The confidential data like vehicle identification number or other sensitive information. This methodology was designed for a particular processor with the defined parameters by [10]. The mechanism in [11] produces a new field called CAN Message-Authenticator (CMA) which contains both the hash value and timing information which will be used to generate the hash. Authentication of each CAN messages can be done thus it can resist replay attack. Here they have considered CAN Identification Number (CIN) which is unique for each ECU in a particular vehicle. The CMA will be used to verify the legitimacy of the message by a legitimate ECU upon receipt of a frame.

C. *Software & Hardware Approaches*

Gateways in the modern car are used to connect the different networks. In order to have a secure communication between these networks, messages must be checked at the gateways before broadcasting the messages on to the networks. For example, messages from the ECUs connected to the networks like LIN and MOST should be prevented from entering into the critical-safety bus systems such as CAN and FlexRay. Firewalls can control the messages based on certain rules and rules may depends upon the ECU capabilities. Firewalls can be a best option to control the messages and it even checks the incoming network traffic.

Intrusion detection and prevention system (IDPS) can be an alternate for cryptographic techniques to regulate external and internal communications as it needs hardware support which is not beyond what is already there in typical microcontrollers present in ECUs especially to secure CAN bus. IDPS monitors the traffic of vehicle bus and detects if there are an unusual activity and initiate processes to bring back the system to safe-mode and prevent from further damage. By regulating the OBD-II port with creating hardware key or password to access the port where it is physically located can protect against illegal entry of devices into CAN. The security mechanisms are effective until it is upgraded eventually. Security software updates may be over-the-air or dealer distributive, are bound to be an integral part of security and safety of the automotive system.

D. *Significance of Firewall*

Firewalls have been the frontier defense to secure networks against attacks and unauthorized traffic by filtering out

unwanted network traffic coming into or going from the secured network. The filtering decision taken according to a set of ordered filtering rules defined based on predefined security policy requirements [12].The complexity of managing firewall policy limited the effectiveness of firewalls even though it is the main step to secure the network.

Al-Shaer and Hamed [13] have developed an anomaly-free firewall rule editor, which greatly simplifies adding, removing and modifying rules into firewall policy. They used the Java programming language to implement these algorithms in one graphical user-interface tool called the "Firewall Policy Advisor". The rule is set according to one or more different filtering fields.

There are two types of hardware and software firewall as per the user point of view. There two types of firewalls for CAN network as follows [14].

- Packet Filtering Firewalls: Static packet filtering firewalls sequence the packets concerning allow or deny. This is done by considering the field's information on the header such as host/destination address, port number. The depth analysis is not done at this stage. Each packet is examined as a single entity. It is unable to defend the fragment and spoofing attacks.
- Circuit Level Gateway Firewalls: These are deployed at the session layer. To determine the requested session is legitimate or not, Gateway firewalls monitor Transmission Control Protocol (TCP) handshake between the packets. By doing this, the public IP addresses are provided to the outside network and not exposing the internal private IP addresses to the external potential intruders. Circuit-level gateway firewalls do not filter individual packets. An attacker may take advantage of this once the connection is established.
- Application-level Gateway Firewalls: The firewalls decide to allow or drop the packets based on application information which is present in the packet and provide protection for specific application layer protocol. The best example for this kind of firewalls is Proxy server firewalls. Both the client and server are connected to these proxies instead of direct connections so any suspicious data or connections can be dropped by these proxy servers. Application firewalls do deep inspection of each session and decide to drop or allow them to pass through the proxy server by using information present in the application protocol payload or header. Application Gateway firewalls can increase the network performance and makes easier to log traffic.
- Stateful Multilayer Inspection Firewalls: The combination of all the types of firewalls listed till now is called Multilayer Inspection Firewall. These firewalls can filter packet at Network layer using Access Control Lists (ACL), identify the legitimacy of sessions at session layers and evaluates at the Application layer. This firewall can provide a transparent mode in which direct connection is available for the client and server. These can also implement algorithms and complex modules to make connections more secure.

E. Packet filtering firewall in the automotive network

The CAN and its security have become hot-topic for researchers and automakers after a number of high-profile hacking activities in the past couple of years. An attacker can have direct access to the CAN-bus through the OBD port. Charlie Miller demonstrated the vulnerabilities of the onboard computers and networks like CAN-bus by linking these onboard computers in the mid of 2010. Miller and Valasek demonstrated the car attack by altering the CAN message and controlled steering wheel by spoofing park assist [15]. The attackers created software called CarShark to monitor communications between the ECUs and insert fake packets of data to carry out attacks [16].

CAN protocol was designed concerned about reliability but not intended to provide secure communication. The embedded computers present in the cars have strong hardware constraints for computation power and memory left for security mechanisms. Because of which ECUs cannot perform complex cryptographic algorithms to perform strong encryptions. Where an attacker can have limitless hardware to perform cryptanalysis and can break simple algorithms. The security mechanism for a car should be such that its requirements should be within the constraints.

The advantage of packet filtering firewall is, firewall requires fewer resources and computation power. The data exchange with the external world can be restricted by the firewall. Even though an external device is authenticated and starts sending data or signals to the network, it is not wise to accept all those data because those external devices might be compromised. Hence there should be a firewall at the gateway which can control the access to the internal network by external devices and acts as a secondary security mechanism [17].

IV. LITERATURE SURVEY

Wolf et al [18] have given Exposures to Automotive Bus systems, Gateway firewalls and its importance. A secured approach was proposed using modern cryptography which is against manipulation and provides authentication and secrecy. This gives the best way to tackle many of the vehicle security issues.

Alex Oyler and Hossein Saiedian [19] have explained how one can compromise CAN bus and ECU through Telematics and found attacking surfaces. The device can be installed via the cellular network on OBD. Countermeasures for

this is to separate external network from the internal network by combining firewall and Intrusion Detection System (IDS) at Central Gateway System (CGS).

Tharaka et al [20] present a detailed study of firewall technologies and firewall capacity along with other firewall technologies in order to prevent unauthorized accesses. They mentioned that high capacity firewall can provide high performance but it is expensive.

Wei YAN has designed a Bi-directional firewall module which includes vehicle status logger, a CAN message filter and storage module. The storage module is used to store a White-list and a Black-list and the CAN message filter is configured selectively chooses any one of these according to the status of the vehicle [21].

Hamed Salehi et al [22] have mentioned that as soon as detecting higher priority attack by Network Intrusion Detection System (NIDS) send some recommended protection information to the firewall which will set appropriate rule to destroy the connection it. The deep inspection of six layers has been explained in this paper.

Adel El-Atawy and Ehab Al-Shaer [23] explained how rules and policies can be represented as Boolean expressions. Implementation and maintenance of this expression can get complex hence they used Binary Decision Diagram (BDD), where each variable need to be checked only once thus improving packet matching time.

Masud et al [24] have implemented a data-driven firewall. Using a classifier, first finds the packet matching to a class contains a setup of rules. Then finds a matching rule for that respective packet. The results showed that the time required for finding matching rule is six times faster than the conventional methods. In this, they used offline training data for classifier and have considered only the packet header. The last rule is with default empty condition so that any packet could match at least one rule.

Anshu Aneja & Vivek Thapar [25] have explored alternate representations for rule sets which are used to remove the redundant computation using Binary Decision Diagram (BDD) approach and implement the multi-dimensional filtering. This takes less space for storage and less look-up time for accepting or rejecting the incoming packets. They obtained average results of 75.24% and 33.74% for comparison for "Most Reject Packets" and "Most Accept Packets" respectively for about one million incoming packets. Results are shown in the Fig.5.

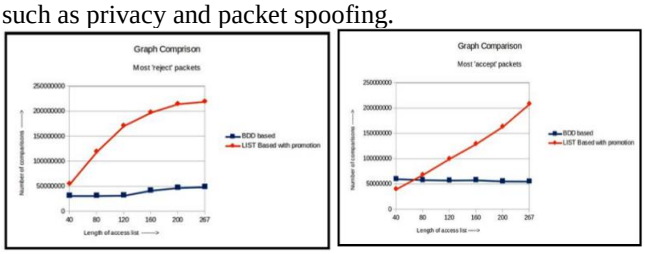
Dongre and Shikalpure [26] attempted to improve the rule matching time by maintaining two different files. The log file consists of information related to the captured packets recently and this is the sub set of the main file. Another file is Index file, which stores Hash values calculated for each packet. Here each incoming packet is not mapped to the main file instead succeeding packets related to the same flow are compared with the log file.

Gupta and McKeown [27] proposed a method for Packet Classification using Hierarchical Intelligent Cuttings (Hi-Cuts). The HiCut algorithm works by carefully preprocessing the classifier to build a decision tree data structure. Each time a packet arrives, the decision tree is traversed to find a leaf node, which stores a small number of rules. High dimensional (considering many fields) requiring smaller storage and comparable query time when compared with other schemes.

James Joy et al [17] presents an architecture for secure automotive communication both external and internal, by using the Smart Gateway which consists of an external and an in-vehicle gateway and a firewall. The Smart Gateway handles authentication, data integrity and secure key storage and management for both external devices connected to the vehicle as well as for the network communication between ECUs.

Pese et al [28] have shown where internal firewalls can be deployed in the E/E architecture and introduced in automotive. The Hardware (HW) firewall (located at the connectivity gateway) shall handle a large, simple and generic rule set to restrict the traffic between domains whereas the Software (SW) firewall shall focus on a small filter rule set for custom-made rules and Stateful packet inspection. Packets which pass the first layer of security (HW firewall) are shunted to the SW firewall for a deeper analysis.

Wei Si et al [29] proposed a hybrid wired/wireless protocol using Backpressure Collection Protocol (BCP) to mitigate DoS attacks by placing a ZigBee at all critical nodes which monitors link qualities and schedules packet transmission accordingly. Emerge of wireless communication into the intra-vehicular network need to face security issues such as privacy and packet spoofing.



"Most Rejected packets" "Most Accepted packets"

Fig.5. Graph comparison for "Most Rejected packets" and "Most Accepted packets" [25].

V. CONCLUSION

In this paper, we give a brief introduction of in-vehicular networks and explained CAN protocol. We summarize certain vulnerabilities on CAN protocol and possible attacks on it. There are many effective cryptographic techniques to secure any network but when it comes to the automotive systems it has few due to resource constraints. IDPS can track traffic inside the network and detect the anomaly activities and prevent before it affects the system. A firewall prevents unwanted traffic from the outside network and acts as a defender at the entry level. There will be fewer chances of getting hacked if we can control the access before the data or signals enter the trusted boundary.

The effective way of securing CAN bus is to implement Packet filtering firewall at the Central Gateway. It is feasible to

implement a software firewall on the Gateway as the software need not know the developer resources and it is embedded during the ECUs software build process. Software updates can easily be done regularly during the scheduled service visit or by over-the-air updates as the firewall present on the gateway. Algorithms like BDD for packet filtering firewall requires less space for storage and lookup time to accept or reject the incoming packets by comparing the results with the listed order method. One should consider all constraints and develop a security framework for automotive system. Further research is needed to bring out the experimental results to decide which optimizing algorithms are best for the automotive systems. The background knowledge of security measures and its drawbacks depicts that the need for firewall and IDPS systems in the car to reduce attacks on CAN network.

Future work: We are motivated for the development of effective countermeasures to secure CAN bus by focusing on practical CAN based attacks in automotive systems. We are exploring ways to deploy firewall at Central gateway and concentrating on a few ECUs which exchange data between an outside world like telematics, Infotainment, and Diagnostics units. We are working on software firewall for CAN bus with framework considering resource constraints of embedded microcontrollers of ECUs at present.

***Abstract*- An exhaustive investigation has been performed in the field of artificial intelligent since last few decades. Moreover, sophisticated gadgets have also been designed based on those algorithms in an efficient fashion. In this article, an intelligent model is designed to reduce food wastage and hunger problem in a competent fashion. A hardware model of a refrigerator is also made where the needy commoners can come and take food they need to fulfil their hunger. The model only responds if a human stands in front of it. If it finds any other living creature other than human is standing then it shows no response. Furthermore, system exhibits no response if same human being appears twice within next 12 hours.**

***Keywords*-** *Intelligent Storage, Object detection, Object recognition, Text to Speech Conversion Video to image processing.*

I. INTRODUCTION

Food waste is an important global issue the reasons for which are many. Only in the EU, a big amount of food are wasted annually with an associated cost estimated more than hundred billion euro. According to The Guradian, US households waste about thousand tons of food on daily basis. Every year, more than a million tons of food produced for human consumption is lost or wasted.

An intelligent and scalable detection algorithm has been proposed in [1] where "Mean Average Precision" (MAP) has been improved by more than 30% with respect to earlier outcome. Basic viewpoint of this paper combines two features i.e. efficient Convolutional Neural Networks (CNNs) and supervised trained data can be applied for segmentation purpose and application oriented fine-tuning purposes respectively. A wide range of image classification based on objective functions has been introduced in [2]. In this article a comprehensive comparison has been made among several variables like "ovens-rest, multiclass, ranking and weighted average ranking SVMs". In this paper several classification techniques have been chosen to train an independent data. Moreover, binary classifier has also been used to identify the accurate class in an efficient fashion. A detailed comparison of these high-dimensional descriptors was performed in this paper and it has been shown that the Fisher vector representation outperforms the others. Thereafter, an attempt has been made based on "Multi-scale Order-less Pooling" technique in [3]. Moreover, CNN scheme have also been applied to execute the classification of image with higher accuracy. Furthermore MOP-CNN scheme with same power has been adopted to execute the above task.

Moreover, the concept of large-scale visual recognition has been discussed in [4], where an eminent design has been adopted and as a result better performance has been achieved. In this mode Back propagation algorithm triggered CNN along with convolutional filters have been used for training purpose. Moreover, techniques like rectification and pooling have also been adopted. On the other hand an exhaustive investigation has been performed on classifier to recognize the multiple task. In this regard, an "off-the-shelf CNN" as well as "OverFeat" having least complex classifiers has been revealed in [5]. From experiment it has been shown that the structures found from deep learning triggered convolutional nets should be the principal entrant in most chromatic identification errands.

The present item uncovering approaches on these abstract interpretations of substances has been uttered in [6]. Here a comparison has been made among human annotators and numerous standard object detectors on a quantity of Picasso portraits. The Cubist painting has also been bring together as a supplementary features for entity identification. To execute the fact different entities have been reorganized in an efficient which can't be identifiable to the human. Finally real time data has been used for experimental purpose and better outcomes has been observed.

In [7] Akata, Perronnin, Harchaoui, and Schmid proposed an model which has been used for robotic clasp discovery purpose. The model has been triggered by CNN network. By adopting this method clasp

discovery along with entity identification have been performed with higher accuracy level. For this purpose two different approaches entitled as single network based entity identification scheme as well as direct envisage clasp coordinates have been used.

On the other hand "PASCAL Visual Object Class (VOC)" has been suggested in [8] where profligate deformable fragment prototype for entity identification has been considered. The speed tailback of the above mentioned structure has also ben suggested. The projected technique performs four times quicker than the preceding profligate technique on "Pascal VOC". In this article it has also been seen that the proposed scheme performs at frame-rate with higher accuracy level for "pedestrian" and aspect recognition. The limitations of the above article have partially overcome in [9]. In this article "Fast Feature Pyramids (FFP)" for entity identification algorithm with better accuracy has been presented. From result it has been seen that the proposed scheme performs significantly quicker than the earlier methods. The tactic is wide-ranging and is extensively pertinent to vision algorithms demanding Fine-grained Multi-scale" exploration.

Meanwhile, the situational object boundary detection has been described in [10]. In this article initially a wide range of situations and numerous entity boundary detector have been defined and thereafter given test images have been classified within predefined situations based on its context. Then appropriate set of object boundary detectors have been applied and run them for different test condition. This method called situational object boundary detection. Most of the approaches for entity edge discovery are inflexible as single predictor has been used to identify the entity edges without considering their contents.

A novel object detection systems has been proposed in [11] in which "Multi-Region Deep CNN" has been applied. The scheme has been proposed for encoding the semantic segmentation-conscious features. Moreover, an enriched version of CNN has been represented for accurate identification of entity. Furthermore, a thought-provoking scheme named frequently stipulating arrangements connecting with continuous variables has also been introduced. As a result real-time "object-oriented state-based specification language" has easily been pronounced. In this paper an assimilation of Object-Z with explicit symbolization of a streamlined subset of the timed fine-tuning calculus has also been presented.

Research has been continued and novel object classifier based on deep network has been designed in [12]. Usually entity identification has been performed by considering two aspects like feature extractor and an entity classifier. Most commonly usable entity identification method is HOG which is hand engineer component. Multi-layer perceptron module has been used to trigger these systems. Moreover, an exhaustive investigation has also been performed on entity identification scheme based on the perspective of classifiers aside from features.

A new perspective of object detection based on YOLO model has been proposed by Gidaris and Komodakis in [13]. The scheme described as 'You Only Look Once' or YOLO which is the profligate wide-ranging entity identifier used in real-time object detection. Form the analysis it has been seen that performance of YOLO is robust and used for identify any kind of object. Moreover, it has also been observed that better precision has been achieved by adopting YOLO model.

Inspired by above investigation an intelligent storage device has been designed in this paper. For this purpose video file has been taken as input and thereafter unique frames are identified by eliminating redundant frames. Next, adaptive intelligent algorithm has been incorporated for identifying the object and also it has been represented by speech. Then lock of the intelligent storage device has been triggered by this speech signal and lock of this device either in open or close condition.

II.SYSTEM MODEL

The unequal distribution of food has led to the existence of chronic hunger in some parts of the world. In the past decade there has been some success in combating global hunger. The aim of this work is to design an intelligent storage system for retrieval of food. The proposed system will get unlocked only when it recognizes a human being in front of it: otherwise, it remains in the locked state. The functional block diagram of the proposed system entitled is shown in Fig.1.

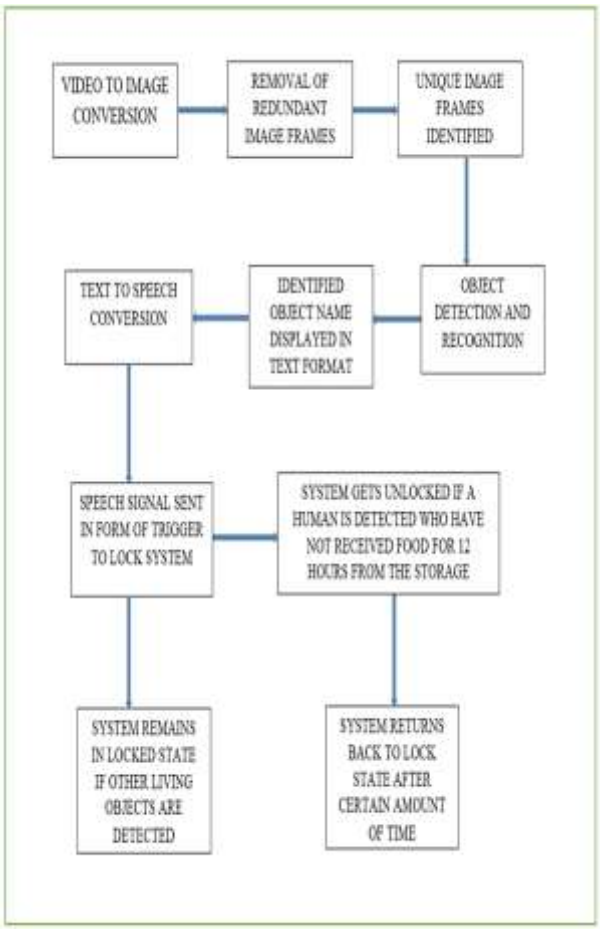

Fig.1 Functional Block Diagram of Intelligent Storage Device

From the above figure it has been seen that unique frames have been identified from the video and thereafter objects has been identified and recognized using Fuzzy K-means algorithm [13]. Next soft computation method has been applied and hence identified object has been described by text and then speech format. Thereafter system becomes lock or unlock based on speech signal which has been treated as a trigger input. After opening the door it becomes close after certain duration (here 10 ms). Moreover, the system can be in locked condition for next 12 hours for the human being who has already taken food.

III.ALGORITHM

The scarcity of food all over the world is not only due to the unequal distribution but also due to the wastage of resources. The flowchart as shown in Fig.2 describes the algorithm of designing the proposed system which will provide food to the commoners and lead to the proper usage of resources.

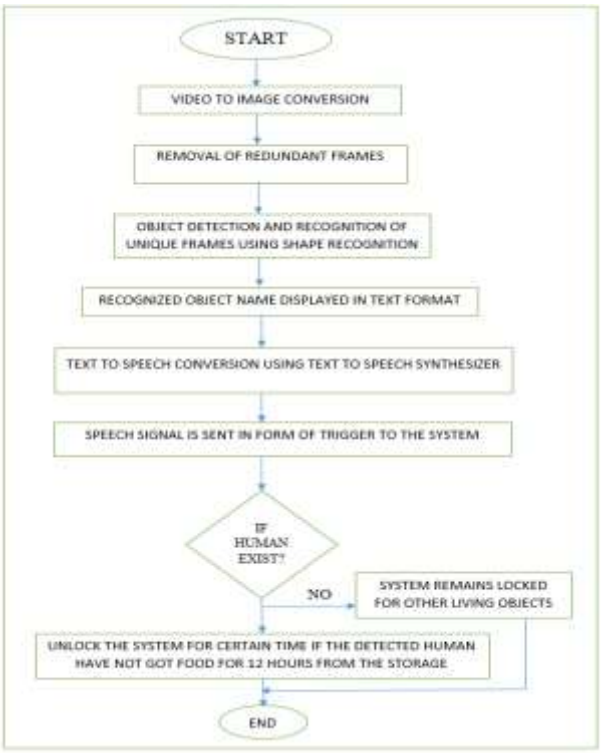

Fig.2. Flowchart of Intelligent Storage Device

From the above figure it has been seen that objects have been detected and identified from the unique frames in an intelligent fashion. Thereafter it has been displayed in text format. From the text, speech signal has been generated and then storage system has been triggered. If human is detected the lock becomes open otherwise closed. The system becomes lock for next 12 hours for the same human being who has already got food from the storage.

IV.RESULTS

The proposed intelligent storage has been implemented both in software and hardware mode. This project consists of a locking system in which the lock is open only and only if the image passes through MATLAB is detected as human. In any other case the lock has been closed. In the simulation part we have taken an image as input to check whether it is a human or not. Depending upon the identification the signal will be sent to the hardware section. Here, The MATLAB 2017b has been used as software and Arduino Uno has been used as hardware. In software section, input and corresponding output have been represented by the following figures:

```
it is a human
Current motor position is 0 degrees
Current motor position is 18 degrees
Current motor position is 36 degrees
Current motor position is 54 degrees
Current motor position is 72 degrees
Current motor position is 90 degrees
Current motor position is 90 degrees
Current motor position is 72 degrees
Current motor position is 54 degrees
Current motor position is 36 degrees
Current motor position is 18 degrees
Current motor position is 0 degrees
```

(a)

```
it is other living object
```

(b)

```
it is other living object
```

(c)

Fig.3 Input images and its corresponding outputs

From the above figures it can be easily conclude that the proposed system easily identified the human being from different types of objects and as human is detected in the image and the text is shown and the speech can also be listened.

Now as the system is able to detect the image as of a human (say Fig. 3a) and the detection will act as the trigger for the hardware system to work. So here the position of servo motor has been changed and start rotating slowly and it has been reached from 0 degree to 90 degree angle and has been stayed in that condition for a predefined time. In that time the door remains open and thus the system allows the user to take the food out from the storage system. After few seconds the motor has been stated for rotating from 90 degree to 0 degree and remains close until and unless next trigger has been sent to the hardware. These facts have been described in Fig.4.

(a)

(b)

(c)

(d)

(e)

(f)

Fig.4 Image of a Human and its corresponding hardware output

On the other hand any species other than human being have been detected door remains close as no triggering input comes in hardware circuit. This fact has been described by the following figures:

(a)

(b)

Fig.5 Image of a Dog and its corresponding hardware output

All the above facts have also been implemented in real time. Some real time captured image and corresponding output have been shown in the following figures:

(a)

(b)

(c)

Fig.6 Real time Human Image and its corresponding hardware output

However, if same person comes more than a time within next 12 hours to the storage it remains close as shown in the following figures:

(a)

(b)

Fig.7 Real time Similar Human Image within 12 Hours and its corresponding hardware output

V.CONCLUSION & FUTURE SCOPE

In this paper an intelligent storage device has been proposed for minimizing the wastage of food as well as distribution of stored food among needy commoners. For this purpose fuzzy K-means classifier has been incorporated within the system for identifying and recognizing the object in an efficient fashion. Moreover, after identifying it has been demonstrated them text as well as speech mode. If human detected door of the intelligent system becomes open due to triggering pulse otherwise it has been closed. Thereafter door becomes open for next 10 ms and then it becomes closed. However door become closed for next 12 hours for the same human being who has already got food from this storage device. The performance of the proposed system can be enhanced in different way. Some intelligent computational algorithms can be incorporated for eliminating the redundant frames. Implementation of model using sophisticated hardware like raspberry pi could be acknowledged as one of the foremost possibilities in future.

