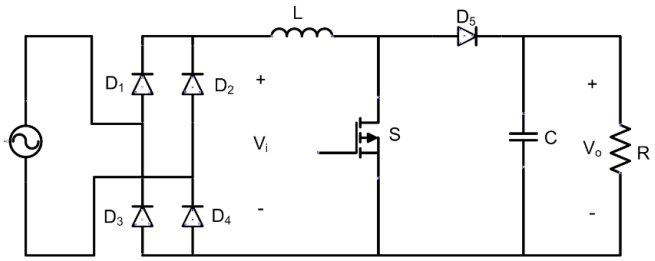

Fig. 1: Conventional Boost converter.

The voltage gain of Boost converter is given as,

$$\frac{V_{o_1}}{V_i} = \frac{1}{1-D}$$

B. CONVENTIONAL SEPIC CONVERTER

A SEPIC converter, followed by a bridge rectifier forms the conventional AC-DC SEPIC converter. DC-DC SEPIC converter is designed as an extension of boost converter by adding a buck-boost converter with it, gives a non-inverting output.

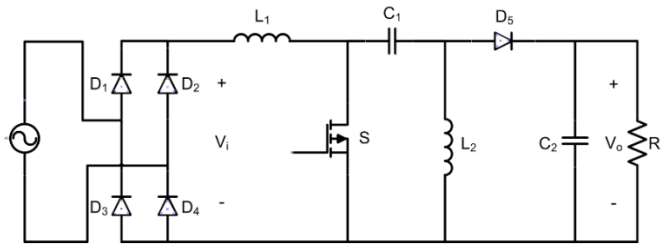

Fig. 2: Conventional SEPIC converter.

The voltage gain of SEPIC converter is mathematically expressed as,

$$\frac{V_{o_2}}{V_i} = \frac{D}{1-D}$$

III. PROPOSED CIRCUIT AND OPERATION

The proposed circuit, CBS converter combines the Boost and SEPIC converter. The proposed CBS converter consists of six diodes (D1-D6), three capacitors (C0-C2), two inductors (L0-L1), a load resistor (RL), and a switch (MOSFET).

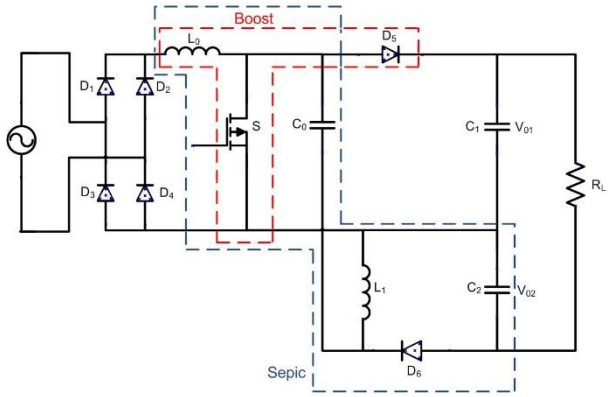

Fig. 3: Proposed CBS converter

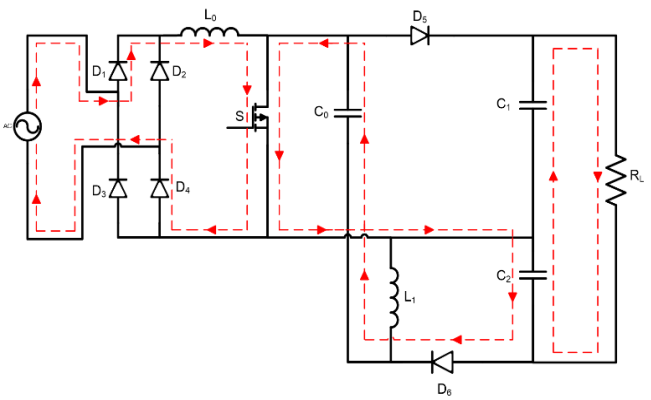
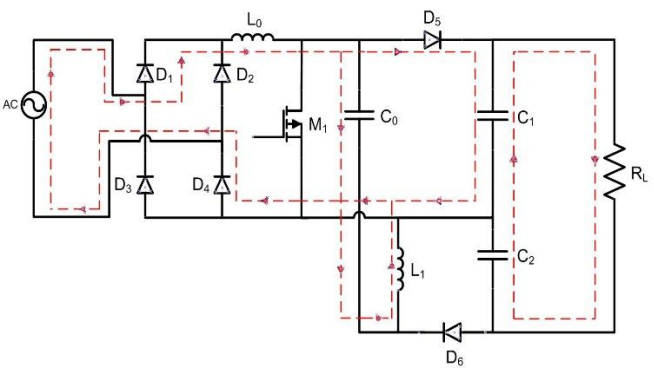
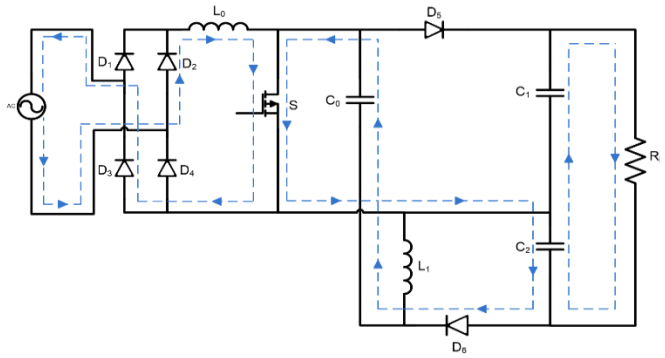
Mode 1 of the operation, which is TON of the positive half cycle of line frequency is illustrated in Fig 4(a). Mode 2, TOFF of positive half cycle of line frequency is shown in Fig 4(b). Similarly TON and TOFF of negative half cycle of line frequency is shown in Fig 4(c) and Fig 4(d) respectively.



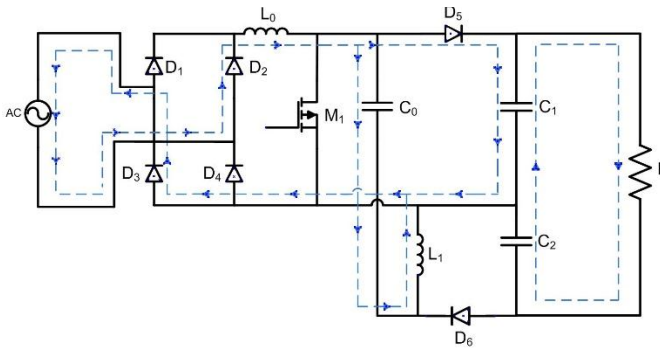
(a)



(b)



(c)



(d)

Fig. 4: Principle of operation of the proposed AC-DC CBS converter (a) Mode 1 (b) Mode 2 (c) Mode 3 (d) Mode 4

Energy is supplied to the load by capacitors C1 and C2. When the switch is off capacitors C0 and C1 are charged by the source, while the load is supplied with energy from capacitor C2. C2 is charged by the capacitor C0 when the switch is on and energy is supplied to the load by C1.

The overall estimated voltage gain of the circuit is given below.

$$V_o = V_{o_1} + V_{o_2}$$

$$V_o = \frac{1}{1-D}V_i + \frac{D}{1-D}V_i$$

$$V_o = (\frac{1}{1-D} + \frac{D}{1-D})V_i$$

$$V_o = \left(\left|\frac{1+D}{1-D}\right|\right)V_i$$

$$V_o = GV_i$$

$$\text{G = Gain} = \left|\frac{1+D}{1-D}\right|$$

IV. CLOSED LOOP TO IMPROVE POWER FACTOR AND THD

In an attempt to improve the input power factor and input current THD, a PI controller is implemented in current mode control. Comparison is made between the actual induction current with the scaled rectified reference current generated from the input voltage. Successive approximation was used to choose the scale factor of the reference current which eventually provided the desired output.

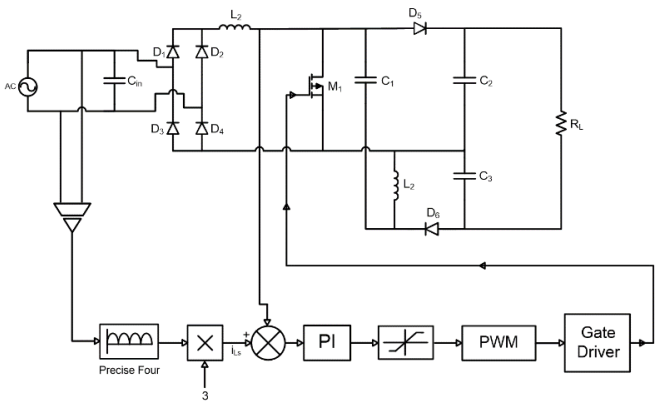


Fig. 5: Close loop implementation of the proposed CBS converter using PI controller

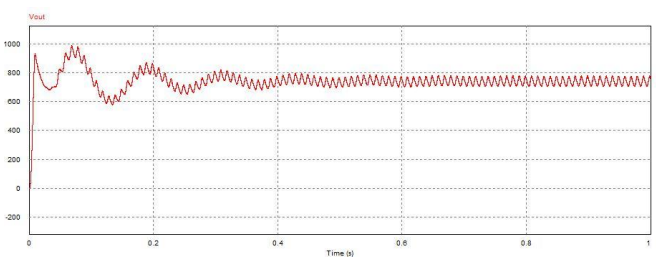
V. SIMULATION RESULTS

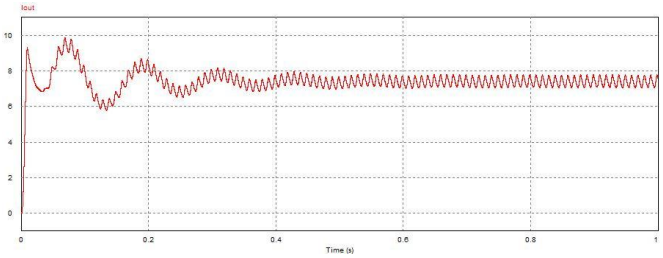
For simulation purposes, the following set of data were used in the proposed CBS circuit, as well as the Boost and SEPIC converter.

.TABLE 1 Design parameters

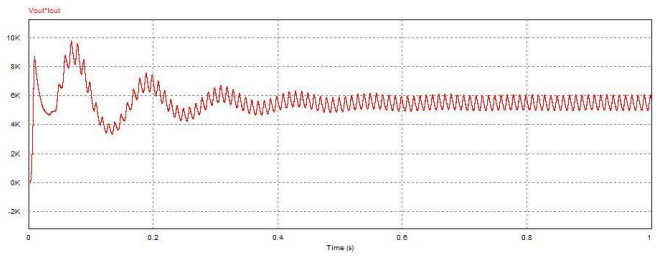
Parameter	Value
Input voltage	325V
Input frequency	50 Hz
Capacitor (C0,C1, C2)	200uF, 500uF, 500uF
Inductor (L0, L1)	5mH, 500mH
Load resistor (RL)	100 ohm



(a)



(b)



(c)

Fig. 6: (a) Output voltage, (b) current and (c) power of the proposed open loop CBS converter for 50% duty cycle.

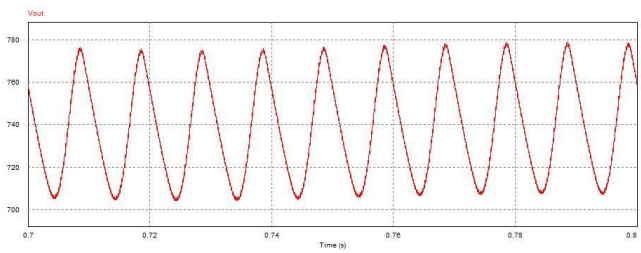


Fig. 7: Output voltage of the proposed open loop CBS converter simulated from 0.4s – 0.5s.

For comparison, the proposed circuit was compared with the conventional Boost and SEPIC converter.

A. Conversion Efficiency

It can be observed from Fig. 8 that the converter proposed here has greater efficiency then conventional SEPIC converter. Initially, the boost converter has slightly higher than the proposed converter but after 0.6 duty cycle, the proposed circuit has higher efficiency. At even higher duty cycles, the proposed circuit has more efficiency than the SEPIC converter.

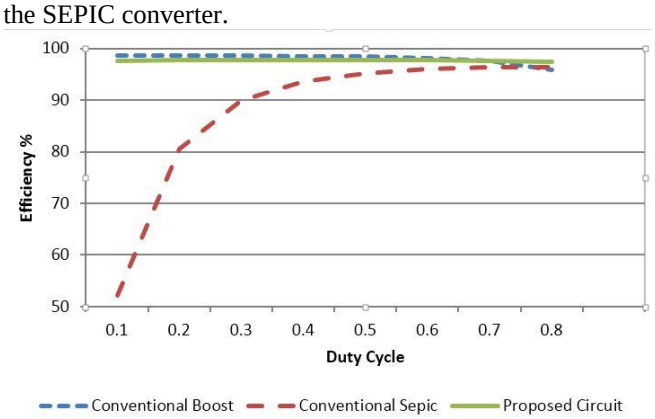

Fig. 8: Conversion Efficiency

B. Input Power Factor

The circuit proposed has a higher input power factor in comparison to the conventional SEPIC converter. Fig. 9 shows that the circuit proposed consistently has a higher input power factor than the SEPIC converter.

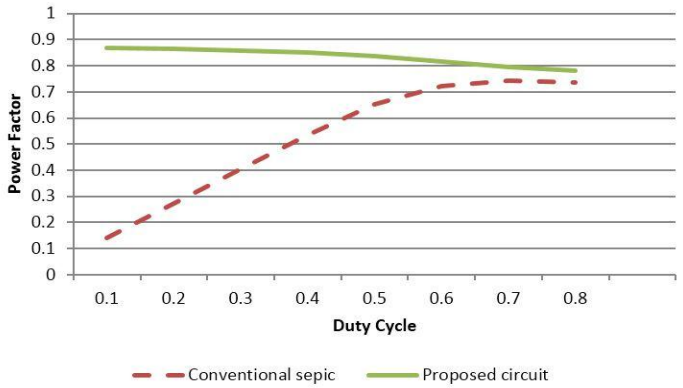

Fig. 9: Input Power Factor

C. Input Current THD

Total Harmonic distortion of the proposed converter is less in comparison to the conventional Boost and SEPIC converter as shown in Fig. 10. However, THD of the proposed converter increases after 0.7 duty cycle.

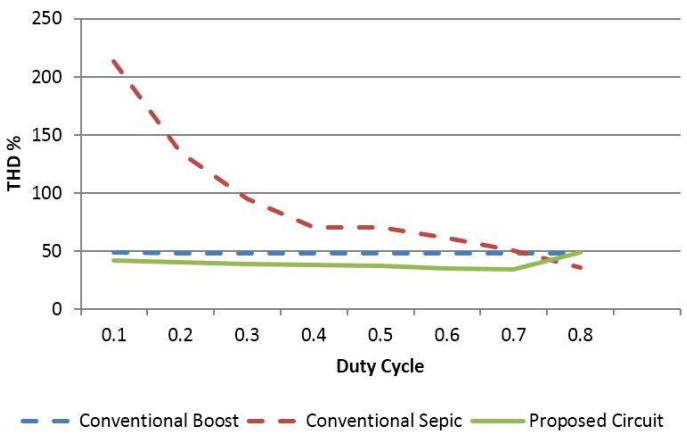

Fig. 10: Input Current THD

D. Average Output Voltage

As illustrated in Fig. 11, the converter proposed has a higher average voltage than the conventional Boost and SEPIC converter. It is also evident that the average voltage of the proposed, as well as the conventional converter increases with increase in duty cycle.

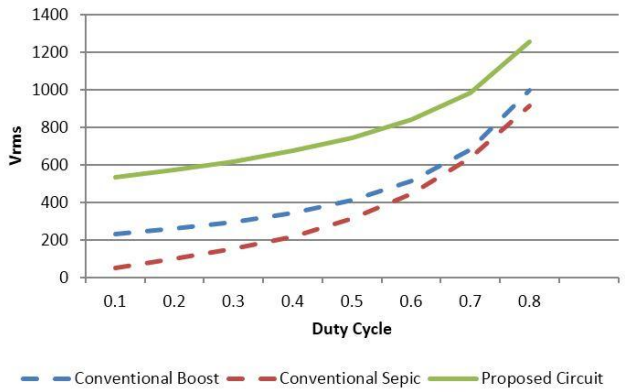

Fig. 11: Average Output Voltage

Implementation of current mode PI controller significantly improved the THD of input current and input power factor with negligible reduction in converter efficiency.

TABLE 2: Open and closed loop comparison

Parameters	Proposed CBS converter (open loop)	Proposed CBS converter (closed loop)
Efficiency (%)	97.8	97.1
THD (%)	39.03	9.94
Power factor	0.86	0.97

The effect of changing the switching frequency on input current THD and conversion efficiency are also observed, keeping 50 duty cycle.

A. Input current THD vs Switching Frequency

From Fig 12, it can be observed minimum THD is achieved around 25Khz of switching frequency.

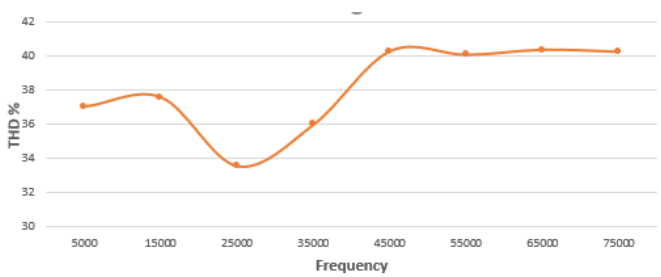

Fig. 12: Input THD comparison with switching

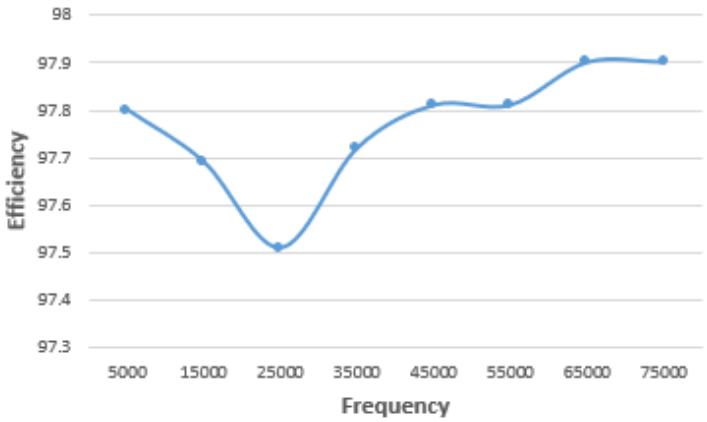
B. Efficiency Comparison with Switching Frequency

As illustrated in Fig 13 conversion efficiency seems to increase at high switching frequency.



(b)

Fig 13: Efficiency comparison with switching frequency

VI. CONCLUSION

The proposed MBS converter designed by cascading Boost and SEPIC converter to obtain the advantages of both the converters. The maximum efficiency the circuit can produce without any controller is 97.8%. However the THD was quite high which is brought down to 9.94% by using the PI controller. The power factor is also improved with the addition of the PI controller. The proposed MBS converter can be effectively used for high voltage DC application like DC micro grid, heater etc.

***Abstract*—This paper demonstrates a method to develop a saturable absorber for effective Mode-Locking in the Ultra-violet region. Discovery of graphene's optical property in two dimensional arrangement had led to research of other two dimensional materials. Tungsten Disulphide has been used as a saturable absorber and is fabricated using Liquid Phase Exfoliation Method with N-Methyl,2-Pyrrolidinone as a solvent. The prepared saturable absorber is used for Mode-Locking of laser to produce ultrashort pulses at 355nm. The pulse duration of 12.5ps is achieved with constant amplitude and periodicity. The energy of the of the pulse is 125pJ. The Mode-Locking mechanism is carried on for few hours to ensure its stability. The Mode-Locked laser hence obtained can be used for dentistry and eye treatments.**

***Index Terms*—Transition Metal Dichalcogenides (TMDs), Mode-Locking, Liquid Phase Exfoliation, UV-vis spectroscopy.**

I. Introduction

Using light as medium and transferring information over long distances is termed as optical communication. Light is transferred inside an optical fiber cable by the phenomenon of total internal reflection. In the field of nanotechnology, nano photonics has been evolving rapidly in the last two decades. Studies are taking place with the aim of discovering the interaction of light in nanometer scale. The various devices used in nano photonics include photodetectors, isolators, couplers, waveguides, polarizers, saturable absorbers and electro-optic devices. [1]

Saturable absorption is the ability of a material to decrease its absorption with increase in intensity. The laser comprises of high and low intensities range. When passing through the gain medium of the resonator/cavity, the saturable absorber absorbs the light till a threshold intensity. For any intensity above the threshold, the absorber becomes transparent and transfers the light as it is resulting in locking of modes of the laser.

Graphene and its study of its optical properties led to the discovery of 2D materials and its ability to act as a saturable absorber. The existence of certain drawbacks in graphene such as zero bandgap led to the search of a better 2D material. This led to the discovery of Transition Metal Dichalcogenides (TMDs). [2] TMD monolayers are thin semiconductors of the composition MX_2, in which M is a metal with not wholly filled d-orbital (through group III to XII) and X is a Oxygen family (Chalcogen) atom. TMDs exhibit a idiosyncratic combination of not having high thickness, indirect to direct bandgap and favorable electronic and optical properties along with semiconducting abilities, which give them application in optoelectronics, medical field and spintronics. Fig 1 depicts the arrangement of WS_2 (tungsten atom sandwiched between Sulphur atoms)

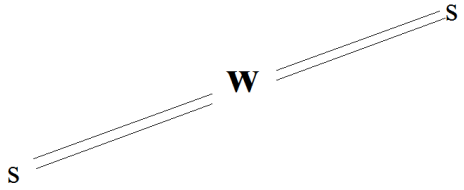

Fig. 1. Arrangement of single layer WS_2

WS_2 is an ideal TMD for its unique optical properties, cost and physical capabilities. WS_2 is a very good lubricant, possesses higher thermal stability, a wider operating temperature range and has absorbance as much as 5-10% of the incident light for thickness of 1nm. WS_2 has high mobility as its effective mass is less. [3] Usually in the insulating regime WS_2 with high mobility at room temperature, shifts to metallic conducting regime at lower temperatures. [4] It can be used in huge temperature and high pressure applications. Liquid phase exfoliation is a process of exfoliation of a TMD in a liquid medium by exploitation of ultrasound to extract 2D layers of the TMD. The nature and properties of the Saturable absorber is characterized by UV-Visible spectroscopy method.

Here, we propose fabricating Saturable absorber using liquid phase exfoliation method which ensures thin film deposition of monolayer or bilayer thickness, also by using this chemical compound Saturable absorber the longitudinal modes in the laser are locked and a gain multiplication inside the cavity is achieved to produce passively mode-locked laser. [5] Passive mode-locking is basically done to modulate the light inside the resonator cavity and to lock the modes of laser light and Q-switching can be obtained when there is a bilayered form of the absorber. Ultra-short pulses hence obtained of UV wavelength can find application in dentistry and eye surgery. In the manufacturing industry, ultra short pulses of laser are used

in laser precision cutting. Its applications range from medicine to manufacturing plants.

II. Methods

A. Fabrication of Saturable absorber

Exfoliation is defined as the addition or removal of the molecule from the layered material structure.The most common materials that undergo the exfoliation method are the Graphites and the Transition Metal Dichalogenides(TMDs). Both the materials comes under two Dimensional materials which has a single or few layers of atoms. Even though the graphite exhibits exotic material properties it has a few drawbacks which leads us to the TMDs a two dimentional material with semiconducting character. Some examples of TMDs are MoS_2 ,$MoSe_2$, and WS_2 etc. Generally exfoliation is done for the layered materials. [6]

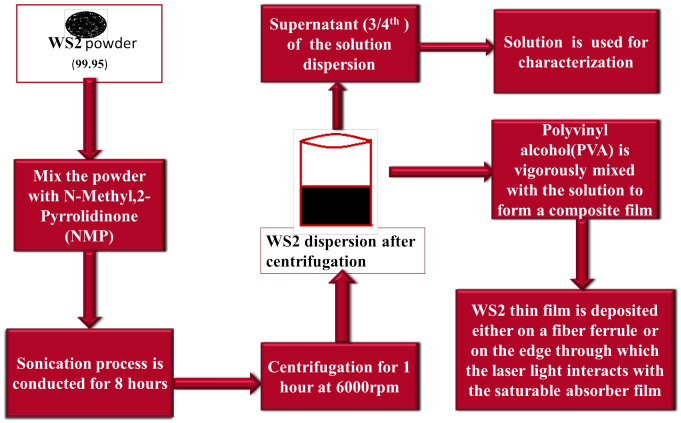

Fig. 2. Liquid phase exfoliation process of tungsten disuphide

Liquid phase exfoliation is very efficient and simple which yields uniform deposition along the substrate. [12] Selection of solvent is very important for the stability of prepared nano flakes. Surface tensions of solute and the solvent should be comparable (solute being WS_2 of 40 mN/m surface tension). As we know surface energies of solid and liquid are almost practically equal, solvent having surface energy near WS_2 is carefully chosen. N-Methyl-2-Pyrrolidone (NMP) has surface tension of 40.79 mN/m, which is closer to WS_2. The lower the difference between the energies the better is the exfoliation process. [7]

The various processes involved in exfoliation process is depicted in Fig 2. WS_2 of 99.9% purity, 2μm particle size is purchased at Sigma-Aldrich, polyvinyl alcohol (PVA) of molecular weight 124000 and NMP is also purchased from Sigma-Aldrich. 5mg/ml WS_2 powder is mixed with the NMP to prepare the solvent mixture. Sonication process is done for eight hours which ensures the breaking down of bonds using ultra sound waves. Centrifugation - The solution is rotated at 6000 rpm for one hour for purification. The upper three forth of the solution is used for characterization. The solution is vigorously mixed with PVA to form a composite film which can be deposited on the fiber ferule for interaction with laser. [11]

B. Mode locking of LASER

The technique of producing ultrashort pulses of very less pulse duration ranging from picoseconds to femtoseconds of the input light is called mode-locking. Mode locking is achieved by inter-locking the different modes oscillating in them that have mildly different wavelengths. [8] Constructive and destructive interference among the modes stimulates the laser to produce pulsating beam. Mode locking is obtained by two methods namely active and passive mode-locking.

Active mode locking is the method of obtaining ultrashort pulses by modulation of the cavity losses. An external modulator is required for actively modulating the resonator losses. An acousto-optic modulator, Pockel's cell can be used for this process. Passive mode locking mechanism is carried out using a non-linear optical device known as saturable absorber. The laser beam oscillates within the resonator through the gain medium and saturable absorber as depicted in Fig 3 and one pulse is sampled after every round trip time.

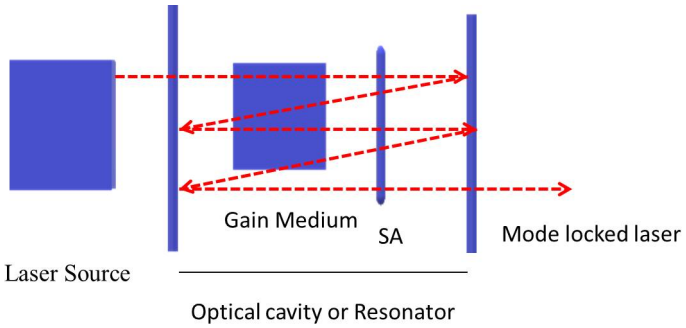

Fig. 3. Mode-locking mechanism

III. Experimental Analysis of Mode Locking

Passive mode-locking is achieved using a saturable absorber. A circuit is designed using VPI photonics software to obtain ultrashort pulses in the ultraviolet wavelength. Simulation is carried out from Table 1.

TABLE I
Simulation Parameters for Mode-Locking Operation

Input Parameters	
Central Frequency (THz)	844.4
Wavelength (nm)	355
Sample Rate (s)	$5120*10^9$
Laser section	Bulk mode, Isotropic
Saturable Absorber	MQW mode, Isotropic
Time delay	1
No. of runs	2
Pulse Duration (ps)	12.5

Fig 4 depicts the circuit designed for mode-locking of laser with saturable absorber and laser section. DC source provides input supply to both saturable absorber and the laser

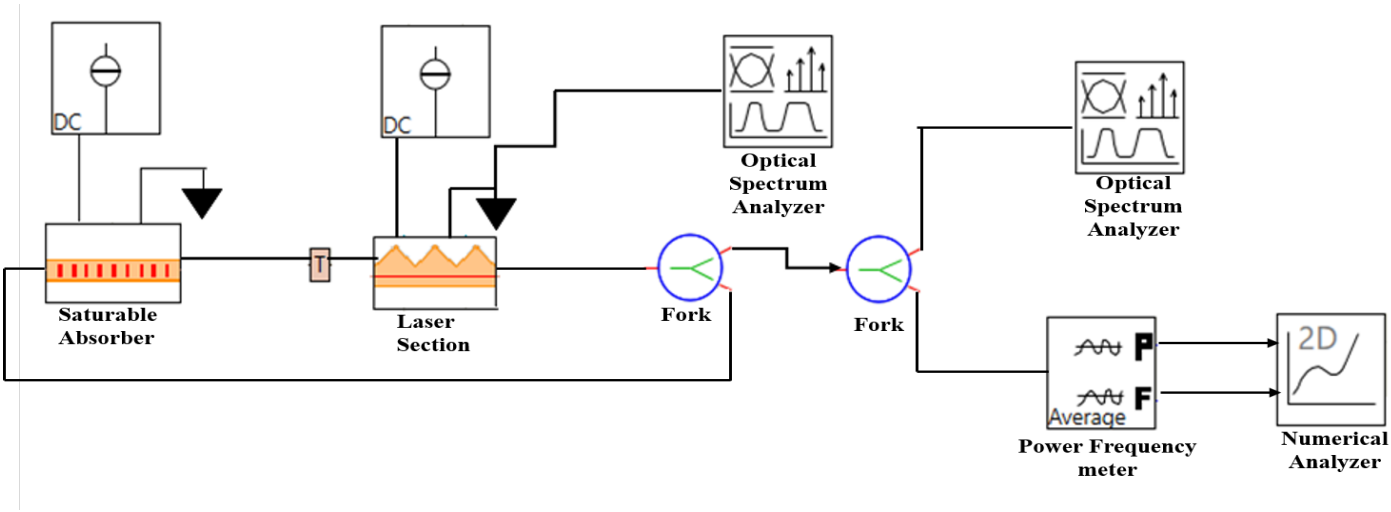

Fig. 4. Experimental set up for mode-locking of lasers

section, Laser section has both bulk and Multiple Quantum Wave (MQW) modes which are respectively used for laser section and saturable absorber. Saturable Absorber is the sample interacting with laser and produce mode-locked pulses. Optical Spectrum Analyzer (OSA) analyses the output signal to produce waveforms. Fork Splits the output from the laser into OSA and back into the circuit for cavity formation. The Optical frequency plot obtained by spliting the signal using a fork is detected using frequency power meter.

IV. Results and Discussion

The simulation of the project was carried out using VPI Photonics design suite (Simulation Software-version 9.9). The LASER section acts as source for the mode-locking using a saturable absorber(Passive modulator). The saturable absorber can be graphene, any 2D materials like Transition Metal Dichalcogenides (TMDs), Metal oxides, Black phosphorous etc. [9] The DC source's output data type was set to samples mode since any passive saturable absorber works only with a sampled input and ultrashort pulses are obtained from sampling the laser light. This output data is collected by the fork, splitting it back to the circuit as feedback as well as to the analyzers. A delay unit of 1 was added between laser section and saturable absorber to avoid deadlocking. Deadlocking has to be avoided since it may lead to ceasing of laser light during the operation. The circuit depicted in Fig 4 is simulated with a input power of 210 mW from where the mode-locking starts. The circuit is run for two cycles since the first cycle has only output through the fork without the feedback whereas the second cycle's output is obtained from feedback signal provided by other arm of the fork back into the circuit hence providing mode-locked regime.

Fig 5 shows the laser signal before Mode-Locking opertion. The waveform depicts many oscillations and irregularities in the laser beam before being locked into modes. This causes uneven power distribution and less energy pulses. Mode-Locking this laser can restricts the power to be delivered

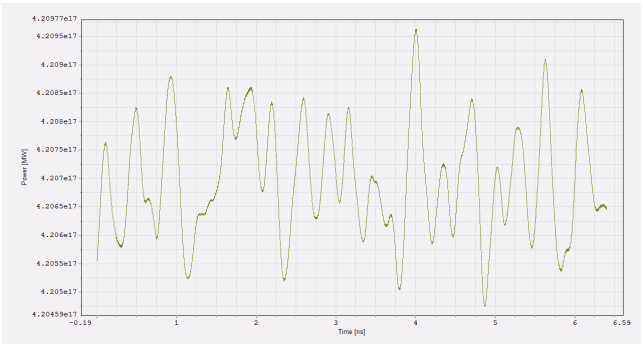

Fig. 5. Laser Pulse before Mode-Locking

at a particular frequency only after every round trip time inside the resonator. The constructive and destructive interference of beams in the resonator

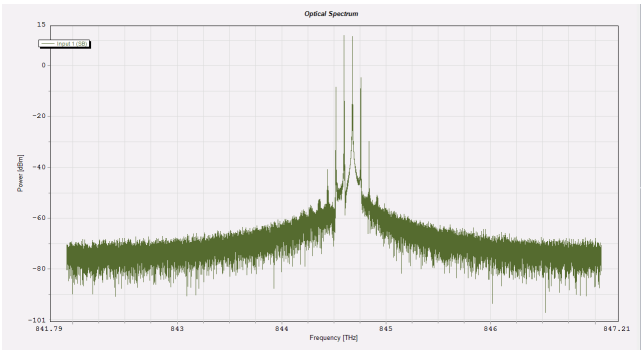

Fig. 6. Mode-locking indicated by Peak at the central frequency of 844.4THz

Fig 6 shows the output simulation of the laser depicting power versus frequency wave which has peak power at the central frequency of 844.4THz. Fig 7 shows optical spectrum of power with respect to the wavelength which indicates high power at 355nm which is in the UV region. Saturable absorber

absorbs the light intensity to a particular threshold and for any intensity above that the saturable absorber acts as a transparent medium giving an output pulse. A peak power of 1mW is obtained at a central frequency of 844.4THz and wavelength of 355nm indicating the mode locked pulse.

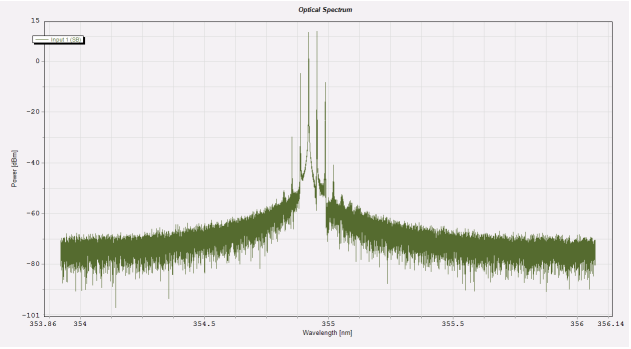

Fig. 7. Mode-locking at a wavelength of 355nm

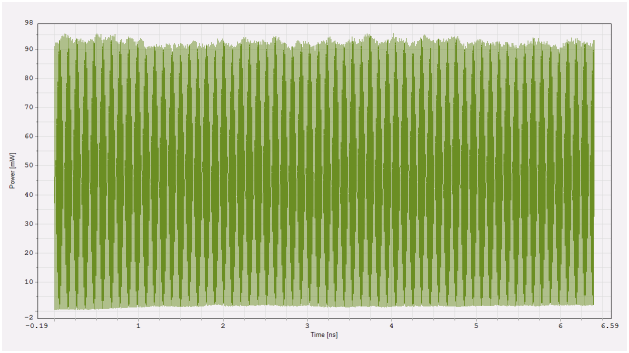

Fig. 8. Mode-locking regime

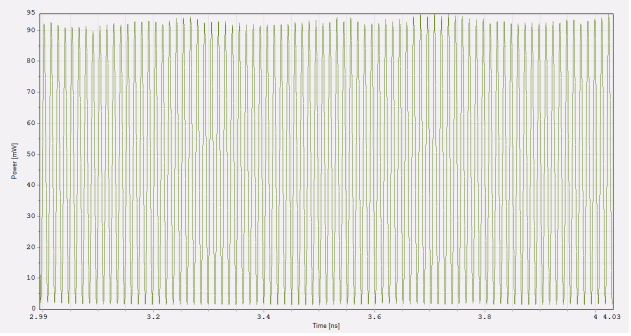

Fig. 9. Mode-Locked pulse over one nanosecond range

The continuous spectrum depicts the periodic mode locking of laser with same amplitude throughout indicating constant mode-locking in Fig 8 after run two. The results indicate the pulses are highly stable. The energy of TE mode locked laser of 125 pJ is achieved. Multiple signal causes high pulse repetition rate in the terahertz range for passive mode locking of the laser pulse, which is caused by the phenomena known as harmonic mode locking.

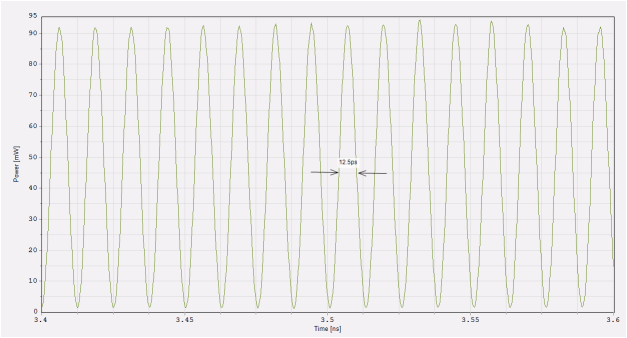

Fig. 10. Pulse duration of 12.5ps

Fig 9 depicts mode-locked laser over one nanosecond range. The waveform shows pulses of equal duration and equally spaced proving it is periodic and stable. Also the pulse duration of each pulse was calculated to be 12.5ps (over 1 ns there was 80 pulses which means 1/80 = 0.0125ns for each mode-locked pulse) is depicted in Fig 10. The pulse duration indicates higher repetition rate. The saturable absorption of the laser depends on the material used as a saturable absorber [10]. WS_2 for saturable absorption with monolayer thickness depends on the rate of transition of electrons from valence band to conduction band due interaction of the laser signal. The optical parameters of the generated pulse is measured using an optical signal analyser. The frequency power ratio is measured using a frequency power meter and a two dimensional numerical analyzer.

The instabilities that can occur during the mode locking operation is caused due to simultaneous Q switching of the laser pulse. Q switched mode locked pulses are not encouraged due to the instabilities it would cause in the pulse train. Q switching is the generation of very high power pulses, which requires higher oscillation in the laser resonator cavity leading to dynamic instabilities. After generating a Q switched pulse the next sequence of pulse would have very low energy, which should be avoided. This instability is avoided by harmonic passive mode locking of the laser and producing ultrashort pulses. [13] If the Mode-Locked and Q-switched condition coexists with no instabilities, a very short pulse of high energy can be obtained which can be useful in providing precision and accuracy.

V. Conclusion

The saturable absorber was developed using tungsten disulphide (WS_2) by Liquid Phase Exfoliation technique, in the range of nano meters. The mode-locking was achieved at the same pump input power of 210mW. The inter-cavity laser was modulated by the Saturable absorber thereby achieving mode-locking at the monolayer thickness areas and Q-switching at bilayer layer areas due to change in modulation depth and absorption coefficient.

Tungsten disulphide is chosen because of its better properties than graphene. Saturable absorption is achieved at ultraviolet frequency of 844.4 THz and wavelength of 355nm.

The pulse duration of the achieved pulse regime was 12.5ps. Hence the energy of TE mode locked laser is 125pJ. The prepared WS_2 is characterized using UV-vis spectroscopy. The measurement of ultrashort pulses could be carried out using auto correlation technique.

***Abstract*— Climate change affects us in almost all daily aspects of life. Specially, disasters like floods. The dam level management system to counter these unpredictable floods has become obsolete. This can been seen in the recent destruction brought upon by floods in the state of Kerala (India). The major reason for the deluge has been reservoir mismanagement. Due to absence of a scientific method to control the outflow from several local dams. Consequently, a first step towards encountering this conundrum in form of a PID controller augmented by a FOPDT (first order plus dead time reinforcement) to manage water levels in a two connected reservoir system is proposed.**

Keywords*— PID controller, FOPDT model, flood control and interacting reservoirs.

I. INTRODUCTION

The interconnected reservoir system regime is common to most of the water management techniques. Some of these include feed-forward control [1, 2], feedback control [2, 3] either without or with feed-forward control and Decentralized and distributed control [4]. Even though these techniques are widely used in normal reservoir level control. Their use in unpredictive situations like floods has been limited. For instance, in Kerala floods, the Idukki dam which is connected to Mullaperiyar dam as shown in figure 1 faced flash floods. The reason for these disastrous floods was the mismanagement of water level and sudden release of water from Mullaperiyar to maintain mandated water level of 139 feet. Hence, to avoid such catastrophes a state of the art system is required. Currently the water level systems are rampant with human biases and myopic constrains.

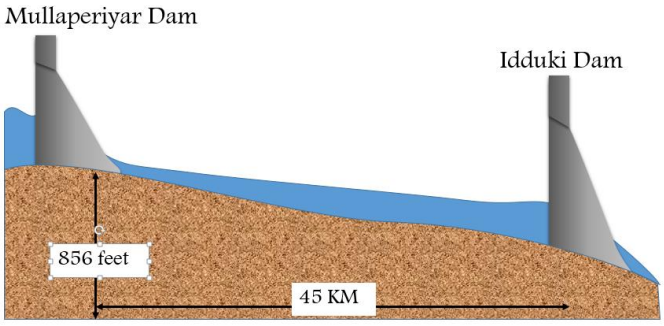

Fig 1: Water flow diagram of two connected reservoir system.

Previously, some amount of work has been done in similar area. In 2009, a paper was published revealing the use of PID and DI (Dynamic Inversion) based nonlinear controller in water management systems [5]. In a different approach fuzzy (logic) supervisor (FZPID) and genetic algorithms (GAPID) have also been utilized [6]. However, a large memory requirement is a prerequisite in these approaches which slows down the response time. Consecutively, in 2010 another research view explored the use of microcontrollers in sensing and controlling water levels [7]. Methods based on this type of techniques helps in creating a robust control scheme. Apart from research papers there are few patents which highlight level sensing systems on small scale [8, 9]. These can further be upsized to larger systems in which level management is required.

Furthermore, in these systems sudden rise of water due to excess rain fall has not been taken into account. Therefore, to avoid such backlashes a system based on PID (Proportional Integral Derivative) controller reinforced by FOPDT (first order plus dead time reinforcement) may serve as a prudent alternative.

II. MATHEMATICAL MODEL FOR TWO RESERVOIR SYSTEM

To understand the governing mathematics behind the operating principles of two interacting reservoir systems, the diagram in figure 1 needs to be expressed in terms of sufficient differential equations. Moreover, these equations must be converted in to a working transfer function. The physical variable such as resistance to water flow should be converted to mathematical entities to handle them in a quantitative manner. The levels of reservoirs which change with time are converted to S-domain. Next, the transfer function is calculated taking q_{in} as the input and h_2 as output. This makes the working relation between these variables easy to counter as they are now mathematical quantities. Finally, this transfer function is incorporated into a Simulink block represented by Tank S-function in figure 3.

A schematic representation demonstrating the mathematical model of figure 1 is depicted in figure 2.

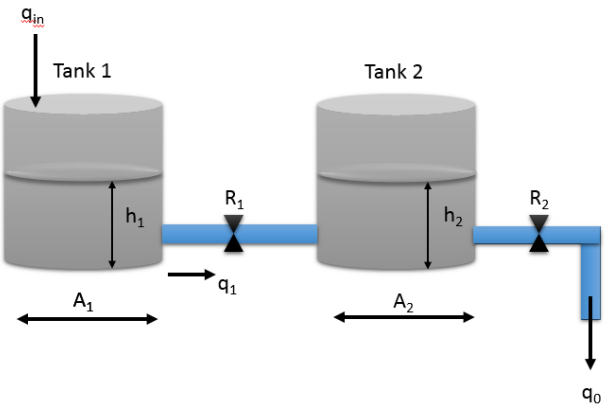

Fig. 2: Mathematical diagram of two connected reservoir system

Wherein,

$q_1(t)=q_{in}(t)$: water flow from external source such as rain in centimeter cube per minute.

$q_2(t)=q_o(t)$:the outflow from tank towards rivers in centimeter cube per minute.

$h_1(t)$: level of water in the first reservoir in meters.

$h_2(t)$:level of water in the second reservoir in meters.

A_s (s=1, 2): area of both the reservoirs in meter square.

and R_s (s=1, 2): the resistances to flow.

In the case of two interacting systems the transfer functions cannot be multiplied directly. Therefore the transfer function of interacting systems can be stated in the form of equation 1 [10].

$$\frac{h_2(s)}{q_{in}(s)} = \frac{R_2}{T_1T_2s^2+s(T_1+T_2+A_1R_2)+1} \qquad (1)$$

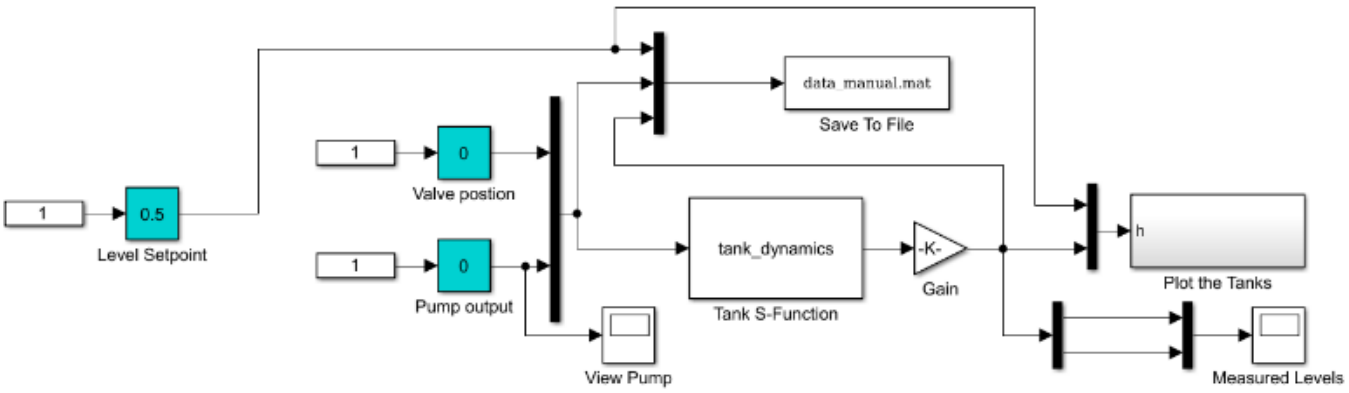

Fig. 3: Simulink model with manual control.

Figure 3 depicts the control strategy used presently modeled in MATLAB [11]. Equation 1 is integrated in this simulation using "Tank S-Function". This scheme is devoid of an automatic controller i.e., the pump output and valve position is controlled manually. To take into account unforeseen circumstances a system backed by a PID controller which will act according to credible information is proposed.

III. PID CONTROLLER

A PID controller is an digitally backed equipment which finds its use in numerous scenarios which need controlling of the control variable to regulate heat level, flow of liquids, pressure in turbines, speed and other process related uncertainties. PID (proportional integral derivative) employs a control loop feedback mechanism to restrain certain conditions in a robust way. They are the most spot on and steady controllers. PID control is a hugely known control regime of goading any system towards a desired outcome or level. PID controller employs closed-loop controlling feedback to guide the actual output regarding a process as proximate to the goal or predefined set point as possible (Figure 4) [12].

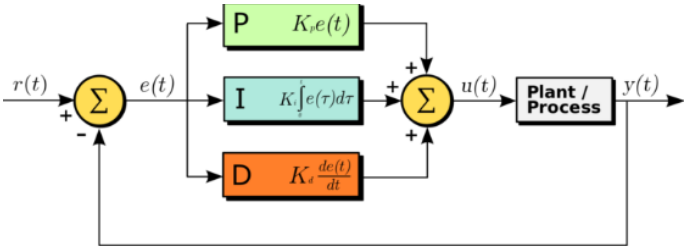

Fig. 4: Block diagram depicting working of a PID controller.

The parameters controlling the working of PID are where Kp, Ki and Kd, all non-negative, denote the coefficients for the proportional, integral, and derivative terms respectively (sometimes denoted P, I, and D). To optimize the stated variables for automatic control of water level in the reservoirs FOPDT (First Order Plus Dead time) technique is employed.

IV. FOPDT MODEL

A FOPDT model is a time tested and sturdy methodology to valuate (give numeric representation to) vital facets of this controller output (CO) to process variable (PV) juxtaposition

for use in determining controller parameter's outline and necessary estimation . In particular, when the CO is a variant quantity: Process gain, Kp, enunciates the distance. Furthermore, how distant the PV can go and remain there. Time constant, Tp, tells us about the pace of the movement for the said control variable.

The reaction graph procedure compels you to perform a step change with respect to the process input, the manipulated variable (MV): From a predefined unchanging state, step and hold the input at a novel value till the reaction variable finally settles to an ultimate steady state. However, disturbances and arbitrary alternate noises stagger the response largely. In continuation, a singular step forces the process far from the needed set point (process response). Furthermore, a single step to the one side of formal will misguide the user away from the nonlinear nature of the process. Therefore, for efficient response graph fitting tests, we usually take into use an up-down-down-up motif, which is a concatenation of step-and-hold leitmotif in the influence. This manufactures four reaction curves. Their average can compensate the influence of noise and perturbations, the pattern takes into account both aspects of the original MV value, makes positive deviations from a nominal response value that are counter affected by negative deviations, and eventually makes the process go back to the mentioned original value. Hence, the controller design is a combination of standard PID controller supported by FOPDT curve fitting technique.

V. CONTROLLER DESIGN

The controller needs to fulfill the prerequisite that the water level mark in concerned reservoirs follows a pattern of predefined set of parameters submitted by the user. Presently, the method used is based upon human intelligence. A dedicated human operator is assigned who is given directions by a bureaucratic committee for controlling the outflow from the concerned reservoir. However, a PID controller can be used pragmatically to avoid any biases. Therefore, dynamic data is needed from the model behavior under set control to feed into the FOPDT model. This will provide the necessary information for robustly approximating the proportional, derivative and integral coefficients of PID controller utilized.

Firstly, without using the PID controller, the pump output was set to 0.5 and the simulation was started.

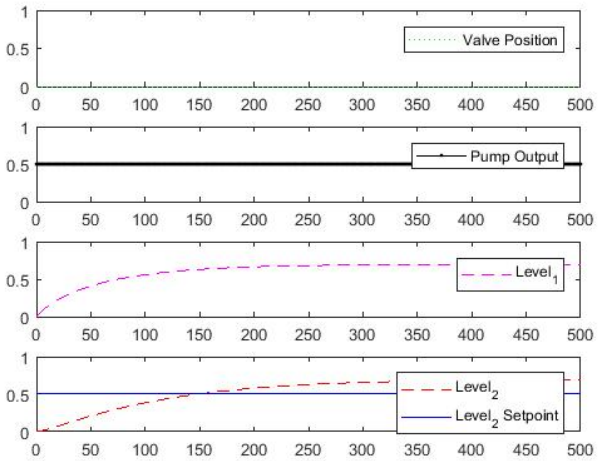

Fig. 5:Level output in reservoirs without using PID controller.

From figure 5 it is observed that the desired set point of 0.5 has been transcended. In real time it means that the water has overflown its set limit.

A data_manual.mat block has been used to extract vital information for the simulation depicted in figure 3. The results stored in the above mentioned block which were then fed into the FOPDT excel calculation sheet.

Model Parameters	
Kp (Gain)	1.388755091
tau (Time Constant)	111.7671239
theta (Time Delay)	8.317417671
Doesn't seem to change with solver	
Minimize Either of These	
Sum of Squared Errors	0.012669935
Sum of Absolute Errors	1.981107474

Fig. 6: Results obtained after curve fitting by FOPDT.

Then curve fitting techniques was used to obtain optimum values of Kp, Ki & Kd (figure 6). After getting the concerned parameters, the pump output block is replaced by a PID controller as demonstrated in figure 7.

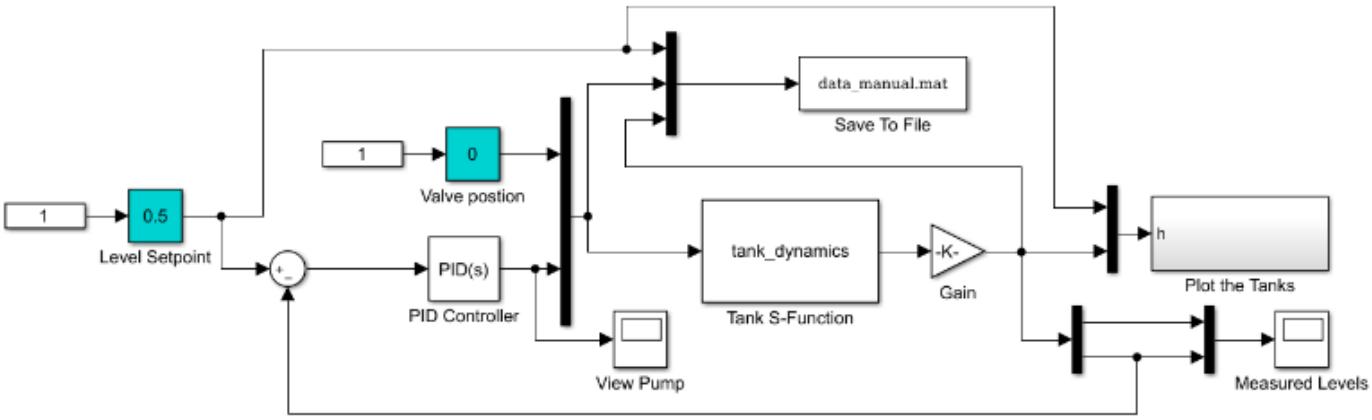

Fig. 7: Results obtained after curve fitting by FOPDT.

Then the simulation was initiated again using the parameters calibrated by curve fitting method.

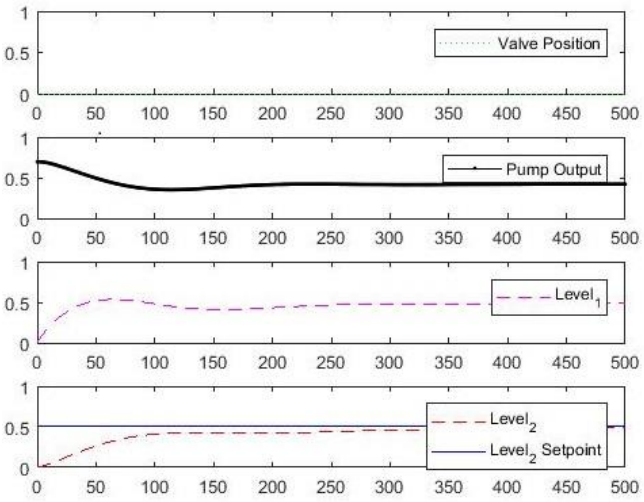

Fig. 8: Level output in reservoirs using PID controller

Now the results have ameliorated which can be observed by the level of water staying below the set limit in figure 8. Notably, the set point given and new output when juxtaposed show negligible diversion from each other. This reduces the chances of a deluge as pump output can be considered as sudden rainfall.

VI. CHALLENGES AND FUTURE PROSPECTS

The main challenge is to practically include a stochastic model which predicts a rainfall pattern. Real time models can be much more efficient and also very complex to develop. Further, the construction aspect of the reservoir also plays a vital role which has not been included in this paper. A large data assimilation is a prerequisite to countering the problem of inaccurate predictions.

Conversely, the future prospects are tremendous. As climate change affects our rain patterns, floods are a real threat. The economical loss of a flood can be saved using scientific methods as proposed.

VII. CONCLUSION

This paper has tried to counter a modern problem of devastating floods with an equally modern solution. The main purpose is to root out the human bias which is currently rampant. The results obtained have exclusively assimilated a method which may prevent future disasters. Finally, this is a step towards a future where such model backed by IOT can usher a new age.

ACKNOWLEDGMENT

Mr. Mohit is grateful to MHRD, India for providing financial support to pursue this research work.

***Abstract*—The computational complexity due to the system's non-linearity and non-convexity , restricts the use of nonlinear model predictive control (NMPC) for fast dynamic real time systems. This paper presents the real time development of the NMPC to control the highly nonlinear fast dynamic single rotary inverted pendulum (SRIP) system in inverted position with 20 millisecond sampling period which corresponds to nonlinear non-convex optimization problem. This challenging problem is solved with online successive linearization and optimization on the compact reconfigurable input/output (cRIO) (field programmable gate array (FPGA)) hardware platform from National Instruments. The effectiveness of the control algorithm with the rapid disturbance rejection capability is validated using experimental results.**

***Index Terms*—Rotary inverted pendulum, nonlinear model predictive control, successive linearization, cRIO, FPGA, real-time systems**

I. Introduction

MPC is applicable for complex multiple input and multiple output (MIMO), Linear/Nonlinear LTI or time varying systems. It has inbuilt Constraints handling capability [1], [2].Also the ability to handle the single input and multiple output (SIMO) or multiple input single output (MISO) by restructuring the formulation. However, linear MPC (LMPC) covers limited operating regions or weakly nonlinearity considerations which may not justify for any of the highly nonlinear industrial plants. Therefore the NMPC shows the strong potential to improve the control and operation of the nonlinear systems [3]. But the main disadvantage is a higher Computational Burden as on for nonlinear optimization problems has to be solved at every sampling instant. In addition the problem becomes too large to solve it online. Therefore, it is difficult to apply NMPC in real time for fast dynamic systems [4] -[6]. To reduce the complexity, the successive linearized NMPC which locally linearizes the model at every control interval is still the promising option for real time implementation of it [7] -[9]. But the online fast computation will be the concern for the rapid control action calculation in the fast dynamic processes.

However, due to enhancement in the electronic hardware platforms there is a large possibility to accelerate the computation time of the controllers for the highly nonlinear systems is increased. The vendors provide the flexibility of the hardware and software platforms which can be handled with ease of use by the user. In the current application domain, the FPGA is being used for predictive control applications.In a survey, mentioned the recent progress in FPGA technology and emphasized the key parameters that may considerably contribute to the development of proficient digital systems for industrial applications.FPGA offers cycle-accurate timing guarantee and easily embedded as a system component. Therefore now a days, the researchers are keen to use an FPGA to speed up the on-line computation of NMPC. Computational speed is improved through parallelization and customizability explained [10]. The efforts of MPC implementation on FPGA for the nonlinear systems are appreciable and therefore, a scope for solving optimum solution of the non-convex nonlinear optimization problem with FPGA is increased [11]. But for implementation using, such as platforms a good knowledge of specific languages such as VHDL/Verilog, system C/system Verilog, etc. required. The choice of language is the target dependent. Less expertise in these languages has been often trouble in developing steps for a Real-Time (RT) target which leads towards the more time consumption in development stage. Real time implementation in cRIO using LabVIEW FPGA reported for the LMPC, LQR, etc. [12]-[14].

The main purpose of this paper is to develop and apply the NMPC to the fast dynamic real time system with minimum implementation time. To this aim,the main contribution of this paper covers the successful implementation of NMPC with online optimization with a successive linearized nonlinear model on the cRIO using LabVIEW FPGA (from National Instruments) using Rapid Prototyping Tools (RCP Tool) with millisecond timescale. For experimental validation the SRIP is used due to its nonlinear fast dynamic behavior. It is unstable at the inverted position with non-minimum phase. Its nonlinear state constraints leads to nonlinear optimization problem. Also the controller developed for it may be applied to the similar practical applications like, In missile launch and control, Lifting cranes on shipyards, Self balancing personal transporter, etc. The paper depicted in the following fashion. Section II briefs about the formulation of the NMPC. Section III discusses in details the utilization of NMPC for the balancing SRIP. Section IV mentions the experimental results of the SRIP system with and without applying the disturbance

which is followed by the conclusion and the future scope.

II. PROBLEM FORMULATION OF NMPC

This section briefs about the formulation of the NMPC that controls the nonlinear fast dynamic system using the successive linearized nonlinear model [7].

A. Model Selection

The system to be controlled using NMPC is generalized by the equation(1)

$$\begin{aligned} \dot{x} &= f(x,u), \\ y &= g(x) \end{aligned} \tag{1}$$

The $f(\cdot)$, $g(\cdot)$ are nonlinear functions of the process model. $x \in \Re^m$,$u \in \Re^n$ and, $y(k) \in \Re^r$ are the state, manipulated input and output vectors of dimensions m ,n and r, respectively. The nonlinear functions (1) are linearized around the current trajectory $(x(k), u(k))$ and discretized at the sampling time T_s. After the discetization the model at sampling instant k in the form of nonlinear discrete state space model [4], [5]

$$\begin{aligned} (x(k+1) &= f(x(k),u(k)), k \geq 0 \\ y(k) &= g(x(k)) \end{aligned} \tag{2}$$

B. Problem Formulation and Solution

The objective function $J(k)$ in (3) is based on the output reference and the future predicted output using the measurement at an instant k.

$$V = \sum_{j=1}^{N_P} \parallel \bar{y}(k+j) - y_r(k+j) \parallel_Q^2 + \sum_{j=0}^{N_c-1} \parallel \Delta u(k+j) \parallel_R^2 \tag{3}$$

where, $\Delta u(k+j) = u(k+j) - u(k+j-1) : j = 1, ...N_c - 1$ and $\|x\| \equiv \sqrt{x^T Q x}$ denoted the weighted 2-norm of the vector x. N_p and N_c are the prediction and control horizon based on the desired set-point trajectory $y_r(k+j)$ and the predictive output $\bar{y}(k+j)$ at instant k for $j = 1, 2, 3...N_p$. The prediction and control horizon should satisfy the condition i.e. $N_p \geq N_c$. Q and R are the weights which are used to prioritize the plants output , the rate of change of control action and the change in control action. The optimization problem of NMPC can be defined as

$$\begin{aligned} \min_{U_k} \quad & V(y(k),u(k)) \\ \text{s.t.} \quad & \mathbf{y}_{min} \leq \bar{y}(k+j) \leq \mathbf{y}_{max} j = 1, 2, ...N_p, \\ & \mathbf{u}_{min} \leq u(k+j) \leq \mathbf{u}_{max} j = 0, 1, ...N_c - 1, \\ & \Delta \mathbf{u}_{min} \leq \Delta u(k+j) \leq \Delta \mathbf{u}_{max} j = 0, 2, ...N_c - 1 \end{aligned} \tag{4}$$

The NMPC controller calculates a sequence of optimal solutions of the problem (3)-(4) in which the first optimal control signal is applied to the system, i.e.,$U^* = u_1^*$. The optimization issue is solved at every next interval by using new process parameters by liniarizing the nonlinear problem at sampling instant as shown in Fig. 1.The optimal move calculated by quadratic programming (QP) is sent to the real time plant.

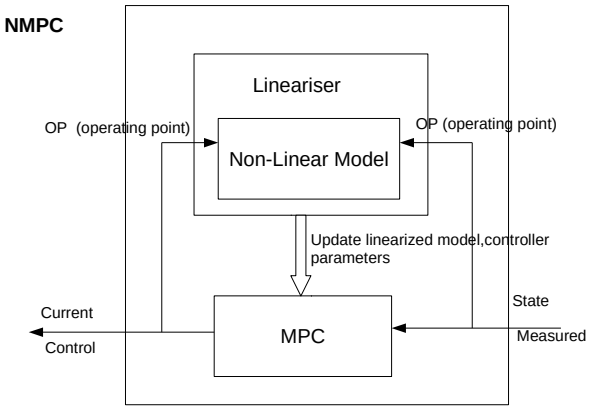

Fig. 1. Successive linearized NMPC

III. NMPC APPLIED TO SRIP

NMPC is implemented using the National Instruments LabView software on the QUARC SRIP Hardware Setup [15]. The highly nonlinear SRIP system is the most popular test platform to assess different control algorithms. The system has a rotational arm and pendulum. The rotation arm is exited by a motor for balancing the pendulum in the inverted position.The SRIP system is represented in Fig.2 which shows that the plan of the rotary arm is orthogonal to pendulum.

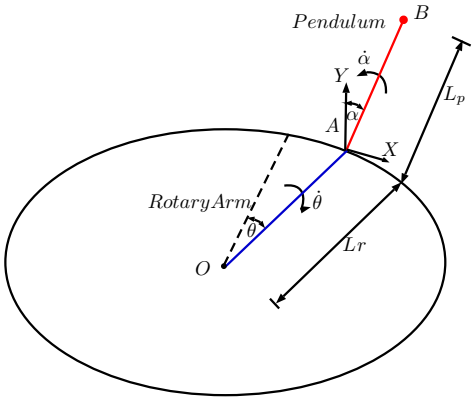

Fig. 2. Typical representation of SRIP system

A. Control relevant model of SRIP

The electrical and torque characteristic equations are formulated by using the values of Inverted Pendulum and Rotary arm parameters for mathematical model derivation. The required hardware system parameters for the state-space model are given in the table 1. There is a state vector x^T=$[\theta, \alpha, \dot{\theta}, \dot{\alpha}]$ and θ represents the rotary arm position, α is the pendulum angle, $\dot{\theta}$ is the rotary arm velocity and $\dot{\alpha}$ is the pendulum angular velocity. The measured outputs are $y^T = [\theta, \alpha]$. The function g maps the rotary arm position and the pendulum position which are the measured outputs. The function f maps the current

state and input to the next state . This model is utilized for prediction of the state trajectory over a prediction horizon N_p and the proper control action taken in order to move the state from an initial condition to the desired position. The nonlinear function of the SRIP based on the states is described by (5) and function for output by (6).

$$\begin{aligned}
f_1 &= \dot{\theta};\\
f_2 &= \dot{\alpha};\\
f_3 &= (d.u + h.cs.cos(\alpha).sin(\alpha) - Br.\dot{\theta}.d\\
&\quad - 2.b.d.sin(\alpha).cos(\alpha).\dot{\theta}.\dot{\alpha}\\
&\quad - d.cs.sin(\alpha).(\dot{\alpha})^2\\
&\quad - cs.cos(\alpha).Bp.\dot{\alpha}\\
&\quad + b.cs.cos(\alpha).cos(\alpha).sin(\alpha).(\dot{\theta})^2)/K_1;\\
f_4 &= (cs.cos(\alpha).u - Br.cs.cos(\alpha).\dot{\theta}\\
&\quad - 2.b.cs.cos(\alpha).cos(\alpha).sin(\alpha).\dot{\theta}.\dot{\alpha} - cs^2.cos(\alpha).\\
&\quad sin(\alpha).\dot{\alpha}^2 - ((a+b) - b.cos(\alpha)^2).Bp.\dot{\alpha}\\
&\quad + ((a+b) - b.cos(\alpha)^2).b.cos(\alpha).sin(\alpha).\dot{\theta}^2\\
&\quad + ((a+b) - b.cos(\alpha)^2).h.sin(\alpha))/K_1; \qquad (5)
\end{aligned}$$

where,$K_1 = (d.(a+b-b.cos(\alpha)^2) - cs^2.cos(\alpha).cos(\alpha))$ and the constants are

$$\begin{aligned}
a &= mpLr^2 + Jr, & b &= 0.25mpLp^2,\\
cs &= 0.5mpLpLr, & d &= Jp + 0.25mpLp^2,\\
d &= Jp + 0.25mpLp^2, & h &= 0.5mpLpg
\end{aligned}$$

The output function $g(\cdot)$ is given by

$$\begin{aligned}
g_1 &= \theta;\\
g_2 &= \alpha; \qquad (6)
\end{aligned}$$

The Jacobian of $f(\cdot)$ and the $g(\cdot)$

$$A = \frac{\partial f}{\partial x} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} & \frac{\partial f_3}{\partial x_4} \\ 0 & \frac{\partial f_4}{\partial x_2} & \frac{\partial f_4}{\partial x_3} & \frac{\partial f_4}{\partial x_4} \end{bmatrix}, B = \frac{\partial f}{\partial u} = \begin{bmatrix} 0 \\ 0 \\ \frac{\partial f_3}{\partial u} \\ \frac{\partial f_4}{\partial u} \end{bmatrix},$$

$$C = \frac{\partial g}{\partial x} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, D = \frac{\partial g}{\partial u} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \qquad (7)$$

by considering the actuator dynamics as

$$\begin{aligned}
A(3,3) &= A(3,3) - Kg^2.kt.km/Rm.B(3);\\
A(4,3) &= A(4,3) - Kg^2.kt.km/Rm.B(4);\\
B &= Kg.kt.B/Rm;
\end{aligned}$$

Therefore, the nonlinear state space equation is given by

$$\begin{aligned}
\dot{x} &= Ax + Bu;\\
y &= Cx; \qquad (8)
\end{aligned}$$

The above described the dynamic model in the continuous time state space form is further descretized with sampling time Ts which is $20ms$. For applying the NMPC, access to the states at the time instant k is required. The output states are mentioned in the (6)directly measured by the by encoders. The other state values (rotary arm velocity $\dot{\theta}(k)$ and pendulum velocity $\dot{\alpha}(k)$ are approximated via a finite difference approximation with respect to the sampling time Ts is mentioned in the (9).

$$\hat{\dot{\theta}}_k = \frac{\theta_k - \theta_{k-1}}{T_s}, \qquad \hat{\dot{\alpha}}_k = \frac{\alpha_k - \alpha_{k-1}}{T_s} \qquad (9)$$

The SRIP is initially at the stable equilibrium position ($\alpha = -180\ \ degree$) and the purpose is the pendulum to be inverted ($\alpha = 0\ \ degree$) and make it stable. Based on the requirement of SRIP controller, the cost function will be formulated as per (3) for stabilizing the inverted pendulum in the upward direction by optimizing the control signal with respective to the constraints defined in (10) position of input (degree) and input voltage (V_m).

$$\begin{aligned}
-10\ degree \leq \alpha \leq +10\ degree \qquad (10)\\
-10\ V_m \leq u \leq +10\ V_m
\end{aligned}$$

TABLE I
DEFINITION OF PARAMETERS IN THE MATHEMATICAL MODEL DEVELOPMENT

Symbols	Parameters	
	Description	***Value***
Rm	Motor armature resistance	2.60 (ohm)
kt	Motor torque constant	0.00767 $(N.m/A)$
km	Motor back-EMF constant	0.00767 $(V.s/rad)$
Kg	Total gear ratio	70
Jr	Motor armature moment of inertia	0.0010 $(kg.m^2)$
g	Gravitational constant	9.81 (m/s^2)
mp	Pendulum Mass with T-fitting	0.127 (kg)
Lp	Full Length of the pendulum (w/ T-fitting)	0.337 (m)
Lr	Distance from pivot to center Of gravity	0.216 (m)
Jp	Pendulum moment of inertia	0.00120 $(kg.m^2)$
Br	Viscous damping coefficient as seen at the rotary arm axis	0.00240 $(N.m.s/rad)$
Bp	Viscous damping coefficient as seen at the pendulum axis	0.00240 $(N.m.s/rad)$

B. Control Mechanism

For the real time control of SRIP, two control actions are required. One is for swing up the pendulum i.e. downward to upward direction and second is to stabilize it in the upward (inverted) position. In this paper two separate controllers i.e. energy based swing up controller [16] and the NMPC for balancing the inverted pendulum are used which are shown in Fig. 3. This paper focused on balance control of the SRIP using NMPC. The switching of two controllers from swing up (switch 1) to NMPC (switch 2) is decided by the pendulum position angle measured by the encoder. The NMPC controller starts working as soon as the pendulum angle is $\pm$ 10 degree. Initially, the values of the different design

parameters were chosen for satisfactory control performance and avoiding excessive computational efforts. The N_p is of 22 samples and N_c is about 3 samples, respectively, with the weight matrices, $R = 0.1$ and $Q = diag([1, 5])$.

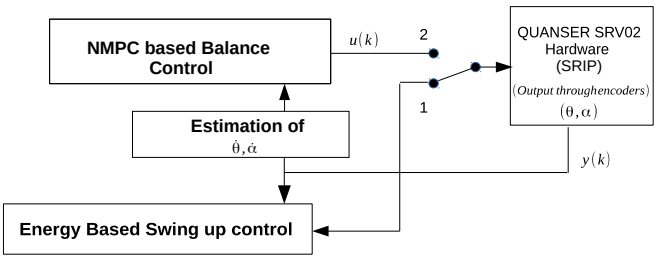

Fig. 3. Block diagram of the control structure for SRIP

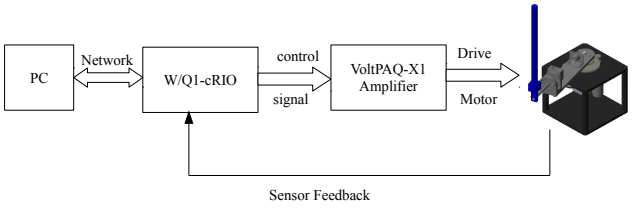
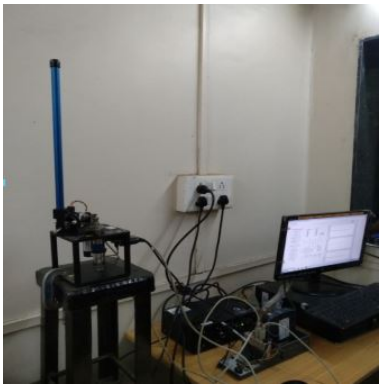
C. Real-Time Hardware Implementation on cRIO

The efficacy of an FPGA based implementation of NMPC for the nonlinear real-time system is demonstrated experimentally using the core FPGA hardware. Once the required time and expected accuracy is acquired through the LabVIEW simulation, other interfacing blocks are also embedded to prototype using cRIO platform. This platform is assuring solution for the easy and fast NMPC algorithm verification.



(a)



(b)

Fig. 4. (a) Interconnections of devices required for real time implementation(b) Experimental lab set up

The experimental set up has Inverted Pendulum with Q1 data acquisition card, SRV02-ET rotary servo, cRIO FPGA, a PC equipped with RCP toolkit 1.2.903, VoltPAQ-X1 Single Channel Linear Voltage Amplifier and NI MAX Measurement and Automation software provided by National Instruments (as shown in Fig. 4 (a). To realize the implementation of complete NMPC controller on cRIO FPGA, hardware-in-loop (HIL) co-simulation method has been used. The real time implementation of the NMPC, the experimental setup for the SRIP system is as shown in Fig. 4 (b). The dynamic response of the SRIP is observed and monitored through the LabVIEW. On this platform, a LabVIEW project, a HIL included in VI, and a host VI is created. On the development computer, the LABVIEW project file manages the cRIO FPGA and all the VIs. The host VI runs on a cRIO, Real Time target. The TCP/IP protocol is used to link between PC and cRIO. It acquires the signals from the Encoders mounted on the plant via the ADC input modules to calculate the control signal $u(k)$ according to the NMPC algorithm and sends it to the SRIP via analog output modules.

IV. Experimental Results and Discussion

The dynamic response of the Inverted Pendulum is observed and monitored through the LabVIEW. The response of the real-time SRIP system before and after applying the disturbance is shown in Fig. 5 and Fig. 6. In the Fig. 5(a) the real time response of the rotary arm for the stabilizing the pendulum in inverted direction (Fig. 5 (c)) has been shown with swing up control. The control efforts (Voltage) required to the rotary arm for controlling the pendulum in the upright position is shown in Fig. 5(b). Due to energy based oscillatory input the time required to reach at vicinity of the initial condition of the NMPC is somehow more, but the NMPC quickly stabilized the pendulum within a second.

For the testing of the robustness of the controller, manually disturbance is applied at the tip of an inverted pendulum at the 40 second, time instant. The extra efforts required to overcome the disturbance in terms of the rotary arm position and the input voltage shown in Fig. 6(a) and Fig.6(b) respectively. The inverted pendulum stabilized quickly against the disturbance within a second which explored in Fig.6(c).

V. Conclusion

The NMPC is successfully controlled and balanced the inverted position of the pendulum irrespective of the 20 ms fast sampling rate. For checking the disturbance rejection capability, the small disturbance is applied manually at the tip of the inverted pendulum. The control input and the rotary arm position follow their respective limits which is defined as a constraints. The pendulum is swiftly returned to the upright position. Real time challenging problems can handle rapidly on cRIO (FPGA) hardware platform with NMPC. For testing the efficacy of NMPC for the nonlinear plant, rigorous experimentation has performed with different sets of tuning parameters. By selecting an appropriate tuning parameters for NMPC, experimental result shows, the NMPC on FPGA achieve satisfactory performance with robustness.

To avoid the requirement of the two separate controllers, the future work may be focused on the formulation of the NMPC

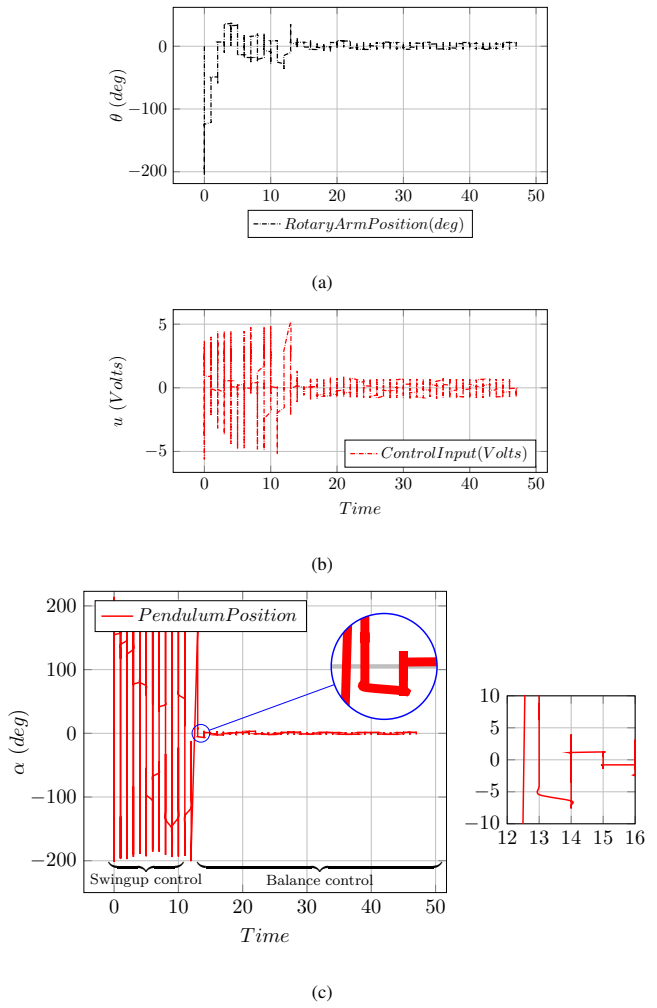


Fig. 5. Qansers SRV02-ET rotary servo systems (SRIP) response of (a) rotary arm (b) control input and (c) pendulum to NMPC algorithm with swing up and balance control without any disturbance

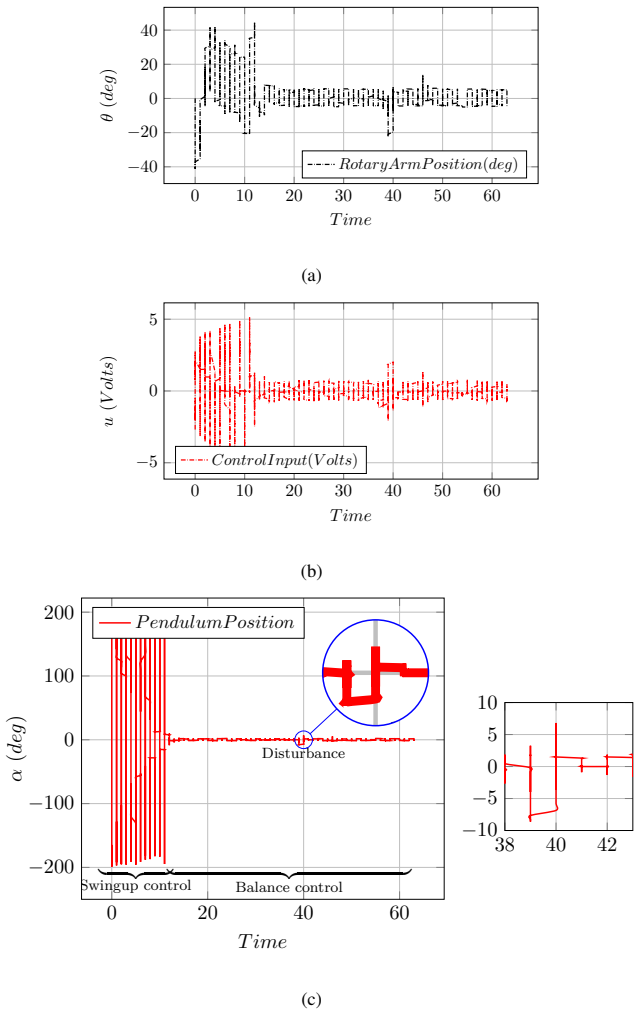

Fig. 6. Qansers SRV02-ET rotary servo systems (SRIP) response of (a) rotary arm (b) control input and (c) pendulum to NMPC algorithm with swing up and balance control with manual disturbance

such that it will be the self sufficient controller for controlling the swing up and the balance control of SRIP efficiently within optimum time.

***Abstract*—Nowadays, almost all countries are facing the problem of internal security from their border areas. Terrorists and intruders are disturbing the tranquillity and consonance of the country. The casualty prompted by the recent Pulwama strike and Uri attack against Indian military force reveals the significance of effective surveillance in the border region and detection of the human intruder in that area to control the terrorist activities on borders. Traditional border patrol systems require a huge number of military persons, and high-cost, high-tech surveillance devices employed in unmanned border patrol systems. Line of sight restrictions and high false alarms are the problems experienced by using any of these techniques. There is a need in developing a multi-sensing system that integrates different technologies to detect the human intrusion with improved system accuracy in flat border areas, border areas with river or pond crossings and border areas covered by dry leaves. The paper proposes a hybrid Wireless Sensor Network system architecture named "PANCHENDRIYA", utilizing the integration of five types of sensors: Geophones, Hydrophones, Microphones, Infrared sensors and Camera sensors for effective surveillance and detection of human intrusion in the above-mentioned border scenarios with early warning capability.**

Keywords—Wireless Sensor Networks, Multi-sensing system, Border surveillance, Intruder detection

I. INTRODUCTION

All governments expressed the necessity of effective surveillance and intrusion detection system to govern the risks of intrusion on borders either for unauthorized goods transportation or for terrorism. India is facing terrorist attacks from Pakistan and violation of truce across the LoC (Line of Control) in Jammu & Kashmir, which presently interrupted the peace and harmony of the nation. Chinese interruptions through the Sino-Indian border also creates problems in that region. Infiltration and violation of truce through LoC is persistent in the last couple of months. These incidents will turn to the need of a multi-sensing system with less human involvement for efficient detection and tracking of human intruders to providing early warning to the Central Monitoring Station after detecting any kind of intrusion by coordinating various technologies.

Wireless Sensor Network (WSN) is an emerging field for connecting the physical and digital world [1]. The WSN framework is used to monitor physical or environmental conditions with the aid of autonomous devices using sensors [2]. WSNs are mainly used in military, health, environmental and home applications [3]. To overcome the challenges faced by the existing surveillance methods, a new multi-sensing system named "PANCHENDRIYA" is proposed to detect the presence and track the human intruder movement through advanced WSNs. PANCHENDRIYA is a new framework with minimum human involvement for solving the problem of unauthorized movement of the human intruders. The paper proposes a new architectural design model for sensing and detection circuits based on the following three scenarios: flat border areas, the border area with river or pond crossings, and the border area covered by dry leaves. The methodology behind the system design is an adaptive platform that could be built later and expanded.

The related works in the border surveillance and intruder detection field is provided in Section II. The system architecture of PANCHENDRIYA is explained in Section III. The block diagram of the system is mentioned in Section IV. WSN model of the system is described in Section V. Section VI explains the overall workflow of the proposed system.

II. RELATED WORKS

The research work of Sun, Zhi, et al., named Border Sense is an architectural proposal consists of three layers namely, Lower layer, Second layer and Higher layer [4]. Underground and ground-based sensors employed in Lower layer improves the quality of monitoring. Multimedia sensors incorporated to the Second layer provides visual information that increases the system accuracy. Unmanned Aerial Vehicles and the lightweight ground robots in the Higher layer provides extra coverage and flexibility to the monitoring system.

Succi et.al., introduced the human intruder detection through footstep signals using kurtosis method under the various style of walking with single and multiple walkers and different test environments [5]. The development of the human

intrusion detection algorithm is based on intrusion detection within the range of the sensors.

Deekshit et.al., work involved a smart geophone sensor network for detecting landslide induced signals by removing different noises that arrive from footstep, rainfall and movement of vehicles [6]. A simple solution using Arduino based data acquisition system with geophone sensor is developed. The resonance frequency is the key factor in a geophone and it has to be kept low for the measurement of the low-frequency signals.

The ground permits the propagation of waves through it. The human footstep signal imposed on the ground is able to detect 100m away from the sensor region under ideal situations. The Rayleigh wave is the main seismic wave considered for human footstep signal detection. It carries 67% of energy from the footsteps and is captured using tri-axial geophones [7].

Passive Infrared sensor (PIR) and MICAz motes are used for human intrusion detection in the border areas [8]. The proposed system captures the direction of the human intruder movement and the speed of walking. The collected information is communicated to the central monitoring station for further analysis. PIR sensor placement follows line topology and a direct line of sight for detection.

Nakadai, Kazuhiro, et al., used a distributed microphone array for human footstep detection. The overall system setup comprises of sound acquisition, event detection and signal conditioning with coarse to the fine procedure for signal peak detection in the time domain [9]. It also uses the Support Vector Machine (SVM) technique for classification of sound signals in a real-life situation and understanding the real event based on the velocity of the sound generated.

Marius Vasile Ghiurcau, Corneliu Rusu, et al., introduced a technique called Time Encoded Signal Processing and Recognition or TESPAR for testing the performance of a monitoring system and concluded that using TESPAR, the classification of sounds generated by human, birds, and vehicles can efficiently be carried out [10]. Complex waveforms can be represented in digital form using TESPAR, which is based on the infinite clipping theory of researchers, Licklidder and Pollack.

Sutin, Alexander, et al., proposed a framework incorporated with Hydrophone sensors named as SPADES (Stevens Passive Acoustic Detection System) for detection, tracing and categorization of dissimilar sounds in surface and submerged outset [11]. The information captured by the Hydrophone sensors is sent to the land-based personal computers for further analysis.

Harish, Palagati, et al., uses video content captured through surveillance camera for intrusion detection and tracking [12]. The proposed method extracts features of the object and semantic contents from the video. The paper also provides information on object movement in the observed area of interest using the semantic content.

III. PANCHENDRIYA - SYSTEM ARCHITECTURE

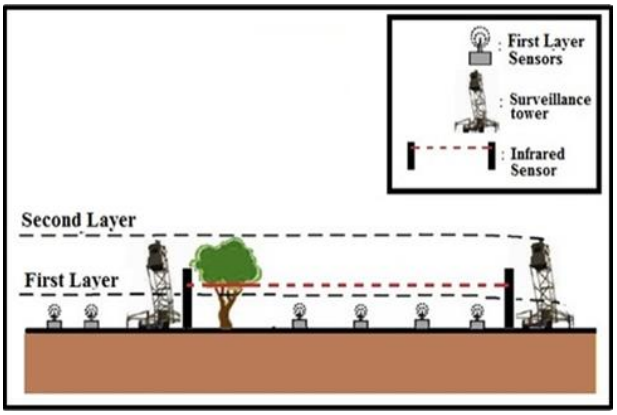

Fig. 1. Different layers of the architecture for a single zone

The proposed system (Fig. 1.) is a multi-sensing system used to monitor and detect any kind of human intrusion in the border area with the aid of low power sensors. The use of low power sensors will improve the efficiency and reliability of the system. A country border is a vast area, which is divided into different zones and the architecture for each zones are designed. The overall architecture of the system contains two layers:

- The First Layer of the architecture contain sensors such as Geophones, Microphones, and Hydrophones that can detect the presence, and track the direction of intruder movements.
- The Second Layer contain surveillance Cameras and Infrared sensors. Cameras provide multimedia information, which enhances the overall system accuracy through visual information and provides better border surveillance. Infrared sensors are used to identify the movement of intruders, whether movement is from Country B (Opposite country) to Country A (Own country) or in reverse direction.

The sensors are deployed based on their coverage range (Fig. 2.), considering the single zone of the overall architecture. The entire deployment region under consideration is covered by the least number of sensors. The proposed system detects the presence and movement of the human intruder by considering three border situations: flat border area, border region with river or pond crossing, and the border region covered by dry leaves. The above-mentioned situations are considered based on the real border region scenarios. When the intruder moves from Country B to Country A, the five sensors involved in the proposed framework performs the following actions. Geophones detect the footstep movement of the human intruder in flat border areas, Hydrophones detects the movement of the intruder crossing the river or pond, and Microphones detects the movement through the dry leaves. The Infrared sensors provide the information of intruder crossing the borderline and finally, the Camera sensors capture the visual information of the intrusion in the border region. The self-excitation capability of Geophone and Hydrophone sensors are helpful to detect the human footstep signals far away from the borderline is helpful to achieve early warning capability.