Abstract - As Branch prediction is a performance improving technique adopted in modern processor architectures. Conventional prediction techniques have advantages such as power efficiency and speedy lookup, but with high miss-prediction rate. Neural network based and two level predictions are complex but offer improved accuracy. But disadvantage of these methods are higher power consumption, exponential increase in the complexity and time of execution ranging from 3 – 5 cycles. Optimized branch prediction should have least miss rate, lower power consumption and fewer complexes. It should use minimum resources also. In this paper the algorithm has been implemented for branch prediction which is particularly useful for superscalar or pipelined processors. With current branch prediction algorithms, the success rate of 99% can be achieved but not more than this as some times the prediction fails and whole pipe has to be flushed again. The method that has been currently implemented with increase in the hardware will always predict the branch correctly. The algorithm is very efficient in reducing time and power consumption while implementing code for processor architecture applications used in embedded systems.

Keywords : Branch prediction, hit rate, miss rate.

I. INTRODUCTION

Branches alter the normal flow of control in programs in unforeseen means that changes the normal fetch and operation of instructions. To bring back fetch operation to normal, large number of cycles till branch outcomes are known and target is detected. About 25% instructions are branch in general purpose processors. One of the easy solution to tackle these is to introduce bubbles and stalling the pipeline. Stalling pipeline increase time for execution of entire code. For higher throughput, in high performance microarchitectures, it is essential to have optimization in predicting branch instructions

Static branches are not difficult to forecast and in majority of systems, compilers offer good attention for such branches. Compilers find difficulty with branches whose outcome is found on run-time behavior. The branch outcomes have bimodal distribution and are not random. Dynamic use a prediction mechanism that adapts in runtime and takes the run-time state of the system in order to make the predictions [1]. Dynamic branch prediction techniques have very good accuracy but there exist few limitations.

The drive for advanced performance processors associated with the predictability of branch outcomes propose to use some prediction mechanism to know the outcome well prior the execution of branches. With very good prediction also, there are possibilities of miss prediction which also consume time as it takes for stalling the pipeline. Hence there is a need for smart branch predictors.

Branch prediction is an essential part of highly pipelined and superscalar processors. Its accuracy greatly impacts the efficiency of a processor, as a miss prediction causes fetching and execution of instructions which, in reality, are not needed by the program, and at the end need to be undone. To give a reasonable evaluation of the execution time of a program on a given target MPSoC, modeling branch prediction is required. The main difficulty with simulating branch prediction is to avoid slowing down the simulation, as it uses large tables to maintain per branch confidence state information and guess the branches outcome. Even a simple share [2] with a 16-bit long branch history requires a 216 entries wide counter table. With a memory wise perfectly optimized program, it represents 217 bit if the table contains 2 bit counters. Considering that entries are not accessed sequentially and that the tables are large, naïve modeling of branch predictors will result in an important number of cache misses and decrease simulation performance for any complex predictor. Branch predictors should then be simulated using a method taking memory constraints into account, i.e. the approximate model should be memory efficient while keeping reasonable accuracy.

II RELATED WORK

In a large parallel computing system, branch instructions can cause errors in a natural flow of instruction fetching, decoding and execution. This may cause delay, because the instruction delivering must generally wait until the actual branch outcome is known. The performance loss is great if the pipelining is deeper [2], [3].

To decrease delay, one can try to forecast the way that a branch instruction will take and begin fetching, decoding and delivering instructions before the branch decision is through. However, an incorrect branch prediction may lead to large delay as wrongly fetched instructions lodge useful functional units, like the ALU, registers and memory bus. Hence there is need for precise branch prediction policies.

Branch prediction policies used are static branch prediction which is implemented using software and dynamic branch prediction which uses hardware system

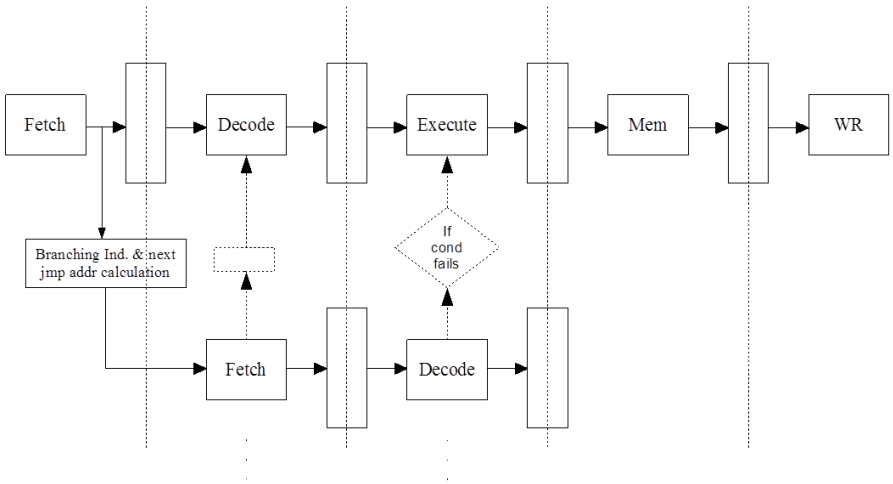

Fig. 1. Hardware for branch prediction in pipelined CPU

III. PROPOSED WORK

The algorithm that has been implemented for branch prediction is particularly useful for superscalar or pipelined processors. The problem is when branching happens, the whole pipe has to be flushed and again filled from the starting of the branched address. Even with current branch prediction algorithms, the success rate of 99% can be achieved but not more than this as some times the prediction fails and whole pipe has to be flushed again. The method that we have currently implemented with increase in the hardware will always predict the branch correctly. This is due to the fact that dedicated hardware is used to check whether the instruction which is fetched is a branching instruction or not [4].

The extra hardware used in our branch prediction is given in figure 1. As we can see from the figure, we will decode the opcode of the instruction for branching in the fetch stage of the pipeline only. This tells the hardware that there is a branch instruction and the address of the branching if the condition is true is also given by the branching instruction itself. For naming purpose, let us call the first pipeline or the original pipeline as pipe 1 and two hardware's for fetch and decode given in the second row of Figure 1 as pipe 2. So, whenever there is a branching instruction, both pipes will be filled by the data, pipe 1 with the consecutive instruction and the pipe 2 with instructions present in the branching address. When this happens, the CPU 1 will check the condition for branching at execution stage, pipe 2 will detect this and if the condition is false, the pipe 2 will flush its contents and the execution will continue regularly [5], [6]. But when the condition for branching turns out to be true, pipe 2 will detect this and pipe 1 will flush its contents. As the pipe 2 is filled with the instructions of the branching address, the contents of pipe 2 will be transferred to
the pipe 1 and the execution of the branching instructions happen. This avoids any stalling in the CPU [7], [8].

This method can be used generally for branching instructions like if-else, for loops etc. But extra and complicated hardware is required in case of 'case' statements and other branching instructions. This can also be used in assembly programming for instructions like BEQ, JMP etc.

IV. METHODOLOGY

The execution and the simulation of the algorithm were done in Linux environment with the help of POSIX Threads and POSIX Message Queues. We used the eclipse environment for the development of the code and the GDB debugger was used for debugging the program. The flow of the program is given in Figure 2.

Algorithm: From the Figure 2, there are two main threads created to simulate the two pipes given in previous section. Then these threads will control the pipeline stages of each pipe. The pipe 2 will have only two stages i.e. Fetch and decode stage. Whenever there is a branching instruction, pipe 2 will detect this and the branching address instructions will be loaded and this also goes through the pipelining along with the actual instructions that goes through the pipe 1[9], [10].

The data that is input this program is a text file which contains the sequence of instructions that needs to be read from the program. Depending on this sequence, the program will execute the instruction. If the sequence is continuous, then it has no branching, but if there are some numbers missing then it indicates that there is a branching instruction [11], [12].

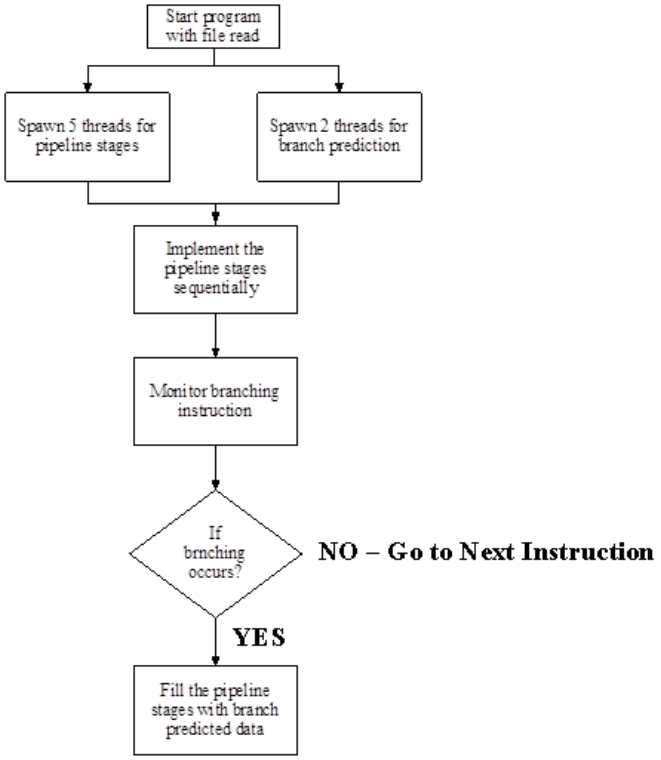

Fig. 2. Flowchart of Simulation

V. RESULTS

When the simulation was done with and without the pipe 2, we can see that there is flushing in pipe 1 if there is any branching instructions, this is not there if we enable the pipe 2 and run the simulation again, this indicates that there is no miss rate and there is 100% hit rate. This is done at the cost of extra hardware. from Figure 3.

In console output of simulation, if there are any branching instructions, the pipe 1 will be flushed and pipe 2 contents will be filled to the pipe 1 and the normal execution happens from then on. This can be used in sophisticated systems where cost of the hardware is not a problem.

VI. CONCLUSION

There are many aspects which will uphold this method. When the algorithm is implemented we can see that there is no miss prediction of branch, the probability of correct prediction is 1 that is 99%. This method can be employed in high performance systems where the cost of the hardware is manageable. The algorithm is very efficient in reducing time and power consumption while implementing code for signal and image processing applications.

As future scope, the work can be further extended with the detection of branch at decode stage itself and thus latency can be further reduced.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to Dr. Sathish Kumar M, Head of Department, ECE, MIT, Manipal for his continuous and constant guidance. Also, I would like to thank other Professors, lab technicians of ECE department for extending their support and help by providing technical help and ideas for the paper, without which It would not possible to come up with this kind of paper.

***Abstract*- As we all know the crisis of fossil fuels (conventional energy sources) occurs in future, which needs to find an optional choice for them. This makes us to move our attention and attraction to a new and known power generation resources. This new energy generation source become alternate and option for generation, transmission and consumption of conventional energy sources. Renewable energy sources take the place of traditional energy sources. Particularly in recent epoch and speedily developments in recent research work. In this paper we trade photovoltaic cells connected with grid and having solid oxide fuel cell (SOFC) as an alternative for grid interruption or fault condition for uphold the power flow supply. Here we instauration the P&O mppt technique with its specific control strategies along with three phase inverter for controlling DC-AC conversion with respect to grid and connected load. Reference frame theory and PLL methodology will also be provided to system for making it more reliable and advanced. An LC filter will also be used to dispose off distortion and harmonics in the system. This smart grid system will help in continuing the supply even grid is off or isolated for a while with the help of SOFC. This SOFC is used to support the system. All the results and waveforms obtained in this smart system will be explained in the paper. This paper makes the system more flexible and advanced.**

Keywords – PV module, boost converter, LC filter, controlled inverter, d-q reference frame, PLL, grid, circuit breaker, SOFC, smart grid

I. INTRODUCTION

In recent time where the competition between the power generation companies are at its peak. Every company needs to become more advanced and take their interest and attention towards non-conventional energy sources. This makes them seeing and fulfilling customers demand for high quality and clean supply. Every nation and its power generation company are extending their research work to seek new energy generation methodology [1]. This further makes them to switch to micro grid and advanced generation system. This system comprises PV modules connected with grid along with SOFC. Power generated by PV and SOFC are considered as clean energy as per the international law for standard power generation [2].

This advanced system eliminated the fault condition occur when grid is off because of some certain reason [3]. Turn off of grid makes the system and supply unstable which leads to create a system disturbance. So to get rid of such undesired situation we connect a SOFC to overcome this critical condition using specific control strategies [4]. Fig 1 of Extensive block diagram testifies the basic working phenomenon of the system.

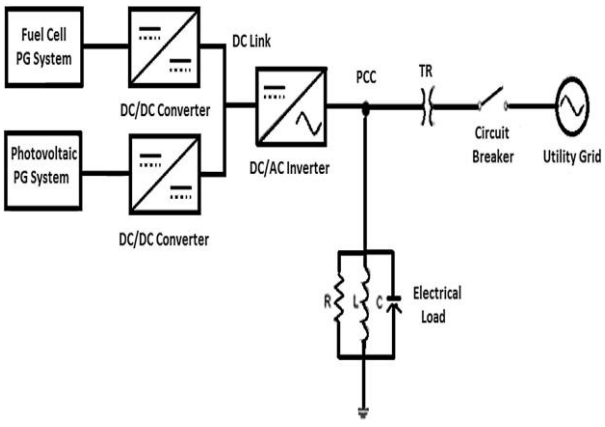

Fig 1 Advanced micro-grid model

For updated and new technology for power generation we believe in micro grids. The main purpose behind this paper is to make a advanced grid connected photovoltaic system which is fed by the SOFC in any fault condition. It works as a backup source of power.

II. GRID CONNECTED PV SYSTEM FOR POWER GENERATION

As we all know the bunch of solar cells called solar array or module. These solar cells basically comprise diode, two resistors and a current source. This PV module generated power is being converted by using a converter.

The introductory PV array model is display in fig.2. this model comprise a diode connected in parallel and two resistors connected in series and parallel combination namely Rs and Rsh with constant current source IL.

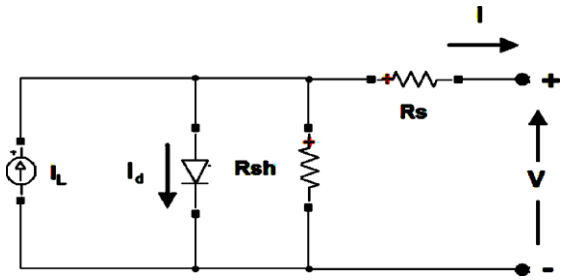

Fig 2 Single diode model of solar PV cell

The characterised equations of PV module and I-V characteristics are explained below.

$$I = I_{pv,CELL}\text{-}I_{Diode}=I_{PVcell}\text{–}I_{0,CELL}\left[exp\left(\frac{q*V}{\propto*K*T}\right)-1\right] \quad \text{- (1)}$$

Where

- $I_{pv,cell}$ the current generated by incident light.
- I_{Diode} is the Shockley diode equation.
- $I_{0,\,CELL}$ is the reverse saturation current or leakage current of the diode.
- [1.60217646 * 10e-19 Coulomb].
- k is the Boltzmann constant [1.3806503 * 10e-23J/K].
- T {K} is the temperature of the PN junction.
- $\propto$ Is the diode ideality constant whose value lies between 1 and 2 for monocrystalline silicon.

An three phase grid associated PV system is specified in fig 3. This model mainly consist a PV module connected with DC link which farther feed the generated supply to the inverter and to a LC filter to reduce harmonics.

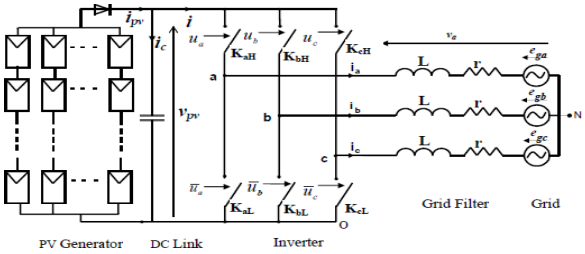

Fig 3 Three phase grid connected PV system.

III. P&O MPPT TECHNIQUE

The perturb & observe technique is broadly used MPPT technique for solar power generation. In this technique we obtain the optimum power output and voltage by comparing the present obtained power with the previously obtained power. When the maximum power is reached we got maximum power point. This technique is basically and practically a "trial and error" analytic approach. P&O algorithm works on sporadically increasing or decreasing the operating current with comparing the previous value. Fig 4 shows the flow chart of P&O technique and Fig 5 shows the P&O mppt algorithm and fig 6 shows the P&O mppt technique used with boost converter.

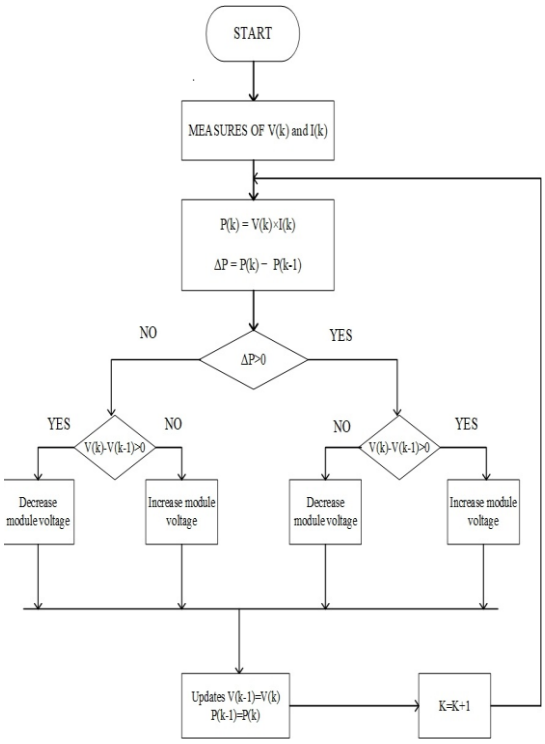

Fig 4 shows the flow chart of P&O technique

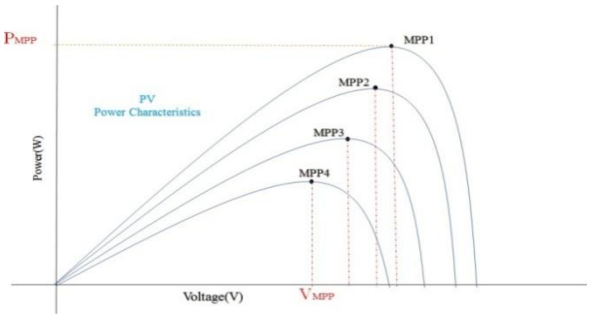

Fig 5 MPP at various Power and voltage

The flow chart of the algorithm is shown in fig 4 reads the value of voltage and current from the module by which the power is calculated. The Kth instant value is saved of current and voltage. The next value is measured again at (Kth+1) instant from which the power is calculated. The difference is calculated by both the instant is taken out. It is observed that on the right hand side voltage is almost constant and slop of the power voltage is negative (dP/dV<0)whereas in left side it is positive (dP/dV>0). The right side curve denotes the lower lower duty cycle near to zero and LHS for higher duty cycle nearly to unity. Depending on the sigh of dP and dV after subtracting dP(P(k+1)-P(k)) and dV(V(k+1)-V(k)) the algorithm decides whether to increase the duty cycle or to reduce it

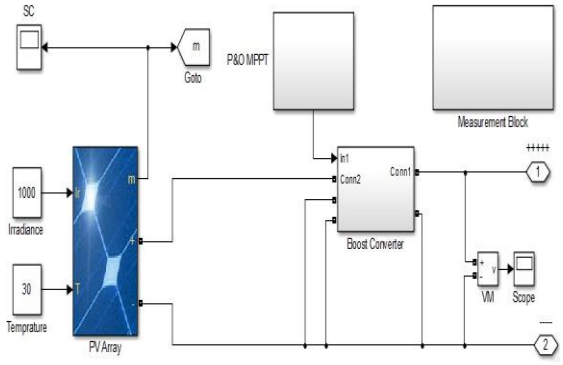

Fig 6 Simulation model of PV array with MPPT and boost converter

IV. Modelling of DC-DC boost converter-

The output voltage obtained by the PV panels is moderately low, so to step up this low level voltage output an DC-DC boost converter is requisite to employ. This converter matches the input voltage magnitude with the desired output voltage. This step up converter comprises a inductor, an diode and high frequency switch. The working phenomenon behind this converter is to manipulate the duty cycle of switch which stimulate the voltage change. Fig 7 shows the basic conventional diagram of DC-DC boost converter.

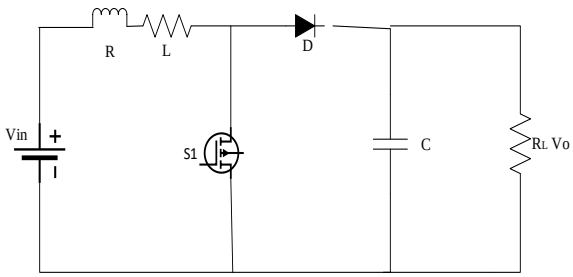

Fig 7 . DC-DC boost converter

Here we have some equations for DC-DC boost converter are specified below

$$D = 1 - \frac{V_{in}}{V_{out}} \quad - \quad (2)$$

$$L_{min} = \frac{(1-D)^2 \times D \times R}{2 \times f} \quad - \quad (3)$$

$$C_{nm} = \frac{D}{R \times F \times Vr} \quad - \quad (4)$$

Where, C_{min} : minimum capacitance ;

L_{NIn} : minimum inductance;

R : boost output resistance;

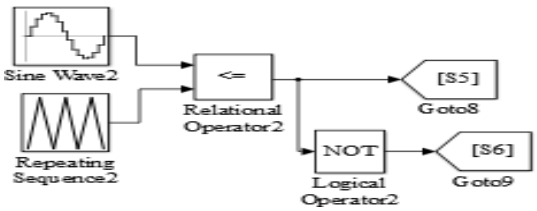
D : duty ratio;

f : switching frequency;

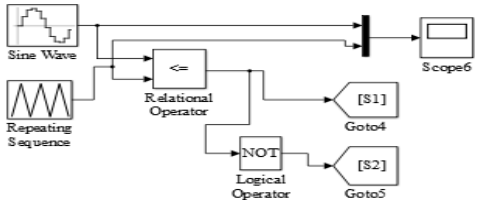
The continuous conduction mode for converter helps in calculating the inductance value. The inductor current IL flows continuously and never stumble to zero while the desired output voltage ripple is premise by output capacitance.

V. Implementation of Sine Pulse Width Modulation Technique

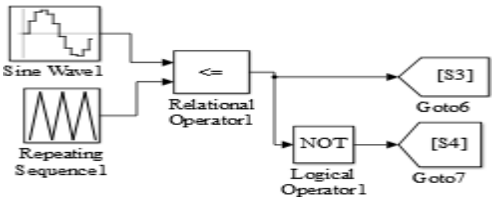
In all the phases, Pulses are generated by analogized the carrier wave with the reference wave and giving the required output which then provided to the switches



(a)



(b)



(c)

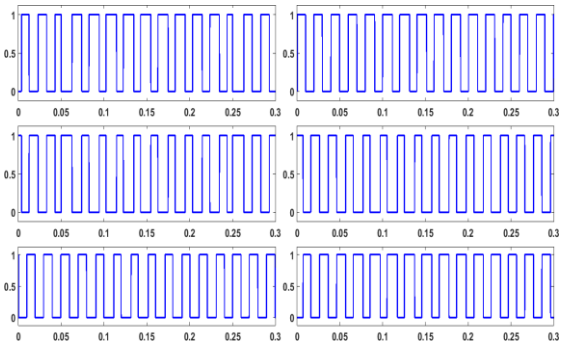


Fig 8. Pulse generated circuit and gate pulses for waveform.

VI. MODELING OF FUEL CELL (SOFC)

SOFC is an electrochemical cell that changes over the chemical energy into electrical energy. The fuel cell is basically differing from traditional batteries as they require a continuous supply of hydrogen and oxygen to corroborate the chemical reaction. This chemical reaction will help in delivering the seriatim DC power supply. Fuel cells have many advantages like better focal point, good and high productivity and better time response without emitting any toxin gases. Following equations will help in foresee the chemical reaction in fuel cell.

$$2H_2+O_2=H_2O \quad \text{- (5)}$$

$$H_2O^{=}=HO+2e^{-} \quad \text{- (6)}$$

$$O_2+4e^{-}=2O^{=} \quad \text{- (7)}$$

The fundamental simulink model for SOFC is shown in fig 9.

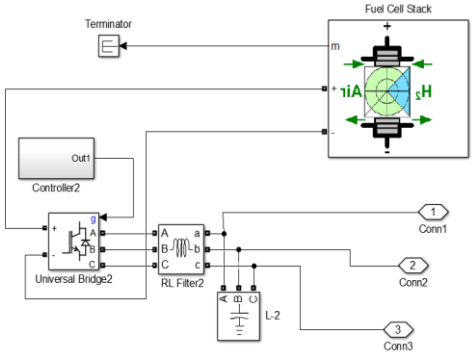

Fig. 9 SOFC subsystem model in matlab

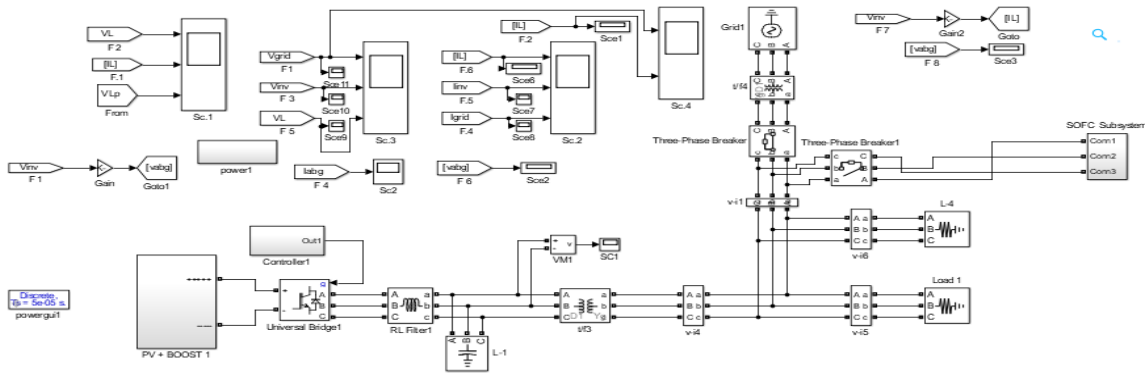

Fig.10 Simulink model of the system in matlab

VII. SIMULATION RESULTS

The simulation result of the above model shows the three phase current and voltage waveform after passing through a LC Filter. The LC filter parameter values are, L= .01 mH and C= 800 µF. Fig 11.1 to 11,3 shows the all possible waveforms.

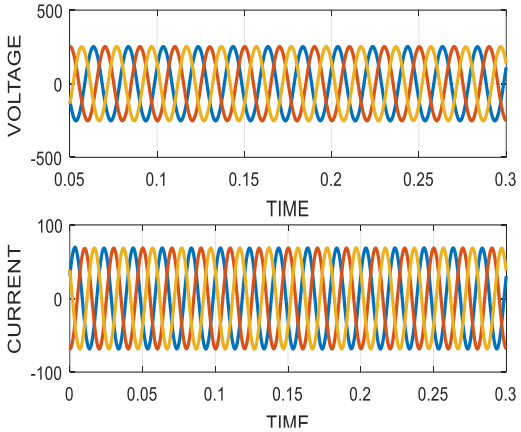

Fig 11.1 Show the three phase voltage waveform of the system when Grid is on.

Grid outage is considered here for specified time duration from 0.05sec., in this condition grid outage voltage, current and power are reduced to zero, so power, voltage and current are disturbed. Due to the condition of grid outage in PV connected system power supplied at loads becomes zero. The Voltage and current waveforms of inverter, grid, loads are shown below when grid is off

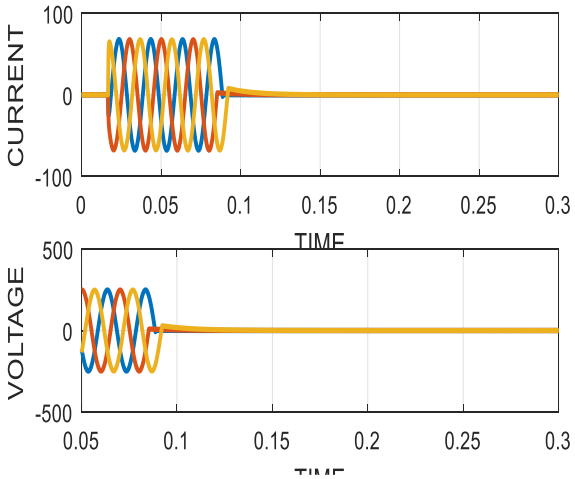

Fig 11.2 show the three phase voltage waveform of the system when Grid is off

Due to the presence of Grid outage all parametric quantities of the system are disturbed, now to resolve this problem we integrated an SOFC in system for specified time duration from 0.05 sec. The voltage and current waveform is shown below

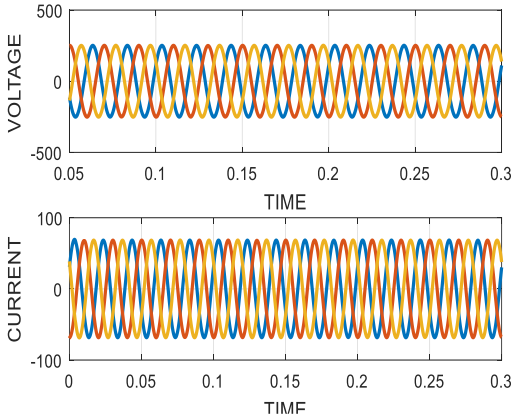

Fig 11.3 Show the three phase voltage waveform of the systemwhen connected with SOFC in it.

Conclusion

The performance of grid connected PV system is analyzed, in which grid connected PV system is compensated by the help of SOFC (solid oxide fuel cell) when grid outage occurs. As soon as there is any fault on the grid side the fuel cell gets switched on to compensate the losses and maintain the three phase output voltage and current. In this hybrid system the fuel cell can be replaced with DG set, wind generator or any other electrical source with the help of PLL technique to maintain the supply output constant. In this hybrid system we can use many energy sources in place of fuel cell like battery, biomass energy generation make this system more advanced . This updation in the sytem makes its usability much easier and reliable in any fault condition and I will place some more energy sources in the system in future.

Abstract- In this study, we describe the design and successful implementation of the smart healthcare monitoring device. This design helps to view the Electrocardiogram signal and heart beat count can measure at very low cost. The real time ECG signal is viewed on laptops and transmitted to mobile phone through Bluetooth with the help of android software. AD8232 is Electrocardiogram sensor which amplifies the signal extracted with the help of ECG electrode. This design helps in monitoring ECG of patients in remote area.

Keywords- Electrodes; AD8232 Sensor; Arduino controller; Bluetooth module.

I. INTRODUCTION

Medical expert systems are increasing day by day where one part is transferrable and smart healthcare nursing devices which can be used in everyday life. Medical applications have greater importance in this fast moving and competitive world. Any change in heart rate or rhythm, or variation in the morphological ECG signal pattern, is a symptom of an arrhythmia, which could be identified by the analysis of stored data of ECG [1].

ECG monitoring system plays an important role in determining cardiac diseases. There are number researchers working on to archive long term ECG monitoring system. Various types of ECG measuring systems have been introduced. The ECG monitoring system that are used currently in hospitals are big and heavy so it is less portable and also the measuring system have 12 electrodes where 2 on anklet 2 on wrist and other electrodes upon chest of the body. These electrodes are gel electrodes which causes allergy and infection in case of regular use so it is difficult to do long term measurement. These devices are very expensive and home monitoring is not possible so the aged people who need to be tested their heart rate frequently is very difficult in this high population, and it is a main problem in hospitals to check the ECG of all the patients. To provide home monitoring system smart technology place an important role where the result of ECG data collected is analyzed and shared with doctor and the family members.

There are various applications which provide multiple health related data such as ECG, finger photoplethysmography, and blood pressure plethysmography [2]. There are several signal amplification filter methods used in order to get the proper waveform. The delayed signal error is normalized using LMS in order to achieve high speed and low latency and SVM classifier method is used to remove noise [3]. The analysis of signal depends on the P, Q, R and S point in the ECG signal waveform the detection of these point has various algorithm and these points are implemented on IOS based smart phone to serve for remote area people [4]. The doctor is able to axis the data from the cloud and provide the detail analysis of various data collected [5]. The removing of noise is so performed by using FIR and FFT filters [6]. The ECG monitoring system can also be designed as the remoteness as a part of their private home network moderately than being more dependable home control system [7]. There are so many devices which detects the ECG signal and these electrodes are used in textiles, seat belts, wrist watch and mobile case [8]. The signal is controlled by controller and sent to the cloud in this survey they have used MSP430 single chip to control the signal [9]. The original ECG signal is compared with the various filter output and also, they have calculated the power spectral density and signal to noise ratio before and after filtering [10]. There are many sensors available in the market to detect the ECG signal like wireless sensors, MEMS and Nano technology is developing different type of portable wireless sensors for the better life [11]. The command used helps in sending and receiving the data from cloud this process is obtained by HTTP and MQTT protocols [12]. Since the smart phone are limited in power consumption and are very easily portable the heart beat data is transmitted to the smart phone, but it requires great

skills to reach out to provide the mobile application to all OS.

In introduction, The review of ECG system design related work is discussed. In Section II the detailed system architecture was discussed along with its application. Section III introduces steps to read ECG data through electrode for analysis and mobile application design. The last section concludes the project work with future scope.

II. SYSTEM ARCHITECTURE

The ECG monitoring system architecture is exemplified in Figure 1, primarily divided into four parts they are: 1. Sensor module, 2. Controller module, 3. Bluetooth module and 4. Android mobile**.**

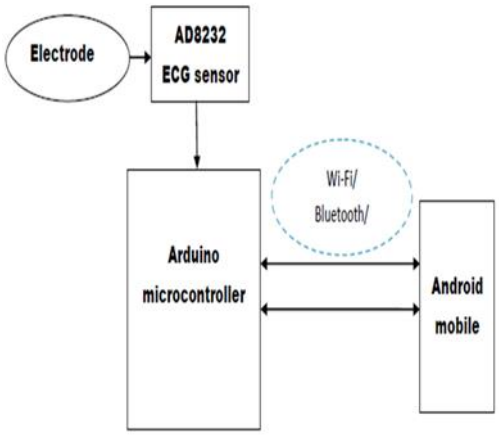

Figure 1: Block diagram of the proposed system

The ECG signal is obtained by placing electrodes on the body part these signals are amplified by using AD8232 sensor which utilize low power and reduce the noise. The output signal of the sensor is given to analog pin of the Arduino Uno board. The threshold level of the heart beat is fixed which will be compared with the obtained signal and thus this data is sent to Android mobile via Bluetooth. Based on the threshold level the real time-tested ECG signal display the result on the mobile with the heartbeat.

A. Sensor module:

The sensor module has two part.

1) Electrodes:

The electrodes used in this project is disposable electrodes which offers fast, easy, and more hygienic which is alternative to reusable electrodes or wet electrodes. These electrodes are pre gelled and these are called dry electrodes which will be good for patient skin. Instead of using 12 lead electrode system and keeping the bulk device its been used 3 lead electrode system devices as shown in Figure 2, where the electrodes are placed on the right-hand wrist (R-Red), left-hand wrist (G-Green) and the right-leg ankle (Y-Yellow).

Figure 2: Dry electrodes with color code pins.

2) AD8232 ECG Sensor:

The heart rate electrical movement is measured by this small chip called AD8232[12]. Figure 3 shows sensor module which is non-harmful and it measure the heart rate and gives the signal which can be directly connected to any controller like MSP430, Arduino, Raspberry-pi. This sensor is designed to extract the signal even when the electrodes are poorly in connection with the body. The extracted signal is then amplified. This design helps to obtain the output signal easily from an embedded controllerdevice or from an analog-to-digital converter (ADC) ultralow power device.

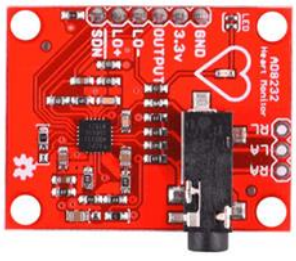

Figure 3: AD8232 Sensor.

The AD8232 is a cohesive front end for signal acclimatizing of heart biopotentials and for heart rate monitoring. It consists of a particular instrumentation amplifier, a right leg drive amplifier, an operational amplifier and a mid-supply reference buffer. In addition, the AD8232 contains leads off recognition circuitry and an

automatic fast reinstate circuit that brings back the signal soon after leads are reconnected. The AD8232 comprises a specialized instrumentation amplifier that amplifies the ECG signal while refusing the electrode half-cell latent on the same stage. This indirect present feedback architecture is possible to achieve by reducing size and power compared with traditional implementations. The below Figure 4 shows pin configuration of AD8232 sensor.

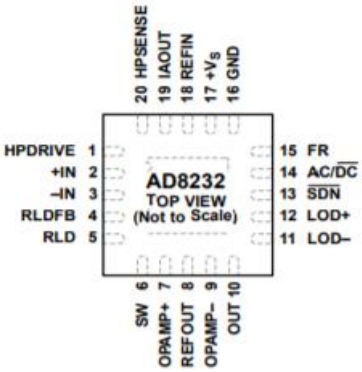

Figure 4: Pin configuration of AD8232 sensor.

B. Controller module:

Based on the Microchip ATmega328P microcontroller Arduino UNO is an open-source microcontroller board which is shown in Figure 5. This board have 14 digital pin and 6 analog pin this controller is programed using Arduino software. This board operates at 5V and its capable of 7V-20V Figure 6 shows the architecture view of arduino uno controller. The Atmel ATmega328 microcontroller is as shown in Figure 7 which is 8bit controller with 32KB program flash memory and it provides 20MHz max clock frequency. The programmable code is written in c.

Figure 5: Arduino Uno controller module.

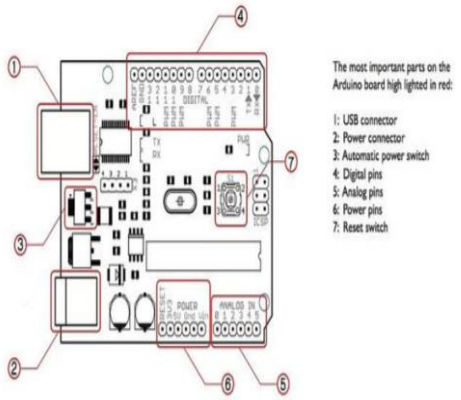

Figure 6: Pin configuration of controller

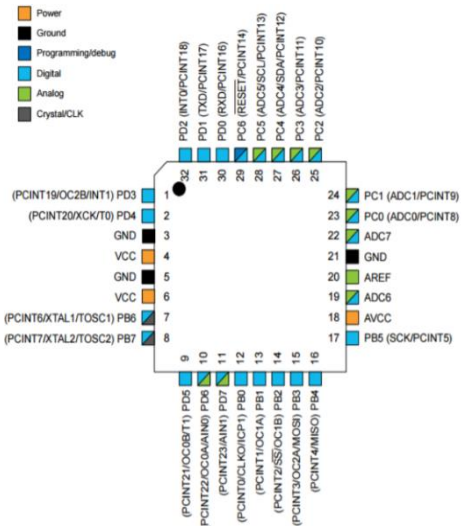

Figure 7: ATmega328 microcontroller coniguration

C. Bluetooth module:

The Transparent serial wireless connection is performed by device HC-05. This module can be used as both master and slave configuration. It has 6 pins and operates at 3.3V. The slave baud rate is fixed to 9600.

D. Android Mobile:

The android code is added to mobile by changing the setting in developers. The run code creates an application. When the Bluetooth of mobile is paired with HC-05 Bluetooth the real time data is sent from controller to mobile during on and display the ECG heart beat and its condition.

III. DESIGN OF MOBILE APPLICATION

This project has two part in software where first part is to control the ECG signal extracted by sensor and second part is sending data to mobile.

Intial the ECG signal obtained from AD8232 sensor is convereted into digital data using Ardunio board. The voltage converted serial data obtained via USB is recived and dispalyed on the monitor. The C program written to filter noise without losing the important data of ECG waveform. The Serial plotter software used to plot the ECG waveform on monitor as shown in Figure 8.

Android application is developed using Java programming language which has built in libraries for Bluetooth connectivity. The filtered signal from Arduino is compared with the threshold value and the condition of the patient is displayed. Figure 9 shows the application before connecting with the Bluetooth . Figure 10 shows the mobile application display window along with the patient result.

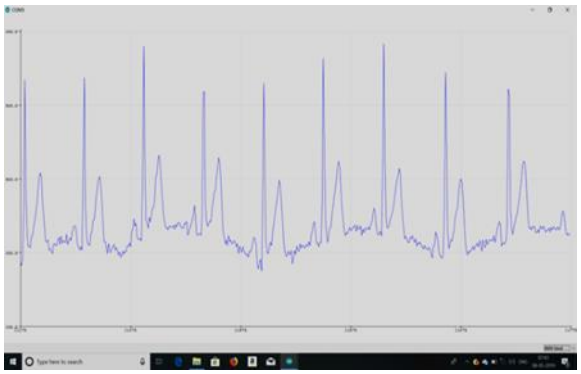

Figure 8: Screenshots of ECG signal

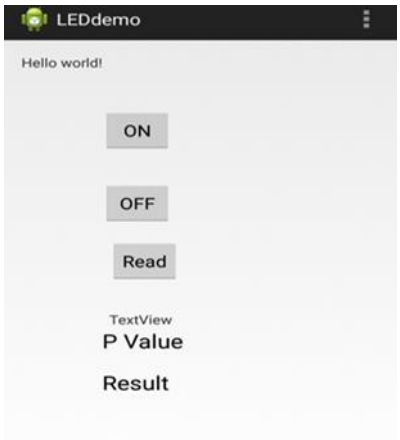

Figure 9: Application developed for android mobile

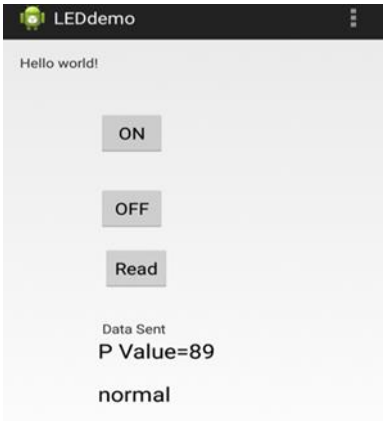

Figure 10: Heartbeat and its condition displayed in android mobile

The working step to monitor ECG signal throgh App is as follow:

Step 1: Placing electrode on the wrist and the anclet based on the color code.

Step 2: Ecg signal acquired throgh electrode is read by sensor and furter processed by controller.

Step 3: Establish connection between the mobile phone and HC-05.

Step 4: Run the code to analyze the signal.

Step 5: ECG signal is displayed with the help of arduino software.

Step 6: Simultaniously the heart rate displayed in mobile application.

IV. CONCLUSION

In this project, we designed and implemented medical related smart technology for remote area and home use which monitors the ECG signal and displays the heart beat in real time use. Three wearable monitoring electrode provides the satisfactory accuracy in real time. These data are filtered and sent to the mobile application. Further studies is on the obtaining the time between R-R interval and also improving the accuracy level of the signal to analyze the various cardiac problems using c code in Arduino software. The future scope of this project is to develop an efficient algorithm for long term analysis and Wifi technology can be used to enhance the data transmission of the signal.

ACKNOWLEDGMENT

I would like to acknowledge the guidance, and opinion given by Mrs. Anitha S Prasad, Assistant professor, Department of E&C, JSS Science and Technology University, Mysuru and Technology for helping as per our need.

***Abstract*-This paper illustrates a (100-120) GHz Low Noise Amplifier (LNA) designed for wideband imaging in millimeter (mm) - wave applications. The design has been made in 65 nm CMOS technology. The proposed amplifier model uses Common Source (CS) configuration in cascaded with cascode topology. The optimum transistor geometries are used to obtain large power gain (S_{21}) and minimum Noise Figure (NF_{min}). The inductive peaking technique is utilized to achieve flat gain and bandwidth extension. The designed amplifier provides a 15 dB gain at 100 GHz and 20 GHz 3 dB bandwidth with input and output matching less than -10 dB and -7 dB respectively. The NF of 4.6 dB at 100 GHz and less than 6 dB are inferred across the total band. The amplifier attains a 1 dB compression point (P1dB) at -12 dBm. The designed LNA achieves -5 dBm IIP3 with 10 mW of power consumption from a supply of 1.2 V.**

Index Terms— CMOS: LNA; Wideband-Imaging; Cascode; mm-wave.

I. INTRODUCTION

Traditionally, the millimeter-wave (mm-wave) circuits were implemented using III/V technologies such as InP (Indium Phosphide) and GaAs (Gallium Arsenide). These technologies have superior execution characteristics such as good electron mobility, less threshold voltage and semiconductor material for substrate to implement mm-wave circuits [1-4]. As of late CMOS innovation is favored for its cost viability, and robustness. The transit frequency (f_t) and maximum oscillation frequency (f_{max}) of CMOS is exceeding 200 GHz [5-8]. At mm-wave frequencies there are some disadvantages lower break down voltage, lower available gain and noise performances [6]. The active and passive device modelling is complicated because of conductive substrate used in CMOS which adds parasitic losses. The metal layers of the CMOS are shrink and in close proximity of the conductive substrate [7].The matching elements, resonators and interconnects quality factor are lower than the insulating substrates.

The capacitive coupling increases with substrate density which reduces the passive devices self-resonance frequency. The careful design needs incorporation of losses and parasitic capacitance effects in active devices and passive devices as the transistors are operating in the limited frequency range. Section II discusses the literature review of newly published papers and section III focuses on the design methodology for circuit development. Section IV describes the circuit design and geometries of the LNA. The results and discussions are presented in section V. Section VI contains conclusion.

II. RELATED WORK

The various LNA designs in W-Band have been presented in recent days. Today, LNA front-ends are mainly implemented using InP MMIC [1], InP HEMT [2-4], SiGe [5], FDSOI CMOS [6] and CMOS [7-8] technology.

R. Raja et al. [1] developed a three-stage single-ended LNA in 0.08 µm InP MMIC technology. The width of transistors in each stage is 30 µm. The LNA shows 24 dB of gain and less than 5.5 dB Noise Figure (NF) at 183 GHz. Alexis Zamora et al., [2] presented broad-band 170-280 GHz two-stage single ended LNA based on high frequency InP HEMT technology using coplanar wave guide-MMIC. The gain and NF of LNA are reported to be greater than 10 dB and lower than 7 dB respectively. The NF is reported to less than 6 dB and it covers (190-240) GHz frequency. Pekka Kangaslahti et al., [3] demonstrated a three stage LNA operating at 180 GHz in InP HEMT MMIC technology. The design consists of two-finger HEMT with gate width of 15 µm in each stage, total 30 µm gate periphery per device. The results of the simulated design, a flat gain of 15 dB from 60 GHz to 200 GHz and 2.5 dB of NF is reported in (100-180) GHz frequency range. The S_{11} is less than -5 dB and S_{22} less than -10 dB in (165-183) GHz. Zheng Wang et al., [6] presented a transceiver in 32 nm SOI CMOS process (210 GHz). The design is implemented with OOK modulation. The LNA comprises of seven stage Common Source (CS) differential topology. The amplifier supports a peak gain of 18 dB with 15 GHz of 3-dB bandwidth and S_{11} of -8 dB. S. T Nicolson et al., [8] presented a 140 GHz CMOS receiver with antenna (on-die) in 65 nm. The receiver consumes 100 mW with a supply voltage of 1.2 V. The LNA consists of six stages with CS topology, exhibits 8 dB of gain at 140 GHz with 10 GHz bandwidth and 63 mW of power consumption from a supply of 1.2 V.

The popular topologies used in LNA design are CS and cascode [11]. However, when frequencies near to f_t/f_{MAX}, the coscode device gain decreases almost close to CS and Common

Gate (CG) devices noise contribution is marginally higher side compare to CS device (0.5 dB -1 dB higher). By considering the above discussions, in majority of LNA designs, an inductor (series or shunt) is placed [12] between the CG and the CS stages. This helps for matching and solves performance degradation issues with respect to gain and NF.

III. LNA Design Methodology

The LNA design involves cascade of three distinct blocks such as the matching networks of input side, output side and gain stage as shown in Fig. 1. In this figure, the reflection coefficient is denoted by Γ. The output side of the Input Matching Network (IMN) quantity is denoted by index S and input side of the Output Matching network (OMN) is mentioned by subscript L. The gain stage input and output matching values are denoted by IN and OUT respectively.

The reflection coefficients of the LNA are Γ_a and Γ_b. The 50 Ω characteristic impedance is Z_O. The behavior of the amplification stage is characterized by its scattering parameters [13].