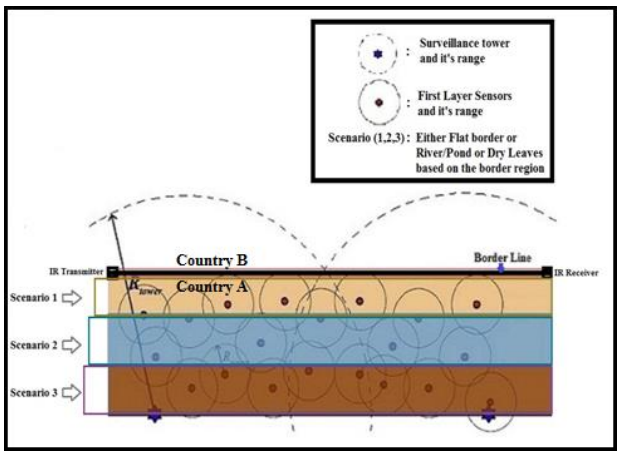

Fig. 2. Deployment of Sensor Nodes for single zone

IV. Block Diagram

The block diagram of PANCHENDRIYA system is shown in Fig. 3. The data acquisition module of the First Layer continuously collect data from each sensors and communicate to the Central Monitoring Station through wireless transmission. The event/signal detection algorithm based on the predefined detection threshold is used for human footstep signal detection in the First Layer. The predefined threshold values of human footstep imposed on each border scenario are fixed based on the various field tests conducted in the testbed. The detected signal is compared with the predefined threshold values. If the detected signal value is greater than the detection threshold value, then there is a human intrusion happening in the border. The Second Layer containing the Infrared sensor with an IR transmitter and receiver section detects the intruder movement between the borderline. The system counts the number of intruders present in the particular sensor region. The Second Layer include Camera sensors that continuously surveillance the border area. Once any kind of intrusion is identified, the Camera sensors rotated immediately to the particular sensor region. The detected signals and the multimedia information captured from the Second Layer through respective data acquisition modules are pre-processed using signal detection algorithm/image processing algorithm in the Central Monitoring Station. Thus, the proposed system achieves in getting a clear picture of the human intrusion occurring in the border area. Once any kind of human intrusion is detected, the Central Monitoring Station sent the warning messages to the border troops for further actions.

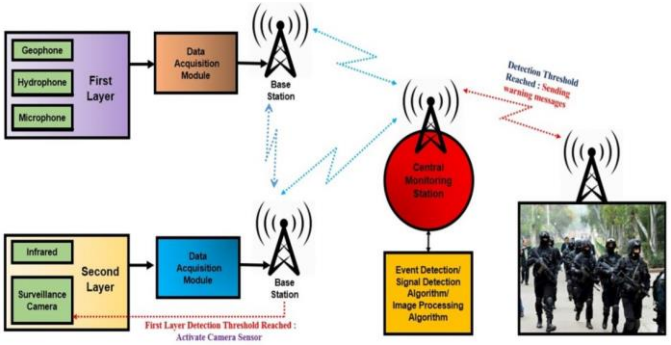

Fig. 3. Block Diagram of PANCHENDRIYA

V. WSN Model

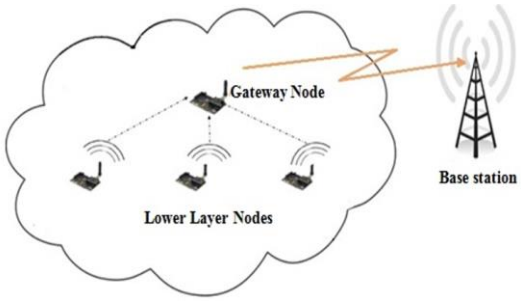

Fig. 4. WSN system architecture

The sensor nodes in the WSN system architecture is shown in Fig. 4. It contains three Lower Layer nodes such as a Geophone, Hydrophone, and Microphone sensors and a Gateway node. The data from Lower Layer nodes are communicate to the Gateway node. Gateway node further forwards the data to the Central Monitoring Station through the base station.

The State diagram of individual Lower Layer sensor nodes in the three particular border scenarios and the state diagram of the Gateway node are shown in Fig. 5. Each individual node is incorporated with different operational states such as:

- OFF: Power null/ energy consumption equals to zero.
- Listen: Radio module is active but no transmission or reception of any packets.
- Sleep: Radio module is inactive and the node is in the sleep mode. It needs some trigger pulse to get back to the listen state.
- Active: Whenever a node is triggered to an active state, it will provide transmission and reception.

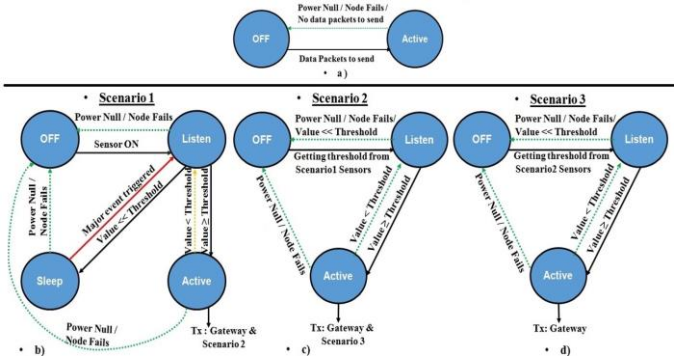

Fig. 5. State diagram of: a) Gateway node, b) Geophone sensor node, c) Hydrophone sensor node and d) Microphone sensor node

VI. Proposed System Flow Chart

The overall work flow of the proposed system is shown in Fig. 6. The test bed is planning to prepare under three border scenarios. The First Level of the testbed include Infrared (IR) and Geophone sensor, the Second Level includes Hydrophone and the Third Level include Microphone and Camera sensor.

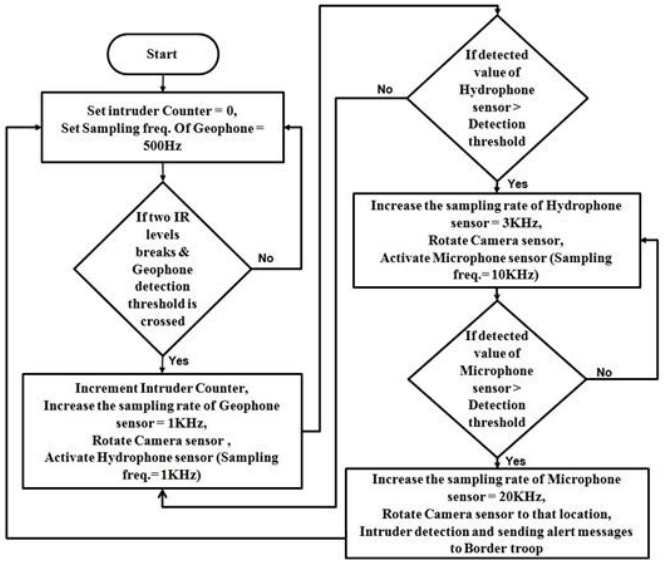

Fig. 6. Overall System Flow Chart

Initially, the bidirectional IR counter circuit is set to zero (no intrusion) and the sampling frequency of Geophone is set to 500Hz. When a human intrusion happens in the border region, the two IR levels are interrupted, showing the sign of intrusion and incrementing the counter value by one. The Geophone continuously monitors the region of interest and self-excited based on the footstep of the intruder. The sampling frequency is increased to 1 KHz, if the predefined detection threshold of the Geophone is crossed. After the First Level intrusion detection, Camera sensor in the surveillance tower immediately rotates into the First Level sensor region, activates the Hydrophone sensor in the Second Level, and collect signals with a sampling frequency of 1 KHz. If the Hydrophone detects signals greater than the predefined detection threshold value, the Camera sensor then rotates into the Second Level sensor region and activates the Microphone sensor in the Third Level. When the detection threshold of the Microphone is crossed, it collects data at a sampling frequency of 3 KHz. If the detection threshold value of the Microphone is greater than the predefined detection threshold due to human intrusion in the Third Level, the Camera sensor immediately rotates into the Third Level sensor region and at the same time, a human intrusion message is sent to the border troop from the Central Monitoring Station. The detection process is iterative. After each detection, the system returns to the initial state and the human intrusion detection process is continued.

VII. Conclusion and Future Scope

The proposed framework "PANCHENDRIYA" delivers a new system architecture, block diagram, overall system flowchart and WSN model for human intruder detection in three different border scenarios such as flat border regions, border region with river or pond crossings, and the border region covered by dry leaves. The proposed multi-sensing approach utilizes Geophones, Microphones, Hydrophones, Infrared and surveillance Camera sensors, and wireless communication capabilities that provide efficient border surveillance and human intruder detection. The future work focuses on building a testbed setup for analyzing the performance of this multi-sensing system and validation of the proposed system based on various test procedures. Thereby the system capability is ensured to detect any kind of human intrusions effectively in the above-said border scenarios, and to provide early warnings.

Acknowledgment

Abstract— ***Disparity map generation is necessary in many 3D applications. This paper focuses on disparity map estimation using local based stereo matching. Stereo correspondence algorithms are categorized as global method and local method. Global based methods are computationally expensive. This paper proposes an improved stereo matching algorithm by using local method which combines cost computation of gradient information and histogram of oriented gradient. The results obtained shows better quality disparity map.***

Keywords— Disparity; Gradient; Histogram

I. INTRODUCTION

Stereo correspondence between the pair of stereo images results in disparity map. The disparity map finds its use in depth estimation which is used in different applications like robotics, 3D reconstruction of scene, and artificial intelligence. Hence disparity map generation is a crucial and a difficult job in the area of computer vision. Stereo correspondence problem aims at finding matching pixels between stereo pair. The stereo correspondence algorithms are broadly categorized into two methods namely local method and global method [1-9]. Active research is conducted in the recent years to solve stereo correspondence problem to obtain disparity map [10, 11]. Local based methods obtain disparity from local information. Local methods are then classified as area based and feature based. Area based method correlate certain patches of area among the images. This method takes an area on the left image and finds an equal sized area in the right image which is closest match possible. This area is called matching window. The x coordinate difference between the centre of the matching window and the centre of the left window is the disparity value. Usually the small sized window will produce more detail but they are prone to more noise. Large sized window produce a smooth disparity map but with less detail. Hence finding the optimal sized window is the challenging task. Feature based method computes the matching pixel by using certain features extracted from the image. These features include corners, edges. Local based methods are simple and computationally less expensive. The global based method computes the disparity using optimization of the whole image globally. Global stereo matching algorithm focuses on minimizing the global cost function. This method is generally less sensitive to local individualities. These methods gives better result but computationally expensive. The accuracy of the local method depends on appropriate selection of similarity measure function and optimal window size. Generally stereo matching algorithm finds corresponding points based on intensity. But they do not perform well near boundaries and depth discontinuities. To reduce this problem many researches are conducted to determine corresponding points in these regions. Authors in [12, 13, and 14] find the corresponding points based on information such as gradient. These gradient based methods perform well near the boundaries. But the individual gradient information may be prone to noise. Hence the proposed method uses histogram of oriented gradients along with gradient value to reduce noise. The authors in [15] combined the gradient of the image and the intensity to find the matching cost. The combined measurement of the cost produced better result than the individual one. Hence combined cost technique is implemented in this paper.Traditional method computes the disparity by comparing only intensity value or gradient value. This paper proposes a novel technique of generating disparity map based on local method by combining the gradient information and histogram of oriented gradients (HOG) to enhance the reliability of the matches. The disparity map obtained is post processed by applying median filter to generate the refined disparity map. The results produced shows that the method proposed in this paper yields better result than the existing approach which is based on gradient information.

Section II includes details of the methodology described in the paper. The results obtained on various kinds of images are given in section III. Section IV includes concluding remarks

II. PROPOSED ALGORITHM

The various steps of proposed method for disparity map generation are as follows

A. Stereo Matching

Stereo matching using local based method relies on cost function for matching. There are various dissimilarity measures for cost computation such as sum of absolute

difference, sum of squared intensity difference (SSD). Here SSD for matching cost of gradient and histogram of gradients (HOG) is used. Gradient of the image plays a significant role in the area of computer vision. Color intensity is sensitive to distortions and illumination differences.Image gradient has structural details of the image. Hence it is insensitive to differences in illumination. Gradient of images are generated from the initial image by convolving it by a filter. Here Sobel filter is used. Every pixel present in the gradient image computes the variation of intensity of the corresponding point present in the initial image, which is in a particular direction. To get the complete range of the direction, gradient images are calculated in x and y direction.

$$\Delta f = \begin{bmatrix} Gx \\ Gy \end{bmatrix} = \begin{bmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{bmatrix} \quad (1)$$

Here $\frac{\partial f}{\partial x}$ gives the image gradient tin the x direction and $\frac{\partial f}{\partial y}$ gives the image gradient in the y direction.

Considering only gradient information may be sensitive to noise, hence HOG descriptor is also used in the proposed method to make it less sensitive to noise. The HOG is a feature descriptor used in computer vision. This counts the number of occurrences of orientation of gradient in a portion of image. HOG descriptor is invariant to photometric transformations. The image is grouped into small connected regions called as cells, and for each connected region we compute a histogram of unsigned gradient orientation. The histograms for all connected regions are then combined to get the HOG descriptor.

The proposed algorithm finds squared differences of gradient value and HOG feature. To compute the squared differences we subtract the gradient value and HOG value of a pixel in the left image with the corresponding gradient value and HOG value in the right image. Then the square of the differences is computed. The sum of squared differences of all the pixels enclosed within the window is then computed. The cost function based on gradient and HOG is calculated as follows

.

$$CG(x,y) = \sum_{(x,y)\epsilon W}^{N} |Gl(x,y) - Gr(x-d,y)|^2 \quad (2)$$

$$CH(x,y) = \sum_{(x,y)\epsilon W}^{N} |Hl(x,y) - Hr(x-d,y)|^2 \quad (3)$$

Here $Gl(x,y)$, $Gr(x-d,y)$ are gradient information of the left reference and the right image. $Hl(x,y)$, $Hr(x-d,y)$ are the HOG values of pixel(x, y) of the left reference image and of the right image, d shows the disparity value. w is the square window of size 8 x 8 that surrounds the pixel (x, y).

The least difference value over the window shows the best matching pixel, and the location of this minimum information gives the optimal disparity of the actual pixel. Here the optimal disparity based on gradient and optimal disparity based on HOG feature is found. This yields two disparity values based on gradient information and HOG value. The disparity map is obtained by combining the weighted sum of two disparities.

$$d = (\propto * d_1) + (\beta * d_2) \quad (4)$$

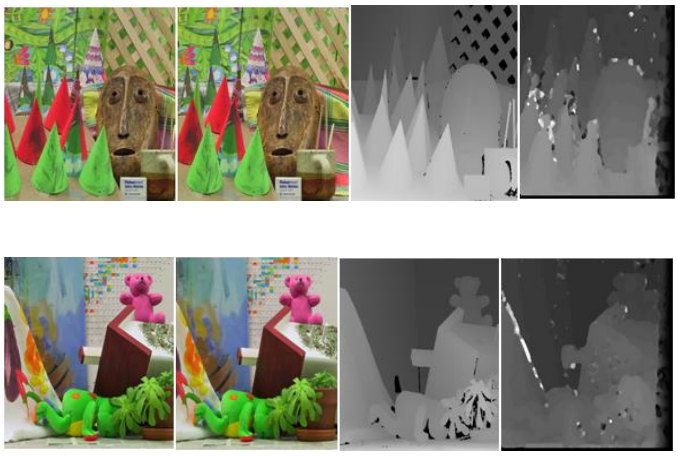
Here d_1 is the disparity obtained based on gradient, d_2 is the disparity obtained based on HOG and $\propto + \beta = 1$. Here we used $\propto = 0.8$ and $\beta = 0.2$

B. Post Processing

The post processing of initial disparity map is performed using a median filter. Median filter selects the median value of the pixels enclosed in a window and replaces each pixel value in the image by the median value ofl the pixels enclosed in the window. This median value is computed by first sorting the entire pixels contained in the window. Then the pixel under consideration takes the value of the middle pixel.

III. EXPERIMENTAL RESULTS

In the proposed method we used images from Middlebury dataset to assess the performance [16, 17].The images like cones, Teddy, Baby were used. Result is shown in Fig 1.



(a) (b) (c) (d)

Fig. 1 Results for images , cones , Teddy, Baby . (a) *Input left* image, (b) Input right image, (c) Ground truth image (d) Disparity Map

Quantitative analysis is done using the metric like percentage of bad matching pixel (PBMP) and root mean square error (RMSE).

PBMP is generally used to analyze the quality of the disparity map.PBP is computed as follows

$$PBMP = \frac{\left[\sum_{x,y} dt(x,y) - dg(x,y) > \delta\right] * 100}{N} \quad (5)$$

Here N is the total count of pixels dt represents the disparity map generated by the proposed method, dgrepresents the disparity map of the ground truth image, and $\delta$is the error threshold. In the proposed method the value of this error threshold is taken as 1. Lower PBMP value gives better quality disparity map.

Table 1 shows the PBMP values calculated using gradient based method and proposed method. We find the bad matching pixel percentage obtained in the proposed method is less than the gradient method.

Table 1: PBMP

	Gradient based	Proposed Method
Cones	2.4246	2.3086
Teddy	1.4160	1.3992
Baby	0.1953	0.1052

RMSE is calculated between the computed disparity map and the ground truth map using the following equation

$$RMSE = \left(\frac{1}{M * N}\sum\sum(dc(x,y) - dt(x,y))^2\right)^{1/2} \quad (6)$$

Here dt is the computed disparity map and dg is the ground truth disparity map. M and N represent the number of rows and columns present in the image. Lower RMSE value gives better quality disparity map.

Table 2 shows RMSE values calculated using gradient based method and proposed method. We find the RMSE of the images obtained in the proposed method is less than the gradient method.

Table 2: RMSE

	Gradient based	Proposed Method
Cones	15.26	14.81
Teddy	15.11	14.87
Baby	8.55	7.27

IV. CONCLUSION

This paper proposes an improved stereo matching method using combination of gradient information and HOG information. The effectiveness of the method proposed is analyzed using different stereo pairs from Middlebury dataset. The results obtained indicate that the proposed method produces high quality disparity map and outperforms the existing method in terms of PBMP and RMSE.

Object Detection and Gesture Control of Four-Wheel Mobile Robot

M. Jain[1], M. Sehgal[1], Y. Kalra[1], P. Jain[1], N. Aggarwal[1], R.Singh[1*], D. Kumar[1] and T. K. Bera[1]
[1]Mechanical Engineering Department, Thapar Institute of Engineering and Technology, Patiala.

Abstract—In this paper, the development of a four wheel mobile robot with gesture-controlled robot arm manipulator system is presented. The accelerometer and wifi based gesture control model is used to manipulate the motion of its arm with human hand. The glove data is used to control the movement of the robot arm for pick and place operation. The object detection algorithm is also implemented to detect the object autonomously. An ultrasonic sensor is used to detect the upcoming object. Under this work, only single object is considered. The prototype model of four-wheel mobile robot with two movable arms is developed. The proposed object detection algorithm is implemented on the physical model to check the effectiveness of the algorithm. After object detection operation, the gesture control based controller is used for pick and place activity. The novelty of this research is collaborative use of object detection algorithm and gesture control scheme.

Keywords— ***object detection, gesture control, four-wheel mobile robot, ardiuno nano, accelerometer.***

I. INTRODUCTION

Nowadays, robotics is emerging domain in the field of technology. A Robot is an electro-mechanical model, operated by a computer program. It can be autonomous or semi-autonomous. An autonomous robot has no human interfacing. Majority of the industrial robots are autonomous as they require high speed. But, some areas have requirement of semi-autonomous or human controlled robots. Mobile robots are used in home environment in today's scenario [1]. Home robots are now working around us and help us a lot in our daily routine activities. The activities such as cooking, cleaning, watering and pet feeding are done by the home robots [2-5]. There are numbers of methods to interact with these robots, such as voice, gesture, and joystick. The voice command is suitable to control call-and-come service [6]. It has disadvantage that it is not suitable for continuous remote control. In such cases, the gesture control is more appropriate for robot's control. There are several methods to collect a human gesture that a machine would be able to interpret. The camera or data glove is used to capture the gesture information. The gestures data can also be collected via Bluetooth or infrared waves, Tactile, optical or motion technology. The accelerometer/gyroscope is best device to control the minute movement of the arm manipulator [6].

In this paper, an attempt has been made to develop semi-autonomous robot. The four-wheel mobile robot with arm and gripper is considered in this work. Firstly, the robot detects the object from its surrounding environment. The simple and very effective object detection algorithm based on single ultrasonic sensor reading is proposed and its effectiveness is checked on the prototype model and this is the novelty of the research work. Secondly, the gesture based controller is developed to control the motion of the arm. To control the movement of mobile robotic arm, the accelerometer/gyroscope and wireless communication using ardiuno are used. The pick and place operation is considered under this research work. Also, the physical model of the robot is developed and controlled with ardiuno board.

This paper is structured as follow: In Section 2, the object detection algorithm is developed using single ultrasonic sensor. 3-axis accelerometer based gesture controller is developed in Section 3. The pick and place application is considered for validation of the proposed controller. In Section 4, the four-wheel mobile robot is discussed. The prototype model of the four-wheel mobile robot is developed in Section 5. Also, experimental work is considered for pick and place application. The results are discussed in Section 6. Section 7, concludes the paper.

II. OBJECT DETECTION

Many researchers have worked on the subject of obstacle avoidance for robots. The fuzzy controller and vector field histogram (VFH) were implemented to avoid obstacles [7]. The real-time path-planning algorithm for avoiding static obstacle based on two LIDAR sensors reading was proposed in [8] and in this paper, the simulation results were compared with the experimental results. The geometric modelling based obstacle avoidance algorithm was developed in [9] and 2-D geometry shapes were considered to develop the obstacle free path. The on-board monocular camera was used to detect the obstacle for mobile robot [10]. In this paper, the attempt is made to develop very simple object detection algorithm based on an ultrasonic sensor that is mounted on front of the robot.

A. Object Detection algorithm

The simple and effective object detection algorithm is developed in this section. Figure 1 shows the flow diagram of the algorithm.

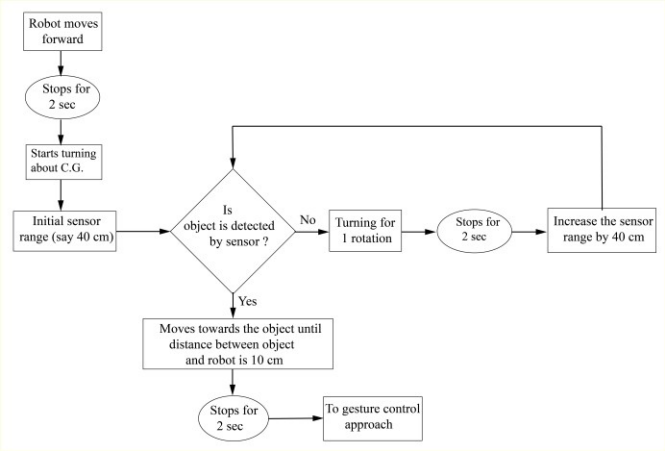

Fig 1. Flow chart of object detection algorithm

Initially, the robot moves in forward direction and then stops for 2 sec. After that, the robot starts turning about its centroid (C.G.). Initially, the ultrasonic sensor range is set to 40 cm. During turning operation, if sensor detects any object within its range, the robot stops in that orientation. If no such object is detected by the robot during first rotation, the robot stops for 2 sec and then, range of the sensor is increased by 40 cm to initial setting i.e. in this case, 40 + 40 = 80 cm. Now, again robot starts turning about its C.G. and searches the object with its range limit of 80 cm. Similarly, same procedure is applied until the object is detected. The proposed algorithm is implemented on the physical model of the robot in later section.

III. GESTURE BASED MANIPULATION

There are many devices available in market to control the gesture manipulation. The full body motion capture device Xsens MVN was used to control the movement of the robot [11]. This device is mostly suitable for animation creation, but could be adapted to other tasks. Myo arm band uses inertia and electromyography (EMG) sensors [12] to control the motion. An image based motion sensing was applied to some situations [13] too. In this paper, 3-axis accelerometer is used to control the 3-DOF (Rotation about vertical and horizontal axis, opening and closing of gripper) of the robotic arm with wifi connectivity.

A. Control approach

A robotic system that allows users to control an industrial robot using arm gestures and postures is proposed. A 3-axis accelerometer is selected to be the input devices of this system and to capture the human gesture-behavior. When compared with other common input devices, especially the joystick/remote interface, this approach using accelerometer/gyroscope is more intuitive and easier to work, besides offering the possibility to control a robot by wireless means. Using this system, a non-expert robot programmer can control a robot quickly and in a natural way. Figure 2 shows the control scheme for controlling the four-wheel mobile robot using blue-tooth, accelerometer and OS module. L298K is used to control the servo motors for wheels.

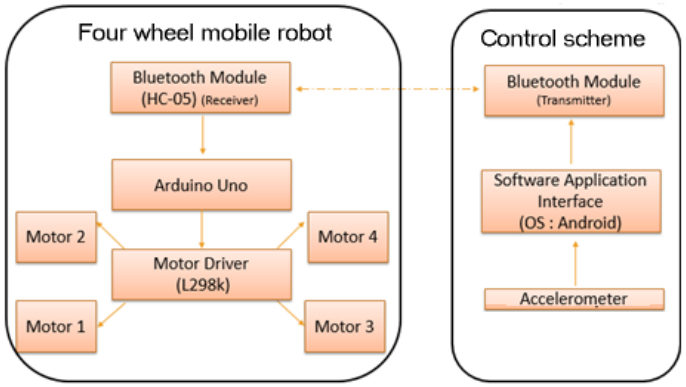

Fig. 2 Control block diagram for four-wheel mobile robot

Figure 3 shows the control scheme for controlling the manipulator action. The manipulator arm is controlled by glove data. The wifi adapter is used to control the arm of the robot. Wifi receiver and transmitter (RC-A-693) are used to control the robotic arm. The accelerometer (MPU6050) is mounted on the glove as shown in Fig. 4 (a).

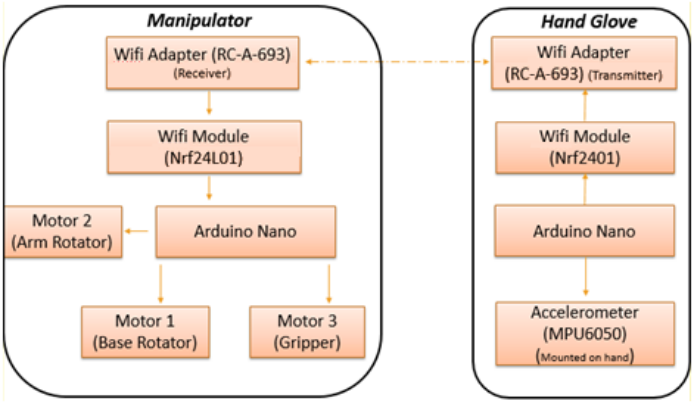

Fig. 3 Control scheme for manipulator

The various actions are assigned to control the movement of the arm. Figure 4 (b-f) illustrates the actions of human hand to control the manipulator. The upward and downward movements of the hand indicate the controlling of the up and down motions of the arm, respectively; left and right movements of the hand indicate opening and closing of the gripper, respectively. After performing numbers of trial runs, the relation between the movement of the hand and arm is developed and is mentioned in Table I.

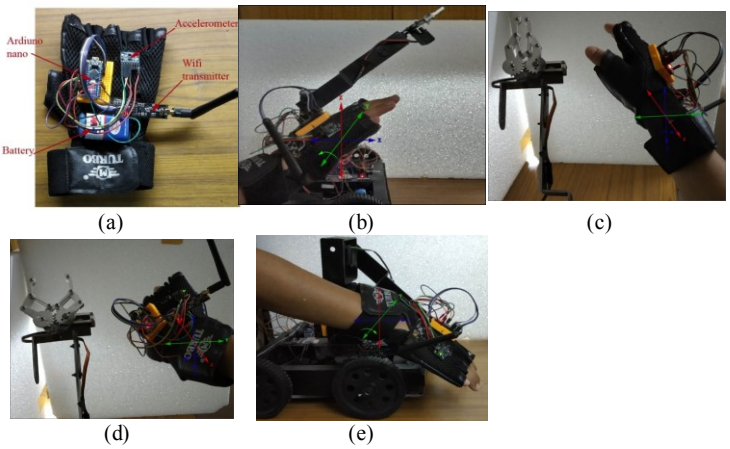

Fig. 4 (a) Glove data, (b) Upward motion, (c) Closing of gripper, (d) Opening of gripper and (e) Downward motion

TABLE I Relations between movement of hand and robotic arm.

Movement of hand (Degree)	**Movement of robotic arm along with gripper**
1^0 CCW/CW pitching motion of hand about y-axis looking from right	1.1^0 CCW/CW pitching motion of robotic arm about y-axis looking from right
45^0 CCW/CW rolling motion about x-axis looking from front	Full closing/opening of gripper

IV. FOUR-WHEEL MOBILE ROBOT

Four-wheel mobile robot without arm is shown in Fig. 5. It is assumed that the robot is symmetrical with respect to its longitudinal axis.

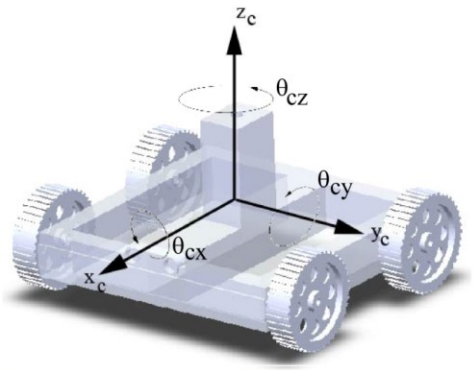

Fig. 5 Four-wheel mobile robot

The robot body motion is described by three linear displacements along three body-fixed axes and the rotational motion is defined by 3 Cardan angles. The robot body is modelled as rigid structure with 6-DOF. The body motion is described by 3 linear displacement along body fixed x, y and z axes and rotation about these axes. The Newton-Euler equations of the robot body are as follows [14]:

$$\sum F_x = m_c\ddot{x}_c + m_c\left(\dot{z}_c\dot{\theta}_{cy} - \dot{y}_c\dot{\theta}_{cz}\right) \quad (1)$$

$$\sum F_y = m_c\ddot{y}_{cb} + m_c\left(\dot{x}_c\dot{\theta}_{cz} - \dot{z}_c\dot{\theta}_{cx}\right) \quad (2)$$

$$\sum F_z = m_c\ddot{z}_c + m_c\left(\dot{y}_c\dot{\theta}_{cx} - \dot{x}_c\dot{\theta}_{cy}\right) \quad (3)$$

$$\sum M_x = J_{cx}\ddot{\theta}_{cx} - \dot{\theta}_{cy}\dot{\theta}_{cz}\left(J_{cy} - J_{cz}\right) \quad (4)$$

$$\sum M_y = J_{cy}\ddot{\theta}_{cy} - \dot{\theta}_{cz}\dot{\theta}_{cx}\left(J_{cz} - J_{cx}\right) \quad (5)$$

$$\sum M_z = J_{cz}\ddot{\theta}_{cz} - \dot{\theta}_{cx}\dot{\theta}_{cy}\left(J_{cx} - J_{cy}\right) \quad (6)$$

First three equations (Eqs. (1)–(3)) are Newton's equations where pseudo-forces appear due to the motions of body about its body-fixed or non-inertial frame. The later three equations (Eqs. (4)–(6)) are Euler's equations which account for gyroscopic moments. The whole set of six equations are referred to as Newton-Euler equations.

V. EXPERIMENTAL WORK

In this section, the physical model of the four-wheel mobile robot with arm is developed using ardiuno module. The proposed object detection algorithm and gesture control approach are implemented on the physical model and are validated for pick and place application. Table II shows the list of electronic equipments used for the development of the physical model of the robot.

TABLE II List of electronic items

Description	**Quality**
Gyroscopic sensor	1
Ultrasonic sensor	1
Servo motor	6
Wireless module	2
Ardiuno (1 uno + 2 nano)	3

A. Development of the physical model

1) CAD model: Initially, the CAD model of the robot is developed using CAD software (*Solidworks*) and the detailed views are shown in Fig. 6 (a-c).

2) Prototype model: In this section, the fabrication of the physical model is done. The chassis of the robot is made of aluminum due to its light weight properties. The ardiuno mega board is used to control the motion of all the wheels of robot and object detection algorithm. Also, the structure of the arms is made of aluminum. The separate ardiuno nano is used to control the motions of the arms. The wifi receiver is used to get command signal from glove data. Figure 6 (d) shows the physical model of the robot.

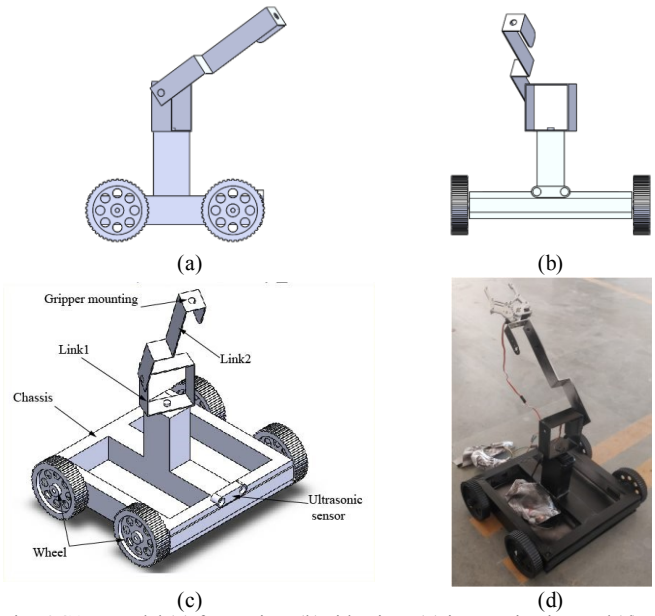

Fig. 6 CAD model (a) front view, (b) side view, (c) isometric view and (d) prototype model

VI. RESULTS

In this section, the experimental results are mentioned and discussed. By performing number of experimental runs, it is estimated that the average maximum linear speed of the robot is 4 cm/s. The experimentation time taken by the robot before pick and place operation is 56s. The linear speed of the robot is shown in Fig. 7 (a). During time 0-36s, the linear speed of the robot is 0 because the robot is turning about its C.G. to find the orientation of the object within its sensor range. After detecting the object, the robot starts to move towards the object. Initially, the speed of the robot is zero and after 2 sec, it reaches to its maximum speed of 4 cm/s. During the period of 38–54s, the robot moves with constant speed of 4 cm/s. Afterwards, when the distance between robot's sensor and object is 10 cm, the robot is stopped. Similarly, the Fig. 7 (b) shows the angular speed (rad/s) of the robot during turning operation. The robot starts turning about its C.G. (first iteration loop) during time span of 0-18s. After 2 sec of stopping, again robot starts turning (second iteration loop) for a time period of 20-33s. The third loop starts from 35s and after 0.34 rad angle, the robot detects the object. Then, the robot starts to move towards the object. Also, the robot's acceleration is shown in Fig. 7 (c). During constant speed of the robot, the acceleration is zero as depicted in Fig. 7(c).

The displacement of the robot is illustrated in the Fig 8. Figure 8 (1-12) shows the overhead pictures of the robot during first iteration loop having ultrasonic sensor range of 40 cm. As depicted from the Fig. 8, the green colored area is 40 cm sensor range zone. During second iteration loop, the range of the sensor is increased by 40 cm to the earlier range value i.e. 40+40=80 cm. Figure 8 (13-26) shows the overhead pictures of the robot while performing second iteration loop. 80cm of sensor range zone is represented by blue colored code. Figure 8 (27-28) shows the result of third iteration loop with sensor range increased by 40 cm to the previous range value i.e. 80+40=120 cm. Once the object is detected by the robot, the robot starts to move towards object until the distance between robot and object is reached by 10 cm as shown in Fig. 8 (29-36). At last, gesture control pick and place operation is done. Figure 8 (37-63) shows the pick and place operation based on gesture controller.

VII. CONCLUSIONS

The purpose of this research-work was to control the movement of the robotic arm with accelerometer/ gyroscope based gesture controller; this was quite effective and easy as compared to other input devices i.e. joystick, keyboard etc. Other important outcome of this research was the implementation of the simple and effective object detection algorithm on physical model of the robot. Also, single ultrasonic sensor was used to detect the object which reduces the cost of the robot. The effectiveness of the proposed algorithm and gesture control scheme were validated on the prototype model of the robot. The pick and place operation was considered under experimental work. The experimental results validate the efficiency of the proposed object detection algorithm and gesture controller. Further, the work will be extended to identify the desired object from the cluster of objects using fusion of ultrasonic sensors and robot mounted camera data.

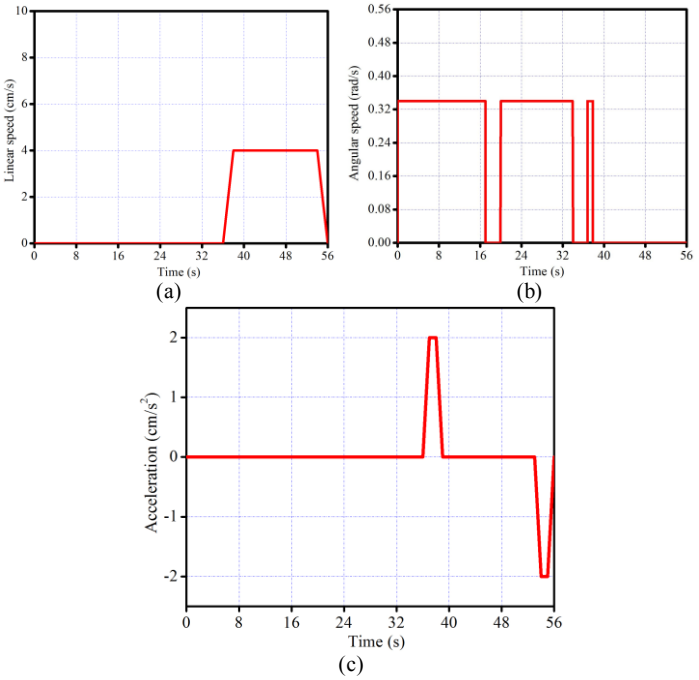

Fig. 7 Experimental results of robot (a) linear speed, (b) angular speed and (c) acceleration.

Fig. 8 (1-12) First iteration with 40 cm sensor range, (13-26) Second iteration with 80 cm sensor range, (27-28) Third iteration with 120 cm sensor range, (29-36) Movement towards object and (37-63) Pick and place operation

Nomenclature

C	robot body
F	Force
J	polar moment of inertia
M	Mass
M	Moment
$x,y,z,$	displacement in three directions
$\dot{x},\dot{y},\dot{z}$	velocities in three directions
$x,\ddot{y},\ddot{z}$	accelerations in three directions
$\dot{\theta},\ddot{\theta}$	angular velocity, acceleration

***Abstract*—Hybrid watermarking is a prevailing technique in the latest research and has a significant amount of real-time applications. Digital watermarking is utilized to protect copyright and security to multimedia content. In this paper, an algorithm is an amalgamation of image watermarking and audio watermarking algorithms. In case of image watermarking algorithm discrete cosine transform (DCT) and in case of audio, discrete cosine transforms (DCT) and discrete wavelet transform (DWT) are used to propose this Hybrid watermarking algorithm. Moreover, to refine the performance of the proposed scheme, error correction technique and Arnold transforms are employed. Peak sound to noise ratio and Bit Error Rate (BER) is applied to estimate the performance of this scheme to counter the Time-Scale Modification and numerous attacks possible on images and audio as well.**

Keywords—digital watermarking; DCT; DWT; Arnold transform; cyclic code; signal processing, TSM;

I. INTRODUCTION

Every user, organizations, etc. have a huge amount of data collection and due to ease in availability of technology and internet or communication network, an immense amount of information has forwarded among numerous clients (or users), Twitter, Facebook, WhatsApp and variant social media. In this scenario, attacks probability on data is fairly high because there is a different kind of techniques and tools which can infringe the copyright, copied or modify the information. So, it is mandatory to provide security, duplication control, owner authentication, protection, etc.to digital multimedia (like audio, image, text, video). There are generally three techniques watermarking, steganography and cryptography. Out of these, digital watermarking came out to furnish an effective solution to these problems stated above and turns into a popular technique. Digital Watermarking embeds the original data into another digital data secretly by applying some algorithm [3] and it assures the user's identification, copyright protection, security, etc.

Digital watermarking can be text watermarking, audio watermarking, image watermarking and video watermarking. All these techniques have an overall three processes: Embedding, Detection, and Attack. In the embedding process, user's data (i.e. watermark) is enrooted into another data (data could be image, audio, text, and video) and in the detection process, concealed data is extracted and in the attack process, numerous attacks are possible on watermarked data that tampered the original content and steal the information like copyrights, ownership, and others.

Watermarking is classified based on perceptivity: (1) Visible watermarking, (2) Invisible watermarking, is frequently used one. Visible watermarking is embedding the picture or logo that is noticed easily. Invisible watermarking is piecing the watermark into an unidentified part of the data which cannot be perceived by eyes and watermarking approaches must be invisible. Invisible watermarking has important features which are security, imperceptibility, computational cost, and robustness. For secure watermarking, secret keys must be used and ensure the protection of copyright [15]. Watermarking system should have the potential of survival against processing attacks that is a robust feature of the system. Computational complexity is also a vital and deciding factor in the copyright of the scheme.

Typically, Image watermarking has divided into two based on respective domains: frequency domain and spatial domain. In the spatial domain, the embedding algorithm implant the watermark into the image right away or refurbish the pixel values [3]. Well-known spatial techniques are least-Significant bit technique (LSB) and SSM (spread-Spectrum) Modulation technique. In frequency (or Transform) domain, manipulate the spectral (or frequency) coefficient of the image to embed the watermark. In comparison with the spatial domain, the frequency domain is most preferable for watermarking because of better characterization of human Visual system. This domain is consisting of widely popular techniques DWT, DFT, SVD, and DCT [2, 4, 8, 16].

In audio watermarking, there are two broad domain categories: (1) Time domain (2) Transform domain. In the time domain, imbed the watermark is directly into time domain i.e. mixing the pseudo-noise patterns to the host audio. This technique brings on the deterioration of the sound file due to prompt modification of bits. In Transformation domain, enables implanting of the watermark into a discernible component of host audio and this gives better permanence. It also utilizes the audio masking property of HAS (human auditory system) [5].

The approach in this paper is motivated by aggregation of more than one watermarking techniques, stated above. Here image and audio watermarking are mingled to structure a new

technique of watermarking that will address issues like copyright protection, authentication, security, etc. and to efficiently counter the numerous attacks which can damage either image or audio or secret data. This scheme will persuade others to fuse two or more than two techniques, the resultant scheme will be more effective, strong and efficient and produce better outcomes.

The structure of the paper is as follows: section II will provide about related work and theoretical background useful for this. Section III describes the proposed scheme and algorithm. Section IV demonstrate the analysis and explanation of results. Section V signifies the conclusion and future work, after this there are references.

II. Related work and Preliminaries

Researchers have been trying to design an efficient watermarking approach to resist any kind of attacks and issues associated with it. This section will briefly describe the various schemes that are valuable for designing this scheme.

Soumitra Roy and Arup Pal [1] proposed a multiple image watermarking scheme based on DCT and repetition code. Watermark's bit is loaded into Blue and green component of a color picture, then DCT is employed after decomposing image into blocks and repetition codes are used to update AC coefficients of transformed block. Few larger AC and DC coefficient are kept unspoiled after DCT's block scanning in case of multiple watermark insertion. That makes the scheme stronger and confident.

Ali Al-Haj [2] suggested about aggregated DCT_DWT watermarking procedure for images. First and just next level of DWT Subbands are picked to place the watermark into host picture, in succession DCT is applied on carefully chosen DWT subbands. This enhanced the performance of this scheme in comparison to both individual watermarking approaches.

Palak Garg et al. [4] presented a layout to guard against unauthorized access by integrating DSWT (discrete stationary wavelet transforms), DCT, Arnold transforms and SVD. Colored watermark is inserted into a colored picture. Addition of Arnold transforms into this hybrid algorithm make it more secure. The result shows good indiscernibly.

Weizhen Jiang et al. [6] said, this scheme has designed for audio to counter synchronization attacks. Audio is fragmented into frames. Encrypt the watermark and generate watermark frame sequence number. Then watermarking sequence number is inserted into wavelet coefficients using mean stable property and take advantage of the global characteristic technique to prevent synchronization attacks such as TSM, jittering, pitch shift, etc. This scheme delivered the qualitative result as higher capacity, robustness associated with quantization length.

Rohit M. Thanki and Ashish M. Kothari [7] drafted a technique to provide security and protection of copyrights to image using human speech signals. Hybrid coefficients of speech is evaluated by employing DCT and SVD. Then embedded into coefficients of the image which are obtained by DWT and FDCuT. Its performance is quite better than other techniques for the biometric system. A noise disturbance occurred when there is an increment in the embedding factor.

Subir and Amit M. Joshi [8] intended to deliver an audio watermarking in which watermark is inserted with the aid of DWT and DCT, then error correction codes and arnold transform is used for advancement in the algorithm. Its performance has measured in SNR and BER. It has outstanding results against others scheme.

A. K. Singh, M. Dave and A. Mohan [9] proposed a hybrid dual watermarking technique for images and it will help in telemedicine. DWT and DCT are employed in sequence to embed the watermark and additionally hamming code, BCH code, and Reed-Solomon code are popular error correcting codes. These codes are added to real bits of watermark for enhancement.

M. J. Tsai and H. Y. Hung [10] demonstrate a scheme which is based on DWT, DCT, and sub-sampling. Image is divided into subbands and watermark is embedded by DWT and DCT, subsample the subband's coefficient is also used in insertion. It was robust under different attacks.

Sobha R. V. and Sucharitha M. [12] suggested an audio watermarking scheme for secret transfer of data. It takes audio watermark of lesser length, inserted into the original signal with DCT and DWT-SVD methods, then encrypted with the secure hash method. Its performance evaluation is based on MSE (mean square error) and PSNR (peak signal to noise ratio). On extracting process, watermark has minimum disturbance and quite good performance under synchronization attacks.

A. Preliminaries

Discrete Cosine Transforms is frequency domain-based technique. It is a frequently used and prevailing technique. Itt employed for compression that transforms the signal from spatial to another domain as well as decomposing of signals. It is basically sum of sinusoids with variable frequencies and magnitudes. Any signal can have multiple AC coefficients but only one DC coefficient is there. It displaces the pixel or frame values on the transformation of data. Low-frequency coefficients are used for storage of details about the signal. DC coefficient has all vital details about the signal, but the AC coefficient has only sufficient detailing. Energy compaction property has a crucial role in DCT. The input signal d(m, n) has a sampled value, m as row and n as a column of reshaped signal and N × M size. Its output is transformed signal e(u, v), has DCT coefficients in u, v row and column respectively:

$$e(u,v) = \sqrt{2/M}\sqrt{2/N} \times \alpha(u)\alpha(v) \sum_{u=0}^{M-1}\sum_{v=0}^{N-1} d(m,n) \times \cos\frac{(2m+1)u\pi}{2M}\cos\frac{(2n+1)v\pi}{2N} \quad (1)$$

Where

$$\alpha(u) = 1/\sqrt{2}, u = 0 \text{ and } 1, u \in (1, M-1)$$
$$\alpha(v) = 1/\sqrt{2}, v = 0 \text{ and } 1, v \in (1, N-1)$$

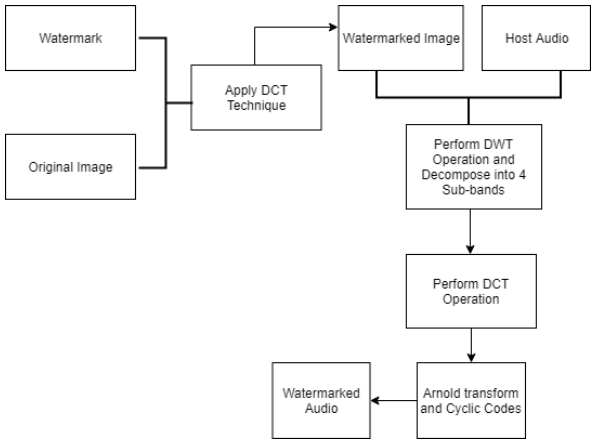

Fig 1. Embedding Procedure

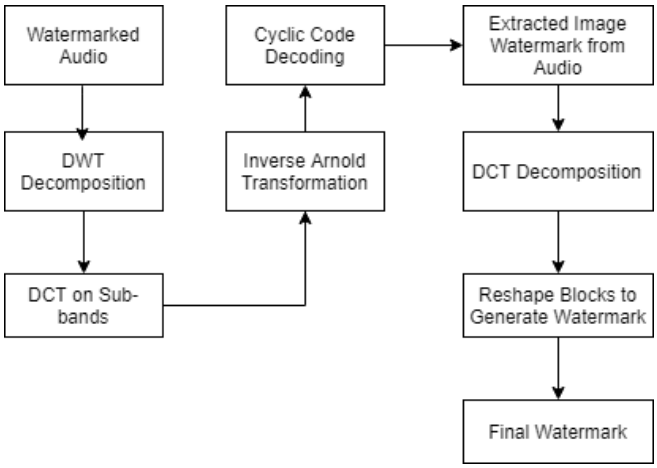

Fig 2. Extraction Procedure

On the extraction process, it is inverse DCT:

$$d(m,n) = \sqrt{2/M}\sqrt{2/N} \times \alpha(u)\alpha(v) \sum_{u=0}^{M-1}\sum_{v=0}^{N-1} e(u,v) \times \cos\frac{(2m+1)u\pi}{2M}\cos\frac{(2n+1)v\pi}{2N} \quad (2)$$

It is well known for the decomposition of a signal into non-overlapping blocks, this is block-based DCT transforms. It has the following output frequency: low, mid, high-frequency subbands. Based on individual's approach, any output frequency band can be picked up for watermark embedding and each band has its own significance.

Discrete wavelet transforms [10,16] is a multipurpose tool and it has its own advantages over DFT and DCT. It compromises with detailed information about the signal (audio/image). It decomposes the signal into several bands which are distributed for watermarked signal and assembled back to get the original signal. When DWT is applied, there are 2-D filters which are used in reshaping and helps in dividing the signal into limited non-overlapping sets that are Lf (lower frequency), Hf (horizontal frequency), Vf (vertical frequency) and Df (diagonal frequency). The first set shows the coarse scale coefficient and other are fine scale. The Level of decomposition is directly proportional to security under attacks.

Error correction code [4, 9]: when there are noise and distortion in the communication channel, it is difficult to recover the data from the channel. The original data is inculcated with extra bits in error correction process. It is used to enhance the recovery process of data. Generally, there are three correcting codes BCH code, Reed-Solomon code, and hamming code. Apart from these three, there is a cyclic code.

Cyclic codes are easy to the device and are linear code over finite fields. Say a block of length n and C is a linear code which is cyclic code. Codes are defined by C only and the next codeword is gained by right shifts operation in between components. C is symbolized into polynomial form,

$$C(x) = c_{0+}\, c_1 X + c_2 x^2 + \cdots \ldots + c_{n-1}\, x^2 \quad (3)$$

This paper uses these cyclic codes.

Arnold transforms [4] is used because it gives supplementary security together with existing watermarking. It does cut and slicing that is aligning the pixel matrix. It worked on the square size matrix of the signal such as M × M. Arnold transform is:

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \; mod\, M \quad (4)$$

Here, (x, y) belongs to original watermark and (x', y') belongs to displaced watermark. It is also known as a 2-D Arnold transformation. It is employed before embedding. It can be recovered in two ways: inverse transformation by inversing the matrix and periodicity of application. Scrambling key is considered as a secret key. It will be used in decryption of signal.

III. The Proposed Hybrid Watermarking Scheme

In this scheme, there is a sequence of algorithms. The first step is image watermark embedding, it is done with the DCT method, second is audio watermark embedding done with DWT-DCT plus cyclic codes. Then audio and image watermark extraction occur in sequence. Fig 1 and Fig 2 represent the watermark embedding procedure and watermark extraction procedure.

A. Image Embedding

Step 1: Read the image (im) and watermark (wt) with sizes of N × M and n × m respectively. After reading wt convert into binary.

Step 2: divide the image into n × n nonoverlapping blocks by employing DCT (dct()).

Step 3: enroot the watermark into the image's blocks. Each watermark bit will be embedded into the first bit of every block

Step 4: after all embedding, now recombination of every cell to get back the image by changing complete row cells of blocks

Step 5: now change row cells into the particular column to generate a watermarked image by inverse DCT (@dct()), and

finally output is stored. It is treated as watermark in the next algorithm.

Fig 3. Inputs to Image watermarking

B. Audio Embedding

In this algorithms, binary cyclic codes are employed on the image's matrix to encode. The character 'μ' is the constant which is μ × 2 is equal to the size of matrix. The watermark key and Arnold transform is used to figure out transform iterations.

Step 1: Utilize DWT technique on the audio signal and decompose that in subbands {Lf, Hf, Vf, Df}.

Step 2: For embedding and processing, this scheme selects Hf and Vf. Then implement DWT (Haar wavelet) on selected subbands like {Hf1, Hf2, Hf3, Hf4} and {Vf1, Vf 2, Vf 3, Vf 4}.

Step 3: Again, select middle bands {Hf2, Hf3}, {Vf 2, Vf3} from above two for three-level DWT implementation and now further pick four subbands from each subband after three-level DWT {W1, X,2 Y3, Z4}. Uniform sized blocks are created by dividing each block and perform DCT on each. Watermarking key is used to generate random sequence (PN1 and PN2).

Step 4: Reshape the binary watermark of size N × N (output of algorithm 1) U = μ × 2 and apply cyclic codes for encoding the watermark. Then for improving recovery, binary codes are used for encoding.

Step 5: Apply second level of cyclic encoding U1 = U(: , 1:2) and U2 = U(:, 2:3) . Matrix U1 and U2 are reshaped. Now map V1 with U11 and U12, and V2 is mapped with U21 and U22. V is a matrix of V1 and V2. Scrambled the V with watermark key.

Step 6: following rules are employed in watermark embedding:

If V(k) = 0
Then m_coff = m_coff + PN1
If v(k) = 1
Then m_coff = m_coff + PN2

Step 7: To generate watermarked audio, perform inverse DCT and inverse DWT.

Fig 4. Watermarked Image

C. Audio Extraction

Step 1: Implement 3_level DWT and decompose the reshaped watermarked audio as a matrix of H × H.

Step 2: Induce 2 random sequence and they have the same length as DCT's mid_band coefficient. DCT is applied to each block's mid_band coefficient.

Step 3: Extraction rule to find watermark bits:

If correlation (m_coff and PN1)>correlation (m_coff and PN2)
V(k) = 0
If correlation (m_coff and PN2) ≥ correlation (m_coff and PN1)
V(k) = 1, it is mined watermark bit matrix.

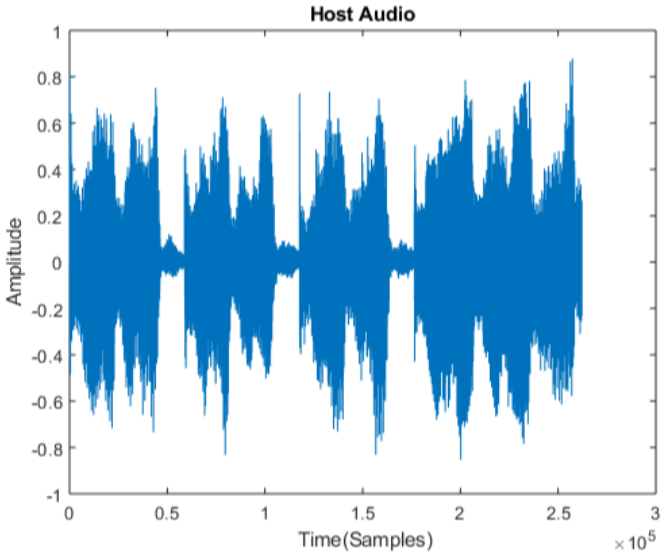

Fig 5. Waveform of Host Audio

Step 4: Apply inverse arnold on V by using watermark key and then reshape it as Ew = μ × 4, create Ew1 and Ew2 from Ew by dividing it horizontally. Then do vertical separation to make Ew11, Ew12, Ew21, and Ew22 of size μ/(2 × 2). Lastly join Ew11 and Ew12 horizontally, as a U1 and same as U2.

Step 5: To create U1' and U2' from U1 and U2 by cyclic decoding. Eliminate the second and first column of U1' and U2' respectively. Then combine these two for finding U.

D. Image Extraction

Step 1: load the extracted watermark picture from the above algorithm and initialize all required parameters and variables.

Step 2: split the picture into nonoverlapping blocks of size n × n.

Step 3: extract the blocks one by one and deploy the DCT method on them. Meantime it store the DCT values in the new block for cross-checking and row_wise formatting in n × n elements.

Step 4: perform the extraction process without using DCT and store its values also.

Step 5: Now compare these values and find the exact watermark by following rules:

If diff ≥ 0
Then ex_bit = 0

If diff < 0

Then ex_bit = 1, extracted bit of watermark is denoted as ex_bit.

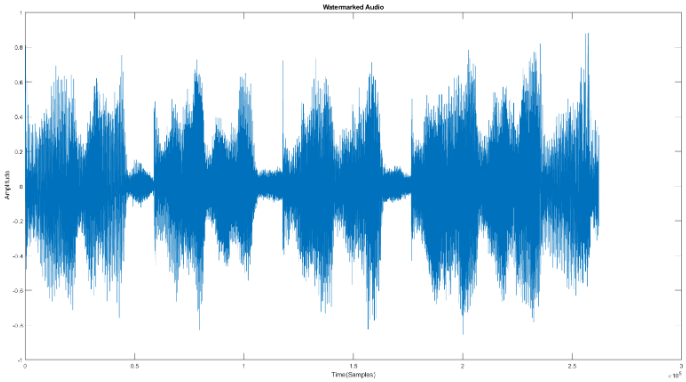

Fig 6. Waveform of Watermarked Audio

IV. Experiment Results and Discussion

In image watermarking procedure, watermark image is taken as 16 × 16 size and other is 32 × 32. Finally, it will generate a watermarked image of 16 × 16 size. In case of an audio procedure, different audio files are taken as original track of 512 × 512 size and all the tracks are of '.wav' format. 7 is the iteration and random sequence length in arnold transform. This paper is implemented on Windows 10 platform, MATLAB v2018Ra and TSM toolbox [11] which will be in action to perform TSM attack.

The proposed scheme is evaluated in terms of the performance parameters like PSNR (peak sound to noise ratio), BER (bit error rate). The Strength of scheme is denoted as BER. Perceptibility property and distortions are recognized by PSNR values. The amount of differentiation between any two signals is calculated as a PSNR value and it also tells about an image's quality (original and extracted picture). It is calculated as:

$$PSNR(dB) = -10log_{10}\frac{MSE}{P^2} \quad (5)$$

Maximum pixel size is P. SNR is calculated for audio signals and is evaluated with respect to noise power. S_{signal} and S_{noise} are the power of audio and noise respectively. SNR is:

$$SNR(dB) = \frac{S_{signal}}{S_{noise}} \quad (6)$$

While communication, the difference between a number of bits in the original image and the extracted image is termed as bit error and the ratio between the number of errored bits to number bit sent is called BER. It is calculated as:

$$BER = \frac{Errored\ Bits}{Sent\ Bits} \times 100 \quad (7)$$

Fig 7. Extracted watermark from Audio

Figures 3 is about initial inputs given to the system, Fig 4 is the output of the image embedding algorithm and it is given as watermark input to audio embedding. Fig 5 and Fig 6 shows the waveform of host and watermarked sounds. Fig 7 is the pulled watermark by the audio extraction process. Fig 8 displays the difference between host and watermarked tracks. Fig 9 is the final watermark which is extracted lastly with image extraction.

This paper also considers the numerous attacks possible on either image and sound. Table I and Table II will show the results of this scheme under two situations when information sharing on safe network and otherwise attacks happen on network. In both scenarios, the scheme is tested and analyzed.

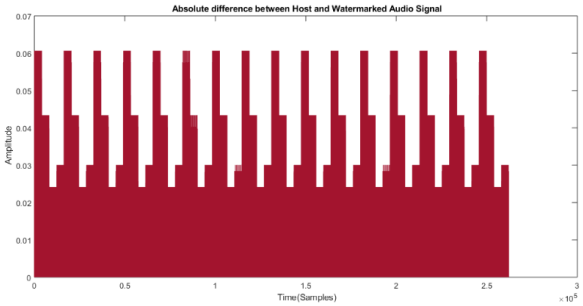

Fig 8. Difference between host and watermarked sounds

In table I, there are five tracks of 5 sec, 7 sec, 1.44 min, 10 sec and 3.34 min same in the order given in the table. For pop audio file BER has value 10 and PSNR value is 62.2154. these values are easily enumerated in MATLAB because it has predefined functions [14]. In the same way, these values are calculated for each example to test the scheme.

Table I scheme analysis under normal scenario.

Sound Tracks	BER	SNR	PSNR
Pop	10	0.201	62.2154
Jazz	3	0.313	52.5294
Classical	4	0.2842	Inf
Bach	0	1.3768	Inf

Looney	3.9	0.198	63.9423

Table II shows the scenario when a scheme is under attacks like signal processing and TSM (time-scale modification). These attacks are either signal processing attacks or synchronization attacks like noise addition, resampling, etc. comes under SP attacks and rest of attacks comes under another type of attacks. In this paper TSM is implemented with variation like TSM – 25%, TSM – 10%, TSM + 10% and TSM + 20%. TSM manipulations are organized with the aid of TSM toolbox [11] which gives TSM implementation. Cropping is done by taking a certain sound length and apply random function. Some minimum and maximum values and attacks happen in-between the range. Resampling is performed by multiplying the original sample rate with an appropriate value.

Table II. The scheme is under attacks scenario

Sound File	**Attacks**	**BER**	**PSNR**
		Proposed Scheme	**Proposed Scheme**
Pop	Random Cropping	18	59.6605

	TSM + 20%	18	62.9138

Noises have multiple types like white noise, AWGN noise, etc. In this study, AWGN noise is used to create an attack. Herein audio samples are utilizing for adding AWGN with its specific value. Most of these manipulations are carried out straightly in MATLAB, it has in-built functions which are dynamic according to the requirement.

Fig 9. Finally extracted watermark

V. CONCLUSION AND FORTHCOMING STUDY

This study delivers the new hybrid scheme which is comprised of two contrasting techniques that are Image and Audio Watermarking. This scheme is relying on blind watermarking approach [13]. This hybrid scheme is generally partitioned into two segments. One is embedding, in which the watermark is enrooted into the picture by utilizing DCT method of decomposing into nonoverlapping blocks and then reshaping, rearranging of these blocks after that perform inverse DCT operation to get the image i.e. watermarked. This will be considered as a watermark to audio insertion process which is implemented by three-level DWT decompose, followed by DCT operation on middle-frequency bands. Here cyclic codes (error correction code) are accustomed for encoding of the watermark and arnold transform which will enhance the security and generate a watermarked audio. Another segment is extraction, the output of previous procedure is input to audio watermark pulling and three level DWT after that DCT applies on particular subbands, then cyclic code decoding and inverse arnold transform acted upon it to withdraw the watermark from a sound file. This will be passed to DCT decomposition, reshaping applied to pull the final watermark in image watermark pulling process.

Numerous attacks are carried out to examine the strength, quality, and invisibility of scheme. Experimental results reveal quite effective response in safe or attack scenario in contrast

with existing approaches. The performance of implemented schemes is assessed in BER, SNR, and PSNR.

A forthcoming study on this scheme will be on making it more robust against other serious attacks like pitch shifting, dual attacks, etc. and this idea will be researched by aggregating other techniques to boost the security and protection against manipulations. The performance parameters like PSNR, SNR, and BER can be modified to improve the robustness and security of this approach.

ABSTRACT:

This paper presents the analysis of two types of boost converter for PV and Wind in a hybrid Micro-grid. The main aim is to improve the voltage gain capacity of conventional boost converter used in PV and Wind sources for a Hybrid micro-grid. Boost converters are dc to dc converter used to increase the input voltage. Conventional boost converters have low voltage gain capacity with high duty ratio. To eliminate this problem a new three level boost converter which improves the voltage gain capacity with low duty ratio is proposed for PV and a new coupled inductor based boost converter is used for Wind, this also has a high voltage gain capacity. Through this modified converter the voltage gain capacity is increased. The circuit is designed in MATLAB/SIMULINK and results are verified.

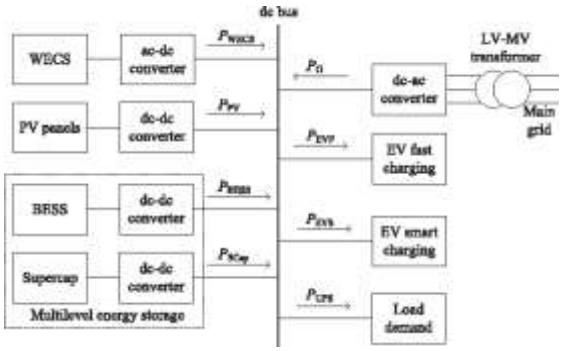
Keywords: Renewable Energy, Boost Converters, DC Micro-Grid

INTRODUCTION

There are many isolated locations in the world, which don't have approach to electricity. There are also many places, which are connected to the grid, but, they don't obtain electricity for up to 10-12 hours in the day. Many of such places are rich in renewable energy (RE) sources such as wind, solar and bio-mass.

Contemporary distribution system is experimenting the use of these DERs and thus forming power clusters [1]. This power cluster is called as Micro-grid. Micro-grid is of two types – Alternating Current Micro-grid (ACMG), and Direct Current Micro-grid (DCMG). If the micro-grid has two type of sources, then it is called a hybrid micro-grid. Basically the DERs such as solar PV systems, fuel cell operates at DC. Using power electronics circuits, a DC link capacitor can be formed to feed DC loads. For AC loads we can use an inverter at each section to convert DC power to AC power and this type of grid is AC micro-grid.

In AC micro-grid most of the DERs supply power to AC mains network and require costly and inefficient power inverters, even where the power may ultimately have delivered to a DC device. [3,5]. Whereas in DC micro-grid all the sources will be DC. In current world electrical loads in buildings such as computers, light emitting diodes (LEDs), etc. are supplied by DC power. Also most of the renewable energy sources produce DC power. Apart from decreasing financial costs, a main advantage of DC micro-grid is that the low risk of dangerous electric shocks from low voltage DC makes plug-and-play grids a possibility [8]. This also reduces the cost of installations of micro-grid, and will embolden end users to take responsibility to understand and control their own energy usage. By executing intelligence and internet facility to DC micro-grid controllers it will further enhance consumer involvement with AC devices – through smart metering and in result with dynamic demand management. In association with schedule of high and low power consumption, therefore it will help to reduce costs. [10] The problem with DC micro-grid is that the renewable energy sources produce only a small amount of power therefore we must use a converter to boost this power to integrate to grid only a small amount of power therefore we must use a converter to boost this power to integrate to grid.



Fig,1. General Micro-grid

Traditionally use of boost converters but these have low voltage gain, hence it should be necessary to increase the number of boost converters. But the efficiency of boost converter is less for high gain i.e. for
very large duty cycle. Therefore, for conventional boost converter we cannot achieve high gain operation. Efficiency will be as poor as 60% for a duty cycle of 0.7[12]. Whereas it will have a highest efficiency for duty cycle of 0.5. To achieve low ripple of ripple free current the use of the Cuk and Sepic converters has been proposed [7]. However, the Cuk and Sepic converters have higher switch voltage and current stresses than the Boost converter, which may result in a low efficiency. Therefore, boost topology may still be preferable.

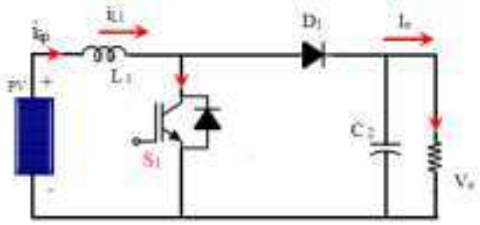


Fig.2. Conventional Converter

Therefore, to overcome these disadvantages of conventional boost converter a modified boost converter is proposed. In this a three level boost converter whose feature includes low devices voltages stress requirement for high voltage application, small inductor size that leads to the reduction of cost and size and can be operated with a wide range input voltage for Wind [13]. And for PV a high gain coupled inductor based interleaved boost converter is used, it has the following features, it improves the transfer characteristics, as well as system efficiency even for high power levels.

PROPOSED SYSTEM

A. Circuit Description

This paper proposes a three level boost converter and a coupled inductor based interleaved boost converter both has high gain. These boost converter has the ability to convert low voltage of PV solar system and wind farm to high voltage without the use of more number of boost converter.

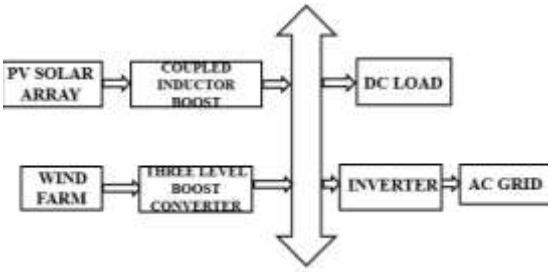

Fig3. Basic Block Diagram

The proposed system consists of a Solar PV array which is designed to give an output of 48V RMS and 67 V Peak. In this each solar cell is designed with 4.75A short circuit current, 1V open circuit voltage, 25deg Celsius system temperature, 1000 W/m2 irradiance. Wind turbine is also designed to have an output of 48V RMS and 67 V peak. The output of solar is boosted using the modified three level boost converter. And the output of wind is boosted using coupled inductor based interleaved boost converter. The output of both these converters are coupled and given to inverter to produce AC voltage for AC applications.

B. Working of Modified converter 1

Fig 4 shows the proposed circuit. It consists of 4 switches S1 to S4, two inductors (L1, L2) and two output capacitors (C4, C5). Output of wind is given to this converter which is AC therefore, first it converted into DC by using diode bridge rectifier boost the voltage to required level of the grid. In this
paper, the output of the converter is coupled with output of coupled inductor boost converter of PV. Then from this coupled output DC loads are directly fed and also an inverter is connected to convert it into AC to feed AC loads.

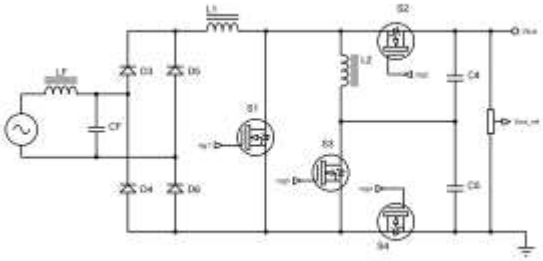

Fig.4. Three Level Boost Converter

Mode 1 : Fig 4 (a) shows mode 1. In this mode the current flows through inductor

L1 , S1, L2 , S3. Therefore, the active switches are S1 and S3. Output is taken across R.

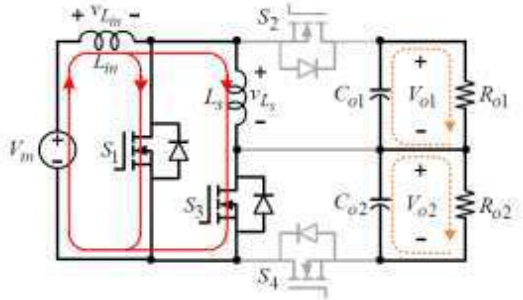

Fig 5. Mode 1

Mode 2 : Fig 4(b) shows mode 2. In this mode there are two current paths. One is through inductor L1 , S1 and Vin. Other one is through L1, L2, S4 and Vin. Therefore switch S1 remains in on state S3 is turned off and S4 is turned on.

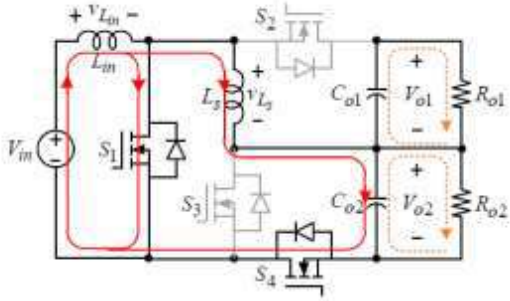

Fig. 6. Mode 2

Mode 3 : In this mode S4 is turned off and S3 is turned on again therefore it is same as that of mode 1.

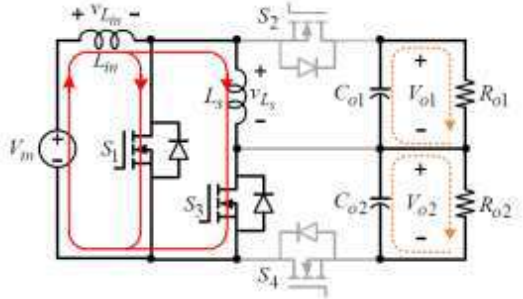

Fig 7. Mode 3

Mode 4 : Fig 4 (d) shows mode 4. In this mode S1 is turned off and S2 is turned on. S3 remains on. Current flows through Vin , L1, L2 and S3. Another path is through Vin L1 , C4 and S3.

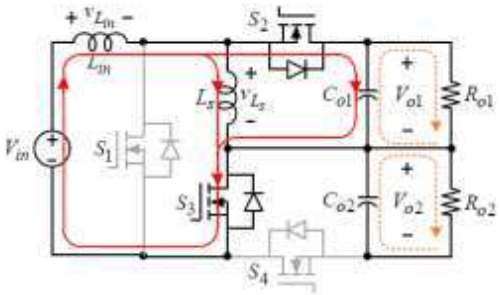

Fig 8 Mode 4

C. Working of Modified converter 2

Fig9. Shows the circuit diagram of coupled inductor based interleaved boost converter. It consists of 2 switches S_1 and S_2, a inductors (L_{in}), coupled inductors(L_1 and L_2) and a output capacitors (C_f) Output of solar is given to this converter which boost the voltage to required level of the grid. The output of the converter is coupled with output of TLB converter of wind.

.

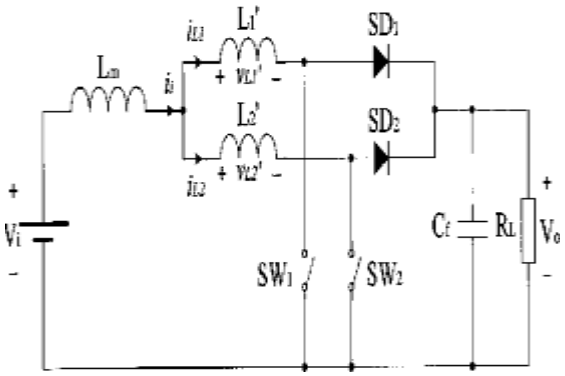

Fig. 9. Coupled Inductor Based Interleaved Boost Converter

Mode 1: Switch S_1 is ON Current flows through inductor L_{in} and L_2 .Both gets charged. Since L_2 is coupled inductor L_1 also get charged due to mutual inductance. Diode SD_1 turns ON and capacitor is charged.

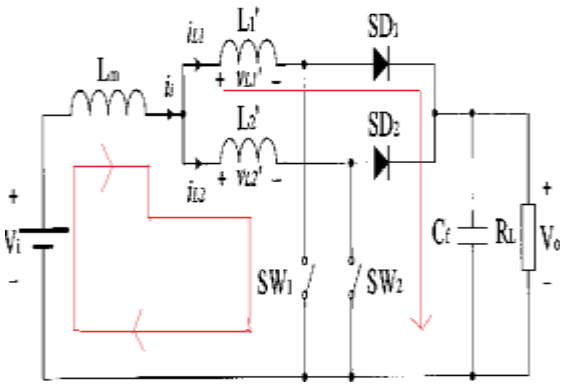

Fig.10 . Mode 1

Mode 2: Switch S_1 and S_2 is ON. All the inductors get charged by the paths of current. Output is supplied from the capacitors.

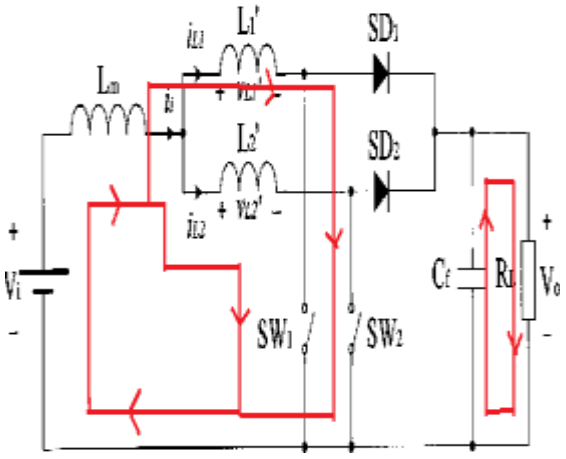

Fig.11. Mode 2

Mode 3: Switch S_2 is turned ON. Current flows through L_{in} and L_1. Since L_1 and L_2 are coupled inductors L_2 also get charged. Diode D_2 is forward biased and capacitor is charged.

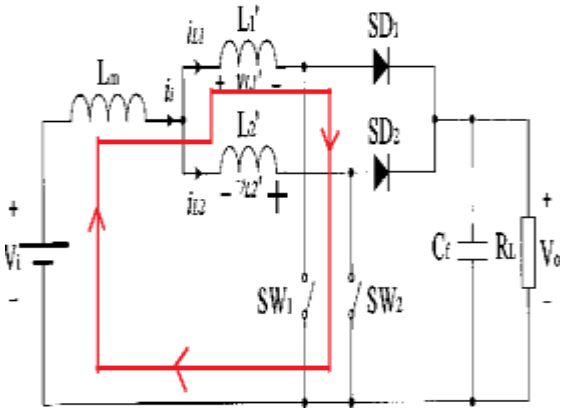

Fig.12. Mode 3

D. DESIGN EQUATION

In the proposed converter the voltage gain is given by

$$V_{in}(1+D)\,T_s/2 = (V_{01}-V_{in})(1-D)\,T_s/2 \quad (1)$$

$$V_{01}(1+D)\,T_s/2 = V_{02}(1-D)\,T_s/2 \quad (2)$$

Where (D) is the duty ratio defined as the time interval when S1 , S3 are both turned on during half switching period (Ts/2).

$$\frac{V_0}{V_{in}} = \frac{2}{1-D} \quad (3)$$

From equation (3) it is clear that the gain is twice than that of conventional boost converter.With minimum input voltage Vin ,maximum current ILin flows through the inductor for a fixed output Po.The inductor value to maintain the ripple is

$$L_{in} \geq \frac{(1-D)DV_0}{4*x\%I_{Lin\,max}} * \frac{1}{2f_s} \quad (4)$$

L_{in}= 280 micro Henry

$$L_s \geq \frac{(1-D)V_0}{z\%*I_{Lin\,max}} * \frac{1}{2f_s} \quad (5)$$

L_s = 960micro henry

In this paper 30% of current ripple of the corresponding average current is given to all the inductors in the circuit.
The current relation between the two inductors is found as

$$I_{Ls} = \frac{R_{01}}{R_{01}+R_{02}} * I_{Lin} \quad (6)$$

Efficiency can be calculated by

$$\frac{Output\ power}{Input\ power} = Efficiency \quad (7)$$

E. CONTROL SYSTEM

Figure 5 shows the control system of the proposed system. During time interval 0 to $DT_s/2$ switches S_1 and S_3 are in on condition. During time interval $DT_s/2$ to $T_s/2$ switch S_1 remain in on condition while S_3 is turned off and S_4 is turned on. In the next interval first situation is repeated. After that upto T_s S_1 and S_4 are off. S_2 and S_3 are in on condition. To obtain this condition it must give same pulse to S_1 and S_3. By giving a delay of half the time period and give it to S_2 and S_4.

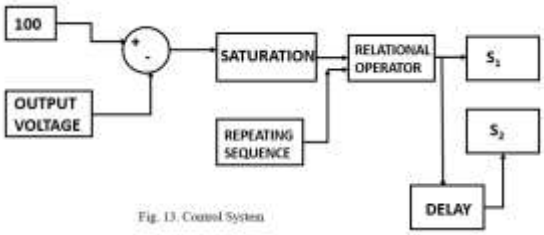

Fig. 13. Control System

SIMULATION RESULTS

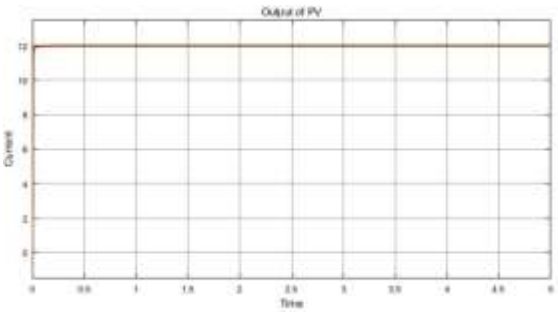

Fig.14. PV Voltage

Fig.14 shows the voltage verses time graph of solar panel. Output voltage is 12V. Voltage increases from zero to 60V. From time 0 to 0.025 voltage is increasing. After that the voltage becomes steady

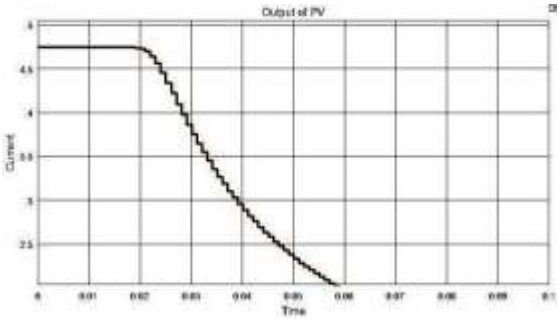

Fig.15. PV Current

Fig.15 shows the current of solar PV. The value of current is 4.7. In these each of these solar cell was designed with 4.75A short circuit current.

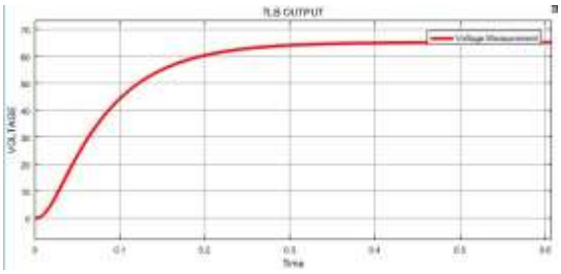

Fig. 16 Output Voltage of Three Level Boost Converter

Figure 16 shows the output voltage of three level boost converter. It is the converter of Wind. It boosts 12V of Wind to 68V after being rectified by the diode bridge rectifier at the front end. It shows a steady increase in voltage. As the PV charges the voltage also increases.

Fig.17. Output Voltage of Coupled Inductor Boost Converter

Figure 17 shows the output voltage of three level boost converter. It is the converter of PV. It boosts 12V of PV to 68V. It shows a steady increase in voltage. As the PV charges the voltage also increases

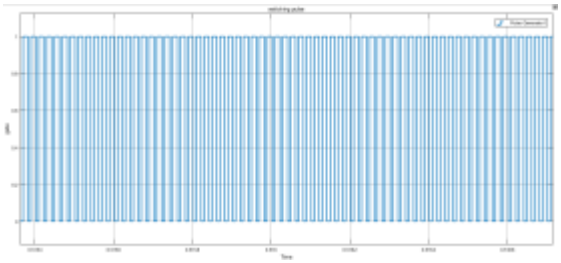

Fig 18. Switching Pulse

Figure 18 shows the switching pulse of the converters. From this it is clear that with this much small duty ration we could boost the voltage 5 times. Therefore, these converters increases the efficiency of the system.

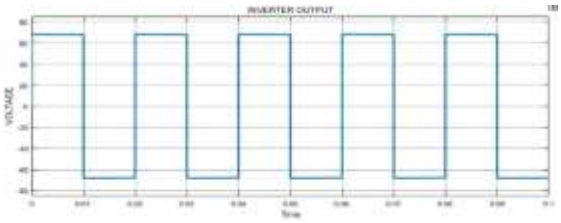

Fig.19. Inverter Output

Figure 19 shows the output voltage of the inverter. The output of both the converters are coupled and given to the inverter. It will produce the AC output for AC applications. It produces 68V AC.

CONCLUSION

This paper proposes two novel high gain boost converter for solar PV system and Wind system in a DC micro-grid. Boost converter is a DC-DC converter used to increase the output voltage. Efficiency of boost converter decreases with increase in duty ratio. This paper showed two high gain boost converter with low duty ratio. Thus we can improve the efficiency of the system. Also the conduction losses are reduced by using three level boost instead of three individual boost converter. Also by using coupled inductor boost the current ripple is reduced. High power. Power sharing. Component rating is reduced and hence cost is reduced. Matlab/simulink based results proved the effectiveness of proposed configuration.

***Abstract*— Now a day's rapid amount of data was increased due to new types of data generation device as well as storage devices. So a large amount of repeated data will be generated and stored in cloud service. Repeated data will be drastically reducing the storage space of the cloud environment. So that we need to do the data deduplication that is data block or chunk exactly stored only once in the environment. Data deduplication can be applied in different storage types, archives or backup storage, primary storage, disk drives, and RAM. The contribution of this paper classifies the data deduplication techniques in the primary storage system and identifies the performance and challenges of each technique in primary storage. Finally, ongoing research issues and undefined design points of deduplication techniques in primary storage are recognized and discussed. Primary storage system contains mutable data that means data often changed or removed, but the backup storage system mainly contains immutable data that is which never changed frequently and also some data could not be deleted at any time. In this article, we are analyzed various deduplication techniques of primary storage.**

Keywords*— *Data deduplication, primary storage, cloud service.

I. INTRODUCTION

Data deduplication is the process of scrutinizing a data set or IO files storing and sending distinct data. Additional copies of the same data removed, maintain exactly one copy of the data in the storage system. It is also the process of eliminating repeated copies of blocks of data and reduce storage. Data deduplication methods make sure that only unique contents are present in the storage system like primary, archive, disks, and flash or tape. Repeated data blocks are pointed through the index of unique content.

Deduplication system design change according to the storage environment. Deduplication classified by the following criteria granularity, locality, timing, indexing, technique, distribution scope. Data deduplication classified based on the different types of storage like primary, secondary, RAM, Solid state drive (SSD)[4]. In that primary, RAM, SSD has less attentiveness need to improve throughput, I/O latency and increase space saving. Nitro methodology helps to improve the SSD cache capacity and provide a better trade-off between SSD durability and performance of the primary storage system[8]. For backup system manage scalability, reliability, and security needs further improvements. Primary deduplicating blocks in primary workloads secondary deduplicating in the backup or archival system. Both primary or secondary more or less similar processing operations.[5][6]. Data to be forms of the byte stream and segmented into chunks or blocks. Major two types of chunking algorithm are fixed size chunking and CDC (content defined chunking).

Benefits of deduplication include:

- Reduced an amount of data space in a storage system.
- In primary storage system maximize the flash storage capacity
- Lower bandwidth consumption.
- Higher data holding periods.
- Fast recovery.
- Reduced tape backups

Deduplication methods works based on the data types Fig 1shows the classification of data types. Data deduplication and multimedia deduplication Date deduplication is document or text, multimedia deduplication image video or audio files. Text deduplication again classified as two types of file-level or block level deduplication. File level deduplication entire files are compared with their hash value. In this method does not give high efficiency. Block level deduplication achieve good efficiency compared with file level. Files are divided as blocks are chunks this process also called chunking. That chunks may be a fixed size or variable sizes depend on the deduplication system. Fixed and variable size chunking gives better storage efficiency.

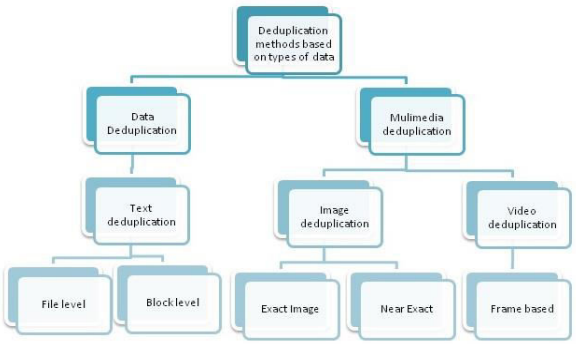

Fig 1. Classification of Deduplication methods

A. *Chunking process*

Each and every chunk have chunk id for unique representation. Chunk id calculated by a cryptographic hash function. Index table maintains the collection of unique chunk information. Chunk information maintained as KV-pair structure, i.e, Key-Value pair. ID denoted as a key and other related information act as a value[7]. Deduplication system searches the newly created chunk id in index table if matches fond new chunk id won't be stored in an index table. Chunking process creates performance issues like time-consuming for chunk id creation and searching process, a large amount of cache memory used for storing index table[7].

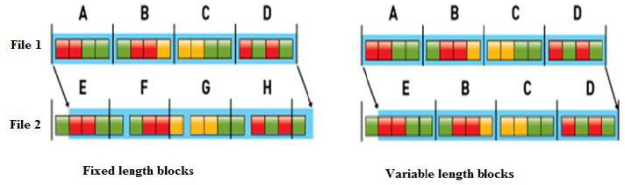

Fig 2. Fixed vs variable size blocks

Figure 2 shows the differences between fixed and variable size blocks for example File 1 sliced as a four fixed block size named A,B,C,D after sometimes file was updated content may be adding or deleting some data from the original file and named as a new file file2, now file2 try to upload in the cloud environment file2 going to be sliced with same fixed size now we get different blocks named as E, F,G, H, all other content of data similar to the file1 except few additional data but even we are getting different block due to fixed size. This what consider as a disadvantage of a fixed length of chunking process small updating will give dramatic changes in the chunking. But processing was easy compared with others. So that variable size chunking reduce the problem of fixed one Fig 2 shows clearly except block E remaining will give the same result So we do not want to save it again simply through indexing we can refer the remaining blocks showed in fig 3. Through this method, we will get effective storage space compared with fixed size block but processing was hard compared with others.

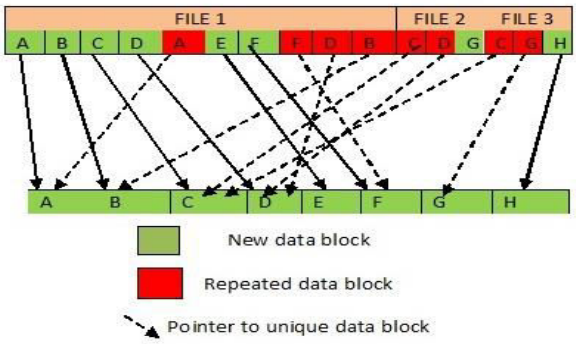

Fig 3.Deduplication reference information

II. Deduplication Methods Primary Deduplication vs Backup Deduplication

For hash deduplication system to find the redundant data whole file break into the block. If data in one chunk similar to data in another chunk, due to changes or updating of any one block even one or two byte of data, two blocks will be generated different hash values and system have to store both the block even major content are similar to each other. Some backup deduplication system used variable size blocks to maximizing the performance of the deduplication system. To find out the block boundaries variable block deduplication needs a lot of computing power. So that primary deduplication system mostly used fixed block size, since primary storage deduplication has to balance write latency against deduplication efficiency.[24]

III. Deduplication Algorithms for Primary Storage

The following two methods are mainly focused on primary storage to decrease storage space and increase the performance of input and output latency.1. Offline deduplication 2. Inline deduplication. Offline deduplication minimizes the additional computational resources and storage area[15]. But it has some following problem of extra reads from the storage, concurrency issues arise. But inline deduplication system overcomes the problem of the offline system as well as reduce the input-output latency.[4]

A Major challenge in primary system tradeoff between space saving and cost. The Smaller size of more number of chunks will give space efficiency but it increases the Larger index structure, so that cost also increased to maintain the index structure. If index too large then partially loaded into the RAM obviously number of disk input and output operations are going to be raised. A Distributed hash table (DST) used to manage the tradeoff between scalability and gain, but it shares the data into distinct client this will arise the problem of privacy and security issues.