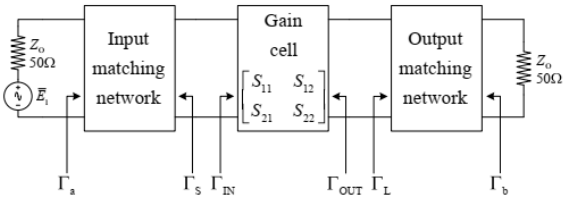

Fig. 1. Basic Amplifier design block

The major trade-offs in designing LNAs are gain, NF and linearity. The matching networks and gain performance are dependent on each other. The two port network theory is used for designing the LNA. To obtain optimum performance of the LNA, the matching networks are the crucial part of the circuit in the design. To improve the available power gain (G_A), the IMN should be modelled.

$$G_A = \frac{1-|\Gamma_S|^2}{|1-S_{11}.\Gamma_S|^2.}.|S_{21}|^2.\frac{1}{1-|\Gamma_{OUT}|^2} \quad (1)$$

and the minimize noise is

$$F = NF_{min} + \frac{4.r_n.|\Gamma_S-\Gamma_{OPT}|^2}{(1-|\Gamma_S|^2).|1+\Gamma_S|^2} \quad (2)$$

In (2), the optimum source reflection coefficient is denoted by Γ_{OPT} and noise resistance is r_n (r_n= R_n/Z_O) and NF_{min} respectively. These three parameters are the noise behavior characteristics of the linear two port network. Since the minimum noise is the main design criteria, Γ_S must be equal to Γ_{OPT}, and to enhance the G_A, Γ_S must be identical to the complex conjugate of the Γ_{IN} (Γ^*_{IN}), where Γ_{IN} is defined by equation (3).

$$\Gamma_{IN} = S_{11} + \frac{S_{12}.S_{21}.\Gamma_L}{1-S_{22}.\Gamma_L} \quad (3)$$

The Γ_{OPT} and Γ^*_{IN} are very distinct in nature, the performance of gain is improved and noise is worsened, and vice-versa. There is a trade-off for designing an IMN between noise and gain performance. The primary objective of the OMN is to boost the operating power gain (G_P)

$$G_P = \frac{1}{1-|\Gamma_{IN}|^2}.|S_{21}|^2.\frac{1-|\Gamma_L|^2}{|1-S_{22}.\Gamma_L|^2} \quad (4)$$

The Γ_L must be equivalent to complex conjugate of the Γ_{OUT} (Γ^*_{OUT}), being Γ_{OUT} given by equation (5).

$$\Gamma_{OUT} = S_{22} + \frac{S_{12}.S_{21}.\Gamma_S}{1-S_{11}.\Gamma_S} \quad (5)$$

The matching networks play an important role to attenuate the noise and enhance the power gain of the LNA which ensure the circuit should be precisely stable. The stability factor (K) is defined in (6)

$$K = \frac{1+|\Delta|^2-|S_{11}|^2-|S_{12}|^2}{2|S_{12}||S_{21}|} > 1 \quad (6)$$

$$\Delta = |S_{11}|.|S_{22}| - |S_{12}|.|S_{21}| < 1 \quad (7)$$

The other two important performance parameters are input and output VSWRs and these parameters are relatively connected to the IMN and OMN. The IMN and OMN are lossless, the conditions to accomplish Γ_a= 0 and Γ_b= 0 are Γ_S= Γ^*_{IN} and Γ_L=Γ^*_{OUT}, respectively. These conditions help to maximize G_A and G_P. The Γ_S=Γ^*_{IN} usually conflicts with the NF_{min} condition at the input side. If the gain stage could be viewed unilateral (S_{12} = 0) the structure of the IMN and OMN is rearranged since the two systems are autonomous of one another. The unilateral condition is practically difficult to accomplish at mm-wave frequencies. The challenging task is to design a matching network for mm-wave frequencies.

The gain stage should be modelled in order to improve the gain and to limit the NF which is satisfying the supply conditions. Inductors are utilized to model IMN and OMN in CMOS process have moderate quality factors (10 to 25), the effect of NF could be exceptionally high. The gain stage should be the most unilateral, possible to achieve the device is unconditionally stable and to minimize the matching networks design complexity.

IV. Circuit Design

Fig. 2 shows the proposed LNA design for wideband support up to (100-120) GHz. The first stage (CS) of the amplifier is designed to minimize the noise level. In this stage, cascode topology will not prefer because of poor noise performance. There are a few choices to defeat this issue such as to minimize the junction capacitance [6], [10] and to use of single transistor design in the early stage to lower the noise produced by the cascade amplifier. The gate resistance (R_G) of the transistor has a large impact on the noise performance. The 100 Ω resistances were used in bias lines. The stability issue at first stage due to poor reverse isolation of a CS transistor is resolved by using a stabilizing resistor (R_C) of 20 Ω between two stages. By placing this resistor the gain diminishes by 2 dB and its impact on overall NF performance is practically immaterial and increases the NF by the value from 0.3 dB to 0.5 dB. The first stage of CS transistor (M_1) m is set to 8 µm. The

cascode circuit is established by the M_2 and M_3 NMOS transistors, both with a length of 65 nm. The widths of M_2 and M_3 are 8 µm respectively. These values were determined using an optimization process based on simulations that use Predictive Technology Models (PTM) [14]. The peaking inductors L_{D1} to L_{D4} are used to enhance the power gain. Both the common source transistors M_1 and M_3 are biased through L_{G1} and L_{G2} respectively with 0.7 V to attain high gain and low NF.

At low frequencies, active devices perform unconditionally stable operation where capacitors acts as an open circuit and at mm-wave frequencies where the substrate losses and parasitic effects are on higher side. The CS transistor offers poor reverse isolation at high frequencies. The first stage of the design suffers stability problem, for avoiding this a resistor is placed between CS and cascode. By adding this resistor, the gain decrease slightly and its impacts on noise is negligible.

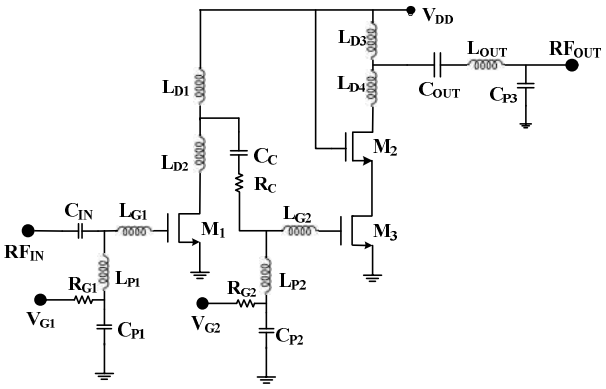

Fig. 2 (100-120) GHz LNA schematic

Cascode is preferred to improve the gain and better reverse isolation in the second stage which is not as crucial for the overall NF. The simultaneous noise and input matching are accomplished by the first stage and the gain performance in a wide bandwidth is obtained by subsequent stages. Table I presents the passive component values of the mm-wave LNA.

V. RESULTS AND DISCUSSIONS

The LNA design and its performance evaluation were carried out through Advanced Design System (ADS) simulation using 65 nm CMOS from PTM. This section discusses performances of gain, noise, reflection coefficients, linearity and stability. The biasing voltage of the transistors is set to 0.7 V. The W-band LNA gain and NF performance is represented in Fig. 3 and has a central operation frequency of (100-120) GHz. At this frequency the LNA gain is 15 dB and NF of 4.56 dB. The gain is larger than 14 dB and NF is smaller than 6.3 dB from 92 GHz to 123 GHz.

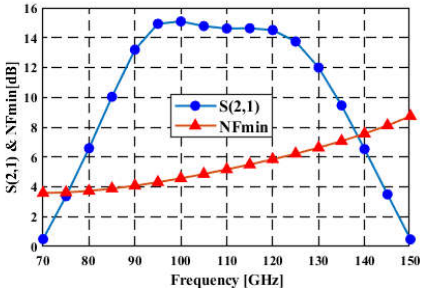

Fig 3. S_{21} and NF of the proposed W-Band LNA

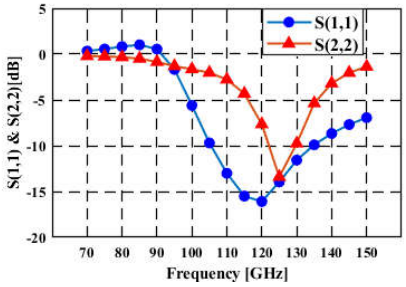

Fig 4. S_{11} and S_{22} simulation results

The proposed LNA matching results are shown in Fig. 4. The input matching S-parameter (S_{11}) is less the -10 dB over the band of interest (106-134) GHz. The minimum S_{11} is reported to -16 dB at 118 GHz. The S_{22} is smaller than -10 dB in the range of frequency (122-130) GHz. The 1dB compression point of the designed LNA is -12 dBm shown in Fig. 5. Fig. 6 depicts the IIP3 and the OIP3 which are-5 dBm and -4 dBm respectively.

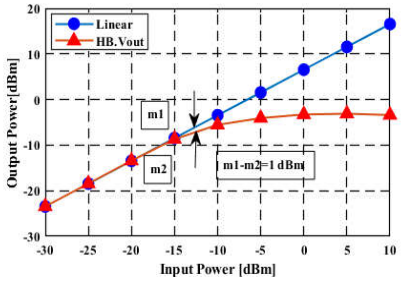

Fig. 5. P1dB simulation result

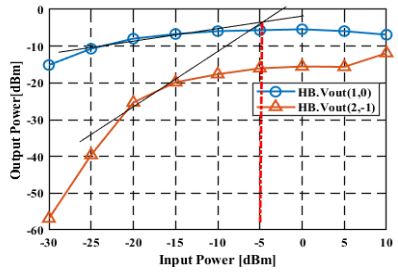

Fig. 6. Simulation result of IIP3 at 100 GHz

The circuit is unconditionally stable in the entire frequency band by taking out the possibility of instability due to noise, might be available in the circuit during power on condition. This is denoted by stability factor (K) and proposed design stability factor is shown in Fig. 7.

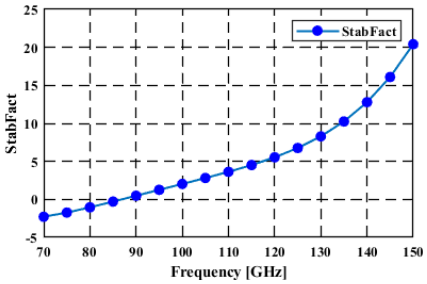

Fig. 7. Stability Factor (K) of the LNA

The performance summary with recently reported cascode mm-wave LNAs is presented in Table II. The presented LNA has good gain, noise and matching performance. The P1dB and IIP3 (linearity) is satisfactory for wireless imaging applications which is achieved with a supply voltage of 1.2 V.

VI. CONCLUSION

A W-Band two stage LNA has been designed and simulated using CS configuration in cascaded with cascode topology. The simultaneous noise and input matching are accomplished by the first stage. The high gain performance in a wide bandwidth is achieved by the subsequent stages. The CMOS LNA achieves a 15 dB of peak gain at 96 GHz along with 3-dB bandwidth of 95-120 GHz. The NF is less than 6 dB reported in the entire W-Band frequency. The IIP3 and P1dB are -5 dBm and -12 dBm respectively. The unconditional stability is achieved from 92 GHz onwards. The proposed design has appreciable gain, NF and good matching performance. Hence the presented LNA is well suitable for 100-120 GHz W-Band imaging applications.

***Abstract* — Segmentation of myocardial contours serves a prerequisite for viability assessment of myocardium which is essential for patient's diagnosis and treatment plan. However, segmenting the myocardial contours more precisely is quite a challenging task. This paper presents an automated segmentation technique for detection of myocardial contours in multiple cardiac MRI frames. Initially, a geometrical template is initialized on each MRI frame using the co-relation technique in order to locate the myocardium region. Later, curved multi-planar reconstruction (curved MPR) image is constructed to detect the epicardial and endocardial edge contours. The detected edges are smoothened using Savitzky Golay filter to obtain final segmentation result. Automated segmentation technique is tested on 12 MRI frames and accuracy is validated on three frames with respect to manually traced endo-epicardial boundaries.**

Keywords – Segmentation, Viability assessment, Cardiac-MRI, Myocardial contours, Curved MPR.

I. INTRODUCTION

Myocardium is a muscular tissue of the heart which consists of striated cardio-muscular fibers that allow heart to contract spontaneously. It is enclosed by two layers with outer layer as epicardium, inner layer as endocardium and the blood is supplied through the coronary circulation. The main function of myocardium is stimulating the heart contractions which are responsible for producing heartbeat. Sample image of myocardium in cardiac MRI is as shown in Figure 1.

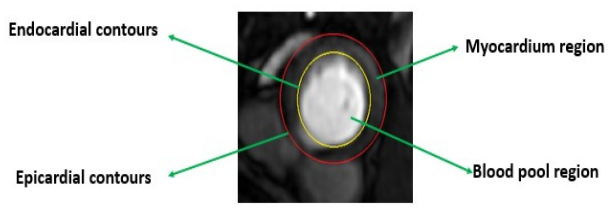

Figure 1: Sample Cardiac MR Image representing myocardium.

In the recent years, there is increase in recognition of cardiac diseases, in particular, myocardial fibrosis. When Myocardial infarction (normally referred as heart attack) occur, there is decrease in blood flow to some portions of the heart that causes the cardiac cells to get damaged. As a result, the damaged cells are replaced by the fibrotic scar or tissue (fibrosis). This remodels the surrounding myocardium and leads to cardiac dysfunctioning. This process is relatively progressive and results in narrowing of ventricular cavities.

Endo-myocardial fibrosis is one such that occurs in inner lining of endocardium where the healthy tissues are replaced by inelastic, thick fibrosis tissues. If the fibrosis is pre-dominant in the left ventricle, then blood flow is reduced from the right portion and causes regurgitation (back-flow) of blood. Also, it may result in left ventricular enlargement, cardiomyopathy, atrial fibrillation etc.

Over various range of imaging modalities, cardio vascular magnetic resonance also referred as Cardiac MR Imaging is popularly used by radiologists for diagnosis rather than CT scans, PETs and ultrasonography imaging. Cardiac MRI provides definite anatomical structure of the heart, detailed information about nature of cardiac disease which helps the doctor to decide about the treatment plan. It's also possible to visualize non-viable, ischemic areas along with the normal tissues with high resolution, by using late-enhanced cardiac MR (LE-CMR) imaging.

Segmentation of myocardium is essential for its viability assessment which is important in patient's diagnosis and treatment planning. This ensures whether revascularization process may benefit the patient. Segmenting myocardium a priory helps to quantify the amount of fibrosis present in it. Proposed segmented result can be used as a template and when superimposed on LE-CMR image, limited search of fibrosis can be done within the template region. Therefore, a prior knowledge of myocardium helps in localization of fibrosis in small region, thereby, improving the accuracy significantly.

In order to locate non-viable tissues in the myocardium, first delineation of endocardial and epicardial contours

should be done. However, segmenting epi-endocardial contours more precisely is quite a challenging task. Manual delineation of contours in the images is intensive procedure and also time-consuming. Therefore, automated or semi-automated algorithms are desired for the purpose. Several related approaches to segment the myocardial contours has been mentioned in the subsequent literature survey.

This paper is organized as follows –
Related work is discussed in section II, automatic myocardium segmentation technique is explained in section III, segmented results are discussed in section IV and concluded in section V.

II. RELATED WORK

In [1], an automated technique is proposed to segment myocardium in LE- CMR images. In every slice of LE-CMR volume, template is deformed such that it fits the myocardial contours. 3D mesh which represents the left ventricle and myocardium thickness is created by using cine MR sequence that provides prior information about the left ventricle. Later it is registered onto the obtained contours to produce the final segmentation.

In [2], an automated technique is proposed to segment left ventricle in 2D LGE-MRI. Circular Hough transforms method is used to detect left ventricle, blood pool region is approximated using morphological active contours method. Later epicardial and endocardial contours are refined using scar and edge information.

In [3], an automated method is proposed to identify microvascular obstruction in LE-CMRI. Initially, the epi-endocardial contours along with scar region is traced manually. Adaptive threshold value is chosen based on normal and scar tissues information and MO regions are identified as the region of pixels with less signal intensity than threshold value. In [4], Fuzzy soft thresholding algorithm is used to identify fibrosis tissues in MR images. First, ROI is defined where the presence of fibrosis is suspected. Image resolution is increased using Interpolation technique. Two classes as (foreground and background) are defined to segment the tissues, where foreground area corresponds to myocardial fibrosis and background represents other tissues.

In [5], fibrosis in left ventricle is detected from delayed gadolinium enhanced images using kernel dictionary learning based clustering. Initially, dictionary is created with two cluster samples i.e. (LGE and non-LGE). Sparse coefficients of input data are used to train K-NN classifier obtained from kernel-based DL approach. Fibrosis is detected in the region between epi-and- endo cardial contours. In [6], myocardial scar is extracted from 3D whole-heart cardiac LE-MRI using max flow-based algorithm. In [7], a 3D visualization tool is developed for detection of left atrial fibrosis from DE-MR images and is compared with EAM.

III. PROPOSED METHODOLOGY

Our proposed automated segmentation technique to detect myocardial contours is described in Figure 2. Initially, Laplacian of Gaussian kernel is modeled as geometrical template and registered on the input MR image using the Co-relation technique. As a result, approximate region of myocardium region is identified with points (x_c, y_c), where (x_c, y_c) are the center points of located myocardium region. Next, the curved multi-planar reconstruction image is constructed using the myocardial center points in order to detect the endo-epicardial boundaries. An edge detector is applied to detect endocardial boundary points initially and later epicardial boundary points are detected. Finally, endo-epi edges are optimized as a smooth curve using "Savitzky Golay Filter" to produce the final segmentation result.

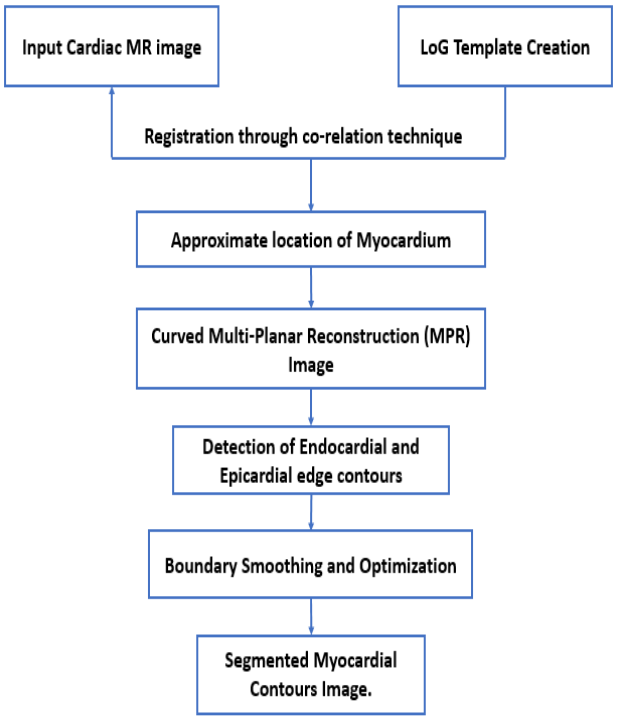

Figure 2: Segmentation Workflow

A. TEMPLATE CREATION

Myocardium is identified robustly as dark, circular annular shape. Hence, a radially symmetric Laplacian of Gaussian kernel with diameter corresponding to the approximate diameter of myocardium is modeled as dark ring. This kernel is correlated with the input MR image.

Kernel's radial profile is defined as follows -

$$f_\rho(r) = \Delta\left(\frac{1}{\sqrt{2\pi\sigma^2}}\, e^{\frac{-(r-\rho)^2}{2\sigma^2}}\right)$$

Depending upon the approximate size and thickness of myocardium, the values of ρ and σ are chosen: where ρ is the radius of the ring whose width corresponds to standard deviation σ and Δ is the Laplacian operator.

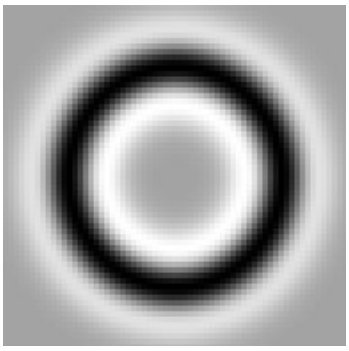

Figure 3a: LoG Template of size $\rho = 20$ and $\sigma = 4$

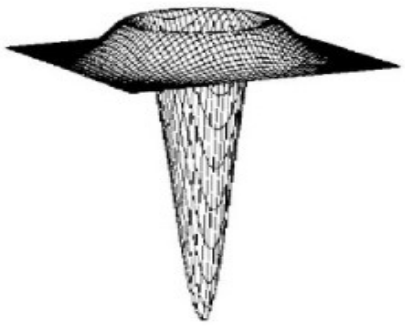

Figure 3b: Three dimensional (3-D) plot of LoG filter.

B. TEMPLATE REGISTRATION

Geometrical template is automatically registered on the input image using the co-relation technique. We compute the co-relation for various values of ρ because size of the myocardium may vary with small value. The value of ρ is chosen as the best response wherever the maximum co-relation match is found. Optimal center co-ordinates (x_c, y_c) of the myocardium is obtained.

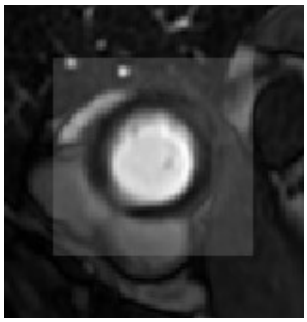

Figure 4: Template superimposed on myocardium region.

C. CURVED MULTI-PLANAR RECONSTRUCTION IMAGE

Myocardium region is constructed as the curved multi-planar reconstruction image with reference of points (x_c, y_c) obtained in the previous step. In the curved MPR image, first the endocardial contour edges are detected and later epicardial contours are obtained. Curved MPR image of myocardium is as shown in figure 5a.

To detect endocardial contours, an edge detector is applied vertically to detect strong edges with maximum intensity change. Average of these edges is considered to obtain the final boundary points. Endocardial contours can be seen as shown in figure 5b.

Since epicardium appears above endocardium, endocardial boundary points and approximate thickness of myocardium is used for detecting the epicardial contours. Edge detector is applied starting from endocardial boundary points up to approximate thickness of myocardium to detect the edge. Epicardial contours can be seen as shown in figure 5c.

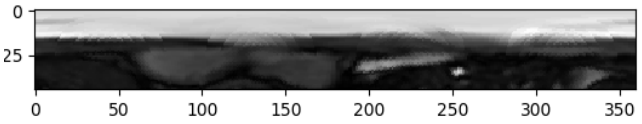

Figure 5a: Curved MPR Image of Myocardium.

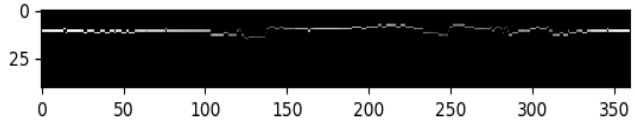

Figure 5b: Endocardial edge contours.

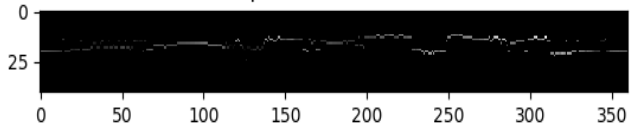

Figure 5c: Epicardial edge contours.

The contours obtained from the above step are drawn on the curved MPR as shown in figure 6a, where blue color

represent endocardial contours and orange color represent epicardial contours. These contours are then optimized as a smooth curve using the Savitzky-Golay filter [12] to produce the final segmentation result.

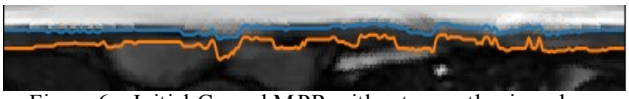

Figure 6a: Initial Curved MPR without smoothening edges.

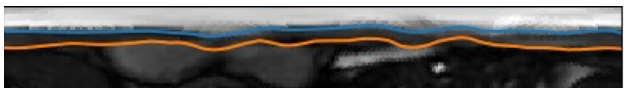

Figure 6b: Smoothened edges using Savitzky-Golay filter.

IV. RESULTS AND ANALYSIS

Figures 7 - 9 illustrates our automated contour detection of myocardium in multiple cardiac MRI frames from different patients. The cardiac images that are used in our project is from the open source Sunnybrook Cardiac Dataset[1].

Sample frames are taken from different patients. For each frame, detected endocardial and epicardial edges images are shown. Curved MPR image with and without smoothening edges is also shown for each image. In order to determine the accuracy of obtained myocardial contours, we have compared with manually traced endo-epi boundaries on the myocardium. Hence, the accuracy of automatic contour detection is validated sufficiently considering manual tracing as gold standard.

V. CONCLUSION

This paper presented an approach for automatic detection of myocardial contours in multiple cardiac MR images. Current work focused on segmenting the myocardial contours in 12 sample MR images from different patients. Future work can be extended to use the proposed work as the template and to superimpose on the LE-CMR image, so that the search of fibrosis can be limited within the template region. This helps to quantify the amount of fibrosis present in the myocardium more accurately.

Abstract – A research indicated that electricity is obliterating extra non-renewable sources for its production. In that, as per Centre for Policy Research (CPR), about 25% of the total production is diverted to meet the daily consumption in an Indian household. Not only this but also, waste management has become an important issue to deal with. According to Municipal Solid Waste (MSW) of India, waste generation in Indian urban communities extends between 200 - 870 grams per day, contingent on the localities' standard of living and the area of the city. Therefore, in this paper we propose a concept that focuses on a sustainable solution using Artificial Intelligence and Machine Learning algorithms for waste and carbon footprint reduction in a home. This concept explains a solution availed with the help of a proposed model called Home Resource Management (HoReM) that is imbibed in a Smart home.

Key words - Home Resource Management (HoReM), Artificial Intelligence, Machine Learning, Internet of Things, waste management, carbon footprint reduction, Smart home.

I. INTRODUCTION

To divert the load of electricity as a primary source of energy for home appliances, the solution proposed is a smart home that uses renewable source of energy which is Solar. Not just that, the smart home is greatly equipped with waste management quotient. A smart home, also known as domotics, is an advanced automated home system that constitutes of smart lights, smart appliances and smart door locks along with slide and motor sensors for every door and window. This system is heavily relied on Internet of Things that uses Internet in the form of Wi-Fi or Ethernet for connectivity [15]. With the need, waste management has also become the key area of concentration. Beginning of that activity from a home in itself is an achievement. The added features of waste management to a home would constitute solar panels, waste water management system, smart thermostats, smart fridge, smart washing machine, smart AC and air purifier, bio-gas connection, e-dustbin, leak detector.

A green smart home would monitor how and when power is consumed and manage it based on data. Starting from the power to execute all the functions of the home, solar panels can be included for partly distributed power generation along with electricity from other renewable resources such as Hydroelectric plants. Using the sensors and the appliance consumption data, smart power storage system can be charged during the day from the panels and can be consumed at nights by the high-power consumers devices like AC, TV leading to less consumption of electricity generated from non-renewable sources. Also, the system can identify the presence and absence of people which can be further transmitted to disconnect the devices that consume standby power.

Using that power, a typical smart heating/cooling sensor will monitor the external temperature through data from weather websites or from a sensor outside the house and tallies it with the body temperature from the data collected via wearable devices and creates an ideal temperature for the user and their family.

For the regular water consumption in various activities such as washing clothes and utensils, taking a shower - a smart water recirculation system can be built which recycles the used water that will remove calcium and magnesium which are constituents of a hard water [13].

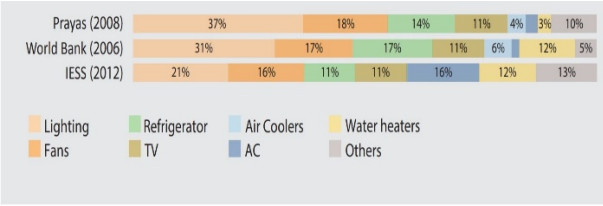
Another safeguarding complimentary solution for decreasing water consumption is leak detection sensors which will be attached to all the pipes at home that will send an alarm to the make motoring system when the tap is not in operation and cuts the supply for that

particular tap. However, integrating a leak detector into smart home network includes actuators that controls water and power sources leading to an alert to the user. And after a certain point of time, if the user fails to react, then it can automatically power off the sources for to control further flow of water [5].

II. LITERATURE REVIEW

According to Bureau of Energy Efficiency (BEE), Indian households accounted represented about 22% of the complete 883 billion units5 of power (whose main source is natural perishable resources) consumption in the year 2014.

As per National Sample Survey Office (NSSO) survey, over 90% of urban family units use power as their key source of lighting. Furthermore, the NSSO's data on families' monthly electricity utilization demonstrates that about 20% of the electrified Indian households expend under 30 units of power for every month while about 80% devour under 100 units for each month. In the urban regions, about 60% of the families expend under 100 units for every month, while 90% of the rural families devour under 100 units depicting in Figure 1.1.



Sources: (Boegle et al., 2010), (NITI Aayog, 2016) and (World Bank, 2008)

Figure 1.1 - 100% stacked column chart demonstrating the electricity consumption of multiple household appliances from different studies

However, electricity is not the only issue that is to be tackled for Indian households. Simultaneously, waste generation has become a major issue. The below mentioned is a waste audit conducted by Press Information Bureau [18], India across 500 households of Hyderabad. Hyderabad is a city with a population of 6.8 million during the 2011 census. The residents were segmented by the income groups as low, middle and high. The incomes were gotten from the property classification they dwelled in. Here, the assumption was that incomes were directly proportional monthly rental costs of the property, real estate value, monthly maintenance costs, and square feet of each flat or villa. Middle (251 households) and High (249 households) income categories were selected as target segments for the waste audit.

Waste was categorized into wet, recyclable and hazardous for variations in food consumption and other factors. Hence, the waste generation was collected across a span of seven days using a digital weighing scale. Each category was again audited in May(summer) and September(autumn) to account for seasonal variations in waste generation.

The results indicated a marginal increase in waste generation amongst High- and Middle-income groups, as shown in Table 1.1. The "middle income" group produced a normal of 0.887 kg of organic waste and 0.235 kg of recyclable waste per house every day. Whereas, the "high income" group produced 0.015 grams higher organic waste and 0.143 grams higher recyclable waste every day.

TABLE 1.1: PRIMARY RESEARCH RESULTS OF THE WASTE AUDIT CONDUCTED ACROSS 500 HOUSEHOLDS

Average Waste Generated per Household per day (in kgs)				
	Wet	**Dry**	**Hazardous**	**Total**
'High income' households	0.902	0.378	0.216	1.496
'Middle income' households	0.887	0.235	0.200	1.322
Final Averages	**0.894**	**0.306**	**0.208**	**1.409**

With rising education and financial gain, the per-capita increment in recyclable waste generated turned as a severe issue for the nation, additional compounded by a population of over two billion. the very fact that nearly 60% of the typical household waste is organic renders options such as RDF and WTE ineffective, due to the low calorific value of organic waste [2].

III. RESEARCH GAP

Even before indulging inside the plans of a Smart home, the key source of entire functioning is possible with the energy in terms of electricity [11]. Also, the highest waste generated would be an e-waste which would contribute majorly in depletion of non-renewable sources of power generation say coal. Therefore, Solar energy will be a dominant electricity source in near future according to Project Drawdown [9]. Currently, the top residential solar panels of 60 individual panels produce an energy between 290 to 360 watts. As per the Tennessee state, a typical 5,000-watt solar electric array that is 80% ideal in terms of output generates about 4,800 kWh per year. Hence, solar energy prevents about 5,760 pounds of CO2 pollution annually.

In the case of Smart lights inside the home, LED lightbulbs set-up cost is initially high however the energy consumption is less than incandescent or compact fluorescent bulbs and lasts longer. An LED bulb consumes up to 25-28 Watts per hour whereas the other mentioned consumes over 40 Watts of energy. Hence, the implementation of alike lighting in smart homes lead to an increase of efficiency by almost 40%.

Installing smart thermostats can also offer major climate benefits. The EPA's Energy Star program confirms that homes with smart thermostats can set aside to $180 every year on warming and cooling.

Recycling, using less water and switching to cleaner cement would all help slow climate change. But the chemicals used in our refrigerators and A/C units trap thousands of times more heat than CO2, so containing them is essential to stopping global warming.

If we prevent refrigerants from leaking and switch to using cleaner chemicals, it would conserve nearly 90 gigatons of C02 out of the atmosphere, according to Project Drawdown's analysis [6]. In fact, the Department of Energy estimates the average household fritters away—and pays for—12,000 unnecessary gallons of water every year. With the implementation of a smart water recirculation system, about two-thirds of water is saved.

IV. COMPONENTS OF PROPOSED MODEL

A. Smart Pay

It is an option enabled via a Smart phone. The Smart Pay will record each and every payment done via credit card, debit card, e-wallets and net-banking. This will keep a track of every transaction performed. These transactions analyzer will help keep a record of money circulation in the system and uploads the data to the cloud.

B. Smart Energy Management

Smart energy management is a combined system of smart grid that react to the local fluctuations. It consists of renewable energy sources. It will help to reduce the monthly expenditure spent on power consumption in the Smart home [4]. This will happen by honing renewable energy source i.e. Solar energy. That will transform the grid system rely less on non-renewable energy leading to reduction of carbon footprint.

C. Smart water recirculation system

The integration of rainwater harvesting system, smart taps, water meters and water flow sensors will help conserve and resend the water into the smart home system for lesser wastage. Additionally, this system will keep a track of the amount of water used, leaked, wasted and future demand as per the consumption pattern [14].

D. Smart appliances

Smart appliances like Smart fridge, Smart lighting, Smart thermostat, Smart washing machine, Smart air conditioner and air purifier will use the smart grid technology to communicates with one another in the system [10]. It helps the user to track as well as work with one tap in the app installed in the smart phone.

E. Smart dustbin(e-bin)

Smart dustbin has a 360-degree camera, LCD interfacing, weight gauge and buzzer that will show the current situation of dustbin to track and segregate the waste. Every motion and regular functionalities are captured via the camera in the form of pictures. This will give the live status of the works being performed inside the smart home. Also, a weight gauge will measure the amount of waste dumped after the camera recognizes the type of waste. Dumping of the waste will intimate the user about the kind of waste being generated on a day-to-day basis for recording and analysis purposes.

Figure 1.2 has two flow charts out of which the first one explains how vegetables/things enter inside the HoReM system. Later, it sends a notification to the user which is tracked from the consumption pattern or about the rotten and unconsumable waste. At last, this data is updated back to the HoReM system.

In the second flow chart, the figure explains how contents inside the fridge is taken out either for cooking followed by consumption or thrown in an e-dustbin. In both ways, the data will get updated in the HoReM system regarding consumption quantity as well as quantity wasted.

Overall, the figure depicts an inter-connection via Smart grid system of Smart pay, Smart refrigerator, Smart dustbin and cloud [16].

V. WORKING PROCESS

In the Smart home system, data is traced at the entry level itself. Figure 1.3 depicts the working model of the smart home. It starts from the minute a product i.e. appliance, groceries, clothes anything is introduced into the Home system. The very first level begins with the Smart Pay option via a Smart phone. The Smart Pay [19]. will record the payment done via credit card, debit card, e-wallets and net-banking which is connected with Home Network of the Smart home [1]. Once that is done, the entire data will perform spend analyzer through it.

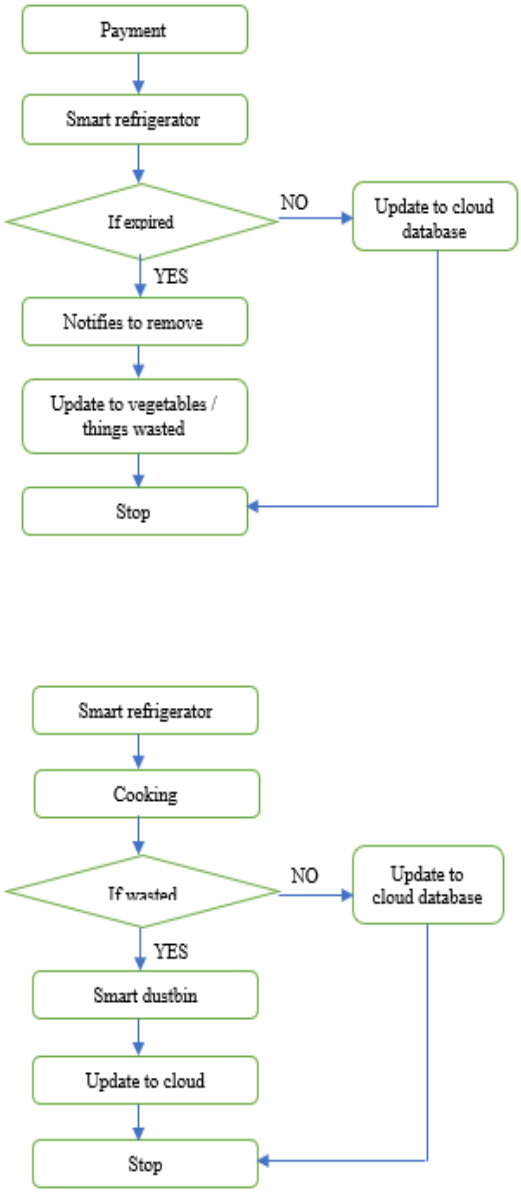


Fig1.2 – Flow chart depicting the process flow of collecting data

Secondly, the data collected will be moved on to the cloud for storage. The cloud here acts as a database for storage and retrieval of the data. Similarly, data is collected from smart lights, programmable thermostats, smart blinds, smart door locks along with slide and motor sensors for every door and window, smart appliances like fridge, washing machine, AC and air purifier. The same would be applicable for a smart Washing machine too. The Washing machine will calculate the amount of detergent stock management and water consumption levels for a particular round of process [12].

As far as the smart water recirculation system, the Water board states that on an average, a low-flow shower head in an Indian household uses about 35 liters of water for a 10-minute shower. Indeterminately, the meter sensors of a smart home shower will measure the amount of water used every single day. The data is run on a probabilistic algorithm say Naive Bayes Classifier and recommends the decrease/increase of flow in tally with the level of water in storage tank as well as on daily usage [8].

When it comes to appliances like Smart fridge, data is collected by sensing the products stored inside it. The bar code scanner would detect the shelf life of the products using the bar codes on the packaging. Later, it will process the time period of product stored inside without regular consumption and notifies about the expiry day that needs to be dumped to the dustbin (which are unfit for consumption). In the same manner, the scanner would measure the products without a packaging like vegetables, fruits and predicts its spoilage period until when it is consumable [17].

Overall all the data is in a process management software called Home Resource Management (HoReM) that allows the smart home to use a system of integrated applications which will manage and automate many background functions related to technology and daily chores.

In this entire process, e-bins would play a key role of detecting what all waste we are dumping out of the system. According to Drawdown's analysis, the food waste accounts for around 8% of the global emissions. Using an ultrasonic sensor, the level of garbage filled in e-dustbin will be analyzed and the LCD interfacing will show the current situation of dustbin. Along with the sensors, the 360-degree camera will identify types of waste using pictures. The detailed analytics measured in kgs/tons will help system to track and segregate the waste based on the image recognition ML algorithm. The waste will be categorized into food wastage – dry and wet, plastic, hazardous and miscellaneous. This will help in order to dump the waste as per the categories. Dumping of the food waste will show the amount of food being wasted on a daily/monthly basis. This data can further reduce waste

generation by intimating the user about the kind of waste being generated on a day-to-day basis.

It is further converted to dashboard using tools and move through Universal Home Gateway. Further, the data collected is sent into the cloud again for analyzing and receiving. After the processing of the data, the information generates a summary using Artificial Intelligence and Machine Learning algorithms. These algorithms will learn from the consumption and waste generation pattern that would result in waste reduction planning. Finally, the summary is shown in the app along with necessary point of changes for efficient saving. It will appear as a recommendation system of what all to consume first and what to dismantle into the garbage.

The summary generated will throw a message to the user saying "The food could have served 200 humans or saved 15 plants" instead of statistical display of numbers. Analogous notification will trigger the user about the waste performed and make them conscious about their decisions. This will lead to a conscious effort of saving and reusing the products in the system without adding it to future waste. Hence, the upliftment will help reduce the wastage, not exactly to zeroth level but to a considerate reduction of wastage. This awareness will bring the waste down leading to a green Smart home which will transform into a sustainable environment.

The app will further assist to generate the upcoming shopping list. It would be rather a recommendation cart that will be created on the basis of consumption pattern of the user. Finally, it will help to manage the money i.e. economy, energy i.e. nature and family i.e. people better – the ultimatum of sustainability.

VI. FUTURE WORK

Overall, sustainability does not reside just in the Smart home as system or few appliances. Rather, the true meaning will be fulfilled with a combination of technology and nature. Currently, the most harmful threat to nature is caused due to lack of regeneration of oxygen and exponential accumulation of Green House gases in the atmosphere. Solution for this threat is planting more trees that will promote the greenery.

In spite of being a grass, bamboo is likewise a genius at putting away carbon and blossoms on a degraded land. It will be equivalent to remove the carbon emissions produced by 50.6 million cars, making it a legitimate environmental change arrangement, according to Project Drawdown's analysis. Hence, bamboo plants will be grown in hydroponic solution as an indoor garden to combat global warming. Also, it would reduce the carbon emissions in the system by circulating more oxygen. Further, the hard water generated out of the Smart water recirculation system can be transferred to hydroponic plants that are used for indoor gardens. The sunlight and soil moisture will be operated via the sensors as well as the actuators.

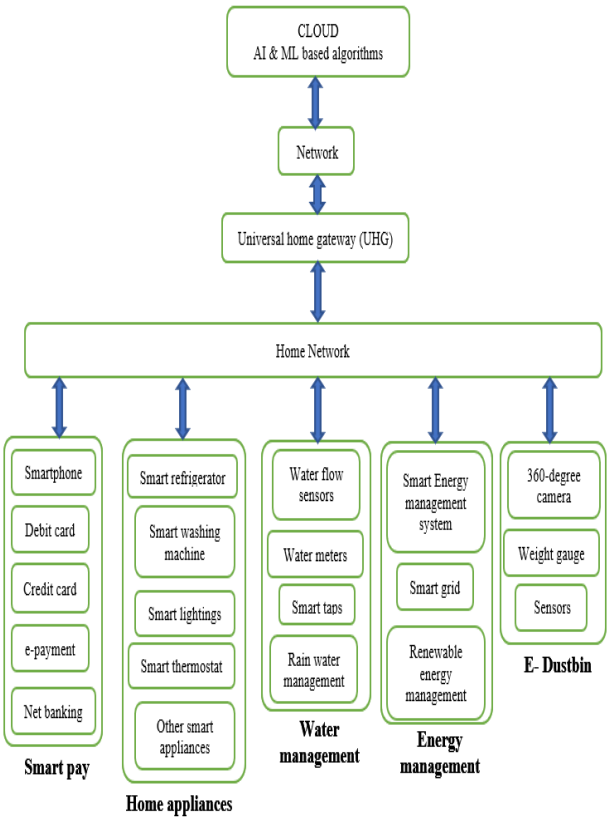

Fig 1.3 – Block diagram of the Smart home integrated with HoReM

VII.CONCLUSION

The proposed Smart home is an apparatus for waste management, reduction of unwanted costs in a household and efficient energy administration. The entire system is built to aid the user for a better way of living. In the quest of an environmental sustainability, the user need not compromise on luxury rather should be mindful of the resources utilized. Hence, the outcome will overall promote sustainability from a very base level. Wherein the base level is home and change begin at home, spreads to the community.

ACKNOWLEDGMENT

We thank our colleagues from the Institute of management, Christ (Deemed to be) University who provided us with insights which were great assistance in shaping our research. We would like to express our gratitude to the faculties and colleagues of Institute of

management, Christ (Deemed to be) University for sharing their pearls of wisdom, reviewing our research and giving us key inputs.

***Abstract*—Imaging Infrared seeker(IIR) is a passive system which works on the reflections from the ambience and tries to deduce intelligible information regarding the targets of interest. Passive systems have complex processing schemes because of the unavailability of active reference signals to synchronize the processing. All the information has to be derived from the raw data obtained using thermal gradients. Manual intervention in these systems is inevitable to provide the initial conditions for the processing to start, unlike active systems where the system automatically configures or maps the surrounding by transmitting a signal. Centroid tracking and image correlation based tracking have been used for IIR tracking extensively in literature. Centroid tracking is highly sensitive to background data and initial tracking window size selected whereas correlation tracking requires a reference template for matching the target parameters which is usually not available up front. Both the techniques have high track loss rate if the background is cluttered. In this work we have proposed a novel infrared tracking technique for IIR seekers by fusing centroid processing with Interacting Multiple Model(IMM) filtering to reduce track loss and improve tracking efficiency.**

Keywords: Centroid Estimation,Correlation tracking, Infrared seeker, IMM filter, Field of view(FOV), Laser range finder(LRF), Readout IC(ROIC), Focal plane array(FPA)

I. Introduction

An infrared system requires specialized optical framework along with integrated ROIC to get the raw image for further processing. Because of complexity and limited expertise, IIR systems tend to be expensive which does not break even for everyday commercial applications which has restricted the technology mostly to military applications. In military applications they are an indispensable tool for territory defence and cross territory enemy intrusion alerts in the border areas especially during dark hours. They form the only source of surveillance available when our optical systems fail. IIR seekers are special class of airborne systems developed for tracking targets of interest, both stationary and mobile, and guide the weapon system towards them culminating in payload delivery for lethal impact. Being mounted on aerial vehicle, the system is tightly constrained by area, processing time and power. Adding to the complexity, IIR systems works on gray scale images which gives very little scope for processing enhancements. Most of the image tracking algorithms proposed in the literature work with colored images [1][2][3][4]. Glasgow and Bell [5] have summarized a brief account of IIR seeker systems available presently and future trends in this field for the interested reader. Traditionally, centroid tracking [4] and correlation based tracking [6][7][11] have been used for tracking the target. While centroid tracking is highly sensitive to background data and initial tracking window size selected, correlation tracking requires a template for matching the target parameters which is usually not available up front. Wanjae Lee et al. [7] proposed a variant of correlation algorithm by estimating the target template every scan with the correlation coefficient between multiple zoomed templates which again requires a reference template for processing. [14][15] propose kalman tracking using single model filters. Single model filters are suitable for no or very little manoeuvring targets. They fail if the target changes direction when passing behind occlusions. In this paper we propose a hybrid approach to fuse data from centroid tracking with IMM filter to handle manoeuvring targets. [8][9][10] present details of IMM filter modelling in detail. We have generated a target model based on background data taken from the field over which we superimposed simulated target data with varying trajectories to closely mimic the real time scenario in the lab. With this approach we improved tracking efficiency and reduced track loss as evident in the simulation results presented. The rest of the paper is organized as follows. Section II briefs on target trajectory modelling. Section III details the proposed methodology. Section IV validates our claim with simulation results followed by conclusions in section V.

II. Target trajectory modelling

The input to the image processor in an IIR seeker is the target image sampled at every 't' seconds. Typically 't' will be in the order of 35ms which should cater for thermal intensity conversion, Non Uniformity correction (NUC), ROIC multiplexing, De-multiplexing and image formation followed by tracking. With this order of sampling rate and pre- processing operations the processing time for tracking is reduced drastically thus, further complicating the problem at hand. There are two methods to generate input video for validating our algorithm.

(a) Generate the trajectory based on the target parameters and map this data to image pixels considering the seeker parameters mentioned in the Table 1.

In this method, at every sampling instant, the range, swath area, pixels occupied by target at that range and range per

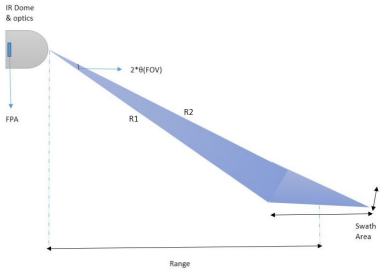

Fig. 1. Seeker Optics

pixel will be calculated. This information is used to generate the target position in the next frame using Equations 1-3 for subsequent processing. This process is continued until the last frame and finally we get a simulated video input to our algorithm.

Table 1	
Parameter	value
Target Parameters	
Range	7000 mtrs
Velocity	70 Kmph
No of Pixel at given range	4 x 4(approx.)
Target Heading	45 deg
IIR seeker Parameters	
Field of view	2 deg $(2 * \theta)$
FPA resolution	256 x 256
Swath area(1D)	2*Range*$tan(\theta/2)$
Range per pixel shift	Swath'area/resolution

$$v(n) = v(n-1) + a * t; \quad (1)$$

$$s(n) = s(n-1) + v(n) * t; \quad (2)$$

$$s(n) = s(n-1) + v(n) * t + 0.5 * a * t^2; \quad (3)$$

where, 's' is the range of the target, 'v' is the target velocity ,'a' is the target acceleration and 't' is the sampling time.

(b) From our previous experience in the field, videos gathered during evaluation trials, discussing with pilots and other colleagues, we narrowed down few trajectory models which we directly simulated at the image level at every frame. From this trajectory, we mapped the target co-ordinates to range and azimuth using parameters from Table 1 and created an input state vector to the IMM filter.

We followed second approach for target generation for our simulations. We considered four phases of target movement. Each phase was coded with a different trajectory model and combined to generate a random trajectory across the image.

III. Proposed Algorithm

A. Centroid processing

$$x = \frac{\sum_{i=1}^{i=m} i \sum_{j=1}^{j=n} I(i,j)}{\sum_{j=1}^{j=m} \sum_{j=1}^{j=n} I(i,j)} \quad (4)$$

$$y = \frac{\sum_{i=1}^{i=m} i \sum_{j=1}^{j=n} I(i,j)}{\sum_{j=1}^{j=m} \sum_{j=1}^{j=n} I(i,j)} \quad (5)$$

where, (x,y) are the centroid co-ordinates, (i,j) are pixel co-ordinates in the received image $I(i,j)$.