Huijun Wu et al., they found the limitations of deduplication techniques in primary storage mainly the following two methods first inline cache, second post-processing deduplication[3]

A. *Inline*

Fingerprint cache mechanism was used to achieve deduplication. Sometimes fingerprint lookup table greater than physical memory size this one considered as a flaw of this method, and also inline cache method does not give a guarantee that all the duplicate blocks are eliminated.

B. *Offline deduplication*

DEDIS one of the offline deduplication method. DEDIS fully decentralized method So it could avoid the single point of failure, It does not depend on storage workload, deduplication achieved on the whole cluster chunks are fixed size of blocks(4KB). most of the techniques do not compare the full content of blocks, in place of checks only chunk signature. DEDIS follows decentralized method so that it maintains an index of unique chunk signature and metadata are distributed. DEDIS overcome the alignment issues of DeDe. Table 1 describes various inline and offline deduplication methods and its performance.

TABLE 1 COMPARISON BETWEEN INLINE AND OFFLINE DEDUPLICATION SYSTEM

Inline deduplication system	Offline deduplication system

• iDedup, Live DFS, DBLK[21] techniques
  • increases the speed of index lookup operation and avoiding disk access.
  • Storage space reduced
  • Centralized deduplication
  • Deduplication target at backup and archival data.
• Opendedup and ZFS
  • reinforce multi-host inline deduplication for dynamic data.
  • Require large RAM capability for indexing chunks.
	• DDE – Duplicate data elimination
	  • For SAN file system
	  • A Centralized metadata server
	  • The Flaw of this method single point of failure.
	• DeDe – Decentralized deduplication
	  • Centralized component avoided
	  • Offline decentralized deduplication for VM volumes
	  • Index structure used that is accessed by all the nodes with the locking mechanism.

C. Post processing

The Drawback of this method before removing the block it was already written into the disk, resource contention was the main problem since a lot of duplicates blocks to be removed.

To improvise the efficiency of caching mechanism they follow a two-phase process, the workload was distributed such a way in the inline phase itself number of duplicates chunks are identified, so that less number of blocks need to be written into the disks. impact of this process input and output performance was increased and the workload of post-processing was reduced.

D. Cache based algorithm

Both LRU and ghost cache carry out poor performance due to memory overhead in the primary storage environment, to accomplish this flaw TLE-LRU (Temporal locality estimation LRU) and hybrid deduplication mechanism arrived. Compared with DIODE SLADE reduce the load of post-processing deduplication process, reduce the cache contention problem for primary storage. In SLADE dynamic locality estimation method was implemented to improve the inline deduplication performance. Table 2 explain about the cache based algorithm and its performance.

In the primary storage environment cache algorithm and ghost cache approach has following drawbacks former cannot manage with fingerprint cache management later it is only for weak locality but it highly affected by memory overhead problem. To overcome these problems the hybrid approach of SLADE with TLE-LRU was implemented. Through this hybrid approach, they achieve high inline cache efficiency, the workload of post-processing deduplication was reduced, improve the inline ration up to 39.70% compared with idedup. Disk capacity also reduced up to 45.08%comparedwith post-processing.[3].

TABLE 2. CACHE BASED ALGORITHM

Algorithm	Performance
1.LRU - least recently used[3]	• Unable to handle a mixed level of temporal locality
2. Ghost cache[3]	• It is For weak locality problem • LIRS(Lower inter-reference recently set) replacement policy and ARC (Adaptive replacement cache). • ARC method better than the LRU
3.SLADE – Stream locality aware deduplication[3]	• Based on the threshold blocks are eliminated whose size greater than the threshold value. • The threshold will be changed dynamically according to the data stream. • It is For primary deduplication.
4. DDFS – Data domain file system [1]	• To improve the fingerprint indexing rate limiting method was used. • It is for backup deduplication
5. DIODE – Dynamic inline off-line deduplication [2]	• It is for primary deduplication. • Deduplication based on file-based file extension, the file type is not enough for deduplication performance

IV. DAC

The single cloud storage server has a number of important issues like vendor lock-in problem, availability, security. Cost increased for user want to migrate from one cloud storage system to another means all the data has to migrate from old service provider to new system this migration cost too higher than the cost of the old service provider this is called vendor lock-in problem. If all the data stored in a single cloud service provider means it can be easily attacked by hackers.

DAC deduplication assisted the primary system in a cloud of cloud it overcomes all the problems in a single cloud server and also avoids the integrity ensure the confidentiality and integrity of outside attacker. DAC removes the unnecessary data and distributes the data among multiple independent clouds. It improves performance and cost efficiency.[16] .DAC used fixed chunking algorithm. Compared to fixed size chunking variable size chunking may be given data redundancy problem in primary storage.[16]. DAC lagging in the reliability analysis and secure data deduplication

A. *Clouds of cloud*

Several systems working under clouds of cloud concept like RACS, HAIL, NC Cloud, Dura cloud, DEPSEY, HYRD, and DAC.RACS used erasure coding to decrease the vendor lock-in problem. HAIL gives the integrity and availability assurance for the stored data. NC Cloud cost-effectiveness, all the above methods used erasure code or network code method for data protection.

In Dura, cloud replication method was used to maintain a copy of user content in different cloud storage provider to give better availability. DEPSEY this method combine the Byzantine quorum system protocol plus cryptographic secret hashing and replication to increase the availability and confidentiality. HYRD integrates both replication and erasure code performance and storage efficient improved but compared to DAC moderate performance only. It also gives a guarantee of availability.

DAC is to address the storage availability issue using replication scheme. Replication method provides better performance and high bandwidth storage overhead, erasure method provides storage efficiency, robustness and high access performance in a cloud of cloud, especially large files.

V. SDM

Once file type was well known then only can apply deduplication manually otherwise not possible for a new type or unknown type[17]. Based on the file type and ratio chunking algorithm will be selected. The ratio for file type less than the predefined threshold means new chunking algorithm will be applied. Problem with this method small size of files because of file size too less than the block size, so a waste of time processing.[19]. SDM overcome the above drawback as well as increase the storage space of the cloud. It automatically detects the deduplication method whether file level or block level based on each file type. For example, mp3 and jpeg are file-level deduplication, pdf, doc and others will perform under block-level deduplication. SDM does not require any configuration process. Its performance level was good in various file type and also improve the speed and accuracy of the system.[18]. The drawback of the SDM method not effective on block-level deduplication scheme compared with others. Processing time increased working under dataset. Sometimes wrong deduplication method selection.

VI. PERFORMANCE ORIENTED AND CAPACITY ORIENTED DEDUPLICATION SCHEME

Performance oriented deduplication scheme (POD) highly improve the performance of the primary storage and reduce the usage of storage space. The following two approaches have achieved these things. Sequence based, idedup and offline deduplication are capacity oriented deduplication. Capacity oriented deduplication scheme mainly focused on storage capacity saving. Table 3 clearly shows the outlook of performance and capacity oriented deduplication scheme.

TABLE 3. OUTLOOK OF PERFORMANCE AND CAPACITY ORIENTED SCHEME

Performance oriented deduplication scheme	**Capacity oriented deduplication scheme**
• Compared with capacity oriented scheme iDedup POD gives better capacity savings.[20] • Small files are a vital role in primary storage of more than 50%. for deduplication, it considers small size files too. • Select –Dedupe • Request-based selective deduplication approach. • Data fragmentation problem minimized. • iCache • Intelligent cache management system.[20] • Read performance and space-saving increased. • It solves the problem of memory contention as well as read amplification	• Capacity oriented concentrate on storage capacity saving. • For deduplication only consider the large request and ignore the small request like less than 4kb, 8kb. • Capacity oriented omitted these small size files this one consider as the most important problem in the performance of primary storage. • idedup • Inline deduplication system [11] • Consider the problem of space allocation between read cache and index cache

VII. TDDFS

Two-Tier storage system implemented to achieve high performance as well as low cost in the primary system. Frequently accessed data stored in the fast tier less active data stored in a low-cost tier. To achieve cost-effectiveness all the file operations are performed in a fast tier and long inactive files are moved from fast to slow tier. Whenever files are migrated from slow to fast tier, if chunks are already available in the fast tier the data migration process could be avoided so that TDDFS gives the best performance in the primary storage system. TDDFS overcome the problem of migration efficiency, deduplication penalty, and isolation between block level management and upper layer application, and also TDDFS solves the deduplication latency and throughput issues. The following four features make TDDFS special and better tradeoff between performance and cost-effectiveness.[7] 1. File migration selection,2. Integration deduplication with file migration,3. Non-Redundant chunk reloading,4.shared chunk management.

SDFS[10] system depends on the situation block size may be fixed or variable size but it cannot manage the two-tier storage system. Lessfs[9] fixed block size for file system it manage the two-tier system but performance less than SDFS and TDDFS. ZFS[13] File-level deduplication compared to other deduplication performance was low. So it does not work under two-tier storage. TDDFS[7] chunking size randomly generated between min(51B) to Max(16KB). TDDFS efficiently manage two-tier storage system and high performance.

VIII. COMPARISON OF DEDUPLICATION METHODS

Table 4 shows a comparison between various deduplication methods with their metrics. In this table, we are compared with the following metrics file system level, performance, efficiency, cost and, its challenges. File system level means whether the file was taken as a whole file or sliced into blocks. The blocks may be sliced as a fixed size or random size.

TABLE 4. COMPARISON OF DEDUPLICATION TECHNIQUES WITH THEIR METRICS

Methods	File system level	Performance	Challenges	Efficiency	Cost
Inline Data Duplication. Idedup [11]	Fixed size	Higher throughput and lower latency. Minimize the extra IOs	Lost the deduplication ratio	H	L
Zettabyte File System ZFS [13]	Fixed size 256 bit block check sums	The most dedup method used the only limited amount of data. ZFS does not have any restrictions. It will be fast while loading dedup tables into the memory	Not optimized for latency.	Mo	L
Duplicate Data Elimination. DDE [22]	Fixed size 32KB	By comparing the hash value of each block, DDE detects duplicate data on the logical block level.	single point of failure system.	Mo	M
Decentralized deduplication DeDe [23]	Fixed size	Decentralized deduplication system. Higher throughput penalty avoided. metadata size was reduced.	In distributed infrastructure needs communication between blocks. Such structure complex and high cost. Alignment issues.	Mo	H
Deduplication of Distrbuted Infrastructure. DEDIS [15]	Fixed size	Fully decentralized avoid the single point of failure.	All distributed service need to maintain both index of unique block signature and metadata	H	H
Stream locality aware deduplication SLADE [3]	Fixed size	Based on the threshold blocks are eliminated whose size greater than the threshold value. The threshold will be changed dynamically according to the data stream.	Designed for primary storage deduplication	H compare with idedup	L
Deduplication-Assisted Cloud-of-Clouds DAC[16]	Fixed size	Overcomes all the problems in a single cloud server and also avoids the integrity ensure the confidentiality and integrity of outside attacker. DAC removes the unnecessary data and distributes the data among multiple independent clouds.	Lagging in the reliability analysis and secure data deduplication	H	L
Tier-Aware Data Deduplication-Based File System TDDFS [7]	Randomly generated between 512B to 16KB	To attain effective capacity utilization of the fast tier TDDFS maintain the deduplicated state of reloaded files.	More intelligent file selection policy needs to improve deduplication ratio.	H	M
Device mapper target for data deduplication Dmdedup [12]	Fixed size	In fast device deduplication structure like fingerprint index. The slower device maintains duplicate data blocks.	Does not have tired storage system concept. Data cannot migrate.	Mo	L
Cache dedup [14]	Fixed size	To increase the space utilization and flash lifespan, cache dedup institute flash-based cache Also, propose cache replacement algorithm (D-LRU, D-ARU) for increase cache performance.	Need distinct data cache for a block in storage and metadata cache for fingerprints	Mo	H
Dynamic inline-offline de duplication DIODE [2]	File level	It is for primary deduplication. Deduplication based on file-based file extension	The file type is not enough for deduplication performance	L	L
Smart deduplication for mobile cloud storage SDM [18]	File level or Block level (fixed size)	Increase the storage space of the cloud. It automatically detects the deduplication method whether file level or block level based on each file type. For example, mp3 and jpeg are file-level deduplication, pdf, doc and others will perform under block-level deduplication.	SDM method not effective on block-level deduplication scheme compared with others. Processing time increased working under dataset. Sometimes wrong deduplication method selection.	L	L
Intelligent cache management system iCache [20]	Fixed size	Improve the read and write performance. Increase the space saving	Lagging in the reliability analysis and secure data deduplication	H	L

CONCLUSION AND FUTURE WORK

The primary deduplication technology has been analyzed in the context of performance, efficiency, challenge, and cost. But still, primary system deduplication techniques have not yet been as successful as backup deduplication technology. Because deduplication achieved in the primary system 68% but in the backup system 83%, and backup deduplication method has drastically increased the efficiency of storing backup data. So that more concentration needs to reduce the deduplication in the backup storage system as well. In future work, we are going to analyze various deduplication techniques in the backup storage system..

***Abstract*—Remote sensing provides timely and reliable information about urban areas and their changing patterns.Detection of urban change is an important factor that affects the supply of food supply, water supply, etc.Detection of land use and land change is essential in order to understand the current situation and plan for the future to avoid scarcity. In this work, we proposed two new framework called Tensor - Deep Stacking Network (TDSN) with back propagation and Deep Stacking Convolution Neural Networks (DS - CNN) for land cover change detection. Changes are detected between the year 2005 and 2015 in the month of September over the Hutong area, Beijing, China. The work has been validated by using Sentinel 2 (4 bands cirrus, water vapor, coastal aerosol, red edge band) and Landsat 8(11 bands) satellite image. All the bands from Landsat -8 image are pan-sharpen to 15m resolution to get more accurate classification result. Bands in the Sentinel -2 satellite image are used to remove cloud present in the raw satellite image. The classification accuracy of proposed work are compared with the traditional classification algorithm Support Vector Machine (SVM). The accuracy of proposed work is 12% is improved in compare to traditional algorithm.**

***Index Terms*—Remote Sensing, Change Detection, Tensor Deep Stacking Network, Back-propagation, Convolution Neural Network.**

I. INTRODUCTION

Remote sensing is the process of obtaining information about the objects or areas from a distance, typically from aircraft or satellites. Remote sensing provides the Earth's periodic image, which is useful in mapping patterns and changes in land use / land coverage over time. Change in land use and land cover has become a central component of natural resource management and environmental monitoring [16]. Growing population was one of the root causes of land cover changes. The effect of changing land cover has resulted in a reduction in fresh water quality. Population growth leads to increased food and fresh water and air demands [1].

Detection of change requires long-term satellite images because scientists are examining an area over a period of time and seeing what changes are being made over that period.Many websites now offer free remote sensing image with high resolution for a day. One of them was USGS [17]. USGS provides free satellite image of Landsat and Sentinel. Landsat-8 is capable of capturing and transmitting 532 Earth images per day. The image is captured using Enhanced Themetic Mapper Plus (ETM+) sensor. This image contains eleven spectral bands. Each bands of 30m resolution except pan-chromatic band which is of 15m resolution. Pan-chromatic band is used for pan-sharpening.

Sentinel - 2 satellite provides 12 bands. Only 4 bands (cirrus, water vapor, coastal aerosol, red edge band) are used in this work. The first three are used to remove the cloud present in the satellite images and the last one helps to detect early signs of food shortages.

The original remote sensing data is severely incomplete and contaminated in the image with artifacts such as cloud, black strip. This increases the difficulty of image analysis.A cloud-free image was formed by cloning the cloud-free satellite image information into their corresponding cloud-contaminated image, assuming that images cover the same coordinates over a short period of time[3]. CNN helps to improve the classification accuracy. CNN is used as a variation of multilayer perceptron designed to reduce preprocessing. In comparison with other image classification algorithms, CNN requires very little pre-processing [15]. This work land cover change are detected for Beijing, china over the period from 2005 to 2015. It is observed that ecological and sustainable changes in agricultural area, water bodies and urban areas.

A. Research Challenges

The (Deep Neural Network) DNN and CNN are proven to be extremely powerful for performing recognition and classification tasks including speech recognition and image classification, training a DNN and CNN are computationally difficult and also extremely difficult to add parallelize across machines [6]. This makes learning at large scale practically impossible. Each satellite image was more than 15 GB in size. It is impossible to train these network with CPU machine. We need a GPU machine to train the network with this huge volume of data. This limitations are overcome by using TDSN but the problem in TDSN was hidden layers are fully

connected layers [14]. Fully connected layer involved more computation and require extra memory to store intermediate results. By replacing the hidden layers with convolution layers reduce computation and also save memory requirement.

II. RELATED WORKS

In Deep learning based predicting missing data for remote sensing analysis [14] use TDSN to predict the missing image in the time series.In predicting remote sensing data using spatial-temporal techniqu. In recent years remote sensing is used in multiple application and it is simple and easy to acquire high-resolution satellite image. By the same time, it creates a challenge for analysis community to interpretation from the images of the huge volume of data. Hence use deep stacking network to predict remote sensing data at the timestamp t. Deep stacking network is stacking of multilayer perceptron with one hidden layer.

In parallel training of deep stacking networks [6] and scalable training of deep stacking network [12] provide parallel and scalable training of deep stacking network. Parallelism reduces the memory and time requirement but arising cost for inter CPU communication. It also demonstrates the full-batch training significantly reduce the error rate by distributing the training dataset over the CPU cluster compare to the mini-batch training using single CPU cluster.Parallelism is achieved by parallelizing the matrix multiplies. The job requires to synchronize all parallel batches distributed over CPU cluster. It must wait for all the dependencies.

In Tensor Deep Stacking Networks (TDSN) [2] the complex functions are calculated from the stacking of multiple simple functions. Each module consists of linear input layer, and output layer, and a two non-linear hidden layer. Non-linear activation function sigmoid is used to map linear input to non-linear output to improve the performance. The input to the first module is corresponding to the first available image in the temporal sequence . For further modules, the output of the previous module along with the new input image is given as input. The final module of the TDSN predicts the actual value. In [11] Forest changes are detected over a period of 29 years (1987 - 2015) using CNN. By using CNN accuracy of image classification was improved around 16%.

III. LAND COVER CHANGE DETECTION

TDSN with back propagation and DS CNN are used to enhance the accuracy of land cover classification. Fig.1 show the overall framework in detail. Our main contribution was adding convolutional and polling layer into Deep Stacking Network. Overall work is divided into three steps. In step one, we applied pre-processing technique on the raw training satellite image, including pan-sharpening, cloud removal. Pan-sharpening helps to get high resolution image and cloud removal helps to remove noise present in the image. In Step 2, land cover classification are done by TDSN with back propagation and DS-CNN. In final step, the performance is measured by comparing the accuracy of two frameworks with the traditional classification algorithms [7].

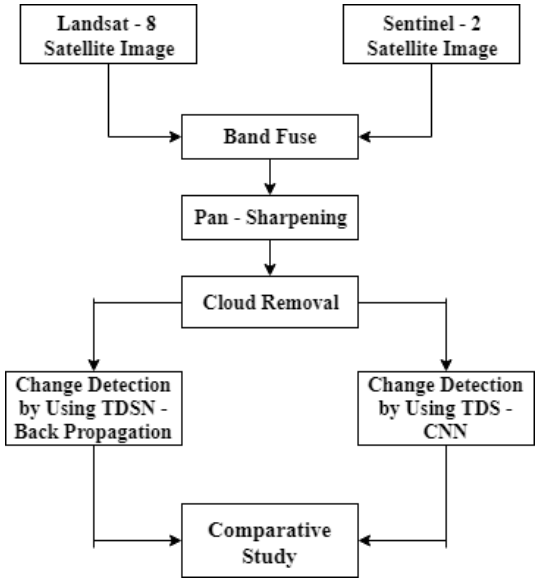

Fig. 1. Overall Flow of Land Cover Change Detection

A. Feature Set Preparation and Pre-Processing

Remote sensing images are collected in the area of Hutong area, Beijing, China, over the year 2005 to 2015. From the year 2005 to 2012 Landsat -7 satellite images are taken. It contain totally eight bands of 30m spatial resolution except panchromatic band which is 15m resolution. For the year 2013 to 2015 Landsat 8 and Sentinel 2 satellite images are taken. Raw satellite image are contaminated with artifacts like cloud, black strips due to fault in sensor used in the satellite. These missing information are formed by clone the information from the cloud-free satellite image into their corresponding clod contaminated image under the assumption that images cover the same coordinates and over a short period of time. Pixel of clod contaminated image are replaced with the pixel from the satellite images. For example, Fig.2 shows how to replace a cloud contaminated pixel from the cloud free image pixel covers the same coordinates as cloud contaminated image.

In the above example 3x3 image are contaminated with cloud and they are replaced with the average of pixel values taken from the cloud free image that covers the same coordinates.

Pan-sharpening was done with the help of pan-chromatic band which is one of the satellite band with high resolution and grayscale bands. For example, consider the Landsat 8 satellite image band 8 (pan-chromatic) have the spatial resolution of 15m, and all other ten bands have 30m spatial resolution. To obtain high resolution multi spectral image, we merge low resolution multi spectral bands of resolution 30 m with high resolution pan chromatic band of resolution 15 m. Bovey pansharpening algorithm shown in Fig.3 was used for pan sharpening. (Red Green Blue)RGB image was converted into (Intensity Hue Saturation)IHS image. After converted into IHS, Intensity part in the image was replaced with pan-chromatic band. Pan-chromatic band (pan) HS was converted

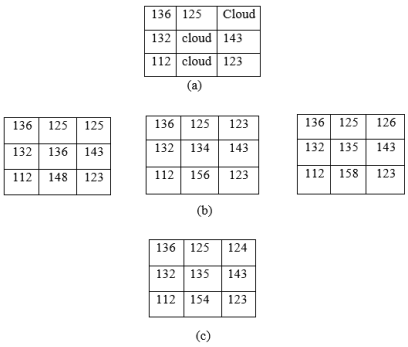

Fig. 2. Cloud Removal. (a). Satellite Image Contaminated With Cloud. (b). Three Cloud Free Satellite Image Covers the Same Coordinates as Cloud Contaminated Image. (c). Cloud Are Replaced With the Average of Cloud Free Image Pixel Values.

back to RGB.

Fig. 3. Pan-sharpening by Bovey Algorithm

Cloud free and pan sharpened satellite image are converted into NDVI image. If NDVI value is negative, it is highly likely that place is covered by water. If the NDVI value is in the range between 0.3 to 1 that area is covered by dense vegetation. Vegetation highly reflects near Infrared and green wavelength. And absorbs blue and red wavelength. If we see more Near InfraRed then it could be a strong vegetation. If the value is nearly by zero that area is it is the highly urbanized area. NDVI image are converted in to pixel and stored in a matrix format. This matrix are converted into dense file format and stored it in .binary extension. The dense format is used to calculate the weight matrix of T-DSN during the training phase. Totally 8 images are used for training from the year 2006 to 2014. The dense file is in the format of N x M matrix. Values are stored in a column-major order. Where N and M are 8 byte signed integer. T-DSN is a supervised learning model. Two images (2005 and 2015) are used for testing purpose, to find the amount changes happened during this 10 years. Target matrix contain three classes -1 represent bare land, 0 represent water area and 1 represent greenery area. Target matrix are stored in the sparse file format. The sparse matrix is in the form of N x M matrix of target labels.

B. Tensor-Deep Stacking Network Model With Back Propagation

The architecture of T-DSN with back propagation for three module is given in the Fig.4. The number of modules in the T-DSN is equal to the number of training images. We designed 8 modules to train 8 images from the year 2006 to 2014. Each module consists of a linear input layer, linear output layer, and two non-linear hidden layers (fully connected layers). The weight matrix W1 and W2 are the maps between the input layer and hidden layers. The weight matrix U map between two hidden layers and the output layer [5].

Each module is basically stacking of simple multi-layer perceptron with two hidden layers [13]. The input to the bottommost layer of T-DSN is raw input image in the first available sequence (2006). The input to the subsequent models are the output of the immediate previous module and the corresponding raw input image in the time series. For example, input to the second module was output of first module and the image vector of time series 2007.The output of each module learns feature for the particular timestamp.

Training vectors are denoted by X= [X1, X2,XN], in which each vector is denoted by Xi=[X1i,.,Xji, .XDi], where D is the dimension of the each input image vector (2947 x 2947), where N is the total number of training samples in the remote sensing time series. L Denote by the number of hidden units and by C the dimension of the output vector.

While training we provide training image as the dense file format and corresponding targets as sparse file format, chunk size (optional), number of blocks, number of iteration network. If chunk size is not provide it automatically get the total available memory of the system and make the chunk size. Once the training gets over it generates weight matrices W1, W2, U for all the blocks of T-DSN. For the first iteration, weights are initialized randomly. For each iteration, weights are modified so as to minimize the root mean square error between actual output and expected output. These weight modifications are made in the backward direction, which is from the last block output layer through each block down to the zeroth block hidden layer. This learning process continues until the weights eventually converge.

Fig.4 shows the block diagram of TDSN- with back propagation. Error at the final block is back propagate in the network. While back propagate make the delta changes in the internal weights to reduce the error in the next iteration. For testing we must provide testing image as a dense file format and path of weight matrices generated during testing and predict flag as command line argument.

We got 90.25% accuracy for first iteration. For the subsequent iteration accuracy was gradually increase. For seventh and eighth iteration there is no change in accuracy (accuracy of seventh iteration = 92.16% and the accuracy of eighth iteration was also 92.16%). So, we stop iterating back the error.

The output at the output layer of the T-DSN is calculated by using the equation 1. The hidden layer output is calculated by using the equation 2 and 3.

$$Y_i = U^T h_i \tag{1}$$

where,

$$h_{1i} = \sigma(W^T X_i) \tag{2}$$

$$h_{2i} = \sigma(W^T X_i) \tag{3}$$

$$h_i = h_{1i} \cdot h_{2i} \tag{4}$$

h1 and h2 are the hidden-layer output vector. U = L x C is an weight matrix at the upper layer of a module. W = D x L

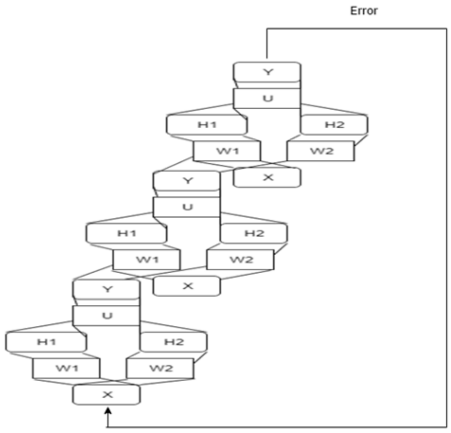

Fig. 4. Block diagram of Deep Stacking Network with Back Propagation with Three Modules.

is a weight matrix at the lower layer of a block, and $\sigma(.)$ is a sigmoid function. Equation 5 gives the formula for sigmoidal activation function.

$$hi = \sigma(W^T X_i) \tag{5}$$

Given target vectors in the full training set with a total of N samples, T = [t1,..,ti,..tN] , where each vector is ti = [t1i,... , tji,..., tCi] T, the parameters and are learned so as to minimize the average of the total square error. At the end of each iteration error is calculated. RMSE is used to calculate the error by using the equation 6. These errors are back propagate in the network and makes the delta changes in the internal weights of TDSN to minimize the error for next iteration. We stop back propagate the error at eighth iteration, there is no change in accuracy of seventh and eighth iteration.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=0}^{n}(Ve - Va)^2} \tag{6}$$

Where Ve denotes expected output and Va denote actual output. This error is used to alter the internal weight to get expected output.

C. Deep Stacking Convolution Neural Network

Advantage of TDSN are parallel training, scalable, does not required GPU machine for large training data set [6][12]. But it takes more time to get trained. Limitations in the TDSN was overcome by replace hidden layers with the convolution layer, pooling layer and then flatten the output of pooling layer. Similar to the TDSN number of modules in the DS CNN is equal to the number of training images. Each module consist of input layer, convolution layer, pooling layer and output layer. Totally eight modules are designed to train the images from the year 2006 to 2014. One images are chosen for every year in the month of September. Input to the first model is the first image in the temporal sequence. In our case input to the first module was image at the year 2005. The input to the subsequent models are the output of the immediate previous module and corresponding input image. In convolution layer the kernel of dimension 224 x 224 is used. Kernel are initialized randomly. Kernel slide over the complete input image of size 2497 x 2497 and along the way perform dot product between the filter and the input image. The output of the convolution layer is given to the pooling layer. Pooling layers reduce the dimensions of the data by combining the neuron from the convolution layer. It reduce computation work involved in the network. Max pooling layer is used as pooling layer. Kernel size of max-pooling layer was selected as 2 x 2. Hence 4-pixel values are replaced by one pixel value. ReLU is the activation function used for DS CNN. Fig.5 shows the DS CNN with three modules.

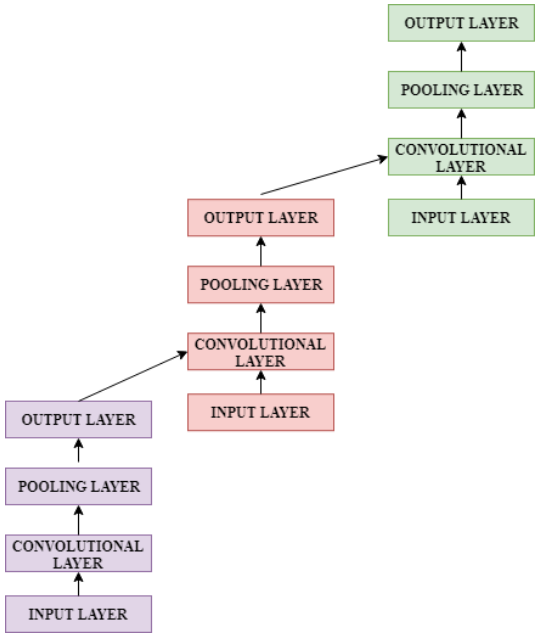

Fig. 5. Block diagram of Deep Stacking Convolution Neural Network

It contains three modules of DS CNN. Each model consists of input layer, two convolution layers, two pooling layers followed by flatten the output of pooling layer and given to the output layer. By adding convolution layer into TDSN, the accuracy of the classification output is improved to 97.37% and also time taken to compute classification was reduced by trimming the image dimension at pooling layer.

IV. RESULT AND ANALYSIS

A. Dataset and Study Area

In order to evaluate the proposed method, the Landsat 5, Landsat 8, and Sentinel 2 satellite images are collected form Land Process Distributed Active Archive Center of the United States Geological Survey (USGS) [17]. These satellite image covers the Hutong area, Beijing, China. It is located at the northern edge of north China. It covers the coordinates of, top-most $39.55°N, 116.23°E$, and bottommost $39.72°, 116.50°E$ around 1370 km^2 study area. The images are collected over the period of 2005 2015 in the month of September. From

the year 2005 to 2012 Landsat 5 image is taken. Landsat 5 satellite uses the Enhanced Thematic Mapper plus (ETM+) sensor to take pictures of the earth. Landsat 5 satellite image contain 8 bands (Band 1 Blue, Band 2 Green, Band 3 Red, Band 4 - Near Infrared, Band 5 - Short-wave Infrared, Band 6 - Thermal Infrared, Band 7 - Short-wave Infrared, and Band 8 Pan-chromatic) except pan-chromatic band all are 30m spatial resolution. The pan-chromatic band has 15m spatial resolution, this band is used for pan-sharpening. Landsat 8 Satellite image, in addition to Landsat- 5 ETM+ satellite bands it also has 3 bands (Cirrus, Thermal Infrared -2, Short-wave Infrared-2). Sentinel 2 satellite we choose only 4 bands (coastal aerosol, cirrus, water vapor and red edge band).

B. Experimental Setup

Pre-processing techniques (band fuse, cloud removal, pan sharpening and NDVI conversion) has been performed using MATLAB (R2018a) in windows 2007 (64-bit OS, 8.00-GB RAM). The framework was designed by using python 2.7 in Linux environment. Keras and TensorFlow are used to build and test the neural network. Keras provides (Application Programm Interface) APIs to design the framework. Keras is build on the top of TensorFlow. Numpy library is used for multi-dimensional matrices multiplication and high level mathematical functions.

C. Performance Metrics

Fig. 6 shows the accuracy of traditional SVM algorithm used in base work [7]and proposed neural network design TDSN back propagation and TDS CNN. Accuracy are calculated by using RMSE given in the equation 7.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=0}^{n}(Vo - Vp)^2} \tag{7}$$

Where Vo denotes original image and Vp denotes Predicted image. n denotes total number of observations.

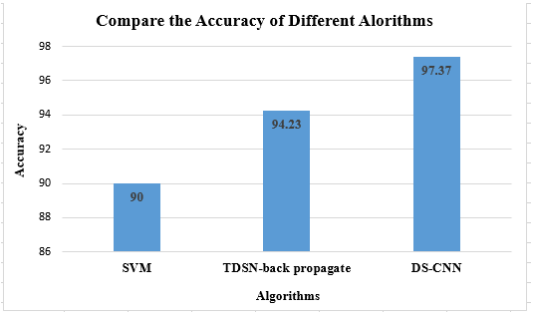

Fig. 6. Accuracy of Land Cover Change Detection.

The accuracy of land cover change detection using DS CNN is improved approximately 7% in comparison to traditional classification algorithm.

Fig.7 shows the accuracy of TDSN output at each iteration. Accuracy had been calculated by using the equation 7.

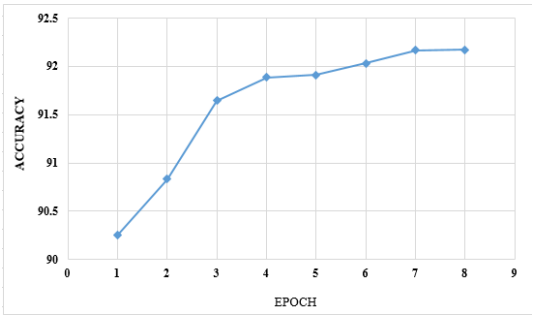

Fig. 7. Accuracy in Each Epoch of Back Propagation.

Accuracy could be improved gradually at each iteration. For each iteration calculate the loss function and make the delta changes in the internal weights of the neural networks to minimize the error and helps to get more accurate output. In the Fig. 7 seventh and eighth iteration was more or less same. So, we can stop propagate the error.

Fig.8 shows the amount of time taken in minutes to find land cover land change detection. From the graph we conclude that DS CNN take less amount of time for classification. Because feature extraction and size reduction was processed by convolution layer and pooling layer respectively, reduce the computation parameters.

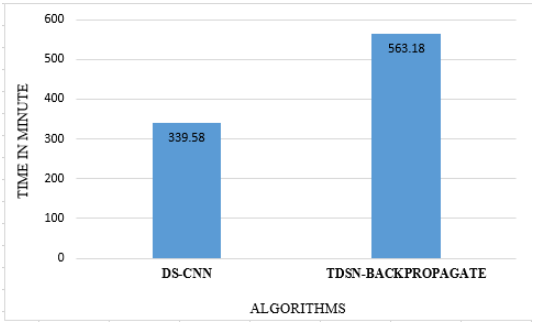

Fig. 8. Time Taken to Complete Classification

V. CONCLUSION AND FUTURE WORK

In this study the accuracy of land cover change detection is improved by adding back propagation into the TDSN it is proven by comparing the classification accuracy to traditional classification algorithm (SVM). But the hidden layers in the TDSN are fully connected so, it takes more time to complete the classification an. Loss function calculation, backpropagate the error to change the internal weights also take time. Limitations in TDSN with backpropagation was overcome by DS CNN. Hidden layers in the TDSN are replaced with the convolutional layer and pooling layer. Convolutional layer helps to extract important feature with the help of kernel and pooling layer helps to reduce the size of the image. The accuracy of DS CNN is also higher in comparison to TDSN with backpropagation. The experiment is carried out during the period of 2005 to 2015 over the area of Hutong,

Beijing, China. Image pansharpening of satellite images into 15m resolution. Raw satellite image contaminates with cloud and artifacts. After land cover changes are detected from the year 2005 to 2015 we collect the 2005 population in Hutong, Beijing, China and population at 2015 and agriculture land, water area and build-ups coverage in 2005 and 2015. Based on this data we calculate the percentage of food shortage arise in the future. This calculator helps to avoid food scarcity in the future. DS-CNN effectively found that the agriculture area was reduced around 12.3%, water bodies are reduced around 9.23% and build-ups are increased to 29.3%.

In future, this work can be extended by changing the filter used in the convolution layer. Edge detection filters like sobel filter can perform well in classification. Replacing the filter used in the convolutional layer with the sobel filter will improve the accuracy of classification result. Which also helps to minimize misclassification error.

***Abstract*— Electric vehicles (EVs) have a restricted range due to its inadequate energy storage space, it takes much longer to recharge. Furthermore, charging stations are not as sufficient as fueling stations for diesel or gasoline vehicles. Therefore, the primary motivation in optimal driving based energy management system (DAEM) is to consume the stored energy in a competent way to perform the entire trip. Moreover, due to avoiding accident, quality of road and other reasons, the road speed limits are restricted, and it is observed in both downtown as well as highway. Keeping various speed limits results in increasing the trip complexity which effects in maintaining a same driving strategy throughout a trip. In the present paper, an investigation of the influence of trip complexity on DAEM results was carried out. Two driving cycles (neighborhood and highway) are considered for constructing various trip complexities for this investigation.**

***Keywords*— micro-trip, electric vehicle, optimal driving strategy, trip complexity, energy management, multi-objective optimization, driving cycle**

I. INTRODUCTION

Now a day's EVs are popular in all over the world. Several problems of environment are relevant in recent scenario. To make the EVs as future of personal transportation and to increase the customers' acceptance, these problems should be overcome by developing suitable technology. Limited charging capacity of battery, long charging time and insufficient charging stations are the major hindrances in EV system [1]. Therefore, the primary motivation to overcome such hindrances is the stored energy is to be utilized in an efficient way which leads to the development of energy management system. From previous research studies [2], it was found that driving behavior of a driver play a significant influence of fuel consumption. By realizing such research findings, an optimal driving based Energy Management System to assist drive (so called DAEM) was proposed in [3]. DAEM presents a driving strategy to the driver for optimal driving by solving a multi-objective optimization problem (MOOP) towards minimizing the energy consumption and trip time, and maximizing driving comfort. In [3], the working principle of DAEM was presented in a simple micro trip that consists of a single driving cycle. After analysizing the DAEM results corresponding to various micro-trip lengths, it was revealed that in addition to assist the driver for proper driving, a significant reduction of EV operating cost through minimizing the fuel consumption and increasing the safety factor can be achieved with the used of DAEM.It was found that DAEM system can reduce the energy utilization (above 1.7% per Km) depending on route type of simple micro-trip with low driving cycle. In [4], an extensive study of the influence of initial battery charge and route characteristics on DAEM results was conducted.

Due to avoiding accident, quality of road and other reasons (not overtaking zone, hospital, school, high traffic, narrow road, bridge, etc.) [5][6], it was observed that the road speed limits are restricted, and it is observed in both downtown as well as highway. Keeping various speed limits results in increasing the trip complexity which effects in maintaining a same driving strategy throughout a trip. In the present paper, an investigation of the trip complexity influence on DAEM results was carried out. Different driving cycles are considered for constructing various trip complexities for this investigation. The proposed investigation is carried out based on a comparison of the battery state-of-charge after trip completion (SOC_{Trip_end}) vs. total trip time (T_{Trip}) plots of the optimal solutions obtained in different trips with varying complexities after solving a MOOP towards finding optimal driving strategy (ODS). An ODS comprises of the optimal values of different driving features namely speed, acceleration and deceleration according to the driving mode type.

The rest of the paper is organized as follows: Section II describes the proposed DAEM system for EV trip planning. The related MOOP is formulated in Section III. Description of micro-trip is presented in Section IV. In section V, results and descriptions are presented. Finally, concluding remarks and scope for future research works are highlighted in Section V.

II. PROPOSED DAEM SYSTEM FOR EV TRIP PLANNING

The architecture of DAEM system is presented Fig. 1 [3]. DAEM has two primary modules, such as interface between human and machine (HMI) and optimal trip planning (OTP). The route information (such as road gradient, wind, road surface, weather, etc) is collected by HMI through global positioning system or wireless communication system such as smart phone, etc. HMI also receives the present values of various parameters (namely battery charge, supplementary load, present driving strategy followed, etc.) through various sensors. HMI transfers both the route and vehicle information to OTP module. OTP module solves the related MOOP corresponding to the route chosen for journey and information related to vehicle drive, and provides a set of optimal driving strategy, ODS (solution). DAEM system guides the driver by suggesting

not only the optimal driving strategy (especially, optimal trip speed, acceleration/ deceleration values and durations for changing a speed) but also the predicted range of EV corresponding to the present battery SOC and the suggested ODS, SOC_{Trip_end} and T_{Trip} predictions [7-13].

Driver normally selects a solution (ODS) based on his preference from the set of ODS provided by DAEM for driving the EV. Alternatively, a technique that is used for making decision in a multi-criterion scenario [14] can be adopted to find a preferably best solution. After a certain period, DAEM is allowed to execute again corresponding to the latest data of route characteristics and vehicle drive to find an ODS for subsequent driving. Knowing the range and T_{Trip} in advance provides the driver an adequate flexibility towards efficiently utilizing the energy with ODS, even in urgent situation including shortage of battery charge. In the same manner, DAEM is allowed to execute consecutively according to the collected information that are found after the previous driving until the completion of trip . Such type of driving based on the DAEM suggested ODS assists driver to accurately manage the energy consumption (E).

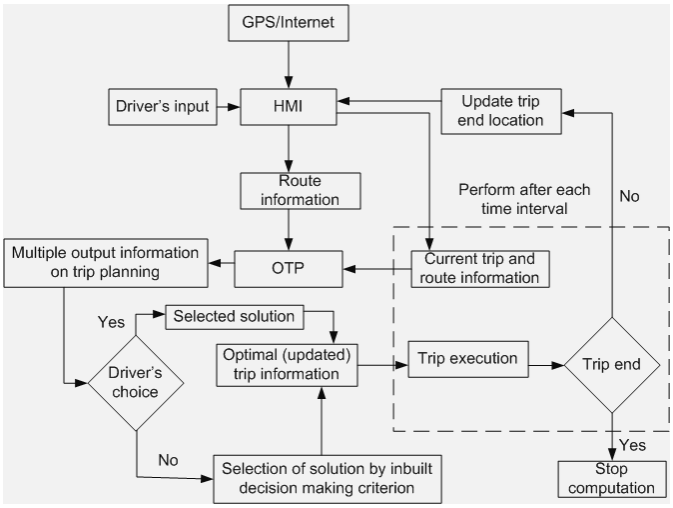

Fig. 1. DAEM system architecture

III. Formulation Of Multi-Objective Optimization Problem

The MOOP for finding an ODS is formulated based on the three objectives, minimizing E, reducing T_{Trip}, and maximizing comfort during driving (i.e., minimization of average jerk experienced), simultaneously [15]. These objectives are depended on various driving features (design variables) and the corresponding relations are expressed as follows:

$$T_{Trip} = f_T\left(v_{ref}, a_{ref}^{1,2,\ldots K}, t_{1,,2,K-1}, k_p, k_i\right) \quad (1)$$

$$E = f_E\left(v_{ref}, a_{ref}^{1,2,\ldots K}, t_{1,,2,K-1}, k_p, k_i\right) \quad (2)$$

$$J_{Avg} = f_{Total}\left(v_{ref}, a_{ref}^{1,2,\ldots K}, t_{1,,2,K-1}, k_p, k_i\right) \quad (3)$$

subject to

$$v_{\min}^{dc} \le v_{ref} \le v_{\max}^{dc} \quad (4)$$

$$a_{\min} \le a_{ref}^{1,2,\ldots,K} \le a_{\max} \quad (5)$$

$$0.3 \ge k_p \ge 0.01 \quad (6)$$

$$3.0 \ge k_i \ge 0.01 \quad (7)$$

During acceleration of speed changing, K number of accelerations ($a_{ref}^{1,2,3,\ldots,K}$) are assumed since in [16] energy consumption is found to be low by utilizing many acceleration rates. $t_{1,2,3\ldots,K-1}$ are the durations of first *K-1* number of accelerations. For simplicity, in this work the deceleration (d_{dec}) was assumed constant depending on v_{diff}_dec (difference between present and desired speeds), as follows:

$$\begin{matrix} a_{dec} = 2.3 \\ a_{dec} = 2.25 \\ a_{dec} = 2.35 \end{matrix} \quad \text{if} \quad \begin{cases} 100 \le v_{diff_dec} \le 129 \\ 50 \le v_{diff_dec} \le 100 \\ 0 \le v_{diff_dec} \le 50 \end{cases}$$

. $v_{\min}^{dc}$ and $v_{\min}^{dc}$ are the allowable EV speed limits that are decided according the type of driving cycle. $a_{\min}$ (=0.1 m/sec^2) and $a_{\max}$ (=3.0 m/sec^2) are the allowable EV acceleration limits., k_p (varying in the range, 0.01, 0.3) and k_i (varying in the range, 0.01, 3.0) are the gains for the PI controller.

IV. Micro-Trip

In real world, the entire travel route of a trip comprises with several micro-trips. A micro trip (MT) is usually described by the portion of two successive stop points (start and end) in the route [17] [18], and the corresponding length is called the micro-trip range. According to safety and road type differentiation, a MT may face four category of road type (driving cycle, DC) based on the speed limits [19] [20] such as (neighborhood (speed range 8 km/h - 40 km/h), urban (40 km/h - 56 km/h), highway (56 km/h - 88.5 km/h), interstate (88.5 km/h - 112.6 km/h). The driving cycle speed limits are required to be followed by a driver as per the traffic rules and regulation.

A MT is considered as a simple type if it follows only one DC throughout its whole length, and such a MT can be demonstrated by the speed vs. distance plot as shown in Figure 2. A simple micro-trip follows three consecutive driving modes in the order, an acceleration mode (a_{ref}) a constant speed mode (v_{ref}), and finally a deceleration model in order to bring the EV to stop.

On the other hand, a complex MT is in general described as a MT consisting of more than one DC. The complexity depends upon the involvement of different driving cycle types, driving cycle lengths, and locations in the micro-trip. Based on such criterions, a micro-trip may be treated as more complex than other. Figure 3 exhibits the speed outline of a typical complex MT that follows first an acceleration mode (a_{ref}) followed by

three different constant speed modes ($v_{ref1_microtrip}$, $v_{ref2_microtrip}$ and $v_{ref3_microtrip}$) and then a deceleration model to stop the vehicle. Unlike to simple micro-trip, the constant speed modes should be associated with at least two different driving cycles in a complex micro-trip. According to micro-trip 1 shown in Figure 3, the first and third constant speed modes correspond to a (high speed) DC and the second (middle) constant speed mode corresponds a low speed driving cycle.

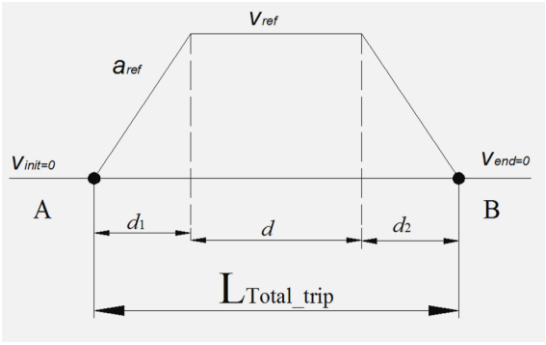

Figure 2. Speed vs. distance of a simple micro-trip

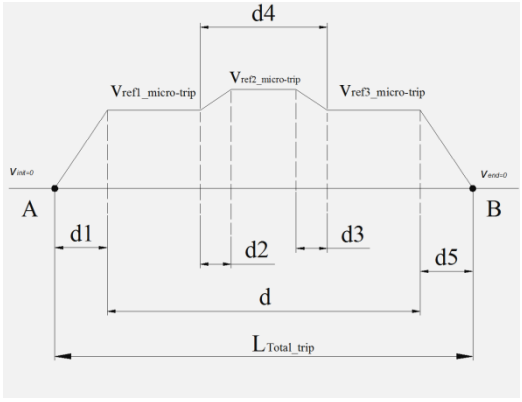

Figure 3. Speed vs. distance of a typical complex micro-trip layout (micro-trip 1)

V. Results and Discussion

For analyzing the MT complexity influence on DAEM results, different case studies are considered, and in each case two micro-trips are assumed, among them one is comparatively more complex than other.

Case I: DAEM results are investigated for a complex MT (microtrip_1) that comprises of two neighborhoods ($v_{ref1_microtrip}$ and $v_{ref3_microtrip}$) and one highway ($v_{ref2_microtrip}$) driving cycles (corresponds to Figure 3) with a simple micro-trip that consists of either a neighborhood or highway DC (corresponds to Figure 2) for the same trip length. Table 1 presents the positions and lengths of the different driving cycles for a 20km trip length. l_h (=d4 in Figure 3) is the length of highway driving cycle in the micro-trip.

TABLE I. ARCHITECTURES OF MICRO-TRIP

Serial No.	Micro-trip distance (km)		Driving cycle
	From	*To*	
1	0	$(L_{Total_trip} - l_h)/2$	Neighborhood
2	$(L_{Total_trip} - l_h)/2$	l_h	Highway
3	$(L_{Total_trip} - l_h)/2$	L_{Total_trip}	Neighborhood

Fig. 4 presents the demonstrative DAEM results (Pareto front) obtained through solving the MOOP presented in Section III using a non-dominated sorting genetic algorithm (NSGA II) [21] for the microtrip_1 of length 20km. Optimization results obtained by varying l_h for the same MT (microtrip_1) are analyzed in order to understand the effect of complexity due to the DC length. . In Fig. 4, highway driving cycle lengths zero and 20 km indicate the corresponding micro-trips are the entirely neighborhood and entirely highway micro-trips, respectively. From Fig. 4, it was found that the Pareto front width in both SOC_{Trip_end} and T_{Trip} is stretched with increasing the highway driving cycle length. With increasing the highway driving cycle length, an opposite phenomenon of the characteristics of SOC_{Trip_end} (increasing) and T_{Trip} (decreasing) is noticed in Fig. 4. The preferred optimal value of SOC_{Trip_end} is determined here using a reference point technique [4] [5] based on ideal point. For different l_h (0, 5, 10, 15, and 20 km), the preferred SOC_{Trip_end} are found as 0.855, 0.856, 0.858, 0.863, and 0.865, respectively. The corresponding values of different parameters of ODS, objectives, etc. are listed in Table 2.

TABLE 2 LIST PREFERRED OPTIMAL SOLUTIONS FOUND IN DIFFERENT HIGHWAY DRIVING CYCLE LENGTH FOR TRIP LENGTH, 20 KM

l_h (km)	SOC	T_{Trip} (sec)	Energy (J)	Jerk (m/sec^3)	V_ref1 (km/h)	V_ref2 (km/h)	V_ref3 (km/h)	1st acc_zone (d1 in Figure 3)			2nd acc_zone (d2 in Figure 3)			k_p	k_i	Actual range (km)
								a_1 (m/sec^2)	a_2 (m/sec^2)	t_1(sec)	a_1 (m/sec^2)	a_2 (m/sec^2)	t_2(sec)			
0	0.855346	1807.38	8397220	11.5067	39.9889	85.9652	39.9235	2.97363	0.387805	2.26759	1.66749	0.408145	24.067	0.155632	1.75886	19986.4
5	0.856298	1611.16	8285350	125.627	39.9996	71.0406	39.9576	2.65058	1.68177	0.850326	1.76513	1.5287	3.17354	0.267 98	2.76021	19986.3
10	0.858101	1388.5	8165130	253.17	39.9941	74.9003	39.9899	2.6917	1.87304	1.08773	1.764	1.52881	5.14697	0.293505	2.87681	19986.3
15	0.863259	1202.53	7894470	57.6981	39.9987	72.8211	39.8996	1.17971	2.00892	0.283359	4.151	1.46134	3.11517	0.277397	0.848691	19986.4
20	0.865426	1008.92	7660530	36.8786	39.9645	74.0497	38.4995	1.29563	0.246616	0.102961	2.64449	2.97196	3.09066	0.274446	1.10591	19987.3

There is a polynomial relationship (presented in Equation (10)) is found among SOC_{Trip_end} and the highway driving cycle length (l_h). According to the nature of trip complexity, the relationship among SOC_{Trip_end} and l_h is varied.

$$SOC_{Trip_end} = 2x10^{-5} l_h + 2.2x10^{-4} l_h + 0.85508 \quad (10)$$

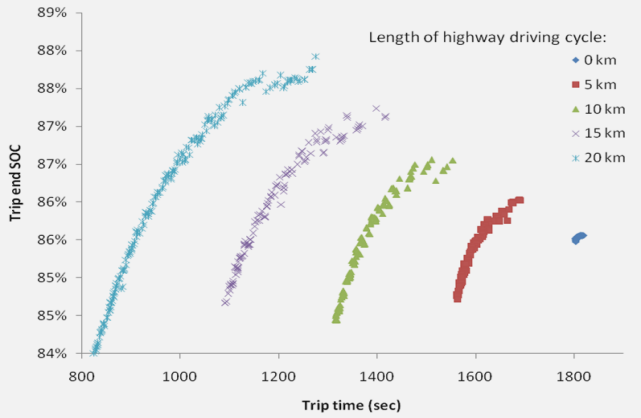

Fig. 4. Variation of SOC_{Trip_end} with T_{Trip} for different complex micro-trips.

Case II: In this case study, two complex micro-trips i.e., micro-trip 1 and micro-trip 2 (as shown in Figure 3 and Figure 5) are considered for investigating the complexity influence on DAEM results. The micro-trip 2 presented in Figure 5 is more complex than micro-trip 1 that presented in Figure 3, in the sense that in Figure 5, there are three highway driving zones with different distributions. In both the micro-trips, the lengths of each driving cycles are kept same for effective comparative analysis.

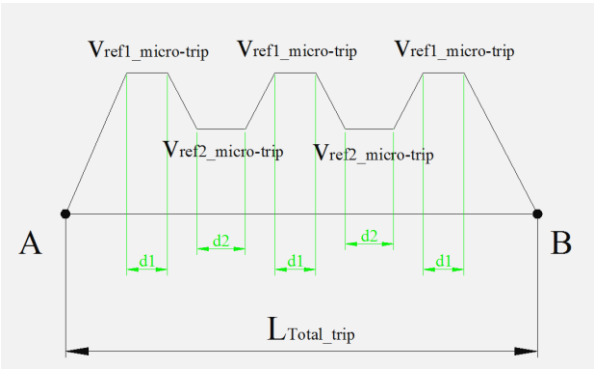

Figure 5. Speed vs. distance of a typical micro-trip layout (micro-trip 2)

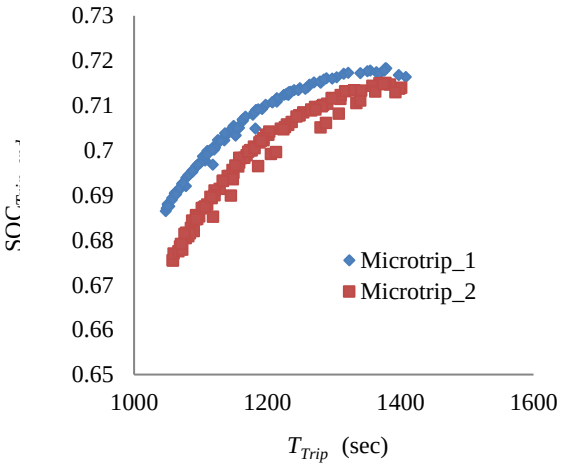
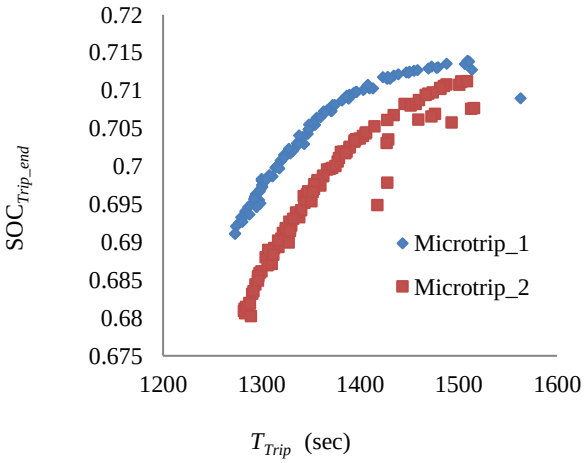
The figure 6 shows the Pareto-optimal solutions of SOC_{Trip_end} with T_{Trip} for the two complex micro-trips (as shown in Figure 3 and Figure 5) for different values of highway driving cycle length. The total trip length for both cases was considered as 20 km.

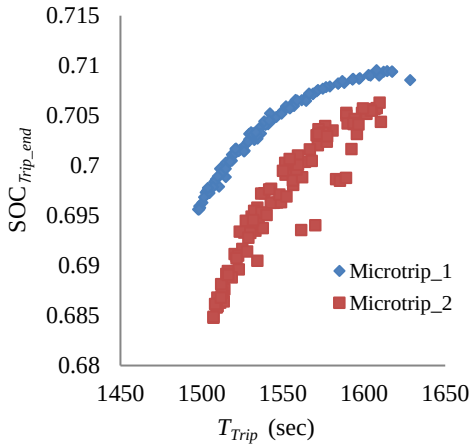
From Figure 6(a), we can see that in complex micro-trip 2, for 15 km highway driving cycle with 20 km trip length, the *SOC* values of the Pareto-optimal range are 0.6754 and 0.7137, respectively. But in complex micro-trip 1, for the same highway driving cycle with 20 km trip length, the SOC values of the Pareto-optimal range are 0.6871 and 0.7168, respectively. For other highway driving cycle say, 10 km and 5 km in complex micro-trip 2 and complex micro-trip 1, the initial and final SOC are 0.6802, 0.7112 and 0.6911, 0.7138 respectively shown in Figure 6(b) and 6(c). On the other hand, the range of T_{Trip} of the Pareto-fronts in both the micro-trips is same. The rate of increase of SOC_{Trip_end} with respect to T_{Trip} was found more or less for both complex trips. But when the highway driving cycle length is low, the micro-trip 2 possess a higher rate of SOC increase with respect to time compare to micro-trip 1, as shown in Figure 6(c). From Figure 6, a low SOC_{Trip_end} in micro-trip 2 compare to micro-trip 1 suggests that the high energy consumption is found when the vehicle runs the same highway cycle distance at a stretch.



(a)



(b)



(c)

Figure 6: Comparative results of micro-trips with different highway driving-cycle lengths (a) 15 km (b) 10km (c) 5 km

The above studies of trip complexity effect on SOC_{Trip_end} reveals that it is exceedingly intricate for the inexperienced predictors that use of previous trips to plan or predict current trips in terms of vehicle range or T_{Trip}. Furthermore, inexperienced predictors unable to suggest any appropriate energy-driving parameters. The DAEM system considers for the route features and the driver's preference while suggesting an ODS that yields in an energy-efficient journey with reducing T_{Trip} as well as discomfort.

Figure 7 demonstrate the variations of optimal speeds of different driving cycles in the optimal solutions corresponding to micro-trip presented in Fig. 3 for two highway lengths, 10 km and 15 km. In low driving cycle (neighborhood) the speed of almost all the optimal solutions is found to lie in high side, and such observation is followed in all such low driving cycles in the micro-trip. Whereas, in high driving cycle the speeds of optimal solutions are varied in its entire range. Moreover, the above observations does not depend on the changes of driving cycle lengths in a micro-trip.

VI. CONCLUSIONS

In this paper, the effect of route complexity on the DAEM results is analyzed. Comparisons of two types of route complexity with a simple microtrip draws the following the observations.

- SOC_{Trip_end} varies polynomial with the length of high driving cycle in a fixed length complex micro trip.
- The rate of increment of SOC_{Trip_end} is higher in micro-trip 2 than micro-trip 1 for low highway cycle length.
- With the increase of trip complexity, high Energy consumption is found for same highway cycle length.
- Optimal speed is found as a high values low driving cycle in contrast to a variation in high driving cycle.
- The research findings help to design and develop an EV-oriented highly-intelligent Advanced Driver Assistance System, equipped with other driving assisting systems, suitable monitoring, learning, reasoning, and management capabilities that will implement efficient EV driving and help to increase its range autonomy and decrease energy consumption.

***Abstract*—Smart grid is an electrical network which supply electrical power to consumer in very efficient and economical manner. This paper presents the load flow analysis of smart grid with renewable energy resource and FACTS devices. Newton Raphson method is use for power flow analysis and the objective of this paper is a development of a 14 bus system in PSAT software with FACTS devices, RERs and performs power flow analysis. The main aim of this paper to give initial framework related to load flow in smart grid with the help of RERs.**

Keywords—smart grid, optimal power flow, PSAT, SSSC device, Renewable energy resource

I. INTRODUCTION

Nowadays world population goes on increases continuously, as population increases energy demand increases and to meet the increasing demand renewable energy along with fossil fuel is used. But fossil fuel is not sufficient to meet the increasing demand for long duration that's why it's used is not preferable in the environmental term. The only solution of higher cost and global warming issue of fossil fuel is the use of Renewable energy resources. Power flow analysis is used to find the power transfer from generation side to consumer thorough the grid connected to it is reliable, economical and stable, it is also useful for the calculation of voltage magnitude and phase angle of load bus, active and reactive power flow in transmission line, active and reactive power injected at the buses. There are various methods for power flow analysis but we use Newton Raphson method because it has high convergence speed and it can control inequality constraint easily.

Smart grid is an electrical network that uses information, computer based remote monitoring and control, communication technologies to improve reliability, efficiency, sustainability of the generation and distribution of electricity.

For planning a development of new network or adding a network into an existing system the power flow analysis is required to calculate the voltage magnitude, phase angle, power flow at each bus and line. Also, it is useful to find the optimal capacity of generating station, line and substation.

In this research we create a model of IEEE 14 bus system and connect SSSC (FACT device) to the line of the system and wind turbine generator to slack bus and perform load flow analysis and the effect of such addition is discussed in the result.

II. STATIC SYNCHRONOUS SERIES COMPENSATOR

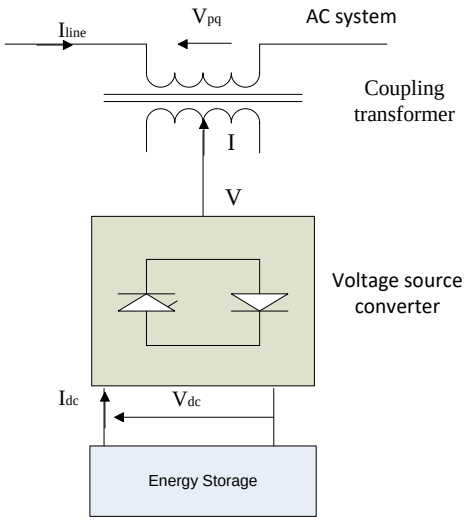

Fig. 1. Functional model of SSSC

SSSC is one of the FACT devices that are used to improve the voltage stability and reduce line losses etc. of existence system. Fig. 1 is functional model of SSSC [4] which consist of voltage source converter which generate a controllable AC voltage at power frequency and connect in series with TL. Output voltage of static synchronous generator is always in quadrature with the line current in order to control the reactive voltage drop and transmitted power. The SSSC work in the two modes, whenever receiving end power is greater than the sending end power or current lags the voltage by 90 degree then it operates on inductive mode. If receiving end power is less than the sending end power or current lead the voltage by 90 degree then it operate on capacitive mode.

III. NEWTON RAPHSON METHOD

Newton Raphson is one of the power flow method and the advantage of this method over the others is convergence occur

very fast, in this research Newton Raphson method is used for power flow and procedure is shown in Fig2.

Steps for load flow analysis by the Newton Raphson method,

Step1: Form nodal admittance matrix.

Step2: Assume initial bus voltage and set nth bus as a ref. bus.

Step3: evaluate P and Q of the system

Step4: form Jacobian matrix

Step5: evaluate power mismatches ΔP, ΔQ.

Step6: set the tolerance value

Step7: if ΔP, ΔQ are less than the tolerance then stop iterations.

Step8: if not then update the value of V and δ and repeat

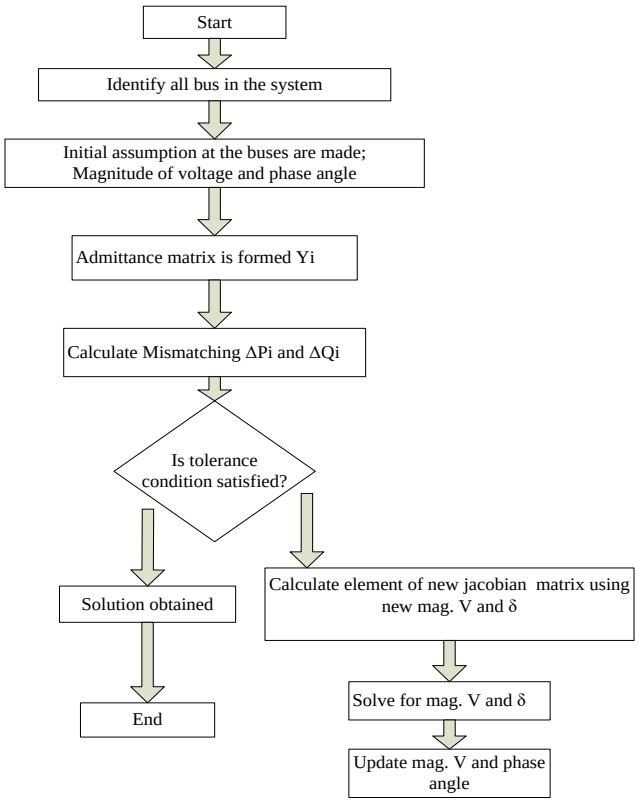

Fig. 2. Flow chart of NR for Load flow

IV. Simulation Model

Creating a simulation model in PSAT software is shown in Fig3. in which IEEE 14 bus system is used which consist of 14 buses, 20 lines, 4 transformer, 11 loads, one generator, two compensator. Input data is taken from the IEEE 14 bus data. Three SSSC are connected to the transmission line between the bus 1 and 5, bus 2 and 3, bus 2 and 4, compensation of SSSC is set to the 25 percent of line and one wind turbine (WTG) generator is connected to the slack bus. Function of wind turbine generator is similar to the other generator but is use is to avoid the the enviromental issue.

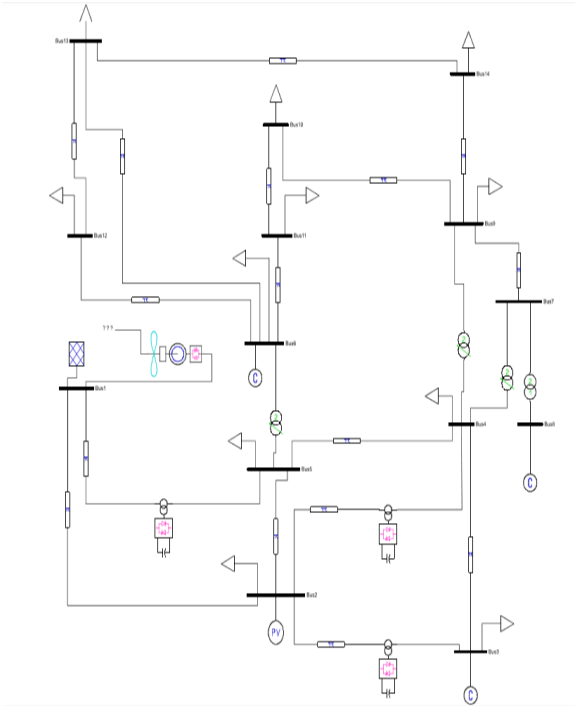

Fig. 3. Simulation model

V. Results

After performing a power flow analysis using Newton Raphson method the result is obtained in the form of voltage magnitude, phase angle, active, reactive power flow etc.

VI. CONCLUSION

In this dissertation work initially perform load flow analysis of 14 bus system in PSAT software and compare with the 14 bus standard result, both are approximately equal and then SSSC and wind turbine generator are connected to the system after the connection simulation result shows that active and reactive power flow in that line increase and voltage profile of entire system also increase. In terms of losses active power loss of the system reduces but reactive power loss is increases and this is shown in table IV. Future scope of this project can be extended with other FACTS devices and optimal power flow methodology, also to minimize reactive power losses..

***ABSTRACT*-- In the cutting edge age, all data is effectively open through sites and because of this reason individuals depend totally on online assets. On the in opposition to its focal points, protection and security in online media are the primary concern overall as a result of the ascent in phishing assaults propelled on the web. The quantity of phishing sites expands each month focusing on in excess of 450 brands, according to the reports distributed by against phishing working groups. Generally boycotts are utilized to distinguish the URL assaults. In any case, with the exponential increment in the quantity of phishing sites, this strategy has its own restrictions and it additionally neglects to identify recently created phishing URLs which can be unraveled utilizing AI or profound learning strategies. Here we present a near report between established AI procedure - calculated relapse utilizing bigram, profound learning strategies like convolution neural network and Recurrent Neural Network long present moment memory as models used to identify noxious Uniform Resource Locators. On correlation Recurrent neural network and long short term memory gave the best exactness of about 98% for the grouping of phishing Uniform Resources.**

***INDEX TERMS*-- Phishing, Recurrent Neural Network, Long Short Term Memory, Internet Service Provider.**

I. INTRODUCTION

In the course of recent decades physical assaults were normal, in any case, we realized how to tackle the issues brought about by it. Later syntactic assault became possibly the most important factor exploiting the vulnerabilities in the virtual products to bargain the frameworks. These days semantic assaults are normally utilized strategies by assailants to get delicate data of a client. It is still kept on being the most occurring assault in the internet.

Aggressors utilize this method principally in light of the fact that people dependably neglect to confirm the veracity of data that they get through web, and make them a simple prey to the hands of online ruptures. Such assaults are generally helped through spam messages and phishing sites, and trap the client to give the qualifications and other delicate information's of the client. Email is viewed as the main vehicle to convey a wide range of noxious assaults. As per IBMs look into group, the quantity of spam sends are expanding enormously furthermore, aside from that, it is seen that the greater part of the messages created are trick. In first quarter of 2017, the level of spam in email traffic added up to 56.9%. Assailants generally sent messages with phishing sites to counterfeit sites which looks genuine to an ordinary client.

Via the post office they blend true connections and false connections so as to make it look all the more engaging. So as to test the credibility of the email, clients can intently investigate its substance for sentence structure or then again spelling slip-ups or on the off chance that it is requesting individual data like charge card number, telephone number and so forth. Larger part of the web clients who are not taught about the security, neglect to browse the substance of messages and land in pernicious sites. There is no certain flame approach to check in the event that somebody has wound up in phishing sites, however checking the site may help in few cases. Present day internet browsers use additional items and modules to distinguish phishing site. Such instruments use boycotting to distinguish noxious sites. Boycotting approaches are for the most part signature based, where a database is kept up to monitor all the known phishing site. Web creeping, manual revealing, honeypots what's more, different techniques in the vicinity investigation heuristics are the different strategies used to identify the noxious connects to refresh the database. Be that as it may, this technique comes up short when an obscure phishing site is experienced and it requires refreshing the database after following the previously mentioned strategies.

AI is a field of software engineering which is connected in pretty much every zone like science, material science, science, liquid elements, horticulture nowadays. It is conceivable to do so in light of the fact that AI systems gain from the information accessible and after that plan a well-suited model to aid choice making by preparing the future information. Also, the information need not be from a particular field, it very well may be anything. This flexible nature of AI is the explanation behind it to wind up prominent in the current world. In this work, we have utilized strategic relapse utilizing bigram as the model in directed AI to test the exactness acquired to order if a given site is malignant or not. Be that as it may, the disadvantage of AI is that the highlights which alone decides the outcome should be picked physically. Profound learning is a part of unsupervised AI which gain from the information without anyone else and structure a model for future use. It has more prominent probability to identify recently produced phishing sites and furthermore need not require manual element engineering. In this paper we center around RNN and blend of RNN with long present moment memory(LSTM) to acquire the exactness in ordering

the phishing sites. While customary computerized phishing gives 5%-14% precision and physically focused on lance phishing gives 45%. The technique is directly in the center with 30% precision and up to 66% at times with a similar exertion as the robotized one. Security is a worry for any open confronting web application. Great advancement practices can help with shielding against endeavors from clients hoping to uncover information or cut down an application. In any case, in some cases not all assault vectors are taken care of and new endeavors will undoubtedly be found. This is the place security programming can help with checking and anticipating unanticipated assaults. So imagine a scenario where you could utilize the intensity of Google's Tensorflow motor to choose whether a given solicitation is viewed as noxious. Well that was the inquiry I was hoping to reply while taking an interest in Slalom's ongoing AI hackathon. The accompanying post diagrams the specialized subtleties of a PoC for a security observing application which was worked with the assistance of a couple different Slalomites. The goal was to assemble an application that can examine approaching solicitations to an objective API and banner any suspicious movement. The application would likewise have a straightforward UI to show these hailed demands and give the capacity to make preparatory move when vital. The group named the name to this pernicious solicitation identification application 'SecuritAI'.

Similarly as with any Machine Learning issue, the information is the important asset for making a shrewd model. For this situation get to logs from an API is the thing that I required. A fake API must be worked to create a decent dataset of access logs to process. Lumberjacks would should be added to the fake API to aggregate access signs in clusters for preparing reason, just as the capacity to stream logs for constant handling. see in fig 1.

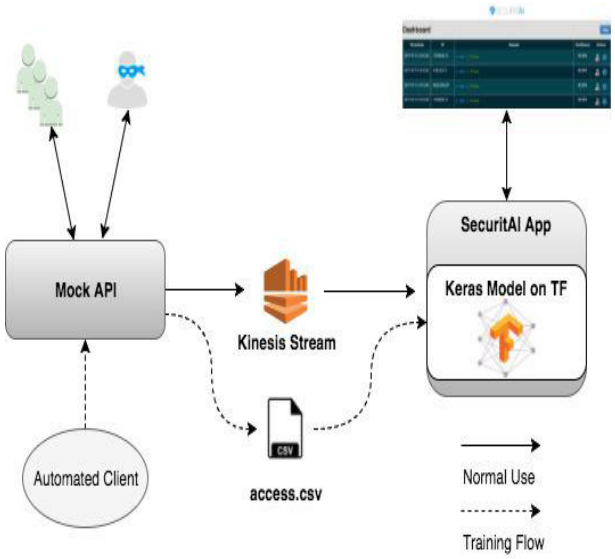

Fig 1. Tensor flow and work model

The paper is composed as pursues. In Section II, we present related work on phishing site recognition. At that point, in Section III, we present the system of Materials and method. In Section IV, we depict result and discussion the point by point procedure of the LSTM and multidimensional highlights. conclusion in Section V. At long last, in Section VI, we finish up the paper what's more, talk about future work

II. RELATED WORK

The Author proposed boycott/whitelist techniques are utilized in numerous examinations and by and by [7], [8], [5], [6], [9], [2]. Be that as it may, these techniques needs to keep up a rundown of phishing sites utilizing a manual/automatically update process as appeared Uniform Resource Locators demands are checked before propelling dependent on a neighborhood database or a database on the cloud. Despite the fact that the boycott/whitelist procedures has fast discovery, overseeing the boycott/whitelist database is wasteful for both the neighborhood database and the cloud database due to the quickly expanding number of phishing destinations. Along these lines, heuristic and Artificial Intelligence approaches have been gotten much consideration in terms of programmed discovery. This can be viewed as a cross breed approach that utilizes boycott/whitelist techniques to ensure clients at the front end while Artificial Intelligence procedures are utilized at the back end (i.e., the server side) to recognize phishing and update on the boycott/whitelist database. A few Artificial Interface systems center around the web structure or web content-based techniques to recognize phishing Uniform Resource Locators [6], [7]. One understood methodology in extricating site page highlights to distinguish phishing destinations is Cantina+ [8]. This methodology depends on 15 highlights web pages, including Uniform Resource Locators highlights and substance highlights, which are costly amid the examination. Another strong work centering on Uniform Resource Locators highlights [2] introduced the adequacy of numerous approaches in the order of phishing Uniform Resource Locators; be that as it may, they didn't solidly think about the blend of numerous highlights to improve the distinguishing proof execution. In view of certain page-positioning highlights, the creators in [5], [7] created web structure-based ways to deal with recognize phishing website pages by utilizing the Google Page Rank esteem. Be that as it may, utilizing just the Page Rank esteem is deficient to distinguish phishing Uniform Resource Locators because of the accompanying reasons. To begin with, numerous phishing sites are made on mainstream sites such as online journals or Google destinations, where the positioning highlights are not helpful for phishing recognizable proof. Second, new Uniform Resource Locators have low positioning qualities that are comparable to phishing Uniform resource Locators. In some particular cases, we can't get Page Rank values from the Application Protocol Interface accurately. Such explicit cases can't be recognized by [8] and [2]. Consequently, consolidating numerous highlights is important to diminish the measure of missed identifications for phishing distinguishing proof .

III. Materials and Methods

With a prepared model the time had come to execute the SecuritAI UI application that would have the model to play out the ongoing expectations. Likewise with the false API, the group stayed with what we knew best, JavaScript. A React UI was worked as a dashboard to screen the movement originating from the flood of solicitation logs. The stream is overseen by AWS Kinesis to connect th e correspondence between the counterfeit API and SecuritAI UI. Now the tech stack is solid, yet one slight issue… Keeras is a python programming library, how is the model assume to make forecasts in JavaScript? Fortunately, there's amp bundle that will help for this need, would be Keras-js p ermits JavaScript applications to run spared Keras models prepared on the Tensorflow motor. Using this python pro gramming library empowered us to run everything from our Node.js application servers.

The way to deal with narrowing our attention on paired arrangement with a LSTM RNN i mplies we are performing managed learning with our model. H ence every log passage in the preparation dataset needs a goin g with name to portray if that logged solicitation is typical o r an endeavored infusion assault. Concerning producing inf ormation to prepare the model, the fake API was used to recreate a straightforward web based business application. For example ridiculed out endpoints for a/login,/look,/checkou t. Since the we don't have an authentic progression of clients to the counterfeit API we consolidated a couple runtime alternatives to run the server and execute demands consequently (for example npm run assault infuse). These begin dire ctions went through an average client stream, just as arbitrarily performing endeavored infusion assaults. We tuned these computerized solicitation streams to run ~100 AP I demands every moment to rapidly gather logs for a preparati on dataset.

A custom lumberjack was connec ted to the server system to yield the ideal dataset design. F or this situation, a csv containing columns of solicitation l og JSON and related mark was every one of that was required. So as to separate among ordinary and malignant solicitation s an 'assault' header was added to every malevolent solicit ation performed from the robotized customer. The mark for ea ch solicitation log passage would then be dictated by checkin g for the presence of that header. On the off chance that 'ass ault' header exists at that point mark the log with '1', and expel the 'assault' header before composing the log, genera lly name the log as '0'. Because of certain impediments of utilizing a ridiculed API to deliver a preparation dataset, and furthermore to guarantee we have a progressively summed up c lassifier just fundamental log fields were extricated ami d preprocessing. These properties included: 'technique', 'inquiry', 'statusCode', 'way', 'request Payload'. Counting fluct uating headers presented some arbitrariness which ruined the grouping realizing, so that was let well enough alone for de gree for this stage. Extra information, preprocessing, and per haps a different classifier could be utilized to investigate the header substance.

A robotized customer was left to keep running for a few hours to aggregate an OK sum p reparing information. To prepare the model rapidly an AWS p2.xlarge Deep Learning EC2 example was utilized to play out the calculations. AWS's Deep Learning AMIs are preinstalled with the vast majority of

the mainstream AI libraries and APIs you have to begin performing substantial preparing on GPUs. The 90 pennies for each hour this EC2 occurrence cost isn't just certainly justified regardless of the time spared preparing a model on an extensive dataset, yet in addition worth sparing time on introducing and arranging Tensorflow to legitimately keep running on a GPU. We found the setup and design on another machine demonstrates to be very tedious to get the conditions and GPU arrangement without flaw for the adaptation of Tensorflow wanted.

$$CDk(\theta,v0) = -\sum_{h} p(h|\, v0)\partial E(v0,\, h) \,/\, \partial\theta + \sum_{h} p(h \,/\, vk)\partial E(vk,\, h) \,/\, \partial\theta$$

$$ai = Inp(vi \,/ 1 - p(vi)$$

To decrease predisposition, the dataset created contained ~50/50 typical and vindictive solicitation logs. The dataset was part into 75% preparing and 25% assessment subsets. After a few emphases the model had the capacity to acquire a truly high precision. This was to some degree expected because of the constrained varieties of solicitation blends that were produced, however by and by it was adequate to work within our short time allotment. The precision and misfortune measurements delineated above are likewise caught in logs by means of an appended Tensor board callback inside the Keras preparing content. These logs are an amassing of checkpoints recorded amid preparing which are helpful for envisioning the model's execution amid and subsequent to preparing

$$L\theta = In(L(\theta v)) = In\prod_{i=1}^{n} \rho(vi|\theta) = \sum_{i=1}^{n} In(\rho(vi|\theta))k)\partial E(vk,h)/\partial\theta$$

$$\theta \leftarrow \rho\theta + \eta\partial In(L(\theta)) \,/\, \partial\theta$$

$$\theta \leftarrow \theta + \eta\partial In(L(\theta)) \,/\, \partial\theta$$

IV. Result and Discussion

The initial step on this MVP was to concentrate on picking a forecast model and demonstrate that it was a solid match for our concern. Recognizing whether a given solicitation is proposed to do mischief or uncover delicate data was the issue to illuminate. To begin we chose to limit our attention on deciding whether a solicitation contains content that can be viewed as an infusion endeavor. Infusion assaults can come in different structures: by shrewd addition of SQL, XML, JSON, or source code into solicitations. We were keen on possibly knowing whether given solicitation is an endeavored infusion or not, this is essentially a twofold grouping issue. There are numerous models which can help with this issue: Random forest Naive Bayes Classifier, Support Vector Machines, Neural Networks, and unsupervised models.

Profound Learning/Neural Networks are getting a great deal of consideration with the most recent achievements in the scholarly world and commonsense uses in the field. They have demonstrated to be uncommon at picture acknowledgment and normal language handling (NLP). Imagine a scenario where we could take advantage of the NLP abilities of a neural system for this order issue. This is the thing that we needed to try out. The JSON log passage as is can't be utilized as contribution for a neural system model. Models require

Table 1.Evaluation of LSTM and RNN

Layers	Type	Output shape	Other parameters	Parameters
0-1	Embedding	(None, 2307, 128)	embedding vector	length = 128 18304
1-2	Convolution1D	(None, 2303, 128)	number of filter = 128	filter-length = 5 82048
2-3	Maxpooling1D	(None, 575, 128)	pool-length = 4	0
3-4	LSTM	(None, 50)	memory blocks 50	35800
4-5	Fully connected	(None, 1) 51	5-6 Activation (None, 1)	Sigmoid 0

numeric contributions to work with, in this way message preprocessing is vital. Since substance of a solicitation log contain different character strings, images, and digits we decide to preprocess every passage into a grouping of characters. Handling the log passages as a grouping of characters is performed by mapping the each character of the solicitation log content to numeric qualities inside a populated word lexicon. The related numeric qualities speak to how as often as possible a character is seen. The word reference is at first made and fitted utilizing the preparation information, that way resulting characters can be mapped to recently observed character esteems. E.g In this fragment of the word lexicon, "," character is the seventh most successive character from the preparation dataset.

An incredible decision for learning an arrangement of characters is a Recurrent Neural Network. All the more explicitly a Long Short-Term Memory variation of Recurrent Neural Networks was picked on account of it's wide use and accomplishment in learning arrangements. Long Short Term Memory are somewhat mind boggling and it isn't the focal point of this post, however having an abnormal state understanding helps while tinkering with a model. More on grouping learning and LSTMs practically speaking can be found in this incredible review by Andrej Karpathy — Unreasonable Effectiveness of RNNs. To rapidly build up the neural system model, we picked to utilize the abnormal state Keras API running over Tensorflow, rather than legitimately cooperating with Tensorflow. Keras enables us to rapidly model our model and spare time by giving a standard setup to Tensorflow. Neural system models in Keras are extremely simple to work with, basically instantiate a model article and begin including layers! The underlying implanting layer

indicates the normal elements of the vector inputs, the LSTM concealed layer is characterized with 64 neurons alongside independent dropout layers to decrease fluctuation, lastly a thick yield layer to create the order certainty.

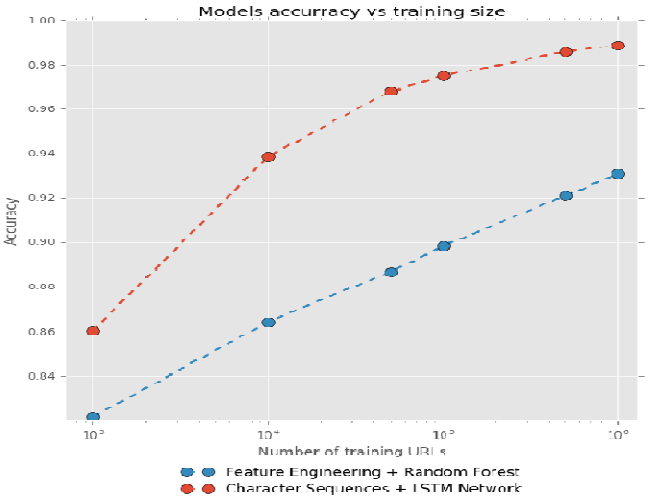

Fig4. Accuracy of LSTM and RF

V. Conclusion

This paper dissected the exhibition of strategic relapse utilizing bigrams, RNN and RNN-LSTM models to distinguish phishing URLs. Profound learning strategies like RNN and RNN-LSTM are ideal over AI techniques as they have the capacity to get ideal component portrayal themselves by accepting the crude URLs as their information. We can guarantee dependent on the outcomes we acquired that, the AI and profound learning based vindictive URL recognition can abandon discovery frameworks assembled utilizing boycotting and customary articulation strategies.

VI. Future Work

A future improvement of our approach will think about applying profound figuring out how to include extraction of website page code and site page content. Furthermore, we plan to actualize our methodology into a module for installing in a Web program

***Abstract*—This research paper depicts a modified partial transmitted sequence (MOPTS) algorithm by applying the normalized Riemann matrix (C) rows for phase sequences with discrete cosine transform (DCT) in time domain for diminishing of peak to average power ratio (PAPR) of several modulations under many sub-carriers based orthogonal frequency division multiplexing (OFDM) after distributing the information into numerous blocks and optimizing with the assistance of phase sequences. Since, original PTS (ORIPTS) algorithm makes use of phase sequences which are random and designing of those phases are also tedious. Henceforth, in this research manuscript we are suggesting a MOPTS algorithm which has definite phase sequences of normalized Riemann matrix (C) along with DCT. Simulation outcomes clearly indicate the noteworthy PAPR performance of MOPTS in comparison with PAPR of original OFDM (OFDMORIPAPR) and ORIPTS.**

Keywords—Partial Transmitted Sequence (PTS);Orthogonal Frequency Division Multiplexing (OFDM); Discrete Cosine Transform (DCT); Peak to Average Power Ratio (PAPR).

I. INTRODUCTION

In wireless communication system [1], one very promising and efficient multiplexing technique exists which is known as OFDM. It has got significant interest due to very high data rates along with the trusted performance of spatial multiplexing and diversity. Moreover, OFDM system possesses smooth equalization [2], good spectral power efficiency along with the easy implementation on hardware by assistance of Fast fourier transform (FFT). Furthermore, it is better due to significant features like small vulnerable to echoes, well-organized bandwidth utilization, it also has protection against narrow-band-co-channel interferences (NBCCI) hence, it improves the capacity of system by providing reliable transmission of information. OFDM procedure has been adopted by several wireless and wire-line system like wireless local-area network (WLAN) [3] IEEE-802.11 a/b/g/n, Long term Evolution (LTE) [4], European telecommunication standards institute (ETSI)[5], Broadcast radio-access network (BRAN), Digital television broadcasting (DTVB)[6],[7], Digital audio-broadcasting (DAB), Digital video-broadcasting (DVB)[8], worldwide interoperability for microwave access (WiMAX) IEEE-802.16 [9], Asynchronous digital subscriber line (ADSL)[10]-[12], Digital subscriber line (DSL). Since, OFDM has numerous advantages but high PAPR is considered as the key disadvantage of OFDM because of this, it suffers from out of band-radiations (OOB) and in band-distortions (IB) [13] and high PAPR leads to non-linearity in high power amplifier (HPA). Moreover, high PAPR enhance complexity of both analog-to-digital converters (ADC) and digital-to-analog converters (DAC). Henceforth, HPA with huge input back-off- power (IBO) is required along with huge word length so as to follow high PAPR [14].

The several solutions for the lessening of PAPR is to adopt the appropriate method which can reduce PAPR just before sending signals from transmitter side. Many procedures have been presented in literatures to diminish value of PAPR like trellis assisted constellation subset selection (TACSS)[15], clipping[16],non- linear companding transforming [17]-[19], peak windowing [20], clipping and filtering [21],[22], active constellation extension (ACE)[23] the above mentioned procedures be appropriate to group of signals distortion whereas other techniques which belong to the category of scrambling practices of signal like PTS [24],[25], tone-reservation (TR) [26],[27], selective mapping (SLM)[28]-[30], block coding [31], interleaving technique [32], tone injection [33]. This paper is prepared as follows. Section-II provides the comprehensive summary of the works supported for PAPR reduction. In section-III briefly shows OFDM, DCT and original PTS technique. In section IV, we show the proposed modified PTS algorithm. Then simulation results are implemented in section V whereas in section VI conclusions are drawn.

II. RELATED WORKS

In literature, numerous papers have been discussed related to high PAPR in OFDM like, In 2019, Gokceli et al. [34] introduced an effective technique for the diminishing of PAPR where clipping noise can be easily filtered and controlled inside passband of the transmitter which ultimately control signal which going to be transmitted. Several results suggested in 5G new radio (NR) mobile network context which demonstrate the efficiency of presented work. In 2019, Sandoval et al. [35] presented the novel hybrid PAPR diminishing method which uses three techniques like iterative modified companding and filtering, convolutional codes, successive sub-optimal cross antenna-rotations and inversion (SS-CARI). Significant reduction in PAPR is attained with help of hybrid technique.