Centroid processing is the earliest algorithm used for IIR tracking and still is the most preferred method in ideal conditions. Once the IIR seeker is cooled and ready to view the image, user scans the environment for potential threats and locks on to the target. The initial window enclosing the target and some background is selected and information is passed on to the image processor, We obtain range information using Laser Range Finder(LRF) present in the cockpit. In other scenarios, ground based radar can be used to get initial range information. This information is required to compute the swath area and other parameters in every scan. After locking the target, the feed is handed over to the tracking algorithm which continuously computes the centroid in the given window using equation 4-5 and moves the window keeping the updated centroid in the center. The Problems with this method are

(a) window size is very critical in this method. The window should enclose the target completely with very little background so that background does not dominate centroid calculation.

(b) As the target range decreases the pixels used to represent the target increase i.e, the target template size varies with range. Accordingly, the tracking window has to be adjusted to keep the ratio of "target pixels/background pixels" almost constant.

The main challenge here is to identify the change in target size. Since we are updating the frames at a very high rate, the change from frame to frame is low. The only reference we have to understand this change are the centroid coordinates. They are two possibilities for centroid to be constant in consecutive frames. (a) The target has halted (b) Target size has increased in the frame. Both the cases have to be handled separately so that problem at hand now becomes to identify the condition. The IMM filter precisely does this and solves our problem. It tracks the target even after centroid input is constant and in further frames reacquires the target preventing track loss.

B. IMM tracking

Interacting Multiple model(IMM) filter is primarily developed to use in active radar tracking [9]. It is a combination of multiple state models which are combined according to model probabilities calculated to give a filtered output as shown in figure 5. It consists of state interaction, model probability calculations and combining state estimates for better tracking. We have considered 2 model IMM (CV-CA) for our algorithm. Equations 6-7 represent state and output equation and equations 8-12 represent the equations for state

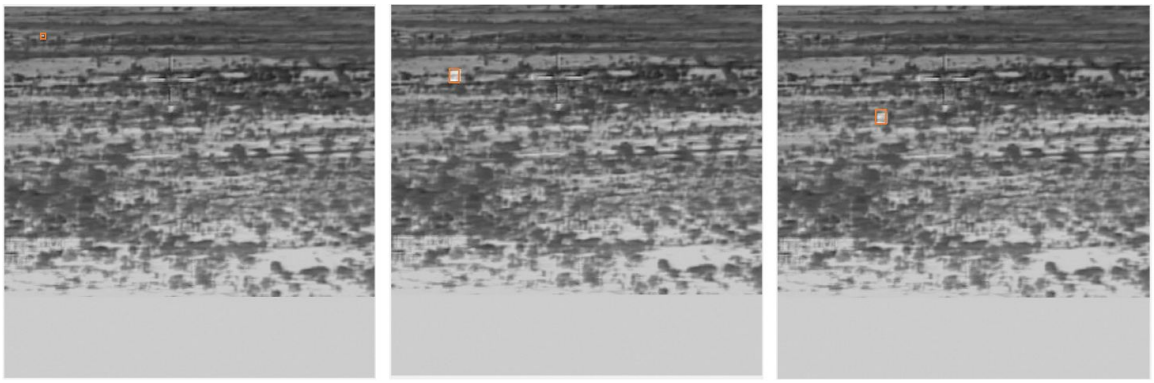

Fig. 2. [a,b,c]Target tracking with centroid processing. It can be observed that the tracking window is following the target correctly in subsequent frames

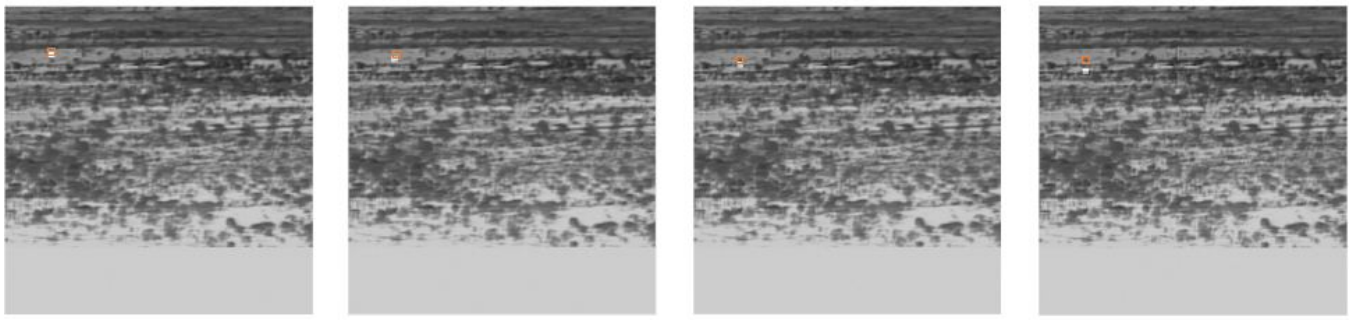

Fig. 3. [a,b,c,d]Target manoeuvre caused centroid jump which led to target window miss as shown in (d).

prediction,state and covariance update equations for kalman filter.

$$X_{k+1} = \phi_k X_k + w_k \tag{6}$$
$$y_k = H_k X_k + v_k \tag{7}$$
$$\widetilde{X} = \phi \hat{X} \tag{8}$$
$$\widetilde{P} = \phi \hat{P} \phi^T + Q \tag{9}$$
$$K = \widetilde{P} H^T (H \widetilde{P} H^T + R)^{-1} \tag{10}$$
$$\hat{X} = \widetilde{X} + K(y_k - H\widetilde{X}) \tag{11}$$
$$\hat{P} = (I - KH)\widetilde{p} \tag{12}$$

where,
X = State estimate
w_k = process noise
v_k = observation noise
P = Covariance matrix
˜ = Predicted values
ˆ = Filtered values
ϕ = State transition matrix
Q = Process noise matrix
K = Kalman gain
R = Measurement covariance matrix
I = identity matrix
y_k = measurement
T = matrix transpose operation

The flow chart of the proposed method is shown in Figure 6. The input to the tracker are the centroid cartesian co-ordinates from the input image which are representative of the target movement across the image surface. Because of the

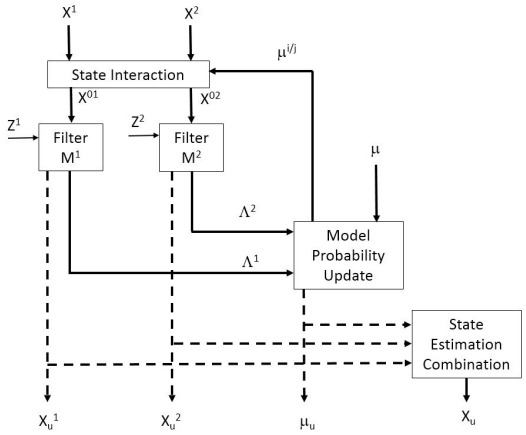

Fig. 5. Block diagram of 2 model IMM processing

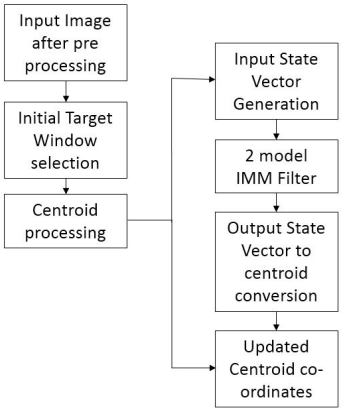

Fig. 6. Flow chart for proposed algorithm

high sampling rate (33 fps) the centroid shift is limited to a few pixels in consecutive frames. This helps in relaxing the input rate to the IMM filter reducing the computations. We have considered every fourth frame for IMM tracking and still obtained good tracking performance. However, when the target moves in and out any obstacle, depending on the area covered by the occlusion we will miss some data frames where the filter will coast or propagates the centroid measurement for few scans. If the obstacle causes a loss in significant number of frames, the target in the visible frame may change in size which may lead to a centroid jump. This jump if in the same direction of previous heading can be handled by single model filter. But if the target changes it course, we need to relock onto the target for tracking. In this case, we can use multiple model IMM filter which can predict different possible positions of the target with varying prediction window sizes to reacquire the target. After acquiring the target from the next measurement, the filter will recalibrate towards the new heading, tracking the target till the hit. Without IMM we cannot acquire targets which have changed heading after the occlusion using only centroid processing. Single model filter is suitable for benign targets where the manoeuvrability of the target is minimum. But this is seldom the case in real time scenario which necessitates the implementation of multi model IMM.

IV. Simulation Results

We have simulated multiple trajectories but due to space constraints presented results for only one trajectory. As mentioned earlier, for our simulations, we have taken background images from the field data and overlaid the simulated target data onto the background image in every frame along with Gaussian noise generating the input video. The video thus generated was fed to the centroid processor with the given initial conditions. The algorithm tracked the target updating the centroid coordinates for the full video without any track loss when there is no manoeuvre as shown in Figure 2. Figure 2 shows the image of the target at different ranges. The target size is divided with range per pixel value at every frame to get the number of pixels to represent the target as seen in the field. Figure 2(a) shows the initial bounding box enclosing the target by the user which is the only input to the tracker. Figure 2(b) and 2(c) show the target with the bounding box tracking the target. Figure 3 shows the case of target miss where the bounding box does not enclose the target due to target manoeuvre. To mitigate this problem, we have used parallel IMM filter channel. After 3 frames of centroid tracking the centroid co-ordinates of the previous 2 frames were input to the 2 model IMM filter in parallel tracking channel as initial conditions. We have simulated the track loss conditions by dropping the centroid co-ordinates in the input vector of IMM filter and observed that tracker was coasting and reacquiring the target in a few frames as seen from the plots in figure 4. It can be observed that when there is loss of data, IMM filter is trying to converge on a suitable model for tracking which is causing the change in model probabilities shown figure 4(b). Figure 4(c) shows the actual trajectory in blue and predicted trajectory in green. As can be observed when there is data loss or change in direction of target motion the predictions go astray but the filter is assigning appropriate weights to the models to get the filtered output(in magenta) which is in line with the true trajectory.

V. Conclusion and Future Scope

In this work we have proposed a novel fusion method of tracking the targets with infrared imaging systems. We have explained the track loss in conventional centroid processing and proposed our method to improve the same. We have implemented parallel channel of target tracking and fused the output to improve tracking efficiency which is apparent from the simulations results. We have considered 2 model IMM which can be further scaled to multiple models to get even better tracking efficiency depending on the complexity of target manoeuvrability and the available resources. We are currently implementing supervised template matching algorithm in third channel to improve resolution in multiple target scenario.

Abstract: **The process of information security entails securing the information by transferring it through the networks preventing the data from attacks. This way of securing the information is known as cryptography. The perspective of converting the plain-text into non-understandable format is known as cryptography that could be possible using certain cryptography algorithms. The security could not be offered by the conventional cryptographic algorithms that lacks in their security for the huge amount of growing data, which could be easily broken by the intruders for their malicious activity. This gives rise to the new cryptographic algorithm known as DNA computing that could strengthen the information security, which does not provide any intruders to get authorized to confidential data. The proposed DNA symmetric cryptography enhances information security. The results reveal that encryption process carried out on plain-text is highly secured.**

Keywords: DNA cryptography, Information security, DNA computing.

I. INTRODUCTION

DNA computing was mainly emerged to solve the directed Hamiltonian Path Problem (HPP), which was proposed by Adleman. The concept of HPP is to obtain the shortest path that traverses along each and every node and then return to the last node in the bounded path. A DNA sequence could be formed by fixing the source node second half part to the destination node of the first half path. This DNA computing solved the problem of HPP and gave a new direction in the field of cryptography.

Figure 1: Chromosomal Sequences from a Genetic Database

The most prominent work in DNA cryptography was carried out by Gehani and they proposed an image encryption algorithm with a help of one-time-pads. Substitution method was also bought up that did the pair wise mapping among the plaintext message and ciphertext algorithm. The encryption and decryption were done by the DNA-chip based approach for the 2D images with one-time pads and observed an enhanced version of steganography by reducing the difference among the disorder strands and the plain text. This form of DNA computing was carried out by many researchers in various fields in order to provide a security for the huge amount of data as shown in figure 1. Various cryptographic approaches were also bought to idea known as DNA-BASED cryptographic approaches. Certain attractive properties were also bought in work by DNA computing such as high storage capacity, maximum efficiency in energy, high parallelism that forms high advantage for the concept of data hiding. The application could be a solution for the signal processing, optimization problems, forecasting as well as clustering. One-gram DNA could contain 108 TB of data. This is equal to 1021 DNA-bases.

The objective of this paper is to provide the following:

- To analyze various approached regarding the DNA cryptography.
- To offer a robust ciphertext with the enhanced cryptographic algorithm.
- To offer an advanced data hiding methods with the enhanced approach.

A. DNA

DNA (Deoxyribonucleic Acid) that is formed by the nucleotides is in the form of biological super molecule, which is the source plasma of all living beings. Deoxyribonucleotides is said to be known as the monomer unit of DNA. Four types of nucleotides bases are found in DNA namely,

- Adenine (A),
- Cytosine (C),
- Thymine (T), and
- Guanine (G)

There are two nitrogen bases for the DNA: 1) Purines 2) Pyrimidines. A and G are said to be the double ring molecules and are termed as purines where the single ring molecules are called pyrimidines that has the base C and T. The capability of DNA could be found in the enormous industries that could serve the purpose of image and data encryption, data hiding, steganography, etc. Several parameters such as temperature, pressure, oxygen ratio etc., should be taken care while executing the DNA operations in various laboratories (identical conditions of several parameters should be maintained). Since the DNA is the sensitive module, this could provide several outputs in various environments. Hence, it could be said that the DNA computation totally depends on the environmental conditions as shown in figure 2. Binary form of converting the DNA sequence is known as the binary coding scheme. In this paper the DNA bases such as A, T, C, and G have been used for the binary scheme of 00, 11, 01, and 10. For instance, DNA sequence "AATCGGAT" has the binary sequence of 0000110110100011. RNA (Ribonucleic Acid) also

consist of the main bases as same as the DNA but here the Thymine (T) is replaced by Uracil (U).

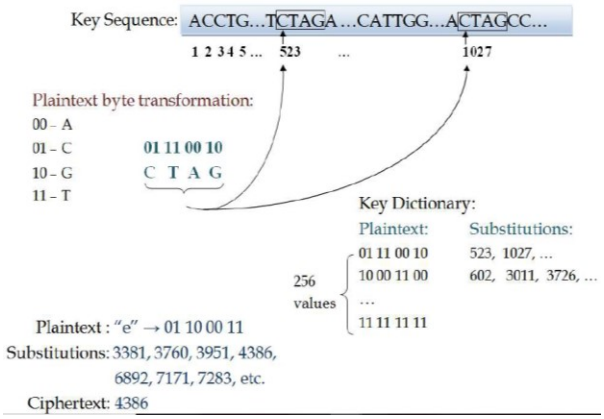

Figure 2: DNA Indexing Algorithm's encryption process

II RESEARCH MOTIVATION AND PROBLEM STATEMENT

The concept behind cryptography is to convert the plaintext into ciphertext (non-understandable format) using several algorithms that falls under cryptography concepts. Cryptography algorithms such as DES, TDES, AES, and RSA that is the multifarious symmetric and asymmetric key algorithms that helps in conversion of plaintext into ciphertext. The security could not be offered by the conventional cryptographic algorithms that lacks in their security over the growing internet usage for the huge amount of growing data, which could be easily broken by the intruders for their malicious activity. DNA could be used in two major roles under the concept of DNA cryptography. DNA acts as a medium for the encryption keys since it has two fundamental properties. The fake DNA and the real DNA sequence have virtually no major sequence. The other point is that there are 163 million DNA sequence available all over the world. Several cryptographic algorithms have been proposed over the last decade. These algorithm ciphertext is more complex than the normal key ciphertext.

III TECHNICAL BACKGROUND AND RELATED WORK

Various algorithms have been created in the concept of DNA computing. Tedious cases such as SAT, DES has been solved with the help of DNA computing in the past two decades. NP complete SAT problem has been solved by Lipton [1] using DNA computing. He also formulated an encoding scheme with the DNA scheme and the author employed a minimum number of variables to solve the SAT problem. In order to crack the Data Encryption Standard (DES), Boneh et al [2] proposed an approach with the DNA computing. Any crypto-system could be cracked with the less key size of about 64-bits with their proposed algorithm. Moreover, their encryption circuit is also small with the cracking mechanism in 916 steps. Each individual step is equal to 32 extractions and it needs at least a day processing for every 10-extraction steps. Altogether, their proposed algorithm could take at least 4 months to crack DES. With the DNA operations hard problem could be solved with the DNA computing techniques that were proposed by Chen et al. [3]. They also solved DES with the DNA technology. Three various functions have been included in the Chen et al.'s anticipated algorithm: 1) Initial function for initialization of the key space with every possibility 2) Encryption process, and 3) Detecting right corresponding key. Enzymes, tubes and short memory strands are all included in the molecular sticker algorithm.

Symmetric-key DNA cryptosystem had been introduced by MingXin et al. [4] that includes the DNA biotechnology imparted into the cryptography technologies. With the DNA probes the encryption and decryption has been formed in this algorithm and the ciphertext has been embedded into the DNA chip (microarray). The advancement of DNA chip leads to the security of the algorithm. For the efficient, reliable and secure transmission of data an algorithm has been proposed by Kar et al. [5]. This algorithm utilizes the DNA keys that utilized 3 keys: 2 keys for the encryption and the remaining one key for sharing the encryption key to the receiver. With the help of string to binary conversion process the plaintext will be converted to binary sequence in this algorithm. Binary coding scheme converts the huge DNA pattern in the form of binary data as the encryption key. The ciphertext could be obtained by applying the XOR and addition operations in the 64-bits plaintext and 64-bits key. Several cryptographic approaches had been proposed by Shiu et al. [6]. The cryptographic approaches with the utilization of DNA approach are as follows: 1) Insertion method 2) Complementary pair method, 3) Substitution method. Finally, they also proved that the substitution method is more efficient than the other two approaches. Data hiding approach has been proposed by Liu et al. [7] with the encryption of ciphertext in a word file with the DNA sequence. Their algorithm utilizes the DNA coding that converts the plaintext into DNA sequence. Chebyshev maps produce two pseudorandom DNA sequence XXOR and YPrimer, and create one time key using preferred DNA sequence key. The output generated includes the YPrimer and the DNA message sequence includes the XXOR. By applying the shift operations in the previously generated output, they could be converted to ciphertext. The word file could be converted to PDF after the encryption of ciphertext into the word file. The receiver will receive the PDF generated. A strong ciphertext algorithm had been proposed by Mandge et al. [8] that include key generation technology with the manipulation of matrix inclusion in the cryptographic algorithm. Initially the plaintext will be converted to a mini-cipher with the several shifting and XOR operations. It is said that if the process is applied to the plaintext each time, we could obtain various mini-

cipher for the similar plaintext since this process includes the secure key generation. After this mini-cipher gets converted to a final ciphertext with several biotechnologies that includes of DNA primers. The substitution method with the single bit complementary rule of Shiu et al. had been enhanced with the table lookup substitution method (TLSM) proposed by Taur et al. [9]. They extended to the two bits complementary rule for the substitution method. The two-bit message is converted to their corresponding letter with the help of TLSM that utilizes the lookup tables [10][11]. On the other hand, Shiu et al. rule could only translate one bit at a time. Moreover, compression of ciphertext is very effective in the TLSM procedure [12].

Complex problem that are difficult to solve in the silicon-based computer could be solved by the DNA computing by the researchers in a polynomial time [13]. The better results could also be generated by the DNA computing that could be used in the field of image processing, clustering and optimization problems. A brief description regarding the problem could be provided by this research work and also helps in analyzing the loopholes from the existing research works[14].DNA operations like Hybridization, Indexing, and PCR have the capacity for a solution of the application in the fields as data hiding, image encryption, and steganography. Several fascinating characteristics have also been present in the DNA that includes vast parallelism, maximum storage capacity as well as maximum efficiency in energy. This forms as an advantage for the data hiding and provides high security for the security purpose for the fast-growing internet data. Hence this could form as a greatest boon to the future for protecting the data [15]. Annealing, Hybridization, Indexing and PCR (Polymerase Chain Reaction) are said to be the DNA operations that has the ability to offer a strong data encryption technique. The powerful cryptography algorithm could be created when the DNA keys and DNA operations are combined together [16]. Cryptographic techniques thus provide greater security for the on-line as well as the off-line private security data. This offers several researchers to find an optimum solution in their research areas. The problem includes the silicon-based computer in polynomial time. Moreover, DNA computing offers greater solution in less amount of time when compared to the silicon computer [17][18].

IV PROPOSED DNA CRYTOGRAPHIC ALGORITHM

The enhanced proposed approaches have been explained in this section that accepts the message in the form of a plaintext and converts it as ciphertext in the form of protein. The receiver receives the protein through the public channel and the decryption process will be applied to receive the plaintext or the message [19]. The binary coding scheme will be shared by the sender and the key will be the codon table of RNA that utilizes the database name, which will be a shared symmetric key with the index number and send through the secure channel to the receiver end in this approach. From the DES algorithm, several substitution and permutation network will be developed through the enhanced algorithm. The functions of the encryption and decryption will be used in the receiver end[20]. Generally, plaintext will be converted into binary value in the encryption algorithm with the utilization of hexadecimal values. A long pattern of DNA sequence will be divided into 32-base pattern such as S1, S2 and S3 respectively. Similarly, k1, k2, k3 will be the 64-bits keys that has the converted 32-base DNA sequence with the binary coding scheme. The encryption block is selected from the 6-bits plaintext. The function of encryption runs from the parameters K1 (64-bits), encryption block, and 64-bits blank cipher block. The output of the encryption will be in the form of cipher block of 64-bits. In the same way, a decryption process will call the parameter k2 for their function with the previous cipher block as input, and 64-bits blank plaintext block. When this process has been executed, the next encryption function will be called with the previous encryption and decryption output with the key k3 as the input. This helps us in receiving 64-bits partial ciphertext block. The fake DNA sequence could be obtained by applying the reverse binary coding scheme inside the partial block. The final ciphertext could be obtained by applying the CDMB technique into the fake DNA sequence. By doing this process, the protein could be obtained which will be send to the receiver end.

The reverse CDMB technique will be applied in the decryption technique, which will be applied to the ciphertext block and it will be first decryption level thereby creating a fake DNA sequence. In order to receive the partial cipher level in the form of bits we tend to use the binary coding technique that tends to produce three 64-bits decryption keys K1, K2 and K3 with the shared information from the sender in the receiving end. Parameter k1 could evoke the decryption function with the selection of 64-bits cipher block as well as the 64-bits plaintext block. Executing this could help in obtaining the plaintext of 64-bits. The encryption function could be evoked with the key k2 with the input of previous output block and 64-bits blank cipher block. Then again, the decryption function should be called after receiving the output of 64-bits block from the previous step that acts as an input in this function with the key k3. This helps in receiving the 64-bits plaintext block. Plaintext P could be obtained by applying the inverse hexadecimal coding.

Algorithm:

I. Procedure for Encrypt (Key K, Plaintext P, Ciphertext C):

Input: Key K, Plaintext P.

Output: Ciphertext C.

Phase 1: Receive K' as 56-bit by applying permutation on K.

Phase 2: Dividing the factor K’ as 28-bits X0 and Y0

Phase 3: Produce Xn and Yn, as 16 blocks such that 1≤n≤16. The set of block Xn and Yn will be formed with the help of the previous block left shift key.
Phase 4: Every concatenated pairs will generate 16 sub-keys, 1≤n≤16.
Phase 5: P that is of 64-bits will be applied with the initial permutation (IP).
Phase 6: IP is divided as P0 and Q0, each consisting of 32-bits.
Phase 7: The pairs of Pn and Qn are obtained for 1≤n≤16, with the help of the two equations:
Pn= Qn-1
Qn = Pn-1 ⊕X (Qn-1, Kn)
Where, X (Qn-1, Kn) = X (Qn-1) ⊕Kn; and X (Qn-1) = Expansion function.
Phase 8: The Q16 P16 blocks of 64 bits is obtained.
Phase 9: The output C is generated by applying final permutation IP-1 to Q16 P16

II Procedure for Decrypt:
Phase 1: Receive K' as 56-bit by applying permutation on K.
Phase 2: Dividing the factor K' as 28-bits X0 and Y0 each.
Phase 3: Produce Xn and Yn, as 16 blocks such that 1≤n≤16. The set of block Xn and Yn will be formed with the help of the previous block left shift key Xn-1 and Yn-1.
Phase 4: Every concatenated pairs Xn and Yn will generate 16 sub-keys, 1≤n≤16.
Phase 5: P that is of 64-bits will be applied with the initial permutation (IP).
Phase 6: IP is divided as P16 and Q16, each consisting of 32-bits.
Phase 7: The pairs of Pn and Qn are obtained for 16≥ n ≥ 1, with the help of the two equations:
Qn-1 = Pn
Pn-1 = Qn ⊕X (Pn, Kn)
Where, X (Pn, Kn) = X (Pn) ⊕ Kn; and Expansion function is X (Pn).
Phase 8: The P0 Q0 blocks of 64 bits is obtained.
Phase 9: The output P is generated by applying final permutation IP-1 to P0 Q0

III Proposed Encryption Algorithm:
Algorithm: Encryption (Plaintext P, Ciphertext C)
Input: Plaintext P, A long DNA sequence > 96 DNA-bases
Output: Ciphertext C
Phase 1: The plaintext or the message is converted in binary form with the help of Hexadecimal value.
Phase 2: S1, S2, and S3 are the 3 DNA sequences chosen from a given 32 bases DNA sequences.
Phase 3: S1, S2, and S3 are converted as K1, K2, and K3 in the form of bits with the binary coding scheme. K1 and K3 are chosen as the encryption key. On the other hand, K2 is made as the decryption. Each key are 64 bits.
Phase 4: Encrypt (K1, P, C')
Phase 5: Decrypt (K2, C', C'')
Phase 6: Encrypt (K3, C'', C''')
Phase 7: C''' is said to be the partial cipher block that is applied with the reverse binary coding scheme and the fake DNA sequence is obtained.
Phase 8: Apply CDMB to obtain the protein sequence from the fake DNA sequence.
Phase 9: PROTEIN sequence is sent to the receiver in the form of encrypted message.

III Proposed Decryption algorithm:
Algorithm: Decryption (Plaintext P, Ciphertext C, Index X and Database D)
Input: Ciphertext C, Key information shared (Index X and Database D)
Output: Plaintext P
Phase 1: Implement reverse CDMB to obtain the fake DNA sequence from the Ciphertext C.
Phase 2: Get the partial ciphertext with the binary coding scheme in the form of bits.
Phase 3: S1, S2, and S3 are the 3 DNA sequences chosen from the shared information by the sender from the DNA databases.
Phase 4: S1, S2, and S3 are converted as K1, K2, and K3 in the form of bits with the binary coding scheme. K1, and K3 are chosen as the decryption key. On the other hand, K2 is made as the encryption key. Each key are 64 bits.
Phase 5: Decrypt (K1, C, P')
Phase 6: Encrypt (K2, P', P'')
Phase 7: Decrypt (K3, C'', M')
Phase 8: Apply the reverse hexadecimal coding to receive the original plaintext P from M.

Conversion of DNA sequence is possible with the proposed scheme that utilizes the DNA encoding table that is shown below. Here the plaintext is been used and each character indicates a DNA pattern with the combination of 3 bases. Several complementary rules has been followed by the proposed algorithm that boost a ciphertext due to perfect complementary rule that follows property like V(W) V(V(W)) V(V(V(W))) V(V(V(V(W)))), where 'W' is any string or alphabet. The complementary rules that have been used in this approach are as follows: (AT) (CA) (GC) (TG), Means V (A) = T.

Table 1: DNA Encoding [6]

A=CGA	H=CGC	O=GGC	V=CCT	2=TAG	…	9=GCG

Receiver knows DNA encoding table, complementary rules, binary coding scheme and RNA codon table using a secure channel made by the sender. Exploitation of substitution method for the algorithm is obtained from Shiu et al.

V EVALUATION

Complexity analysis for the proposed algorithm was carried out since it exposes the security level of the algorithm for real-time applications.In this work the computational time of the algorithm was analyzed employing complexity theory methods. The input consists of alphabets; special character and alphanumeric.The obtained conclusions were tested to be true through the implementation results.

Table 2: Measurement of Key-Table Computation Run-Time

Nucleotides (key length)	Runtime (ms)
3000	66
4000	300
6000	436
8000	566
9000	636
10000	866

Table 3: Measurement of Encryption Runtime

Size of Plain-Text	Run-time (ns)
86 KB	6
100 KB	13
300KB	36
1000KB	66
13000KB	76

Table 4: Measurement of Decryption Runtime

Cipher-text Size (KB)	Run-time (ns)
86 KB	16
100 KB	33
300KB	46
1000KB	53
13000KB	66

The sum of all the operations represents the execution time of the proposed algorithm. The number of operations contains variable as well as constant based on input parameters. Based on the approximations from complexity theory, the smallest possible class of functions is employed to represent the growing rate of the algorithm's runtime, for instance, the number of operations for 1 + 2n would be O(n) in-terms of complexity; if the number of operations is 4 + n + n3, then the complexity would be O(n3). The experimental results have proved the correctness of the estimated complexity. In order to see the progression of the runtime, the program was executed at different, progressively increasing values of n and m. Figure 3 depicts graphics of the runtime growing rate for the key table computation, encryption and decryption processes. The execution time measurements are presented in Tables 2 - 4.

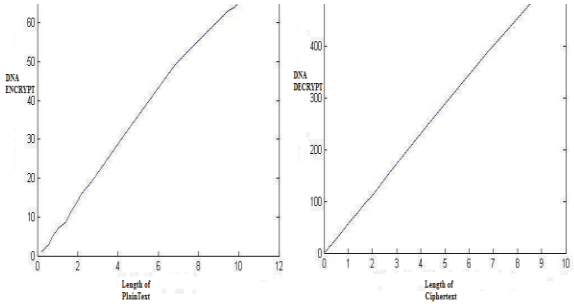

Figure 3: Results of DNA Encryption and DNA Decryption

VI CONCLUSION AND FUTURE WORK

Cryptography based security services could be seen in many sectors that includes several areas that includes digital certificate, banking sectors, image and message encryption etc. Certain algorithms such as DES, TDES, AES, and RSA are multifarious symmetric and asymmetric key cryptography algorithms that exists metamorphosis of plaintext into ciphertext. As the next level of evaluating the efficiency of the proposed algorithms, the following methods will be conferred as future work:

- Statistical measurements
- Key space analysis

***Abstract*—In the present letter, we are designing a co-planar waveguide rectangular patch antenna with an area of (Lp×Wp) mm^2 .This is exciting by using a feed line having the dimensions of (Lf×Wf) mm^2. An FR-4 substrate occupying the volume of (L×W×H) mm^3 is used. A ground plane having an area of (Lg×Wg) mm^2 is designed on the top of the substrate and an aperture of (Ls×Ws) mm^2 is cut on the ground to improve the bandwidth characteristics. The s designing and simulation was done by using microwave studio computer simulation technology (MS-CST). From the results, it is observed the proposed structure is operating at 3.4 GHz (i.e., IEEE 802.16-WiMAX-worldwide interoperability for microwave access), 5.15 GHz (i.e., IEEE 802.11a-WLAN-wireless local area network), 3.1-10.6 GHz (UWB-ultra-wideband), and 8-12 GHz (X-band) applications. And it is also observed that the proposed antenna exhibits nearly Omni directional radiation patterns, return loss (S11) <-10 dB and VSWR (voltage standing wave ratio) <2 and gain≤5 dB except at the resonant frequency, 6.75 GHz within the UWB range.**

Keywords—rectangular patch; microstrip feed line; WiMAX; WLAN; UWB; return loss; gain

I. INTRODUCTION

Compared to conventional microwave antennas, patch antennas have many merits such as light weight, less cost, linear & circular polarization is possible, dual polarization and dual frequency antennas will be made possible, compatible with MMIC (Microwave Monolithic Integrated Circuits), designs, etc. However the serious disadvantages of microstrip patch antennas (MPAs) are lower bandwidth (BW) and efficiency [1]. These drawbacks can be overcome by introducing ultra wideband (UWB) technology. The Federal communications Commission (FCC) had assigned an unlicensed band of 3.1 to 10.6 GHz for ultra wideband communications in Feb. 2002 [2]. The UWB antennas have several merits compared to conventional patch antennas such as large bandwidth (7.5 GHz), low power consumption (nW), high data rate (> 100Mbps), low complexity, low cost, good time domain resolution etc. [3]. In [4], an elliptical patch with defected ground having step slots was presented to produce UWB characteristics. In [5], an L strip antenna having inverted shape with coplanar waveguide feed and defective ground for UWB applications was proposed. In [6], a triangular patch was designed for providing ultra wideband communication. In [7], a novel antenna having CPW feed for UWB applications was designed. This antenna provides constant return loss and low group delay throughout the frequency band. In [8], a rectangular monopole with truncated ground plane was introduced to operate over a wideband of 3.1 GHz – 11 GHz frequency range. An elliptical patch antenna with co-planar waveguide feed was implemented in [9] to provide UWB characterization. In [10], a monopole elliptical antenna which gives minimum ringing and dispersion of the pulses in time domain were designed. In [11], a UWB octagonal patch with defected ground structure was presented. This antenna produces good impedance matching characteristics by substituting a matching transformer between patch and feed line. In [12], a square patch with parasitic structure and pairs of slots wich are rotated L shape was presented to enhance the bandwidth which includes UWB. In [13], a rectangular antenna which produces triple band like WLAN, WiMAX, and UWB applications were presented. In [14], a patch which has two parallel slots and the antenna became E shaped to produce wideband characteristics for wireless communications. In [15], a U shaped stub is excited by a feed and rectangular slot in the ground was presenting UWB characterization. This paper presents a rectangular slot antenna in which a rectangular patch is excited by CPW feed line to operate at WiMAX, WLAN, UWB and X-band applications. The organization of this paper contains introduction, geometrical structure of

antenna, results and discussion, Far-field gain patterns, surface current distribution and conclusion.

.

II. GEOMETRICAL STRUCTURE OF ANTENNA

The Schematic representation of proposed antenna is depicted in Fig.1. This occupies the volume of (Lp×Wp×Tp) mm^3. A ground plane of size Lg×Wg mm^2 is fabricated on FR-4 material having the dimensions of 50×50×1.6 mm^3.an aperture size of 27.1×40.1 mm^2 is etched on the ground to obtain the wider BW. The parametric values of the proposed structure are represented in table. I. This antenna is operating at various wireless communications that is shown in return loss plot.

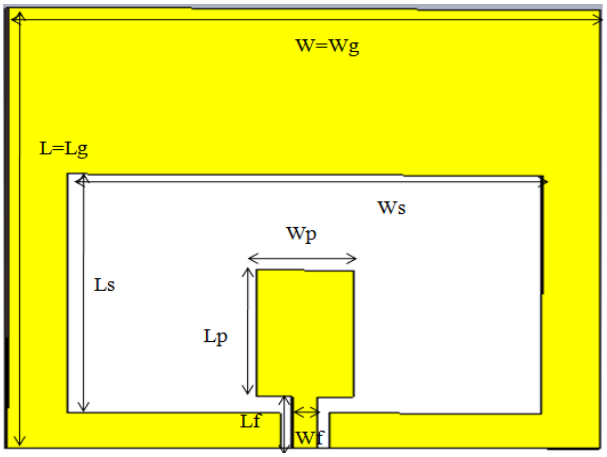

Fig. 1. Desired structure of antenna

TABLE I. ANTENNA PARAMETRIC DIMENSIONS

Parametric symbol	Parametric Value (mm)	Parametric symbol	Parametric Value (mm)
L	50	Wf	2.1
W	50	Tf	0.1
H	1.6	Lg	50
Lp	9.4	Wg	50
Wp	8.2	Tg	0.1
Tp	0.1	Ws	40.1
Lf	4.5	Ls	27.1

III. DISCUSSION OF RESULTS

In our work antenna design software (CST) is used to design and simulating antenna. By optimizing the antenna parameter values, the required return loss (S11<-10 dB) and VSWR (<2) are obtained. Here the S-parameter, S11 represents the square of the ratio of incident wave to reflected wave at the input terminals of antenna. VSWR represents how well the load is impedance matched to the source. The required MPA is operating in the frequency band of 1.48-12.34 GHz, in which it operates at 3.4 GHz (WiMAX), 5.15 GHz (WLAN), 3.1-10.6 GHz (UWB) and 8-12 GHz(X-band) frequencies. These resonating frequencies are shown in S-parameter plot. The antenna provides an absolute bandwidth of 10.86 GHz and fractional bandwidth of 157.16%. The simulated return loss, VSWR and radiation gain pattern at resonant frequency are depicted in Fig. 2.The best value of return loss and VSWR occurred at 1.75 GHz are -27.7 dB and1.08.The far field gain at resonant frequency 6.75 GHz is 6.2 dB.

IV. FARFIELD GAIN PATTERNS

The antenna far-field gain patterns in 3-dimensional (3D) and 2-dimensional (2D) H & E plane patterns are represented in below fig. 3 at 3.1, 3.4, 4, 5.7 and 10.6 GHz frequencies from (a) to (o). From these patterns, we concluded that the antenna produces nearly Omni-directional patterns and gain is almost less than or equal to 5 dB except at the resonant frequency, 6.75 GHz. The far field gain values at different frequencies are tabulated in Table II.

VI. CONCLUSION

A CPW fed ground slotted rectangular patch antenna was designed and simulated by CST. The antenna produces wider bandwidth of 1.48-12.34 GHz, which includes WiMAX, WLAN, UWB and X-band. This antenna also provides S11=-27.7 dB, VSWR=1.08 and almost gain≤5 dB except at the design frequency, 6.75 GHz. The antenna also exhibits nearly omni-directional patterns and also observed the surface current distribution at various frequencies. This antenna is meant for short range and low gain. The transmit power will be increased to increase the range and gain will be increased by antenna array. This antenna is suitable for various wireless communications.

***Abstract*—Data fusion is the process in which integration of multiple data sources produce more consistent, efficient, and useful information than that provided by any of the individual data source. The fusion methods can be broadly classified with the help of class information. The fusion methods such as serial feature fusion, parallel feature fusion and canonical correlation analysis (CCA) does not contain any class information. That is, they are unsupervised fusion methods. The methods such as cluster CCA, Generalized Multiview Analysis, Linear Discriminant Analysis, Multiview Discriminant Analysis, Discriminative Multiple CCA, Locality Preserving CCA (LPCCA), BGLPCCA, MGLPCCA contain class information. Applications of each fusion methods are also taken into consideration.**

Keywords—Fusion; CCA; Supervised; Locality Preserving; Discriminant Analysis.

I. INTRODUCTION

Real world comprises of huge amount of information. Information can be a text, image, video, audio and so on[1]. This information is obtained from multiple sources and through various acquisition techniques. It is also known as multi modal information. The importance of this type of information is growing expeditiously. Thus, information fusion is becoming significant research topics in pattern recognition, deep learning [2], biometric authentication, real time human action recognition [3][4], behavior recognition [5] etc.

The data obtained from single source can undergo various issues such as noise, unacceptable error rates, occlusions, variations in light conditions and so on. Several attempts were made to improve the performance of systems which capture data from only single source, but they were not so effective due to the problems listed above. Here comes the idea of information fusion, fusing data from different sources and improve the quality of extracted knowledge. The interpretation and integration of two or more information are very important for the effective usage of data in various applications. Information fusion is mainly used in three concepts [6]:

i. Preprocessing: Quality of the raw data is increased before data mining tasks are applied using information fusion in this step. This is referred to as data cleaning.
ii. Model Building: Information fusion is applied to data for building model. It is used in two ways either to define a model or to combine several data models.
iii. Information Extraction: To build summaries or conclusions from the original raw data, to reduce number and dimensionality of records.

Information fusion is considered as the natural integration of multiple sources, features extracted, and the decision thus formed. Information fusion is widely applicable in human action recognition too. Since, it is inefficient or insufficient to characterize various motions of a person. This invariance [7] is due to the variability of same actions by same or different person, and due to the variability of different actions by same or different person. Information fusion thus combines different feature vectors to provide efficient results [8].

In multimodal information fusion we are using data collected from different and variety of sources, these are helpful to improve the classification or recognition accuracy. This multimodal information has the capability to provide complete and effective description of specific pattern with intrinsic characteristics. Fig.1. shows the fusion process.

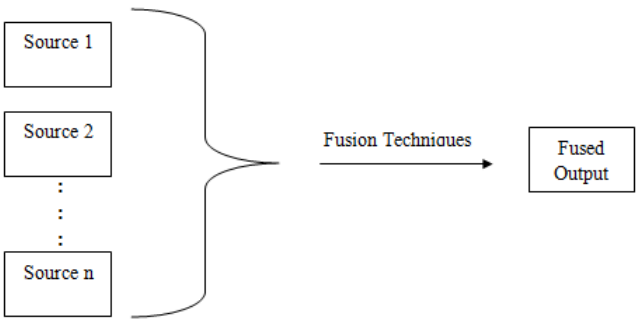

Fig. 1. Fusion Process

The major challenging task in this type of information fusion is the finding of effective method for the task. This method should provide high performance and efficient results. This

survey focuses and discusses on different fusion techniques and their applications in real life.

The rest of this paper is organized as follows. Section 2 briefly provides an overview of the fusion techniques which also explains different supervised and unsupervised fusion techniques. Section 3 compares different fusion techniques. Section 4 concludes the paper with future scopes.

II. FUSION TECHNIQUES

Information fusion is comprised of discriminative feature selection, identification of redundant features and their elimination, preserve information and computational complexity. Information fusion techniques can be broadly classified into supervised and unsupervised fusion techniques. Information collected from multiple sources are then given to the efficient fusion techniques which are capable of making effective use of those information and brings upon more accurate results. A faulty or poorly designed multimodal system could degrade the whole performance of the system and bring upon negative impact.

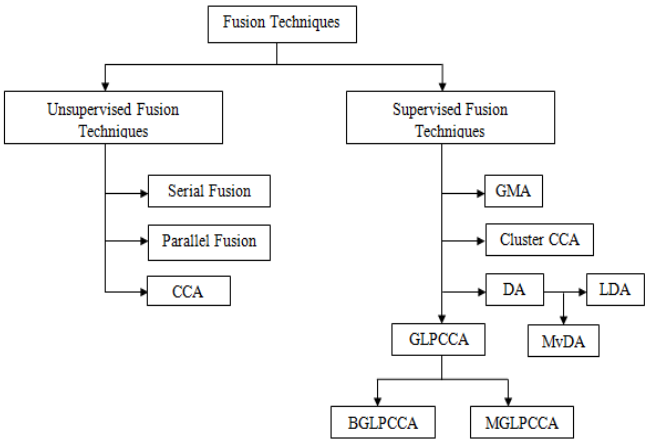

Fig. 2. Overview of Fusion Techniques

Fig. 2. shows how fusion techniques are divided based on their prior knowledge and all. Fusion techniques can be broadly classified into supervised and unsupervised fusion techniques based on the predefined class information. Supervised fusion techniques are those techniques in which predefined class labels are given and training is done on behalf of that. The supervised fusion techniques are then classified into GMA, Cluster CCA, DA, and GLPCCA. While unsupervised techniques are those techniques which do not have any predefined training set and these techniques are classified into Serial fusion, Parallel fusion and CCA.

A. Unsupervised Fusion Techniques

This section discusses about various unsupervised fusion techniques and how it is useful for producing efficient results and their applications in real world. Unsupervised fusion techniques produce results without making use of any training sets.

Serial Fusion [9] is considered as a type of incremental fusion, since it is a method of combining observations from one source to the other sources. In other words, serial fusion can be considered as an information fusion model between two sources. This kind of fusion combines two or more sets of features into a union vector. There exists two feature sets namely, *X* and *Y*. Feature set *X* has *m* dimensions and *Y* has *n* dimensions. Serial fusion will provide a *(m+n)* - dimensional feature vector.

In *Parallel Fusion*, we use a fixed set of sources where all observations from sources are drawn to a central fusion center. It is generally used in reliable information from multiple sources, but their type should be the same or the data should be of equal status. And the solution to this problem is zero padding the lower dimensionality to have same size Parallel fusion model produces better results than the serial fusion model [9]. It produces a complex vector rather than a union vector after combining feature sets.

Canonical Correlation Analysis (CCA) [10], is a type of technique which is used to find a common shared space between two sets. This common shared space maximizes the correlation between the feature samples from two sets. CCA is considered as a version of PCA with multiview. Two views with additive noise related to a hidden class is given, CCA possess a subspace where covariance of noise is directly proportional to the signal covariance. CCA is a multivariate technique which is one of the least frequently used. But is a useful strategy when there are continuous variables for estimating the strength of relationship between two or more dependent and independent variables.

TABLE I. UNSUPERVISED TECHNIQUES

Technique	Application	Description
Serial Fusion	Collaborative Signal Detection	Uses sequential probability ratio test (SPRT)
	Personal identity verification	Fusion between fingerprint and face matchers
	Arrhythmia Classification	Fusion of SVM and logistic regressions
	Iris Recognition	Incremental approach which optimizes the time complexity
	Liver diseases classification	Uses a two-level serial feature fusion procedure
Parallel Fusion	Collaborative Signal Detection	Uses tree-based aggregation scheme
	Channel aware decision fusion in wireless sensor networks	Incorporates fading channel layer
	3D shape-based face recognition	Use combination rules such as consensus voting, rank-sum, nonlinear rank-sum and highest-rank majority rule.
	Membrane Protein Subcellular Localization	Represents the protein sample in complex space.

	Prediction	
	Fusion in distributed sensors	Uses a multiple level parallel decision fusion model
	Kalman Filter	Two-layer fusion structure
CCA	Intelligence and Executive Functioning	Used to found out that the executive functioning measures maintain unique variance with the intelligence.
	Remove Muscle	High performance than a low-pass filter.
	Artifacts from the Electroencephalogram	MANOVA procedure utilized for canonical analysis
	Tourism Industry	n use a steady-state visual evoked potential
	Brain-Computer Interface	(SSVEP) in brain-computer interface (BCI) systems.
	Climate Prediction	By highlighting the spatial patterns of predictor or predictand.
	Fast Active Appearance Model Search	Efficient in modelling the dependency between model parameters and texture residuals.

B. Supervised Fusion Techniques

This section discusses about various supervised fusion techniques and how it is useful for producing efficient results and their applications in real world. Supervised fusion techniques are those techniques which have predefined class information for predicting future labels or for further processing.

Generalized Multiview Analysis (GMA) is a fusion technique which helps in cross modal or cross view classification and retrieval. It can be generalized to further unseen classes and bears an efficient solution which is based on Eigen value. It is also applicable in multiple domains. It is an extension of CCA [11]. Kernel GMA maps to a non-linear space then carries out GMA which helps in obtaining projection directions v_i for the i^{th} view. This is considered as the first step towards multiview feature extraction and a superior alternative for CCA. It leads to a discriminant common subspace. It only considers intra-view discriminant information but not inter-view discriminant information. And also, an extension of Fisher Discriminant Analysis when it is applied to cross-view matching.

Cluster Canonical Correlation Analysis (Cluster CCA) is used in two sets of data points for joint dimensionality reduction [12]. It also helps to find discriminant low dimensional representations that could maximize the correlation between two sets. Meanwhile, it segregates the data sets into different classes. Kernel cluster CCA is an extension of cluster CCA which takes into account the nonlinear relationships between the data sets.

Discriminant Analysis (DA) is used in classifying objects into two or more mutually exclusive and exhaustive categories [13]. Discriminant analysis can be broadly classified into *Linear Discriminant Analysis (LDA)* and *Multiview Discriminant Analysis (MvDA)*. LDA is a supervised data dimensionality reduction fusion technique [14]. It considers the relationships between the various training images and their relationship to the training set as a whole; not plainly use the training set to find the basis vector. The very first stage of the LDA is the labelling of the training data set, which in turn specifies that all images of a single specimen is in the same class and images of different specimen are in the different classes of the training set. The next stage is the cluster separation analysis which uses separation matrix. LDA method makes it easier to distinguish the classes into various clusters by minimizing within-class correlation and maximizing between-class separation.

Discriminative Multiple Canonical Correlation Analysis (DMCCA) is used for information analysis for multimodal and fusion [15]. And is responsible for the extraction of high discriminant characteristics of multimodal information representations. It also finds feature set that could maximize within-class correlation and minimize between-class correlation which in turn can bring upon better utilization of the multimodal information. To bring discriminability, DMCCA uses all features; to bring cross-view correlation, uses all observations from different feature sets; It uses smaller set of parameters. It helps in revealing the complementary representations and the intrinsic structure from different modalities to improvise the recognition task. Different patterns are represented among identified multiple feature subsets by minimizing the Frobenius norm [16].

Globality Locality Preserving CCA (GLPCCA) is a fusion technique which preserves both local and global structures during establishing the correspondences. It improves the discriminative power of the features. Locality Preserving CCA(LPCCA) is used to capture the local structure of given data samples but not the global structure and preserves the local structure in the new found out learned space. GLPCCA is a modifies version of CCA to include both local and global structure details [17]. The GLPCCA technique can be classified into Biset GLPCCA (BGLPCCA) and Multiset GLPCCA (MGLPCCA). BGLPCCA is fusion technique which deals with learning the common feature subspace between two sets. MGLPCCA deals with three or more sets for fusing [18].