Tang et al. [36] proposed a clipping noise method of compression in which modification is done in time domain

signal. The reduction in computation complexity has been obtained because it utilizes only one fast fourier transform (FFT). The presented work demonstrated better BER and PAPR reduction performance as compared with traditional ICF method, while Rateb et al. [37] presented a small complexity technique for the diminishing of the PAPR based upon linear scaling of some part of the signals coefficient with the help of a factor. The research work studied many inspections which leads to key choice of factors and finally, achieved large gain. The effective reduction in PAPR is obtained with negligible effects on the bit error rate (BER).

In [38], an effective PAPR lessening method proposed which deals with time domain kernel matrix in order to generate signal with minimum PAPR. It also employed the curve fitting approaches to optimize the scaling factor. The projected method is found to be more efficient as equated with traditional clipping and filtering technique. However, our prior research [39]-[42] have documented several schemes such as, In [39], SLM technique has been proposed which uses DCT matrix based phase sequences. Remarkable gain obtained in comparison with conventional SLM technique. In [40], a combination of PTS and Bose chaudhuri hocquenghem codes (BCH) have been projected to reduce PAPR. Simulation results revealed the significant improvement in the performance with the assistance of proposed work as compared with the conventional PTS and OFDM system. In [41], a highly optimized phases are obtained and applied in SLM algorithm. Simulations results obtained show the extraordinary performance of planned work in contrast with OFDM. In [42], Gupta et al. presented the SLM algorithm along with the usage of Hadamard matrix as a phase sequences which help in diminishing the PAPR. The performance of proposed work is better in contrast with traditional OFDM. In [43], authors projected a different method which is based upon iterative clipping and filtering (ICF) with easy clipping of signals along with filters so that small error vector magnitude and minimum PAPR can be achieved.

In [44], Goel et al., presented a companding method which transform rayleigh distributed-probability-distribution function (PDF) of the magnitude of OFDM signals into a form called as quadrilateral PDF. So, it is called as quadrilateral-companding transform (QCT). This scheme offered a decent tradeoff between PAPR diminishing and BER. Rakshit et al. [45] demonstrated a new small complexity sub-optimal PTS system with its basis in the implementations of differential evolutions (DE) technique in short MBLX-DE, it reduces the PAPR.

Singh et al. [46] proposed a hybrid technique based upon SLM and PTS and this scheme reduced the PAPR from 6 dB to 5 dB. This scheme is compared with other techniques and results are found to be better. Vittal and Naidu et al. [47] planned new small complexity PTS system by using random phase sequences matrix (RPSM) for PAPR decreasing in OFDM. The key aim is to obtain best phase sequence to diminish PAPR and complexity by reducing the number of inverse fast-fourier transform (IFFT).

In this paper, a modified PTS (MOPTS) algorithm has been proposed which uses Riemann matrix (C) rows as the phase sequences along with DCT in time domain for the lessening of PAPR. In this paper firstly, we will propose the algorithm so that smallest PAPR based OFDM signals can be created. The simulation results clearly show the best performance of MOPTS algorithm in comparison with conventional PTS technique and original OFDM system.

III. OFDM, DCT AND ORIGINAL PTS ALGORITHM

A. System Models

In OFDM [36] input information is modulated by phase shift keying (PSK) as sub-carriers in frequency domain. Now, frequency domain OFDM signals consist of N sub-carriers are represented as $X = [X^0, X^1, X^2, \dots X^k, \dots . X^{N-1}]$ where X^k represents block of data for kth sub-carriers.

The discrete signal in time domain of OFDM [2] can be represented as,

$$x(n) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} X^k \, e^{\frac{j2\pi kn}{N}}, n = 0,1,2 \dots . . N-1, \quad (1)$$

where n represents discrete sampling-index, k is index of frequency, N denotes total number of sub-carriers.

Oversampling [8], [36], is generally considered for the better approximation of continuous-time OFDM for PAPR. Now, if the oversampling factor is denoted by L then information can be extended by inserting $(L-1)N$ zeros with LNpoints data block of IFFT. For [2] the enhancement in the accuracy of PAPR, sampling of discrete baseband signal must be under $L \geq 4$.

The time domain conversion [36] of oversampled $X(k)$ is obtained by IFFT module to obtain$x(n)$:

$$x(n) = \frac{1}{\sqrt{NL}} \sum_{k=0}^{NL-1} X^k \, e^{\frac{j2\pi kn}{NL}}, n = 0,1,2 \dots . . NL-1, \quad (2)$$

where X^k represents block of data for the kth subcarriers.

The range of the time domain signal $x(n)$ is evaluated with the assistance of $PAPR$. It is represented as

$$PAPR(x(n)) = 10log_{10} \frac{\max_{0 \leq n \leq NL-1} (|x(n)|^2)}{E[|x(n)|^2]}, \quad (3)$$

where $E[.]$ represents operator of expectation [8], [36]. The $PAPR$ lessening of any technique is calculated by complementary cumulative distribution function $CCDF$ denoted by[39][53]:

$$CCDF = Prob\{PAPR > PAPR^0\}, \quad (4)$$

where $CCDF$ estimates probability of OFDM signal PAPR that exceeds provided threshold $PAPR^0$.

B. DCT Equation

The discrete cosine transform (DCT) is represented [48] as

$$d^n = \sqrt{\frac{2}{N}} \beta^n \sum_{m=0}^{N-1} x^m \cos\left(\frac{\pi n(2m+1)}{2N}\right), \quad (5)$$

Where N different symbols of data.

$$\beta^n = \begin{cases} \frac{1}{\sqrt{2}}, & n = 0 \\ 1, & n = 1, .. N-1 \end{cases} \quad (6)$$

C. Riemann Matrix

The rows of normalized Riemann matrix (C) are preferred as phase sequences for PTS algorithm. Now, Riemann matrix

(M) [49],[50] is attained by eliminating first column and first row of matrix B, where

$$B(i,j) = \begin{cases} i-1 \; if \; i \; divides \; j \\ -1 \; otherwise \end{cases} \quad (7)$$

By using the equation (7), Riemann matrix (M) [51] of the order 4 can be presented as:

$$\text{Riemann matrix } (M) = \begin{pmatrix} 1 & -1 & 1 & -1 \\ -1 & 2 & -1 & -1 \\ -1 & -1 & 3 & -1 \\ -1 & -1 & -1 & 4 \end{pmatrix} \quad (8)$$

If the Riemann matrix (M) with size $D \times D$, then the values of the normalized Riemann matrix (C) will be $\left\{\frac{1}{D}\right\} M$.

D. Traditional PTS Method

In traditional PTS arrangement[24],[52], an oversampled input information symbols X is segregated into numerous sub-blocks $X^v = [X^{v,0}, X^{v,1}, X^{v,2} \ldots\ldots, X^{v,NL-1}]^T$, $0 \le v \le V-1$, with the condition that

$$X = \sum_{v=0}^{V-1} X^v \quad (9)$$

Now, by using $IFFT$ to individual sub-blocks, the vectors of sub-signals $x^v = [x^{v,0}, x^{v,1}, \ldots\ldots x^{v,LN-1}]^T, 0 \le v \le V-1$ are created. The phase rotating factors $b^v = e^{j\emptyset^v}$, where $\emptyset^v \in [0, 2\pi)$ for $v = 1,2, \ldots V-1$. The phase rotating factors are generally the elements of predefined set denoted as $b^v \in \left\{ e^{\frac{j2\pi l}{W}} \middle| \; l = 0,1,2, \ldots . W-1 \right\}$, where W denoted as size of phase rotating factors. The phase factors are $b_u = [b_u^0, b_u^1, \ldots . b_u^{V-1},], u = 0,1 \ldots . U-1$, where U signifies total OFDM signals created. Now, with the uth phase vector, the uth OFDM signal is denoted as

$$x_u = [x_u^0, x_u^1, \ldots\ldots, x_u^{LN-1}]^T \quad (10)$$

$$= \sum_{v=0}^{V-1} b_u^v \, x^v, \;\; u = 01,2 \ldots U-1 \quad (11)$$

Since, all the first factors of phase rotating $b_0^v, 0 \le v \le V-1$ are generally assigned with value 1, $U = W^{V-1}$ signals of the OFDM are created in the traditional PTS method. Lastly, best OFDM signal x_{opt} with smallest PAPR worth among U OFDM signal is chosen for transmission, that is,

$$x_{opt} = \underset{u=0,1,2 \ldots U-1}{argmin} \; PAPR(x_u). \quad (12)$$

Block diagram of above mentioned traditional PTS method is denoted by Fig. 10.

IV. Proposed Modified PTS (MOPTS) Algorithm

The MOPTS algorithm which uses Riemann matrix (C) as phase sequences along with DCT for the diminishing of the PAPR (Fig. 10).

Steps for projected MOPTS algorithm are denoted as:

Step 1: Information Y possesses length N, after passed through digital modulator, is denoted as $G = [G_0, G_1, G_2, \ldots . G_{N-1}]$ where N being total number of the sub-carriers. Oversampling represented by L is performed for the better approximation of the PAPR.

Step 2: The oversampled information symbols is divided into several sub-clocks $G^v = [G^{v,0}, G^{v,1}, G^{v,2} \ldots\ldots, G^{v,NL-1}]^T$ with $0 \le v \le V-1$ as condition given by

$$G = \sum_{v=0}^{V-1} G^v \quad (13)$$

Step 3: Now, after applying IFFT to the separate sub-blocks, time domain OFDM signal is denoted as

$$g(n) = \frac{1}{\sqrt{NL}} \sum_{k=0}^{NL-1} G[k] \, e^{\frac{j2\pi kn}{NL}}, n = 0,1,2 \ldots\ldots NL-1, \quad (14)$$

The vectors for several sub-signals

$$g^v = [g^{v,0}, g^{v,1}, \ldots \ldots . g^{v,LN-1}]^T, 0 \le v \le V-1 \quad (15)$$

Step 4: Taking the DCT of the time domain sequence using equation (5) and represented as

$$s^v = DCT(g^v) \quad (16)$$

The vectors for the numerous sub-signals, $s^v = [s^{v,0}, s^{v,1}, \ldots \ldots . s^{v,LN-1}]^T, 0 \le v \le V-1$

Step 5: The phase rotation vectors are chosen in time domain for the optimization of the data from normalized Riemann matrix (C) obtained by considering $\left\{\frac{1}{4}\right\} M$ from equation (8).

Step 6: The phase factors which are selected from rows of normalized Riemann matrix $(C)$are $p_u = [p_u^0, p_u^1, \ldots . p_u^{V-1},], u = 0,1 \ldots . U-1$, where U denotes total number of OFDM signals is denoted as

$$s_u = [s_u^0, s_u^1, \ldots\ldots, s_u^{LN-1}]^T \quad (17)$$

$$= \sum_{v=0}^{V-1} b_u^v \, s^v, \;\; u = 01,2 \ldots U-1 \quad (18)$$

Step 7: Now, calculate and find out the smallest $PAPR$ which is represented as

$$PAPR\big(s_u(n)\big) = 10log_{10} \frac{\max\limits_{0 \le n \le NL-1} (|s_u(n)|^2)}{E[|s_u(n)|^2]}, \quad (19)$$

$$s_{opt} = \underset{u=0,1,2 \ldots U-1}{argmin} \; PAPR(s_u(n)) \quad (20)$$

*Step 8:*Finally, $CCDF$ for the PAPR is calculated as

$$CCDF(PAPR(s_{opt})) = Prob\{PAPR(s_{opt}) > PAPR^0\} \quad (21)$$

where $CCDF$ denotes the probability of the symbols that exceeds the provided threshold $PAPR^0$.

V. Simulation Results

The significant factors considered for the performance investigation of MOPTS algorithm such as oversampling value (L), sub-blocks partition (V) and rows (U) of normalized Riemann matrix (C) are 4 each whereas sub-carriers (N) are 64,128 and 256. The iterations of 9000 OFDM blocks are also considered. The modulation schemes which are considered for the simulations are 16-PSK,32-PSK and 64-PSK.

From Fig. 1. to Fig. 9. depict CCDF of the PAPR of original OFDM (OFDMORIPAPR), original PTS (ORIPTS), Modified PTS (MOPTS).

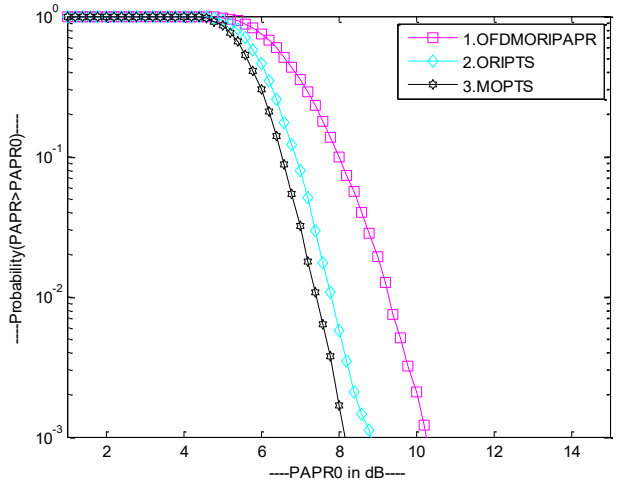

Fig. 1. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 64 sub-carriers and 16-PSK

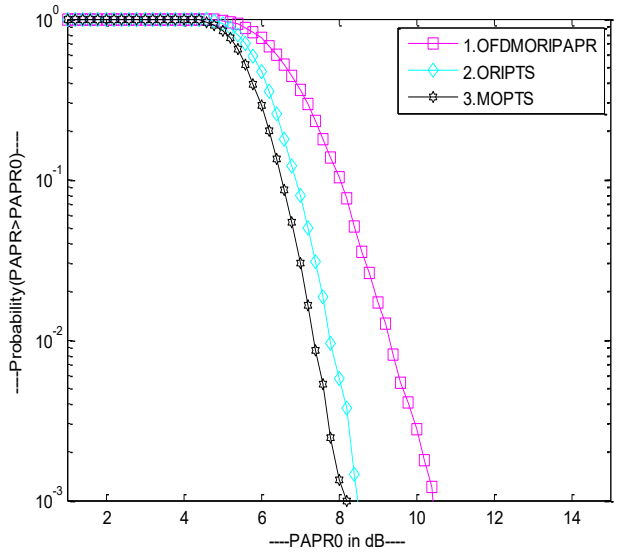

Fig. 2. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 64 sub-carriers and 32-PSK

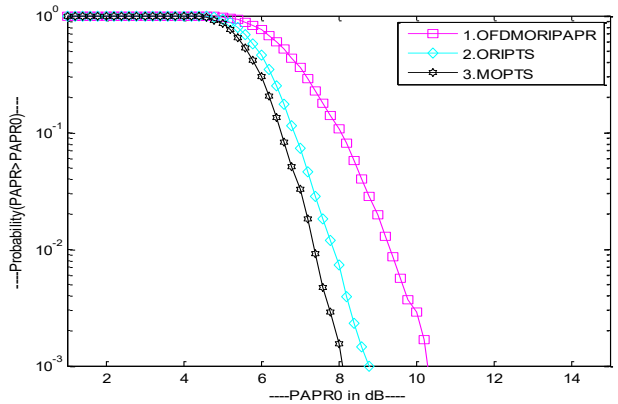

Fig. 3. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 64 sub-carriers and 64-PSK

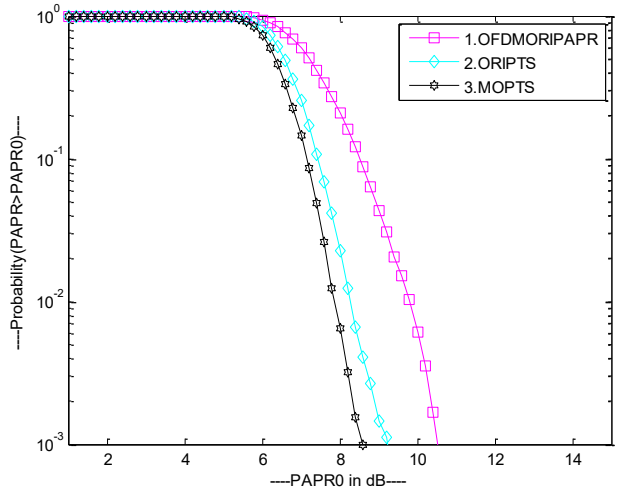

Fig. 4. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 128 sub-carriers and 16-PSK

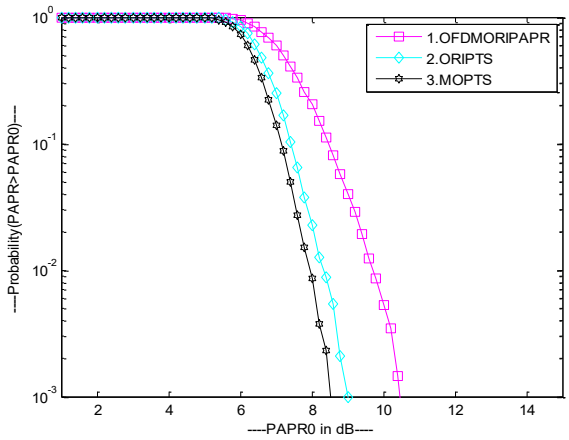

Fig. 5. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 128 sub-carriers and 32-PSK

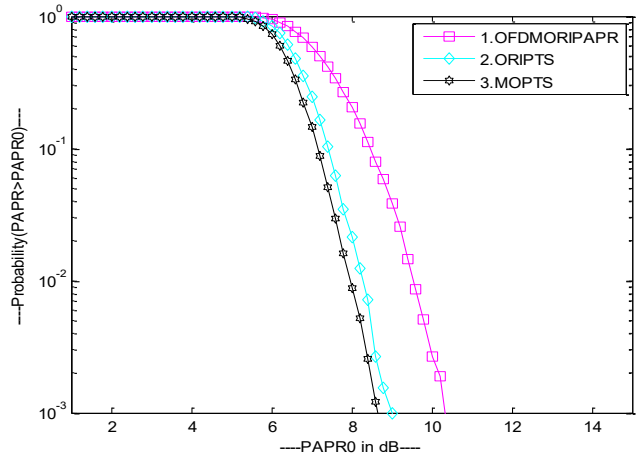

Fig. 6. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 128 sub-carriers and 64-PSK

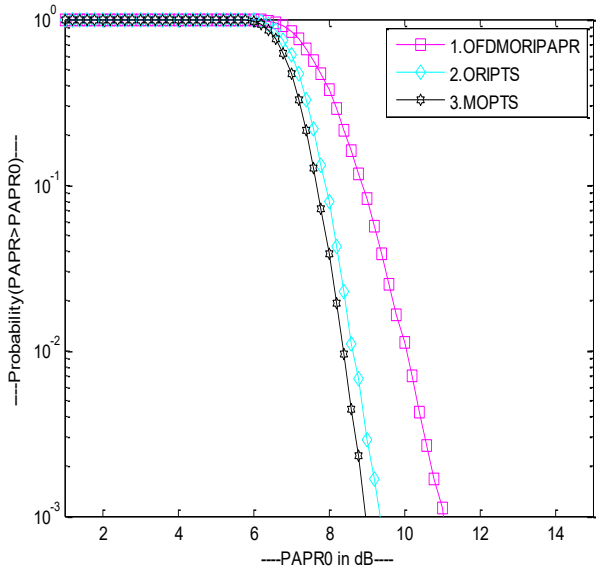

Fig. 7. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 256 sub-carriers and 16-PSK

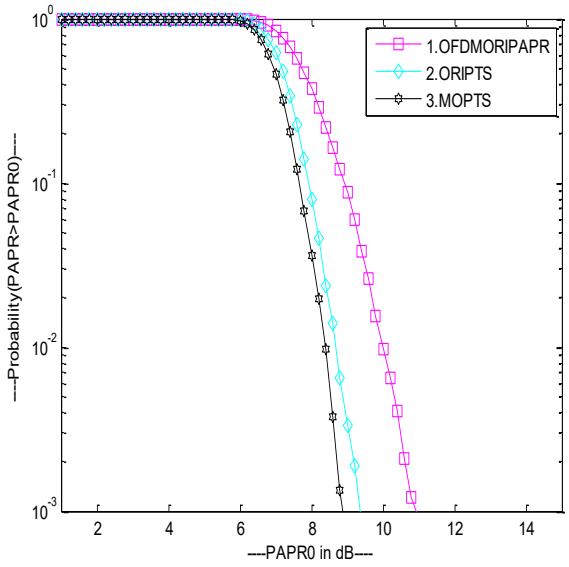

Fig. 8. PAPR diminishing comparison of MOPTS, ORIPTS and OFDMORIPTS under 256 sub-carriers and 32-PSK

In Fig. 1. With 64 sub-carriers and 16-PSK, MOPTS has remarkable PAPR reduction in comparison with ORIPTS and OFDMORIPAPR which is about 0.70 dB and 2.1 dB better than ORIPTS, OFDMORIPAPR respectively similarly it can be easily understood for Fig. 2. and Fig. 3.

In Fig. 4. With 128 sub-carriers and 16-PSK, MOPTS has remarkable PAPR reduction in comparison with ORIPTS and OFDMORIPAPR which is about 0.60 dB and 1.82 dB better than ORIPTS, OFDMORIPAPR respectively similarly it can be easily understood for Fig. 5. and Fig. 6.

In Fig. 7. With 256 sub-carriers and 16-PSK, MOPTS has remarkable PAPR reduction in comparison with ORIPTS and OFDMORIPAPR which is about 0.39 dB and 2.19 dB better than ORIPTS, OFDMORIPAPR respectively similarly it can be easily understood for Fig. 8. and Fig. 9.

It is easily agreed from the Table I. that performance of the MOPTS for N=64 and 64-PSK is best in contrast with 32-PSK and 16-PSK.

As number N depicted in Table I. is increasing from 64,128, and 256 for 16-PSK then the corresponding increase in the PAPR is also observed as 10.21 dB, 10.42 dB and 11.00 dB respectively but remarkable PAPR reduction is achieved by MOPTS algorithm as 8.11 dB,8.60 dB and 8.81 dB respectively.

VI. Conclusion

In this paper, PTS scheme has been emphasized to diminish PAPR difficulty of OFDM. Though, PTS scheme undergoes the difficulty of designing and obtaining phase sequences which help in diminishing this problem of PAPR. So, this is the most significant concern which requires the advanced solution. Focusing on this objective, a modified PTS (MOPTS) algorithm has been designed in this paper, which uses normalized Riemann matrix (C) and DCT in time domain whereas the main aim behind using normalized Riemann matrix (C) is the optimization which assists in finding the best phase sequences for the PAPR reduction. Additionally, the proposed MOPTS algorithm can easily generate phase sequences which was difficult in the traditional PTS scheme. Simulation results have been accomplished by comparing MOPTS, ORIPTS and OFDMORIPAPR. The final results, in principle, have depicted that proposed MOPTS algorithm is robust as compared with ORIPTS and OFDMORIPAPR. Furthermore, the futuristic aim of the proposed work is that, it can also be implemented using M-QAM.

***Abstract*— This paper presents a hybrid framework for reconstructing the scene of objects from a geospatial dataset from point clouds. The method addresses the processing issues of large data points in 3D space and uses spatial clustering to determine the context membership for points. It further uses the min-cut based graph algorithm to segment the resulting polyhedral surface of the object in the scene. Spatial clustering is performed using k-dimension search tree in multidimensional space for segmenting and assigning memberships of point to possible clusters. Size of these clusters controls the background penalties for use during graph cuts for generating multi-object polyhedral objects. The results in this paper are compared to other methods and it is observed that the min-cut graph-based approach outperforms simple Delaunay triangulation and Euclidean estimate based method for surface construction. It can classify objects with better accuracy into separated structures and enabling more efficient visual communication and rendering performance. Geospatial reconstruction problems especially those used for visual communication can use the min-cut based method to construct multi-object scenes for faster rendering performances and reduced data management overheads.**

Keywords*—*min-cut algorithm, point cloud, 3D surface reconstruction, surface triangulation, Visualization

I. INTRODUCTION

Many geospatial applications especially those used for visual communication of a scene of objects often require identifying and processing surface point organized as point clouds. These point clouds contain hundreds and thousands and even millions of points representing 3D spatial occupancy of objects. These points are results of surface returns recorded from sensors like LIDAR devices. This makes computing several geomorphic aspects of the objects and features possible. However, the size of these data sets are very large and results in a lot of computational overheads due to the very discrete nature of the points in the point cloud. Working with point cloud data is actually an informatics problem which relies on processing large data values and involve a higher degree of complexity. Among several interesting application being addressed, reconstruction of the geospatial objects especially from arbitrary point clouds[1] is of greater interest for geospatial computing problems. With these large set of points in the point cloud, computation requirement increases multifold and traditional methods and algorithm perform poorly. Therefore, it becomes a potential candidate for big data processing and management problem.

Reconstruction and visualization are challenging problem especially from an unorganized set of points in point clouds[2]. If surface details are not very important, representing the object surface using the polyhedral structure can lead to a more efficient organization. Triangulation is used for approximating these surfaces and in fact, this itself can lead to improved rendering performances. Various algorithms are available to process these surface data and often combined together for better results. The problem of reconstruction can be broken down into two sub problems. First, it involves identifying separate object structures from an unstructured set of points within the given point cloud data. Second, it requires constructing the triangulated surface from them. Studies suggest that simple clustering algorithms perform poorly for problems involving identifying objects from the scene with multiple objects and experience severe performance issues.

A more robust approach for clustering is needed that is equally applicable to large and big data sets. Representing objects using triangular polygons requires identifying vertices and edges that define the object surface. Simple triangulation from unorganized points often leads to deformed surface approximations. The problem of deformation exacerbates with a scene with multiple objects. Fused objects are often seen while reconstruction and lead to extra and redundant storage requirements. Such results can prove to be a great hindrance for critical geospatial reconstruction based applications and thus must be addressed specifically. Visual communication of the scene under investigation experiences erroneous surface patch and deformed shapes.

This paper addresses the aforementioned challenges and issues in surface reconstruction and proposes a hybrid framework that comprises of spatial clustering of objects in multidimensional space followed by an efficient triangulation using graph cuts. This paper starts with a brief into a literature survey of related work followed by a description of input data and experimental setup. Subsequently, the framework for multi-object scene triangulation is presented followed by experimental results and discussion. Finally, the observation is presented with future pointers for the research in the concluding remarks. The details each of these are described next in discussions to follow.

II. Literature Survey And Related Work

The problem of Identification, segmentation, and triangulation of object surface have been addressed in past research works. As a problem of visual analytics as discussed in [2] and [3], it has been approached in different ways. Segmentation has been one of the fundamental tasks in identifying and thereby reconstruction. Segmentation of object structures from LiDAR point clouds has been discussed by many including work demonstrated in [4], [5], [6] and [7]. The method discussed in [4] is limited to ordered point clouds and uses scan-line-based ground segmentation algorithm. Although it could successfully segment objects its performance on solid surface generation is unknown. Similar work was performed in [5] using the histogram-based methodology to separate the building clusters from other structures. This work is also limited to the geometric description of structures using point data. Other related works of identifying and segmenting objects from point cloud have been addressed. Segmentation of objects from unstructured point cloud has been discussed in [8] and attempts to identify tree crowns from airborne LiDAR point clouds. However, most of them classify the foreground and background objects only and limit object visualization using point description.

Reconstruction of the object's surface using triangulation has proved more efficient for rendering purpose. Variants of surface triangulation include direct triangulation method, ball pivoting method[9], Voronoi-based algorithm[10], Delaunay based method [10] can provide faster ways to generate surfaces. However, most of the experimental attempts have focused on improving the surface quality for a scene with a single object. While these methods largely satisfy expectations for smaller objects, they suffer from performance and deformation issues for large datasets with rapidly varying surface elevations. An optimized method for reconstructing large geospatial structures such as the reconstruction of sand dunes discussed in [13] provides a pathway to generate surfaces from rapidly varying structures. It is noteworthy to see that all these methods treat foreground objects as one object or perform poorly for scenes with multiple objects. The results are deformed structures and often not suited with closely spaced objects.

Multi-object classification and labeling have been addressed at a small level. One way to achieve the objective of multi-object reconstruction and visualization to with optimal performance is to use a graph-based approach for segmenting of objects. This approach can use graph-based concepts especially to cull away weak links between the identified clusters and thus achieving the objective. Correctness and speed is more important in reconstruction based visual communication and therefore unnecessary computations must be avoided. Min-cut based approach discussed in [14] can be used for this purpose. Although this method was limited to the segmentation problem, it can be further extended and used together with some modifications for generating the physical surface of distinct objects in the scene. This forms the basis of our method presented in this paper.

III. Data And Experimental Setup

The experimental validation of the proposed framework for reconstructing polyhedral surfaces of multi-object scene uses geospatial data organized as a point cloud. The point cloud organizes points in 3D space with its spatial coordinates along three dimensions. These points represent the return from the surface obtained during acquisition from LiDAR sensors. The snippet of sample data set presenting a multi-object scene is shown in Table 1. The 3D view of the point data set is shown in figure 1. The data represents the geometrical structure with the center of projection positioned along positive y-axis during data acquisition. Data assumes no point normal information in the originally stored point cloud and hence requires only point processing in raw form. For simplicity of handling, the data is organized in ASCII format. The corresponding height map is shown in Figure 2. Note that, the data represents surface returns and therefore carefully approximates object surface. As it is viewed as a collection of unstructured points, preprocessing is important to prepare and make it suited for experimentation.

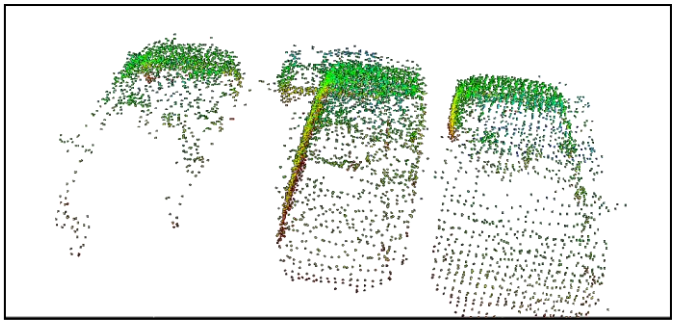

Figure 2: Height map of sample Point cloud

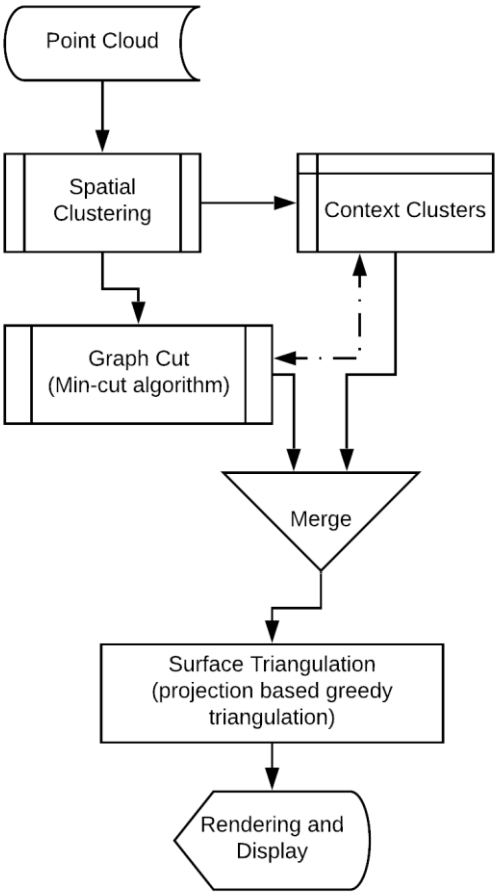

Figure 3: Framework for Multi-object triangulation

The details of the framework and relatedr operations are described next.

IV. Framework For Multi-Object Surface Triangulation

To achieve multi-object segmentation and surface reconstruction, a hybrid framework is proposed comprising of spatial clustering in 3D space and an optimized triangulation controlled by graph based algorithm. The workflow of the proposed framework is shown in Figure 3. The input to the framework is an unstructured set of points stored as a point cloud. The point cloud is subject to initial preprocessing in order to identify isolated outlier points and removed from the data set. The objective function is an odd-ordered filter that culls away point that has no neighbors. These are essentially outlier that is present in the input as the result of acquisition or storage errors. Ground and non-ground sections are identified using the algorithm described in [15] Points classified as non-ground points are taken for further processing. These non-ground points are further processed using the region growing approach as described in [16] for clustering the points into possible objects (see Figure 4a). The simple directed triangulation would result in the poor, fused and deformed surface as shown in Figure 4b. Therefore these clusters are further processed before attempting triangulation of the surface.

Some points especially those at the boundaries of the cluster are sometimes wrongly classified to belong to a different cluster. To overcome these erroneous classifications, a context membership function is used together with graph-based links between the points during the surface reconstruction process. This context membership function assigns the weight to the edges between the neighboring points which are influenced and updated from values of neighbor edges. The weight w_{ij} for the edge between points p_1 and p_j are estimated using the following relation

$$w_{ij} = e^{-\left(\frac{d}{\sigma}\right)^2} \quad \ldots (1)$$

Where d denotes the distance between points and σ defines the common spacing of points. Theoretical approximation of each cluster is computed and distance values are computed for each cluster. A decision criteria together with the distance and weights between points is developed for arriving membership decision for points especially at the boundaries. Intuitively, the farther the points are, the better is the probability for the edge to be culled away.

Edges which have more neighbor edges have more weight and tend to have higher context membership to a specific cluster. Context membership is computed using k-nearest neighbors within the specified radius and thus greater affinity to points relatively closer to each other. This method helps to identify dense clusters inherently comprising of clusters with relative homogeneity of spatial coherence. The result of such coherence is shown in Figure 4c.

Weak edges (longer edges) are identified using distance relationship between points which together with context memberships to respective clusters help in disassociating them. Weak edges have relatively less weight and are links between clusters (potential objects). The links between the points are represented as a graph. The min-cut algorithm discussed in [14] together with context membership is applied to the clusters to segment the objects into distinct objects. Background penalties are computed to control the expected distance d from the center of the cluster. The background penalty is computed as

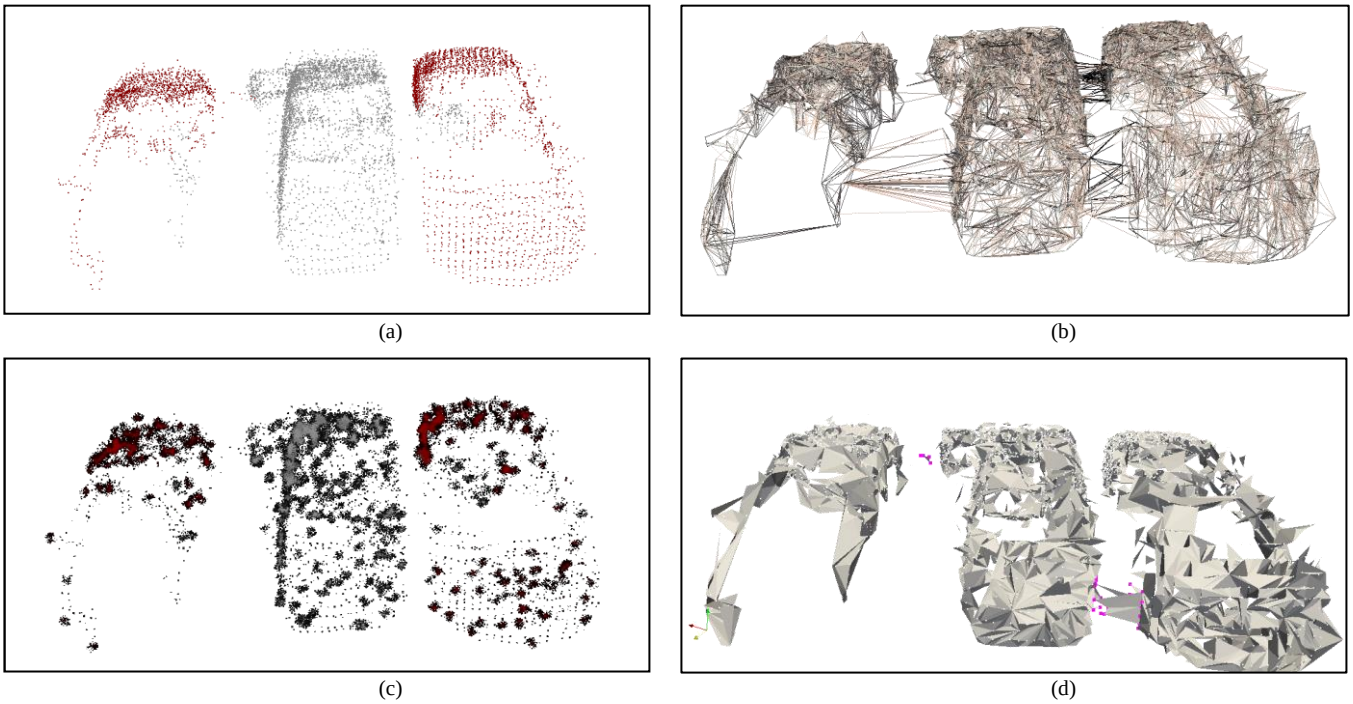

Figure 4: Intermediate stages during surface triangulation: (a) Cluster of objects and point membership (b) Default triangulation using direct triangulation methods (c) Context Clusters and its membership to respective objects (d) Final triangulation of scene using Context Clusters and min-cut algorithm

$$Penalty_{back} = \frac{d_{center}}{radius} \quad \ldots (2)$$

The value of distance to the center is computed as $d_{center} = \sqrt{(x - x_{center})^2 - (y - y_{center})^2}$. The value of radius defines the distance from the center of object beyond which no points are expected.

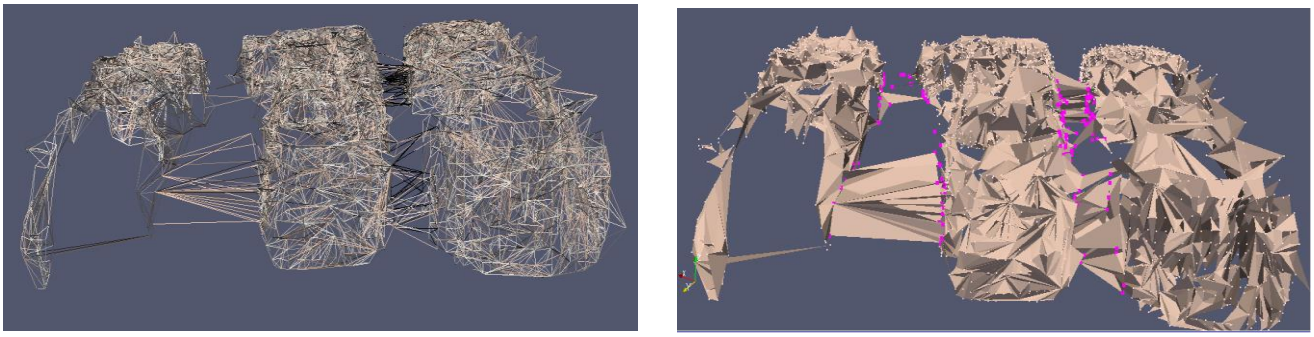
The optimized triangulation described in [13] is applied to the clustered point cloud for a surface generation as shown in Figure 4d. During triangulation, the membership function is again used to check any cross triangulation arising across clusters. The size of the cluster and thus the resulting object structure is controlled interactively by setting the radius and value of k-nearest neighbors during the triangulation process. The benefit of applying triangulation after the min-cut algorithm is that it reduces false positive links and thus results into improved triangulation and gives better visual results. The algorithm although doesn't offer much flexibility but offer good results for objects that are placed on the planar horizontal surface. The variation on the object surface is handled correctly by the membership function and thus gives better surface approximations.

V. SIMULATIONS AND EXPERIMENTAL RESULTS

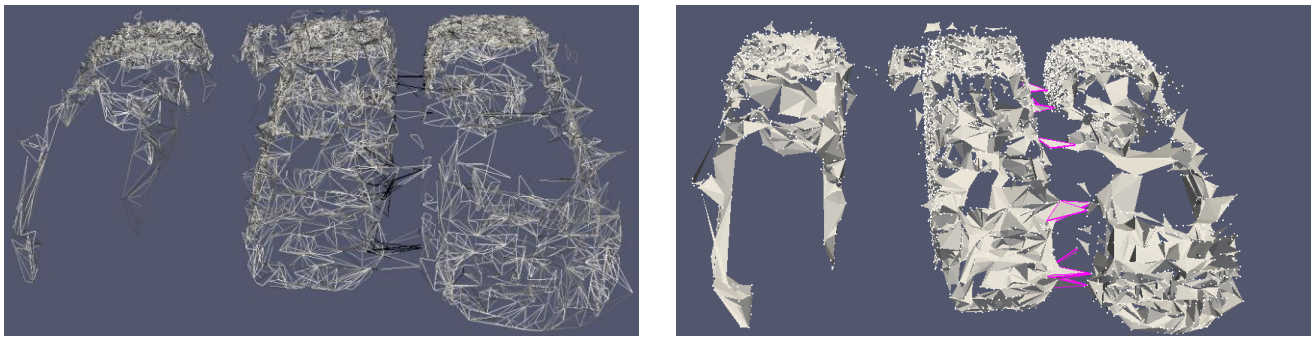
The proposed models for generating polyhedral surface has been tested on large dataset encompassing points of the order of several thousand and millions of points on varied geospatial structures. To demonstrate the reconstruction capabilities, the method is applied to a scene comprising of three cars. The scene is stored using point cloud comprising of surface returns represented as points with its elevation values along z-direction. Reconstruction performance is compared for three methods namely direct triangulation, Euclidean estimate based method, and min-cut based method. The result of context cluster which identifies the objects (cars in this case) is shown in Figure 5.

During the process of reconstruction, the non-ground points are first triangulated using the direct triangulation method. For showing the reconstruction capabilities of the proposed method the non-ground points are first triangulated using direct triangulation discussed in [17]. The corresponding mesh model and the solid shaded surface are shown in Figure 5a. Although it performs well on the single object but falls on multiple objects that are lying close to each other. It generated redundant triangular links between possible objects and thus leads to incorrect and deformed surface structures.

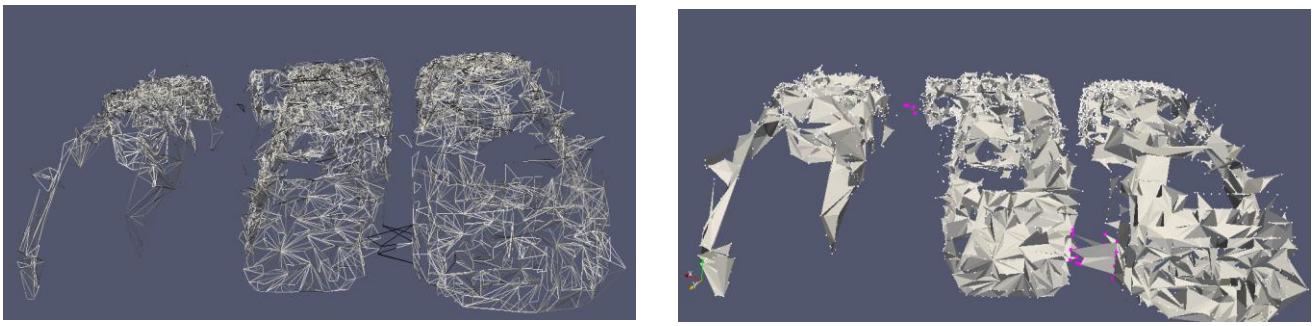
The point cloud data is also processed for clustering and identifying possible objects using Euclidean estimator for computing the member points. The result of triangulation is shown in Figure 5b. Results using the proposed framework exhibits significant improvement. The min-cut graph-based method reduces the redundant links and thereby the false



(a) Reconstruction using Direct Triangulation: Mesh Model (left) and Solid Model (right)



(b) Reconstruction using Euclidean Estimation: Mesh Model (left) and Solid Model (right)



(c) Proposed Method: Context Clusters and Min-Cut based Method

Figure 5: Reconstruction using Various Methods: Surface showing Surface Triangulation (Left) and Solid Surface (Right)

triangulation that fuses the objects together. The segmented point cloud and the corresponding mesh model using the proposed method is shown in Figure 5c.

It is observed that (see Figure 6), the object segmentation and thereby reconstruction performance is significantly improved using the proposed use of min-cut based framework. The accuracy of min-cut based reconstruction is better compared to both direct triangulation and Euclidean estimator based method. The occurrences of false positive are reduced to the considerably both for edge links and for the triangulated cells in the reconstructed scene with multiple objects. Simple triangulation results in maximum false positives and generates deformed and fused structures. Euclidean estimator is good when the cluster of points is distant away from each other. Use of context clustering together with the min-cut algorithm generates good results for close objects in the point cloud.

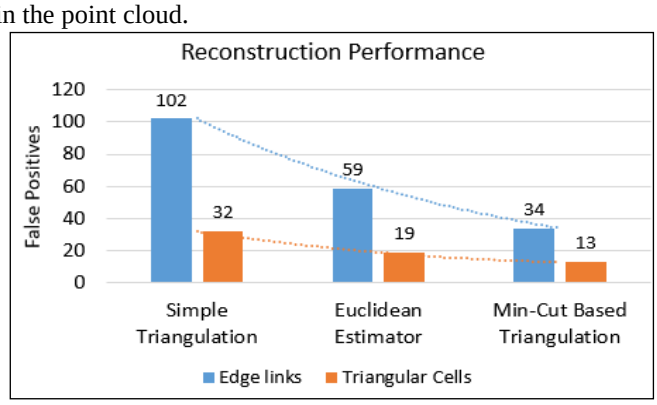


Figure 6: Performance Measure Based on False-Positive Response

VI. Observations and Applications

It is established from the experimental work that min-cut based approach helps to segment object embedded among point cloud and also found useful in surface triangulation as it has influence in determining the weak edges. The use of context membership closely binds the points belonging to the object and prevents surface points from disassociating from its neighbors. The proposed method successfully eliminates loosely connected cluster however cluster of points that are tightly connected with more connected still show some triangulation. This is primarily because of data acquisition error and can be eliminated with more accurate measurements.

Some of the potential applications that are identified where the method discussed above finds its use are listed below.

- Tree crown detection from the sparsely populated forest.
- 3D Building profiling and rooftop detection from airborne surface returns
- Identifying bridges in real 3D space
- Identifying robust microwave coverage in 3D space

Many more related emerging applications can find immense use of the method discussed in this paper for multi-object reconstructions.

VII. Conclusion

This papers demonstrated the successful use of the graph-based min-cut algorithm for identification and reconstruction of the surface for a scene of multi-object spatial structures. Multidimensional clustering of points followed by min-cut based approach gives improved results compared to direct triangulation. The method also established the use of context membership of a point to clusters and its significance in determining the potential links used during min-cut implementation. The accuracy is better than simple triangulation and similar known methods and offers significant performance results. The proposed results set the pointers for fast rendering of multi-object scenes especially reconstructed from unorganized point clouds. Future work can focus on combining triangulated ground surface and multiple objects for interactive visualizations. This work can also be extended for evaluating and studying surface deformations, modeling optimized 3D viewing system for faster rendering requirements.

Abstract*— MapReduce is a popular programming model for handling Big Data in a Distributed computing Environments. Hadoop is popularly used for short jobs and desires low response time. During shuffling phase, large volume of data generated by the map task needs to be accessed to perform shuffling and sorted before being transferred across the network to the reducers. It may generate huge network traffic and consume high bandwidth. Hence a Pre-shuffling scheme is proposed for shuffle intensive applications in this paper to minimize the network traffic because network connects is likely to become limited resource when many applications subscribe the cluster. Here a push model and two stages pipeline being used in shuffling phase of Hadoop MapReduce. Experiments have been conducted on web server log file of NASA and rnsit.ac.in. Experimental result show that proposed Pre-shuffling scheme substantially reduces the network traffic and slightly faster compared to conventional Hadoop. The proposed push model in the pre-shuffling scheme with 2-stage pipeline reduces the run time by an average of 17.3% for click count application.

Keywords — MapReduce, Pipeline, Push Model.

I. INTRODUCTION

Hadoop is an open source implementation of MapReduce framework. It is mainly utilized to process gigantic data in a parallel and distributed environment, the map function is executed on every input data split and emits <key, value> pair as output. Several map tasks may run in parallel either in single/multiple machines. The intermediate data set having the similar key are transferred to same reducer and the reduce task starts after all the map task generates the output, till then reduce task has to wait, because the execution of reduce task will not take place in parallel with the map task. The map output is sent across the network to the reducers, Shuffle is the process of interaction between the map and reduce task of an application. The quantity of map output delivered from mapper to reducer across the network may have an impact on the execution time. Hadoop applications are categorized into Non-shuffle and shuffle intensive application. In shuffle intensive applications, during shuffle phase, huge quantity of intermediate data are generated, which results into network traffic and consumes high bandwidth and large number of I/O operation.

In this paper, a Pre-shuffling scheme is proposed, where in a fraction of intermediate data emitted by map task will be sent immediately through the pipeline to the reducers. Therefore, it is not necessary for the reducer to wait till the map task generates the complete output. It facilitates the overlapping of data computation and data transfer of map tasks, this may result into reduced the network traffic, data transfer time with improved throughput because of data pipelining. The map and reduce task running in the same node are synchronized to provide the overlapping facility, due to which the execution time required for the shuffle intensive applications is reduced.

The rest of this paper is organized section wise and the details of each section are as follows, in Section II related work is described briefly. Detailed description of proposed method Pre-shuffling scheme is given in Section III and its implementation is mentioned in Section IV. Experimental results are presented and discussed in Section V. Section VI presents the conclusion of this paper.

II. RELATED WORK

MapReduce [4] performs the computations on data intensive applications, log analysis etc, using various computing environment like dynamic cloud and multi-core environments [10].Duxbury et al created a scheme to evaluate the performance of network interconnects on MapReduce. During shuffle phase, large amount of data need to be transferred across the network to the reducer causes high network traffic and consume high bandwidth. Shuffle phase consume maximum time, hence in this paper Pre-shuffling model is introduced to decrease the network load. The intermediate data is aggregated at each node to reduce the quantity of intermediate data to be delivered across the network to reducers [8]. Compared to aggregated technique, for shuffle-

intensive applications the partially masking the latencies for reduce tasks is very efficient.

MapReduce is extended to provision database management systems for processing structured files [7]. Parallel data processing policy called pig system is developed to integrate it with Hadoop. Here the compiler generates the Hadoop programs sequentially. Pig latex, a programming language used for pig to execute the data analysis application in parallel and also provides an opportunity to improve the overall performance.

III. PROPOSED PRE-SHUFFLING SCHEME

MapReduce has map, reduce and shuffle phase. During the shuffle phase the map output is partitioned using hashing function and each partition having similar key is transferred to the same reducer, then reduce function is used to process the assigned partitions. To obtain the intermediate data to the shuffle phase, HTTP requests are sent to the five task trackers (default value) by the reduce task. Job tracker has a list and location of all the task trackers and each task tracker transmits the heart beat message periodically to job tracker. If a map or the reduce task is finished then new task is allocated the job tracker. Also, identifies the reduce task start time, the data block to be processed and separate queue is maintained for map and reduce task.

In conventional MapReduce, i.e, in pull model, each reduce task has to fetch the intermediate data and does not provide synchronization between the map and reduce task. Reduce tasks are not started till the complete intermediate data is received. To reduce the shuffling phase time, push model is proposed called as Pre-shuffling scheme. Here, the intermediate data generated from the map tasks are sent immediately to reduce task via shuffle phase, soon after the intermediate data is emitted. The job tracker allocates map/reduce task to the available task tracker. In Pre-shuffling scheme, map tasks are allowed to identify the partitions to be sent to the reducers. The reduce task sorts and keeps the tuples in the node, on which the reduce task is to be launched. After the map tasks are completed, reduce task applies the reduce function to process the allocated <key, value> pairs.

After the submission of the job, if sufficient slots are available for execution, all the tasks are launched. Then the communication channel is established between the map and reduce task, as each map task chooses the reduce task to push the intermediate data, as soon as the small portion of the data is generated. If sufficient slots are not available to execute the reduce task, the output of the map task is stored in the in-memory buffer, the reduce tasks are launched whenever the free slots are available. Then the data is transmitted from the buffer to the reduce task. In conventional MapReduce, the time required to perform the shuffle phase is greater than the map phase. In order to improve the performance, 2-stage pipeline is used in Pre-shuffling scheme. It sends the data through the pipeline to the reduce task soon after the fraction of data is generated from the map task. It overlaps the execution and data transfer during map phase which in turn results in increased throughput.

Two separate threads are created here. The input data is processed and emits the output using the first thread. As soon as the map task output is generated, it will be delivered immediately to reduce task. These threads execute in parallel using pipeline and store the map task output in the buffers, to avoid sending the data directly to the reducers. Buffer sends the map task output to the reduce task as soon as the fraction of data is generated. Suitable threshold value may be used to represent the size of fraction of data (usually 80% of buffer size). Once the size of buffer reaches the predefined threshold, the intermediate results are sorted based on the keys. then the map task output is stored in local disk. Second thread is triggered to verify the availability of sufficient free slot to launch the reduce task. If the node is ready to launch the task, then the communication channel between the mapper and reducer is created. The aggregated data generated using first stage pipeline is delivered to the reducer during the second stage pipeline. If no nodes are not available to launch the task, then the second stage pipeline waits till the map output is received by reduce task. The main objective is to improve the throughput during the shuffle phase using pipeline.

In Pre-shuffling scheme, the amount of data to be sent from map task to reduce task can be controlled dynamically by configuring the buffer size. Large value of threshold represents the huge volume of map output to be delivered to the second stage pipeline. Lesser value of threshold represents each portion to be pushed to the reduce task is large. If the network connects are not overloaded, then the performance of the map task will become bottleneck, to overcome from this, buffer size is increased, so that large amount of data is pushed to the reduce task. It is suggested to have higher threshold value for buffer size with high speed network interconnects.

IV. IMPLEMENTATION

In MapReduce, Map phase has *Map* and *Map-transfer*, the map task processes the input data and then sorts and stores the output into the in-memory buffer. Sort operation will create the partitions consisting of all the tuples having the same key. The map output stored in the buffer is sent to the reducer during map-transfer phase. Reduce task is split into two phases: *shuffle* and *reduce*. Reduce task receives the map output and merge sort is applied on the map task output. The shuffle phase consumes largest time, as it performs merging and sorting operation on the large amount map output. Therefore in the Pre-shuffling scheme, as soon as the data of the map output is generated, aggregate and sort operations are immediately performed. Reduce task applies the merge sort function after receiving the complete map output from all the map tasks during the Pre-shuffling scheme.

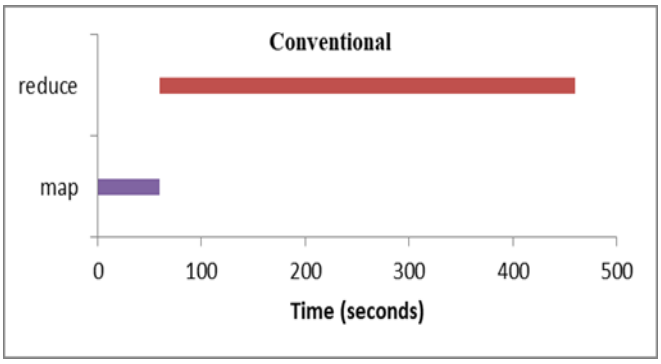
Master node observes every task performance and assigns progress score between the range [0, 1]. The value of the progress score for the map task depends on the amount of

input data processed. Pre-shuffling scheme, monitors the progress of reduce task and assigns progress score value, It depends on what amount of data is distributed to the different phases of reduce task, it combines the progress score and the intermediate data, then reduce task receives the partition and the associated partition score. The reduce task progress is estimated by taking the mean progress score of entire corresponding partitions.

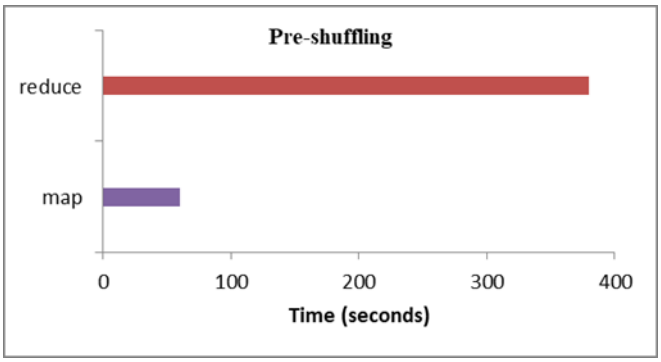
In heterogeneous cluster, different nodes execute tasks at different speed. After the considerable progress of reduce task, progress score is stored into a temporary file on HDFS. In this proposed work, the map task output is sent immediately to reduce task using pipeline. This overlaps the transfer time between the mappers and reducers and improves the throughput. During the network congestion in the cluster, Pre-shuffling and the pipeline method shows significant improvement in the performance of the Hadoop MapReduce.

V. Experimental Results and Discussion

For analyzing the performance of Pre-shuffling scheme, Hadoop cluster is created using 10 data nodes and every computing node in the cluster is furnished with two dual-core 2.4GHz processors, 2GB main memory and an operating system Ubuntu 10.4 is used to conduct experiment. The block size is varied to evaluate the performance. Data replication feature is not considered during the evaluation, because the Pre-shuffling scheme with replication substantially improves the performance of the Hadoop. To evaluate the performance Click count application is executed on the Academic and Research Webserver log file such as NASA and rnsit.ac.in with 1 GB data set. Figure 1 display the completion time for both map and reduce task of Click count application on Hadoop with and without Pre-shuffling scheme. Figure 2 shows the execution time for Click count application with 1GB dataset on Hadoop with and without Pre-shuffling scheme. It is found that the proposed scheme decreases the execution time by 17.3% compared to conventional Hadoop. In Figure1, it is also observed that the reduce task begins after the entire map tasks complete their execution. Where as in the proposed scheme, Reduce task starts execution almost soon after the map task has begun. In conventional Hadoop, the map task has completed its execution almost at 50 seconds and at 60 seconds in the proposed work, because some of the operations of the shuffle phase is performed by the map tasks, instead of reduce task in the conventional MapReduce. The Pre-shuffling phase handled by the map task is an effective method to reduce the load on the reduce tasks. Therefore, the proposed work completes the execution much faster than conventional MapReduce.



a. Conventional



b. Pre-shuffling

Fig 1: Execution Time of both map and reduce task (a) conventional (b) Pre-shuffling Scheme

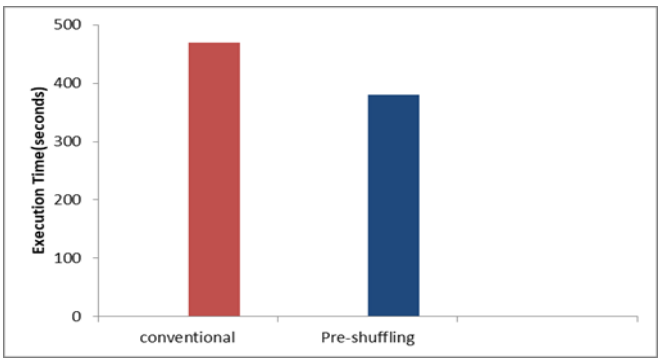


Fig 2: Execution Time of both conventional and Pre-shuffling for click count application with 1GB data set

Experimental results for varied input data blocks

To assess the performance of the Pre-shuffling scheme, Click count application is executed for varied data block size. Figure 3 demonstrates the performance of the Pre-shuffling scheme increases as the block size increases, i.e. from 64MB to 128 MB. Increased block size from 128 MB to 256 MB would results into decrease in the performance by 1.6%.An Experimental results shows the substantial improvement in the

performance of the Hadoop MapReduce using Pre-shuffling method for the block size not greater than 128 MBS.

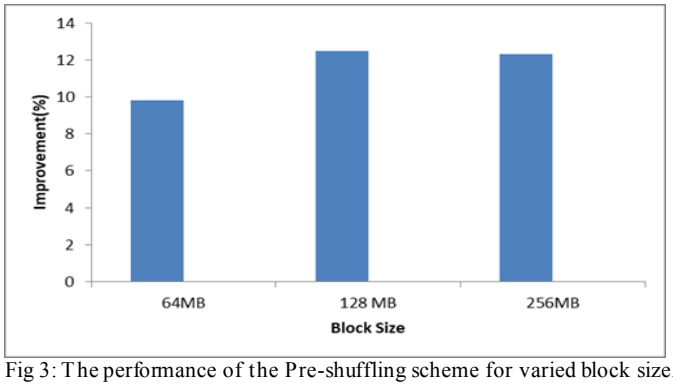

Fig 3: The performance of the Pre-shuffling scheme for varied block size.

VI. CONCLUSION

During shuffle phase, the Shuffle-intensive application generates high network traffic and Disk I/O operations. Hence Pre-shuffling scheme called push model is proposed, here two stage pipelines are used to increase the performance of Hadoop. In Pre-shuffling scheme, map tasks moves the map output across the network to the reducer soon after the data is generated and also reduce task starts execution immediately rather than waiting to receive the complete intermediate data. In first stage pipeline, the aggregated intermediate data of every map tasks are stored temporarily in local buffers. The second stage pipeline identifies the free slots in a node to launch the reduce tasks, and then establishes the communication channel to transfer the intermediate data. Click count application has been used to evaluate the performance. Experimental results revealed that execution time using Pre-shuffling scheme is improved by 17.3% compared to conventional Hadoop. Pre-shuffling scheme *has* improved the execution time by utilizing the resources effectively. In Pre-shuffling scheme, as the size of the input data is unknown, deciding the start time of the reduce task is a challenge. Hence, some adaptive algorithms need to be developed in future.

***Abstract*— Latency-aware computation is required for prominent technologies like Internet of Things. Things that are connected in IoT environments generate large volumes of real-time data which are generally processed in the cloud. But, the processing of these generated data entirely on the cloud cannot be considered as an efficient solution for time-sensitive IoT applications. To address this issue, a new paradigm, Fog computing, was proposed. Fog computing essentially extends cloud computing and services to the network edges, thus bringing most of the capabilities of the cloud much closer to where the data source is located. Time series analysis is a class of machine learning algorithms that provides deeper insights about the future. The latest trends consist of using deep learning algorithms for performing time series analysis, which have proved to be more efficient than the traditional statistical approaches. This paper aims to replicate a current day Industrial Internet of Things (IIoT) scenario by simulating a secure fog computing environment in which the edge data centers are authenticated by a Certificate Authority, perform time series analysis over pre-collected dataset using Long Short Term Memory (LSTM) neural networks and forecast the required result, along with an intelligent optimization of the network using an efficacious dynamic task offloading mechanism in a secure way.**

Keywords*— *Fog Computing, Internet of Things, Deep Time Series Analysis, Task Offloading, Security, Load Balancing

I. INTRODUCTION

Cloud computing is a method for delivering Information Technology (IT) services in which resources are retrieved from the Internet through web-based tools and applications, instead of a direct connection to a server. Cloud provides three service models: Infrastructure as a Service (IaaS, Platform as a Service (PaaS) and Software as a Structure (SaaS), and enough security features measures. Cloud computing has several advantages and disadvantages as well. But with the change in the networking connectivity and different needs, the cloud computing model has been extensively in use even though it possesses some major potential disadvantages.

Fog computing is extending the cloud computing paradigm network to the edge of the network from the network core. It is an example of highly virtualized platform which provide storage of data, computations, and other networking services between end devices and traditional cloud servers. Fog computing architecture is an arrangement of hardware, and software, and physical and logical elements of the network to implement an IoT network. The major architectural factors include the physical and geographical placements of fog nodes, their hierarchical arrangement, the numbers, types, protocols, topology, and data bandwidth capacities of links between fog nodes, devices, and cloud, the hardware and software design of the individual fog nodes, and how the complete IoT network is established and managed. Fog networks primarily aim at meeting stringent latency requirements, reduced power consumption of end devices, providing real-time data processing, distribution and control of computing resources, and forwarding the network traffic to centralized data centers.

The Fog computing architecture mainly consists of end devices (sensors, mobile devices etc.), edge devices (routers, base stations etc.), Edge Data Centers, which are data centers with limited processing and storage capabilities and Cloud which acts as the central storage having greater processing capabilities. Edge data centers (EDCs) are deployed to reduce the processing and propagation. The nature of EDCs deployment in practice is distributed and they are position between cloud and data sources. Effective load balancing strategies are implemented to reduce the job response time and to improve resource utilization in Fog environment.

Since Fog is a distributed environment, it is susceptible to many security vulnerabilities in the programmability, naming, privacy and scalability such as data tampering, Denial of Service attack, information injection, manipulation, privacy leakage etc. The measures for providing security of data are confidentiality, integrity, availability and privacy requirements. Confidentiality ensures that only the communicating entities have access to the data that is being transmitted. The correct and consistent delivery of data to the authorized users without any undetected modification is achieved by integrity mechanisms. Also, the data should be available to the authorized intended recipients at the required point of time. Authentication and access control is the process of establishing proof of user's identities and providing access to only those users. Finally, privacy requirements ensure the secrecy of all the information and services.

Time series is a continuous or discrete sequence of observations recorded at regular intervals of time. Time Series Analysis is referred to the process of making predictions about the future on the basis of time series data.

In time series analysis, the time period can be measured in any suitable unit of time. The process of using neural networks for forecasting the future values of a time series is known as Deep Time Series Forecasting. There are numerous applications including forecasting and utility studies that employ these methods.

II. RELATED WORKS

In [1] Zhang G.P proposed a hybrid method for time series analysis which combines both Auto-Regressive Moving Average (ARIMA) model and Artificial Neural Network (ANN) model. In [2] Xiaojun C. et al. presents a system that monitors and forecasts air pollution in real-time using IoT. According to the relationship between the pollutants concentration in the last 24 hours and concentration of current pollutants, next 24 hours' network for prediction is established. In [3] Mitra P. et al. proposed a IoT-based approach on a mesh-connected wireless sensor node that uses a simple ANN model for flood forecasting purposes. In [4] Angshuman Ray et al. presented a model that uses ANN for predicting air pressure where the development, training and testing of the model with ground-level air pressure which was collected over a 7-year period. The difficulties that are faced while training artificial neural networks with continuous time-series data were overcame using the model developed in [4].

In [5] Hu P. et al. proposed a framework for face identification and resolution based on fog computing to improve the processing capability and save bandwidth. Security issues includes intrusion detection, data management issues, malicious detection technique, man-in-the-middle attack, data protection, malicious fog node problem. In [6] Alrawais A., et al. provide a scheme and show its usage of fog computing for improving the efficiency of certificate-revocation distribution in connected environments like IoT. In this paper they also give a summary of the major challenges in security and privacy of IoT environments.

In [7] Ningning S., et al. study the architecture of a fog environment and build a graph model of the fog layer and use the vertices to represent the data dependencies between tasks, and edge indicates the link bandwidth. In [8] Verma S, et al. proposed a Load Balancing architecture for the Fog environment. The time required for the clients to access the resources increases with the increase in the distance of servers in Cloud environment. Therefore, the resources are brought as close as possible to the end users in Fog environment to solve this problem.

III. PROPOSED WORK

A. System Design

The technical specifications and requirements were thoroughly analyzed and studied in order to design the system. System design thus had been an approach to solve the issue of creation of the system. Fig 1 describes the design of the proposed system. Initially, a network is created using a no. of Raspberry Pi and a PC which acts as a server. All the Raspberry Pi's except one act as the Edge Data Centers. The one that is not considered as an Edge Data Center is used to send the Air Quality data to the EDCs present in the network. The server device is used to authenticate the EDCs and perform the load balancing. All the EDCs are authenticated at the beginning itself so that the entire system remains secure. The data to be processed from the data sending Pi to the EDCs takes place only after ensuring that the EDC is an authenticated one. Once the data is received at an EDC, it performs the processing. Here, the EDCs perform deep learning using Long Short Term Memory neural networks and perform the pollution forecasting, if any of the EDCs is overloaded, it shares its load to another EDC, only after assuring the authenticity of the destination EDC, and the EDC performs the time series analysis. The load balancing over the Fog environment is done in a dynamic and a secure way.

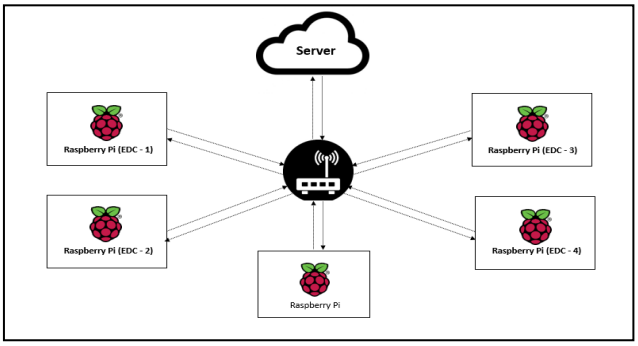

Fig. 1 The Proposed system

B. Secure Authentication

The security of the entire system works on the most fundamental assumption that the server is already secured by some means of hardware installations like the Trusted Platform Module (TPM). Therefore, this server system is considered to be Certificate Authority that performs the authentication of the Edge Data Centers in the network.

A certificate authority (CA) is a credible entity that manages and issues digitally signed documents called digital certificates to the requesting entities. A digital certificate is a kind of document which contains information about the issuer of the certificate and also the information about the requesting entity such as its public key, name, organization, contact information and date of expiration. Whenever an entity needs to be authenticated and if it doesn't have a digital certificate, it requests for one to the CA. The CA verifies the identity of requesting entity and generates a certificate for the applicant, signs it with private key of CA. These certificates can be used at a later time for authentication purposes between entities. Any entity of the system can verify that the certificate is signed by CA using the public key of CA.

In this system, the server, which is the Certificate Authority, issues a self-signed certificate for itself, making it an authenticated entity. The cryptographic algorithm RSA, one of the most efficient algorithms for key management, is used for the public-private key pair generation for the digital certificate. The keys generated using RSA are of 4096 bytes. The digest method used for signing the certificate is SHA-256, and the validity period of each certificate is set to 1 year. Now, the server and the Edge Data Centers generate public-private key pairs of length 4096 bytes, and request the Certificate Authority for getting their certificates signed by the Certificate Authority. The Certificate Authority creates a public key-ring among the Fog nodes by

broadcasting all the public keys to each node. A key-ring is a file that consists of encryption keys. In this case, the public keys are stored, forming a public key-ring. If any EDC wants to send a message to other devices present in the network, it looks up the public key of the corresponding the device to which the message is to be sent, and encrypts the message using this public key. The message can be decrypted by the receiver using its own private key. The certificate generation algorithms are described in Fig 2. The network created in the work consists of five Raspberry Pi's, among which four are chosen to be the Edge Data Centers, and the remaining one is selected as the client device, which has the entire dataset in its storage and sends the data as parts to other EDCs.

The Fog environment is now fully set-up and fundamental security measures are implemented in the system. Next, the data has to be sent to the EDCs present in the network.

Certificate Generation for Certificate Authority

1. If(no self-signed certificate available OR certificate is expired)
2. Create public-private key pairs.
3. Generate certificate signing request .
4. Self-sign the certificate.
5. Add public key to the public key-ring.

Certificate Generation for Edge Data Centers

1. If(no certificate available or certificate is expired)
2. EDC creates public-private key pairs.
3. EDC generates certificate signing request and sends to CA.
4. CA asks for the passphrase.
5. EDC provides the passphrase.
6. If(valid passphrase)
7. CA generates certificate and signs it.
8. Adds EDC to the authenticated list.
9. Sends the certificate to EDC.

Fig. 2 Certificate Generation algorithms

As mentioned before, the one Raspberry Pi, in which the entire dataset is stored, when compared to the industrial implementation, is actually a data generating devices like sensors present at the topmost layer of the Fog computing paradigm. Just like the sensors send the real-time collected data to the EDCs, similarly that single Raspberry Pi sends the data to the EDCs as well. But the difference here is that, the data that is sent to the EDCs is sent in a very secure way.

As per the Fog computing paradigm, only small volume of data that is collected is sent to the EDCs for the necessary processing. Similarly, the client Raspberry Pi, sends only 1000 records from the whole dataset to each EDC. In our system, the client sends the data to any random EDC. Well it has to be noted that data is sent over to only authenticated EDCs.

When the client sends the data to an EDC, the client Raspberry Pi sends its public key to the EDC. The EDC then generates a session key. A session key is a randomly generated key which is used for symmetric encryption and decryption of confidential data that ensures secure communication between two communicating entities. This session key is encrypted using public key of the EDC and sends it to client EDC. The session key can be decrypted only by the intended client EDC using its own private key. Now the communication is made secure and both of them have session keys safely stored with them.

Next the data that is to be sent has to made secure so that no one can use this information that is being sent between them. The data, that is, the 1100 records, are first hashed using SHA-256 (Secure Hash Algorithm 256). SHA-256 is a powerful cryptographic hash function which takes input of any size and produces a 256-bit (32-byte) hash value known as a message digest. This ensures the integrity of the data that is sent. After hashing, the data and the hash value are appended together into one single entity, and encrypted using the AES-256 (Advanced Encryption Standard 256) algorithm. AES is the US government standard for symmetric key block cipher encryption and decryption. It is 128-bit block cipher which can choose key size from 128, 192, 256 bits. The design of AES is based on a substitution permutation network (SPN). The key that is used here for performing the AES operation is the session key that was generated before. Now the data that is to be sent is now secure. This data is sent to the EDC, which performs the decryption operation and stores the data. Once the EDC has the data with it, it runs the LSTM on the data. Once successfully completed, the results are stored into a file. This is how data is sent to all the EDCs in an authenticated manner (described in Fig 3) and once the data reaches the EDC, the LSTM is performed over the data and results from each EDC are appended to the bottom of a single file in the server. After the intermediate results are received, a single variate LSTM is performed over the intermediate results, and the RMSE value is computed.

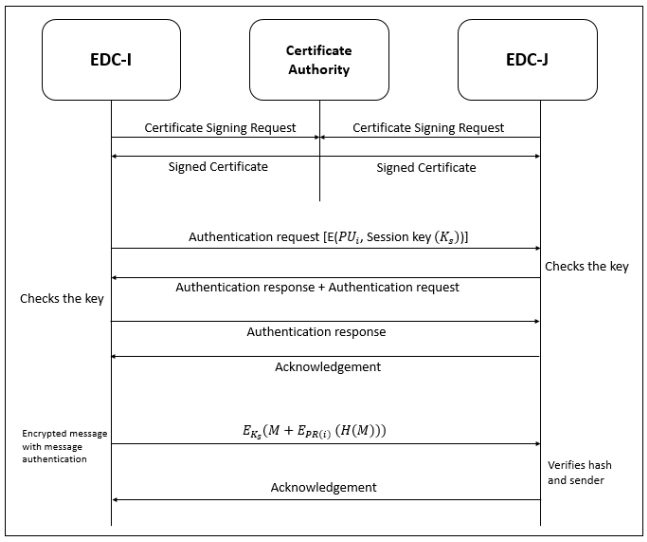

Fig. 3 Secure communication workflow

C. Dynamic Task Offloading

Load balancing is an efficiency improvement strategy in which the workload is distributed among multiple computing resources such as clusters, network links, computer nodes etc. The main aim of load balancing is the optimization of resource usage in minimized response time with maximum throughput. It generally considers multiple factors instead of a single component to increase the reliability and availability. Usually, task offloading involves dedicated software or hardware such as multilayer switch or a DNS server process. In our system, load refers to the CPU load, and along with that, the Memory load, Disk load and the thermal heat is also considered. The task offloading to

other EDCs is based on the values of CPU load of the EDCs.

In the previous section, the secure authentication and communication between the Fog nodes have been explained in detail. The load balancing occurs when the data reaches the EDC. When the data is received by the EDC, it checks its own load, that is the CPU load value. An EDC is considered to be overloaded if the value of the CPU load is greater than or equal to 85%. After checking the load, if it is not overloaded, then the LSTM can be run on the EDC. If the EDC is overloaded, using the Breadth First Search algorithm, it broadcasts requests for the current load information to every EDC in the network. After getting load information from all the EDCs, it sorts all the load information received and selects the EDC with the most minimal load. The data is then sent to the EDC with the most minimum load, and the results are stored in the same file. And if, all the EDCs are overloaded, then the data is sent to the server, and it performs LSTM as a sub-process, the only reason being a PC does not have that processing overhead. This process continues until the entire dataset is sent from the client Raspberry Pi to the EDCs. Note that load balancing is done only after authenticating the EDC to which next data is to be sent, and processed. The load balancing algorithm is described in Fig. 4.

Load Balancing algorithm

```
1.  If(EDC-I is overloaded)
2.    EDC-I broadcasts load request to all EDCs.
3.    Upon receiving the request;
4.      EDC-J determines its current load.
5.      EDC-J sends its load information alongwith its identifier.
6.    Upon receiving load information from all EDCs;
7.      EDC-I checks for EDC with minimum load.
8.      If found
9.        Sends the data to that EDC for processing.
10.     If not found
11.       Sends the data to the upper layer of Fog architecture.
```

Fig. 4 Load Balancing algorithm

D. Long Short Term Memory Neural Network

Unlike the feed-forward neural network, RNNs contain hidden states which are distributed across time, which allows to store a lot of past information efficiently. The core idea is that recurrent connections ensures memory of previous inputs to persist in the internal state of the network, and thereby influence the output of the network. At each time step, the network processes:

1.The input attributes (x_t)
2. Updates its hidden state via activation functions (y_t) and
3. Uses it to make a prediction of its output (z_t).

These steps are similar to the general feed-forward neural networks. However, the value held in the delay unit is fed back to the hidden units as additional input. The delay unit enables the network to have short-term memory. This is because it stores the hidden layer activation values and/or output values of the previous time step. At the subsequent time step, it releases these values back into the network. In other words, the RNN has a "memory" which stores information about those calculated by the hidden units at an earlier time step. Time-series data contain patterns ordered by time. Information about the underlying data generating mechanism is contained in these patterns. Since the delay unit exhibit persistence, RNNs take advantage of this ordering. It is this "short term" memory feature that allows an RNN to learn and generalize across sequences of inputs.

The memory block contains a memory cell and three multiplicative gate units - the input gate, the output gate, and the forget gate. After activation of input gate, the input is multiplied with memory block, output is multiplied with output gate and all the preceding cell values are multiplied with forget gate. The gates control the information flow into and out of the memory cell.

The Role of Gates: Long term dependencies in LSTM are explicitly modeled using gating mechanism. The input, forget, and output gate learn what information to store in the memory, how long to store it, and when to read it out. By acquiring this information from the data, the network learns how its memory should behave. The input gate gradually learns to protect the cell from irrelevant inputs. It controls the flow of input activations into the memory cell. Information enters the cell when the "write" gate is on and those information remains in the cell as long as it's forget gate is "off". The forget gate allows the cell to reset itself to zero when necessary. The output gate controls the output flow of cell activations into the rest of the network. By turning on its output gate, information can be read from the cell. The LSTM learns to turn off a memory block that is generating irrelevant output.

The working of the memory block system can be considered like this: The input gate takes input from the cell at the previous time-step, and the output gate from the current time-step. A memory block can choose to "forget" if necessary or retain their memory over very long periods of time.

IV. RESULT ANALYSIS

The overall system is secured to the maximum limit as much as possible by using most efficient algorithms for the purpose. The basic network security characteristics are assured in the system:

(i) **Confidentiality**: The proposed system uses AES-256 for encryption purposes. For the key management purpose, RSA has been used in the proposed system, since RSA being one of the most secure algorithms used for key-exchange. RSA is better when compared to other key-exchange algorithms as it is not susceptible to attacks like Man-in-the-Middle attack which is present in Diffie-Hellman algorithm. RSA can also be used for signing digital signatures as well.

(ii) **Integrity**: The messages that are being sent between the Fog nodes are properly hashed using one of the best hashing algorithms SHA-256. Any message that is being sent between the Fog nodes cannot be altered by any intruder. Thus ensuring the integrity of messages.

(iii) **Authentication**: Any message that is sent inside the Fog network is sent only to authenticated nodes. The authentication of these nodes is provided by the server which acts as the Certificate Authority and provides certificates to the nodes that request for one. Only nodes having a signed

certificate from the server are sent the information. The system is secured from the masquerading attack by proper authentication of the Fog devices. This is done by storing specific passphrases in the intended Fog devices. Therefore, when EDCs request for getting their certificates signed from the CA, the CA asks the EDCs to provide the passphrase in return. If the EDCs provide the valid passphrase, they get their certificates signed by the CA. Hence if any device somehow enters the network, and requests the CA for getting its certificate signed, the request will be eventually declined by the CA as this malicious device does not know what is the passphrase. Another authentication technique that is introduced in the system is the message authentication between EDCs to ensure that neither of the EDCs can later deny that they haven't sent the message. This is done by hashing the message and encrypting it using the sender EDC's private key which can be decrypted using the sender EDC's public key, which makes the system secure from the repudiation attack.

A. Security Evaluation

The system was subjected to many cryptographic attacks and the results were thoroughly analyzed:

1. Masquerade attack: All of the EDCs have a passphrase stored in them initially. The CA asks for the specific passphrase from the EDC when it requests the CA for getting its digital certificate signed. If the entered passphrase is the valid one, then only the CA signs the certificate coming from the EDC, therefore any other device which tries to pretend as any of the EDCs present in the network cannot even request the CA for signing its request as the device which tries to masquerade an EDC will not have the passphrase with it.
2. Message Modification attack: The proposed system checks for the integrity of the messages that are being sent over the network. The integrity is checked using the hashing algorithm SHA-512 which produces a hash for the message. This hash is validated when the message is received. If the hash value is invalid, then a receiver informs sender to resend the message as the receiver understood that the message has been modified by and intruder.
3. Repudiation attack: In the proposed system, proper message authentication mechanism is incorporated. The message that is being sent is initially hashed by the sender, encrypted using the sender's private key, and then sent to the receiver. The receiver after the getting the message decrypts it using the sender's public key, thus ensuring that the sender cannot refuse later that it ever sent a message.
4. Denial-of-Service attack: The proposed system is invulnerable to masquerade attack as a proper defensive mechanism been taken in the initial stages itself. The DoS attack is very much prevented by keeping a list of authenticated devices in all the EDCs. If in case, a malicious EDC somehow enters the Fog network and starts sending communication requests for performing a DoS attack, the communication with that EDC does not proceed until it is verified that it is an authenticated device by looking in the list of authenticated EDCs. The requests coming from EDCs are multithreaded inside the network, therefore the thread dies if any request from an unauthenticated device is received. The DoS attack is very difficult to handle as it needs very powerful servers to handle the excessive incoming requests coming from different devices based on their time, and block the malicious device for some time. The proposed system does not use powerful EDCs, therefore the DoS attack could be prevented only up to a limit because of the performance constraints of the devices used.
5. Key Brute Force attack: The proposed system uses RSA algorithm for generating the public-private key pairs. The RSA algorithm generates keys of size 4096 bytes. Therefore, it takes centuries to break the keys even if powerful quantum computers are utilized.
6. SSH Brute Force attack: The proposed system is secured from the SSH brute force attack by using passwords that cannot be easily determined for accessing the root. Passwords consisting of special symbols, numbers, upper and lowercase letters and of length 12 characters.
7. Dictionary attack: The proposed system is made invulnerable to dictionary attack by assigning passwords that are not at all present in the dictionary.

B. Load Balancing

The factors that were considered for offloading the tasks are:

1. CPU Load: It is the percentage of the processing workload over CPU. This is the major factor that determines whether the load has to be shared with other Fog nodes or not as processing is what it matters in the Fog architecture.
2. Memory Load: It is the percentage of memory that is currently being used up.
3. Disk Load: It is the percentage of disk that is currently being used up.
4. System Temperature: It is the current temperature of the system. The temperature of the system is another factor as the Fog nodes become more heated up with the increase in temperature, and may get destroyed if more processing load is given to these heated up Fog nodes.

The factors mentioned above for a Fog node decide how the load balancing is performed in the Fog environment. A specific threshold value has been set for each of the factors before-hand. If any of the Fog node has reached the threshold value for any factors, then that node is not considered for sharing the task from other Fog nodes. If all the EDCs are overloaded or heated up, then the PC which acts as the server system is given all of the task based on the assumption that a PC has better system cooling capabilities

and can handle more tasks when compared to the smaller edge devices.

The performance of the load balancing algorithm in the proposed system depends upon the latency in the Fog environment, that is, the time taken for processing the dataset in the Fog environment. It was reported to be 270 seconds on an average with load balancing whereas it was found to be greater without load balancing.

C. Deep Learning

The performance plot of the time series analysis in Cloud environment is shown in the Fig 5. The RMSE value for the analysis in the Cloud environment was found to be 0.031 on normalized values of pollution for the entire test data points. The Fog architecture also brings up an RMSE value very much closer to that observed in the cloud environment and was found to be 0.0386. This is illustrated in Fig 6. The predictions from both environments were found to be similar.

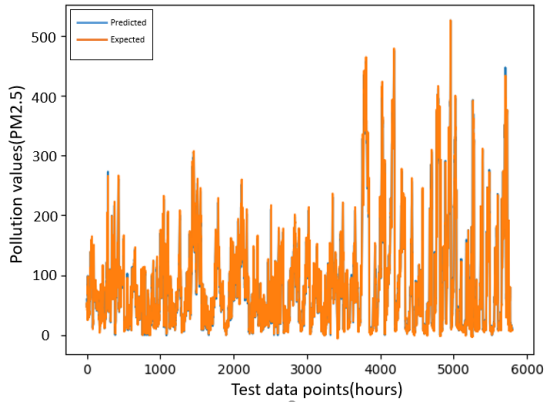

Fig. 5 Line Plot of LSTM Forecast v/s Expected Values in cloud environment

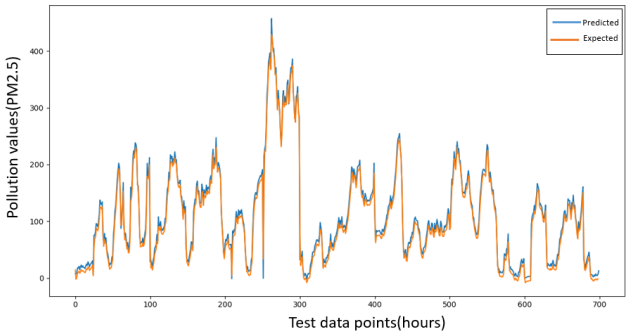

Fig. 6 Line Plot of LSTM Forecast v/s Expected Values in Fog environment

V. CONCLUSION

All the study that has been carried out in this work are by identifying the factors that adversely affect an IoT ecosystem when integrated with a cloud, thus explaining why a new paradigm known as Fog Computing came into existence. Even though the Fog computing environment is a very much optimized IoT network, it still possesses many major issues like security over the network and lack of proper task offloading mechanism since IoT devices are very small and have only limited processing capabilities. Thus overall aim is to create a Fog Computing environment using IoT devices and process a time series data collected before-hand using one of the most efficient deep learning algorithms inside the fog environment and also solve the security and task offloading issues by deploying an intelligent and secure load balancing technique. In future, the work can be extended to wireless, mobile, dynamic and scalable Fog networks, which may have multiple hops in between, with support for multiple applications in different domains.

***Abstract*— In the modern era of globalization, an alarming increment in energy consumption is perceived all over the world which results in the scarcity of primary energy resources in the near future. Due to expeditious economic growth and increasing population, many countries are planning to explore existing Renewable Energy (RE) sources to fulfill increasing energy demand. Selection of suitable alternative RE must be addressed in multi-criteria decision making (MCDM) problem because it involves multiple criteria which are conflicting in nature. This paper proposes an integrated method which is a combination of Additive Ratio Assessment (ARAS) method and Z-numbers. The proposed method namely ARAS-Z, Z-number is used to consider the degree of self-confidence along with the fuzzy number to handle the uncertainty involved in the human judgment used in the evaluation of criteria weights. ARAS is applied for the assessment and prioritization of feasible alternative RE sources based on utility degree. A comparative analysis of the proposed method is done with other MCDM methodologies for checking the effectiveness and capability of the proposed methodology.**

Keywords*— *Renewable Energy Selection, TFNs, MCDM tools, Z-number, Ranking of FNs, ARAS method.

I. INTRODUCTION

In this modern era, Energy becomes an important globally discussed issue. The rising population, rapid economic developments, and technological advancements lead to a huge energy demand for all over the world. The expanding industrialization improves the living standard of people but on the other side, it leads to the rise of global energy demand at a surprising rate. The rising energy demand has been fulfilled by fossil fuels such as petroleum, coal and natural gases. The different countries have different primary energy reservoir and some countries have a limited amount of reservoir that they are unable to fulfill their growing energy demands. The primary resources also have various adverse effects on the environment such as ejection of greenhouse gases and these resources also requires a heavy amount of conservation cost, high maintenance, and pricey in nature. As a result of these issues, developing alternative energy resources is necessary. One remarkable kind of alternative energy sources is non-conventional sources.

In the Paris agreement, India sets an aim to obtain 40% of its total electricity production from non-conventional energy sources by 2030 [1], [2]. A prototype is drafted by the Central Electricity Authority in which 57% of the total electricity capacity will be generated from Renewable Energy (RE) sources by 2027 [3]. So, there is a need to make an effective transition from primary resources to RE sources. Adopting and choosing RE sources is a multi-criteria decision making (MCDM) problem that incorporates both quantitative and qualitative aspects such as technical, environmental, political, economic, and social which are conflicting in nature. MCDM methodologies are efficient methods that are used for the assessment of various RE sources and further used to rank them in order to select the best one.

II. LITERATURE REVIEW

In past research, numerous MCDM approaches have been used widely in the field of RE resource selection. San Cristobal [4] presents the VIKOR method combined with the AHP methodology used to estimate the weights of the criteria and then rank the alternatives resources in order to select the best RE investment project for Spain. Abdolreza et al. [5] present COPRAS methodology integrated with AHP to estimate and evaluate the RE project. Chatzimouratidis and Pilavachi [6] and many other researchers applied an AHP methodology to evaluate the best alternative RE resources considering both quantitative and qualitative criteria.

But the prioritization of suitable alternative RE resources while considering several conflicting criteria becomes more challenging decision process due to the presence of incomplete information and uncertainty in human thought. So, to handle it the concept of fuzzy set theory is used. Turskis and Zavadskas [7] present ARAS method in the fuzzy environment to obtain an appropriate site among several alternatives for the logistics center. Wang, Luo and Hua [8] and Tasri and Susilawati [9] present fuzzy AHP to evaluate the conflicting criteria in an uncertain environment and rank the alternatives in order to select the optimal one. Wang, Huang, Chai and Nguyen [10] propose the TOPSIS method integrated with FAHP for the selection of wind power plants site in Vietnam.

Even though fuzzy numbers have the capability to handle the ambiguity and vagueness, but it is unable to consider the degree of self-confidence of information. To overcome this limitation Zadeh [11], introduced the concept of Z-number. The fuzzy

number along with the certainty degree (reliability) is coined as Z-number which has more expressive power as compared to fuzzy numbers. Chatterjee and Kar [12] present the COPRAS method integrated with Z-number to obtain the optimal RE resource among various feasible alternatives. Z-number concept is practiced successfully in distinct fields to resolve complex MCDM problems, but in the field of RE resource selection, the application of Z-number is little and restricted.

This paper proposes an Additive Ratio Assessment (ARAS) methodology integrated with Z-number and Ranking of generalized fuzzy number concept to choose an appropriate RE alternative. Decision makers (DM) compare the various criteria in a fuzzy environment considering the degree of self-confidence then decision matrix is evaluated to obtain fuzzy weights and to get crisp weights, ranking of generalized fuzzy number is used in which the fuzzy weights are ranked and finally ARAS is applied to rank the feasible RE resources with the help of utility degree. To justify the effectiveness and capability of the proposed method, comparison of the proposed method is done with the several other MCDM methods such as VIKOR, TOPSIS, and COPRAS.

III. PRELIMINARIES

A. Triangular Fuzzy Number (TFN)

Zadeh (1965) [10] gave the fuzzy number concept. DM believes that they are more convenient in expressing their opinion in TFNs as it is a triplet of three values (p1, p2, p3) indicating the lower, the more probable and the higher value (p1 ≤ p2 ≤ p3). Mathematically, the membership value of a TFN $\tilde{E}$ = (p1, p2, p3) can be defined as:

$$\mu_{\tilde{E}}(x) = \begin{cases} 0 & , \quad x < p1 \\ \dfrac{x - p1}{p2 - p1}, & p1 \le x \le p2 \\ \dfrac{p3 - x}{p3 - p2}, & p2 \le x \le p3 \\ 0 & , \quad x \ge p3 \end{cases} \tag{1}$$

B. Z-Number Concept [11]

Zadeh proposed the concept of Z-number [11] to enhance the reliability of the information because it is not enough to consider only fuzziness restriction while dealing with uncertain and imprecise information but also its degree of self-confidence. It is defined as an ordered pair of fuzzy numbers: Z = ($\tilde{A}$, $\hat{R}$) where $\tilde{A}$ determines the restriction of the evaluation and $\hat{R}$ determines the measure of the reliability of fuzzy number $\tilde{A}$.

IV. PROPOSED METHODOLOGY

This section describes the proposed method ARAS-Z, in which both tangible and intangible criteria are evaluated to obtain their weights and then ARAS is applied to rank all the suitable alternatives in order to get the optimal RE resource. The proposed methodology comprises of several steps as described below:

Step 1: Determine the Criteria and Alternatives

This step specifies the various alternative RE resources and the evaluation criteria that are involved in the decision-making process to solve the problem.

Step 2: Construct a pairwise decision matrix Y

A pairwise comparison matrix is formed by the decision maker in which corresponding values are given in linguistic terms expressed in Z-number. The fuzzy restriction values and its certainty degree are described in TFN_S and to obtain the decision matrix, $Y = [Z_{ij}]_{n\times n}$, where Z_{ij} is the evaluation value of criterion i in criterion j and n is the number of criteria, the corresponding value is taken from the codebook by the decision maker. The codebook of fuzzy restriction values [10] and its reliabilities for the criteria are shown in Table I.

Step 3: Conversion of Z-number into TFN_S

Each element of the pairwise decision matrix represented in Z-number is transformed into fuzzy numbers by applying fuzzy expectation [13] to obtain the pairwise fuzzy comparison matrix.

Step 4: Normalization of pairwise fuzzy comparison matrix

The normalization of a comparison matrix is required to scale each criterion value C_i (i=1,2,..n) in the same measurement range as different criteria have different measurement units.

- Summation of each row of pairwise fuzzy comparison matrix is done by applying the fuzzy arithmetic operations [8], $\hat{Y} = \left(\tilde{y}_{ij}\right)_{n\times n}$ where $\tilde{y}_{ij} = \left(p1_{ij}, p2_{ij}, p3_{ij}\right)$, $\tilde{y}_{ij}^{-1} = \left(\frac{1}{p3_{ij}}, \frac{1}{p2_{ij}}, \frac{1}{p1_{ij}}\right)$ for i, j = 1,…, n & i ≠ j.

$$V_i = \sum_{j=1}^{n} \tilde{y}_{ij} = \left(\sum_{j=1}^{n} p1_{ij}, \sum_{j=1}^{n} p2_{ij}, \sum_{j=1}^{n} p3_{ij}\right), \tag{2}$$

$$i = 1, \ldots, n$$

- Fuzzy weights of the evaluation criteria are obtained by normalizing the above rows [8].

$$\hat{W}_i = \frac{V_i}{\sum_{j=1}^{n} V_i} = \left(\begin{array}{c} \dfrac{\sum_{j=1}^{n} p1_{ij}}{\sum_{j=1}^{n} p1_{ij} + \sum_{k=1,k\neq i}^{n} \sum_{j=1}^{n} p3_{kj}}, \\ \dfrac{\sum_{j=1}^{n} p2_{ij}}{\sum_{k=1}^{n} \sum_{j=1}^{n} p2_{kj}}, \\ \dfrac{\sum_{j=1}^{n} p3_{ij}}{\sum_{j=1}^{n} p3_{ij} + \sum_{k=1,k\neq i}^{n} \sum_{j=1}^{n} p1_{kj}} \end{array} \right), \tag{3}$$

$$i = 1,2, \ldots, n$$

Step 5: Determination of the weights of evaluation criteria

After normalization, the fuzzy weights of the criteria are obtained that are represented in TFN_S but in order to get the weights of the criteria in the crisp, ranking of fuzzy numbers are done by using defuzzified value, different heights and different spreads [14].

- Apply the center of area method to defuzzy the fuzzy weights.

TABLE I. LINGUISTIC TERMS OF FUZZY RESTRICTIONS & ITS RELIABILITY AND THEIR TFN VALUES

Fuzzy Restrictions			Fuzzy reliability	
Saaty Scale	**Definition**	**TFN Scale**	**Definition**	**TFN Scale**
1	Equally Important	(1, 1, 1)	Not Very Likely (NL)	(0.1, 0.1, 0.5)
3	Weakly Important	(2, 3, 4)	Likely (L)	(0.1, 0.5, 0.8)
5	Fairly Important	(4, 5, 6)	Very Likely (VL)	(0.5, 0.7, 1)
7	Strongly Important	(6, 7, 8)	Extremely Likely (EL)	(0.7, 1, 1)
9	Absolutely Important	(9, 9, 9)		
2	The intermittent values	(1, 2, 3)		
4	between two adjacent scales	(3, 4, 5)		
6		(5, 6, 7)		
8		(7, 8, 9)		

$$x_{\hat{W}_i} = \frac{(p1_i + p2_i + p3_i)}{3}, \text{i} = 1, \dots, \text{n.} \quad (4)$$

- Calculate the spread $STD_{\hat{W}_i}$ of each fuzzy weight.

$$STD_{\hat{W}_i} = \sqrt{\frac{\sum_{j=1}^{3}(\hat{W}_{ij} - x_{\hat{W}_i})^2}{3-1}}, \quad i = 1, \dots, n. \quad (5)$$

- Then the fuzzy Score of each fuzzy weight is calculated.

$$Score_{\hat{W}_i} = \frac{x_{\hat{W}_i} * 1}{1 + STD_{\hat{W}_i}}, \quad i = 1, \dots, n. \quad (6)$$

- Fuzzy Score gives the final weights of the criteria in crisp. The greater the value of $Score_{\hat{W}_i}$, the higher the weight of $\hat{W}_i$, where i = 1,…,n. The weight vector of the evaluation criteria is $W^T = [w_1, w_2, w_3, \dots\dots, w_n]$.

Step 6: Evaluation of alternative RE resources with ARAS methodology

Evaluation and ranking of feasible alternative resources are done by ARAS method [15]. Utility degree derived from the ARAS method helps to prioritize the alternatives. The utility function value is directly proportional to the evaluated weights of the criteria and the relative effect of values and it is used to determine the complex comparative efficiency of the suitable alternatives. As the RE resources are prioritized based on utility degree, so higher the utility function value better the RE resource.

V. IMPLEMENTATION AND ANALYSIS

Cristobal data [4] is used for the implementation of the proposed method. Cristobal presented the VIKOR method for the evaluation of feasible alternative RE resources for the RE plan started by the Spanish Government in 2005. The proposed methodology is implemented in the following three steps:

Step 1: Two categories of evaluation criteria (C_E) are used in the proposed model namely benefit and cost criteria. Benefit criteria are Power (C_{E1}) in Kilowatt, Operating Hours (C_{E4}) in Hours/year, Useful Life (C_{E5}) in Years and Tons of emissions of CO_2 avoided/year (C_{E7}) in tCO_2/y. Cost criteria are Investment Ratio (C_{E2}) in €/Kilowatt, Implementation Period (C_{E3}) in Years, Operating and Maintaining Costs (C_{E6}) in € $\times 10^{-3}$ / Kilowatt hour.

In this study, thirteen alternatives RE resources are considered namely: Wind power P ≤ 5 MW (R_{E1}), Wind power 5 ≤ P ≤ 10 MW (R_{E2}), Wind power 10 ≤ P ≤ 50 MW (R_{E3}), Hydroelectric P ≤ 10 MW (R_{E4}), Hydroelectric 10 ≤ P ≤ 25 MW (R_{E5}), Hydroelectric 25 ≤ P ≤ 50 MW (R_{E6}), Solar Thermo-electric P ≥ 10 MW (R_{E7}), Biomass (energetic cultivations) P ≤ 5 MW (R_{E8}), Biomass (forest and agricultural wastes) P ≤ 5 MW (R_{E9}), Biomass (farming industrial wastes) P ≤ 5 MW (R_{E10}), Biomass (forest industrial wastes) P ≤ 5 MW (R_{E11}), Biomass (co-combustion in conventional central) P ≤ 5 MW (R_{E12}), Biofuels P ≤ 2MW (R_{E13}). Assessment values of alternatives corresponding to each criterion are shown in Table II.

Step 2: Table III calculates a pairwise comparison matrix using Table I. To determine the evaluation weights of the criteria firstly, Z-numbers are converted into TFN_S using fuzzy expectation then a pairwise fuzzy comparison matrix is normalized using (2), and (3) to obtain fuzzy weights. Further ranking of fuzzy weights represented in TFN_S is done using (4), (5), and (6) to retrieve weights of criteria in crisp. Lastly priority weight vector W = [0.290, 0.109, 0.025, 0.143, 0.154, 0.059, 0.192] is obtained. Based on the opinions of the DM_S, Power (0.290) possess the highest priority and Implementation period (0.025) possess the least priority in the RE selection problem.

Step 3: In this step, the assessment of alternative resources is done by applying the ARAS method on Table II data. The normalized weighted decision matrix, the optimality function value S_i and the utility function value K_i are presented in Table IV. Final ranks of alternative resources are also listed in Table IV. Based on the calculated utility degree value K_i , the optimal alternative RE resource is R_{E12}.

VI. RESULT ANALYSIS

To verify the efficiency and capability of the proposed ARAS-Z method, evaluation of the weights of the criteria and the prioritization of viable thirteen alternative resources are done using utility degree. Spearman's rank correlation coefficient (SCC) [5] is used to compare proposed ARAS-Z methodology with other MCDM methods namely VIKOR, TOPSIS, and COPRAS as shown in Table V. The SCC between the final ranking and the ARAS-Z, VIKOR, TOPSIS, COPRAS methods are 0.99, 0.96, 0.99, 0.99 respectively. Since ARAS-Z method has the highest SCC value (0.99) as TOPSIS and COPRAS, so it justifies the capability and effectiveness of the proposed method.

VII. CONCLUSION

The problem of prioritization of suitable alternative resources becomes complex due to the presence of multiple conflicting criteria and uncertainty in the information. ARAS method integrated with Z-number is proposed for the prioritization of feasible RE sources. In real-world decision problems, uncertainty is pervasive in nature. To handle the uncertainty in this problem, the degree of self-confidence is considered along with fuzzy numbers and a pairwise comparison matrix is formed. Weights are evaluated by ranking the generalized fuzzy numbers which are used further in the ARAS method to prioritize the alternatives using utility degree. Based on the SSC, a comparative analysis is done to validate the capability and effectiveness of the proposed model. Proposed ARAS-Z model has the capability to handle the uncertainty while the other MCDM methods used in the comparison do not consider the uncertainty factor involved in the decision problem which is the main limitation of other MCDM methods.

mohanapriya@it.sastra.edu

***Abstract*—Software Defined Network is an emerging fifth generation network architecture in which data and control planes are decoupled. The programmable network provides standard open interfaces which is vulnerable to data leakage attacks. Existing Open Flow protocol lacks in crypto standard where messages are communicated between data and control planes are in unencrypted form. Open Flow messages are prone to passive attacks such as sniffing and traffic monitoring. Diffie-Hellman Key Exchange algorithm is implemented in Open Flow protocol version 1.3 where random private keys are generated for each incoming network traffic flows. In this research work, secure defense mechanism is proposed where Restricted Boltzmann Machine algorithm is incorporated in controller that detects Distributed Denial of Service attack traffic flows. The performance of Software Defined Network is measured using performance metrics namely bandwidth utilization of controller, delay of request and response messages from switch and controller, encryption and decryption time of Open Flow messages. The proposed secure defense mechanism is an extended work of previous research work on detection of Distributed Denial of Service attack in Software Defined Network controller. The proposed secure defense mechanism out performs existing work with respect to metrics such as bandwidth utilization, delay, encryption and with decryption time.**

Keywords—Software Defined Networks; Data Leakage Attack; Restricted Boltzmann Machine; Man-in-the-Middle Attack; Self-learning; Distributed Denial of Service; Diffie-Hellman Key Exchange Algorithm

I. INTRODUCTION

Data is considered as an important asset in all the sectors like educational institutions, industries etc. Securing data of the intended network is the foremost concern for the network administrator. The most common attacks found in networking environment breach the meaning of data that corresponds to an individual. Man-in-the-Middle attack [1] is the top most category of data leakage attacks which breaks integrity and confidentiality of the stored data. In order to protect the network from data leakage, applying suitable crypto standard for the process of encryption and decryption is needed.

In this research work, data leakage security attack of one of the fifth generation (5G) network named Software Defined Network (SDN) [2] is concentrated. SDN architecture is improvised comparatively from the conventional network. In conventional network [3] setup, data forwarding and data management modules are tightly coupled which lacks in network customization according to the user needs. Researcher communities from Stanford University seek great interest to create an open network that is feasible to integrate customized user applications. Finally SDN is obtained as a product that has Open Flow (OF) [4] protocol that acts as an interface between data forwarding and data management modules.

SDN [5] is an emerging alternate 5G network architecture where data forwarding and data management modules are decoupled each other. SDN is a three layered network architecture where the bottom plane is the data plane whose responsibility is forwarding the incoming network traffic flows. The middle plane is the control plane [6] that is responsible for taking authoritative decisions. In data plane [7], for each and every switch the component named flow table is integrated.

Flow table records the entries of incoming network traffic flows with features such as physical and logical addresses for future analysis. Physical address of incoming traffic flows include source and destination Medium Access Control (SRC MAC) and (DST MAC) address of a machine (or) host where the traffic is originated whereas logical address of network traffic flows include source and IP (SRC IP) and destination IP address (DST IP), Protocol type, Virtual Local Area Network Identifier (VLAN ID). The top most plane is an application plane [8] where user customized applications are incorporated.

The threat vectors of SDN architecture regarding data leakage security attack include vulnerable data plane [3], vulnerable controllers [9], vulnerable data-control plane [10] communication interface, and vulnerable apps in application plane.

The objective of this research work is to incorporate Diffie-Hellman Key Exchange algorithm used for the process of encryption and decryption of messages originated from the data plane to the control plane and vice-versa for providing enhanced security. In control plane, unsupervised Restricted Boltzmann Machine (RBM) algorithm is incorporated that self-

learns network traffic flow features to detect malicious traffic flows.

The major contributions of this research work includes that this is a first paper to use crypto standard to provide additional security in SDN. The messages interacted between data and control planes are in encrypted form so that data leakage (or) man-in-the-middle attack is reduced comparatively than the existing methods. Unsupervised RBM algorithm self-learns network traffic flow features that detect malicious IP addresses that cause data-leakage security attacks. The proposed defense mechanism has higher accuracy in terms of attack detection than the existing methods and it is an extended work of [11] wherein the detection mechanism lacks in OF protocol crypto standard is incorporated to provide security against data leakage attacks.

The paper is organized as follows. Section 2 discusses the related works on data leakage security attacks in SDN. Section 3 discusses the proposed defense mechanism against data leakage security attacks, section 4 details the experimental setup, section 5 reveals the results and discussions and finally section 6 concludes with future research directions.

II. Related Work

Cheng Li et al [12] proposed a prototype system to detect MITM attack with packet modification using Bloom Filters based on SDN by extending the OF protocol. Zhang et al [13] proposed Convincing Mechanism for MITM Detection (CMD) to detect man-in-the-middle attack in OF channel. The topology and connection characteristics of network traffic are fed as inputs to CMD, without analyzing the packet contents. CMD results with good time accuracy and performance.

Sebbar et al [14] proposed a detection mechanism to prevent Man-in-the-Middle attack in Multi-SDN controller environment. The proposed detection mechanism concentrates on the vulnerabilities of Open DayLight (ODL) controller. Effective countermeasure is also proposed to prevent attacks on the league monitor's monitoring service.

Lin et al [15] proposed a defense approach called "Packet forwarding based on BUFfer sharing (PBUF)" that pools the idle switches to mitigate threats in SDN. Buffer management module gleans the statistics of incoming packets and analyzes the table-miss packets. The packet forwarding module is designed to forward table-miss packets to the idle switches to prevent switch (or) controller to be overloaded. Imran et al [16] discussed comprehensive approaches of DDoS attacks in SDN environment. The authors presented various DDoS attack mitigation strategies based on the different classes based on the methodology in handling malicious traffic flows.

Wavelet analysis method was introduced by Julian et al [17] to detect anomalous conditions raised due to man-in-the-middle attack in SDN. Unique characteristics of reported anomalies are used to classify the type of DDoS attack. Mohana Priya & Shalinie [18] proposed a detection system with an unsupervised RBM algorithm in SDN controller. The RBM algorithm self-learns the reliable network metrics to detect DDoS attacks in SDN. Data Leakage Prevention System (DLPS) is proposed by sultan [19] to detect and prevent confidential data in use, transit and at rest.

DLPS use different techniques to analyze the content and context of confidential data. Braga et al [20] discussed a light weight method to differentiate attack traffic flows from normal traffic flows using Self Organizing Map (SOM). Feng et al [21] considered parameters to detect DDoS attack traffic flows include Average Number of Packets in Per Flow (ANPPF), Average of Duration per Flow (ADF), Percentage of Pair-Flows (PPF) and Growth of Single Flows (GSF).

III. Proposed Defense Mechanism

The proposed secure defense mechanism consists of 2 distinct phases namely network traffic flow generation phase and attack detection phase as shown in Figure 1. In phase 1, legitimate and an attack traffic flows are generated using real time network emulator named mininet. SDN controller will monitor the incoming network traffic flows and also analyzes the performance of the network by deeply inspecting the flow structure.

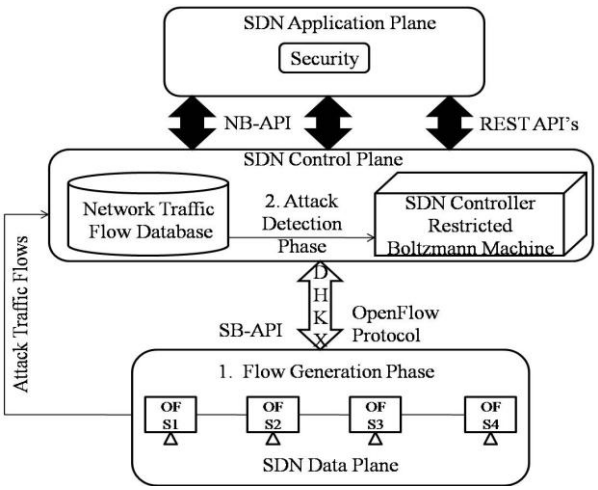

Fig. 1: Block Diagram of Proposed Defense Mechanism

The generated network traffic flows are stored in the database for future analysis. The network traffic flows in the database are pulled through appropriate Structured Query Language (SQL) queries to the SDN controller. It is deployed with RBM algorithm to detect DDoS attack and its variants. In SDN context, for every incoming unknown traffic flows, the data plane switches send PACKET-IN request as a query message to the SDN controller.

The controller in turn reply with the PACKET-OUT response message to the data plane switches through OF protocol. As SDN provides open standard interface as South Bound - Application Programming Interface (SB-API), it is vulnerable to data leakage security attack. In data leakage security attack, the OF messages communicated between SDN

data and control planes are known to attackers. In order to provide enhanced security, all OF messages transferred between data and control planes are encrypted by secretly exchanging the keys between the sender and receiver. Exchanging of secret keys has been done by Diffie-Hellman key exchange algorithm.

In the existing OF protocol version 1.3, if the logic of Diffie-Hellman key exchange algorithm is incorporated, it will generate random prime numbers to generate private and public key pairs to encrypt and decrypt the original message. Finally, key generation process is initiated between the sender and receiver to check whether the secret key exchanged are equal (or) not. Figure 2 shows the Diffie-Hellman key exchange steps as follows:

Algorithm 1 : Diffie Hellman Key Exchange in Open Flow Protocol

Input : OF Request Messages from Data Plane Switches in Encrypted Form.
Output : OF Response Messages from SDN Controllers in Encrypted Form.
1. Assume prime number P.
2. Select α, such that α is less than and primitive root of P.
3. Assume PR_A and PR_A < P.
4. Calculate PU_A :
   $PU_A \rightarrow \alpha^{PRA}$ mod P.
5. Assume PR_B and PR_B < P.
6. Calculate PU_B :
   $PU_B \rightarrow \alpha^{PRB}$ mod P.
7. {Private, Public key pairs} of users are generated
8. Encryption Process of an OF switch Request Message:
   $PU_A = \alpha^{PRA}$ mod P.
9. Decryption Process of a Controller Response Message:
   $PU_B = \alpha^{PRB}$ mod P.
10. Key Generation and Verification at User A, User B:
   10.1 : At OF switch, find the key value K.
   $K = (PU_B)^{PR}{}_A$ mod P.
   10.2 : At SDN Controller, find the key value K.
   $K = (PU_A)^{PR}{}_B$ mod P.

Fig. 2: Diffie Hellman Key Exchange Algorithm in Open Flow Protocol

RBM algorithm is deployed in SDN controller in which for the training phase, the network is trained using contrastive divergence algorithm to update the weight matrix (W_{mn}). The training procedure of CD algorithm has traffic flow features namely source IP address, Destination IP address, Source MAC address, Destination MAC address and protocol type. Visible layer of RBM neural network is trained with the traffic flow features and the hidden layer of RBM processes the input metrics. There exists positive and negative gradient of the network in which the probability of training data is increased by computing the product of visible (v_m) and hidden layers (h_n).

Gibb's sampling procedure is used to update the weights between visible and hidden layers. The network traffic flow features are reconstructed from the available feature vector of traffic flows. The reconstructed network traffic flow features are fed as input to the next level hidden layers. In RBM, two layers exists namely visible and hidden layer. The extracted features of a dataset are fed as inputs to the visible layer where as the reconstructed network traffic flow features are fed as inputs to the higher level hidden layers. Visible layer of RBM has inputs such as source IP address, Destination IP address, Source MAC address, Destination MAC address and protocol type.

RBM is depicted in Figure 3 and its energy configuration [11] of RBM is given as follows:

$$E(V,H) = -\sum_{i=1}^{n}\sum_{j=1}^{m} w_{ij}\, h_i v_j - \sum_{j=1}^{m} b_j v_j - \sum_{i=1}^{n} c_i h_i \quad (1)$$

where,
w_{ij} = Weight matrix connecting hidden and visible layer.
v_j = Visible layer.
h_i = Hidden layer.
b_j & c_i = Bias Units of Visible and Hidden layer.

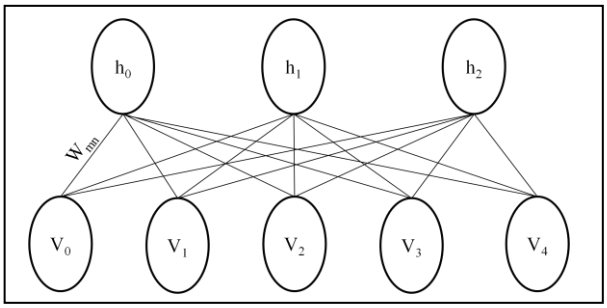

Fig. 3: Structure of RBM

RBM structure is conditionally independent given visible to find the probability of hidden layer and given hidden to find the probability of visible layer.

$$P\left(\frac{h}{v}\right) = \prod_i P\left(\frac{h_i}{v}\right) \quad (2)$$

and

$$P\left(\frac{v}{h}\right) = \prod_i P\left(\frac{v_j}{h}\right) \quad (3)$$

In this research work, the probability of hidden layer is computed given the inputs in visible layer. RBM detects DDoS attack traffic flows and data leakage security attacks with metrics such as hit count of encrypted request packets to the controller from data plane switches, energy consumption of data plane switches (E_{con}(SW)). E_{con}(SW) is measured based on the energy consumption of active switches, energy consumption of active interfaces, number of ports enabled and it is given as follows:

$$E_{con}\ (SW) = E_{con}\ (SW_{active}) + E_{con}\ (Interface_{active}) + \sum_{k=1}^{R} n_{ports\ .r} * E_{con}\ (Ports_{enabled}) \quad (4)$$

where,

$E_{con}\ (SW_{active})$ = Energy consumption of active switches.

$E_{con}\ (Interface_{active})$ = Energy consumption of active interfaces.

$n_{ports\ ,r}$ = Number of ports available in a switch and

$E_{con}\ (Ports_{enabled})$ = Energy consumption of ports enabled.

Figure 4 shows the phases of proposed defense mechanism in a bottom up approach of SDN with all the technical concepts incorporated in each of the component is illustrated. Legitimate and attack traffic flows are generated in data plane, as a follow up modified Diffie Hellman key exchange algorithm is incorporated in OF protocol to enhance its security. The encrypted OF messages from data and control plane is monitored by SDN controller which consists of RBM algorithm that self learns the network metrics, request messages. Based on the knowledge base, SDN controllers identify (or) detect the newly incoming unknown traffic flows.

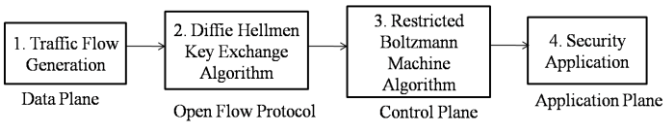

Fig. 4: Phases of Proposed Defense Mechanism

IV. EXPERIMENTAL SETUP

The experimentation has been carried out in Ubuntu Operating system version 15.4 with mininet emulator. In mininet, the data plane of SDN consists of Open Virtual Switch (OVS) that has three hosts namely h1, h2 and h3 interfaced with softwarized POX controller. The procedure of modified Diffie Hellman Key exchange algorithm is incorporated in OF protocol version 1.3 to encrypt the OF request message originated from data plane and decrypt the OF response message from the control plane. RBM algorithm is implemented as a python code named rbm.py in POX SDN controller. RBM algorithm self-learns the OF request messages to detect attack traffic flows. The logic of Diffie Hellman Key Exchange algorithm is implemented using ns-3 [22] tool. POX controller integrated with mininet is bridged with the ns3 simulator tool for interfacing OF protocol with data and control plane.

Wireshark is installed in the target victim to analyze the incoming network traffic flows. nmap tool is used to trace the network performance metrics such as bandwidth utilization of controller, delay of request and response messages from switch and controller, encryption and decryption time of incoming OF messages.

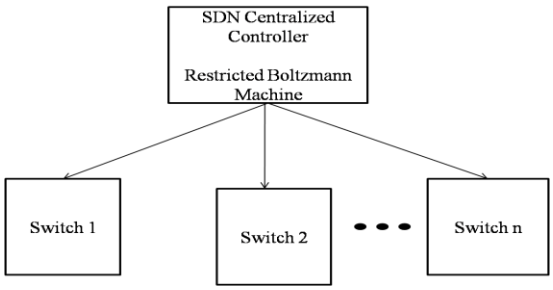

Fig. 5: Experimental Network Setup

V. RESULTS AND DISCUSSIONS

In this section, results are illustrated for various network metrics namely bandwidth utilization of controller and energy consumption of switches. Figure 6 illustrates that bandwidth utilization of controller which can be measured by the generated PACKET-IN request message from the dataplane switch.

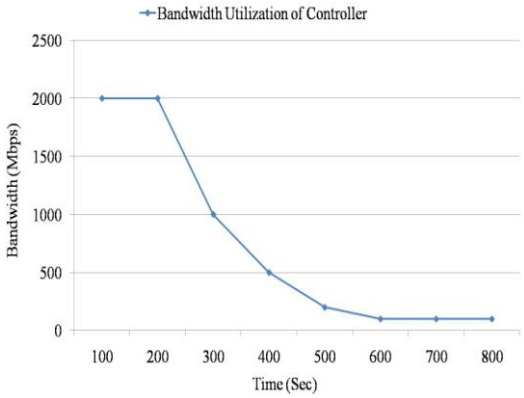

Fig. 6: Bandwidth Utilization of Controller

The inference shows that bandwidth utilization is higher until 299th seconds, when RBM algorithm is deployed in SDN controller at 300th second, bandwidth utilization is reduced gradually and stabilized until analysis with respect to time parameter.

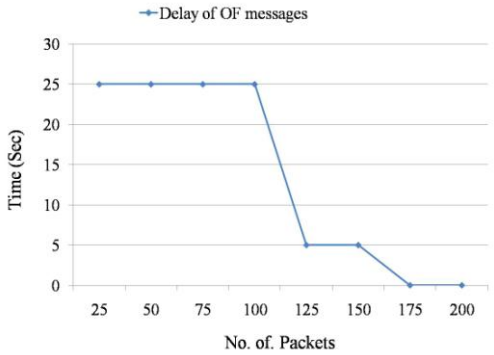

Fig. 7: Delay of SDN Controller

Figure 7 shows the delay of transferring messages from data plane switches and SDN controller. Delay of OF

messages can be calculated based on the Round Trip Time (RTT) originated from data plane switches and SDN controller. When Diffie-Hellman Key Exchange algorithm is deployed at OF protocol, delay parameter is reduced even in case of DDoS attack traffic flows.

VI. Conclusion and Future work

SDN is an emerging fifth generation network architecture subject to active and passive attacks like DDoS attack and traffic monitoring, sniffing etc. The proposed defense mechanism is also deployed with RBM algorithm in SDN controller and Diffie-Hellman key exchange algorithm in Open Flow protocol. The proposed defense mechanism is deployed with RBM algorithm in SDN controller and Diffie-Hellman key exchange algorithm in OF protocol. The proposed defense mechanism outperforms the existing work based on bandwidth utilization, delay of request and response messages from switch and controller, encryption and decryption time of incoming OF messages. The future work is to provide application level security of SDN.

Abstract- Phishing is the major problem of the internet era. In this era of internet the security of our data in web is must. Phishing is one of the most harmful way to stolen the credential information like username, password or account number from the users. Users are not aware of this type of attack and they become a part of the phishing attacks. It may be losses of financial found, personal information, reputation of brand name or trust of brand. So the detection of phishing site is necessary. In this paper we design a framework of phishing detection using URL.

Keyword – Web mining, data mining, phishing URL, Fuzzy logic, Classifier.

I. INTRODUCTION

Day by day number of phishing URLs have grown rapidly. Phishing sites look same like original sites but the code behind the site is different or the link of the page is followed the incorrect path and collect the information from the users. Every time attackers choose the different options to collect the information. Phishing attempts have grown 65% in the last year according to PhishMe's Enterprise Phishing Resiliency and Defense Report.

According to the research in 3rd quarter of the 2017 the percentage count is[1] 41.99% sites are used to steal the information while using the payment gateways online. 17.7% sites pass the phishing mail via mail address. 15.48% possibilities are there to steal the information from the financial institutions.

II. BASICS OF PHISHING:

Phishing has two types (1) Spear phishing : attack on personal information to increase the probability of the attack. (2) Clone Phishing: Attacker mails the link and previously mail containing the phishing site or web fraud.

Whaling: They target the higher profile and business email on behalf of the high profile manager.

Filter evasion: They were target the users as sending the images and send the hidden text on those images.

Website forgery: They own to fraud

Convert Redirect: They will show the login box on their page or give some popup to the site.

Phone Phishing: They will target the people and send the SMS on the mobile phone as a bank authority and can achieve the credential information from the user via fraud SMS. This techniques borrow ideas from the traditional phishing, phone based social engineering techniques and many more new techniques.

Feature extraction process is also defined in the [3] paper. Authors define the group of features and design some rules for features extraction to check the legitimacy of site. First of all author divide all the features set in to the group of feature set, based on that result they calculate the value of True Positive, True Negative, False Positive and False Negative.

III. FUZZY LOGIC MODEL

A. Fuzzification

The Fuzzification of the fuzzy logic is described by the linguistic variables which is the best advantage of the fuzzy logic system. In this step, linguistic values of the phishing variable are design output such as medium, high and moderator. Fuzzification is also known as the decomposing a system input and / or output into one or more fuzzy sets.

Trapezoidal or Triangular shaped method is most common way to divide your result. Mostly result may be dependent on the rules of fuzzy logic. Hence, rules may be differ from one method to another method although the representation of the result is expressed in simple way.

B. Rule Evaluation

Rule evaluation is used to create the rules for the member functions. Every member functions of the input and output has rules in fuzzy logic. They provide fuzzy rules in form of (If...then) for every member function.

C. Aggregation of the rules

Combine the rules of the membership functions consequents previously scaled into the single fuzzy set. All the rules combine in the same manner and it will combine into a single fuzzy set, this process only occurs once for each output variable. This process works only before the finale defuzzification process.

D. Defuzzification

It is the process of transferring the output of the fuzzy set into the crisp output, in our case we can say that the crisp output in terms of Phishing or Legitimate. Centroid technique is used to defuzzify the data.

VI. PROPOSED METHODOLOGY

Web content mining, web usage mining and web structure mining is also a part of the web mining [7]. We follow the Web URL Mining. The source of phishing attacks are mostly from email, websites and malware. The links (URL) provided in phishing emails draws user into entering phishing website. In website based phishing, website is copy of the original website which looks like same but, the aim is different.

To overcome the problem of phishing we design a framework to detect it using the fuzzy logic as a classifier. We used only URL based features for the extraction process[10]. For that we collect our dataset from the Phish tank site, Open phish site and the URL of the website which can live on the web. We were collecting the 1000 URLs for our dataset purpose.

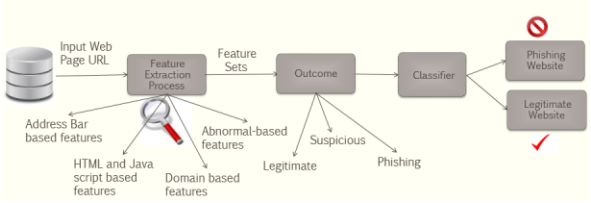

Fig 1. Architecture of the system

Using MatLab tool we code the program which can extract the features from the entered URL. We have different feature sets, out of them we were extract some feature which can based on URL of website. Observed features are conclude in the table 1 [3][4].

TABLE 1
FEATURES OBSERVED IN THE LITERATURE SURVEY

Feature	Legitimate	Suspicious	Phishing
Ip address	Otherwise	-	Exists in URL
Length of URL	-	>=54and <=75	>75
Request URLs in source code	less than 20%	between 20% and 50%	Otherwise
URL of anchor	2	5	Different from anchor
Redirect Page	Correct source <=1	>1and <4	otherwise
On mouse Over	-	-	Use fake URL
Prefix or suffix separated by '_'	Not include	-	Domain part include '-'
Number of '.'	2 dots	3 dots	>3
Number of '%'	2	More than 2	More than 2
Number of '='	2	More than 2	More than 2

URL having '@'	Not present	May be there	Present
Host name	Need hostname	-	-
Popup Window	Not using popup	>2 and<4	More than 4
Age of domain	Otherwise	>1and<2	<1
DNS record	Present	-	Empty
Web page rank 1,00,000	<100000	>100000	Otherwise
Right click	-	Showing an alert	Disable
Status bar	Otherwise	Not change	Change the status bar
Number of '&'	Not present	May be there	Present
Number of '?'	Not present	May be there	Present

V. PROPOSED FEATURES USED FOR IDENTIFICATION OF PHISHING WEBSITE

Long URL

W3 defines the standards and rules for the URL. They were defining maximum54 characters in the URL. Original site not contain more than 54 characters. If length is between 54 to 75 character than it is possible to define the phishing site. It is also known as suspicious site because it may be legitimate also. Maximum numbers of the URL in dataset are defined as phishing due to the long URL.

$$if\{\, URLlength\ < 54\ \rightarrow feature = Legitimate\,\}$$
$$Else\ if\{\, URLlength \geq 54\ and\ \leq 75 \rightarrow feature = Suspicious\,\}$$
$$Else\{\, feature = Phishing\,\}$$

Length of hostname

Hostname has always a fixed length to identify the legitimate URL. When more than 25 characters are present in the URL than it is identifying as phishing site used to make fraud and intentionally collect the credential information from the user.

$$if\{\, Hostname\ length \leq 25\ \rightarrow feature = Legitimate\,\}$$
$$Else\{\, feature = Phishing\,\}$$

Dots:

Number of dotes define the sub domain and multi sub domain in the URL. Top level domain and second level domain is always available in the URL of any website. URL having less than three dots is legitimate sites. If URL having exact 3 dots are known as suspicious site means it may be phishing or may not be; now it is dependent on the other features also.

$$if\{\, Dots\ in\ URL < 3\ \rightarrow feature = Legitimate\,\}$$
$$Else\ if\{\, Dots\ in\ URL = 3 \rightarrow feature = Suspicious\,\}$$
$$Else\{\, feature = Phishing\,\}$$

Slashes

A path with the data is always in a hierarchical form shown as a sequence of a segment separate with the'/'. This feature is also become an important part of the URL when we need to found out the segments of the URL. Less than three slashes are proving the legitimacy of the site. Whereas more than four slashes in the URL is defines as the phishing site.

$$if\{\, Dots\ in\ domain\ < 3\ \rightarrow feature = Legitimate\,\}$$
$$Else\ if\{\, Dots\ in\ domain = 3\ \rightarrow feature = Suspicious\,\}$$
$$Else\{\, feature = Phishing\,\}$$

@ Symbol

'@' symbol leads the browser to ignore everything suffix it and redirect to the link typed after @ symbol. W3 rules says @ symbol rarely used in the real URL. It has low significance because in rare case it is present in the dataset. Only 1% site is phishing out of the total dataset. The probability of this symbol is less according to our research of the dataset.

$$if\{\, URL\ having\ @\ symbol\ \rightarrow feature = Legitimate\,\}$$
$$Else\{\, feature = Phishing\,\}$$

& Symbol

It is one type of the query delimiter to separate the key and value which can be passed through the URL. More than two query variable are passed in the URL cause harm to the website because it shows the value of the key.

$$if\{\, URL\ having\ \&\ symbol\ \rightarrow feature = Phishing\ \}$$
$$Else\{\, feature = Legitimate\ \}$$

 # Symbol

The symbol of '#' is used for the optional fragment. Maximum two optional fragments are used in the legitimate URL. Phishing URL contain more than two '#' symbol. It is optional fragment so rarely present in the URL. It has low significance from all the features. In the dataset of my research are contains only four URLs which has '#' symbol.

$$if\{\, URL\ having\ \#\ symbol \leq 2 \rightarrow feature = Legitimate\ \}$$
$$Else\{\, feature = Phishing\ \}$$

% Symbol

Every URL needs to create in the proper format. But sometimes creator's intentionally put unwanted characters in the URL to confuse the users. Unwanted characters like'%' are present in the URL than it can be a phishing site.

$$if\{\, URL\ having\%symbol\ \rightarrow feature\ Phishing\ \}$$
$$Else\{\, feature = Legitimate\ \}$$

? Symbol

The significance of '?' symbol in URL is more important, however it can be used by attacker to stolen the information from the user. When any developer wants to submit the data of webpage into database at that time question mark symbol is used, but in legitimate sites, this symbol is not used.

$$if\{\, URL\ having\ ?\ symbol\ \rightarrow feature = Phishing\ \}$$
$$Else\{\, feature = Legitimate\ \}$$

DNS Record

Domain Name system stands for DNS. WHOIS database stored the record of the every domain of every URL. We code the program into .net that can provide the connection with WHOIS database and extract the data from the database.

$$if\{\, DNS\ record\ is\ Empty \rightarrow feature = Phishing\ \}$$
$$Else\{\, feature = Legitimate\ \}$$

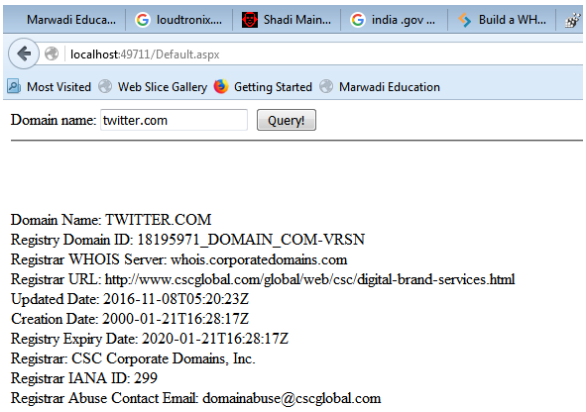

Fig 2. WHOIS Database

For every domain of the URL we check that entered URL is present in the WHOIS record or not. WHOIS database is also known as the third party domain.

Our code connects with the WHOIS database using the port number and extracts the record of entered domain name.

Unicode in URL as PayPal

PayPal is the gateway of the money transferring. PayPal keyword is not used in every URL. Every keyword has its own meaning like 'PayPal' is secured and used when online tractions are done. It follows the proper way to use in URL. Attackers used such type of keyword to confuse the user and to stolen the credential information using the wrong URL.

$$if\{\, URL\ having\ Paypal\ string \rightarrow feature = Phishing\ \}$$
$$Else\{\, feature = Legitimate\ \}$$

We have the three outputs after extracting the features from the URL and that is phishing, suspicious and legitimate. Now, we have the Fuzzy Inference System in the MatLab simulink which can help to decide the output in two forms only named as Phishing and Legitimate.

Now we use the classifier as the next step of our system. We used fuzzy logic for the classifier to classify the suspicious URL into the Phishing and legitimate URL.

For the input and output we have to decide the membership functions and according to those functions rules of the every member are created. According to that rules our final outcome is generated.

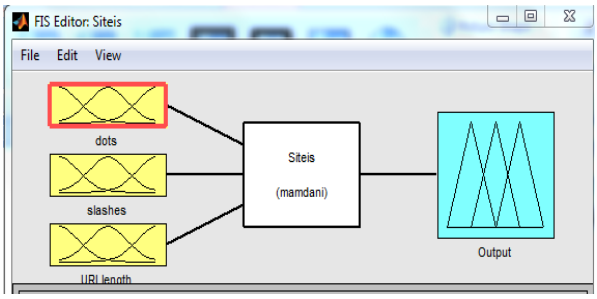

Fig. 3 Fuzzy Inference System design

First of all we design a layer for the features. For the suspicious URL we define the layers to classify it. According to the table1 we can easily examine the significance of the features[12].

Table1: Design a layer for the suspicious site

Criteria	Component	Layer No.
URL & Domain	No. of Dots	**Layer 1**
Weight=0.3		Sub weight=0.5
	No. of Slashes	
Weight=0.2		
Web Address bar		**Layer 2**
	URL Length	Sub weight=0.5
Weight=0.5		

Maher Aburrous et.al [5] designs a layer and a rule for the fuzzy technique. After the design the layer there is next step which is called as the Rule developing. Rules are defined to come with the result which contain either positive or negative in terms of phishing or legitimate[9].

Performance Matrix

There are mainly four possibility exists to find the performance of the system. Four possibility are True Positive, True Negative, False Positive, and False Negative.

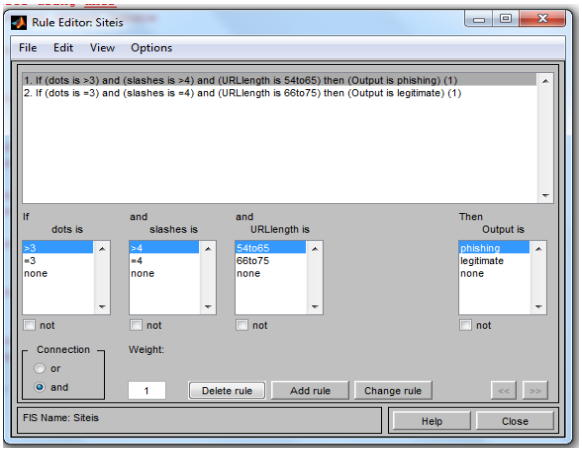

Fig. 4 Rule editor

Assume that Np denotes the total number of original sites Np denotes total number of phishing sites. If $(nh \rightarrow H)$ denotes original URL, then $(np \rightarrow H)$ denotes phishing sites classified as original $(nh \rightarrow P)$ denotes original sites classified as phishing and $(np \rightarrow P)$ denotes phishing sites classified as phishing. The evaluation matrix used in the [6][7].

True Positive Rate: The ratio of the number of phishing sites identify correctly.

$$\text{TP} = \frac{np \rightarrow P}{Np}$$

True Negative Rate: Ratio of original websites identified correctly.

$$\text{TN} = \frac{nh \rightarrow H}{Nh}$$

False Positive: The ratio of number of original websites classified as phishing.

$$\text{FP} = \frac{nh \rightarrow P}{Nh}$$

False Negative: Ratio of number of phishing websites classified as original.

$$\text{FN} = \frac{np \rightarrow H}{Np}$$

Accuracy: Measurement of correctly identifies value. The ratio of true positive rate and true negative rate with the total rate.

$$ACC = \frac{(TP + TN)}{(TP + TN + FP + FN)}$$

VI. CONCLUSION

The group of features is effective in detecting web phishing. Our model constructed using both phishing and legitimate URLs including the features which have been extracted from these models. In this paper fuzzy classifier is implemented using MatLab and the best results are achieved with 91.46% accuracy.

Features of our research are mostly dependent on URL, however using other group of the features user can achieve the best result. Using Different type of data set can be affect to the result of the system. Also the machine learning techniques play the important role as a classifier.

Abstract— The importance of digitally integrated circuit is increasing since it has many features such as low power, reliability, propagation delay and noise margin. An energy efficient technique and a new CMOS (Complementary Metal Oxide Semiconductor) logic family called Adiabatic logic, based on reversible switching principle is discussed in this paper. Adiabatic technique is used to increase energy efficiency of logic circuits. The principle is based on energy recovery in which the power supply recovers the charge without heat generation. Minimum power consumption is achieved when the charging and discharging path has a MOS transistor instead of a diode. The simulation is carried out for 2-bit Array Multiplier using 45nm CMOS technology in Cadence Virtuoso environment. Power saving of more than 40% is achieved by Adiabatic logic circuits in comparison with conventional CMOS circuits but with increase in area. The Gate is controlled by power clocks. The method of switching achieves less power dissipation, but complexity of circuit increased. Energy stored in load capacitor is reused in Adiabatic logic whereas energy is discharged to the ground in case of traditional conventional logic.

Keywords— Conventional CMOS; Adiabatic Logic; Half adder; 2-bit array multiplier; PAL; Clocked CMOS logic; CCAL;

I. INTRODUCTION

The power consumption has become a major design parameter for VLSI circuit designers as VLSI technology is improving day by day. Many technologies have been developed to reduce integrated circuit power dissipation. Adiabatic innovation is one of the promising advancements for low power activity of the circuit. The logic of charging recovery or Adiabatic switching techniques is based on slowing down energy transfer and retrieving charge from logic. Dynamic power consumption of the circuit is reduced by Adiabatic logic [26].

In Adiabatic logic, compelling power saving was achieved compared to conventional CMOS circuits. Adiabatic circuits outputs are valid only during a specific phase of the power clock cycle. Therefore, to drive the Adiabatic cascaded Logic chain, multi - phase clocking is required. [20].

In this paper multiplier using Adiabatic Logic is simulated. The method used to multiply two 2-binary numbers is identical to the multiplication of decimal numbers based on partial product calculation, shifting and combining them. A similar approach but that which is simpler than decimal multiplication is to multiply two binary numbers by multiplying the long multiplicand by 0 or 1, as multiplication by 0 or 1 results either in the same number or zero. A representation of a 2-bit array multiplier is as shown in Fig. 1. The maximum product term can be 11 * 11 = 1001, a 4-bit number.

The rest of the paper is organized as follows. Section II provides review of literature. Section III presents description of conventional design. In section IV Adiabatic logic is discussed. Section V presents implementation of 2-bit array Multiplier using Adiabatic Logics. Section VI presents results and their analysis obtaining during the course of the results and Section VII presents conclusion drawn from result obtained from section VI.

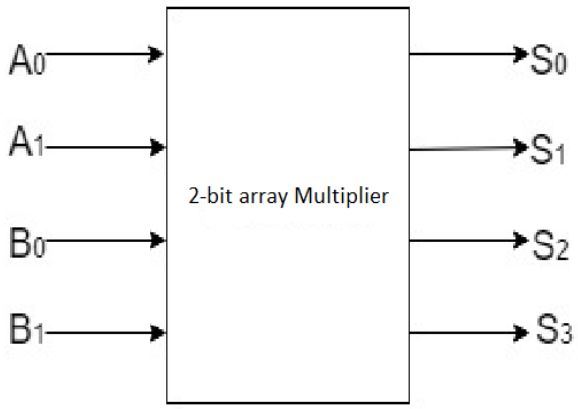

Fig. 1: Block diagram of 2-bit Multiplier

II. LITARATURE REVIEW

A. *Clocked CMOS Adiabatic logic(CCAL)*

He Li et al [15], introduced CCAL technique that is used to reduce consumption of power. Various adiabatic logics such as clocked CMOS, eight level inverter chain CCAL, Quasi Static Energy Recovery Logic (QSERL) are compared with CCAL technique. It has static logic and tristate output which is managed with help of pwr. CCAL has two advantages over QSERL, high operating frequency up to 500MHz and low power dissipation.

B. *Pass transistor Adiabatic Logic(PAL)*

Mahendra Singh Dhaka et al [17], proposed NOR logic Gate using 2PASCL and PAL logics which is simulated on 180nm and 90nm technology to obtain the comparison of significant power saving.

III. Conventional Design

A. Conventional CMOS 2-bit array Multiplier

Multipliers are vital block employed in numerous digital circuits. An overview of the two - bit A_1A_0 and B_1B_0 numbers to produce the four - bit $S_3S_2S_1S_0$ product as shown in Fig. 3. The Multiplication illustrated in Fig. 2 is implemented as shown in Fig. 3. The bits of each partial product are computed by multiplying two bits of the input. Since two-bit multiplication is the same as the logical AND operation, AND Gates can be used to generate the partial products [6]. Half Adders and AND Gates as shown in Fig. 3 are used to implement a 2-bit Multiplier.

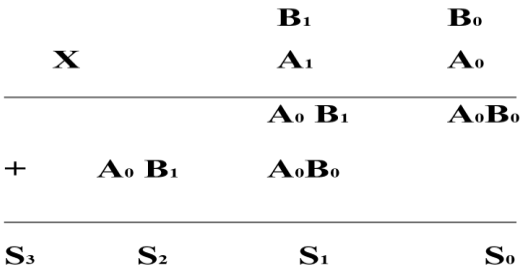

Fig. 2: Illustration of 2-bit Multiplier

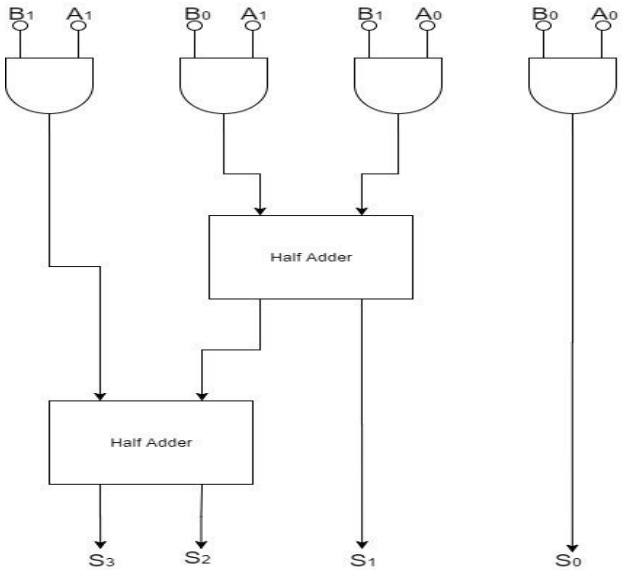

Fig. 3: Block diagram of 2-bit Multiplier

B. Clocked CMOS Logic

Fig. 4 shows the block diagram of a clocked CMOS Gate. It consists of a static logic circuit with clock and /clock controlled tri-state output network. Both P1 and N1 are conducting when clock signal is logic high. Since both the PFET logic block and NFET logic blocks are linked to the output, a standard static logic gate is degenerated by the circuit. When the clock changes from logic one to logic zero, both PMOS P1 and NMOS N1 are in cutoff. Hence the output out is in Hi-Z (high impedance) condition. Both PFETs and NFETs logic blocks are disconnected from the output during this time interval, so there is no effect on the outputs unless the clock reaches the logic one.

IV. Adiabatic Logic Style

Adiabatic word comes from "Thermodynamics" where there is "no exchange of heat with the environment" [22]. But practically this condition cannot be met due to the presence of resistive components in the system or a design. The energy consumption could be minimized in the system by decreasing the switching speed and also obtaining outputs under certain conditions.

In Adiabatic Logic sinusoidal or trapezoidal power source is
in use. As shown in Fig. 5 the output can be analyzed at four phases of the clock namely,

a) Precharge phase

b) Evaluation phase

c) Discharge phase

d) Idle phase

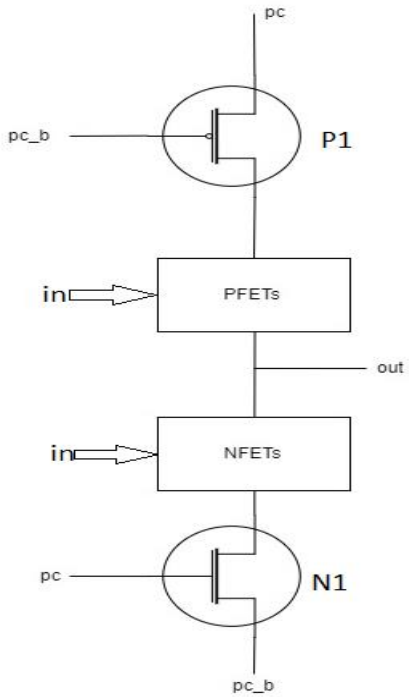

Fig. 4. Block diagram of Clocked CMOS logic

During idle phase/wait phase the circuit is idle. In precharge phase depending upon input the load capacitance (node capacitance) either charge up or does not. In evaluation phase, the output is stable, so that next stage can be analyzed.

Finally, in discharge/ recovery phase the charge is recovered back to power source [23].

Adiabatic Logic is divided into two classes namely,

a) Fully Adiabatic Logic style

All load capacitance charges are recovered in fully Adiabatic circuits and feedback is given to the power supply. Because of which fully Adiabatic circuits are slower and more complex than partial Adiabatic circuits [23].

b) Partial Adiabatic Logic style

In partially Adiabatic circuits a portion of charge stored in the capacitor is transferred to ground, i.e. some heat is dissipated. Therefore, only part of the energy can be recovered, but these circuits can be easily implemented compared to fully Adiabatic Logic circuits [23].

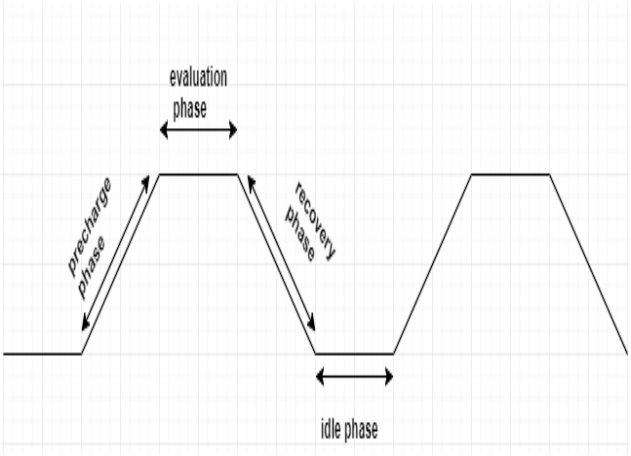

Fig. 5: Four phases of the clock [2]

A. Pass transistor Adiabatic Logic(PAL)

Pass transistor Adiabatic Logic is twin rail Adiabatic Logic with moderately less complex equipment and works through a phase power clock. The basic structure of PAL logic consists of two blocks: memory block and logic block. In pre-charge phase the logic block either charges or discharges based on the input values. In evaluation phase the memory block retains the output values. The inputs make a conduction path from the input to one of the output node when the sinusoidal power clock rises. Output is valid only when sinusoidal power clock at its peak. The supply then tilts down to the zero value from the top, recovering energy stored in the capacitance of the output node. Fig. 6 shows the basic structure of the PAL.

B. Clocked CMOS Adiabatic Logic(CCAL)

Fig. 7 shows the basic structure of Clocked CMOS Adiabatic Logic. Each Clocked CMOS Adiabatic Logic circuit comprises of the CMOS logic component that acts as the logically evaluation component (connected to input) and the clock control component (connected to clock pc) that controls the connection between the logic component and the output node. The CCAL is supplied power by the clock pc and pc_b which are sinusoidal and complimentary.

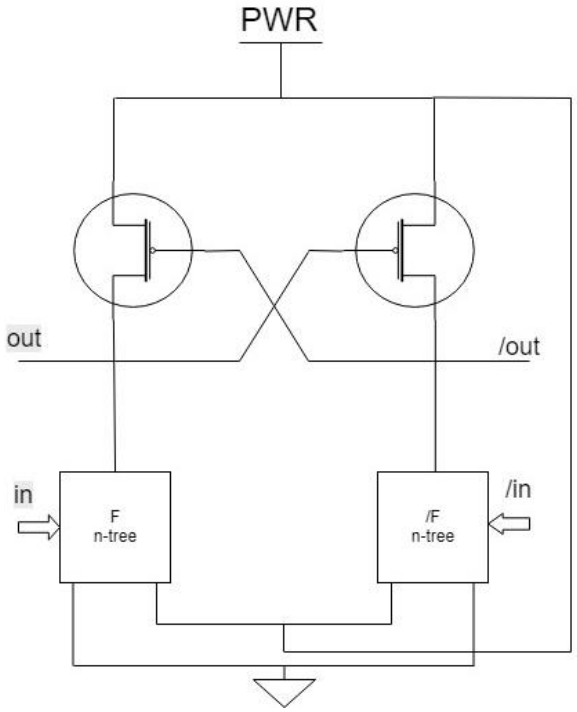

Fig. 6: The basic structure of PAL

V. CIRCUIT IMPLEMENTATION OF 2-BIT ARRAY MULTIPLIER

2-bit array multiplier is designed using conventional CMOS design, Clocked CMOS logic, PAL and CCAL Techniques using Cadence Virtuoso tool 45nm technology with power supply of 1V and 400MHz frequency. For verification of schematic results, the transient analysis is performed by launching ADEL. Graph of the total power is obtained for implemented circuits. 2-bit array multiplier designed using half adders and AND gates are shown in Fig. 3.

A. Conventional CMOS 2-bit multiplier implementation

Fig. 8 shows the schematic implementation of Conventional 2-bit array Multiplier. The 2-bit inputs to the multiplier are a_1a_0 and b_1b_0 and 4-bit output of the Multiplier are $s_3s_2s_1s_0$ bits. Four conventional AND gate and two conventional single bit adders are used to design 2-bit array multiplier. Fig. 9 shows transient response of conventional 2-bit array multiplier.

B. Clocked CMOS 2-bit array Multiplier

Fig. 10 shows the schematic implementation of Clocked CMOS 2-bit array Multiplier. It consists of a static logic circuit that is controlled by clock and clock b with a tri-state output network. Fig. 11 shows transient response of Clocked CMOS 2-bit array Multiplier. From Fig. 11 it is observed that

output is valid only when clock signal is logic high and high impedance when clock is logic low.

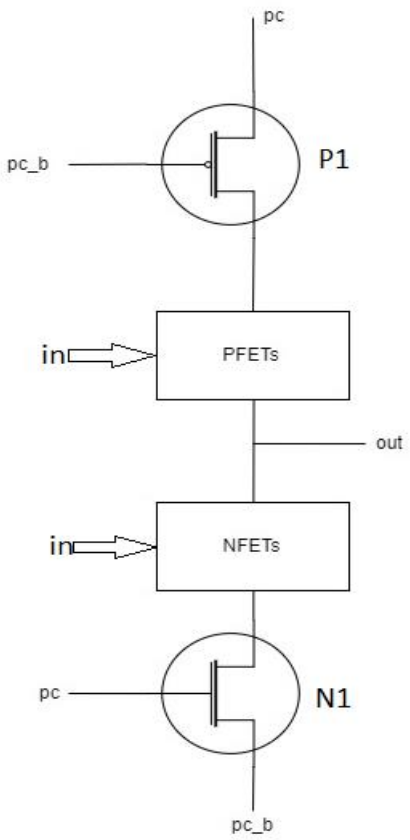

Fig. 7: Block diagram of CCAL

C. PAL 2-bit multiplier implementation

Fig. 12 shows the schematic Implementation of 2-bit array Multiplier using PAL technique. pwr_1, pwr_2 and pwr_3 are power supplies of circuit to drive a cascaded Adiabatic Logic chain [23]. Fig. 13 shows the PAL 2-bit array multiplier's transient response. From Fig. 13 it can be observed that Adiabatic outputs $s_3s_2s_1s_0$ are valid only when the sinusoidal power supply is at its peak value.

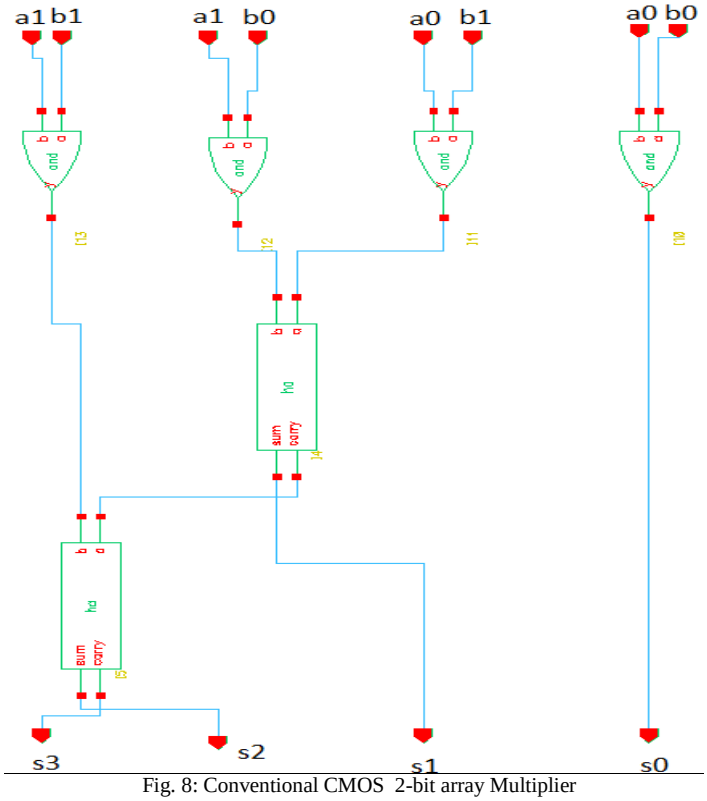

Fig. 8: Conventional CMOS 2-bit array Multiplier

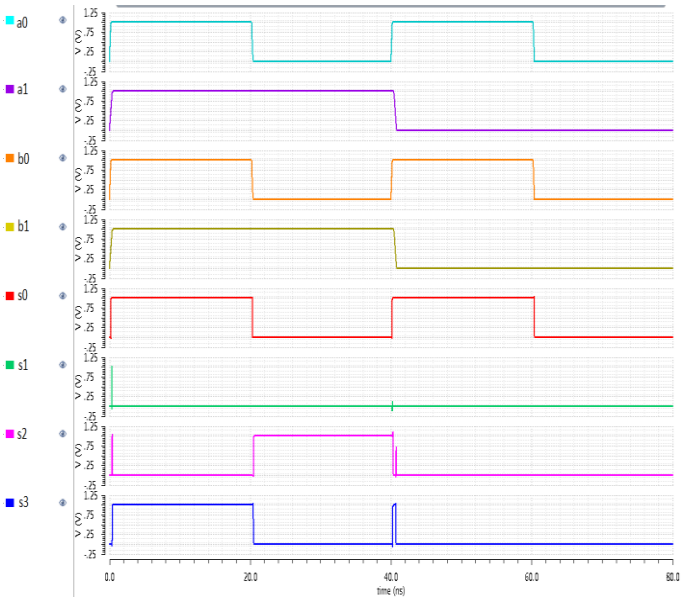

Fig. 9. Transient response of Conventional 2-bit array Multplier

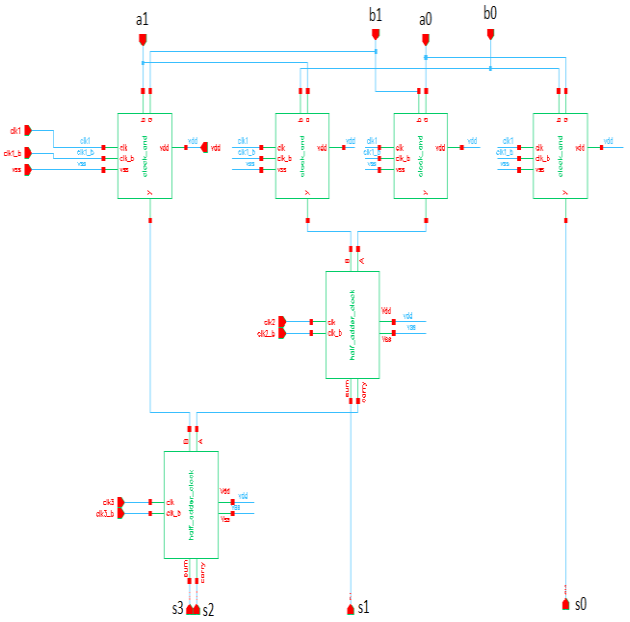

Fig. 10: Clocked CMOS 2-bit array Multiplier

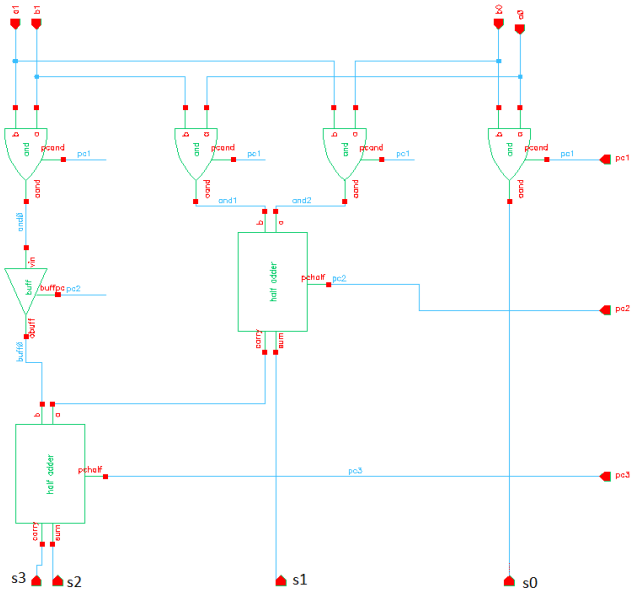

Fig. 12. PAL based 2-bit array Multiplier

D. CCAL 2-bit multiplier implementation

Fig. 14 shows the schematic implementation of 2-bit array Multiplier using CCAL technique. pc_1, pc_2 and pc_3 are power clock of to drive the Adiabatic cascaded logic chain [15]. Fig. 15 shows transient response of CCAL 2-bit array Multiplier. From Fig. 15 it can be observed that Adiabatic outputs $s_3s_2s_1s_0$ are valid only when the sinusoidal power supply is at its peak value.

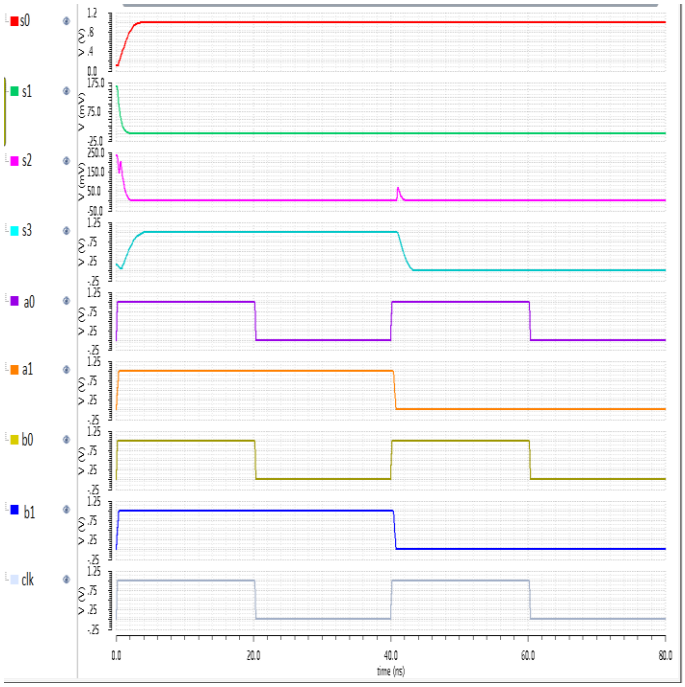

Fig. 11: Transient respond of Clocked CMOS 2-bit array Multiplier

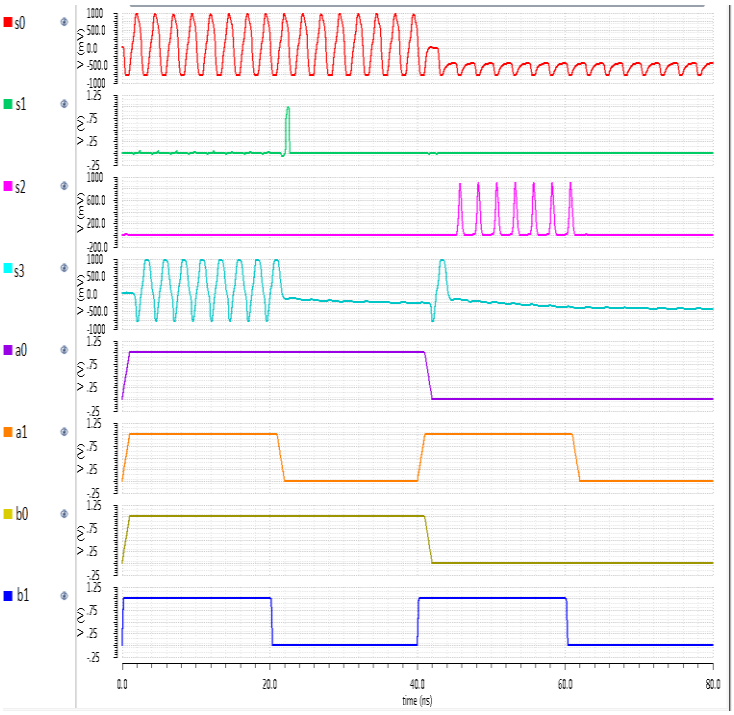

Fig. 13. Transient response of 2-bit array Multplier using PAL

In contradiction to CMOS technique the charge stored in capacitance is recovered by power supply instead of dissipated as heat [23].

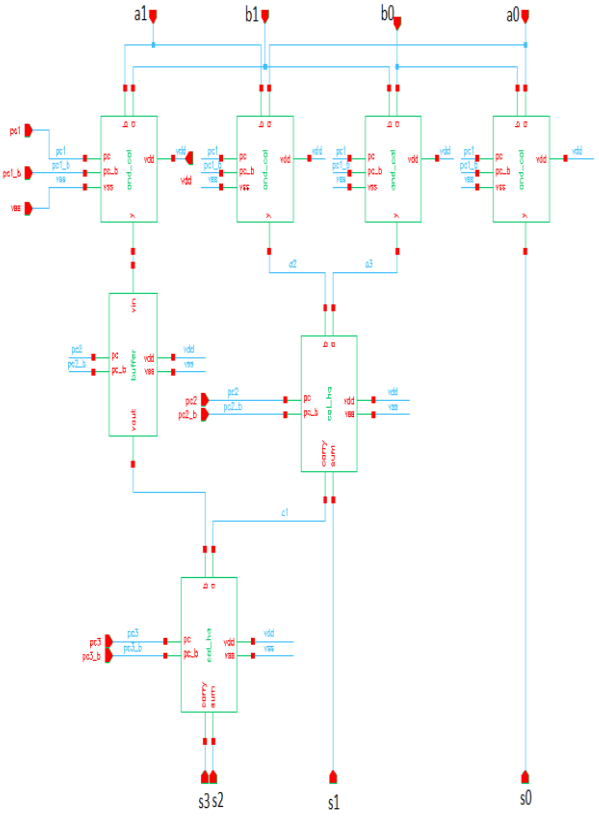

Fig. 12: CCAL based 2-bit array Multiplier

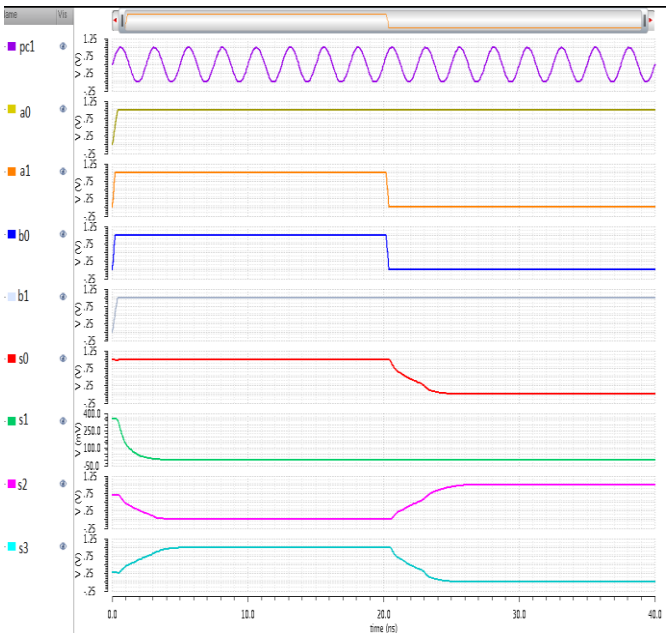

Fig. 13: Transient response of 2-bit array Multiplier using CCAL

E. Power Analysis

Fig. 13, Fig. 14, Fig. 15 and Fig. 16 shows the total power dissipation of 2-bit array Multiplier using Conventional CMOS, Clocked CMOS, PAL and CCAL techniques. Total power dissipation is obtained using Cadence Virtuoso tool.

TABLE I. POWER ANALYSIS OF 2-BIT ARRAY MULTIPLIER

Design Method	Maximum power(μW)
Conventional Design	76.11
Clocked CMOS	94.625
PAL	25.9
CCAL	47.29

Table I. shows the maximum power of 2-bit array Multiplier using conventional CMOS logic, Clocked CMOS logic, PAL and CCAL.

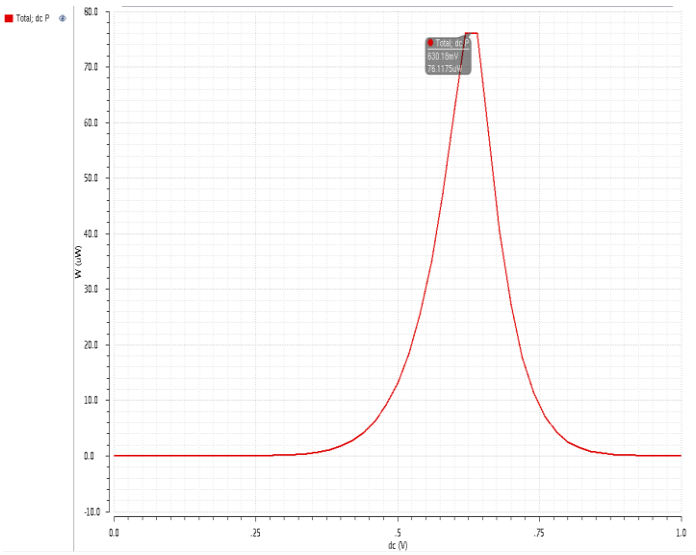

Fig. 14: Total power of Conventional CMOS 2-bit array Multiplier

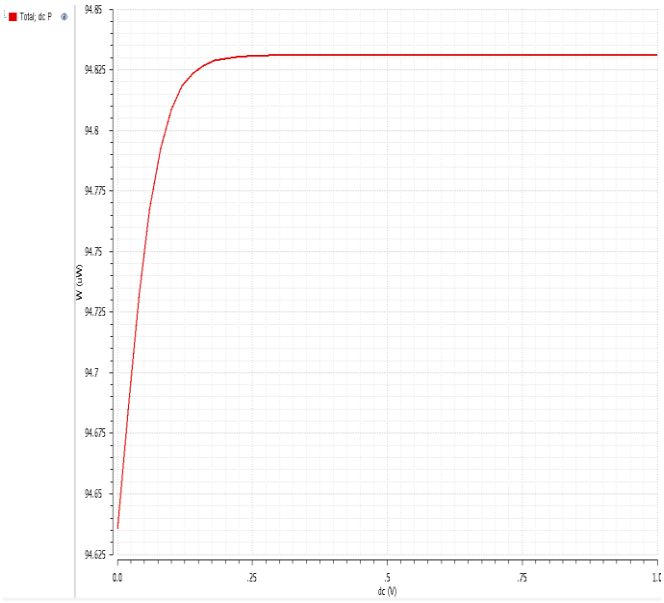

Fig. 15: Total power of Clocked CMOS 2-bit array Multiplier

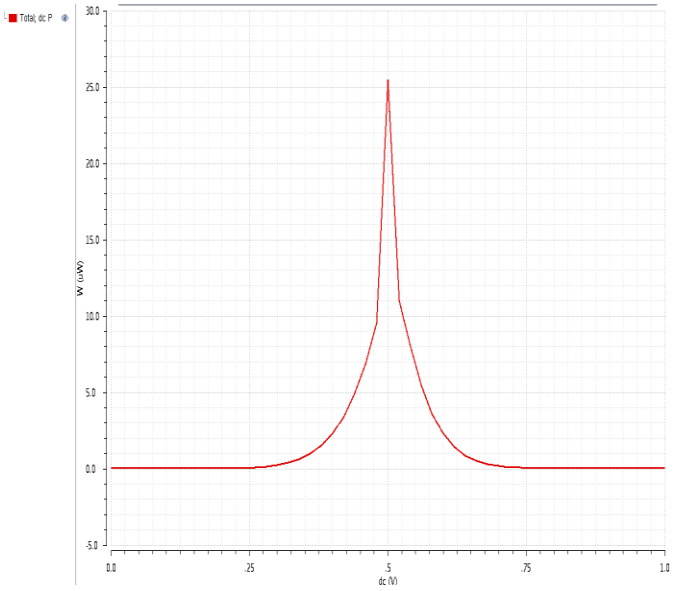

Fig. 16: Total power of PAL 2-bit array Multiplier

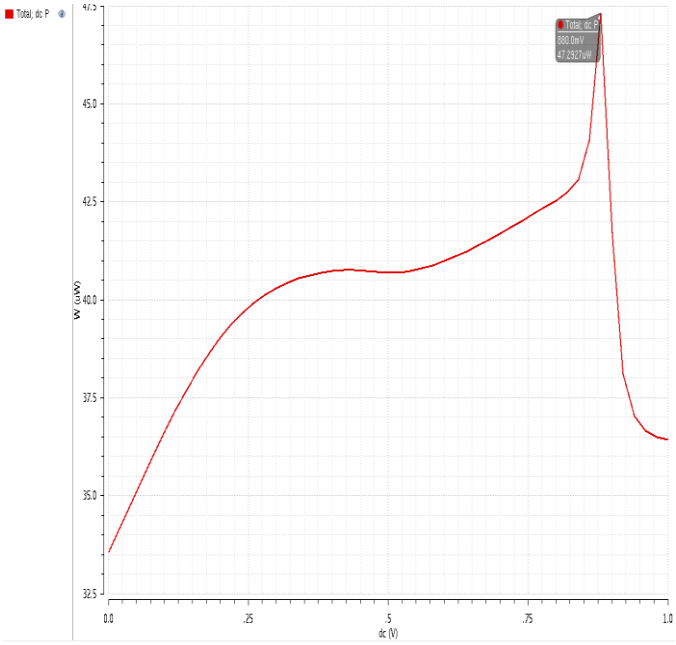

Fig. 17: Total power of CCAL 2-bit array Multiplier

Maximum power consumption of PAL and CCAL logic is less compared to CMOS logic and Clocked CMOS respectively. In CMOS logic and Clocked CMOS logic power is dissipated as heat whereas in PAL and CCAL power is reused. Power reused by turning MOSFETs ON only when they have same potential. When no current flows through MOSFETs they turn off and use a power supply capable of recovering or recycling energy by electric charge. To achieve this, the Adiabatic Logic circuit's power supplies used constant current charging rather than constant voltage charging [18]. From Table I, it is observed that maximum power of PAL is less then maximum power of CCAL.

VI. Conclusion

The 2-bit array Multiplier is simulated and analyzed using GPDK 45nm technology, at 1V, with clock frequency of 400MHz and load capacitance of 0.01 pF for conventional CMOS, Clocked CMOS, PAL and CCAL. From the comparison of the result obtained, the maximum power consumption of the circuit calculated is considerably low in Adiabatic Logic circuits compared to the CMOS circuits. Adiabatic operation promises a significant reduction in power consumption as it reuses the energy stored in the capacitor instead of discharging [17] it to ground and also Adiabatic Logic uses sinusoidal power supply instead of constant voltage supply. It is found that the 2-bit array Multiplier designed using PAL logic consumes less power when compared with CCAL since number of power supply employed in CCAL is more. It is observed that, the circuit area is not increased in CCAL where as there is a 50% area increase in PAL.

Future work includes design and simulation of different multipliers under different Adiabatic techniques. Layout of the Multiplier can be designed in order to find area, delay and other parameters for the same.

Abstract— **In recent years there has been an exponential increase in the number of automobiles available to the consumers. Due to high density of vehicles, the potential threats and road accidents are increasing. The vehicles itself designed in such a way to provide lot of services for users in transit such as toll, infotainment and gaming. The vehicle can able to communicate with other vehicle in order to provide updates about different road situations and dangerous conditions, which results in saving time and lives. This new emerging technology called Vehicular Network (VANET) helps in achieving this communication. The main aim of this work is to develop the prototype for the prevention of chain collisions of vehicles on highways, by sending an indication of collision of the collided vehicle to the preceding vehicles. VANET provides the communication between vehicles and road-side units (RSU) with an aim of providing efficient and safe transportation. The ultrasonic sensor interfaced with the on board unit (OBU) has a controller which detects the collision of the target vehicle and sends the information to the OBU of preceding vehicle. This is accomplished by employing NodeMCUs. Both the NodeMCUs uses user datagram protocol (UDP) to communicate with each other. The RSU provide a hotspot for both NodeMCUs to connect. The present format is a prototype model that can adapted with inputs from different sensors to provide more reliable data to the preceding.**

Keywords— VANET; Collision; User Datagram Protocol; Road Side Unit; On-Board Unit; NodeMCU; Ultrasonic sensor; Target Vehicle; Sensors.

I. INTRODUCTION

Each year many people suffer from different traffic causalities around the world. This leads to the increased investment of financial resources in order to improve the road safety and help the driver by providing assistance. The vehicle internally has its own safety advancements like seat belts, air bags etc. But when during travel the safeness is also being ensured by Intelligent Transportation system (ITS). The major key part of ITS is Vehicular Network (VANET) [1]. VANET is based on the same principle of Mobile Ad hoc Network (MANET) but differs in mobility patterns. The term VANET is first mentioned in 2001 under car-to-car ad hoc mobile communication and networking applications, the networks are formed and relaying of information is done among cars. The architecture of VANET supports vehicle to vehicle (V2V) communication and vehicle to infrastructure (V2I) communication. The communication types are given in Fig.1. This would results in providing applications like road safety, navigation and other internet services.

With the availability of heterogeneous environment, the vehicles in VANET can able to connect with UMTS, Wi-Fi or WiMAX to avail the required services [2]. It is proved that Wi-Fi is the best suitable for vehicles to get access when it moves in high speed. The communication is carried out between vehicles and access points which may be fixed or mobile. The method of dissemination of messages used by the vehicles in VANET environment is broadcasting. This type of message dissemination is done after regular intervals inorder to increase the data rate and resources are get saved. UDP is used to communicate between the two vehicles primarily because establishing low-latency and loss-tolerating connections [1].

There are two vehicular units, the one in the front is termed as target vehicle and the preceding vehicular is termed as host vehicle. Both are connected to the same local network. When the target vehicle is met with a collision, the motor driving the host vehicle is stopped to avoid the collision. This scenario is considered in highways with both the vehicles are assumed to be travelling in the same lane. The collision scenario is depicted in Fig.2.

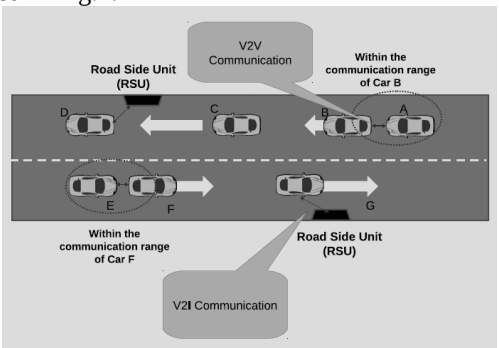

Fig. 1. VANET communication between vehicles and RSU

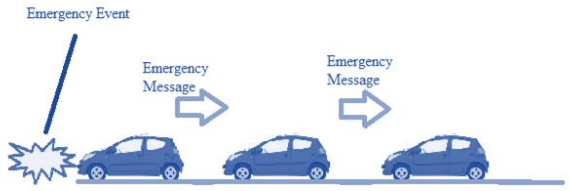

Fig. 2. Application of VANETs in avoiding chain collision

The rest of the paper is organized in the following order:
The recent works on experimental evaluation of VANET is carried out in section II. The methodology adopted is mentioned in section III. The proposed work is presented in section IV. The distance calibration of ultrasonic sensor is given in section V. The experimental setup is presented in section VI The application of VANET is listed in section VII. The future scope of work is given in section VIII and followed by conclusion in section IX.

II. RECENT WORKS

Certain works deals with the implementation of VANET using VNsim, which is a VANET simulator, used to evaluate different VANET technologies. They present novel techniques that substantiate the mobility models of vehicles with good approximation to real-world movement patterns [3]. Previous works deals with the evaluation of performance of V2V and I2V multi-hop communication based on IEEE 802.11b, where the distance and LOS are the factors affecting its performance and have also suggested that the use of ad hoc networks could extend transmission [4]. Others have evaluated the impact of obstructing vehicles on V2V communication using IEEE 802.11p, where the vehicles blocking LOS significantly attenuated the signal [5]. Another also uses IEEE 802.11p standard with 500 byte frame, which obtained the best performance follower by a 50 byte frame which had byte rate decreased by 60% compared to the former. Using a higher byte rate of 1460 was less stable than 500 byte rate transmission [6]. Others have evaluated the IEEE 802.11p standard, which improved safety of vehicles, but have significant downfalls in high dense traffic [7].

III. METHODOLGY

A. Hardware Requirements

- Pic Microcontroller (PIC16F877A) x2
- NodeMCU x2
- Ultrasonic Sensor(HCSR-04)
- L7805 Voltage regulator x3
- L298D Motor Driver x2
- DC motor x2
- Mobile Hotspot

1) PIC16 Series Controller

It is a reduced instruction set computer (RISC) type architecture [8]. It has been made with complementry metal oxide semiconductor (CMOS) type with harvard architecture. The PIC series with this architectcure has separate bus for program and data. The features of the controller is mentioned in Table 1.

The main advantage of CMOS and RISC combination is low power consumption and noise immunity compared to other fabrication techniques. With the use of flash technology the data in the memory is get retained after the power off. It is comfortable to reprogram and erase in PIC16F877A.

TABLE I. GENERAL FEATURES OF PIC16F877A

Parameters	Values
CPU	8-bit PIC
Total number of Pins	40
Voltage needed for operation	2 V > and < 5.5 V
General Purpose Input/ Output Pins	33
Analog to digital Converter (ADC)	Eight Channel and 10 bit
Timer Module	Two 8 bit Timers One 16 bit Timer
Comparators	2
Communication Peripherals	Universal Asynchronous Receiver and Transmitter (UART) , Serial Peripheral Interface (SPI), Inter Integrated Circuit (I2C),

a) Core Features

- High performance RISC CPU.
- It supports instruction in word
- As it is based on RISC architecture the instruction execution takes single clock cycle.
- The clock speed for PIC series is about 200MHz and the time taken for instruction to execute is 200ns
- The stack is about 8 level needed during interrupt servicing.
- The PIC series is capable to support 14 sources of interrupt.
- Power on Reset (POR).
- Power-Up Timer (PWRT) and oscillator start-up timer

2) NodeMCU

It includes an firmware which has Wi-Fi module design for Internet of Things (IoT) applications. NodeMCU is an open source IoT platform. The term "NodeMCU" is actually a firmware works based on Lua scripting language.

a) Steps to program NodeMCU

i) Build the firmware with necessary modules needed.
ii) Perform Flashing the firmware to the chip
iii) Do the uploading part of code to the device.

NodeMCU acts as the communication module between the vehicles in informing about the road situations and further more updates [8].

3) Ultrasonic Ranging Module HC-SR04

The HC-SR04 module provides a non-contact measurement reading from 2cm to 400 cm. The module has four pins which has the function of transmitter and receiver called as trigger and echo pin [10]. The specification of sensor is summarized in Table II.

The basic principle of work:

- It emit short and high frequency sound pulses at regular intervals of time.
- These waves travel with the speed of the sound.
- If it get met with an obstacle it get reflected back as echo which is received by the sensor via echo pin

$$Distance = \frac{Time * Speed\ of\ Sound}{2} \quad (1)$$

TABLE II. SPECIFICATIONS OF ULTRASONIC SENSOR

Parameters	Values
Operating Voltage	+5V
Theoretical Distance measurement	2cm to 450 cm
Practical Distance measurement	2 cm to 80 cm
Accuracy	3mm
Angle Covered	<15 degree

B. Software Requirements

- MPLAB X
- Arduino IDE
- Proteus Professional 7.6

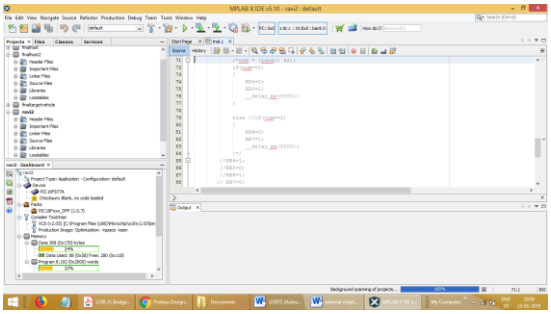

Fig. 3. MPLAB IDE

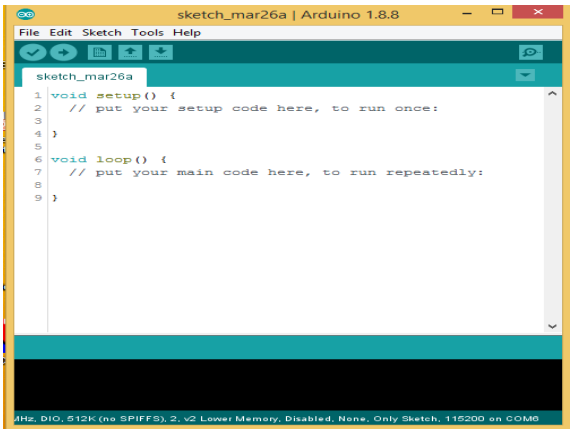

Fig.4. Arduino IDE

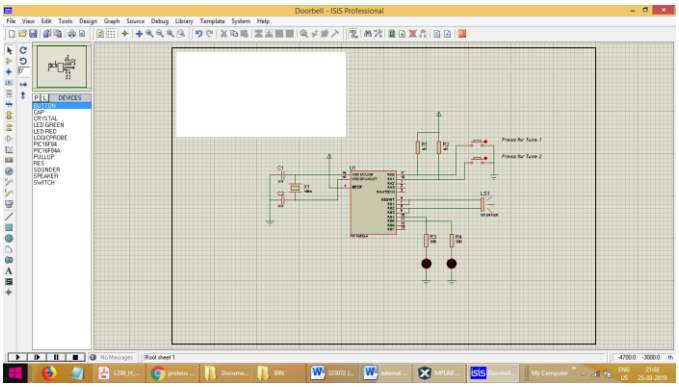

Fig. 5 Proteus Design Suite

The PIC controller is programmed using MPLAB IDE and the environment is shown in Fig. 3. The Wi-Fi module is programmed in Arduino environment and it is shown in Fig.4. The design of the entire prototype is done using proteus software and it is shown in Fig.5.

IV. PROPOSED WORK

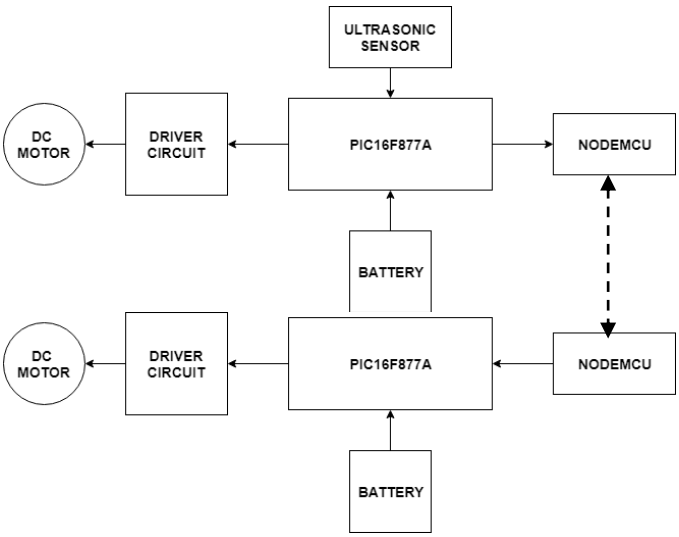

Fig. 6. Block Diagram – a) Target Vehicle b) Host Vehicle

There are two vehicular units, the one in the front is termed as target vehicle and the preceding vehicular is termed as host vehicle. Both units have a Pic microcontroller and a NodeMCU for wireless communication between the two units. The block diagram is given in Fig.6. The ultrasonic sensor is only interfaced with the target vehicle as the distance to collision acts as the real time parameter based on which the two units communicate. When both the host and target vehicle are powered, they connect to the Wi-Fi hotspot which acts as a road-side unit (RSU). After which both the DC motors of the respective vehicular units' starts to rotate depicting the vehicle movement.

When the target vehicle detects an obstacle very close to the ultrasonic sensor, a message indicating collision is passed to the host vehicle and the DC motor of the host vehicle stops rotating. Thus the collision is avoided. This prototype provides the implementation of the VANET using microcontrollers with vehicular to vehicular communication acting as the backbone in this methodology to avoid chain collisions especially in highways.

The circuit diagram is given below.

- The ultrasonic is connected to PORTB with Trigger and Echo of ultrasonic to pins RB1 and RB2 respectively in target vehicle.
- The DC motor is connected to PORTB pins RB4 and RB5 in both the vehicular units.
- PORTB RB7 PIC16F877A is connected to D1 of NodeMCU in target vehicle and D0 of NodeMCU is connected to the PORTB RB2 of PIC16F877A in host vehicle..
- Both driver circuits are powered by 9V batteries separately.

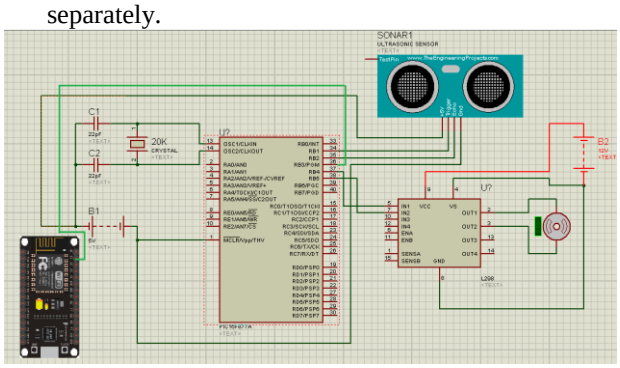

Fig.7. Circuit Diagram – Target Vehicle

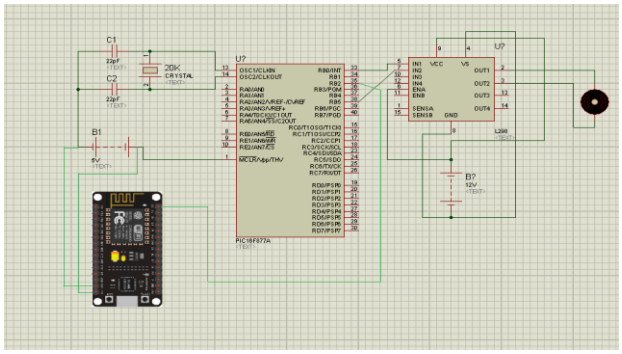

Fig.8. Circuit Diagram – Host Vehicle

The main PIC microcontroller is used to which an ultrasonic sensor and DC motor is interfaced. The NodeMCU is used to take the output from the microcontroller and send the information through the local port to the receiving NodeMCU. The motor driver is connected in between the DC motor and microcontroller. The motor will stop rotating when the distance to collision sensed by the ultrasonic sensor is less than 2cm.

The main PIC microcontroller is used to which the DC motor is interfaced. The NodeMCU receives the message from the other NodeMCU and gives this output to the PIC microcontroller. Upon receiving this the microcontroller stops rotating. The circuit design of target and host vehicle is done and given in Fig 7 and 8 respectively.

The flowchart in Fig.9 gives the flow of the vehicle collision detection using NodeMCU and ultrasonic sensor module.

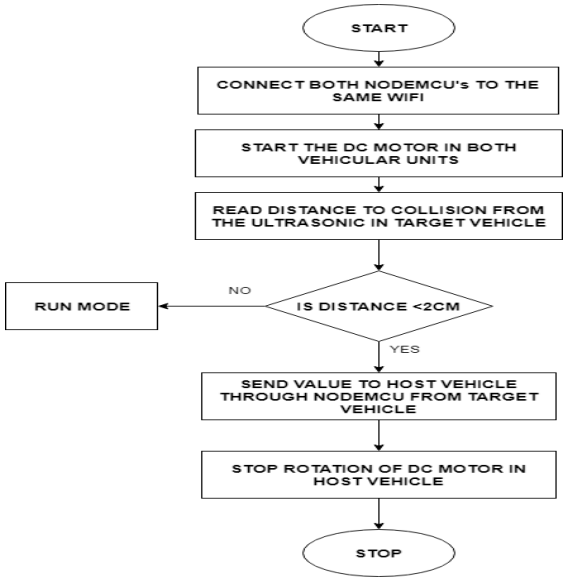

Fig.9. Flowchart of the proposed model

V. DISTANCE CALIBRATION

The pins (1,4,5,7) of PORTB are set as output and pin 2 is set as input. This is done using the keyword TRISB. Timer 2 is used to calculate the distance to collision in ultrasonic sensor use these formulas

$$Time_Taken = (TMR1L|(TMR1H \ll 8)) \quad (2)$$

$$Distance = \frac{0.0272 * Time_Taken}{2} \quad (3)$$

When a high pulse is given to trigger pin of ultrasonic sensor the timer 2 is started. It runs until an Echo signal is received from the ultrasonic sensor. By converting this time information to distance and if condition is given which makes pin 7 high when the distance is less than 2cm. This also causes the DC motor to stop rotating. In NodeMCU, it first connects to the Wi-Fi network and configures the UDP protocol

```
udp.beginPacket(ServerIP, 2000);
udp.write(a,1);
udp.endPacket();
```

Once an input signal is given to the pin 1 of NodeMCU it causes it to send information inn a prescribed local port.

The NodeMCU listens to the prescribed local port at all times. When a message is received it causes the pin 0 to go high. This is read by the PIC microcontroller and stops the motor from rotating by setting the pins 0 and 5 low.

```
TRISB5 = 0; //DC motor pin output
TRISB2 = 1; //RB2 is input pin for Wi-Fi module
TRISB0 = 0; // DC motor pin output
```

VI. EXPERIMENTAL SETUP

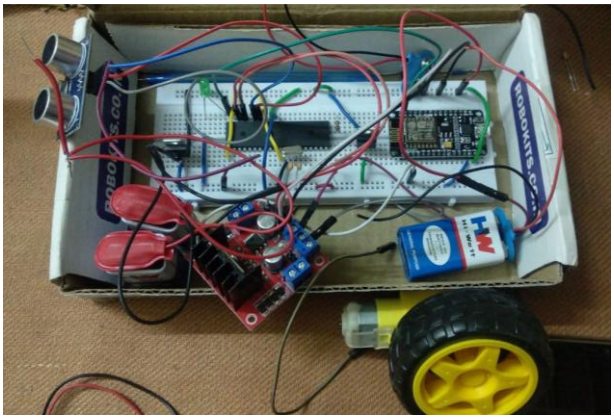

Fig.10. Target Vehicle model

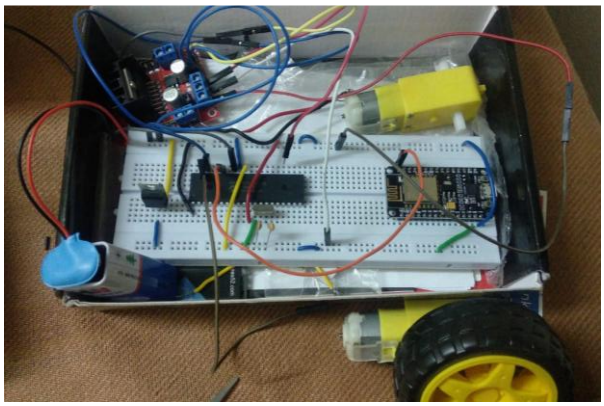

Fig.11. Host Vehicle model

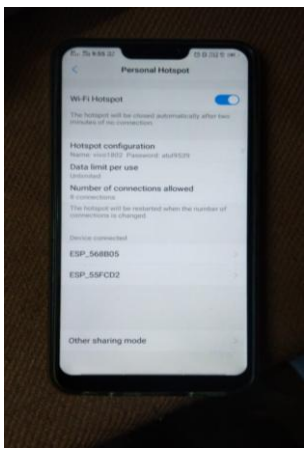

Fig.12. NodeMCU connected to the Wi-Fi Network

The experimental set up of target vehicle and host vehicle is given in Fig 10 and 11 respectively. The mobile is used as hotspot where two Wi-Fi module of host and target vehicles are connected and information got exchanged. The Fig.12 depicts the hotspot for Wi-Fi module.

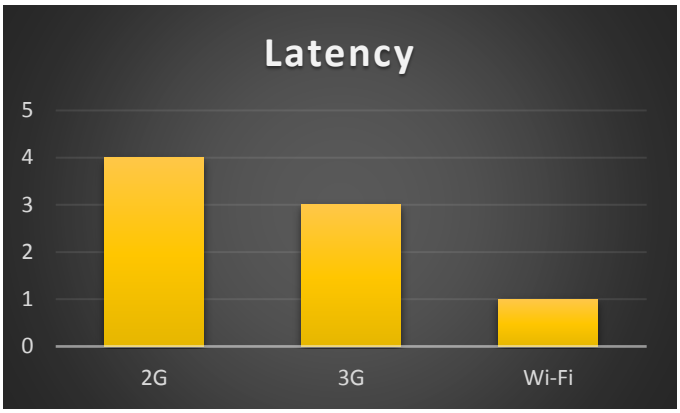

Fig.13 Latency comparison using different network providers

The experiment was conducted using 2G, 3G and Wi-Fi (NodeMCU module). The comparison chart is presented in fig 13. The NodeMCU delivers the messages to neighboring vehicles with less latency which makes the proposed work to provide assistance to driver and to use of safety applications.

VII. APPLICATIONS

THE APPLICATIONS OF VANETS INTO FOLLOWING CLASSES:

A) Safety Applications

- Real-time traffic: The infrastructure unit in VANET is enabled with memory so that all real time information are get stored and it is readily available to the user when they request for it. The real time data can about traffic information, congestion details etc.
- Co-operative Message Transfer: The vehicles in VANET environment are able to cooperate among themselves to exchange messages. Reliability and latency is the major concern but it may automate emergency brakes in case of potential accidents.
- Post-Crash Notification: A vehicle can able to broadcast the warning messages about its position to nearby vehicles.

B) Commercial Applications

- Remote Vehicle Personalization/ Diagnostics: It helps in downloading of personalized vehicle settings or uploading of vehicle diagnostics from/to infrastructure.
- Internet Access: Vehicles can access internet through RSU if RSU is working as a router.

C) Convenience Applications

- Route Diversions: Alternate route can be taken in case of traffic congestion.
- Electronic Toll Collection: Payment in toll can be automated
- Time Utilization: The traveler is able to access net during transit for web browsing and mailing services. The heterogeneous access network provides all requested services for the user.

VIII. FUTURE ENHANCEMENT

The designed prototype can be enhanced by adding more features. The utility of this project can be extended further by increasing the number of sensors to visualize the surrounding environment. This will provide more safety protocols and makes the driving and travelling more safe and enjoyable. Infotainment services can be providing transferring appropriate media through the Wi-Fi network with less latency. The message packet can have more secure protocols so as to stop manipulation of the critical data and to avoid chaos on the roads. With the right equipment it can be implemented on a full scale vehicle and avoid collisions.

IX. CONCLUSION

The designed prototype has all the features to be implemented into a successful commercial model for sales as vehicular equipment. At present there is no cheap technology and haven't been fully deployed on the roads. It has high scope for Indian roads, especially due to persistence of haphazard driver.

***Abstract*— with a lot of people looking forward to greener food and due to declining earth conditions for doing the same, developing a replica of the field from the past century in a small box is a high-time requirement. This is achieved by real-time controlling and monitoring of environmental parameters by designing a space efficient (nullifying the need of balcony farming) and least human interface (in accordance with our busy lifestyle) based system. It is helpful in producing non-toxic vegetables and making the availability of seasonal and exotic crops anywhere anytime. This is achieved by controlling, monitoring and providing environmental parameters like soil moisture, temperature, humidity and light. Real-time monitoring of these parameters and taking necessary control decisions will result in the improvement of yields. Firstly depending on a crop, the required parameters are set and provided by continuous monitoring of the system and when the optimum conditions goes below a threshold value the required action is taken based on the previously stored information. Using microcontroller as a decision maker and Analog-to-Digital Converter along with the sensors to collect the information and to do the needful. This user-friendly application helps in increasing the harvest of organic crops.**

Keywords*— *Indoor Artificial Environment, Real-time monitoring, Arduino UNO

I. INTRODUCTION

There is a constant need for saving agriculture due to the decreasing land space and corresponding climatic conditions. Due to various political and economic reasons the farmers are finding it difficult to survive. Also as the climatic conditions have changed drastically over the past few years, providing the exact required optimum conditions is not possible. Additionally to give more yields out of less available resources, farmers have switched over to chemical methods which over the years proved to be harmful to the human kind. With more people getting awareness about the harmfulness of these chemicals, they are opting towards organic products which are not readily available without any adulteration. So a solution to the problem is to have our own plants and harvest out of it. But this is not possible in an urban household where there is no space. There are places that suffer adverse climatic conditions, where growing what we need is not possible for that environment. So in order to overcome all these problems, a novel design which is completely organic and can fit within the urban kitchen space and which can also provide the liberty to try any exotic plant from any part of the world right in the kitchen has been proposed. It is designed with maximum automation as possible, so there is less human intervention which is in accordance to urban lifestyle. This cultivator uses a microcontroller as the brain to which the required programs are uploaded and the system is controlled [1]. There is a real-time monitoring and corresponding controlling of plant parameters like soil moisture, humidity and temperature. Arduino Uno microcontroller is used. This controller has input/output pins which are easily compatible with most of the sensors in comparison to the other microcontrollers [2]. Arduino is much cost effective and is an open source computer hardware and software company. Any variations in the requirements will trigger the corresponding response. The initial setting of the soil is the only parameter where human hands are required in this proposed work, hence maximizing the automation. Below is the description of the hardware used to build the prototype, followed by system design and experimental results with pictures. The paper is concluded with final observations and its future scope. Finally the paper ends with acknowledgement and the list of references.

II. HARDWARE RESOURCES

Some of the main hardware components used is detailed below:

1. ARDUINO UNO:

It is the brain (micro-controller) of the system. Three Arduino boards have been used in this system. One consists of the LCD screen and the keypad to take the required input from the user, the second one contains all the sensors and their corresponding actuators and the last one is for the grow light. The first two boards work in master-slave fashion, whereas the last one is kept separate to avoid the delay of the system performance. It is open source software and is easily compatible with most of the sensors. Hence, this micro-controller is chosen.

IEEE Conference Record #45982; IEEE Xplore ISBN: 978-1-7281-1261-9

2. DHT 11 SENSOR (TEMPERATURE AND HUMIDITY SENSOR):

Fig.1 DHT11 MODULE

This device has two different sensors incorporated in it as shown in Fig.1. The humidity sensor consists of two electrodes sandwiching a moisture holding substrate. The change in humidity causes respective changes in the conductivity or resistance between the electrodes which is in turn converted to the required value in humidity. The temperature sensor uses a thermistor, which is a variable resistor whose resistance changes with the temperature.

3. SOIL MOISTURE SENSOR:

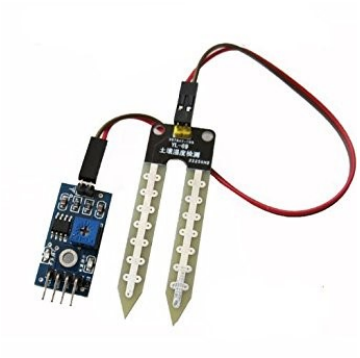

Fig. 2 SOIL MOISTURE SENSOR

This sensor consists of two electrodes which creates a voltage proportional to the permittivity of the dielectric medium between them which in turn gives the water content of the soil as shown in Fig. 2.

4. GROW LIGHT:

Fig. 3 GROW LIGHT

It's an artificial sunlight used for plant growth which provides the exact spectrum required for photosynthesis akin to that of the sun [9]. The Arduino board used for grow light as shown in Fig.3 is programmed to switch the light ON and OFF according to the average photo-period requirement of the plant which is six hours.

5. HUMIDIFIER:

Fig. 4 HUMIDIFIER

This system uses a wick of paper, foam or cloth which draws the water and makes the air absorb the moisture which is then vibrated in ultrasonic range to atomise the water as shown in Fig.4. This is activated in response to the drop in humidity than the optimum required value.

6. LCD (16X2) DISPLAY:

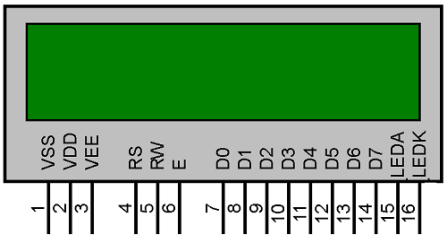

Fig.5 PIN DIAGRAM OF LCD

An LCD display, whose pin diagram is as shown in Fig. 5, is used to give suggestions on the different types of crops available. The data and the optimum parameters are collected for three crops-spinach, coriander and fenugreek. Table 1 shows the parameter requirements of these crops.

Table 1 LIST OF PLANTS AND THEIR PARAMETERS

Sl. No.	Plant	Temperature	Humidity
1.	Coriander	4-24 ^{O}C	30-50%
2.	Spinach	15-35 ^{O}C	60-80%
3.	Fenugreek	8-27 ^{O}C	30-40%

7. HEXADECIMAL KEYPAD (4x4)

Fig. 6 KEYPAD (4x4)

From the different crops displayed on the LCD, a crop is selected to the seed sown, one of the plants is selected using keypad as shown in Fig. 6. Column scanning method is used to program the keypad.

III. SYSTEM DESIGN

The project is designed to create an artificial environment for the optimum growth of the plants where the optimum required conditions are supplied, maintained and controlled as shown in Fig. 7a. In this design three Arduino boards are used to compensate the lack of input/output pins in a single Arduino board required for the design. Here the sensors and their corresponding actuators are connected to the Arduino (Slave) and keypad and LCD is connected to the Arduino (Master) and these two Arduinos are interfaced to each other by master-slave configuration to work according to the required specification.+5V DC power supply is given to the boards through the USB cable.

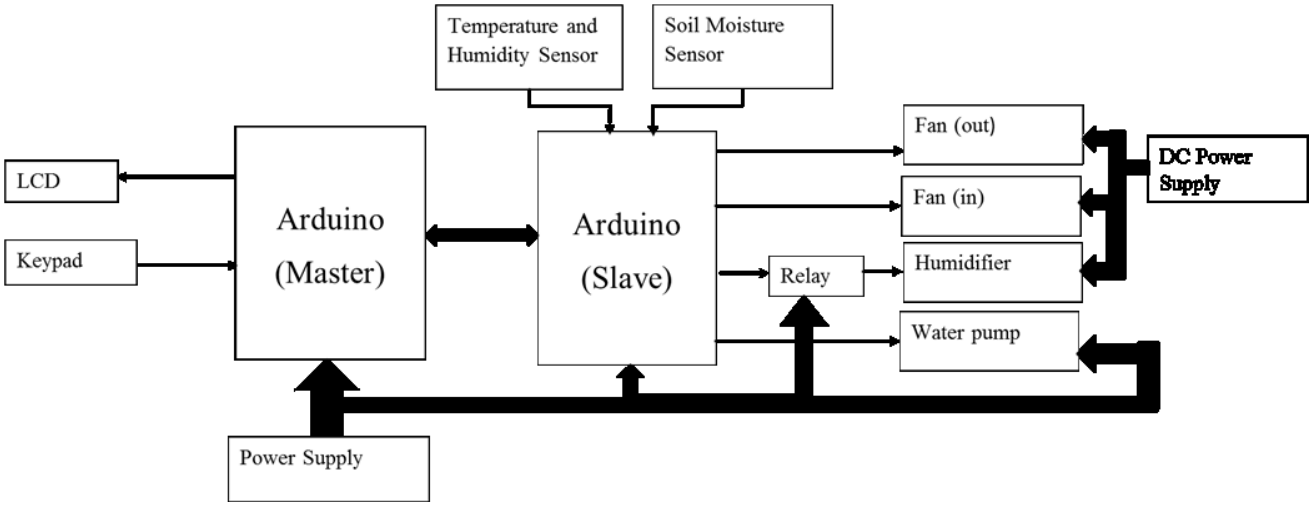

Fig. 7a BLOCK DIAGRAM OF THE PROPOSED SYSTEM

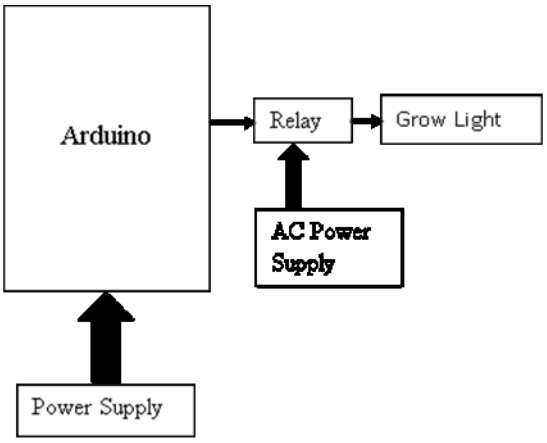

Fig. 7b BLOCK DIAGRAM OF THE PROPOSED SYSTEM

The keypad is used to select a plant out of a list (which contains three kinds of plants: Spinach, coriander and Fenugreek) displayed on the LCD. Threshold parameter values for each plant is stored in the microcontroller so by selecting a particular plant the corresponding plant threshold parameter value is taken and the setting of the microcontroller changes accordingly.

In the design the temperature sensor, humidity sensor, soil moisture sensor are connected to the analog input pins of the controller which receives the analog values from the sensors these values are compared with the defined range of values accordingly fan(OUT), fan(IN), humidifier, water pump correspondingly will be turned ON and OFF. Grow light is connected to the digital output pin via a relay to the third Arduino which is used to control the light as shown in Fig. 7b. , whereas humidifier is connected to the digital output pin of Arduino (Slave) to regulate humidity inside the device. The LCD assures if the plant has got selected or not. Hence the artificial environment is provided to the plants for their optimal growth. The flowchart explains the complete design of the model as shown in Fig. 8.

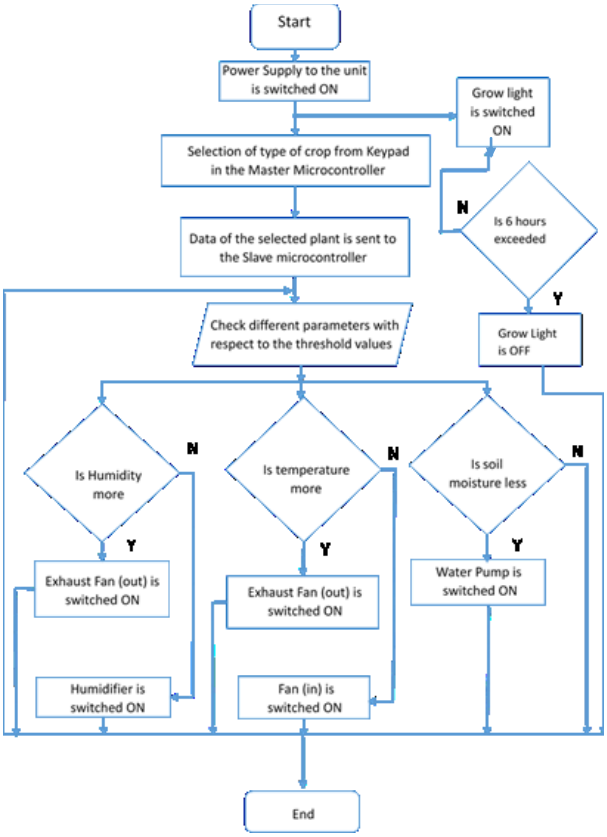

Fig.8 FLOWCHART OF THE PROPOSED SYSTEM

IV. EXPERIMENTAL RESULTS

The prototype of the design is as shown in the Fig 9a. The sensors and actuators are connected to the Arduino boards which respond in accordance to the way it is programmed using Arduino Uno Software. For experimental purpose, a spinach plant was grown inside the device. According to the parameters defined for spinach, the corresponding actuators were observed to be working under the supervision of the sensors.

Fig. 9a Front view of the prototype

1. As soon as the system is switched ON, LCD screen displays the available plants which can be grown in this system, whose parameters are pre-loaded in the Arduino memory.

2. Depending on which crop has to be grown, respective number is chosen through the keypad.

3. Once the number is chosen, the entire set of optimum parameters are sent from the master to the slave and hence the required actuators are activated. The grow light switches ON/OFF according to the plant requirements programmed as shown in Fig. 9b.

4. The soil moisture sensor senses the moisture content of the soil, if it goes below the threshold, then that information is provided to the microcontroller. In turn it switches ON the water pump. Once the requirement is met the water pump is turned OFF.

5. The temperature sensor part of the DHT sensor continuously monitors the temperature of the system. If it is below the threshold Fan (IN) will be switched ON otherwise Fan (OUT) will be switched ON for air circulation as shown in Fig.9c.

6. The humidity sensor part of the DHT sensor monitors the relative humidity of the system. If it is below the threshold humidifier will be switched ON otherwise Fan (OUT) will be switched ON.

Fig. 9b Internal view of the prototype

Fig. 9c Top view of the prototype

V. CONCLUSION

The objective was to design and create an artificial environment for the optimum growth of a plant in an urban kitchen space where the optimum required conditions are supplied, maintained and controlled.

1. When the soil moisture is less than the required quantity the water pump will be switched ON providing sufficient amount of water to the plants.

2. When the humidity is less than the threshold, humidifier will be switched ON else the Fan (OUT) will be switched ON.

3. When the temperature is less than threshold Fan (IN) will be switched ON while Fan (OUT) will be switched ON otherwise.

4. Grow Light will be switched ON and OFF for every 6 hours which compensates the average sunlight requirement for the plants.

The plant cultivator device can make a vegetable plant grow in its artificial environment which is automated in giving necessary conditions for its healthy growth. It can be implemented in urban kitchen spaces and can also be used in restaurants where quality of food is given at most importance. This addresses the problem of rising cost of vegetables and it provides organic vegetables.

It has characteristics of space and cost efficiency and also save time in monitoring the plant. Sensors and its corresponding actuators reduce the effort of the user. It is eco-friendly as well.

VI. FUTURE ENHANCEMENT

This system can be expanded in the following directions:

1. It has only default three plants stored in Arduino's memory. It can be modified in such a way that users can add new plants by using the SD card.

2. It can be used for research purposes of plants in indoor environment by including data logging.

3. Heating Element can be used for increasing heat inside the device so that the device can be used in extreme cold climatic conditions.

4. GSM technology can be used to receive messages regarding plant environment and growth.

5. For more controlled plant growth CO_2 sensor can be used to provide enhanced accuracy of the plant growth.

VII. ACKNOWLEDGEMENT

The advancements in technology that we see today are the perseverance and brain of many engineers. The fact that engineering is creating a significant reform in the way of life of the society for good reasons is what we take pride in as engineers.

We would like to convey our sincere gratitude to Amrita Vishwa Vidyapeetham for providing us with the necessary infrastructure, also to Karnataka State Council for Science and Technology (KSCST), IISC Campus, Bengaluru a wing of Karnataka state government which recognises the projects and provides funding for the projects to carry out the projects based on real time solutions for the problems that is encountered in the society. This work is funded by KSCST under the category 41st Students Project Programme for the academic year 2017-2018 and has been selected for the state level exhibition.

***Abstract*—Intrusion detection system(IDS) is a preventing measure against different harmful cyber-attacks. It has a key role in securing our information and communication technology system. As the internet evolved, the dynamic growth of network traffic data generated which become a challenge for traditional machine learning algorithms. Performance of a classifier solely depends on feature selection and classifier. Traditional machine learning algorithms can't perform well with huge network traffic dataset. So ML algorithms are not optimistic. In this paper, we implemented Convolution neural network(CNN-1D) for NIDS(Network Intrusion detection system) on NSL-KDD benchmark dataset. CNN automatically fetch network traffic features from the dataset. in this paper, we trained our model 500 epoch. We also compared performance of different ML(machine learning) algorithms & DL(deep learning) approaches with our CNN-1D approach with metrics of AC (accuracy), DR (detection rate) and FAR (False alarm rate).**

***Index Terms*—IDS, CNN (Convolution neural network), Deep learning, Machine learning, NSL KDD**

I. Introduction

The Internet emerged as a essential way of life for every individual. Rapidly development in computer technology, the Internet transformed the way of living, studying and working environment. Attackers use this development as an opportunity to exploit the Information system. Different type of cyber-threats is increasing day by day which is very harmful to information safety. These attacks are threats for security measures availability, integrity, and confidentiality. Here we have a challenge that how can we identify various network attacks, more especially unforeseen attacks. That why many researchers focused on network security. There are many ways to protect the network from an intrusion i.e. encryption, firewall, authentication,antivirus and IDS. The advantage with IDS is that it can detect abnormal behaviors of security threats before it happens[1]. It provides a better way to identify the attacks than other protection mechanism because it can identify the attack from the network traffic flow. Detection of intrusion is very similar to classification problems such as the problem of binary or multi- class classification, i.e. differentiating the behavior og network traffic is normal or abnormal.So multi-class problem into 5 class classification problem i.e. detect whether this belongs to a normal or any four types to malicious attacks: DOS (Denial of Service), Probe (Probing), U2R (User to Root) and R2L(Root to Local). in fact, our primary objective of IDS is to effectively identify the intrusive behavior. When traffic of network is correctly classifying the malicious attack, then the network administrator would take preventing measure to protect network accordingly.

John Anderson in 1931 introduced a significant work on Intrusion detection in his research paper. Depending of the behavior of network & network types intrusion detection broadly classified into two main categories (1) NIDS:NIDS abbreviated as network intrusion detection & it performs the inspection on the content of the network packet to identify intrusive or harmful behavior in the traffic of network. (2)HIDS:HIDS abbreviated as host intrusion detection and it performs deep investigation on log files, system files, file structure, system log files and other type of logs in every system. In real life application, many organizations implemented the combination of NIDS and HIDS. In this paper, we target the NIDS for intrusion detection.

On the basis of classification and analysis of network traffic,IDS detection methods are divided into 3 main categories: 1)Misuse or signature-based detection. 2)anomaly-based detection and 3)state full protocol detection. Signature-based detection works on the predefined rules and signature. Networks administrator have to write/update a signature to their database for a different attack.They are used to effectively detect the known intrusion or attacks with almost zero FARs. Even though signature-based detection has a high ability to detect known attacks, they are less applicable in real time due to their ineffectiveness to identify the unknown or unforeseen attacks. These unknown attacks can be detected only once they got identified by some other technique or we tagged the signature manually.To identify the unknown attacks,anomaly-based detection works on the heuristic approach. Anomaly-based methods analyze the normal behavior and current behavior of network to detect anomalies as deviations from normal behavior. The main problem with anomaly-based techniques is that they have a high false alarm rate because sometimes they categorized previously unseen system behavior as an anomaly which is actually not an anomaly. To tackle the problem of high false alarm rate, organizations use the hybrid approach of Signature-based and Anomaly-based detection.

Every machine learning technique comes under shallow learning and they mainly focused on feature selection and feature extraction,so they can't efficiently tackle the problem of intrusion data classification of huge networks that comes in

the real-time network environment. With the rapid increment in the size of datasets, many classification problems results in drop in accuracy. Machine learning is not fit for effective analysis and forecasting requirement of high dimensionality with dataset. In shallow learning, features selection process takes long time and need expert knowledge. The effectiveness of most ML algorithms hugely depends on the selected features. On the other side, deep learners extract features automatically from the dataset and help to extract better representation to create better models.

II. Related Works

Professor Hinton [2] introduced the concept of deep learning in 2006, afterward various new models proposed by many researchers. Thus deep learning becomes a subpart of machine learning field. In recent years, many research papers and implementation models developed and generated remarkable development in field of computer vision, image recognition [3] and action recognition [4]- [6]. Although deep learning has been around for decades but due to limited computed resources, it's not implemented. The true potential of deep learning has been recognized widely when Convolution neural network (CNN) has recently established remarkable development in the field of deep learning [7]. There are various papers comes on which ML methods are applied for detection of intrusion. M.N. Mohammed [8] applied SVM to identify intrusion in WLAN (wireless local area network). W. Feng [9] done intrusion detection using combing SVM and ant colony optimization. H. Wang [10] develop a framework which is based on SVM (support vector machine) and in this paper they augmented the features of their dataset. G. Kim [11] uses decision tree for anomaly detection with signature detection. A.S. Eesa [12] uses decision tree for feature selection using cuttlefish optimization algorithm. A. Sharma [13] uses artificial neural network with reduced feature set. Papers [14]- [17] uses Naïve Bayesian approach for intrusion detection. Although for Optimization purpose, Genetic Algorithm used in many papers [18]- [21]. A.A. Aburommman [22] applied an ensembling method using SVM, KNN, and particle swarm optimization techniques for IDS. W. Li [23] applied KNN classifier to wireless sensor network. C. F. Tsai [24] wrote a review paper in which he applied a hybrid approach of various Ml algorithms to classify the harmful traffic.

Performance of a machine learning classifier solely depends on feature we selected during feature engineering. Another limitation of ML classifiers that they are unsuited for huge network where network traffic data is generated at very fast rate. To process this huge traffic data machine learning algorithm are not fit because they not only minimize the accuracy but also increases calculation cost and time. To ensure the security of a network, a good IDS archives a good accuracy in less time. Therefore, we implemented deep learning model to identify the intrusive behavior of the huge network accurately and within time.

E. Hodo [25] briefly discussed the previous work done under shallow and deep learning for the intrusion detection. N. Gao [26] introduced deep belief network (DBN) for the intrusion detection in which training and back propagation performed by Restricted Boltzmann machine (RBN). J. Yang [27] uses the combination of RBN and SVM, in which RBM performed feature engineering and selection while SVM used for training the data comes from RBN to increase training speed.

Due to advancement in technology and processing power, GPU (Graphical process Unit) can perform intensive calculation. They also supported distributed and parallel computing which helps to train the deep learning models easily. Q. Niyaz [28] used auto encoder technique for features selection in unlabeled data and on the second stage for classification purpose they used Random tree or J48 algorithms. J Kim [29] proposed RNN (Recurrent neural network) for intrusion detection, in this paper they used network traffic as a sequence for RNN. H. Sak [30] used LSTM (Long Short Term Machine) that is a variation of RNN for acoustic modeling at large scale. D.Gibert Llaurado [31] applied CNN on the malware classification. In his paper he presented two cases, in first case data converted in gray scale image and features are learned from those images. In the second case, the deciding factor for malware classification was x86 instructions. B. Kolosnjaji [32] used system call sequences for malware classification using CNN. R. Upadhyay [33] used first time CNN for the Intrusion detection system. K. Wu [34] implemented Convolution Neural network using CNN. In his paper, he converted 1*122 dimensional feature vector into 11*11 image data and applied CNN on this image dataset. In this paper he improves the classification accuracy of intrusion detection on NSL- KDD dataset using a variation of CNN model.

This paper is ordered as per section given below sections. Section II comprises proposed methodology and in this step, we discussed every step of our model. Under this section, there are some subsections are presented like A) Dataset description B) Data preprocessing C) Methodology D) Evaluation metrics. Section III contains the experimental result and discussion. And last section IV contains conclusion and future work.

III. Proposed Methodology

Here proposed intrusion detection model using CNN contains the following four phases:

Phase 1: Data Preprocessing – This step involves data unifying process and data normalization. To fit the data to our model categorical data converted to numerical data.

Phase 2: Training – This step involves building the relationship among different features of independent variables and tuning the parameters to improve the accuracy of the model.

Phase 3: Testing - Testing step involves a process in which a subset of original dataset chooses for testing purpose against training. If we are not satisfying with accuracy of model, then model will repeat the training phase again.

Phase 4: Evaluation – This step involves evaluation process of model performance. Evaluation metrics in figure 1 showed above four steps of intrusion detection using CNN and proposed our CNN-1D model for NIDS in this paper.

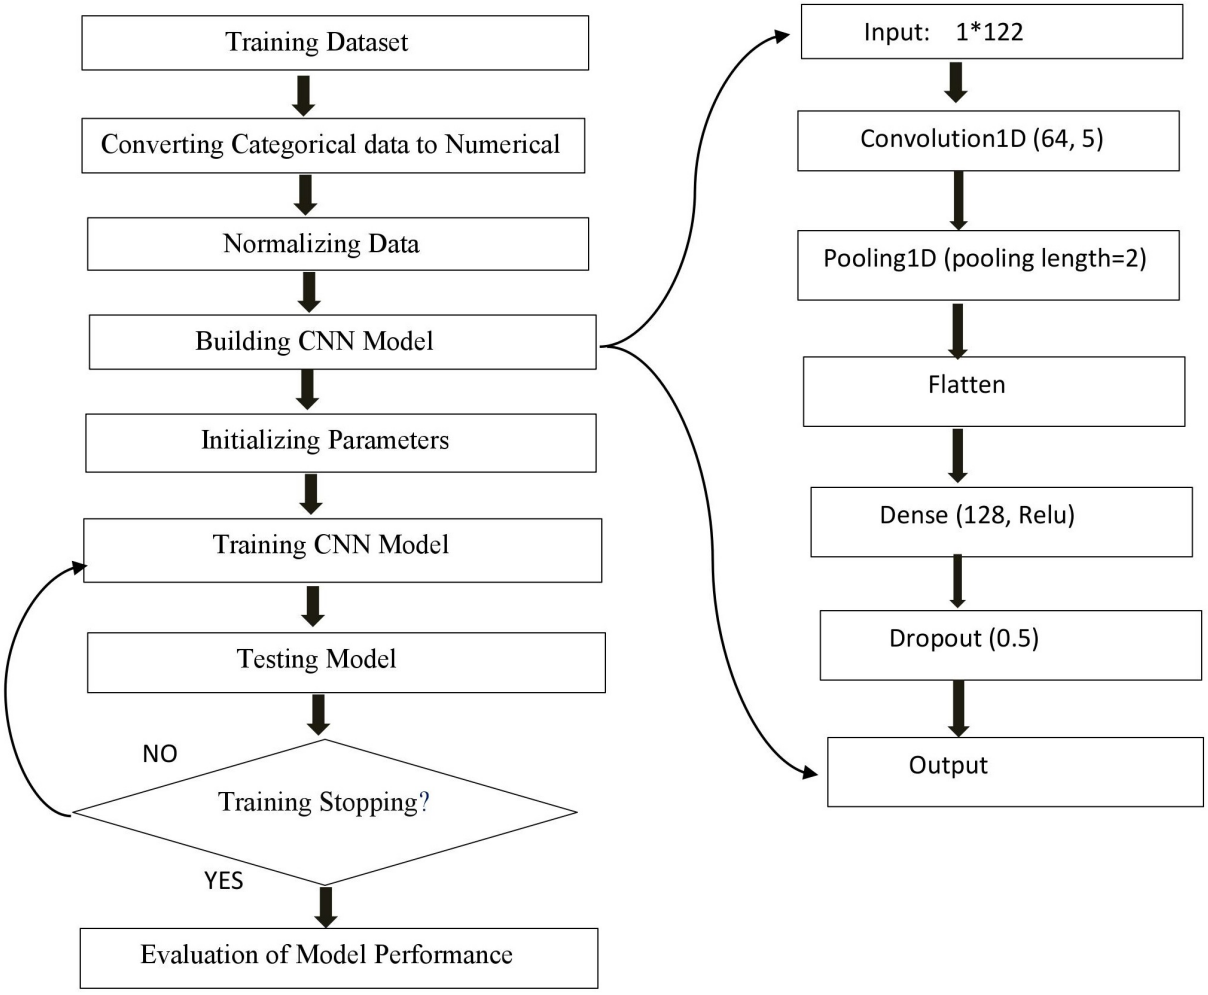

Fig. 1. Flow chart of Intrusion Detection using CNN-1D

A. Dataset Description: NSL KDD Dataset

NSL-KDD dataset is modified version of KDDCUP'99. In 2009 Tavallaee [35] selected NSL-KDD dataset from the most widely used network intrusion detection dataset KDDCUP'99. The number of records in KDDCUP'99 are very redundant that leads a model to be biased towards more frequency of redundant records. Even through NSL-KDD dataset is also old dataset. still, it's used as a benchmark dataset for intrusion detection by many researchers due to lack of public availability of network intrusion detection dataset. The instances of NSL-KDD dataset also reasonable which help to reduce time to run the experiment on whole dataset rather than randomly choosing a portion of the dataset.

NSL –KDD contains one of category named normal which represent normal behavior of traffic and other 22 attacks which are primarily grouped under four categories shown in table 1[35]. Every record of the dataset contains 41 features and one target class label. Out of 41 features attributes, 7 features are symbolic types and others are continuous type.

TABLE I
ATTACK TYPES IN NSL-KDD DATASET[35]

Attack Types	Attacks in NSK-KDD dataset
DOS	Back,land,pod,smurf,teardrop,neptune, MailBomb,Udpstrorm,Processtable,Apache2,Worm
Probe	ipsweep,satan,nmap,portsweep,Mscan, Saint
R2L	imap,warezclient,ftpwrite,named,spy, guesspasswd,multihop,phf,Snmpgetattck, sendmail,Xlook,Httptunnel,Xsnoop,Xlook
U2R	Rootkit,perl,Sqlattck,Ps,Xterm,loadmodule, buffer_overflow

"The NSL-KDD dataset contains four datasets KDDTrain+, KDDTrain+_20Percent as training set and KDDTest+,

KDDTest-21 as testing dataset. KDDTrain+_20Percent contains 20% subset of KDDTrain+ and KDDTest-21 contains subset of KDDTest+ that does not contain some of the records labeled as 21. The instances of four datasets and their attacks are shown in Table II[35]."

TABLE II
INSTANCES OF ATTACK TYPES[35]

	Datasets		
Attack types	**KDDTrain+**	**KDDTest+**	**KDDTest-21**
Normal	67343	9711	2152
Dos	45926	7458	4342
Probe	11655	2421	2402
R2L	995	2754	2754
U2R	52	200	200
Total	12593	22544	11850

B. Data Preprocessing

Before applying our dataset to model, we have to preprocess it because some of fields of our dataset contains categorical data. All of deep learning and machine learning model performs scientific operation on numerical data. So we have to unifying our dataset in numerical data. Our data preprocessing process divided into two subparts: 1) Numericalization 2) Data Normalization.

1) Numercalization: NSL-KDD contains 38 numerical attributes and 4 categorical data. Categorical data fields like 'protocol_type','service','flag' and 'attack label' are converted into numerical values using one hot encoding technique. Categorical field like 'protocol _types' has 3 types of attributes: TCP, UDP and ICMP are encoded into three dimensional vector (1,0,0), (0,1,0) and (0,0,1). Similarly, other feature 'service' has 70 attributes and 'flag' has 11 attributes which are converted into numerical values using one hot encoding. So after numercalization our 41 features converted into 122 features.

2) Normalization: There are some features which are not in same scale. Normalization converts the numerical values of the dataset to bring all feature values within same range.If we are not performing normalization, then our model will bias towards higher values of features. Each feature normalized values within range of [0-1] according to equation (1).

$$S_{normalized} = \frac{S - Min(S)}{Max(S) - Min(S)} \tag{1}$$

Where Max represent maximum value and Min represent minimum value of for every feature.

C. Methodology

The architecture of our CNN model has shown in figure 2[34]. The architecture of CNN model consists of 5 layers which are 1)input Layer, 2)convolution layer, 3)pooling layer, 4)fully connected layer, 5)Output layer. An CNN model has multiple convolution layers and pooling layers. The terminologies and variables of model are described below[34]:

n = n represents the no. of samples
l = l represents no. of convolution layer & pooling layers
$s_p = s_p$ represents the instance p where p = 1,2, 3.....,n
$fm_k = fm_k$ represents the feature map of layers k where k = 1,2,3,.....,l and fm_0 denotes the input sample of s_p.
$w_k = w_k$denotes convolution filter of layer j where k = 1,2,3.....,l
$b_k = b_k$denotes bias of a layer k where k = 1,2,3, ...,l
$o_p = o_p$ denotes output of sample p where p = 1,2, 3.....,n

The network traffic data of TCP/IP packets given to convolution 1D layer in the form of an input vector of dimension $s = (s_1, s_2, s_3....., s_{k-1}), s_{122}, cl)$ where s_k represents features and cl represents class lebel of dataset. Convolution 1D create a feature map fm using convolution operation with filter w_j on input data. The convolution operation can be expressed using following the equation (2).

$$fm_j = f(fm_{(k-1)} \bigotimes w_k + b_k) \tag{2}$$

where $\bigotimes$ =convolution operation
f(x) = Activation function

In this paper, we used a non-linear activation function called Rectified Linear Unit (ReLU). After application of convolution layer, pooling layer applied which minimizes the size of feature map fm_j . The mathematical equation of pooling layer can expressed using following equation (3).

$$fm_k = pool(f(fm_{k-1})) \tag{3}$$

In our paper, we used max-pooling on every feature map which chooses most relevant and significant feature with maximum value . Many features maps collects many features and newly created features provided to fully connected layer. In binary classification we have used sigmoid activation function while in multi-classification we have applied softmax activation function to fully connected layer that gives probability distribution of each class. The mathematical expression of fully connected layer can be given as following equation (4).

$$o_i = softmax(w_{fm0} \bigotimes fm + b_0) \tag{4}$$

After applying various convolution layers and pooling layers, feature map fm transformed into a vector. Then outputo_i obtained from fully connected layer which classify the data into different class labels. After o_i obtained ,the difference between o_i and the expected value calculated using loss function. The goal of our training of our model to decrease the error rate. To calculate the loss function, weight updation of back propagation uses the stochastic gradient descent technique .

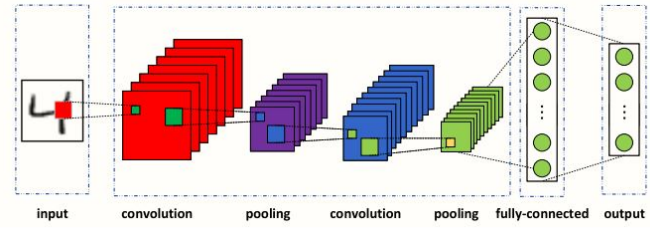

Fig. 2. Architecture of Convolution Neural Network[34]

From table II, we can see KDDTrain+ dataset contains samples unbalanced. For illustration purpose class "normal" having more than 50 percent of records. However other class "U2R" contains only 0.04 percent records. This will create problem in our training, our model will be biased towards higher frequency of records. This whole scenario called class imbalance problem of dataset. To overcome this problem, we used oversampling method called Adaptive synthetic sampling approach (ADASYN).
To tackle the problem of imbalanced problem,there are 3 main approaches which are mostly used:

1) ENSEMBLE-BASED METHOD: This method works on meta-algorithms that uses multiple classification algorithms into one model with the help of boosting and bagging algorithms. This method helps in order to decrease the variance (bagging), bias (boosting) or improves prediction(stacking).

2) COST SENSITIVE BASED METHOD: This method modifies the weights of cost function as per to their distribution of records. The class which contains less frequency of records have larger weights of their cost function and on the other side, the class which has higher frequency of records have small weights of their cost functions.

Lets us suppose we have j classes in our dataset n_1, n_2, n_3..... n_j. Then weights of their cost functions class i will be as:

$$w_j \approx \frac{max}{n_j} \tag{5}$$

Where max represents the maximum number.

3) SAMPLING-BASED METHOD: Sampling based methods either increase or decrease the no. of sample in the total dataset. The oversampling methods increase the frequency of records which are in lower proportion while undersampling decreases the frequency of records which are in higher proportion. And the hybrid approach of oversampling and undersampling not only increment the records having less proportion but also decreases the records of higher proportion. In this paper, we used Oversampling method named ADASYN. Adaptive synthetic sampling approach (ADASYN) is a modified version of Synthetic Minority Oversampling technique(SMOTE). First, it calculates K-nearest neighbors of the minority class of each record in the class. Then draw the line between neighbors and generates random points on lines. After that, it adds some random small values to points thus making it real. Thus these sample points have a little more variance than samples which are taken from their parent samples.

D. EVALUATION METRICS

THere are many criteria to measure the performance of a model. We will choose appropriate metrics according to the problem statement. In our paper we have used AC (accuracy), recall(Detection Rate or DR), FAR (false alarm rate) and confusion matrix as performance measures. There are four parameters which will help to evaluate our model.

TP: TP abbreviated as true positive that are no. of anomaly samples which are classified as anomaly by classifier.

TN: TN abbreviated as true negative that are no. of normal samples which are classified as normal by classifier.

FP: FP abbreviated as false positives that are no. of normal samples which are classified as anomaly by classifier.
FN: FN abbreviated as false negative that are no. of anomaly samples which are classified as normal by classifier.

TABLE III
CONFUSION MATRIX

Actual Class	**Predicted Class**	
	anomaly	***normal***
anomaly	TP	FN
normal	FP	TN

From table III following performance metrics are calculated.

Accuracy(AC): Accuracy is one of the main performance measure of any model. It is the no. of samples correctly classified over total samples.

$$AC = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

DR (Detection Rate): Detection rate also called recall. DR is a measure that tells about percentage of samples correctly classified over the total number of anomaly samples.

$$DR = \frac{TP}{TP + FN} \tag{7}$$

FAR (False Alarm Rate): False alarm rate also called false positive rate. FAR shows the percentage of samples incorrectly rejected by total normal samples.

$$FAR = \frac{FP}{FP + TN} \tag{8}$$

Confusion Matrix: Confusion matrix is a performance measure of a classifier which gives a matrix of predictions over actual samples in classification. Confusion matrix describes how much model is confused among actual class and predicted class as shown in table III.

IV. EXPERIMENTAL AND DISCUSSION

To implement this research paper, we used the most famous deep learning library keras [36] using tensorflow [37] as backend. The experiment performed on the PC that have configuration of Intel(R) Xeon® CPU E5-2650 v3 2.30 GHz, 8 GB memory without GPU acceleration. Our experiment has been performed on both classification binary (normal or anomaly) and multiclass classification (Normal, Dos, Probe, R2L, U2R). There are many algorithms applied to Intrusion detection. Early only ML algorithms used for IDS but now days high end processing power help to use deep learning models for IDS.
In binary classification we compared the performance of machine learning models like J48, Naïve Bayes, NB Tree, Random Forest, Random Tree, Multi-layer Perceptron, SVM, RNN as mentioned in paper [38] with our CNN-1D model. Likewise, we also compared other machine learning algorithms with our model for multiclass(5-category) [34] classification problem.

A. BINARY CLASSIFICATION

In binary classification we have converted 41 dimensional feature set into 122 dimensional feature set. So our model takes 122 input nodes and produces 2 output nodes. In CNN, we can insert as many convolution and Pooling layer. In this paper we called both layers 'multi hidden layer' as combine. We implemented our model for one and two multi hidden layers. Different parameters for multi hidden layer 1 and multi hidden layer 2 are taken as: For One multi-hidden layer, convolution layer 1 filter size & stride are taken as 5 and 1 respectively. And pooling layer 1 filter size & stride taken as 2. In two multi-hidden layer , convolution layer 1 & 2 filter size and stride taken as 5 and 1, and pooling layer 1 & 2 filter size and stride taken as 2.

Accuracy and detection rate for different multi-hidden layers shown in table IV.

TABLE IV
EXPERIMENTAL RESULTS ON DIFFERENT LAYERS

Multi Hidden Layer	**KDDTest+**	
	AC	***DR***
1 Layer	84.29%	74.62%
2 Layer	82.38%	72.18%

From table IV, we can conclude that 1 layer has higher accuracy and detection rate for KDDTest+ dataset. So we have chosen layer 1 for binary classification. The confusion matrix of layer 1 classifier is shown in table V.

TABLE V
CONFUSION MATRIX OF BINARY CLASSIFICATION

Actual Class	**Predicted Class**	
	anomaly	***normal***
anomaly	9576	3257
normal	283	9427

Detection rate and False alarm rate also considered two main measure of performance in classification problem. Table VI compares the detection rate and False alarm rate of given in paper [38] with our CNN-1D model. Here we can clearly see that DR of our model is high with margin 1.72 % and FAR is lower with difference 0.15%.

TABLE VI
DETECTION RATE AND FALSE ALARM RATE OF RNN AND CNN-1D

Metrics	**Models**	
	RNN	***CNN-1D***
Detection Rate (DR)	72.90%	74.62%
False Alarm Rate(FAR)	3.06%	2.91%

Fig.III shows accuracy comparisons between different ML algorithms described in paper [38] with our CNN-1D model. Accuracy of our model is 84.29% in binary classification on NSL-KDD benchmark dataset. Accuracy of our model is higher than all machine learning algorithms and also slightly higher than RNN [38] with margin of 1.01%.

B. MULTICLASS CLASSIFICATION

In multiclass classification (5-category), we performed classification for 5 classes (Normal, Dos, Probe, R2L, U2R). The problem in multiclass classification is that KDDTest+ dataset is highest unbalanced. The number of instances of R2L and U2R are very low in KDDTrain+ dataset. We performed classification algorithm on unbalanced dataset. The accuracy of this experiment is higher than accuracy of balanced dataset. But detection rate and false alarm rate extremely low compared to balanced dataset. So we chose oversampling method (ADASYN) to make the dataset balanced. All results in below section are evaluated on balanced dataset. We trained our model for 500 epochs. The filters used in this experiment 32 & 64 and the filter length was 3 and 5 respectively. The accuracy and detection rate of 64 filter along with 5 filter length was highest. In this subsection we compared accuracy of different ML algorithms & deep learning algorithms with our CNN-1D model as shown in fig.4.

From fig. 4 we can see that accuracy of our CNN-1D model are slightly lower than RNN [38] and CNN [34] model

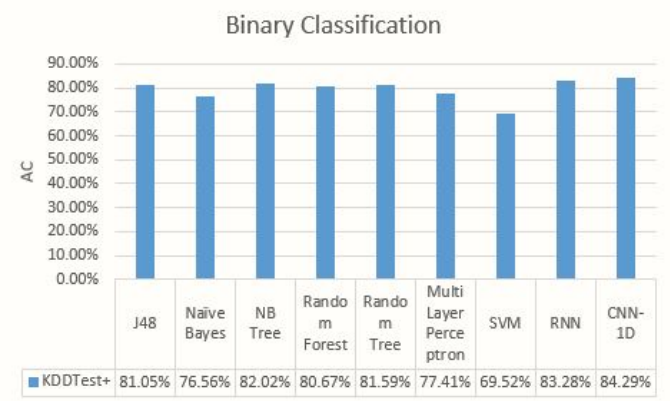

Fig. 3. Performance of CNN-1D and other models in binary classification.

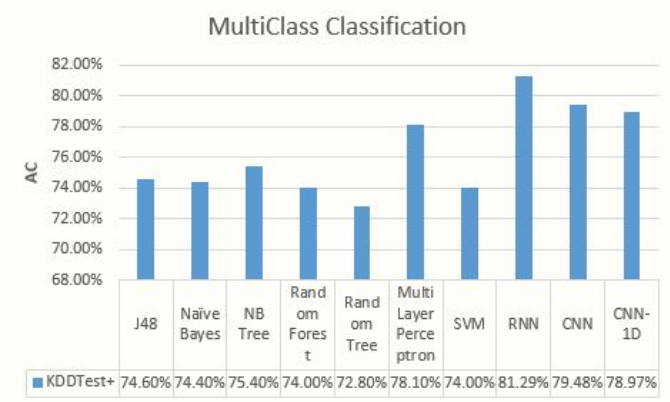

Fig. 4. Performance of CNN-1D and other models in the five category classification.

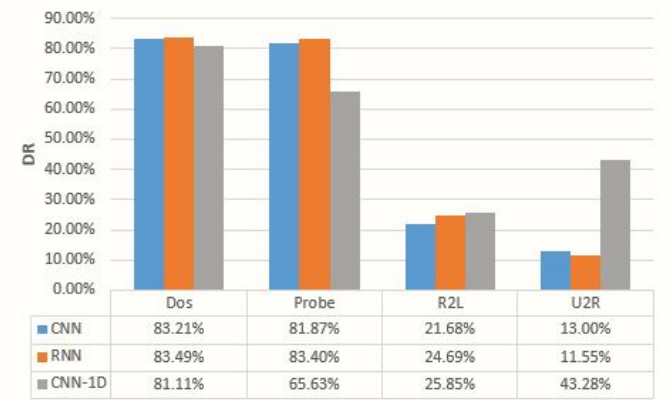

Fig. 5. Detection Rate of Different Models.

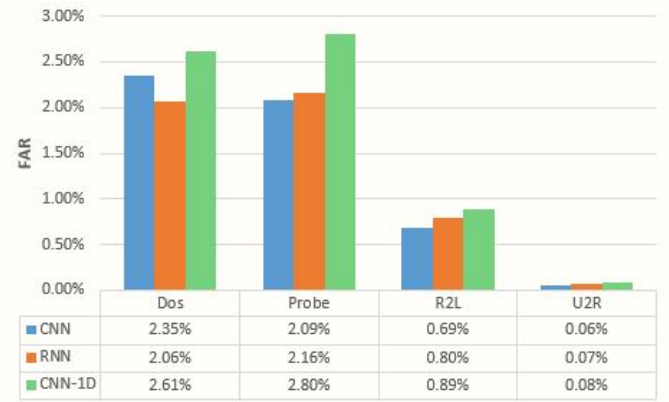

Fig. 6. Detection Rate of Different Models.

with difference of 2.32 percentage and 0.51 percentage. But accuracy of our model is higher than all other machine learning algorithms. Results shows that automatic feature selection of deep learning are better than manually feature selection of traditional ML algorithms. That is the reason deep learning is used in many fields.

TABLE VII
CONFUSION MATRIX OF MULTICLASS CLASSIFICATION ON KDDTEST+ DATASET

Actual	**Predicated Class**				
Class	**Normal**	**Dos**	**Probe**	**R2L**	**U2R**
normal	9389	71	221	20	9
Dos	1245	6051	21	143	0
Probe	512	320	1589	0	0
R2L	2083	3	41	746	12
U2R	24	0	1	13	29

Detection Rate (DR) and False alarm rate (FAR) of our CNN-1D model are computed using confusion matrix shown in table VII. DR's and FAR's of different attacks are compared with CNN [35], RNN [39] and our CNN-1D model in Fig. 5 and Fig.6 respectively. From fig. 5 we can that DR of Dos & Probe are decreased in our model, while DR of R2L and U2R are increased from both models CNN [34] and RNN [38]. FAR's of each attack type shown in fig 6, FAR of our model are slightly lower than CNN [34] and RNN [38] but they are still competitive.

V. CONCLUSION

A deep learning algorithm can automatically extract features from huge dataset. CNN-1D model for NIDS is proposed in this paper to detect anomaly or attack from a huge network IDS. CNN mainly used on image datasets, however we used time series CNN-1D in this paper which shows that CNN can be applied for tabular datasets. To deal with class imbalanced problem in multiclass classification, we used oversampling technique(ADASYN) which improved detection rate and false alarm rate. The evaluation of experimental results we can conclude that our CNN-1D approach for network intrusion detction performs better than all other IDS models. The accuracy & Detection rate of our approach is higher than all existing approaches in binary classification. In multiclass classification our accuracy, DR and FAR are slightly lower but still they are competitive to CNN [34] and RNN [38].

There is still space for improvement in future. We will try to improve the detection rate of Dos and Probe and reduce the

FARs of all four attacks. To achieve the goal, we will modify the structure of our model.

Abstract— **The rapid use of renewable and sustainable energy sources in distributed generation system, the importance of energy storage devices forcing the researches to develop new key technologies. For continual power deliver, make greater use of renewable electricity sources, together with solar and wind. Power electronic converters are mostly connected among the different voltage buses and storage systems. Bidirectional dc-dc converter topologies are used for providing charging or discharging. This paper presents the quadratic nature for obtaining higher voltage gain ratios in step-down (buck) and step-up (boost) converter's operating states with reduced charging and discharging ripples. Proposed scheme has been developed and analyzed using MATLAB/ simulink.**

Keywords – Buck converter, Boost Converter, ESD, Quadratic dc-dc converter schemes.

I. INTRODUCTION

Electric power created by sustainable power sources is unsteady in nature, in this way delivering an awful impact on the utility grid [1]. The storage of energy can be possible in two ways, one is magnetically (using inductors) and another one is electrically (using capacitors) [2]. DC-DC converters change the voltage level which might be upper or lower, storing and releasing the energy at distinct voltage. Basically voltage & frequency stability can be realized by the use of such ESDs in sustainable energy sources, for example, sun-based and wind. Because of operational prerequisites of the conveyed age framework, ESDs need such type of DC-DC converters which can permit charging and discharging. The job of Energy storage gadgets in the expanding entrance of inexhaustible and maintainable vitality sources is broadly perceived. Various devices supported electrochemical energy storage systems likewise; ultra capacitor, batteries.

This paper presents traditional buck and boost quadratic converter which comprises of DC-DC boost converter with a coupled inductor for the distributed generation system [3]. Basic step-up converters give higher voltage gain but these converters face the issue--due to limited reverse recovery issue of diode and power losses [4-9]. For obtaining proposed converter for higher voltage gain, two inductors and capacitors have been used [11-14].

In this article buck-boost converter has been simulated which are bidirectional in nature. These converters are very helpful in distribution generation system as conventional converters are less efficient to work in higher frequency regions. This converter is moreover depicted by a fundamental control system since it is only imperative to control one power semiconductor for each movement mode. The additional power semiconductors remain reliably on or continually off. Quadratic converter shows up with DC transformation proportion that offers an essentially more extensive change extend, persistent input and yield current, diminished charging/releasing ripple and moreover direct control hardware.

II. ELECTROCHEMICAL ESD

Electrochemical devices are basic elements of electrochemistry which are highly demanded resources that provide reliability in the solutions of telecommunication applications. These devices are basically eco-friendly in nature.

A. Supercapacitors

Supercapacitor is generally used to store electrical energy in which two parallel plates separated by an insulating medium i.e. dielectric. To achieve a high value of the capacitor, electrochemical double layer capacitance or ultra capacitors used which possessed large surface area carbon electrodes. As compared to conventional capacitor, supercapacitors have greater capacitance and high energy density.

B. Batteries

Batteries are mostly made up of consisting one or more electrochemical cells which obey principle of the electrochemical energy conversion. The Bidirectional nature of the DC-DC converter is responsible to flow

the power from the DC-grid to the battery or vice-versa as shown in fig.1.

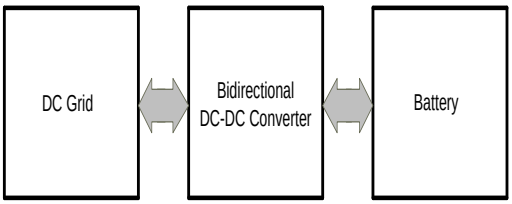

Fig.1.Basic scheme of bidirectional converter

III. QUADRATIC BUCK- BOOST CONVERTER

Figure 2 and 3 show the most known topologies with wide voltage range that is step up and down converter. These topologies are characterized by the use of passive elements.

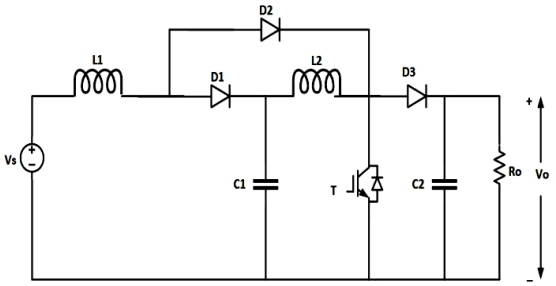

Fig.2. Traditional quadratic boost (Step-up) converter

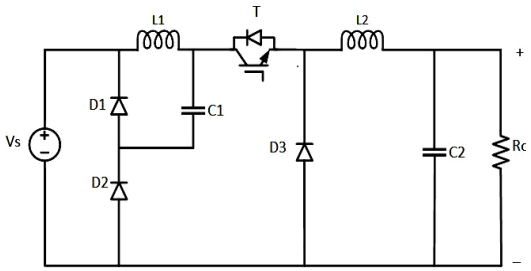

Fig.3. Traditional quadratic buck (Step-down) converter

With the analysis of these previous traditional quadratic buck (step-down) converter and traditional quadratic boost (step-up) converter, it is found that these converters hold the unidirectional power flow using the extra passive elements compared to the normal power circuit, which provide the additional power losses. Individually both the converters possess uncertainty in duty ratio. These limitations are rectified by the new bidirectional quadratic dc-dc converter.

The new bidirectional buck-boost quadratic converter comprises four IGBT switches, capacitors, inductors. Additionally RC filter is connected in the input and output side of the proposed converter which reduces the output voltage spikes and minimizes the charging and discharging ripple. The quality of the proposed converter is, the only one active switch is responsible for each mode of operation.Fig.4. shows the proposed bidirectional quadratic nature buck-boost or step up-down converter.

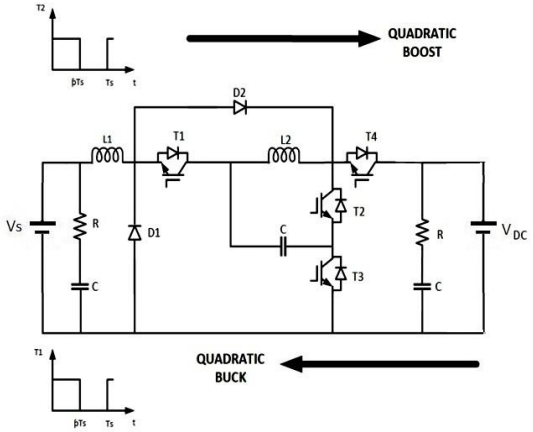

Fig.4. Proposed bidirectional quadratic buck-boost converter

A. *Operation in Boost(step-up)Mode :*

In the discharging mode transistors T_1 and T_4 are turned-off and the transistor T_3 is turned-on. The circuit operation can be split into two different phases over one half cycles as discussed below:

First phase**:** during this time T_2 is turned-on during δTs .during this time period, storage device deliver its energy to the L_1 and capacitor to the L_2, this shows the rising nature of current in both L_1 and L_2. The circuit diagram of the first phase is shown in Fig. 5 (a).

Second phase**:** In the second phase, the transistor T_2 will be turned-off in the duration of (1-δTs). In this stage, both the passive elements (L_1 and L_2) discharge. During this time-interim the inductor L_1 transferred energy to the capacitor and inductor L_2 transferred energy to the load. The circuit diagram of the second phase is shown in Fig. 5 (b).

These phases explained the voltage gain of this converter in Boost mode can be obtained. In this analysis, the average voltages of both the inductors are equal in the first and second phase, the following relationships are received:

$$\delta V_S + (1-\delta)(V_S - V_C) = 0 \quad (1)$$

$$\delta V_C + (1-\delta)(V_C - V_O) = 0 \quad (2)$$

Here, $V_O = V_{DC}$

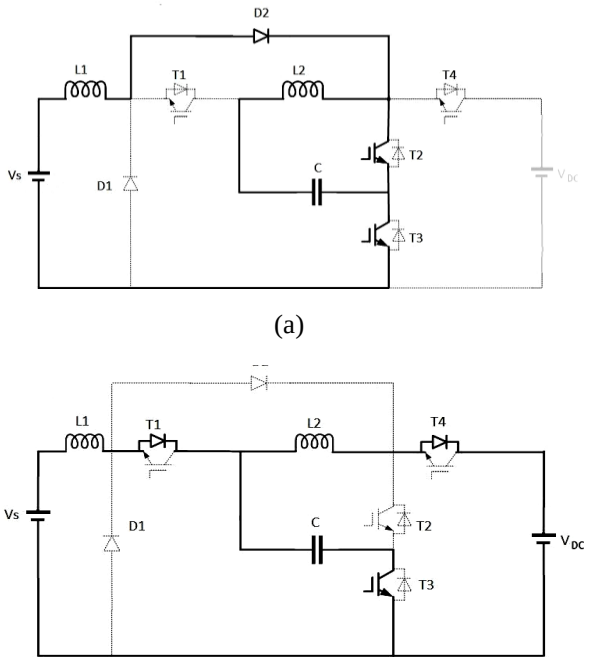

Fig.5. Equivalent circuits during one switching period for the boost mode of the storage system.

By the the preceding equations, the input to output voltage gain in step-up mode can be obtained from equation (3).

$$V_O(1-\delta)^2 = V_I \tag{3}$$

According to the above analysis, these two operating phases present following relationships that are

$$\frac{I_{L1}}{I_{L2}} = 1/(1-\delta) \tag{4}$$

Fig. 6 shows the operational waveform for Boost mode.

B. Operation in Buck (step-down) Mode:

In the charging mode of the buck converter, the energy will be transferred from the load to the storage device i.e. battery. This mode of operation is executed by the transistor T_1. Thus, the transistors T_2 and T_3 are turned-off and transistor T_4 is turned-on. Similarly the two modes of the buck converter as discussed below. First phase**:** In this phase transistor T_1 is turned-on during the time interim of δTs. In this duration of time, the current will be transferred from the load to the inductor L_1 and from the capacitor to the inductor L_2 in Fig. 7 (a).

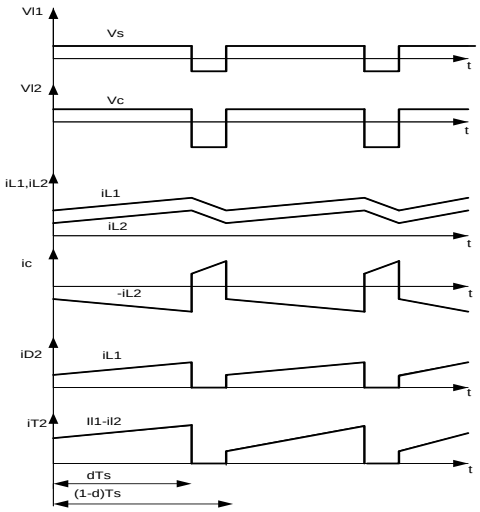

Fig.6. Operational waveforms of boost mode

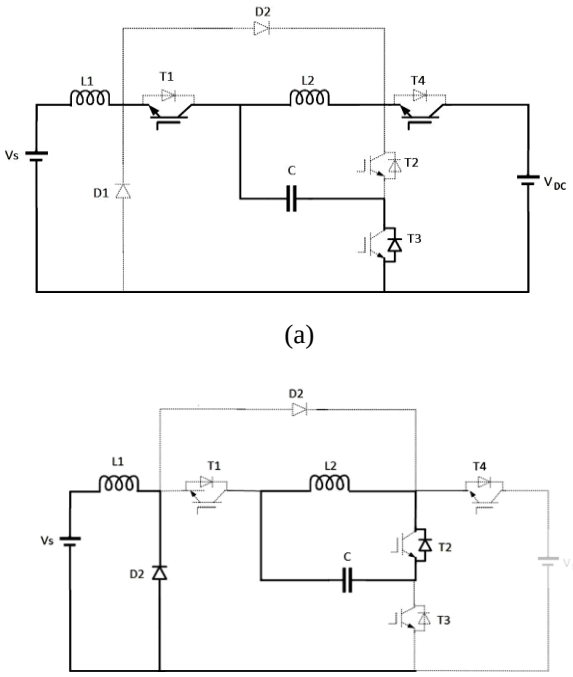

Fig.7. Equivalent circuits during one switching period for the charging mode of the storage system.

Second phase**:** In this phase transistor T_1 is turned-off in the duration of (1-δTs). Energy stored in the inductor L_1 will be delivered to the capacitor C and L_2 will now be transferred to the storage device in Fig.7.b). From the assessment of these two stages is conceivable to accomplish the voltage addition of this converter buck mode. Hence, taking into account that the normal voltages of both the inductors equal to zero, the accompanying connections are acquired.

$$\delta(V_S - V_C) + (1-\delta)V_S = 0 \quad (5)$$

$$\delta(V_C - V_O) + (1-\delta)V_C = 0 \quad (6)$$

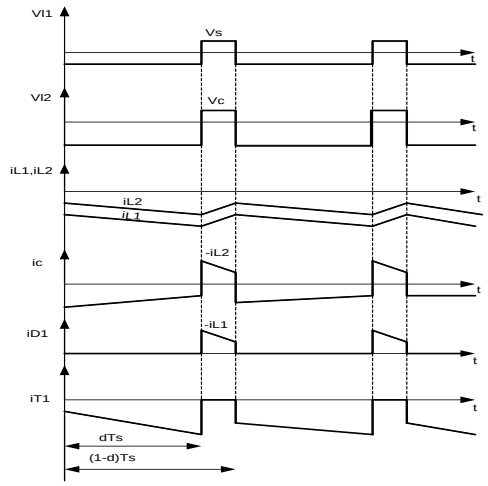

Fig. 8.Operational waveform of the proposed converter during buck mode.

$$\frac{V_o}{V_s} = \frac{1}{\delta^2} \quad (7)$$

The operational waveforms of buck (Step-down) converter during Buck mode are shown in Fig.8.

IV. SIMULATION RESULTS

Boost mode (Forward mode): This mode shows the power stream from the ESD to the load. This simulation has been done using Matlab / Simulink platform. Fig. 9, shows the Matlab model of bidirectional quadratic dc-dc boost converter. The converter operation has been simulated for V_S = 48V (battery voltage), V_O = 180.0 V, L1 = 1.0 mH, L_2 = 2.20mH, C = 150.0 µF ,R_{in}=0.1ohm, C_{in}=47.0µF and with a switching frequency of 15 kHz. The simulated waveforms of the input & output voltage, and ripple in the inductor current as shown in fig. 12.

Buck mode (backward mode): This mode represents the power flow from the load ESD. Operating modes of the proposed bidirectional quadratic converter have been verified through numerical simulations. The simulation depicts the model of bidirectional quadratic dc-dc buck converter.

Similarly, the waveforms of input voltage & current, and ripple current, voltage across transistor T_1,

V. CONCLUSION

The classical quadratic buck and boost converter requires extra passive elements like inductors and capacitors due to which in the case of unidirectional power flow these converters shows the uncertainty in duty cycle and many other drawbacks which make these converters less efficient. In this paper, a bidirectional quadratic buck-boost converter has been analyzed. In this analysis, different modes of charging (buck) and discharging (boost) have been explained. From the analysis, it has been evident that bidirectional DC-DC buck-boost converter provides less ripple with less component count compared to conventional quadratic buck and boost converter which make the system more compatibles for energy storage system. Here, RC filter has been introduced which reduces the spikes in the output voltage and also minimizes the charging or discharging ripple. In charging mode (buck) analysis has been done for 180v (V_{in}) and 48v (V_{out}).Similarly for discharging mode, analysis has been done for 48v (V_{in}) and 180v (V_{out}). MATLAB / Simulink platform has been used to verify the result.

***Abstract*— Energy management plays important role in any business. The productivity of an organization will be increased by efficient use of the energy. Energy management reduces system cost and also helps user in analyzing the total energy consumed. In this paper the energy management is carried out efficiently at Siemens by collecting data from the power meters consumed by building and developing a web application in cloud using Raspberry Pi and Modbus Communication protocol. The paper also gives the configuration details of Node RED in Raspberry Pi.**

Keywords— Energy Management, Raspberry Pi, Modbus Communication protocol, Node RED

I. INTRODUCTION

Efficient method of energy management is to use Raspberry Pi for building a web application which gives information about the amount of energy consumed by devices. Raspberry Pi is a small, portable and inexpensive computer which is full-featured on a single board. Keyboard, mouse, monitor, speakers can all be attached to it. In the energy management application Raspberry Pi is used to create documents, web browsing, interface between devices and the cloud. The Raspberry Pi comprises of different interfaces for other external devices. It consists of RAM, graphic chips, processor, Ethernet port, CPU, power source connector UART, memory card etc.

The implementation uses cloud space to store the energy consumed information. Cloud storage provides digital services that enhance the productivity and increase the efficiency of entire business. It is an open platform which allows user to build and run the apps. The data present in cloud can be later analyzed by the user. The cloud has unlimited storage capacity and can be used in any real time application. The project uses serial protocol called Modbus Communication Protocol. It transmits the information from the electronic devices using serial lines. It is used to communicate among the devices which are connected in same network. It is mainly used for industrial applications. Each device communicates with Raspberry Pi with unique address. Based on device address data can be collected from the desired device and analysis of result can be achieved. Displaying and analysis of the data is the last step in the implementation.

The data present in cloud is analysed by different methods like Load monitoring, Load profiling, Load forecasting. Load monitoring is used to analyse the changes in voltage, power and current used by building, home appliances etc. It measures amount of energy consumed at a given instant of time. Using load monitoring sudden rise in the amount of energy consumed can be obtained so that no damage is occurred.

The variations in the electrical load for an instant of time are illustrated by load profiling. It is very useful to plan the amount of power required for future use. In the project bar charts and line charts are used to plot the variations in the power consumptions. Short term, medium term or long-term demand of electrical power required is predicted by load forecasting.

The load forecasting helps the companies in managing electric supply to their customers. Efficiency and revenue of company can be increased by load forecasting. It helps them to plan and act on their capacity and operations.

II. RELATED WORK

When Comparison between microcontroller and Raspberry Pi is carried out, Raspberry Pi is proven to be more useful hardware in IoT projects. Also, the use of Raspberry Pi as a cloud server or as a storage device is given in the paper [1]. Raspberry Pi is used for industrial meter reading to collect data from energy consuming devices [2].

The unnecessary wastage of energy will reduce the efficiency for example in house or industry. Thus to avoid the unnecessary wastage of resource the authors in paper [3] have proposed a method which uses Bluetooth communication present in the user's phone. Raspberry Pi is connected to the Bluetooth which helps in communication. Raspberry Pi usage made the implementation cost effective.

The paper [4] presents self adaptive framework which has steps like planning, monitoring, analyzing, execution etc. The method is based on dynamic power management. It uses control loops. The private cloud infrastructure consists of sensor, virtual machines, hypervisors, host etc. The implementation is carried out in Agile cloud environment. The overall result is that energy consumption is decreased and energy efficiency is increased.

The paper [5] mainly focuses on data logging. The implementation uses communication area network protocol, it

also uses Raspberry Pi and IOT devices. The implementation was carried out to build a data logger system. The system intakes different parameters as input from various sensors like temperature, pressure, coolant temperature sensor, oil sensor, ambient air pressure sensor etc. The calculated sensor data is given to electronic control module and with the interface of the Raspberry Pi controller the data was pushed to cloud and stored data could be viewed in the laptop or PC.

In paper [6] RPiaasa efficient cloud testbed built which uses Raspberry Pi is introduced. The data used to store in the cloud is not secured always. Hence, the paper [7] proposed a method that allowed user to store data securely and also access the data with security from cloud storage. The method prevents the data been leaked to unauthorized users by providing security. It gives access on to the authorized users. The method uses the encryption process; it encrypts the data at client side. The secret key used for encryption is same used for decryption.

The various steps for building IOT platform, creating HTTP connections, Creating assets, sending commands to Raspberry Pi and uploading the information was also mentioned in paper [8]. The collected data from building is represented in smart meters and then forecast tools display it. The data is stored in database and used to plot the variations in data consumed by each building [9].

In the paper [10] ZigBee sensor network is used for energy management. The system proposed consists of three components that is environmental information entity, power monitoring entity and control devices all three are used to monitor and collect environmental information such as humidity and temperature. Each component uses Zigbee interface. The paper [11] gives introduction about Amazon web services, how AWS can be used to compute power and provide various services. The authors in paper [12] explain the importance of energy monitoring, managing and controlling.

III. DESIGN

The design of energy management system comprises of combination of hardware and software implementation. The hardware used here is Raspberry Pi and software part is pushing data to cloud. It has several steps. They can be summarized as follows:

1. The real line data such as voltage or current consumed by the building is read from the power monitoring devices through modbus communication protocol.
2. The interface between the power meters and the cloud is the Raspberry Pi.
3. The Raspberry Pi is configured using Node RED and necessary modbus drivers are installed into the Node RED.
4. Using web tokens, the data is pushed into the cloud.
5. Data visualization in the dashboard consisting of graphs and charts.
6. Analysis of the result.

The complete flow of the system is presented graphical as shown in Fig. 1. And the block diagram is as shown in Fig. 2.

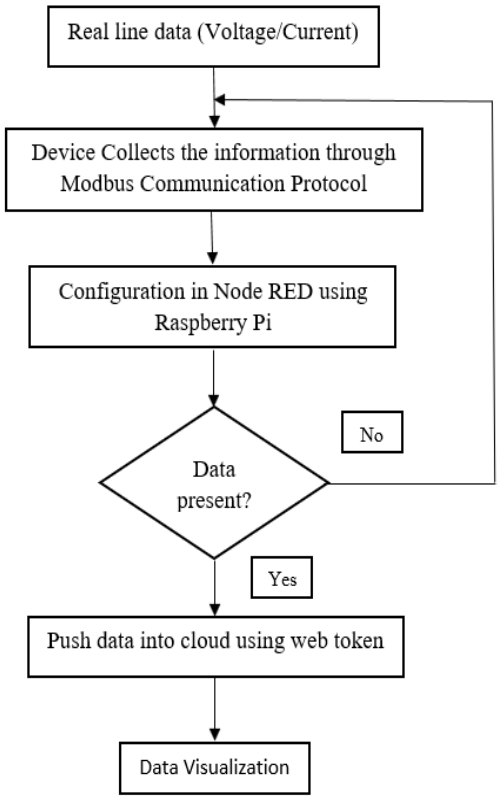

Fig. 1. Flowchart of energy management system

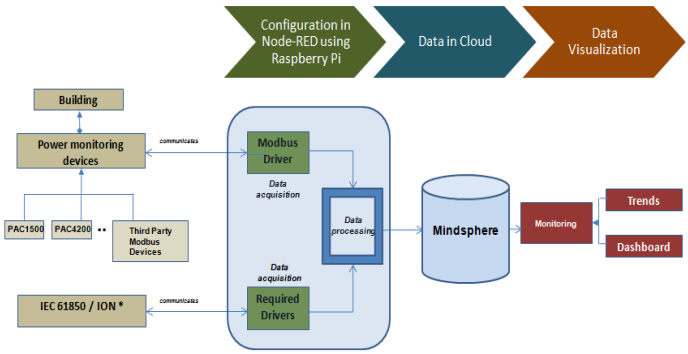

Fig. 2. Block diagram of energy management system

IV. EXPERIMENTAL SETUP

The whole implementation consists of Raspberry Pi 3 B+ as an interfacing tool between power meters and cloud. The main features of Raspberry Pi are:

- Multicore processor which consists of ROM, RAM and Ethernet ports all on single chip.
- Low cost device which is Credit card size.
- Uses Linux operating System.
- Has ability to run multiple programs.
- It is mainly used in IoT-applications.

Various connections that are necessary to configure Raspberry Pi 3 B+ are as shown in Fig. 3.

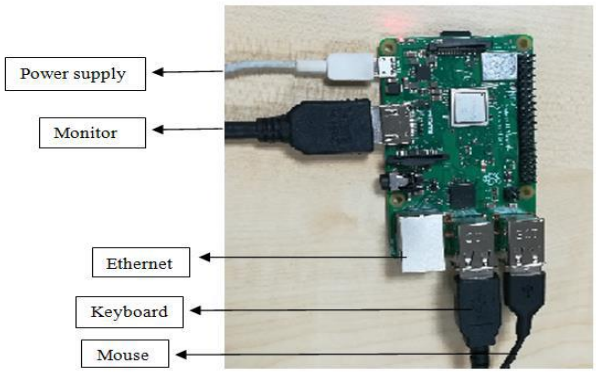

Fig. 3. Raspberry Pi 3 B+ set up

A. *OS Installation*

Steps involved in installing Raspbian OS are as follows:

1. Set up the SD card which acts as an internal storage in Raspberry Pi. Once the card is set up it is ready for Raspbian OS installation.
2. Download the Raspbian OS. To download the Raspbian OS go to raspberrypi.org website and click Download the Raspbian and extract the file.
3. Raspbian OS image file will be installed.
4. Next step is to download Disk Imager to write Raspbian OS in the SD card. To download click on the link installation guide present in raspberrypi.org website. Then download the windows version. Click on source force project page link and download the file. Next extract and install the downloaded file by unchecking the View README.txt and press finish.
5. Win32 Disk Imager-1.0 window will be opened. Select correct drive location according to SD card in Device Selector. Copy the path of Raspbian OS image and paste in Image File. Select the image file once again click on write button and press yes. Success message pops up. Click ok.

B. *Configuring Node RED in Raspberry Pi*

Node RED is a programming tool for creating flow of the hardware devices, APIs, services etc. Node-RED has an internet browser-based editor, which may be used to create JavaScript features. It is communication gateway software which is used to connect modbus drivers and cloud. Node RED has many standard nodes using which flow is created.

Steps to install Node-RED into Raspberry Pi:

1. Insert the configured SD card into the Raspberry Pi.
2. Connect the Raspberry Pi to the monitor in order to have a display of the board.
3. Connect the Pi to the internet.
4. Open command window and install Node-RED using Script command.
5. Open the Node-RED in web browser.
6. If the modbus drivers are not installed then in the root directory of Node-RED install it using the command npm install –g node-red-contrib-mobus.

Fig. 4. shows the Node-RED configured in Raspberry Pi.

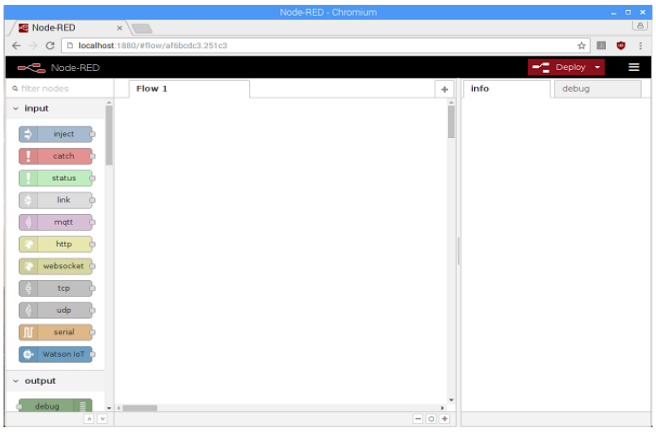

Fig. 4. Node-RED editor

In the device network communication between the devices is carried out by Modbus Communication Protocol hence, modbus drivers are installed in Node RED. Modbus is a serial communications protocol used to connect industrial electronic devices. It is an open source protocol and easily deployed protocol. Three types of Modbus are Modbus RTU, Modbus ASCII and Modbus TCP/IP. Its functions are to read and write the data from and to the devices respectively. Modbus works on master and slave concept. Modbus master is the device which requests the information and Modbus slave is the one which supplies the information. Modbus can have 1 master and 247 slave devices having 247 unique slave addresses for the communication. In this implementation master is the power meters ad slaves are the measuring points like active power, apparent power etc.

V. Results and Analysis

The Node RED flow is created in local browser at http://localhost:1880. Using various nodes like Inject node, Debug node, Function node, Modbus read etc the flow for the project is created. It is as shown in the Fig. 5.

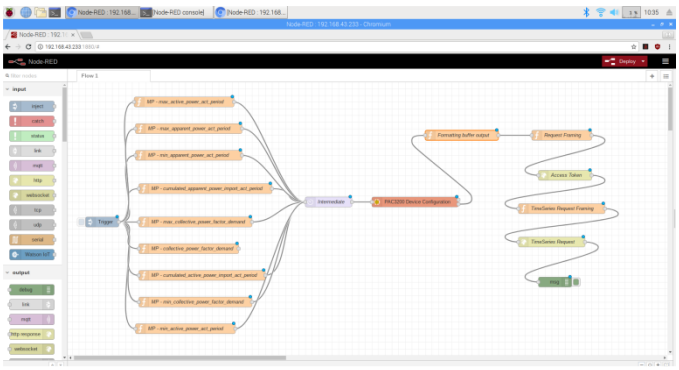

Fig. 5. Json flow in Node RED

The various nodes/steps used to build the above flow are:

1. Inject

The Inject node is used to trigger the flow by clicking the node button. It automatically triggers the flow at regular intervals. The intervals at which the injector can be triggered are at a particular instant, on demand or periodic.

2. Function

Function node passes message though a JavaScript function. Here function node depicts the various measuring points that are supported by power devices. It has function code set to 4 means modbus input register port is set. UnitId is the device ID. Address is the modbus address for each measuring point. dpName is data point name.

3. Intermediate

An intermediate node takes parallel input from every measuring point. If suppose there are 10 data points, each data point should be sent at the output at same time.

4. Modbus Read (Modbus Network)

The IP address is obtained to a device by modbus network; this has to be tagged in the Host address. Default port set is 502.

5. Formatting buffer output

The buffer data is an array. It has to be converted to the float data to give it to the time series. The line msg.result = float [0] is used to convert the buffer output to float.

6. Request framing

It depicts the header in postman software.

7. Access token

It provides security against unauthorized users. It provides authentication by giving user to enter username and password.

8. Time series request framing

Bearer is added to the access token.

9. Time series request

Same asset ID as of device is tagged in the URL.

10. Message

The output status is displayed using deploy node.

The output after creating a flow using above node is as shown in the Fig. 6. The Debug Slider present in the left side of the image gives the information of successful deployment which tells data is pushed into the cloud.

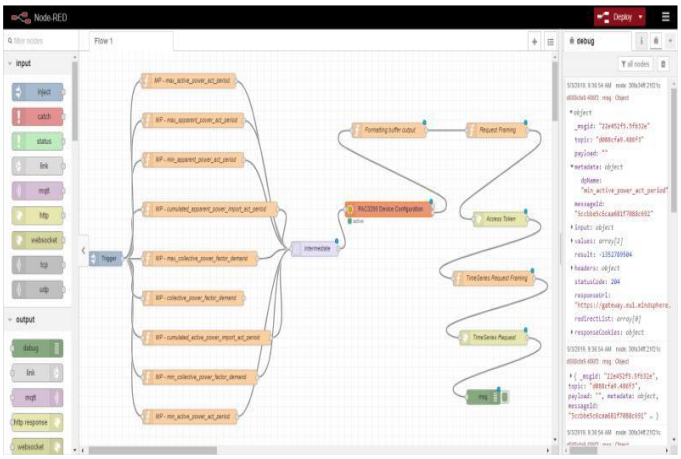

Fig. 6. Node RED output

The next step is displaying data present in the cloud to the dashboard. The data is displayed in the form of gauges, bar chart and line chart. The bar and line chart gives the comparison of data at two different time series. Fig. 7 shows the gauges displaying measuring points such as cumulated active power import, cumulated apparent power import and collective power factor demand.

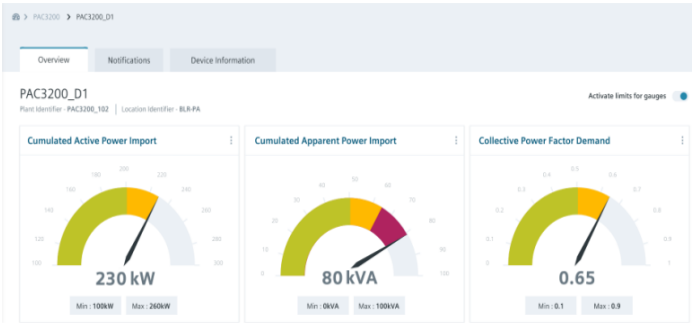

Fig. 7. Energy monitoring dashboard containing gauges

Fig. 8 shows the bar chart, the dashboard has power demand, time of use, usage percentage, minimum value, and maximum value display.

Fig. 8. Energy monitoring dashboard containing bar chart

Fig. 9 shows line chart which displays the cumulated active power import values has date time picker.

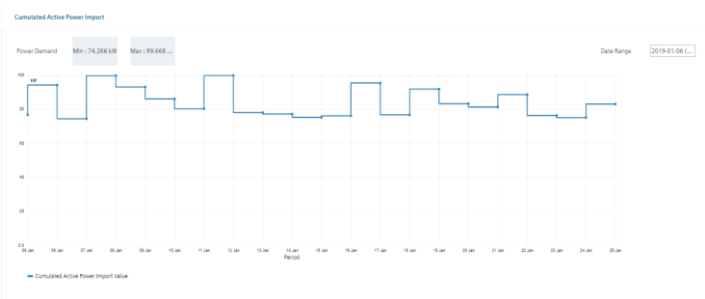

Fig. 9. Energy monitoring dashboard containing bar chart

VI. Conclusions and Future Scope

The energy management system is built efficiently using a cloud application and Raspberry Pi interfacing between power meters and the cloud. As Raspberry Pi is low cost device and consumes less power also Node-RED is open source software. Hence, the system built is cost effective. The data visualization helps user to analyze the power consumed at particular instance and avoid unnecessary wastage of energy.

The future scope of this work is to build a Mobile Application with same features in an optimized way. Also to generate the web application, this would automate the Node-RED flow. The application can be used by industry, homes or any

organizations. Raspberry Pi can also be connected to various sensors to collect data instead of connecting it to network.

ACKNOWLEDGMENT

I acknowledge with immense pleasure the guidance and support extended by Siva Ganesh Kumar and Nithin A, Siemens Technology and Services Private Limited, Bengaluru, India.

I thank Dr. Nagamani K, Professor, Department of Telecommunication Engineering, R. V. College of Engineering, Bengaluru for her timely suggestions and contribution in successful completion of the work.

I thank the company Siemens Technology and Services Private Limited, Bengaluru, India for providing the resources required to carry out the implementation.

Test Pattern Generation to Detect Single Stuck-at Faults for Combinational Circuits Using ZBDD.

Antony Thomas, J. P. Anita
Department of Electronics and Communication Engineering
Amrita School of Engineering, Coimbatore
Amrita Vishwa Vidyapeetham, India.
Antony231j@gmail.com, jp_anita@cb.amrita.edu

***Abstract*—In this work generating test pattern using zero suppressed binary decision diagram (ZBDD) to generate test patterns for combinational circuit has been used. The ZBDD for combinational circuits are first obtained then test patterns are generated from it, similar approach is used for fault injected ZBDD and XOR operation is performed of both the set of test patterns to generate test pattern to detect the fault. This approach will reduce the power consumption during test mode of acircuit.**

Keywords— ZBDD, stuck-at-faults, test pattern.

I. INTRODUCTION

The advancement in VLSI technology has enabled us to implement millions of transistors and gates on a single IC. As Moore's law backs up the claim that number of transistors in a circuit doubles every 18 months. The VLSI technology has found its application in many different fields and some situations were performance and robustness are of high demand. Hence testing of these devices becomes an essential part of the development cycle.

As complexity of the circuits increases testing of the circuits become more difficult, challenging and power consuming. Over the last couple of decades or so engineers have constantly tried to develop different approaches to test the ICs, to reduce the effort and power consumption in the test mode. Several algorithms and models have been used to make the process of testing easier. One among these is BDD (Binary Decision Diagram). BDDs have been used studied comprehensively for a theoretical approach. When complexity issue is considered, number of nodes in the BDD are inspected. BDD helps in an easier way to work around and manipulate the Boolean functions [1]. The techniques using BDD is helpful in many applications which uses CAD. Hence the usage of memory becomes a critical factor while using BDD. The order in which variables are present is an important factor which contributes to the size of BDD and hence it also influences the memory consumption. Therefore, there are several approaches which are developed to reduce the size of BDD and thereby reducing the memoryconsumption.

In [2] and [3] different techniques have been introduced to reduce the size of BDDs. In [2] the minimization technique is performed by exchanging the variables in BDD in such a manner that it is optimum. It is performed using and algorithm called Friedman's algorithm. Along with that greedy method is used which is based on exchanging of variables which are adjacent. Mainly performed for 3,4 variables. There are several other methods which are employed in variable reordering. A heuristic method in which the graph is dynamically reorder, that is during the time of BDD construction. It helps the graph to stay more compact [7]. The algorithm that uses bidirectional swapping and oscillates to such that the best possible order of the variable is obtained. This algorithm shows that the number of cycles required for reorder is drastically reduced. One of the main advantages of this is that computation cost is drastically reducing the computation cost. In [4] a different type of approach is used in memory consumption reduction. It is by lessening the number of paths present in BDDs. Also, applications in CAD such as DSOP (disjoint sum of products) minimization and method for integration of SAT and BDD is also described in it. Another approach to make test pattern generation easier is using *Reduced Ordered Binary Decision Diagram* (ROBDD) [5]. In ROBDD based approach redundant paths in the BDD are removed which will reduce the complexity.

Here work proposed is ZBDD based test pattern generation. It further reduces the number of paths present in the BDD. Further explanation of ZBDD and ROBDD is explained in section II. The advantages of using ZBDD are generating a set of relaxed test vectors [6], reducing memory consumption and process of test pattern generation is faster which is evident from the cache hit. ZBDD serves another advantage which is to reduce test power. When circuit the circuit is operated in test mode it tends to consume more power than when operating in functional mode. Hence if ZBDD is used for test patter generation, it will help in reduction of power consumed when the circuit is beingtested.

II. BDD, ROBDD AND ZBDD

BDD is a non-cyclic, graphical and a compact way of representing Boolean functions which are mainly used in CAD based applications. By replacing the nodes in the BDD with multiplexors it can be directly diagramed into circuits [4]. Consider the Boolean function $F(W,X,Y,Z) = \bar{W}X + YZ$. The BDD graph is represented in Fig.1.

From Fig.1 it can be observed that there are two nodes at which the graph terminates. These are called the leaf nodes which can either be '0' or '1'. 'W' is called the parent node or

root node. The leaf not will not have any child nodes. Each intermediate node will have a parent node and child node. The dashed line Represents the case corresponding to which the variable will take a '0' value and solid line represents the case were the variable will take value '1'. From the BDD it can be observed that the areas which are circled are isometric. These isometric subgraphs can be integrated and hence it will further reduce the size of BDD.

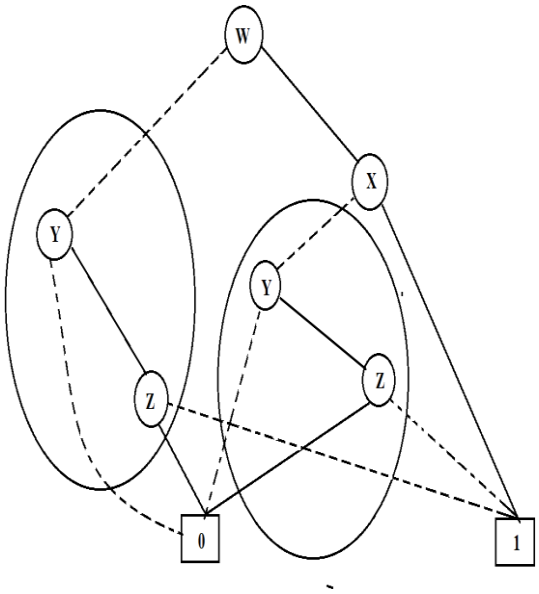

Fig.1: BDD of function $F(W, X, Y, Z)$.

Fig. 2 shows the BDD in which the isometric subgraphs have been removed. It is the ROBDD form of the same function.

ROBDD based implementation can be performed in various manner. One of the ways is to substitute nodes in ROBDD by MUX or INVERT-AND-XOR. The ROBDD based circuits can be further used to test multiple stuck at faults also [6].

Another form of BDD in which the branch which is solid line, that is '1'-branch which will terminate at leaf node '0' is removed. In this situation it helps in removing the redundancy which existed for a better representation. In the work proposed here use of ZBDD is made because of the reasons mentioned above. Analyze the example of the same function, f(W, X,Y,Z), the ZBDD of the function is given in Fig. 3. Here it can be observed that the solid line from Z to leaf node '0' is removed. By the removal of this path the test pattern that is generated will be more relaxed. To extract test vectors, a traversal shall be made from root node of the of the ZBDD to the leaf node. Consider the example, path from root node W through X. The vector generated for that path will be 11XX (assuming order of variables to be W, X, Y, Z).

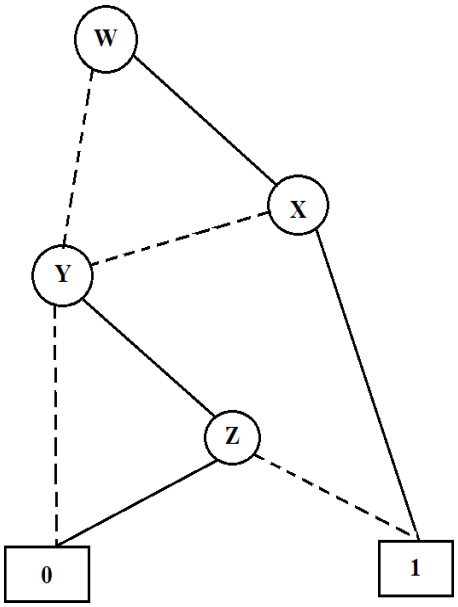

Fig .2: ROBDD of function $F(W, X, Y, Z)$

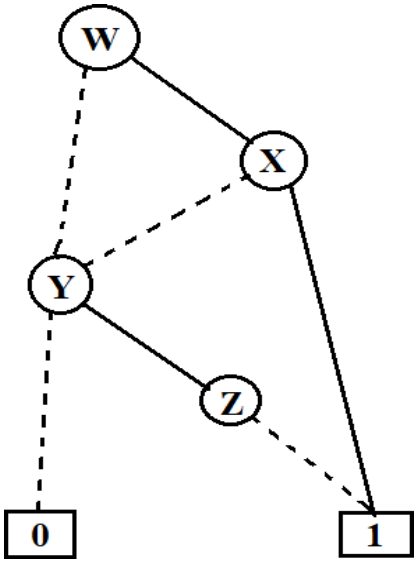

Fig. 3: ZBDD of function $F(W, X, Y, Z)$

III. PROPOSED WORK

Here the method that is employed is manipulation of ZBDDs and generate the test patterns. The approach is to use CUDD (Colorado University Decision Diagram) tool to perform the manipulation on ZBDD. To perform that combinational circuits written in textual form known as BLIF (Berkeley Logic Interchange Format) is used. Using CUDD memory related parameters are also captured. The BLIF format is written in the form as shown. It is described a circuit when viewed as a directed acyclic graph with each node describing combinational logic. Each node will have couple of levels, a single output and a logic function describing it.

Following is an example of a model for a circuit written in BLIF format:

.model<name of the model>

.inputs<input ports>

.outputs<output ports>

<command>

……..

.end.

To generate the ZBDD nanotrav is used. It is a program available with the CUDD package. It takes the input as BLIF file and generates the ZBDDs for the primary outputs. After running the program test vectors are obtained as well. To generate test vectors to detect a stuck at fault, a fault injected circuit is required. Hence, in the BLIF file available for a fault-free circuit a fault is to be injected. The vectors generated by the faulty circuit ZBDD and the vectors generated by the fault free circuit ZBDD, XOR operation is performed among them. The result obtained is the test pattern to detect that stuck atfault.

IV. INJECTING FAULTS

In injecting a fault in a circuit, which can be either stuck-at 0 or stuck-at 1 is done in the BLIF file of the circuit. For stuck- at 0 fault an and gate with one input as '0' and other input the net at which the fault is to be injected is used. Similarly, for stuck-at 1 fault OR gate with one input as '1' and other input as net at which the fault is to be inserted is used. This operation is done in the BLIF file of the circuit which is used to generate the ZBDD. To inject this a C++ program is written. Fig.4 shows the steps that are executed by the program.

Once the faulty BLIF file is generated it is again run using nantotrav. The nanotrav generates the test vectors for the injected fault circuit.

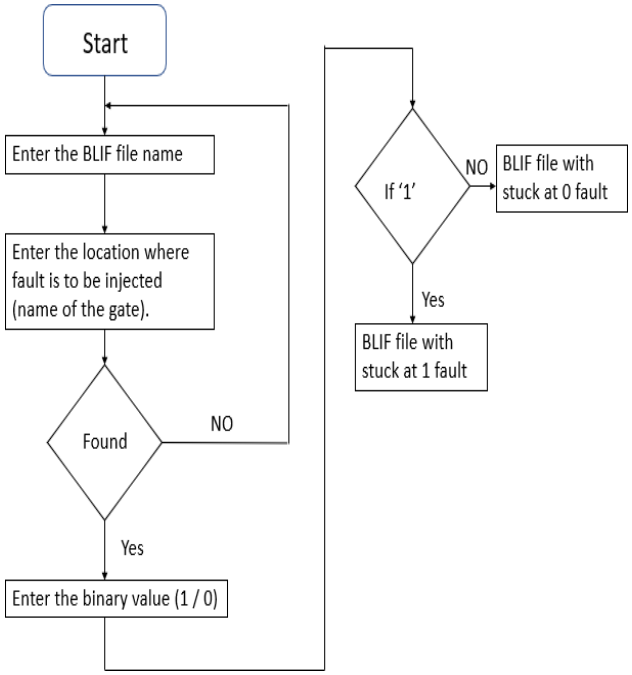

Fig. 4: Steps executed by the C++ program to insert fault.

To obtain the test patterns to detect the fault that is injected, the test vectors from the faulty ZBDD is XORed with the test vectors from the true ZBDD. The vectors which are obtained from ZBDD one which has the greatest number of don't-care conditions are taken because it gives more relaxed set of test patterns.

Along with the test vectors, there are several other parameters which are obtained by running the nanotrav program for both true as well as faulty ZBDDs. Some of them are CUDD modifiable parameters and some of them are non-CUDD modifiable parameters. The description about these parameters are further discusses in section V.

V. RESULTS AND ANALYSIS

After nanotrav program is ran and test vector is obtained for both true and faulty ZBDD, it is XORed to get the test vector to detect that fault. Along with that certain parameters are also considered which are shown in Table I and Table II. Among the CUDD modifiable parameters the following are the parameters that are analyzed.

Maximum number of variables sifted while reordering: It is the number of variables that is removed while the ZBDD is reordered. As discussed in section I, reordering is an important aspect to reduce the size of binary decision diagrams. Sometimes there might be certain variables which can be removed while reordering because those variables act as redundant variables. Variable sifting will help reduce the size of the ZBDD which intern will help in reducing the power consumption required for testing also the computational cost will reduce.

Maximum number of variable swaps per reordering: The number of variables that is are swapped also is a part of reordering which will help in the reduction of size of ZBDD. If the order in which the variables are written, and we can manipulate that ZBDD in such a way that the order in which we write the variables also helps in removing redundant paths and reduces the complexity ofZBDDs.

Cache entries: cache entry is created when a block data from the main memory is written into cache memory it is called cache entry. So, cache entry helps in reducing the time that is required for the computation because the time taken for a program to access data from the main memory is much more than the time required to access from cache memory. The cache mainly holds the data which are frequently used by the program.

Cache hits: when the requested data is present in the cache entry it is called cache hit. More the cache hit faster the execution of the program will take place.

TABLE I.
BDD RELATED PARAMETERS GENERATED BY CUDD

Circuit name	Number of ZBDD variables	Number of ZBDD nodes	Number of variables sifted per reordering	Number of variable swaps per reordering
C17	10	27	1000	2000000
C880	120	7784	1000	2000000
c432	72	2318	1000	2000000
c1335	80	62142	1000	2000000
C1908	66	80194	1000	2000000
C17 with stuck at 0 fault	10	10	1000	2000000
C880 with stuck at 0 fault	120	7718	1000	2000000

TABLE II.
MEMORY PARAMETERS GENERATED BY CUDD PROGRAM

Circuit name	Number of cache entries	Number of cache hits
C17	3276	21
C880	524288	11360425
C432	65536	119531
c1335	484562	10672811
C1908	524288	3079343
C17 with stuck at 0 fault	3276	5
C880 with stuck at 0 fault	524288	113680971

VI. CONCLUSIONS

In the work done, the ZBDDs are used to generate the test vector which helps us to obtain a relaxed set of test vectors. Test vector for testing single stuck at faults for the combinational circuits have been obtained. Apart from these the parameters which are generated by running the CUDD program which includes both memory operation related and ZBDD parameters are also analyzed and it is observed that lesser memory time is consumed for ZBDD to generate test vectors as cache hits is high also a greater number of variable reordering also takes place.

***Abstract*— The Requirement of system capacity is increasing due to the rise in the number of computer users. This can be achieved by optical communication using WDM technology. Using WDM technology multiply many carrier signals onto a single optical fiber using different wavelength to boost up capacity. Dispersion effects the transmission of the signal along an optical fiber. In the proposed model, three techniques for dispersion compensation (per, post, and mix) has been designed using dispersion compensation fiber (DCF) in 8 channel WDM. According to this topology with the help of 5 Gbps transmission data rate model is compared non-return-to-zero (NRZ), return-to-zero (RZ) pulse in which signal mode fiber (SMF) has been considered using the length of 120 km. The results such as Q-factor and bit error rate (BER) represent pre-compensation scheme using RZ gives better results and also output power at EDFA calculate using optisystem 7.0 software.**

Keywords— WDM, DCF, FBG, SMF, NRZ, RZ, BER, MZM, EDFA.

I. INTRODUCTION

In recent years, glass fiber communication has become one of the most pillars of contemporary telecommunications networks that is because of its fast development and its broad vary of applications. Nowadays, these fashionable telecommunication networks have become additional and additional complicated. In optical network [1], WDM topology is presently widely used in telecommunication infrastructures and is expected to play a key role in upcoming generation networks and the future net. WDM is a strategy for transmitting information from various sources over a similar fiber optic connection in the meantime whereby every datum channel is carried individually exceptional wavelength. WDM innovation can amplify the limit of the current fiber optic system without including extra strands. In WDM [2-4] every correspondence channel is assigned to an alternate recurrence and multiplexed onto a solitary fiber. At the goal, the wavelength is spatially isolated to various collector areas. Henceforth the limit of optical transmission frameworks can be expanded utilizing WDM. When totally different wavelengths of lights pulse propagate in associate glass fiber, it undergoes a development of dispersion which ends up in a very temporal spreading. The most common topology used for compensation of nonlinear effects of dispersion is DCF (negative value of dispersion coefficient minimize the positive value of dispersion coefficient in fiber [5]) and FBG that reflect a particular wavelength [6-8]. Likewise, there are a couple of sorts of enhancers, for instance, SOA, EDFA, and Raman that have been acquainted with experience the lessening impacts. However, EDFA [9-11] still offer higher results. A comparative analysis is done between NRZ and RZ pulse [12]. Difference between NRZ and RZ is the symbol rate use a clock pulse in RZ. Pre, post and symmetric design are generated and describe which give the best result [13].

In this paper, II consists of dispersion compensation techniques, III consists simulation sat up for are applied methods, IV consists of Q-factor, BER result and simulation layout and last discuss the result.

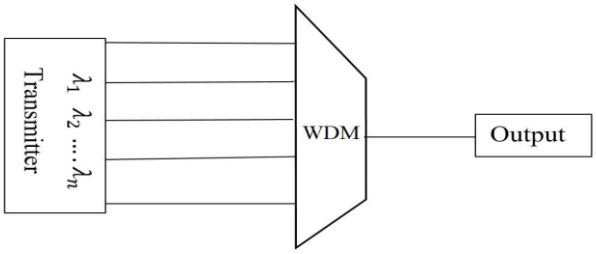

Fig. 1 Simple working block of WDM

II. DISPERSION COMPENSTION TECHNIQUES

In chromatic dispersion, the light totally different wavelengths travel at the side of different velocities in single mode fiber. Beams will arrive at the receiver at different times even beams propagate along with the same path. The result is broadening of the pulse. Pulse spreading in chromatic dispersion applied in the network is calculated using equation (1).

$$\Delta t = DL\Delta\lambda \quad (1)$$

Where D is the dispersion parameter, L is fiber length. DCF, FBG use for compensating dispersion. DCF has negative dispersion between -70 to -90 ps/nm/km. Since the 1980s for compensation of dispersion, the idea of DCF is introduced. DCF has negative dispersion coefficient which reduces/decrease the positive dispersion coefficient when SMF is applied in the WDM model. So that, dispersion is zero.

$$D_{SMF} L_{SMF} + D_{DC\,F} L_{DCF} = 0 \quad (2)$$

D and L represent dispersion and length of fiber respectively. In FBG [14], [15] a particular wavelength is reflected and all rest wavelength is passed. This particular wavelength is reflected by Bragg grating. The wavelength calculates using equation (3).

$$\lambda_{bragg} = 2\, N_{eff}\, \Lambda \qquad (3)$$

λ_{bragg}= Bragg's wavelength, N_{eff} effective refractive index when light propagates in fiber and Λ is the grating period of variation.

III. MODELING OF 8X5 GBPS WDM OPTICAL TRANSMISSION

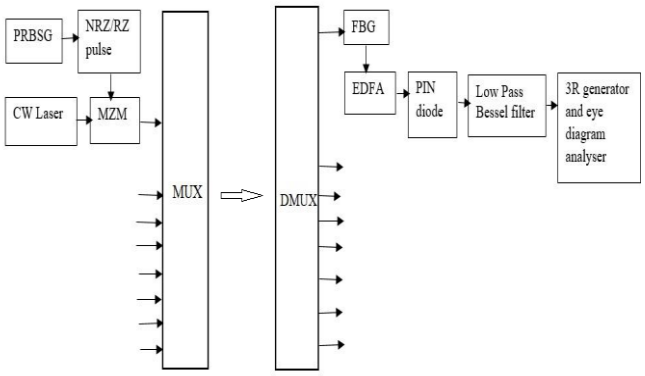

Fig. 2 Principal model of 8 channel WDM for dispersion compensation

Figure 2 shows the principal model of the paper. In this displaying, at transmitter part use CW laser which is nonstop wave laser, NRZ (non-come back to-zero) or RZ (come back to-zero) beat produce, pseudo-arbitrary piece grouping generator (PRBSZ) and Mach Zehnder modulator (MZM). Advanced sign is produced by PRBS generator and heartbeat generator likewise optical sign is created utilizing CW laser which is adjusted with the assistance of MZM show persistent wave laser, NRZ (non-come back to-zero) or RZ (come back to-zero) beat create, pseudo-arbitrary piece succession generator (PRBSG) and Mach Zehnder modulator (MZM). Digital signal is generated at 5 Gbps and optical signal generate using frequency range 193.1 to 193.8 THz (C band) and 0 dB power at the laser. Dense wavelength division multiplexer (DWDM) multiply/set all wavelength at 10 GHz bandwidth. At the end of the demux, an electrical and light signal modulate optical signal generates back in electrical using a pin diode, low pass Bessel filter, 3R generator, and eye diagram analyzer which show the result. The multiple channels using 8 ports DWDM model is introducing, for compensation of scattering in pre, post, and mix or symmetric model. In pre-compensation model DCF placed before SMF and in post-compensation DCF placed after SMF. DCF is used by placing both sides of single mode fiber in the dynamic compensation model.

In the pre-compensation model length of DCF is 25 km. and use 120 km SMF. In modeling gain, EDFA is used which have variable gain between 10 to 30 dB, in first optical amplifier use 10 dB gain and in second use 15dB gain. Different parameters are set in model i.e. dispersion at DCF, attenuation, dispersion slope, dispersion at FBG, Bandwidth of wavelength division multiplexer (WDM). Using 100 GHz spacing frequency range used in the layout is which is start at 193.1THz at every channel. 3R generator performs three types of work like improving the shape of the output pulse, again amplify the data pulse and retiming. Subsystem blocks which connect to WDM are represented transmitter modal at channel 2 to 8. Subsystem 2 and 3 represent receivers at output channels.

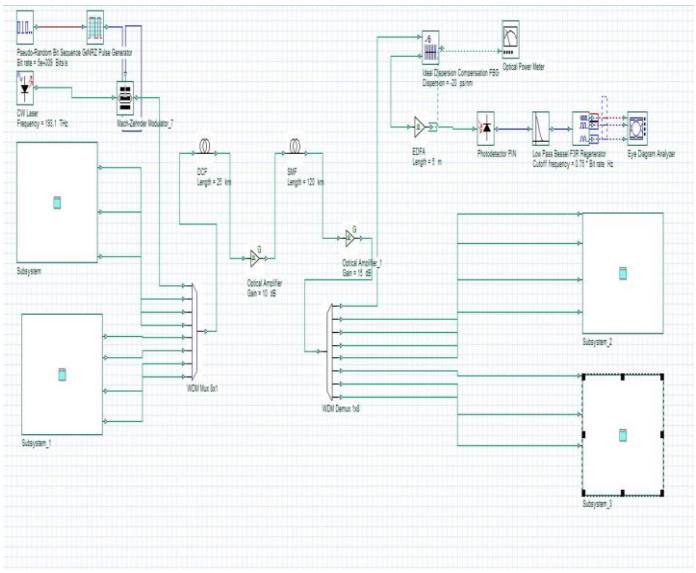

Fig. 3 Simulation layout of pre-compensation using 8 channel

TABLE I. BASIC PARAMETER OF WORK ARE

Parameters	DCF	SMF
Length (km)	25	120
Attenuation (dB/km)	0.2	0.2
Dispersion (ps/nm/km)	-80.4	16.75
Dispersion slop ($ps/nm^2/km$)	-0.3	0.075

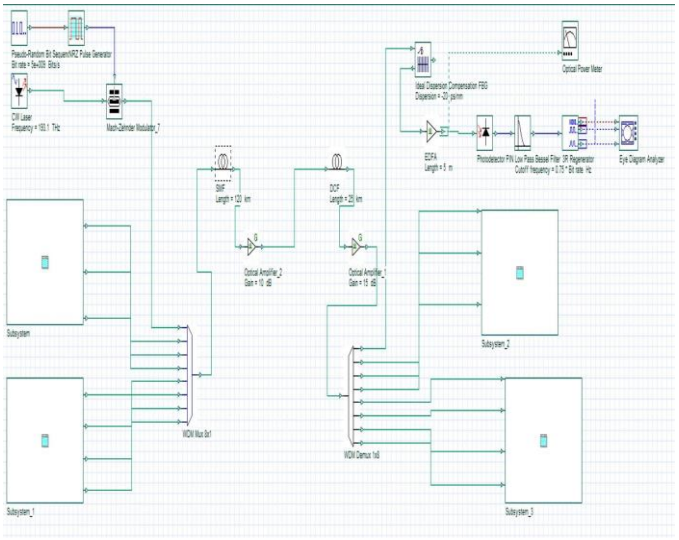

Fig.4 Simulation layout of post-compensation using 8 channel

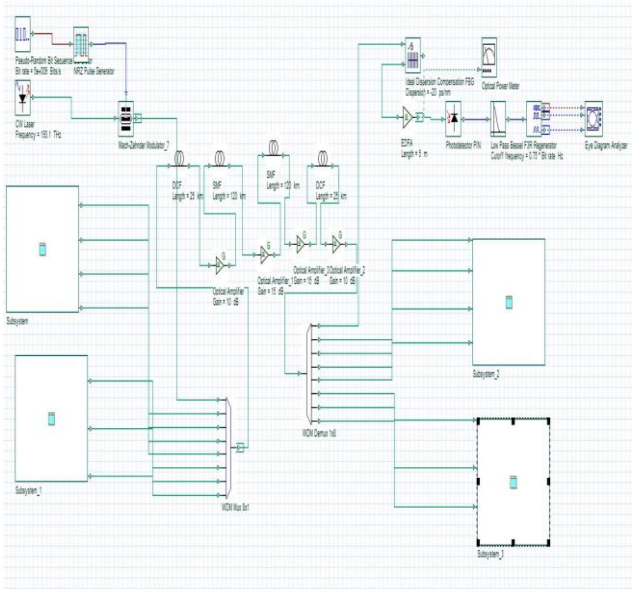

Fig..5 Simulation layout of mix model compensation using 8 channel

IV. RESULT AND COMPARISON

When simulating the model result is generated at eye diagram analyzer, max Q factor and minimum BER of per, post, and mix model at all 8 channel can be seen. The criteria for acceptable value of Q factor is greater than 6 and BER is less than 10^{-12}. Tables are generated using NRZ (table II, III) and RZ (table IV, V) pulse simulation. When seeing RZ pulse performance is better to compare to NRZ pulse. Using NRZ pulse at channel 3 output of Q factor is 8.7355 and BER is $7.51e^{-19}$ which is greater than all output value of post and mix compensation. Like this using RZ max Q factor is 19.3928 and BER is $4.38e^{-84}$ which is better than all pre, post, and mix compensation. NRZ and RZ coded pulse result shown that pre-compensation scheme using RZ pulse gives good performance in table 5. Also, the output power valve of EDFA at the receiver part shown in Table VIII and IX. Eye diagram of NRZ and RZ pulse also shown in figure 6 and 7. Graph plots between Q-factor (NRZ and RZ) and channels are shown in figure 8.

CANCLUSION

To minimize the chromatic dispersion a new optical transmission model in introduced using optic system 7.0 software. This design uses 8 channel wavelength division multiplexer (WDM) to test the reliability of the system which increases the use of bandwidth and result remain valid. In this paper use both compensators, DCF, and FBG. DCF use along SMF between MUX and DEMUX and FBG at receiver using -20 ps/nm/km. Pre, post and symmetric (mix) compensator, three scheme are developed to decrease chromatic dispersion using 120 km. SM fiber and 25 km. dispersion compensator fiber. When analyzing the performance of three scheme using Q factor and BER, see that pre model using RZ pulse gives much better result compare to all post and mix model. Using output power meter, the output power is analysis at EDF amplifier. In further, compensation dispersion and nonlinear effect by increasing the number of the channel at multiplexer input point and applied on a complex system.

Collaborative Filtering based Recommender System using Regression and Grey Wolf Optimization Algorithm for Sparse Data

Sneha V.[1], Shrinidhi K.R.[2], Sunitha R. S.[3], Dr.Mydhili K. Nair.[4]
[1,2,3,4] Department of Information Science and Engineering
Ramaiah Institute of Technology, Bangalore, India

***Abstract* - In this epoch of technology, where recommendations are the backbone of E-commerce and Media-services, one of the extensively used approach for implementing recommender systems is Collaborative Filtering. This approach recommends items by identifying users who share similarity in rating the items by observing the user-item ratings matrix. In the real-world, users only rate a limited number of items from the catalogue leading to high sparsity in user-item ratings, which makes it difficult to identify similar users and recommend items accurately. To handle sparsity in user-item matrix, which is one of the major challenges encountered while implementing recommender systems, the paper proposes a technique of Collaborative Filtering using Regression to predict the ratings of unrated items on the basis of the user's history of ratings and similarity to other users, combined with - a nature-inspired algorithm called - Grey Wolf Optimization (GWO) algorithm applied to optimize the loss function. Personalised recommendations can be provided to the users for those highest predicted ratings. The proposed technique is observed to perform well in highly sparse data scenarios in terms of accuracy, user coverage and different variants of hit rate.**

Keywords—Collaborative Filtering; recommender system; sparse matrix; regression; grey wolf optimization; evaluation metrics; hit rate

I. INTRODUCTION

With the striking rise in the number of digital users and it's consequence of rapid increase in the amount of data being generated on the internet, it has become important for industries to filter, map and provide users with the relevant information according to their personalised preferences. Recommender systems have therefore become the backbone in various domains including leading platforms of E-commerce ranging from Amazon, Alibaba and Flipkart, Media-services like Netflix and YouTube, Social-Media Platforms like Facebook and News websites. They help in planning the marketing strategies for these industries in order to increase sales by enhancing user experience and achieving better user satisfaction, as they fulfill the user need by recommending the items of user interest, which in turn leads to establishment of loyalty of users. It also helps in bringing those items into the notice of the user which are not easily seen by the user while browsing through these platforms, until and unless filtered.

One of the extensively used approach in building a Recommender system is Collaborative Filtering (CF), which identifies users who share similar interests in items. The central premise of it being, "if user P shares similar opinions as user Q on topic T_1,T_2,T_3, ... ,T_{n-1} then the user P is likely to have the same opinion as user Q on topic T_n". This technique of collaborative filtering is used when identifying the dominant factors of individual items which are to be recommended are intricate in nature to perform content filtering. Under such circumstances, identifying like-minded users help in recommending a new item to a user which has been rated highly by another user who shares similar choices and preferences. Identifying convergent profiles of users can be done by using the history of identical ratings given by the users to the same set of items.

Most often traditional approaches of CF Recommender System encounters the problem of Data Sparsity since all possible interactions between each user and item are not available in the user-item ratings matrix. This matrix faces the problem of sparsity as users review and rate only limited items when compared to the number of items that are present in the catalogue. [3-4],[11-12] To deal with the missing values in the user-item ratings matrix, the paper proposes the concept of Regression based Collaborative Filtering combined with GWO for a dataset that consists of ratings given by users to items. It searches for similar users on the basis of the user's past record of ratings and predicts the missing ratings. The nature-inspired optimization algorithm GWO[1-2] helps in predicting optimal ratings by optimising the loss function.

The remaining sections of the paper is structured as follows: Section II exhibits the literature review on the challenges faced by recommenders, results of regression techniques applied on sparse datasets and surveys on GWO and its applications. Section III contours the algorithm and equations of GWO proposed by Seyedali Mirjalili et al.[1] Section IV presents the proposed recommender system and Section V examines the results of proposed system and investigations on various evaluation metrics. Finally, Section VI concludes the work.

II. LITERATURE REVIEW

In the recent decade, several works have been conducted in order to build efficient recommender systems. G. Adomavicius et al describe collaborative, content based and hybrid recommender approaches which are the current

generation of methods to implement recommender systems and they provide the overview of implementing these recommenders on a broad scale satisfying high-scaled applications. They also provide insights on the various limitations of these methods including data sparsity and cold start issues.[11] Xiaoyuan Su et al also have investigated on the various research trends and problems faced by the current generation of recommenders. They also talk about data sparsity being one of the major challenges in real world data when collaborative filtering technique is applied to implement recommenders, as finding similar neighbours in a sparse data is difficult, leading to less accurate recommendations being made to the user.[12]

To overcome this major issue of data sparsity, Wang Bailing et al discussed the Three-Tier Network Architecture of a Recommendation System built on the basis of a Regression Model which established that the prediction of preference of the test user for the test item can be calculated using the correlation score between the item and the user. The experimental results presented by them indicated that regression can perform superior when compared to traditional CF algorithm.[5] Similar approach of linear regression using the linear correlation indicated by Pearson Correlation Coefficient discussed by Xinyang Ge et al showed that the approach of regression helps in providing better accuracy in recommending and appealing the users.[8] Slobodan Vuceti et al addresses the problem of data sparsity in CF by using Regression. They also have proposed the approach of predicting the user's preferences for the unrated items on the basis of ratings provided by an active user for the items in the catalogue by combining statistical methods. They provided experimental evidence obtained that their proposed approach is superior to non-personalised predictors even when the rating matrixes are very sparse and also that the regression based recommendations can be applied to data with high sparsity scenarios.[7]

Seyedali Mirjalili et al who proposed the concept of GWO based on inspiration drawn from the nature have discussed on the differences of using conventional gradient optimisation technique vs meta-heuristics optimisation techniques. They proposed GWO stating it had derivation-free mechanism, flexibility, simplicity and avoidance of local optima.[1] Ali Parsian et al used GWO in back-propagation algorithm to find the optimal values for weights and biases. They discussed the drawbacks of gradient based back propagation which usually has slow convergence rate and tends to get trapped in the local minima which is overcome by using GWO. GWO has the feature of global searching where the wolves aim at finding optimal solutions in different directions in order to minimize the risk of being stuck at a local minimum.[1] The GWO algorithm also helps in incrementing the convergence speed by setting the parameter A.[9] S. Hosgurmath et al proposed the technique of using GWO with Linear Collaborative Discriminant Regression Classification for Face Recognition where GWO was again used to find optimal weights that had to be assigned to features. They also show a comparison of their proposed algorithm using GWO working better than Regression Classification without GWO for different image datasets.[10]

III. GREY WOLF OPTIMIZATION ALGORITHM

GWO is a meta-heuristic technique of optimisation which simulates the leadership hierarchy of the grey wolves that are widely known for their hunting strategies in groups. The wolves in the pack are ranked according to their strength and fitness, with Alpha being the chief, followed by the Beta, Delta and Omega. In the pack, generally, Alpha wolves are responsible for taking decision while Beta are subordinate wolves that assist Alpha while taking decisions and ensures that all subordinates obey and give feedback to Alpha. Delta wolves are accountable for watching boundaries and protecting the pack while Omega wolves are the weak ones of the pack that follow the rest.[1-2]

In the GWO algorithm, the objective of the pack is to search the optimal solution for a given problem by implementing the three milestones of hunting as observed in the natural behavior of the wolf packs - exploration (searching for the prey,) exploitation (encircling the prey), and finally launching the attacking on the prey. As multiple iterations of the algorithm are carried out, the wolves try to get as close as possible to their prey by updating their positions. The fittest solution (one with least distance from prey) is considered as Alpha wolf which guides the wolf pack in every iteration along with the help of the second and third fittest solution, called Beta wolf and Delta wolf respectively. The rest solutions are treated as Omega wolves. Algorithm and equations of GWO is briefed in this section.[1]

A. *Parameters Initialisation Phase*

- Initialise the grey wolves in the pack P (pack size)
- Initialise vector 's' which linearly decreases from 2 to 0 as follows -

$$s = 2 - current_{iteration} * (2 / total\ iterations) \quad (1)$$

- In order to initialise vectors U and V two random vectors r_1 and r_2 are initialised in the range [0,1] as follows -

$$U = 2 * s . r_1 - s \quad (2)$$

$$V = 2 * r_2 \quad (3)$$

B. *Population Initialisation Phase*

- Initialise random positions for each wolf in the pack P
- Calculate the fitness of each wolf using -

$$D = |V.X_{prey}(t) - X_{wolf}(t)| \quad (4)$$

where X_{prey} and X_{wolf} is the position of the prey and the wolf at time 't' respectively

$$X_{wolf}(t+1) = X_{prey}(t) - U.D \quad (5)$$

$X_{wolf}(t+1)$ is the positional difference of the wolf with the prey i.e the fitness score for that particular wolf

C. Rank-wise ordering phase

Based on their fitness score for all the wolves in the pack, they are ranked as

- W_{alpha} = Fitness of First best wolf of the pack
- W_{beta} = Fitness of Second best wolf of the pack
- W_{delta} = Fitness of Third best wolf of the pack

D. Updation phase

while $current_{iteration}$ < total iterations or until optimal solution is obtained do

- for each wolf in pack P do

  Update the position of the wolf using the given equations

  $$D_{alpha} = |V_1.W_{alpha} - W(t)| \quad (6)$$

  $$D_{beta} = |V_2.W_{beta} - W(t)| \quad (7)$$

  $$D_{delta} = |V_3.W_{delta} - W(t)| \quad (8)$$

  $$W_1 = W_{alpha} - U_1 . D_{alpha} \quad (9)$$

  $$W_2 = W_{beta} - U_2 . D_{beta} \quad (10)$$

  $$W_3 = W_{delta} - U_3 . D_{delta} \quad (11)$$

  $$W(t+1) = (W_1 + W_2 + W_3) / 3 \quad (12)$$

  end for

- Reinitiate the values of V, U and s
- Update the fitness score for each wolf in the pack
- Update W_{alpha} , W_{beta} , W_{delta} based on their fitness score
- Increment $current_{iteration}$ by one

end while

E. Producing Result

- Return fitness score of the optimal solution (W_{alpha})

The algorithm parodies the search process and hunting strategies of the grey-wolves with an objective of finding the prey. This algorithm is now proposed along with regression for predicting the non-existing values in the user-item rating matrix and optimizing the loss value, thereby addressing the sparse rating matrix in recommender systems.

IV. PROPOSED RECOMMENDER SYSTEM

The process begins with setting arbitrary value for population of the grey wolves (nominee solutions) and assigning ranks to any three wolves as Alpha wolf, Beta wolf and Delta wolf. The parameters initialisation phase of the GWO algorithm is executed. Since the wolves have no idea of where the preys (optimal solutions) lie in the $m * n$ dimensional search space, in order to execute populations initialisation phase each wolf in the pack assigns a set of random values that is used to initialise the weights and bias to be given to identify the user-user similarity. Therefore, each wolf must assign itself a list of $(n * n) + m$ number of random values where m and n indicates the number of items and users in the user-item ratings matrix respectively. The first $(n * n) - n$ values of the wolf can be assigned as the weights to be allotted to each user-user combination (W_u) to check the similarity between them. The remaining $n + m$ values can be assigned as bias for each user (B_u) and each item (B_i). It is to be noted that similarity of a user or item with itself is not allotted a weight.

To prevent users who give high ratings or items that have high ratings from dominating the prediction, we need to tone down all dominating variables by normalising the dataset. This is done by calculating the mean deviation for the all the ratings in the dataset.

$$\sum_{i=0}^{m}\sum_{j=0}^{n} r[i,j] = r[i,j] - \bar{r} \;\; if\; r[i,j] \neq \emptyset \quad (13)$$

$$\sum_{i=0}^{m}\sum_{j=0}^{n} r[i,j] = 0 \; if\; r[i,j] = \emptyset \quad (14)$$

Each wolf now needs to make its prediction of the ratings which is made by using the Regression algorithm. To make predictions based on user similarity, equation (15) which represents the regression line equation is used. Each cell of rating matrix has its regression line equation to check its similarity with other users which are the features to be considered and each of these features are assigned weights chosen by the wolves. The predictions are normalised by calculating their average based on the number of users who have reviewed the item, so that none of the user's ratings dominate the prediction.

For each wolf, $\sum_{i=0}^{m}\sum_{j=0}^{n}\ (p[i,j]\ =$

$$\sum_{k=0}^{n}(Wu[k,j]*(r[i,k]-\ (Bu[k]\ +\ Bit[i]\ )))$$

$$+\ Bu[j]\ +\ Bit[\mathrm{i}]\ +\overline{r}\ )\qquad(15)$$

Root Mean Square Error (RMSE) is the applied loss function for the proposed technique. The loss function is calculated for the predictions made by each wolf based on its prediction on the initial rating matrix which is used to indicate the fitness score of the wolf.

For each wolf,

$$\mathrm{RMSE}=\sum_{i=0}^{m}\sum_{j=0}^{n}(\sqrt{(r[i,j]\ -\ p[i,j])^2})\qquad(16)$$

According to the RMSE obtained by each wolf in each iteration the ranks are re-ordered. Each wolf (nominee solution) updates its list of weights to be assigned to features following the lead of Alpha, Beta and Delta (since they have the least RMSE value), using the GWO algorithm, trying to reach the optimal solution. The central premise being if these wolves have the least fitness scores, it implies that the weights assigned by these wolves are closer to the optimal weights that are needed to be assigned for making accurate predictions while making recommendations. Therefore all other wolves in the pack must update the weights according to the weights of these three wolves using the procedure mentioned in the updation phase.

Over the course of iterations, the wolves estimate the probable ratings, their fitness scores are calculated, their ranks are reordered and weights are updated on the basis of new Alpha, Beta and Delta elected at every iteration. The parameter 's' decreases from 2 to 0 through the iterations with an eye to accentuate exploration and exploitation. The wolves tend to converge towards the prey and diverge from the prey when U < 1 and U > 1 respectively in order to maximise the solution search space as much as possible and also to get closer to the optimal solution. Finally, the termination of the algorithm occurs on satisfying the end criterion i.e., either reaching desired optimal solution or reaching the end of iteration count that was initialised. On running the model, all the sparse values are filled with predictions made by the Alpha wolf (the best solution), hence handling the issue of data sparsity. Based on the prediction matrix retrieved, personalised recommendations are made to each user for those highest predicted ratings since the predicted ratings are obtained on the basis of his earlier ratings of items and the similarity of other users.

V. Experiment Outcomes and Investigation

For the evaluation of the proposed recommender system, the open sourced Movielens dataset is examined. This dataset is highly sparse with sparsity ratio as 0.8630 implying very less interactions between the movies and the users. This dataset was divided into four datasets. Each of the sub dataset was trained using regression and GWO and the testing was carried on 3 folds of the test dataset. Various evaluation metrics for the recommender systems [13] are calculated to investigate the proposed model. To measure the accuracy of the model root mean square error and mean absolute error are calculated. The variants of hit rate like cumulative hit rate and average reciprocal hit rate which are the evaluation metrics to identify how well the recommendations are made using top ' k' recommendations is calculated for the model. Finally the user coverage of the model is measured to identify the spread of the recommender model for the users. The results obtained on implementing the proposed recommender systems are discussed in this section.

A. Root Mean Square Error

Root Mean Square Error (RMSE) is calculated by taking the root of the squared difference between the initial user-item rating and predicted rating denoted in equation (17). It gives a measure of how far the predictions are from the initial ratings using the test sets. If the obtained RMSE is less, it implies that the wolves have reached closer to the actual ratings. The RMSE obtained for the proposed model for the test splits of different datasets is shown in Table I.

$$\mathrm{RMSE}=\sum_{i=0}^{m}\sum_{j=0}^{n}(\sqrt{(r[i,j]\ -\ p[i,j])^2})\qquad(17)$$

TABLE I. RMSE OBTAINED FOR THE DIFFERENT DATASETS

Dataset S.No	Test-Split 1	Test-Split 2	Test-Split 3
1	0.4568	0.4128	0.3081
2	0.5146	0.3890	0.5595
3	0.3053	0.4251	0.3052
4	0.3627	0.2922	0.3110

B. Mean Absolute Error

Mean Absolute Error (MAE) is the absolute difference between the initial user rating and predicted ratings, which has to be ideally less. It gives the average magnitude of the error over the test samples as shown in Table II where all the individual difference of ratings have equal weightages while contributing to the error.

$$\mathrm{MAE}=\sum_{i=0}^{m}\sum_{j=0}^{n}(\ |(r[i,j]\ -\ p[i,j])|\ )\qquad(18)$$

TABLE II. MAE OBTAINED FOR THE DIFFERENT DATASETS

Dataset S.No	Test-Split 1	Test-Split 2	Test-Split 3
1	4.6325	4.3995	3.4678
2	6.9207	4.5682	7.3803
3	3.4179	5.2566	3.0345
4	4.8467	3.6051	4.6019

C. Cumulative Hit Rate

Cumulative Hit Rate (CHR) is the measure to keep the count of hits - a match between the top 'k' recommended items and previously rated items by the user - based on a threshold. The hits are considered if any one among the top 'k' recommendations in the predictions match with the items already rated by the user in the initial ratings test set, given that the rating is above a threshold, say 3.5 as used for results in Table III. This technique of considering a 'hit' based on a threshold ensures that the user actually likes the item that is being recommended to him. Higher CHR is an indication of a good recommendations.

$$CHR = hits \,/\, n \qquad \text{If actual rating} > \text{threshold} \qquad (19)$$

TABLE III. CHR OBTAINED FOR THE DIFFERENT DATASETS

Dataset S.No	Test-Split 1 (%)	Test-Split 2 (%)	Test-Split 3 (%)
1	71.42	63.15	66.67
2	76.92	62.50	79.17
3	88.89	69.23	87.50
4	60.00	68.18	75.00

D. Average Reciprocal Hit Rate

Average Reciprocal Hit Rate (ARHR) is greatly a user-centered metric, which concentrates on considering a hit based on the rank of the prediction in the top 'k' recommended list. Reciprocal of rank of the first hit among top 'k' recommendations is taken for each user in the test set which is further summed up and divided by the total number of users in the set. This metric gives preference to the position of the hit in the recommended list as users tend to concentrate largely at the beginning of the recommendation list. It should preferably be higher. Table IV gives the reading of ARHR for different datasets.

$$ARHR = \left(\sum_{i=1}^{n} 1/rank[i]\right) / n \qquad (20)$$

TABLE IV. ARHR OBTAINED FOR THE DIFFERENT DATASETS

Dataset S.No	ARHR (%)
1	100
2	100
3	100
4	100

E. User Coverage

User Coverage (UC) is the measure of how many users are recommended good recommendations of items from the catalogue. It is calculated by sorting the top 'k' recommendations from the predicted ratings and then checking if the user has been recommended any item with the predicted rating above the set threshold for rating. The higher, the better. For testing the model, the threshold set was 3.5 and the average of the user coverage obtained from the test sets is displayed in Table V.

$$UC = hits \,/\, n \qquad \text{If predicted rating} > \text{threshold} \qquad (21)$$

TABLE V. UC OBTAINED FOR THE DIFFERENT DATASETS

Dataset S.No	UC (%)
1	96.67
2	96.67
3	100
4	100

VI. Conclusion

With the rise of digital content distribution, people now have access to online platforms on an unprecedented scale. Therefore the crucial part of the competition for e-commerce platforms and media services is about how to deliver the right content to the right people at the right time. In the real world, data generated in the platforms is highly sparse which leads to inaccurate recommendations made to the users on implementing CF algorithm. The proposed recommender using regression for prediction and GWO of optimizing loss function is observed to perform well on highly sparse datasets. Observations were made by investigating the proposed model on the prominent evaluation metrics of recommenders like CHR, UC, ARHR and evaluation metrics for accuracy like RMSE and MAE. For future studies, the proposed model can be tested on big data and online A/B tests can be conducted for the proposed model to evaluate the system and the feedback of a user has to be taken into consideration to test the correctness of the model.

***Abstract*—Automatic Short Answer Grading (ASAG) has been an area of active research over the last decade. Researchers and data scientists have tried and proposed various approaches based on classical Natural Language Processing, Information Extraction, Vectorization of text, Frequency Based Techniques etc. However, a single method appropriate for all types of short answers and thereby acceptable to all is yet to be found. This paper presents results of work done on ASAG using a Deep Learning approach. The results show the effectiveness of word embedding, hyperparameter tuning and activation function selection for improved classification.**

***Keywords*—Neural networks ; embeddings ; word2vec ; Doc2vec ; automatic evaluation**

1. Introduction

The increasing reach of the internet has improved the quality of living of individuals in a big way. One of the areas having maximum impact is education. Information and Communication Technology (ICT) has bridged the gap of geography and even time, thereby enabling the successful implementation of anytime anywhere learning. However, for correct evaluation of learning outcome, the assessment methodologies need to be automated. Increased number of enrollments for courses increase the load on human evaluators manifold and it becomes impossible to correctly assess the learners answers. The problem is further compounded if the answers are in free text, where the learner is creating his or her own natural language expressions to present the answer.

While evaluating a large number of free text answers in an unbiased manner becomes difficult for the human evaluator owing to variations in mood, mental fatigue, work load and other influences, automating the process has its own challenges. Natural Language Processing being computationally heavy and a complex domain, extracting semantical sense from the answers and evaluating them with the same finesse and benevolence of a human evaluator is a tough ask. It is for such factors that automated evaluation has shifted towards multiple choice type (MCQ) questions in most high stake examinations.

While the efficacy of MCQ type lies to be debated, text based answers have the propensity to return an evaluation of the learners retention, understanding and application skills. Also, the text based answers enhance the creativity of the learner by restricting the scope of presenting their knowledge to only selection of answers amongst some available choices. However, the aim is to evaluate the knowledge gained and not testing the memorizing capability of a learner,so this scheme of evaluation is not appreciated much. It is for such reasons that Automatic Short Answer Grading (ASAG) has gained importance and is under current study.

In this paper we propose a model that considers the fact that every student has a unique writing pattern and evaluate on the basis of semantics of the answers. In the method proposed in this paper, encoding of answers is done using an available scheme for encoding sentences to paragraph vectors, efficient enough to preserve the semantic relation amongst the constituting words .Then the encoded vectors are fed into another neural network that actually does the grading task.

The next section of this paper shares view on related work, using different methodologies. Section 3 sheds light upon some basics of deep learning and section 4 illustrates its use on the proposed work. Section 5 mentions about the experiments performed, its result and analysis and section 6 shares the conclusion of the mentioned approach.

2. Related Work

Building an automatic evaluator for short answers has been an intriguing task for quite a while. Researchers have adopted various techniques for accomplishing the task, however a common platform is yet to be achieved. The task of evaluation of student answers started long ago with first related work published in 1966 by Ellis B. Page[1] which proposed the idea to grade essays by computer.

This paper focuses on evaluation of short answers. Since the problem of evaluation of short answers has existed for long, concerning many of the researches, many approaches have been suggested to target the problem. One such approach that has always been quite popular is LSA[2](Latent Semantic Analysis). LSA preserves well the semantic relations of text but lacks syntactic relatedness. So, syntactically enhanced models were attempted to be built by [3]Kanejiya, Dharmendra, Arun Kumar, and Surendra Prasad. To enhance the performance of the evaluator, attempts were made to combine it with some other models, [4]Lapata, Mirella, and Regina Barzilay (in 2005) suggested that LSA in combination with some other models can retain entity correlation and semantic relatedness. Also, the idea of LSA being used as corpus based evaluation scheme as proposed by [5]Mohler, Michael, and Rada Mihalcea shows LSA to be a really efficient method but with the restriction of being domain specific and also it being effected significantly by the corpus size. Many other methods may not have the advantages that are possessed by LSA but still have proven to be efficient in their own way.

BLEU[6] (bilingual evaluation understudy) is another method which appeared quite frequently for evaluating short answers automatically. Despite not being able to attain high correlation, the method was suggested to be the sole technique for evaluation of short answers by Pérez, Diana, Enrique Alfonseca, and Pilar Rodríguez[7]. As said, BLEU as a stand alone system performs well while LSA was found to be effective for large corpus. Pérez, Diana, et al.[8] proposed in their work a combined schema of both the techniques. However using both techniques at a time can be computationally inefficient.

A concept that is found to be used along with the said techniques is ontology. Domain ontology in combination with LSA enhances the performance of the evaluator as proposed by Devi, M. Syamala, and Himani Mittal[9].Similarly, a work on collaborative use of BLEU and ontology for grading short answers with considerable result is presented by Selvi, P., and A. K. Bnerjee[10].

Also, many approaches involving NLP methods are administered for evaluation as task involved information extraction and NLP has been doing good in this field[11]. Semantic enhanced NLP performs better than lexical matching[12]. NLP is also used in combination with other techniques or with some alterations,[13]Jana and John used NLP and knowledge representation to develop a scoring model for short content or can be based on particular approach of NLP like parts of speech tagging[14].

Deep Learning being a more recent technique presents itself as a bright option to solve the problem under consideration. However, this has not yet been much employed in the domain of ASAG and hence this work. This paper proposes the idea of using deep learning and neural networks to embed the answers into paragraph vectors and then to evaluate them to assign deserving marks using another network which will be fed with vectors obtained from previous network.

3. Deep learning and neural networks

Deep learning and neural networks with multiple level of abstraction in its processing finds its wide application in the area of text processing and are proven to be considerably efficient. An artificial neuron is designed on the basis of a biological neuron in terms of its functionalities as well as the basic structure[15].An artificial neural network is made up of numerous interconnected artificial neurons organized in multiple layers each performing some computation and conveying the computed output to the next layer.

3.1. Deep Neural Nets

A *deep neural network[16]* is an artificial neural network which has multiple hidden layers, apart from the input and output layers. The essence of a *deep* neural network lies in its *depth.* A deep NN can be a significant tool in representing complex, non-linear relationships.

3.1.1. Biological Neuron

A *biological neuron[17]* is the basic building component of the neural network in the human brain that is responsible for reaction to various stimuli. There are millions of such neurons that collectively form the super complex and powerful network. These neurons communicate with each other through various electrical and chemical signals generated.

Each neuron mainly consists of three components: the *soma*, the *dendrites* and the *axon*. There are numerous dendrites associated with a single neuron which are responsible for collecting signals from other neurons. The signals received are then processed in the soma and then the result,which is also a signal is transmitted to other attached neurons through the axon. The neighboring neurons are not exactly attached to the neuron, and there exists a small gap between them called the synapse.

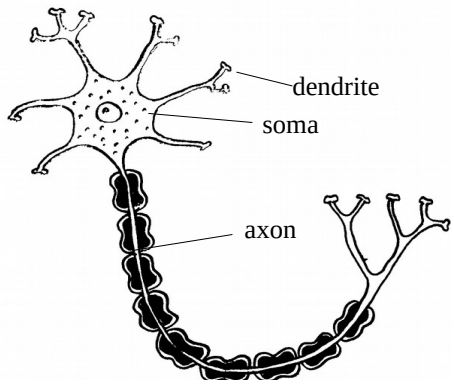

Fig1: Biological neuron

3.1.2.Artificial Neuron

Artificial Neurons were inspired by the concept of biological neurons. Much like a biological neuron, an *artificial* neuron also takes some input values and produces an output. The output value generated decides whether or not the neuron fires. If x_1 , x_2 , x_3 , …. x_n are the inputs provided to the neuron and the respective weights associated with each input are w_1 , w_2 , w_3 , …. w_n then the output is generated in the following manner:

i. Firstly, the sum of the weighted inputs is calculated. Let y_in be the calculated sum. Then y_in is given by,

$$y_in = x_1w_1 + x_1w_2 + \ldots\ldots + x_nw_n = \sum_{i=1}^{n} xiwi \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\text{eq.(1)}$$

ii. The output associated with the neuron, y_out is given by,

$$y_out = f(y_in) \ldots\ldots\ldots\ldots\ldots\ldots\text{eq.(2)}$$

where f is known as the *activation function* since it decides whether the neuron is activated, i.e. it fires, or not.

iii. A few examples of activation functions are identity function, step function, sigmoid function etc.

A simple diagrammatic representation of an artificial neuron is given in Fig2.

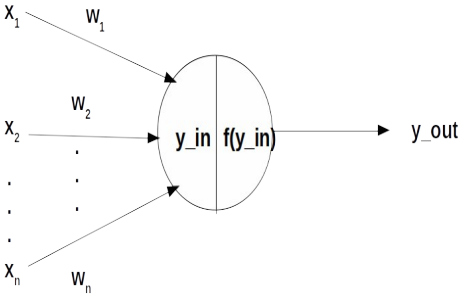

Fig 2: Artificial neuron

3.1.3. Artificial Neural Network

An *Artificial Neural Network* or an ANN is a network of many artificial neurons that interact with each other in an organized way to achieve a certain goal. The neurons in an ANN are structured into three layers, namely the *input layer*, the *hidden layer* and the *output layer.* An ANN consists of exactly one input layer and one output layer, but the number of hidden layers may vary depending upon the developer's choice. However it is always advisable to keep the number of hidden layers at the minimum possible value. No other guidelines are available for the same. The number of nodes per layer is also not fixed, and depends upon the developer to decide. Keeping in mind this flexibility in choice, it is suggested that the developer of a system experiment with small tweaks to the model, as even a slight change may highly affect the accuracy of the system.

In an ANN, each neuron, also known as a "node", is connected to other neuron in the immediate next layer by a connection which has a weight associated with it. These connections may either be unidirectional or bidirectional. An ANN in which each node of a layer is connected to all nodes in the next layer is known as a fully connected network.

A diagrammatic representation of a Feed Forward ANN with one input layer with 'i' nodes,one hidden layer with 'j' nodes and one output layer with two nodes is given in Fig 3.

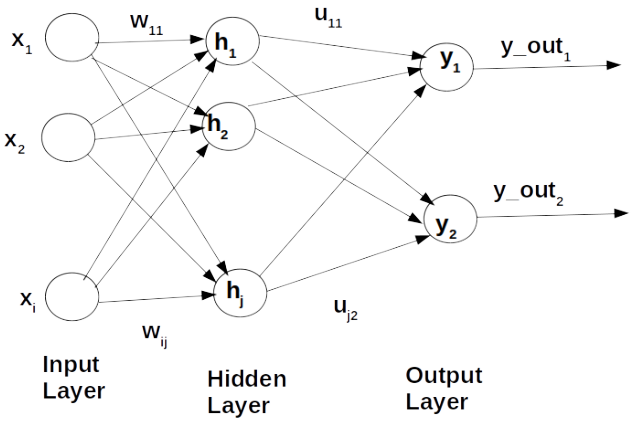

Fig 3: Artificial Neural Network

3.2 Converting Answers to Vectors

It is expected that each student will have a unique way of expressing his/her understanding over the topic. Therefore, it is likely that student answers will be comprising of different words depending on their own preferences. However, neural network computations cannot be directly carried out on words. So, the words must be represented in numeric forms and these numeric representations are expected to be fed into a neural network so that further computations can be carried out.

Initially,an attempt was made to ascertain a function to encode words by using product of three function values, where first function returned the sum of 52 raised to the power of numerical value of the words' compositional alphabets' positional value in english alphabet series, for example, the word "rat" , function f_1(say) would be calculated as,

$$f_1 = 52^{18} + 52^{1} + 52^{20} \quad \ldots\ldots \text{eq.(3)}$$

considering that 1-26 is the positional value of a-z (in lower case) and 27-52 is the positional value of A-Z (in upper case) . The second function returned the part of speech tagged value of the word, i.e., the second function f_2(say) for the same word "rat" would return,

$$f_2 = \text{Part of speech value("rat")} = 10 \quad \ldots\ldots.\text{eq.(4)}$$

considering value for noun (here, "rat") is 10 and similarly for each part of speech a unique value is assigned and the third function returned the positional value of the word in the sentence. If the function is represented by f_3, then for the sentence "rat is a rodent animal", the value returned by this function for the same word "rat" would be,

$$f_3 = \text{position of("rat")} = 1 \quad \ldots\ldots\ldots\ldots...\text{eq.(5)}$$

as the word "rat" appears at position 1 of the sentence and then finally applying summation function to all the values obtained for the constituting words of sentence. However, the function did not result as to what was desired and thus the requirement raised to shift from this customized embedding to some more precise scheme that would provide a representation which could better portray the answers along with preserving the relationships between the words. And thus the idea switched to use already existing schemes for word embeddings.

3.2.1 Word Embeddings

Embeddings in neural networks have proven to be of immense significance to meaningfully represent words in transformed vector space with much reduced dimension. There are various models available implementing word embedding built on some underlying architectures. Some of such schemes are Word2vec[18][19] based on local context window, Glove[20] considering global matrix factorization based on Latent Semantic Analysis and Single Value Decomposition and many more each performing notably in their own way.

3.2.1.1 Word2vec

The model of Word2vec is based on two architectures , namely, Continuous Bag of Words(CBOW) and Skip-gram. The words in the answers are first encoded using one hot encoding and then input to the network. In the former mentioned architecture, the context words are fed into the network and current word is obtained as output and in the later one current word is fed in the network and the context is obtained as output. The network employs one hidden layer which uses usual summation function and the output layer that either uses hierarchical softmax or negative sampling as the activation function. After training the network, when the weights are settled the output layer is tossed off and the weights are retained as vector representations and thus the number of nodes in the hidden layer is equivalent to the vector size thus obtained and therefore is the count of features considered for embedding. The model is said to preserve semantic relations, analogies and linear regularities between the words. Apart from that, the embedding scheme transforms the words into a vector space that is efficient enough to have words to retain the euclidean distance as well as the cosine distance between them.

3.2.1.2 Doc2vec

Based on word2Vec, another model is available known as Doc2Vec[21]. As the name suggests, it is very similar to Word2Vec just that instead of word vectors this model directly converts the answers to paragraph vectors and the input to this type of network is encoded word with a paragraph id. The architectures underlying are Distributed bag of words(DBOW), which is very similar to skip-gram and distributed memory paragraph vector(PV-DM), which is similar to CBOW. The model considered for embedding in this paper is Doc2vec using the distributed memory approach.

For fig.4, pos is the position of target word in its context, n is the size of context window,w(i) is the i^{th} word, w1,w2… w_m are weights of m number of nodes of hidden layer.

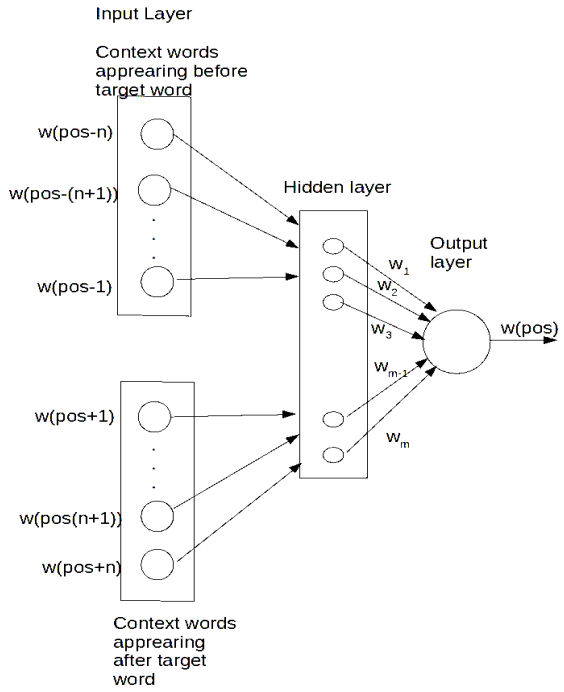

Fig 4: CBOW

4. Proposed Work

The vectors thus obtained from the said network are derived and fed into another neural network which performs the actual evaluation task. Apart from employing another network, grading of answers was also attempted using the cosine similarity between the answers. Although the results obtained were not poor but this approach would be highly rigid to the training set of answers. For instance, if the training set would consist of answers having low marks or very high marks and if an average answer would arrive for testing, then the similarity would be found with either the higher marked or lower marked answer, awarding exact high or low mark respectively. And thus, this is not expected to be a fruitful way of evaluation. So, it is preferred to use another network to do the evaluation.

In this paper, the model uses the dataset consisting of a question , a model answer , sample answers and their respective human evaluator given scores or the actual scores. The question, model answers , sample answers and actual scores were stored in a file and the sample answers and actual scores were read when needed in the program. The sample answers read were stored in (key , value) pairs in the form of dictionary, where the *key* represents the answer and the *value* is the corresponding score of the answer given by the human evaluator. There were a total of 30 answers from which 22 were used for training the model and 8 answers were used for testing the model. The training answers and the testing answers were first converted to vector forms using Doc2Vec as previously said and two models were generated . In another neural model, these vectors of the answers were fed to the neural network and automated scores were generated. The model trained by comparing the automated and the actual score and trying to minimize the difference between them. Hence, the model generated automated scores for the sample answers. The model was then trained on 8 answers of the dataset as mentioned before. Training set consisted of 73.33% of the dataset and testing set consisted of 26.67%.

The model created is Keras sequential model . The sequential[22] model consists of many layers arranged in a linear fashion. In our model , there are four layers and ReLU, that is rectified linear unit is used as an activation function in the first layer, as it cannot be used in the output layer. The Softmax activation function is used in the last layer, that is the output layer and is considered best for multi-classification problems . It gives the output in the form of probabilities whose sum would be equal to one .The activation functions are used to get the sum of the weighted values from the nodes and convert them for the activation of next layer . The ReLu activation used gives same value for the positive weights and zero for weights less than zero . As already said, we cannot use ReLu for output layers as it is considered best to be used as the default activation in the beginning .

The loss function[23] used is ‘sparse_categorical_crossentropy’ .The cross entropy gives the values in between 0 and 1 as the output in the probability form. The loss function is used to calculate the model error . Cross Entropy measures the difference between the two probabilities, that is the estimated and the predicted values. The loss function value is to be minimized to get a better model.

The models used different number of nodes in different layers. The output changes according the the number of nodes . The models need to know the input value , here the vector size is taken in the first layer called the input layer as the input value.

5. Experimentation and Results

In Table 1, observations are noted with different number of nodes in input layer, output layer and hidden layers and it can be seen that how tweaking the number of nodes in each layer will affect the output accuracy of the model. It was further observed that keeping the shape of the model such that number of nodes first increased then decreased gave better results.

Table 1 : Observations noted according to number of nodes in different layers

INPUT LAYER	HIDDEN LAYER 1	HIDDEN LAYER 2	OUTPUT LAYER	OBSERVED ACCURACY (IN %)
35	35	23	11	37.5
35	23	19	11	62.5
50	43	21	11	75
35	29	25	21	25
50	37	29	21	62.5
10	15	17	21	25
10	12	19	21	12.5
10	16	16	21	37.5
9	10	10	11	12.5
9	10	11	11	25
35	42	37	11	50
35	**39**	**23**	**11**	**87.5**
50	62	47	11	75
35	42	30	21	25
50	57	39	21	62.5

With the model tuned with hyper parameters giving the best result (of 87%, mentioned in Table 1) , Table 2 shows the the actual score, that is the human expert awarded score and its corresponding automated score provided by the model proposed in this paper.

Using this score representation the model can be further evaluated for other evaluation metrics such as,

Precision = 0.867/4 = 0.2164

Recall = 2/4 = 0.5

F-score = 0.302

Since, this is a multi class issue these metrics do not give good results, however, some other still give appreciable results,

Mean absolute error = 0.4375

Root Mean Square error = 0.637

Table 2 : score comparison of the best observation value:-

ACTUAL SCORE	AUTOMATED SCORE
4.5	4
4	4
3.5	5
5	5
4.5	4
4.5	4
5	5
4.5	4

6. Conclusion

This paper proposes an idea to evaluate short answers using neural networks. Initially, to embed the free-text answers into appropriate vector representations, Doc2vec is used with underlying architecture of PV-DM. This architecture is highly analogous to the CBOW architecture. Therefore, the vector representations of answers used in this model is quite efficient as Doc2vec not only converts the answers to vectors but also preserves the semantic relationships. The answer vectors thus obtained, when fed into another neural network, with tuning of the hyper parameters would award scores to student answers automatically with appreciable results. Thus, it can be deduced that even without complex algorithms or facing computational overheads, a model can be designed using neural networks which with proper hyperparameter tuning can result in an accuracy of 87.5% . With more exploration and refinements the model can be improved for even better results .

***Abstract* - Inter-satellite Wireless Communication is the latter day technology in which communication can be done between two satellites. This paper reports the performance of Wavelength Division Multiplexing (WDM) using Chirped modulation technique, CSRZ modulation technique and Alternate chirped NRZ modulation technique. The total number of channels used are 32 with different bit rates of 15 Gbps, 20 Gbps and 42 Gbps with OWC range of 750nm. The main concept of the system is to achieve high Quality factor and minimum Bit error rate. From the observations it has been concluded that Chirped modulation technique shows maximum Quality factor with minimum Bit error rate at 15 Gbps and Alternate chirped NRZ modulation technique shows good results at 20 Gbps and 42 Gbps as compared to CSRZ modulation technique.**

Keywords-Inter-satellite link, WDM, Chirped modulation, ALCNRZ, CSRZ.

I. INTRODUCTION

Inter satellite optical wireless communication links are having momentous role in interchanging of information between satellites. Due to turbulences and pointing errors, FSO systems are less frequently used for the transmission of data and signals. For exchanging of information or data between two satellites Inter satellite link One satellite connect with another satellite through this link as whether the satellite is in same orbit or in the another orbit. Data can send with the speed of light. Is-OWC system also has lot of advantages as there is no license required for such a communication system less cost is involved for designing, small and lightweight components required, less power consumption, can handle huge bandwidth and so on. These links shows a good performance in ultraviolet and infrared bands. Continuous Wave Laser is used as a source of light in inter satellite optical wireless links and due to its high reliability and high speed of operation it can operate at higher transmission bit rates. In order to enhance the system performance latest modulation techniques can be used which also help to increase the system efficiency as well as reduce delays. Wavelength Division Multiplexing is a technology in which number of optical carriers gets multiplex on a single optical fiber by using different wavelengths. Wavelength Division Multiplexing (WDM) technique is used to produce a system with higher data bit rate. WDM multiplexing technique is used to obtain flexibility in Is-OWC system. Is-OWC system is used for earth tracking mission, deep space optical communication is possible, and communication between two satellites is possible through this link. Considering the fact that space being vacuum, chances of distortion of the signal is reduced. Due to misalignments and vibrations, errors such as the pointing error arise in the tracking system of the satellite. In order to reduce the pointing errors and overcome nonlinear effects, a suitable combination of various modulation and multiplexing schemes are used. Important parameters used in Is-OWC system are: Quality factor, Bandwidth, Bit error rate, Power etc. Quality-factor provides a description of an output signal. It is a dimensionless positive value which indicates the quality of signal. Bandwidth plays an important role in Is-OWC system as wider the bandwidth more amounts of data can flow with less number of collisions which produces a high Quality-factor. Bit error rate defines a number of errors received by total number of transmitted bits. As distance increases transmission losses increases. So in order to decrease noise level, the rate of transmission power has to increase.

The paper is organized in five sections. The basic introduction of Is-OWC system is described in section I. The System description of Is-OWC system is provided in section II. Results and discussion is explained in section III. Conclusion is discussed in section IV and finally Future scope is discussed in section V.

II. SYSTEM DESCRIPTION

The design model of the simple Is-OWC system is shown in the fig.II (a). In the system there are two satellites the transmitter being in the first satellite and receiver in the second satellite. In between two satellites the OWC channel can be considered as propagation medium. The electrical and optical signal in the first satellite is modulated and is passed on towards the OWC. Satellite second helps to amplify the low and weak signal so that it can travel to long distance.

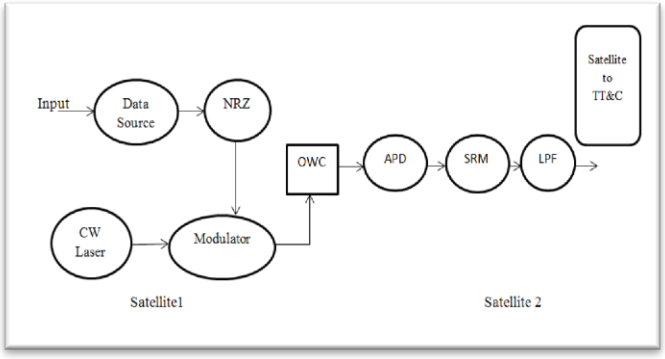

Fig.II (a) Simple Is-OWC system

The system using Wavelength Division Multiplexing technique with different modern modulation schemes namely Chirped, CSRZ and Alternate Chirped NRZ is simulated and analysed in this paper using Optisystem 15 software. 32 channels operating at bit rates of 15 Gbps, 20 Gbps and 42 Gbps are multiplexed together and the signal is passed towards the OWC channel having a distance of 2840 km. Demultiplexer helps to demux the 32 channels and pass the signal to receiver side which will regenerate the signal and amplify it. Fig.II (b) shows the block diagram of the Chirped modulation technique. It is considered as a highly preferred modulation technique in which frequency increases or decreases with time. The chirped rate is defined as a rate at which frequency changes. The chirp with positive rate is defined by one bit period whereas with negative rate it is defined as zero bit periods. Its function is to enhance high immunity to interference, contains high spectral efficiency. The Chirped modulation along with RZ Pulse generator produces high quality factor and shows better performance for long distance transmission in Is-OWC system. It consists of pseudo random bit sequence generator followed by RZ pulse generator that passes its signal through the fork 1*2. The Continuous Wave laser produces an optical input which passes through the LiNb Mach Zehnder Modulator. LiNB MZM controls the amplitude of an optical signal and resulting in an output that can be obtained from the optical spectrum analyser. The frequency taken here is 193.1 THz and the extinction ratio taken is 20 dbm. Fig.II (c) shows output of the chirped transmitter.

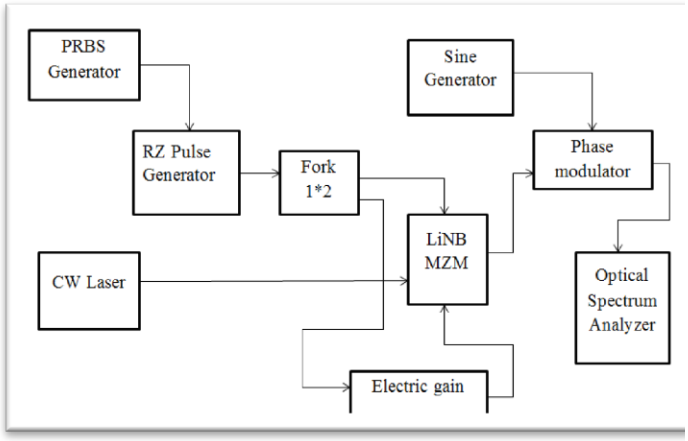

Fig. II (b) Block diagram of Chirped modulation technique

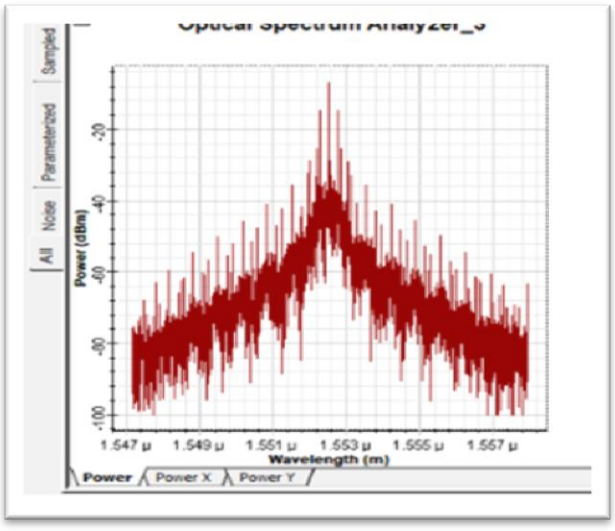

Fig. II (c) Optical spectrum analyser of Chirped modulation technique

Fig.II (d) shows the block diagram of the CSRZ modulation technique block diagram in which modulation takes place in two stages. CSRZ modulation technique has 180^0 phase shift between adjacent bits and also highly immune to cross phase modulation and Self phase modulation. As from the name it indicates that the Carrier signal is suppressed in it. The main motive of using this modulation technique is to reduce nonlinear tolerances in the channels and improvement in the spectral efficiency in high bit rate system. CSRZ modulation technique has no carrier components because during phase alternation, in the optical domain it produces no DC components. In first Mach Zehnder Modulator, intensity modulation is carried out whereas in second Mach Zender Modulator, a sinusoidal signal having frequency equal to half of the bit rate of the original bit sequence and due to this half of the bit rate, the bits 1s have positive sign and rest others have negative sign. Output of CSRZ modulation technique is shown in Fig.II (e).

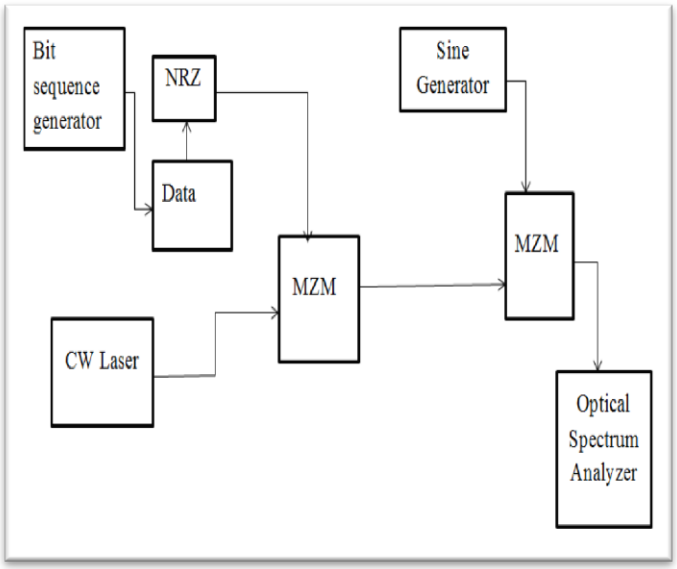

Fig. II (d) Block diagram of CSRZ modulation technique

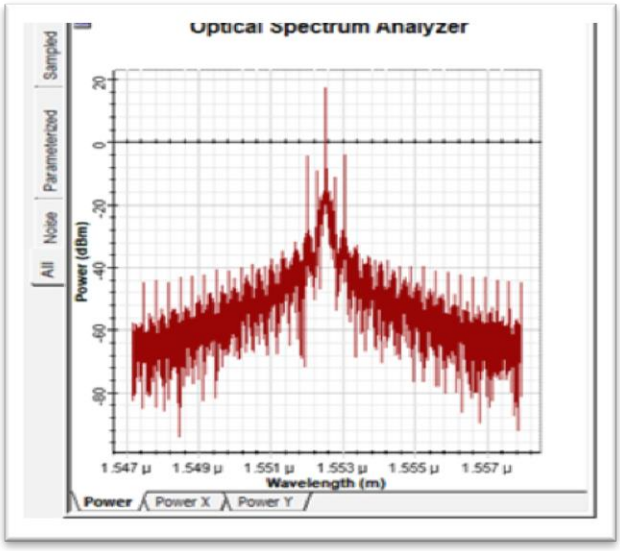

Fig. II (e) Optical spectrum analyser of CSRZ technique

Fig.II (f) shows the block diagram of the Alternate Chirped NRZ modulation technique. The pre-chirping of an optical pulse at the transmitter part makes the better transmission performance of the system but this results in the broadening of the signal spectrum. This implementation of pre-chirping can be realized by using either passive components like optical

fiber, fiber piece or by using active components for example Phase Modulator Or Mach- Zehnder Modulator. Thus this method of pre-chirping has to be chosen very carefully. Alternate Chirped NRZ is considered as an advanced modulation technique as it shows an improvement in the performance of the system as well as helps to increase the efficiency of the system. It also improves nonlinear tolerances due to which error like pointing errors arises which degrades the system performance. Alternate chirped NRZ helps the system to enhance its transmission length and also it is useful because of its simple design. The main target of using Alternate chirped NRZ is to enable a high speed optical transmission over long haul distances. Fig.II (g) shows output of Alternate chirped NRZ modulation technique.

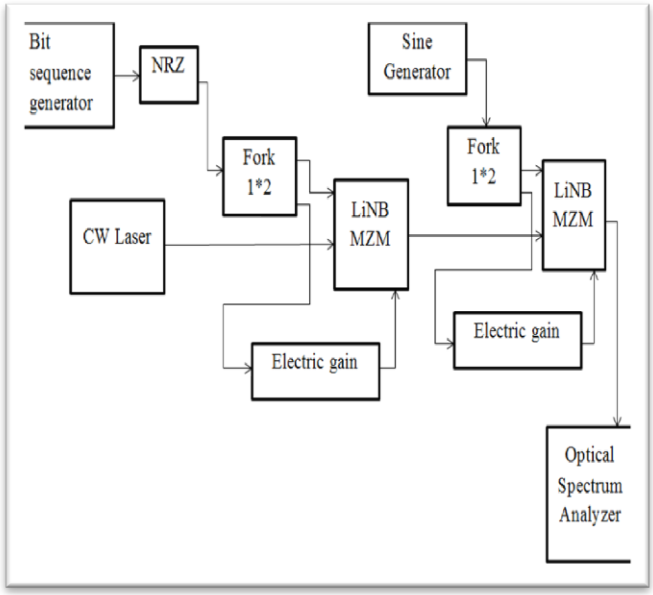

Fig. II (f) Block diagram of Alternate chirped NRZ modulation technique

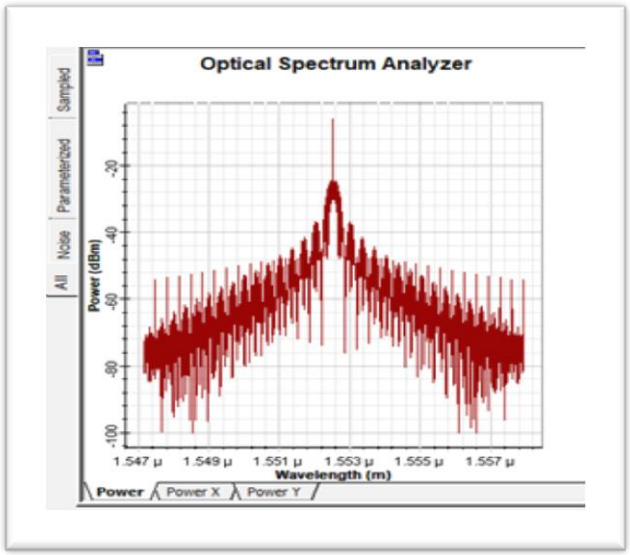

Fig. II (g) Optical spectrum analyser of Alternate chirped NRZ modulation technique

III. RESULTS AND DISCUSSION

The following are the eye diagrams of Chirped, CSRZ and Alternate chirped NRZ modulation techniques at the bit rate of 15Gbps.

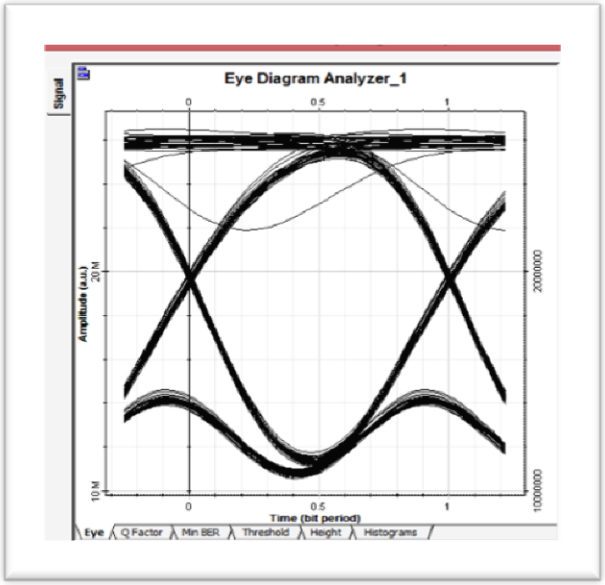

Fig.III (a) Eye diagram of Chirped modulation at 15 Gbps

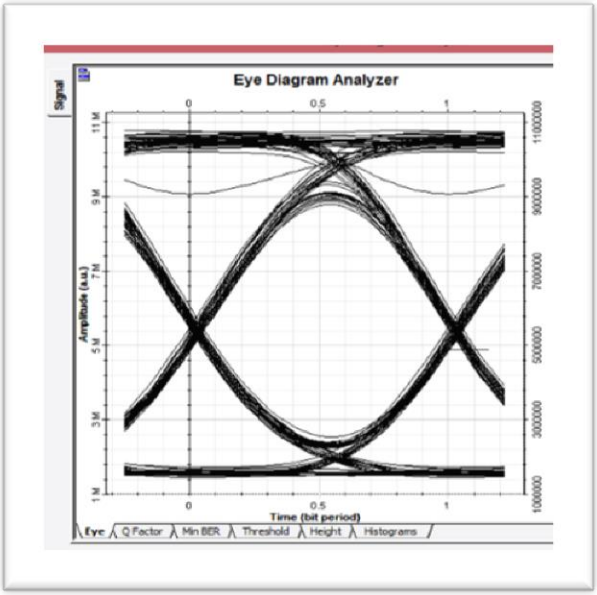

Fig.III (b) Eye diagram of CSRZ modulation at 15 Gbps

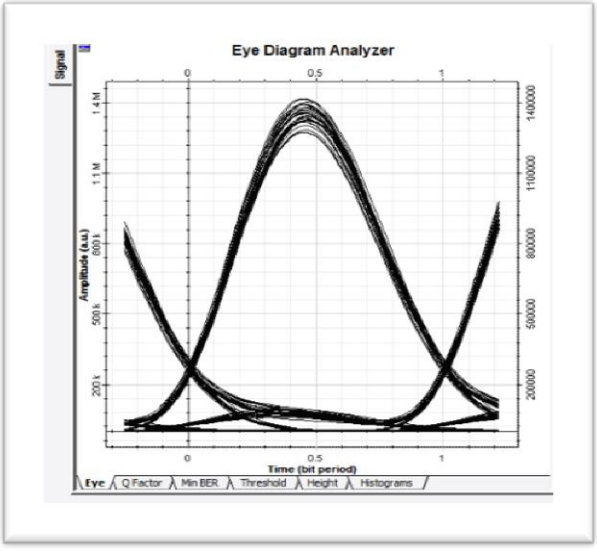

Fig.III (c) Eye diagram of ALCNRZ modulation at 15 Gbps

In this section, the results from simulation of proposed WDM based Is-OWC system are presented and discussed. In Fig.III (a,b,c), from an eye diagrams, it is observed that Chirped modulation technique shows a higher Quality factor , larger eye opening, greater eye height as well as greater eye width which indicates less distortion of the signal.

Fig.III(d,e,f) shows an eye diagrams at bit rate of 20 Gbps and out of the three modulation techniques, Alternate Chirped NRZ modulation technique shows a minimum error with a recorded Quality factor of 13.0075 which indicates a lesser distortion in the signal as compared to the other two modulation techniques.

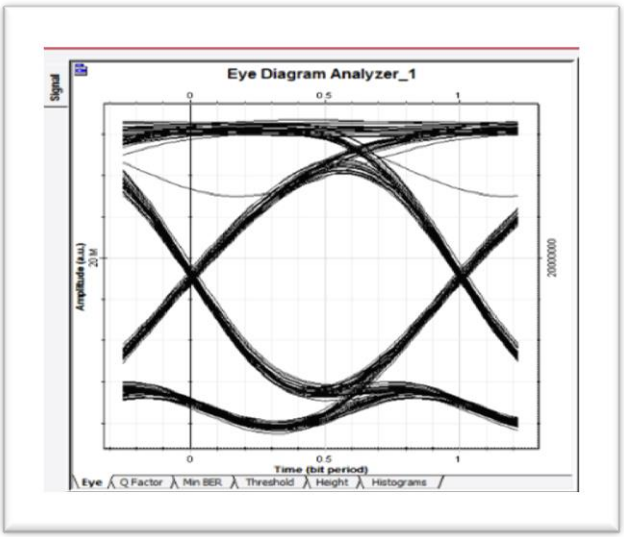

Fig.III (d) Eye diagram of Chirped modulation at 20 Gbps

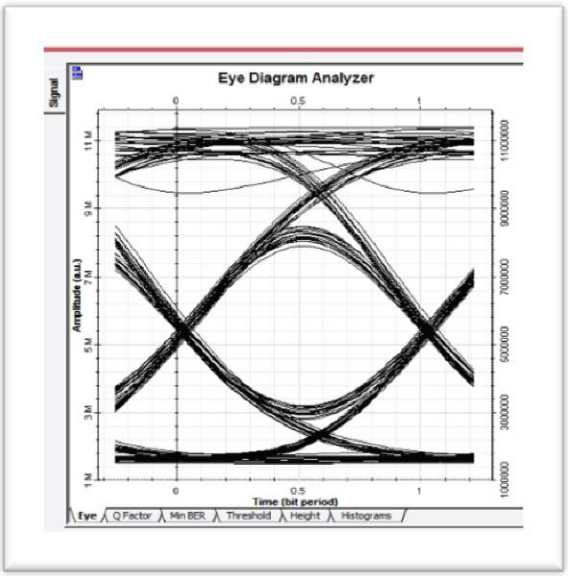

Fig.III (e) Eye diagram of CSRZ modulation at 20 Gbps

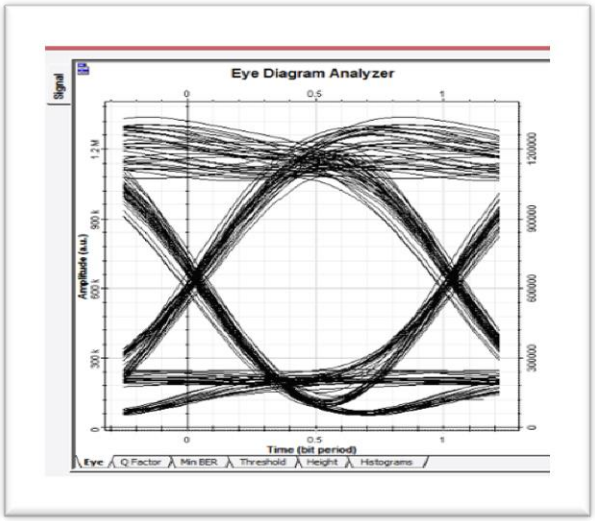

Fig.III (f) Eye diagram of ALCNRZ modulation at 20 Gbps

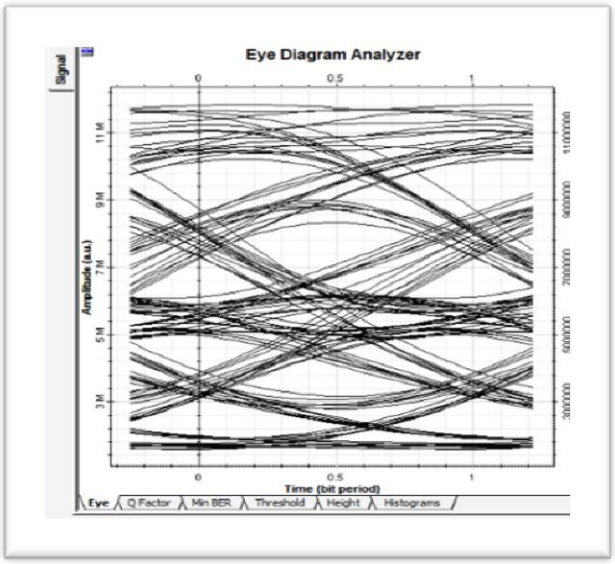

Fig.III (g) Eye diagram of chirped modulation at 42 Gbps

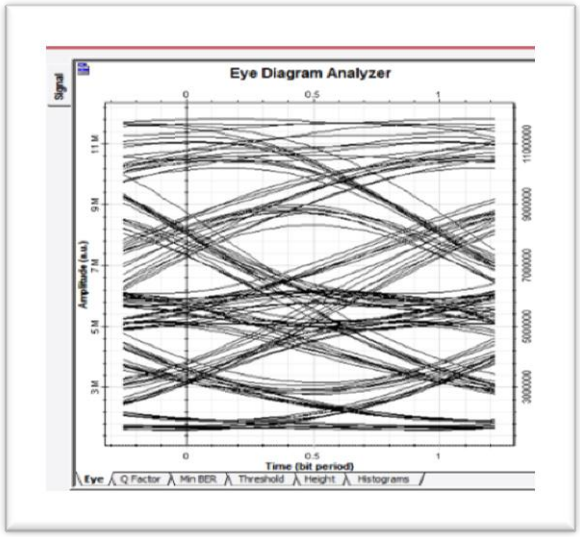

Fig.III (h) Eye diagram of CSRZ modulation at 42 Gbps

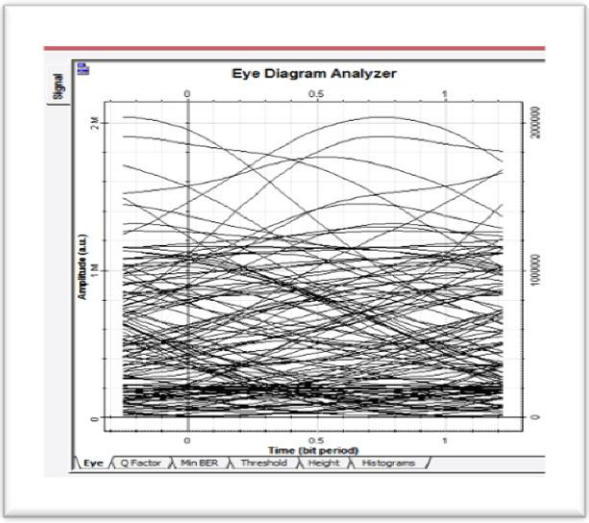

Fig.III (i) Eye diagram of ALCNRZ modulation at 42 Gbps

Fig.III(g,h,i) shows eye diagrams of Chirped, CSRZ and Alternate Chirped NRZ at 42Gbps in which signal Quality degrades as the bit rate goes higher from 20Gbps to 42Gbps.

Table 1 Simulation parameters for the proposed ISOWC system

Parameters used	Values
Bit rates (Gbps)	15, 20, 42
OWC range (nm)	750
No. of samples	4096
Distance (km)	2840
EDFA gain (dbm)	43
Channels used	32
CW laser frequency (THz)	193.1
Extinction ratio (db)	20
Power (dbm)	30

From this section it's clear that out of three modulation techniques namely Chirped, CSRZ and ALCNRZ, Chirped modulation shows maximum Quality factor of 25.9058 with minimum BER of 2.75641e-148 at 15 Gbps .Alternate Chirped NRZ shows best performance at 20 Gbps with Quality factor of 13.0075 and BER of 5.36441e-039 whereas at 42 Gbps again Alternate chirped NRZ shows comparatively better results with Quality factor of 1.62723 and BER of 0.0460834.

Following are the points which help to achieve high Quality factor and minimum Bit error rate

1. EDFA Black box amplifier helps to improve the quality factor of signal.
2. Large WDM bandwidth also improves the signal quality as it reduces the collisions between signals.
3. By increasing CW laser power signal strength increases and it can travel long distance range.

Table 2 shows the comparison of the results for three different modulation techniques used.

Bit rates (Gbps)	Analysed parameters	Chirped modulation	CSRZ modulation	Alternate chirped NRZ modulation
15	Q-factor	25.9058	10.0218	20.3406
	BER	2.75641e-148	5.93527e-024	2.10918e-092
20	Q-factor	9.78423	4.77399	13.0075
	BER	6.44456e-023	8.63686e-007	5.36441e-039
42	Q-factor	1.33877	1.39046	1.62723
	BER	0.0893258	0.0791607	0.0460834

IV. CONCLUSION

From the results and discussion it has been concluded that after comparison between three different modulation techniques having bit rates of 15Gbps, 20Gbps and 42Gbps, Chirped modulation technique shows maximum Q- factor and minimum Bit error rate at 15 Gbps. At 20 Gbps ALCNRZ shows maximum Quality factor with minimum Bit error rate. Whereas at 42 Gbps again ALCNRZ shows better results as compared to other two modulation techniques. From results it has been also concluded that Quality factor decreases as the bit rate and distance increases between two satellites. BER increases with the increase of bit rate and distance between two satellites. Signal with lower bit rate cover long range transmission without much distortion.

V. FUTURE SCOPE

1. Development of Inter-satellite optical network protocol which is used to provide access internet.
2. Transmission of data or information for satellite observation.
3. Communication between satellite clusters.
4. Path prediction model for Is-OWC system.
5. Theoretically advantages of using optical link over RF link have been mentioned in various papers and Books but the performance analysis in terms of QOS has not been done. So it can be considered in future work.

***Abstract*— This paper presents a new development in recent machine learning model, a particle swarm optimization (PSO) based Emotional neural network (PSO-EmNN), for daily rainfall-runoff modeling of catchment Seaton at Trebrownbridge, Cornwall, United Kingdom. The EmNN is inspired by neurophysiological information of brain which simulates emotions as additional parameters with conventional weights and biases to improve the networks learning ability. The PSO is used for tuning the parameter set of EmNN to get optimal values of parameters. The performance of the developed model is validated through RR modeling. Further a PSO based artificial neural network (PSO-ANN) is used to compare the efficiency of the proposed approach. The result demonstrates the superiority of the PSO-EmNN over the PSO-ANN in terms of prediction accuracy.**

Keywords*— *Rainfall-runoff modeling; data-driven model; particle swarm optimization

I. INTRODUCTION

Rainfall-runoff (R-R) is a intricate process in the earth's surface. Reliable and accurate assessment of runoff is important for water resources planning to design urban sewer system, flood risk management plan, etc. R-R models are classified as three categories, (i) data-driven model, (ii) conceptual model, (iii) physical law based model [1]. The implementation of physical models and conceptual models requires several environmental parameters and knowledge of the hydrological system. Recently, data-driven models are gaining their popularity because of its ability to handle the non-linear relationship of the generated hydrological data set. These types of models map the input to output data without requiring the knowledge of the hydrological system. When the accurate prediction is much more important rather than the laws of physics, the data-driven models are considered as the best alternative R-R modeling practice. Current studies show that classical models, for example auto-regressive integrated moving average, may not capture significantly the non-linear nature of hydrological processes. Authors of [2] have shown that data-driven models can give similar or better result compare to theory-driven models. The artificial neural networks (ANNs) are the most widely used black box R-R models [3, 4]. But due to gradient based learning ANN may not perform significantly to predict river flow. Currently, hybridization of ANN with metaheuristic algorithm enhances the learning ability of the neural system and overcome from the longer time network training, overfitting and local minima stagnation problem. Several studies show that the antecedent variable for R-R modeling are considered as only rainfall or rainfall and runoff or temperature, evaporation, evapotranspiration in addition to rainfall/runoff [5-7]

This paper considers a new category of ANN called emotional neural network (EmNN) [8]. The EmNN was developed for pattern recognition, clustering, and prediction task. Nourani [9] presented the first hydrological implementation of EmNN in R-R modeling and showed that EmNN has better capability to predict peak flow as compared to ANN. The EmNNs have been successfully used for learning complex systems [10, 11] and in several prediction based applications [12]. They are classified as brain emotional learning (BEL)-based neural networks [13-15] and emotional back propagation (EmBP)-based neural networks [16, 17]. Where the BEL networks closely represent the human emotions and show an efficient learner than the EmBP networks. This paper uses BEL networks for R-R modeling. BEL networks were created from the structural computational model of emotional brain (EB) [8] and applied successfully in various application domains [12, 18, 19]. Authors of this paper use the PSO to learn EmNN and applied in RR modeling. The result of the proposed approach shows the better capability to predict river flow compared to the PSO-ANN.

This paper is organised as follows; Section II presents used data for this study. Section III describes basic framework of EmNN and proposed PSO-EmNN. Results are presented in section IV. Section V presents conclusion of this study.

II. DATA USED

The catchment of the United Kingdom (UK) from one hydrometric area 48 is used to access dataset and downloaded from the national river flow archive (NRFA) website (https://nrfa.ceh.ac.uk/data/search)[20]. Fig. 1 shows the region of the catchment. The daily rainfall and runoff dataset from the Seaton at Trebrownbridge catchment are utilized for river discharge forecast.

Fig. 1: Catchment Seaton at Trebrownbridge

The river Seaton at Trebrownbridge catchment (Fig. 1) increases on the Caradon Hill. The extension of the catchment is linear (no tributaries). It has negligible disturbance with the natural flow regime. The catchment extent is 39.1 km2. The gauge level is at 26.6 m AOD. The highest flow was 13.2 (m^3/s). The catchments data in between 2010 to 2015 is utilized for model run.

The accumulated rainfall rate was taken from the center for ecology and hydrology-gridded estimates of areal rainfall (1km resolution) [21] which is scaled to mm per day.

III. PROPOSED WORK

A. **Emotional Neural Network**

The main findings of EB have been stated in [22-24] by LeDoux. The EB has the shortest path to make a quick response to the input. Such faster response motivated the researchers to design a model of EB and applied the model in several engineering application. The structural model of EB is based on the lymbic system (LS) theory of emotion [25, 26]. Figure 2 shows the anatomical model of emotion. In EB, there are two kinds of responses for amygdala (AMYG) component,

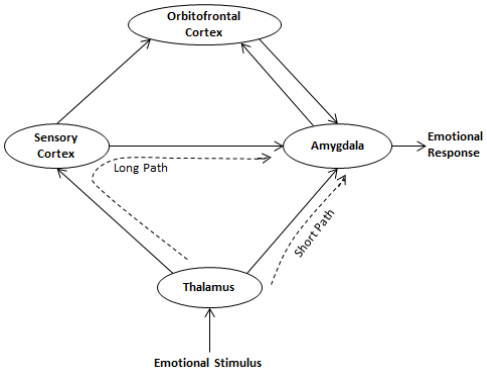

Fig. 2: Anatomical model of EB

one follows the shortest path from thalamus which is faster and imprecise, where the second follows the longest path through sensory cortex (SC) which is slower and precise (Fig. 2). AMYG can provide a quick response based on these paths. The orbitofrontal cortex (OFC) and AMYG interaction control the imprecise information. Where the OFC manages the decision making process under uncertain environment and estimates uncertainty [27, 28]. Overall the utility of EB is to provide a quick imprecise response under the uncertain and unpredictable situation.

B. **A practical EmNN**

The BEL-based EmNN [26] is shown in Fig. 3 which is based on the OFC-AMYG interactions. Where, each of the subsystems related to input dimension. Figure 3 shows the shortest path and the longest path of input flow to the AMYG subsystem. The OFC receives input from AMYG to prevent the final output.

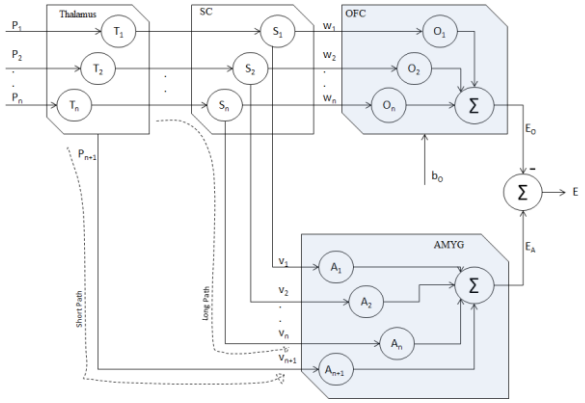

Fig. 3: An EANN based on the OFC-AMYG interconnection

The input pattern is illustrated as {p_1, $p_{2...}$, p_n, p_{n+1}} which are used for feed forward computation. The target value is used for the backward learning process of the model.

The input patterns enter to the thalamus and then forwarded to the SC. The two input patterns are received by AMYG. They are p_1, $p_{2...}$, p_n from SC and an imprecise input p_{n+1} from thalamus. The calculation of input p_{n+1} is formulated by Eq. 1. The related weight of imprecise input is v_{n+1}. The max operator defines the uncertain information.

$$P_{n+1} = \max_{i=1..n}(p_i) \tag{1}$$

The OFC acquires the input pattern from SC. The final output is formulated by Eq. 2.

$$E = E_A - E_O \tag{2}$$

Where, E_A and E_O specify the outputs of AMYG (Eq. 3) and OFC (Eq. 4) respectively.

$$E_A = \sum_{i=1}^{n+1}(v_i \times p_i) \tag{3}$$

$$E_O = \sum_{i=1}^{n+1}(w_i \times p_i) + b_O \tag{4}$$

Where v_i and w_i are the weights of the AMYG and OFC respectively, b_O is the OFC bias and p_i is the input pattern. In the final output (Eq. 2) OFC output inhibits the EMYG output (E_A).

C. **The proposed PSO-based EmNN**

The PSO is used to train the EmNN network by tuning the parameters of EmNN. PSO is a popularly used metaheuristic algorithm for optimization task [29]. PSO minimizes the fitness score (objective function) of particles in order to find

the best solution to the problem domain. Here the particles are represented as follows;

$$Particle_k = [v_1, v_2, .., v_n, v_{n+1}, w_1, w_2, .., w_n, b_O] \quad (5)$$

If the number of inputs is *n* then the number of features in a particle is 2*n*+2. The output of the model is calculated by Eq. 2 with the j^{th} input pattern and assigned weights of k^{th} particle. The fitness function of a particle is calculated as:

$$fitness_{train}(prticle_k) = \frac{1}{m}\left(\sum_{j=1}^{m}\left(O^j - T^j\right)^2\right)^{0.5} \quad (6)$$

Where O^j is the output of the j^{th} input pattern and the related target is T^j. *m* is the total number of samples. The process flowchart of the proposed PSO-based EmNN is shown in Fig. 4.

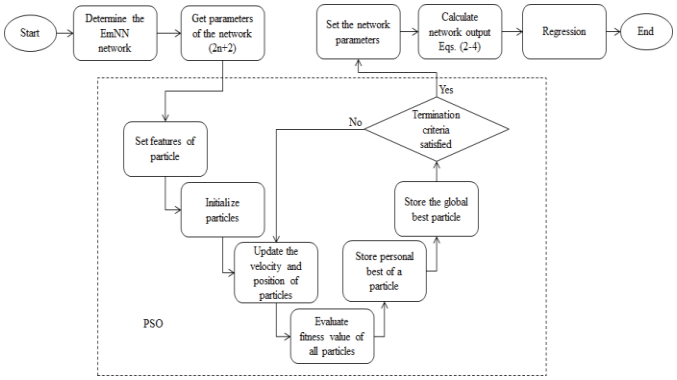

Fig. 4: Process flowchart of PSO-based EmNN

IV. RESULT ANALYSIS

The rainfall and discharge data of the catchment are considered as input to the proposed PSO-based EmNN model to predict next-day discharge. Based on the best performance of models [9], the 2 days lag of runoff value, and current day runoff and rainfall data are considered as the input for the proposed model. The PSO-ANN is used to compare with the proposed model. The catchment's data in between 2010-2015 is bifurcated as 70% training and 30% testing dataset.

To learn PSO-EmNN model, PSO parameters are initialized as: (i) c1=1, (ii) c2=2, (iii) w=0.7, and (iv) wdamp = 0.9. The number of populations is 30. The minimum and maximum values of particle features are considered as -5 and 5 respectively.

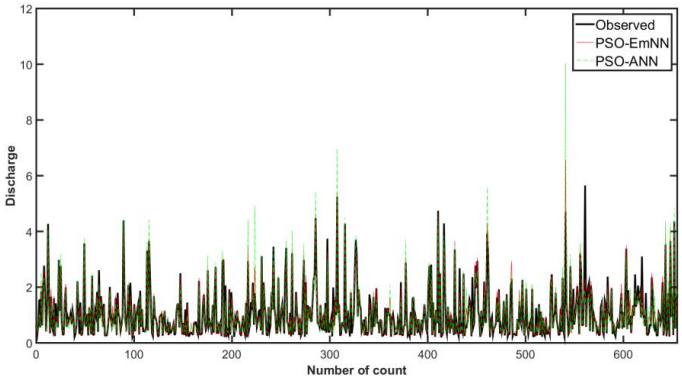

Fig. 5: Predicted vs. observed discharge in test period

The training dataset is used to learn the proposed model. PSO is used to tune 2n+2 number of EmNN model parameters. Where n is the number of inputs. After 50 numbers of run of PSO with EmNN generations, the lowest fitness valued particle is selected to fit the EmNN model. Thereafter, the test data set is used to predict the unknown one-day-ahead discharge.

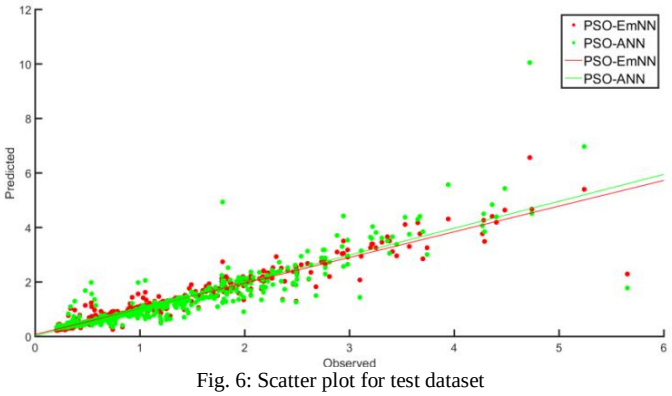

Fig. 6: Scatter plot for test dataset

Figure 5 shows the test case of PSO-ANN and PSO-EmNN. The proposed model shows better prediction capability compare to PSO-ANN. The scatter plot (Fig. 6) shows that the observed vs. predicted points are closer to the regression line of PSO-EmNN compare to observed vs. predicted points of regression line for PSO-ANN. Table 1 described the four performance measure metrics including r, MAE, NSE, and RMSE values of both models. From the Table 1, it is evident that proposed model has better prediction capability compare to PSO-ANN model in R-R modeling. Statistical comparison of training and testing phase with prediction of both models show PSO-EmNN is the most realistic model compare to PSO-ANN (Fig.7).

Table 1: The performance measure matric values of models

Model	R	MAE	NSE	RMSE
PSO-ANN (train)	0.907	0.201	0.819	0.462
PSO-ANN (test)	0.911	0.176	0.8	0.399
PSO-EmNN (train)	**0.936**	**0.132**	**0.876**	**0.383**
PSO-EmNN (test)	**0.964**	**0.106**	**0.929**	**0.238**

V. CONCLUSION

This paper developed a new PSO-based EmNN model and applied in R-R modeling in a catchment. The proposed model is compared with the PSO-based ANN model. The various performance metrics described the superiority of the PSO-EmNN compare to PSO-ANN. Therefore, it is a better alternative data-driven model for hydrological modeling and can be used in other engineering application area. Further, data from the other catchment should be used to validate the performance of the proposed model. Moreover, in future various hydrological models can be considered to compare with the performance of the proposed model in R-R modeling.

***Abstract*—Digital filterbanks in hearing aids employ an array of filters to selectively amplify sound of different frequencies to compensate hearing loss. The use of filterbanks leads to a higher usage of silicon area as there are many filters, each generating a sub-band. Reconfigurable warped digital filter is a Variable Digital Filter (VDF) that can be reconfigured to function as a low-pass, band-pass or high-pass filter with cut-off frequencies that can be varied on-the-go. We propose a system with reconfigurable warped VDF that uses a single prototype filter for generating all the necessary sub-bands. The proposed system automates the generation of the control signals for reconfiguring the filter and pipelines the processing of each sub-band to generate the requisite magnitude response. The proposed architecture is designed to achieve good audiogram matching with minimum matching error.**

Keywords—digital hearing aid, variable digital filter, reconfigurable filter, audiogram matching.

I. INTRODUCTION

A Hearing aid is an electroacoustic device for compensating hearing loss. Hearing loss, as defined by the World Health Organisation (WHO), is the inability to hear 25 dB of sound in, at least one, ear. The WHO categorizes hearing loss as mild (25 to 40dB), moderate (41 to 60dB) and severe (60dB and greater) [1]. The increase in the hearing threshold caused due to hearing loss is not uniform over the range of audible frequencies i.e., there is low hearing sensitivity at certain frequencies. The hearing aid is used to selectively amplify the range of frequencies of sound at which a person experiences low sensitivity. An audiogram is a graph which gives a detailed description of a person's hearing threshold as a function of frequency. Audiograms are unique to the ears of every person; therefore, digital hearing aids are designed in such a way that it should be able to match any audiogram. Digital hearing aids make use of digital filterbanks to adjust the magnitude response for different frequencies of incoming sound signal such that it matches one's audiogram with minimum error.

Digital filterbank is an array filters that split the input signal into multiple sub-bands. Filterbanks used in digital hearing aids have three main components – the analysis block, the processing block and the synthesis block [2]. The analysis block splits the signal into multiple sub-bands. The processing block amplifies each of these sub-bands appropriately and the synthesis block combines all the processed sub-bands to generate the required output signal. A different filter is used to generate each sub-band in the filterbank, which translates to larger silicon area when implemented. A non-uniform filterbank, that generates sub-bands with varying bandwidths and centre frequencies, outperforms uniform filterbanks in terms of matching error and flexibility [3].

The objective of the proposed design is to use a single filter instead of a filterbank, which can be reconfigured without the need to update the structure or the filter coefficients, to generate-process-synthesize audio signals. To achieve the said objective, the reconfigurable warped digital FIR filter designed by Sumit J. Darak et al. in [5] is made use of in the proposed architecture. The filter design proposed in [5] has the capability of being reconfigured to function as low-pass, band-pass and high-pass filter on-the-go, along with fine control over cut-off frequency for low-pass and high-pass, and centre frequency and bandwidth for band-pass modes of operation. In this paper, an architecture is proposed that makes use of the reconfigurable warped digital FIR filter, designed in [5], along with the supporting control system to generate various sub-bands for the application of digital hearing aid. The proposed architecture is capable of generating requisite sub-bands by an automated process that applies minimal changes to the control parameters of the reconfigurable warped filter. The system processes the sub-bands and synthesizes the processed output to match audiograms in digital hearing aids. The proposed architecture inherently saves silicon area because a single filter is used to generate all the required sub-bands at no cost of reduced audiogram matching. The proposed architecture is designed to function like a non-uniform filterbank with comparable audiogram matching capability.

The paper is organized as follows. A survey on the existing filterbanks is presented in Section II. A review on the existing reconfigurable warped filter is given in Section III. The proposed system architecture is presented in Section IV. In Section V, the implementation and the results are presented. Finally, the paper is concluded in Section VI.

II. LITERATURE SURVEY

Various designs of non-uniform filterbanks have been researched recently where Variable Digital Filters (VDFs) are used for sub-band generation. VDFs are filters whose cut-off frequency fc can be changed on-the-fly [4]. Reconfigurable filters are filters whose mode of output responses (lowpass, highpass, band-pass and band-stop) can be changed on-the-fly

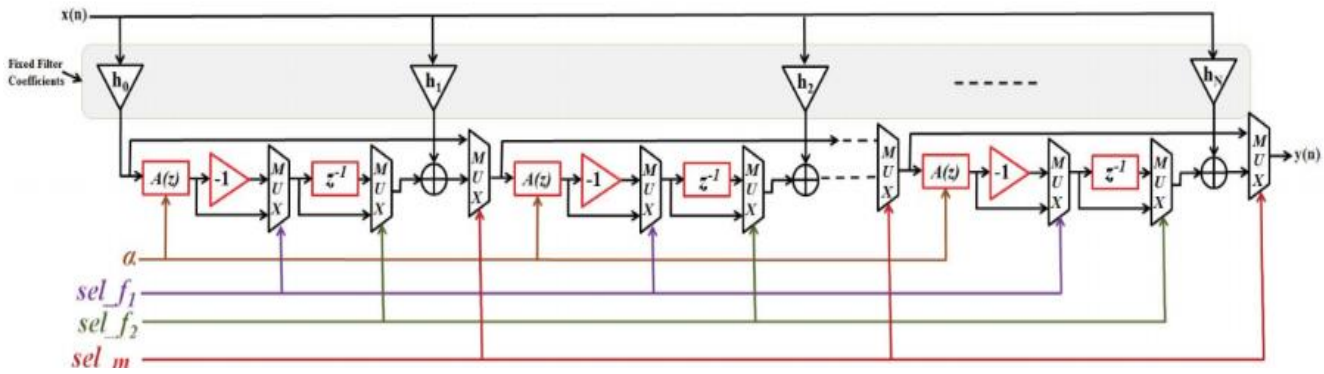

Figure 1. Reconfigurable Warped VDF [5]

[5]. A number of different approaches to VDF design are available. They include transformation approaches [6], Farrow structure-based approaches [7] – [9], and frequency response masking-based approach [10]. It would be beneficial to design a filter structure with a smaller number of bands and which can be reconfigured with minimum change in parameters. In [11], adaptive filters, which are warped filters, are designed using reduced second-order transformation and they provide fixed-bandwidth bandpass responses at an arbitrary centre frequency. However, if the bandwidth needs to be changed, the filter coefficients will need to be updated, which will incur a large number of memory read and write operations. In [12], a coefficient decimation (CDM) technique for realizing low-complexity VDFs with fixed coefficients is proposed. However, filters designed using this technique can only adopt a finite set of cut-off frequencies. In [5], a low-complexity reconfigurable VDF implementation by combining warped filters (using all-pass transform) along with CDM-II technique is proposed to achieve fine control of cut-off frequency over the entire Nyquist band for all 4 modes filter responses.

III. Reconfigurable Warped VDF

The reconfigurable warped VDF is proposed by Sumit J. Darak et al in [5]. The architecture provides variable low-pass and high-pass responses with a fine control over the cut-off frequency and variable bandwidth bandpass or bandstop responses at a tuneable centre frequency on-the-fly without the need to update the filter coefficients. The reconfigurable warped VDF filter architecture is shown in Fig 1 borrowed from [5]. The all pass structure is shown in Fig 2, borrowed from [5]. In this architecture, a low-pass prototype filter with fixed coefficients is used. The fixed-bandwidth bandpass/bandstop responses at an arbitrary centre frequency are obtained using reduced second order all-pass transformation, and the CDM technique is used to change the bandwidth.

When an all-pass structure is used in the place of a unit delay, warping occurs which can be mathematically described as follows,

$$G(z) = H(A(z)) \quad (1)$$

Where,

$$A(z) = \left(\frac{-\alpha + z^{-1}}{1 - \alpha z^{-1}}\right) \quad (2)$$

In this structure the filter coefficients are fixed. Here, α is the warping coefficient which controls the warped frequency response and |α| should be less than 1. The range of values of

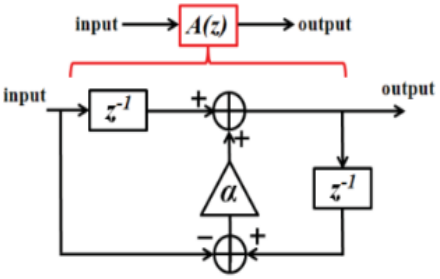

Figure 2. First order all-pass structure [5]

α from -1 to 0 increases the cut-off frequency while the range 0 to +1 decreases the cut-off frequency. At the value 0 of α, the cut-off frequency remains at the same value as that of the prototype filter. Coefficient Decimation (CDM) is implemented using the multiplexers controlled by signal sel_M. The actual multiplexer select line values are stored in lookup tables (LUTs) for each M, where M is the decimation factor, while sel_M provides the address for LUTs. The output of the previous coefficient's adder, which bypasses the present coefficient's operations, is connected to the 0th data-line of the multiplexer and the output of the present coefficient's adder is connected to the 1st data-line. The select signals, sel_f1 and sel_f2, to the two multiplexers after the all-pass structure decide the type of all-pass transform that is applied and thus the output response, i.e., low-pass, high-pass, band-pass, and band-stop responses with values {1,1}, {0,1}, {0,0}, and{1,0} respectively.

IV. Proposed System Architecture

The proposed architecture makes use of the reconfigurable warped filter proposed in [5] by building the necessary control system around the filter. The filter is reconfigured and reused to process the same input multiple times to generate and process each sub-band. This requires memory blocks on either side of the filter to store the input signal and intermediate output signals i.e., sub-bands. Then, the intermediate filter outputs are added together to generate the final output. The reconfigurable filter is operating at a higher rate to process all the required sub-bands, necessitating the use of memory block at the output for rate conversion.

The architecture is composed of 3 basic blocks – input memory block, reconfigurable filter block and synthesis block, shown in Fig 3. The memory block stores the incoming signal. The filter processes a data-block of *l* data elements in one configuration. The same data-block of *l* data elements is

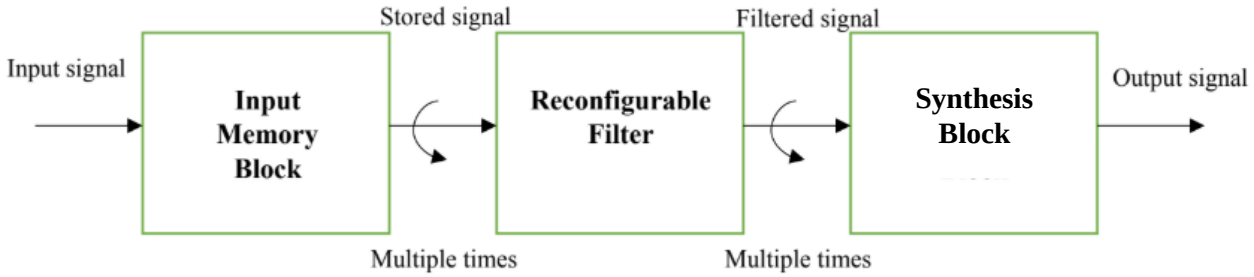

Figure 3. System block diagram

processed again in the next configuration. The output of the filter for each configuration is temporarily stored. At the end of N configurations, all the filter outputs for each configuration are added and the final output is stored. The stored final output is then read at the requisite rate, while at the same time, the filter starts working on the second data-block.

A. Input Memory Block

The incoming signal is stored in a RAM. The write address is generated by a counter counting from 0 to $2l - 1$ at a lower rate. The read address is generated by either of 2 enabled counters, one that counts from 0 to $l - 1$ and the other that counts from l to $2l - 1$, both at a rate of N times higher than the input datarate. Either one of the counters are enabled at any given time. The addresses 0 to $l - 1$ hold the odd indexed data-blocks while the addresses l to $2l - 1$ hold the even indexed data-blocks. Once a data-block is processed, it can be overwritten. Fig 5 shows the input memory block for N = 5 and l = 40000.

B. Reconfigurable Filter Block

The data read from the input memory block enters the reconfigurable filter block. For N configurations, N values of α, sel_f1, sel_f2, sel_M are precomputed and stored in memories. Additionally, the gain values for each of the N configurations are also stored. All the control signal values for each configuration are stored in identical memory locations. Therefore, a single counter counting from 0 to N – 1 incrementing at a rate of (N × Input datarate)/l, can generate the addresses for all the stored control signal values. An increment in the counter changes the control signal values entering the filter which leads to reconfiguration. An edge-detector connected to the same counter generates the reset pulse, such that all the delay elements within the filter are reset at the time of reconfiguration. Each configuration of the filter processes the read data-block of l data elements and generates an intermediate output that has l data elements. Fig 4 shows the reconfigurable filter block for N = 5 and l = 40000.

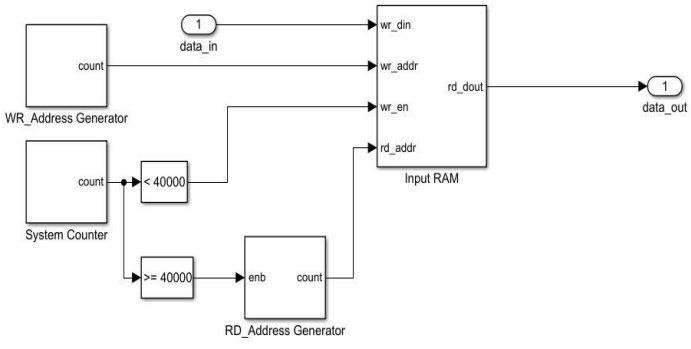

Figure 5. Input Memory Block

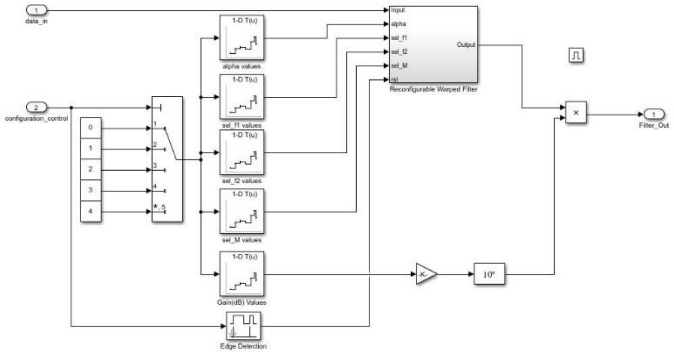

Figure 4. Reconfigurable Filter Block

Table 1 shows the values stored in the LUTs whose address is driven by sel_M and Table 2 shows the filter configurations decided by sel_f1 and sel_f2 values.

TABLE I. LUT STORED VALUES DRIVEN BY SEL_M

Tap No.	sel_M		
	M = 1	***M = 2***	***M = 3***
1	1	1	1
2	1	0	0
3	1	1	0
4	1	0	1
5	1	1	0
6	1	0	0
…	…	…	…

TABLE II. CONFIGURATIONS OF MODES OF OPERATION

Mode of operation	Control Signals	
	sel_f1	***sel_f2***
Low-pass	1	1
Band-pass	0	0
High-pass	0	1

For a given prototype lowpass filter with cut-off frequency β and the required cut-off frequency w_c, both in radians per second, the value for α can be computed by the formula given by [13],

$$\alpha = \frac{\sin(\frac{\beta - w_c}{2})}{\sin(\frac{\beta + w_c}{2})} \qquad (3)$$

For a given prototype lowpass filter with cut-off frequency β radians per second, a bandpass filter configuration of the reconfigurable warped filter has a passband region of β radians

per second. When CDM is applied with a decimation factor M, the passband region is given by [4],

$$Passband\ Bandwidth = M \times \beta \qquad (4)$$

C. Synthesis Block

The intermediate outputs for each of the filter configurations generated must be separately stored. Therefore, there are N registers, each of width l, that are enabled conditionally. A counter counting from 0 to N – 1 incrementing at a rate of $\frac{N \times Input\ datarate}{l}$, is compared to fixed index values to enable the correct registers. At the end of N configurations, all the registers are enabled again to add the outputs of each configuration and at the same time, the first configuration output of the next data-block from the filter is stored in the register. The output of the adder is stored in a RAM, with the write addresses generated by a counter counting from 0 to l – 1 at a rate of $N \times Input\ datarate$, and enabled at the same time as all the registers at the end of N configurations. The stored output in the RAM can be read and sent out as the final processed output at input datarate itself. Therefore, both the input RAM and the output RAM can use the same counters, only, write address generator for input RAM is used as read address for output RAM and read address generator for input RAM can be used as write address for output RAM. Fig 6 shows the synthesis block for N = 5 and l = 40000.

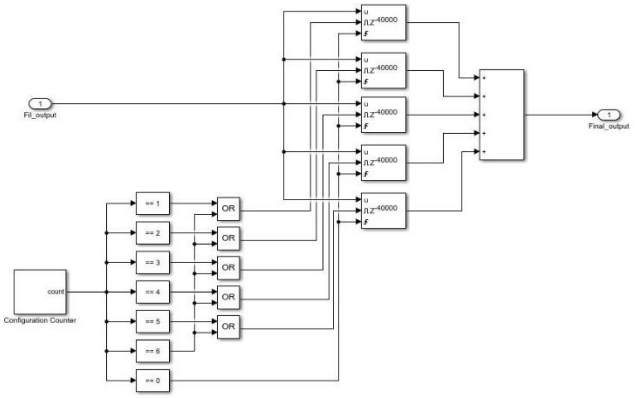

Figure 6. Synthesis Block

V. Implementation and Results

The above mentioned designed is modelled in Simulink using a prototype low-pass filter of the order n = 60, having a cut-off frequency of 500 Hz. The prototype filter has a stop-band attenuation of -60 dB and has 0 dB pass-band gain. The filter architecture is designed for a total number of configurations of N = 9, for a data-block size l = 20.

The audiogram, borrowed from [14], for mild-hearing loss at high frequencies is used for simulating the operation of the filter architecture for verifying audiogram matching operation and computing the matching error. The audiogram used is shown in Fig 7. The hearing sensitivity of the left ear is denoted by circles 'o' and that of the right ear is marked with 'x'. The audiogram for the right ear is used for result analysis here. The reconfigurable filter is reconfigured 9 times to generate 9 sub-bands of varying bandwidths and gains, to best match the audiogram. Equation (3) is used to compute the required α values. The control signals for each configuration is given in Table 3.

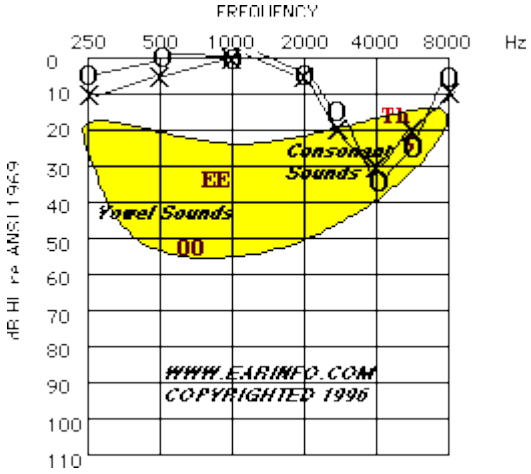

Figure 7. Audiogram for mild hearing loss

TABLE III. Control Signal Values for Simulation

Control Signals	Sub-bands								
	1	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*
α	-0.2	0.9	0.75	0.67	0.42	0	-0.3	-0.55	0.6
sel_f1	1	0	0	0	0	0	0	0	0
sel_f2	1	0	0	0	0	0	0	0	1
sel_M	1	2	1	1	2	2	1	2	1
Gain(dB)	4	7	7	13	28	22	18	12	10

The audiogram matching is done by adding the cumulative effect of all the filter responses i.e., sub-bands generated by each configuration of the reconfigurable filter. Fig 8. shows the audiogram matching, where the overall filter response is shown in blue and the audiogram is shown in red. The audiogram matching is done with an error margin of ±6dB. Matching error is shown in Fig 9.

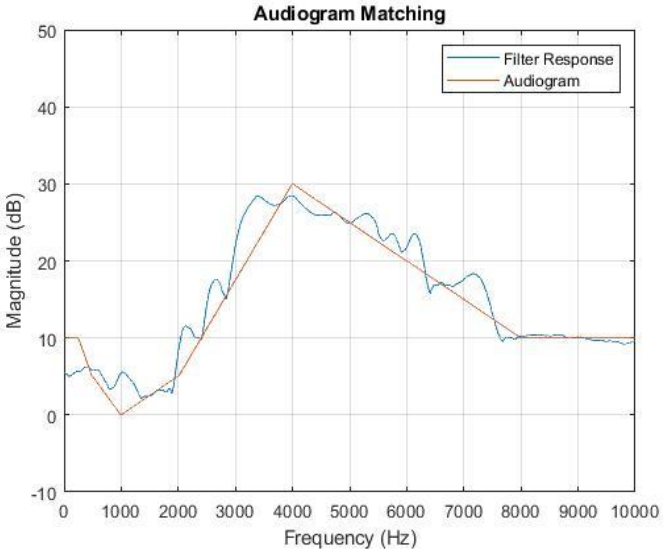

Figure 8. Audiogram Matching

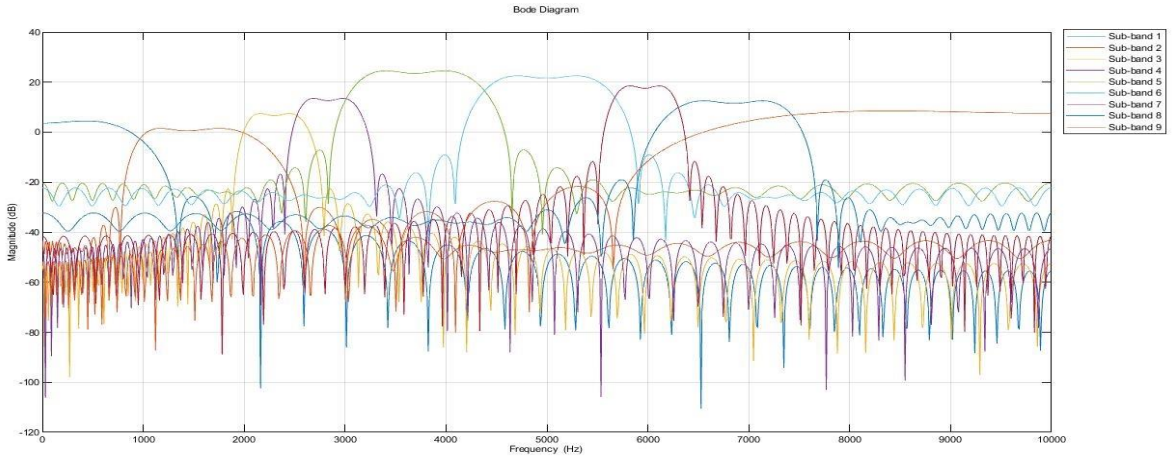

Figure 10. Sub-band Generation

The sub-band generated by each configuration is shown in Fig 10.

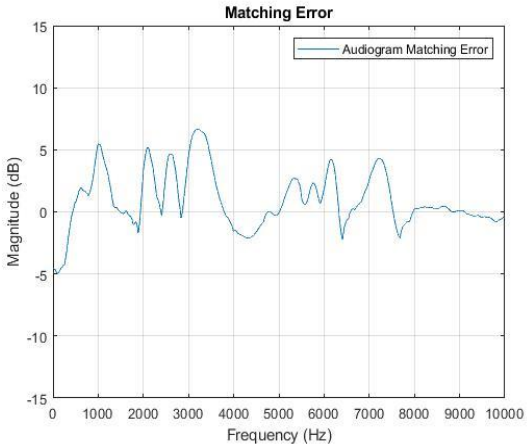

Figure 9. Matching Error

Using the error graph, the matching error is computed as 2.487dB, wherein matching error is the root-mean-squared value of error between the audiogram and the filter response. The matching error of 2.487dB and peak error of 6.1dB is comparable to the matching error in [14] where the same audiogram is used for the analysis of the results.

VI. Conclusion

Reconfigurable warped digital filter is a successfully made use of by the proposed system for the application in digital hearing aids. The proposed system successfully automates the generation of control signals for the reconfiguration of the filter from low-pass to band-pass and high-pass with the required cut-off frequencies. The necessary sub-bands with requisite gains are generated. The proposed system also processes the sub-bands in a pipelined manner to have the magnitude response for optimum audiogram matching. The system achieves good audiogram matching with low matching error comparable to other filterbank designs.

***Abstract*— In this paper, microstrip patch antenna is designed with different geometries on the ground plane to achieve low cross polarization level. Linear shaped Defected ground structure (DGS) and fractal defected ground structure (FDGS) have been used to suppress the cross polarization. A microstrip patch antenna with FDGS is designed with lossy substrate FR-4 at 2.2GHz using Ansoft HFSS simulator. Moreover, it is observed that FDGS shows low XP level of -72dB with good return loss and gain.**

Keywords—Square Patch antenna, Cross Polarization(XP), Defected Ground Structure (DGS), Fractal Defected Ground Structure (FDGS).

I. INTRODUCTION

In many applications, antennas should propagate in similar polarization to achieve an optimal performance. A purely polarized antenna will have low cross polarization level. Definitions and applications of XP level are explained in [8]. Formerly, there are number of investigations related with appliance of DGS in reducing the cross-polarization radiation of microstrip patch antennas.Microstrip antenna technology and performance of patch antennas are described in[10][12]. DGS is applied by integrating slots or defects on the ground plane of the microstrip patch antenna. There are various shapes of DGS. Circular patch antenna which has been etched with two circular slots on ground to suppress XP level (5-8dB) has been studied [7] with bandwidth of 160MHz. L shaped asymmetric DGS has been implemented for probe-fed circular microstrip antenna [2] with XP level suppressed up to -15dB. DGS has been used for effective suppression in XP radiation up to -30dB [1] in prob- fed microstrip antenna. In probe fed circular microstrip patch antenna the XP level has been suppressed by (10-12dB) [3]. Circularly polarized patch antenna with arc shaped DGS has suppressed XP level from (18-30dB) [4]. In [6] they have explored circularly polarized microstrip antenna with two different DGS geometries, namely circular ring with suppression (5-7dB) and two arc shaped DGS with suppression (7-12dB). XP suppression level of (7-12dB) has been achieved in [5] with Circular microstrip patch antenna having arc shaped DGS.Since a simple and compact microstrip patch antenna has not yet been designed with low XP level. So, in this paper, a microstrip patch antenna with FDGS has been proposed with low XP level to ensure high isolation between desired and undesired signal.

II. ANTENNA GEOMETRY AND WORKING PRINCIPLE

The proposed antenna is designed to operate at 2.2 GHz. Frequency with FR-4 substrate of dielectric constant 4.4 and thickness 1.6mm. The antenna geometry is chosen as per the equations given below. The ground and patch dimensions are optimized using parametric analysis in HFSS.This antenna is fed using co-axial feed line.

A. Mathematical design

The dimensions of proposed antenna:

- Patch width:

$$W=\frac{c}{2f_r\sqrt{\frac{\epsilon_r+1}{2}}}$$

Where c=speed of light

f_r=resonant frequency

- Patch length(L):

$$L= L_{eff} - 2\Delta L$$

Where $L_{eff} = \frac{c}{2f_r\sqrt{\epsilon_{reff}}}$

$$\Delta L = 0.412h\frac{(\epsilon_{eff}+0.3)\left(\frac{W}{h}+0.264\right)}{(\epsilon_{eff}-0.258)\left(\frac{W}{h}+0.8\right)}$$

- Substrate height(h):

$$\frac{W}{h} >1$$

- Effective dielectric constant (ϵ_{eff}):

$$\epsilon_{eff}=\frac{\epsilon_r+1}{2}+\frac{\epsilon_r-1}{2}\left[1+12\frac{h}{W}\right]^{-0.5}$$

- Ground plane dimension:

$$L_g = L + 6h$$
$$W_g = W + 6h$$

B. *Simple microstrip patch antenna*

A basic microstrip square patch antenna without DGS has been designed for comparative analysis with the proposed antenna with different DGS geometries. Microstrip patch antenna without DGS has been implemented in High-Frequency Structure Simulator (HFSS). It is shown in the Fig. 2.

C. *Microstrip patch antenna with DGS*

The DGS is implemented by placing a slot on the ground plane and adjusted in such a way that it will provide efficient coupling and suppresses the higher order modes. TM_{02} mode is the higher order mode in a rectangular or square microstrip patch antenna. A vertically polarized strong field located near the patch edges ensures the excitation of TM_{02} mode. So, in the design we need to check where the vertically polarized strong fields are located and DGS should be employed on that field ensuring that it should suppress that fields.

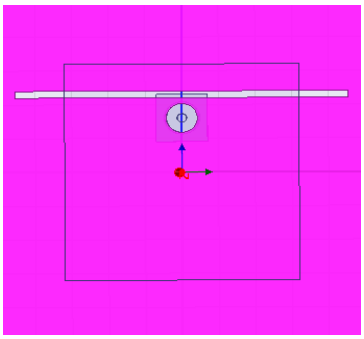

Fig. 1. Square patch antenna with linear shaped DGS

In the design the vertically polarized strong fields appeared at the edges of the patch. So the DGS should be placed on either one of the patch edges. Once the position at which DGS has to be placed is fixed, we need to select the shape of the DGS that we implement. There are different shapes of DGS such as circular, spiral, square, rectangle, L- shaped, Dumbbell, V shaped, U shaped and so on.

D. *Microstrip patch antenna with linear shaped FDGS*

The Linear slot DGS is used as the reference for the FDGS as a self-iterative structure. And as for the positioning it is similar to the design of the DGS.Ansoft High Frequency Structure simulation (HFSS) is used to analyze the performance of antenna. The optimized parameter values of this antenna are:
Ground and patch dimensions:
W_P=32mm, Lp=32mm, Ws=50mm, Ls=50mm
FDGS dimensions:
L_1=10mm, L_2=5mm, W_1=2.5mm, W_2=1.5mm

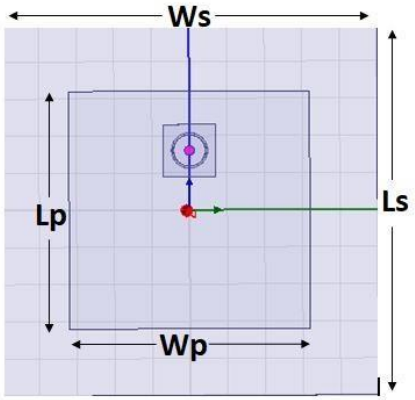

Fig. 2. Microstrip patch antenna

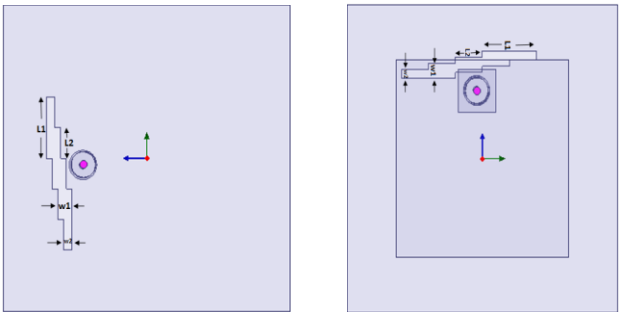

a) b)

Fig. 3 a) FDGS with parameters b) MSP with FDGS

III. SIMULATED RESULTS

XP level plot of the microstrip antenna has been analyzed and the value is 51.2dB. Here XP level has been measured as the distance between the actual polarization and polarization which is 90˚ to that. In the plot two graphs have been plotted with same frequency for $\phi=0^{\circ}$ and $\phi=90^{\circ}$ and the difference between them came to be 51.2dB. For the betterment of XP level suppression, different slot shapes have been attempted.

In this design of microstrip patch antenna with Linear shaped DGS XP level has been suppressed up to -67 dB is shown in Fig. 4.

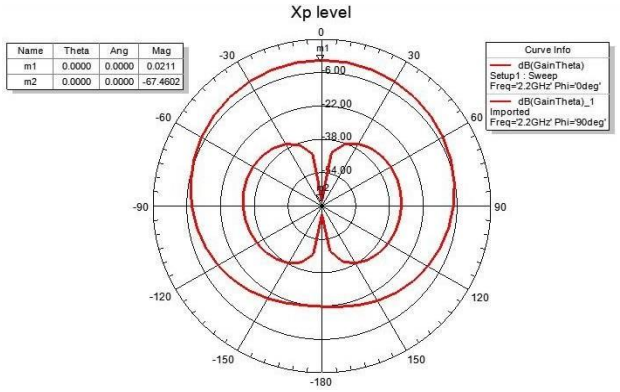

Fig. 4. XP level plot for linear shaped DGS.

E. Microstrip patch antenna with FDGS

In the appliance of linear shaped fractal DGS, the XP level is -72dB.The change in FDGS dimensions will not affect the resonant mode original design. The XP graph with each iterative FDGS geometry is presented for comparison. At the fourth iterative it shows an incremental result obtaining XP level -72dB (Fig. 5.).

TABLE 1: XP Suppressions for the different geometries on the ground plane of microstrip patch antenna.

Patch	Design	Geometry	XP suppression
Square	Without DGS	Without DGS	-51dB
Square	With DGS	Linear shaped	-67dB
Square	With FDGS	Linear shaped	-72dB

IV. CONCLUSION

Basic microstrip patch antenna with two different geometrics of DGS have been designed and analysed. With comparative results, it was observed that microstrip path antenna design with FDGS has attained the maximum XP suppression which probably increases the antenna performance. The comparative results are shown in table 1. The proposed design has improved the suppression of XP upto -72dB. Thus, the propounded concept has been implemented to achieve low cross polarization level ensuring the good performance of antenna.

***Abstract*— Nowadays most of the data transmission is done through digital communication and hence security and efficient data transmission is always a desirable property for any data communication. At present, Advance encryption standard (AES) is most widely used cryptographic technique. This AES uses static s box for encryption and decryption which remains constant irrespective of the key. Numerous analysts have experimented and revealed that there are some weak points [1] in the static s-box as it is static and known to all. Therefore, in our proposed algorithm we modify AES such that it uses dynamic sbox which is key dependent and compare the avalanche effect of basic AES with our proposed algorithm.**

Keywords—Advance encryption standard(AES),Avalanche effect, Strict avalanche criterion(SAC),Dynamic S-box.

I. INTRODUCTION

Information has been an utmost priority of concern for any country's security. Therefore, there was a strict need for building a highly secure encryption algorithm. In 1997, National institute of standards and technology (NIST)[2] adapted AES as a new cryptographic algorithm to replace age long DES. Vincent Rijmen and Joan Daemen[3] named this algorithm as Rijndael and submitted to NIST where their algorithm was selected among 15 participants.

Since most of the block ciphers uses static s box which is the only non-linear part in AES. So, there was a strict need to make this nonlinear part dynamic that is making it key dependent [4]. Many authors have tried to change s box in the case of-

Krishnamurthy[5]in this paper they created dynamic behavior in sbox by rotating the sbox and this rotation value was key dependent and compared avalanche effect[6] of basic AES with their proposed AES but this scheme has a more complicated decryption algorithm.

Abdullah al mamun[7]in this paper they used random byte to modify s box by performing ex-or on all bytes of s box and hence discussing parameters like time security, avalanche effect and strict avalanche criterion. But this algorithm didn't have key dependent sbox.

Harshali zodpe[8]this paper enhances the security features of AES.in this they have generated a new algorithm for constructing s box and key scheduling algorithm using a PN sequence generator i.e. they have designed PN sequence generator using a 8 bit LFSR and compared avalanche effect of both algorithms and found satisfactory results, but this algorithm violates the basic construction of AES.

Jurumi[9] in this paper they added an extra block in encryption named s-box rotation which uses an offset, generated by performing ex-or on all bytes of round key and the resulting bytes were used to rotate the sbox. Also, they compared avalanche effect on different samples for both schemes and found satisfactory results.

This paper is organized in such a manner that section II consist the explanation of basic AES. In Section III we have described our proposed algorithm which makes sbox key dependent by modifying basic sbox and simulated using Isim simulator from Xilinx ISE. The simulated results are shown in section IV and conclusion in section V.

II. BASIC AES

Advance encryption system is symmetric cipher which uses the same key for encryption as well as decryption. AES is a block cipher which performs operations on blocks of data. AES uses 128-bit plaintext and uses variable keys viz 128,192 and 256. Depending on the size of the key it performs different rounds of operations i.e.10 rounds for 128 bit key, 12 rounds for 192 bit key and 14 rounds for 256 bit key. At present, the most used key size is 128 bit[10].

At internal level of AES, cipher key is expanded to 11, 13 and 15 keys for 10, 12 and 14 rounds respectively. Then the plaintext is copied into an array named state array. State array is 4x4 matrix where each array contains byte of plaintext arranged horizontally [11].

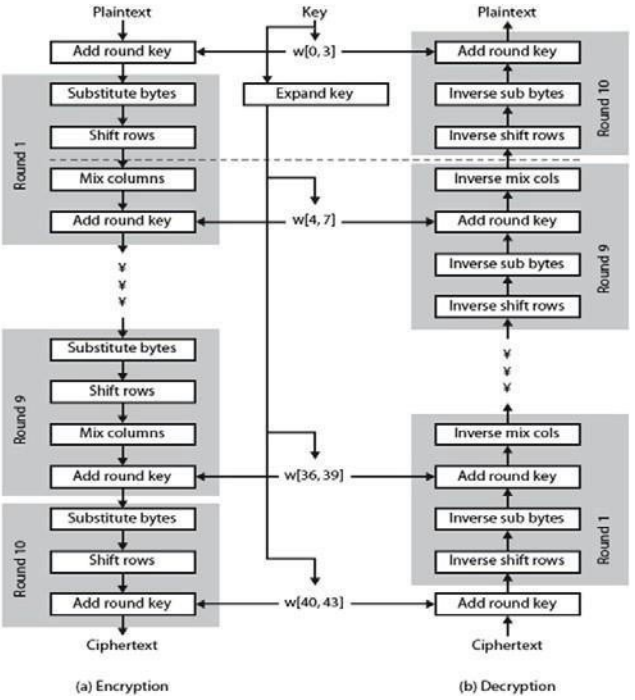

Fig. 1. AES algorithm

A. *Key expansion*

AES involves a key scheduling algorithm which generates a 128 bit unique key for each set of rounds. This algorithm performs operations on words each of word length of 32 bits. Therefore, a key consists of 4 words.

The operations performed in each round to generate a new key are-

- The last word of previous round is rotated 8 bits to the left
- The resulting four bytes are substituted with sbox
- The resulting four bytes are XORed with the first word of the previous round.
- The first byte of result four byte is XORed with round constant (Rcon) that varies for each round.

B. *Add round key*

- It is the initial step of encryption process and also a important step in each round.in this step, 128 bit plaintext array is xor-ed with 128 bit key which is also formed as a state array generating a 128 bit output.

C. *Sub Bytes*

Sub bytes stands for substitution of byte, in this step each byte is substituted with a byte from a 16x16 look up table which contains 256 distinct values. The 16x16 look up table is named as substitution box or S-box.

To substitute a byte from state array, the input left most 4 bits denotes row and right most 4 bits denotes column of s box. Suppose the input byte is a4.so, we inspect rows for a(inhex) and column 4(in hex) and their intersection gives the resultant output.

Fig. 2. AES sbox

D. *Shift rows*

This step performs left shift cyclically on different rows. Such as first row of state array is left unchanged, second row is shifted 1 time, third row is shifted 2 times and third row is shifted three times cyclically to the left.

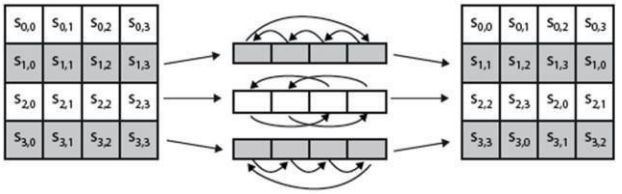

Fig. 3. Shift row operation

E. *Mix column*

This step takes a column from state array and provides matrix multiplication with affixed matrix and produces a output column.

$$\begin{bmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{bmatrix} \begin{bmatrix} s_{0,0} & s_{0,1} & s_{0,2} & s_{0,3} \\ s_{1,0} & s_{1,1} & s_{1,2} & s_{1,3} \\ s_{2,0} & s_{2,1} & s_{2,2} & s_{2,3} \\ s_{3,0} & s_{3,1} & s_{3,2} & s_{3,3} \end{bmatrix} = \begin{bmatrix} s'_{0,0} & s'_{0,1} & s'_{0,2} & s'_{0,3} \\ s'_{1,0} & s'_{1,1} & s'_{1,2} & s'_{1,3} \\ s'_{2,0} & s'_{2,1} & s'_{2,2} & s'_{2,3} \\ s'_{3,0} & s'_{3,1} & s'_{3,2} & s'_{3,3} \end{bmatrix}$$

Fig. 4. Mix column operation

III. PROPOSED ALGORITHM

This proposed algorithm consists the same set of rounds as performed on normal AES. Here the key dependent sbox is generated by performing operations on basic sbox and hence we don't violate basic construction of AES and rather enhance the security of basic AES.

We perform following steps to generate key dependent s box-

Encryption

- Select an initial key for encryption.
- Key[z] is selected from lower byte of round key.
- Generate s box, as generated in standard AES as SBOX[i].
- Computing dynamicSBOX[i] =SBOX[i] ⊕ key[z].
- Substitute each byte from dynamicSBOX[i] and continue for each round

Decryption

- Select key[z] from lower byte of round key.
- Generate inverse s box, as generated in standard AES as invSBOX[i].
- Computing invdynamicSBOX[i] =invSBOX[i] ⊕ key[z].
- Retrieving each text by substituting each byte from invdynamicSBOX[i].
- Continue performing above steps for each round.

A. AVALANCHE EFEECT

Avalanche effect is a very important property for a block cipher. It gives the idea that how does output varies by changing one bit in the plaintext. The degree of randomness is calculated through avalanche effect. If the avalanche effect is not of higher degree than cryptanalyst can guess the plaintext by monitoring the cipher text. The avalanche effect is calculated as-

$$\text{Avalanche effect} = \frac{\text{number of times cipher bit changes}}{\text{Total number of bits in plaintext}}$$

Strict avalanche criterion

To measure diffusion and confusion for an algorithm SAC property is used.it was introduced first by Webster and Tavares in 1985[13]. For a function to satisfy SAC it should change the output bits at least by 50% probability when input bits are flipped.

IV. Experimental results

We have simulated AES encryption and proposed AES encryption on Xilinx ISE 14.7. To study avalanche effect, we have considered plaintext 'a56dc6d5230d9529d96c95c019604d10'and key

'31d851641c5044465d8012fa5ce640b6' and generated cipher text for both algorithms.

Then first bit of plaintext is flipped and its variations is compared with the previous cipher text. This is repeated 18 times by flipping various bits of plaintext as shown by bit variance index and at last changing 128th bit of plaintext and compare its cipher text with the cipher text of the original plaintext.

Table 1 Dynamic s box of proposed algorithm for round 1

In the above table we have generated dynamic sbox for the first round by using last bytes of round key. Similarly, we can have different s box for different rounds. Therefore, multiple sbox can be generated and hence static behavior of sbox from AES can be avoided hence improving its security. In the below table we have shown avalanche effect variations of basic and proposed AES.

Table 3 avalanche effect of dynamic AES

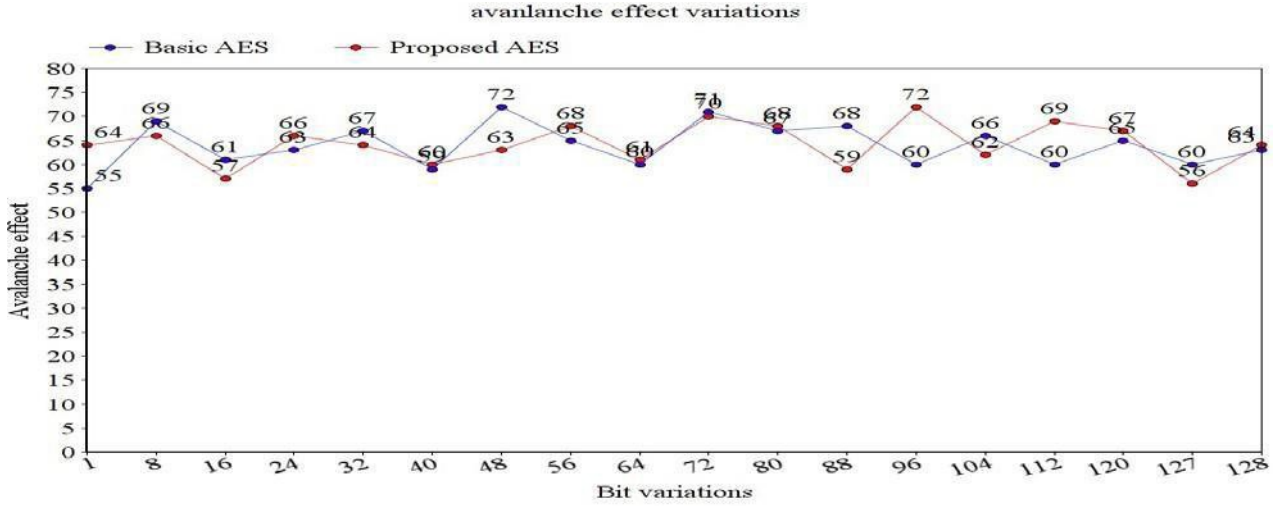

Fig. 5. Variations of basic AES and dynamic AES w.r.t bit variation Index

From the above graph we can infer that proposed algorithm shows better avalanche effect in most cases as compare to the basic AES algorithm and proposed algorithm satisfies strict avalanche criterion greater number of times as compared to basic AES algorithm. In this paper, we don't contradict security of AES rather we take AES as our basic block and doesn't change its mathematical calculations and make SBOX key dependent. Therefore, basic AES algorithm is not violated in this paper.

V. CONCLUSION

In this paper, we have successfully generated key dependent sbox whose avalanche effect is found to be greater than the basic AES.

We have studied that basic AES algorithm uses static sbox which can be attacked in future while in our proposed algorithm it generates multiple sboxes for different rounds that is sbox changes with respect to key and hence increasing the security of cipher. However, it will take extra hardware to ex-or key with sbox as compare to normal AES. So, this algorithm can be used where Security is the utmost priority. Therefore, its application includes military, banking sectors where security is the fore most criteria.

In the future work, this algorithm can be extended to AES-192 and AES-256 implementations and can be verified for larger number of samples.

***Abstract*-Full-Duplex Optical wireless system for simultaneous transmission and receiving of MIMO signal in both upstream and downstream. The system representation and simulation is done with higher carrier frequency. The current system is a LOS setup and system also uses 16 QAM modulation techniques. The efficiency of the system is done on the basis of bit-error rate, eye opening, and quality factor and so on.**

Keywords-Wavelength division multiplexing, multiple input/multiple output, optical wireless system, Quadrature amplitude modulation.

I. INTRODUCTION

Next generation communication networks such as 5th Generation or beyond it requires a significant plunge in the data rates. With the increase in capacity, the data rates of the optical downstream system could be alarm by employing digitized transferable method [1].Optical wireless system can be very useful for pliable access networks and resilient for mobile downlink system [2]. Many researchers work on the MIMO OWC system for transmitting the signal efficiently [2]. But in the proposed system, Full duplex is used for sending the signal downstream as well upstream simultaneously. As in the mobile downstream, radio over radio fiber system has been presented for supple, less delay and low data rate transmission. Signal transmitted through MIMO system is 25 GHz of the frequency. MIMO enables to improve the quality of OWC system. Apart from this Full-Duplex fiber optical wireless system is indispensible for the continuous transmission of downstream and upstream of the data without any delay. In addition to it, MIMO [3] signals were transmitted separately in the downstream and upstream direction. Moreover, Quadrature Amplitude Modulation (QAM) is used for lower error rate as the distance is more [4]. OWC caters more coverage area whereas multiple input and multiple outputs provides diversity advantages. The transmission of the optical signal from central station to the base station via optical fiber with the distance of 20 km and further the signal is transmitted to mobile users [5] through OWC. Owing to less error rate providing capacity QAM is generally used. In this, 16-QAM is implemented over a distance of 20 km [6]. As the order of QAM rise the data rates. In 16 QAM 4 bits are used to represent the symbol. The baud rate is ¼.The signal transmitted through local oscillator (LO) from Central station to Base station, it assist to reduce the maintenance cost, complexity and power consumption also[7],[8]. The implementation is done by using LOS conditions by using 16 QAM. As LOS conditions are provided between receiver and transmitter to get high SNR[3], [9], [10]. Even MIMO can give gain under LOS conditions which provides little channel difference. In this paper we proposed the Full- Duplex fiber optical wireless system for MIMO signals at higher carrier frequencies. The current system uses Wavelength division multiplexing (WDM) as intermediate frequency over fiber in the optical link [11]. We

transmit the 16-QAM MIMO OFDM signal over 75 GHz of frequency in bidirectional [12], [13].

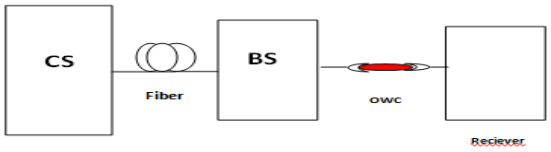

Fig.1. 2 X 2 MIMO system

This paper is organized as follows, the section I is introduction part which explains the literature work of existing paper. Section II demonstrates the experimental setup and III section tells about the results of the work done in the section II and the last IV section is of conclusion.

II. EXPERIMENTAL SETUP

The experimental setup of Performance analysis of Full-Duplex MIMO fiber-OWC system is modeled on Opti-system version 14.0 in Opti-wave. For the analysis of Full Duplex transmission, the OFDM signals send over distinct directions constantly. In downstream, two optical signals transfer from CW laser with a frequency difference of 50 GHz which further modulated by MIMO OFDM. The modulated signals are combined by optical coupler. Circulator is used to separate downstream and upstream signals. The signal transmitted from central station to base station via 20 km bidirectional fiber. Bidirectional fiber are commonly used which has high range of transmission in both the directions. From the base station the signal is further transmitted through optical wireless channel to users. The received signal is amplified by EDFA and filtered by optical Bessel filter. The signal received is optical signal which is converted to electrical signal by suitable photo diode. The desired signal is up converted to 80GHz of the frequency over a distance of 2.5 km. The desired signal amplified and down converted to original signal and outputs captured by an oscilloscope and demodulated and calculated on Eye diagram analyzer. In upstream, the signal is up-converted up to 80 GHz by using mixer. The local oscillator signal for up- conversion could be taken from downlink signals. The signals of up conversions are first amplified and then transmitted through 2.5km of optical wireless channel at remote area unit. The signals amplified before being coupled by photo diode for down converting the original MIMO transmitted signals. The received signals are amplified by low Bessel filter prior to modulating optical signals from CW laser diode using wavelength different from those in downstream. The received signals are transmitted to Central station via 20 km of fiber. Then signals amplified via EDFA and recovered by Bessel filter and photodiodes. The received signal is connected to oscilloscope to receive the output of the signals.

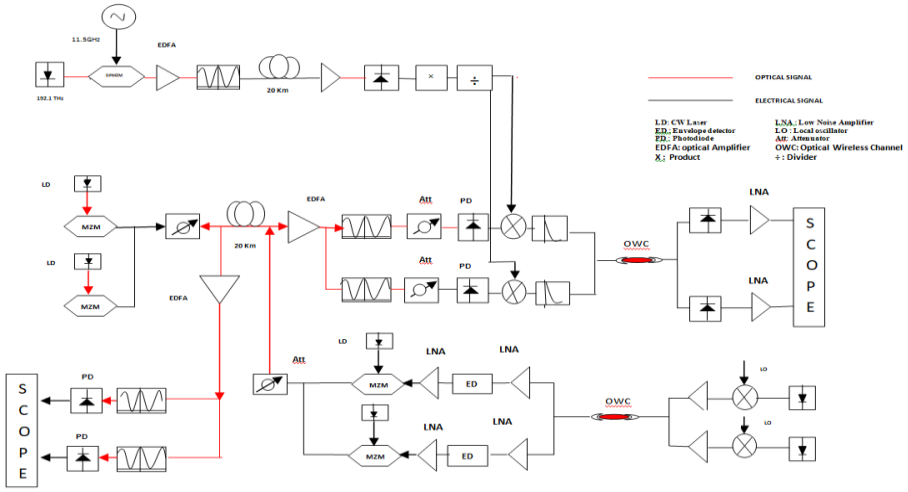

Fig. 2 Experiment Setup of Full Duplex MIMO Fiber-OWC System

III. RESULTS:

The signal is transmitted by CW laser to Dual-Machzender by 16 QAM having 4 bits used to represent the symbol where baud is ¼ of the bit-rate where the signal is up-converted to 11.5GHz of the frequency and the signal is further transmitted to the fiber in single direction and RAU and receiver channel by using following parameters.

Table1.Simulation Parameters used for the proposed Full Duplex MIMO Fiber-OWC System.

Parameters and Components Used	**Values**
CW Laser (Downstream)	193.1THz
CW Laser(Upstream)	192.1THz
Single fiber length	20Km
Bidirectional Fiber	20Km
OFDM Bandwidth	2 GHz
Local oscillator(upstream)	11.5GHz
EDFA length	5 m
OWC distance	2.5km
OWC wavelength	1550nm
Bit rates (Gbps)	40

Simulation Results:

The simulation of 2x2 MIMO 16 QAM OFDM modulations over 20km of the signal through optical fiber as well as bidirectional fiber in both upstream and downstream direction. Fig.3 shows the transmitted signal from central station over the frequency of 80 GHz.

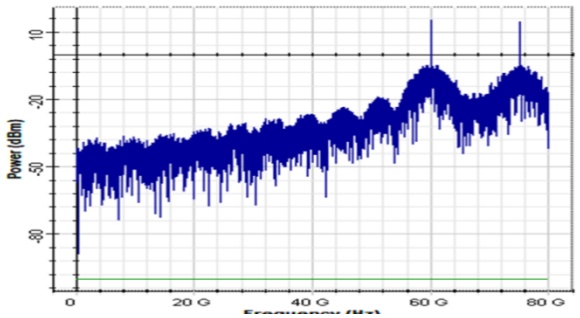

Fig.3 Transmitted Signal of Central Station

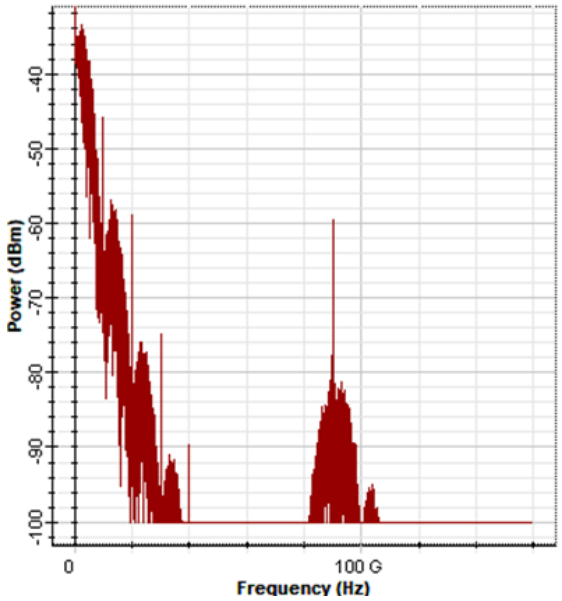

Fig.4 Received signal of MIMO Fiber-OWC System

The received signal of MIMO Fiber-OWC System at the output of the RF spectrum Analyzer_1 is as shown in the Fig.4.The signal analyzed after the transmission of the signal at the output by optical fiber over a distance of 20 km as shown in Fig.5 And signal received and transferred by bidirectional fiber over 20 km is show in fig 6.

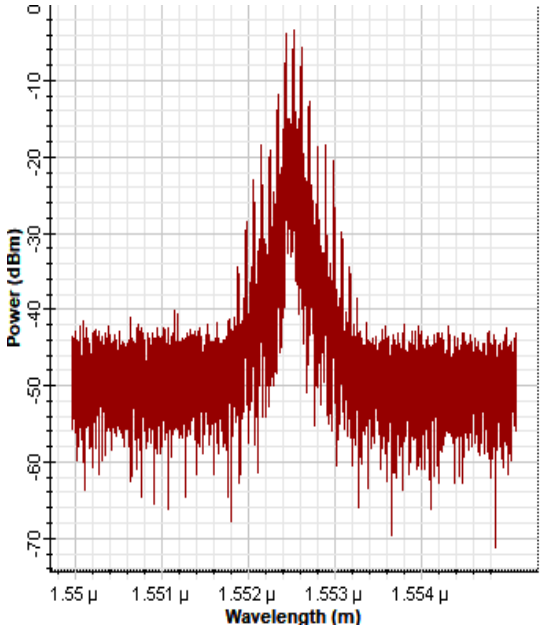

Fig.5 Signal of Fiber

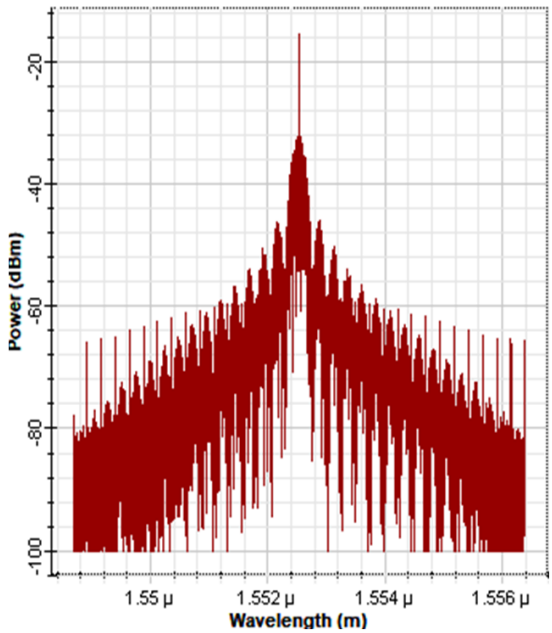

Fig.6 Signal of Bidirectional fiber

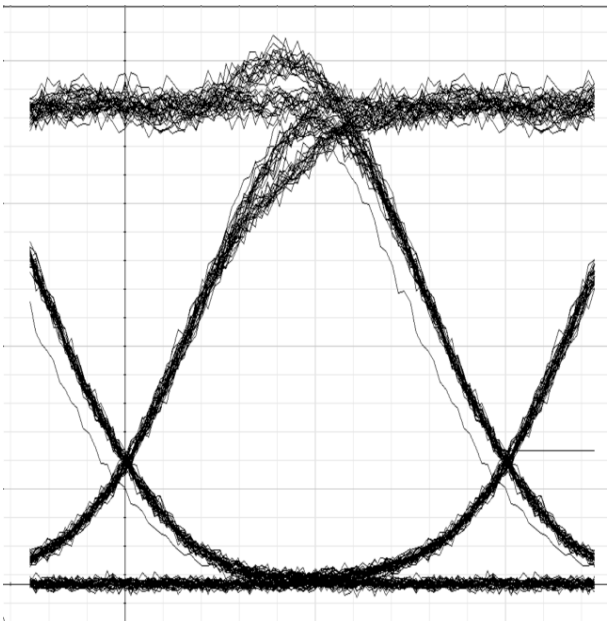

Fig 8. Eye diagram Analyzer

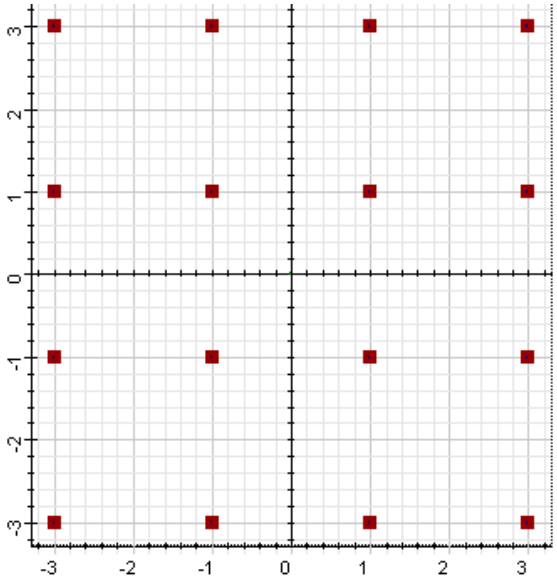

Fig.7 Constellation Diagram of 16 QAM

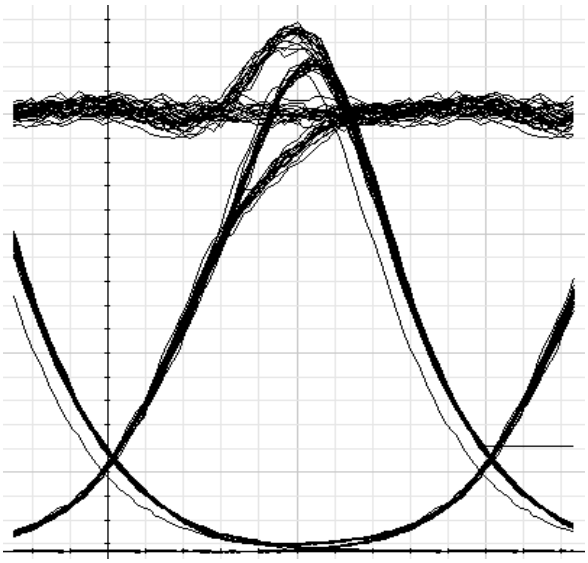

Fig 9. Eye diagram Analyzer_1

The above figure shows the result of 16 QAM at the receiver side. The resulted signal of the Full Duplex 16 QAM OFDM MIMO fiber Optical wireless communication system has been achieved by eye diagram analyzers. The signal of the upstream is shown in Fig.8 and downlink signal in Fig.9and results of the eye –diagrams are written in table 2.

The table below tells about the output received by the eye diagram analyzers and tells the bit error rate, eye height and quality factor of both upstream and downstream of the system.

Table 2. Results of simulation

Parameters	Q-factor	BER	Eye-Height
Eye diagram Analyzer	20.9887	3.72486e-098	1.7488e-005
Eye diagram Analyzer_1	25.1211	1.36735e-139	1.40363e-005

Conclusion:

In this paper, the signal from Full-Duplex MIMO OFDM fiber OWC is send in downstream and upstream by using higher carrier frequencies which lies in W-band. This system is scalable to large-scale MIMO and spectral- efficient owing to the use of WDM system in optical link. The performance of the signal is analyzed by BER and eye diagram. This system is helpful in transmitting large signals for future networking in better way such as tele-medicines, multimedia, telecommuting and many more. The system have full potential to provide the triple play services for upcoming years by increasing its bandwidth so it can be connected to the last miles of network. Apart from this we can increase the efficiency of the system by using Massive MIMO at 64 QAM OFDM to meet the needs of the customers in better way.