TABLE II. SUPERVISED TECHNIQUES

Technique	Application	Description
	Face Recognition	multiple posture images of person are used to

GMA		learn pairs of pose-specific projection directions.
	Text-Image Retrieval	Semantic Correlation Matching (SCM) with a linear kernel is used.
	Facial Expression Recognition	Uses a Discriminative Shared Gaussian Process
Cluster CCA	Cross-Modal retrieval	Brings high correlation between text and image
	Energy Calculation	reproduces high accuracy configuration-interaction correlation energies
DMCCA	Handwritten Digit Recognition	Applicable for postal mail sorting, bank check processing, form data entry etc.
	Audio-based Emotion Recognition	By fusing prosodic features, MFCC features, formant frequency features.
	Visual-based Emotion Recognition	Gabor wavelet features are used to represent visual information
LDA	Analysis of facial images	Allows objective evaluation of the significance of visual information in different parts of the face for identifying the human subject.
MvDA	Face recognition across pose	Performance improvement by employing more discriminant information in both inter-view and intra-view variations.
GLPCCA	Human action recognition	Fuse depth and RGB modalities

III. COMPARISON

TABLE III. COMPARISON TABLE OF FUSION TECHNIQUES

Techniques	Advantages	Disadvantages
Serial Fusion	Fusion model between two sources	Used for fusing from two sources only
Parallel Fusion	Applicable to reliability information from different sources while the type same	Data needed have been obtained or data of equal status
CCA	Multiple dependent and independent variables.	Lacks class information
LDA	Supervised data dimensionality reduction	Homogeneity of variance
GMA	Helpful in cross view application & retrieval	Impossible to compute within-class variations with single sample per class.
cluster CCA	non-linear relationships between two sets	correlation between same classes
MvDA	Even applied to classes not presented in training set	Cannot be used when there is insufficient data to define sample means
DMCCA	Cross-view correlation is obtained from all observations from different feature sets	Can be used only with a much smaller set of parameters
GLPCCA	Improves the discriminative power of features	Difficult to form the projection matrices

Table III is a summary of the performance of fusion techniques discussed so far. The table describes about the advantages and disadvantages of each fusion techniques.

IV. CONCLUSION

In this survey, we have surveyed about different fusion techniques which could bring more efficient results. We have analyzed different fusion techniques and classified them into two dimensions: supervised fusion techniques and unsupervised fusion techniques. The fusion techniques are used to reduce the size of feature set to be given for further processing. Supervised fusion techniques are used nowadays since it increases the chances for better results. The most recent supervised fusion technique is the Biset or Multiset Globality Locality Preserving Canonical Correlation Analysis (BGLPCCA or MGLPCCA) which preserves both the local and global information of the data samples. Even though, they are very much useful for wide sector of fields they have drawback too. they got a complex problem in forming the projection matrices. Future works of fusion techniques could be aimed at optimizing this problem of forming projection matrices.

Swheel: Low-Cost Smart Wheelchair with Wireless Control

Tushar Agarwal, Shloka Bhalgat, Chirag Khandhar, Bhumika Khetan

Department of Computer Engineering, Sinhgad College of Engineering, Pune, Maharashtra, India

***Abstract*- The aim of this project is to make a low cost, multi-modal control and an easy to operate a smart wheelchair. To meet the user-specific needs we have implemented a prototype for a smart wheelchair having two major features: (1) Android based application which includes touch-enabled buttons, gesture recognition, voice recognition, and (2) Remote OS installation mechanism. The proposed system is capable of obstacle detection with object detection using Ultrasonic Sensor with real-time object distance, and slope detection using three-axis accelerometer. The accuracy of our system is 91.58% for slope detection as calculated by the 3-axis accelerometer on a variety of slopes and 85.85% for obstacle detection for a variety of obstacles as detected by the ultrasonic sensor. Also, it can send an SOS message which is a notable feature of this project. All these features are controlled wirelessly using Bluetooth on an Android-based application.**

***Keywords*: Smart Wheelchair, Low-cost, Android Application, Wireless controlled, Remote Firmware Update, Slope detection, Obstacle Detection.**

I. INTRODUCTION

According to Census 2011, the disabled population by type of disability in India is found to be significant in the case of movement or locomotive disability. Going by the numbers the movement type disabled population is found to be the highest with 5,436,604 people out of a total 26,810,557 disabled in all, which is approximately around 20.

Although the ongoing improvements in science and technology have changed the way a typical individual carries on with his life, there are a certain group of individuals who have not yet been able to gain an advantage from this advancement. Specifically, impaired individuals that have restricted versatility are not able to do things which a fully functional human (physically) can do. A smart wheelchair aims to help those incapacitated and physically disabled people by empowering them with portability which would incredibly encourage them to do various things and flourish in life. We have aimed to solve this problem based on the Census 2011's report which suggests that the highest number of disabled populations by type is "Locomotive Disabled."

There are no sources in the current document.

Specific mention of the following was made in the definition for Census 2011:

Paralytic persons

- Those who crawl
- Those who can walk with the help of an aid
- Have acute and permanent problems of joints/muscles
- Have difficulty in balancing and coordinating body movement
- Have loss of sensation in the body due to paralysis, Leprosy, etc.

Table I. Disabled Population by Type of Disability in India (2011)

Type of Disability	Persons	Males	Females
Total	26,810,557	14,986,202	11,824,355
In Seeing	5,032,463	2,638,516	2,393,947
In Hearing	5,071,007	2,677,544	2,393,463
In Speech	1,998,535	1,122,896	875,639
In Movement	5,436,604	3,370,374	2,066,230
Mental Retardation	1,505,624	870,708	634,916
Mental Illness	722,826	415,732	307,094
Any Other	4,927,011	2,727,828	2,199,183
Multiple Disability	2,116,487	1,162,604	953,883

Thus, significant research has been carried out so far for the development of a smart wheelchair, which ultimately aimed at packing maximum features on their proposed model, but not many could achieve this and finally restricted their scope. We aim not to eliminate this trade-off but to minimize it in the maximum possible way. This means packing maximum features at a low cost is the aim of this project.

II. SYSTEM OVERVIEW

The smart wheelchair is capable of obstacle detection with the Ultrasonic sensor. Also, slope detection using three-axis accelerometer, along with this facility of sending an SOS message is a notable feature of this project. All these features are controlled wirelessly using Bluetooth on an Android-based app and aim at providing these features at an affordable price. Following Fig. 1 shows the overall system architecture.

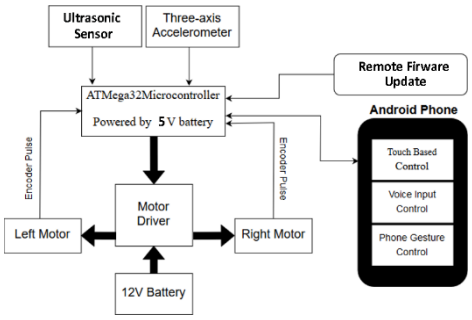

Fig. 1 System Overview Diagram

As per the above diagram, the system is powered by Atmega 32A microcontroller which is controlled through an android application (Swheel). The two important sensors viz. Ultrasonic Sensor for Object Detection and Three-axis Accelerometer for slope detection are also connected to the microcontroller. For the physical locomotion two motors, each of 150rpm is connected through its respective motor driver to the microcontroller. The input power requirement for the motors to operate is 12V which is further stepped down to 5V to power the microcontroller.

There is also a provision to connect a USB programmer which meets the Remote Firmware Installation feature.

III. FUNCTIONAL OVERVIEW

A. Multimodal Input: It refers to the provision of multiple modes to operate the wheelchair through an android application viz. Touch-enabled buttons, Gesture recognition using an accelerometer and, Voice recognition.

B. Obstacle Detection: Obstacle detection is done using the Ultrasonic Sensor where the motion will be suspended for some time until the pathway is clear. This feature has a high priority because it accounts for the user's safety.

C. Slope Detection: Slope detection is done using the 3-axis accelerometer. If any slope detected which is more than the defined threshold then the motion of the wheelchair will be stopped and an SOS message along with the user's location will be sent to the emergency contacts. This feature has a medium-to-high priority because of the threshold calculation.

D. SOS Message Support: SOS message support is provided using the android app. The user can send an emergency message along with the current location to the emergency contacts. This feature has medium priority owing to circumstances which "may" occur. Its usage will be limited.

E. Remote Firmware Update: Firmware updates of the wheelchair will be provided using a web app where the user can download the latest burnable firmware file. This file must be burnt using an executable burner software called "Swheel Burner" to transfer the latest released code to the wheelchair.

IV. OPERATIONAL DETAILS

We have used Atmel Studio for programming of the ATmega32A and Android Studio for the mobile application. The PCB and circuit diagram are designed using EasyEDA and Proteus. The Gerber format specification file created is then used to print the PCB which is mounted atop of the chassis. The circuit diagram given below represents the interconnections between all the circuit components required for the wheelchair. This is the primary circuit of our hardware unit which justifies all the necessary components and connections required.

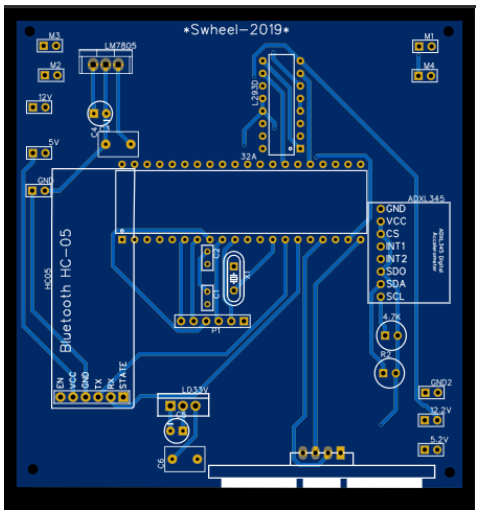

Fig 2. PCB Design

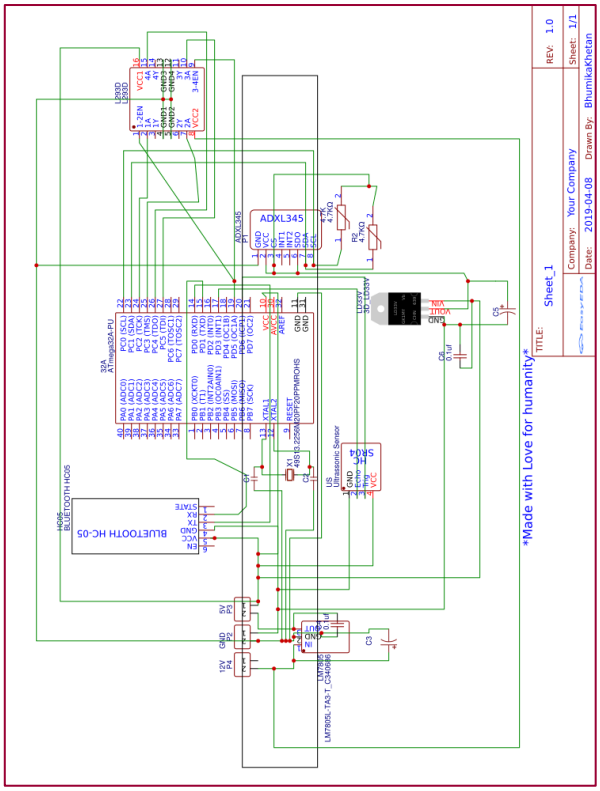

Fig 3. Circuit Diagram

A. Bluetooth Connectivity: The Bluetooth adaptor for the Android phone is checked. If found, the client class makes a socket with the Mac address of the device. the data transfer is done using the send receive class where a buffer is used to store the sent MPC as shown in Table II. We are using the USART module for Bluetooth connectivity. USART is used for communication between ATmega32A and HC-05 which is in turn connected to Android phone. We are enabling receiving and transmitting module in USART. Also, interrupt receiving is enabled.

Table II. Message Passing Codes

Operation	Code	Flow
Forward	F	Mobile to Controller
Backward	B	Mobile to Controller
Left	L	Mobile to Controller
Right	R	Mobile to Controller
Stop	S	Mobile to Controller
Toggle	T	Mobile to Controller
Obstacle Detected	O	Controller to Mobile
Slope- greater than or = 45	a	Controller to Mobile
Slope (Up)- 15 to 45 degrees	b	Controller to Mobile
Slope(Down)- 15 to 45 degrees	c	Controller to Mobile
Slope- less than 15 degrees	d	Controller to Mobile

B. Manual Input: Five buttons are given for manual input as follows- Left, Right, Forward, Backward and Stop. After selecting one button the related MPC as shown in Table II will be sent from Android to HC-05. HC-05 will transfer these codes to microcontroller ATmega32A using use USART module interrupt receiving. At the receiving end, the microcontroller will take those codes and according to the specified functionality, the movement of the chair will be deciphered.

C. Gesture Input: The readings from the inbuilt accelerometer are used to decide the gesture which is given by the user. It depends on the x, y, and z-axis at which the mobile is held. For example, IF (x less than equal to -4 and x less than equal to 4) and (y greater than equal to -9 and y less than equal to -2) and (z

greater than equal to and z less than equal to 10) is satisfied then FORWARD motion is enabled. The related MPC as shown in Table II will be sent from Android to HC-05. HC-05 will transfer these codes to microcontroller ATmega32A using use USART module interrupt receiving. At the receiving end, the microcontroller will take those codes and according to the specified functionality, the movement of the chair will be deciphered.

D. Voice Input: Using the Android TexttoSpeech and RecognizerIntent libraries the voice control module is implemented. The TexttoSpeech object the default language which the user is using on his/her phone. The input will be given in the same language itself. However, we have targeted only the Indian disabled community so English, Hindi, and Marathi will be preferable. After the input is given using the Google text to speech window, the result is displayed on the user's screen. The RecognizerIntent object is used to read out the input command from the screen. The related MPC as shown in Table II will be sent from Android to HC-05. HC-05 will transfer these codes to microcontroller ATmega32A using USART module interrupt receiving. At the receiving end, the microcontroller will take those codes and according to the specified functionality, the movement of the chair will be deciphered.

E. Obstacle Detection: Ultrasonic sensor is being used for obstacle detection. The trigger in the ultrasonic sensor is used for transmitting ultrasonic sound is activated for 15µs. After that, the microcontroller will wait for the Echo of that sound. Based on the time required for receiving the echo we will estimate the distance of the nearest object. If the obstacle is not within a safe distance to the user, then the MPC as shown in Table II for obstacle detection will be sent to the Android phone.

F. Slope Detection: ATmega32A is connected to ADXL345 for slope detection. ADXL345 uses TWO WIRE INTERFACE for communication with ATmega32A. Three-axis values will be determined by the accelerometer module. These values will be used for slope calculation for the wheelchair. If the slope is safe, then the corresponding MPC as shown in Table II will be sent to the Android phone. If not, the motion of the wheelchair will be halted, and the call and SOS message feature will be activated.

G. SOS Message and Call: The telephony library in Android is used for SOS call and message. First, the SMSmanager object is created and then the permission for allowing the application to make call and SMS for allowing the application to make calls and SMS is checked. If allowed, the default SMS is sent to the entered phone number. Similarly, to make a call, action call intent is called.

H. Remote Firmware update: Using this functionality developers can release firmware updates for the wheelchair. Following are the steps to be followed:

Step 1: As shown in Fig. 4 user need to open our web app.

Step 2: Click on Download Update Button.

Step 3: Connect the wheelchair to the PC using a USB cable provided along with the kit.

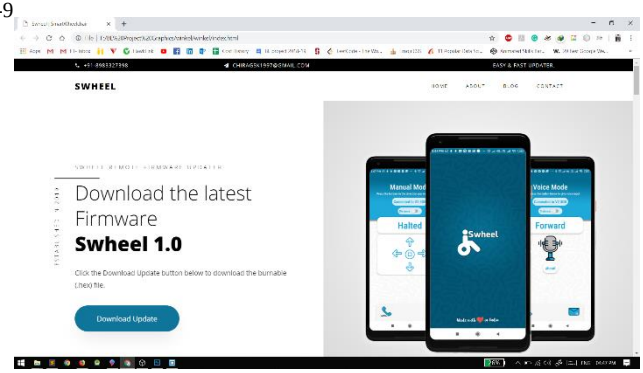

Fig 4. Web app for downloading the latest firmware.

Step 4: As shown in Fig 5. Open the Swheel Burner Application provided along with the kit and select the downloaded file from the file picker.

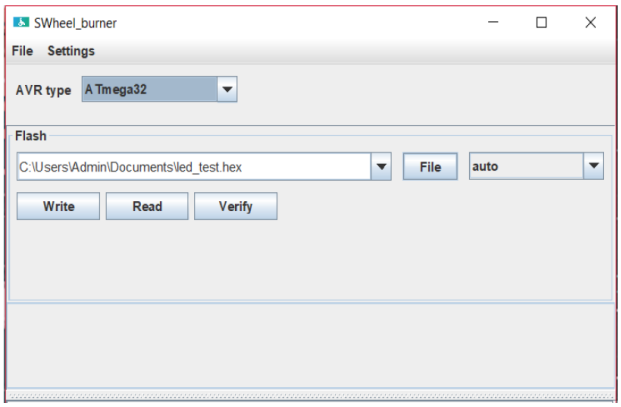

Fig 5. Swheel Burner for burning the firmware.

Step 4: Click Verify and then Burn.
In this way, new firmware can be installed on the wheelchair.

V. COST

It would cost ₹2,500 for developing the system (Kit). In addition to it, wheelchair cost would vary as per the user requirement. Following table describes the cost of the components required in building up this system.

Table III. Cost

No.	Item	Rate(INR)	Quantity	Price(INR)
1	ATMega32 Microcontroller	120	01	120
2	Motor Driver	42	01	42

VI. RESULTS AND DISCUSSIONS

The following Fig 6 shows the snapshot of our Android application along with the snapshot of the prototype.

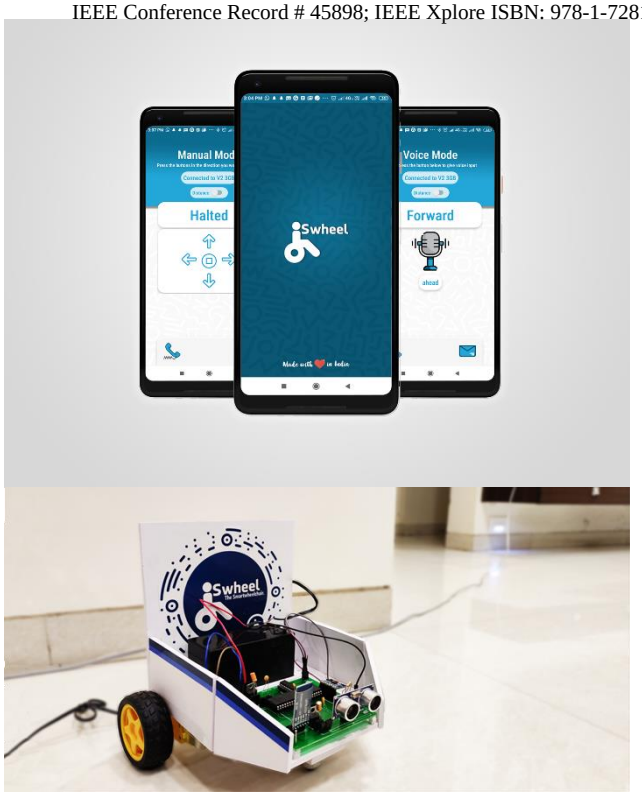

Fig 6. Application and Prototype snapshots

The system was tested for Slope Detection and Obstacle Detection for over 100+ values. The following Table IV illustrates the observed versus the calculated readings obtained by the accelerometer for slope detection.

Table IV. Accelerometer data values

X	Y	Z	Calculated	Observed	Accuracy

976	-40	-384	68.41	73.41	93.19
Mean Accuracy					91.58

The above Table IV illustrates the value returned by the 3-Axis Accelerometer, which is used to calculate the angle of the chair with the surface on which it is rested i.e. the slope. This is calculated using the following formula:

$$\boldsymbol{\theta = \tan^{-1}\left(\frac{X}{\sqrt{Y^2 + Z^2}}\right)}$$

For example, if the Accelerometer returns the X, Y and Z co-ordinates as say, X = 392, Y = 44, Z = -828 then,

$$\theta = \tan^{-1}\left(\frac{392}{\sqrt{44^2 + (-828)^2}}\right)$$

$$= \tan^{-1}\left(\frac{392}{\sqrt{1936 + 685584}}\right)$$

$$= \tan^{-1}\left(\frac{392}{\sqrt{687520}}\right)$$

$$= \tan^{-1}\left(\frac{392}{829.168}\right)$$

$$= \tan^{-1}(0.4728)$$

$$\theta = 25.30°$$

Thus, the calculated values of the angle are verified with the observed value. The observed values of the slope are calculated using Plum Bob method. Thus, testing the prototype for over more than 50 test cases on a variety of surfaces, we have achieved an accuracy of **91.58 %**.

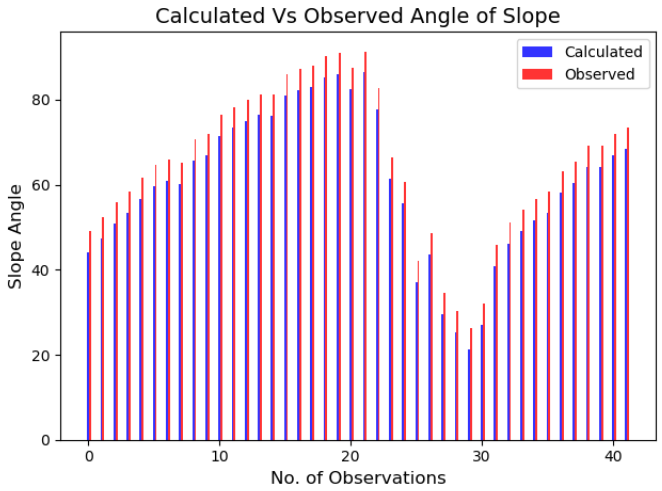

Fig 7. Calculated Values against the Observed value of the angle of Slope

The following Table V illustrates the observed versus the calculated readings obtained by the Ultrasonic Sensor for obstacle detection.

2027	34	36	94.44
Mean Accuracy			85.85

The above Table V illustrates the value returned by the Ultrasonic Sensor, which is used to calculate the distance of an object in front of its line of action. This is calculated as follows:

Speed of sound = 340 m/sec

$$\frac{1}{Speed\ of\ sound} = \frac{29.412\mu s}{cm}$$

$$Distance = \left(\frac{Time\ \times Speed\ of\ sound}{2}\right)$$

… The denominator is 2 because sound travels back and forth.

∴

$$Distance = \left(\frac{Time}{2\ \times 29.412}\right)$$

$$Centimeters = \frac{(microsecond/2)}{29}$$

$$Centimeters = \frac{(microsecond)}{58}$$

Thus, Time is returned by the sensor as output,

$$\boldsymbol{distance = \frac{pulse}{58}}$$

The distance obtained is rounded off to the nearest lowest integer.

For example, if the ultrasonic sensor returns a pulse value say 274 then,

$$distance = \frac{274}{58} = 4.724\ \approx 4cms$$

Thus, the calculated values of the distance are verified with the observed value. The observed values of the distance are calculated manually using a metric scale. Thus, testing the prototype for over more than 50 test cases on a variety of objects, we have achieved an accuracy of **85.85 %.**

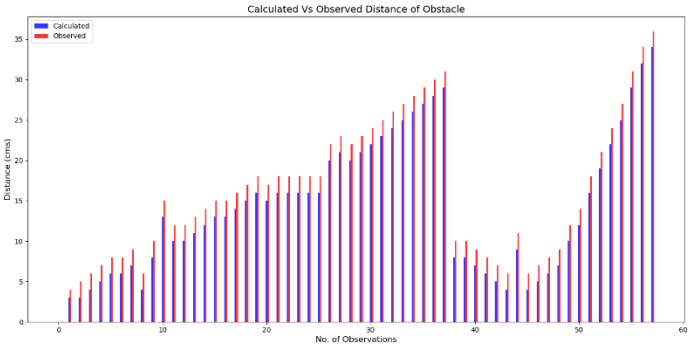

Fig 8. Calculated Values against the Observed value of the distance of the obstacle.

With all these results, the responses on the slope are observed carefully by testing on different slope angles. The Overall accuracy of this system is also compared with the accuracy calculated in the referred base paper titled" Low-cost Smart Electric Wheelchair with Destination Mapping and Intelligent Control Features [1]. The accuracy achieved in this publication is 76% for a 20-degree slope and 96% for the horizontal surface. Whereas our system has achieved an accuracy of 91.58% for a variety of slopes and horizontal surfaces ranging from as low as 20 degrees to as high as 86 degrees.

Table VI. Results

No.	Type of Test	Number of observations	Accuracy
1.	Slope Detection	100	91.58%
2.	Obstacle Detection	120	85.85%

VII. CONCLUSION

In this paper, we have constructed a model of a smart wheelchair which is controlled using an Android phone offering touch, voice control, and gesture-based input modes. Different types of safety measures such as slope detection, real-time distance-based obstacle detection, SOS message, and call are successfully assimilated. Also, a feature for remote OS installation/update is also provided. Everything aforesaid is done in consideration to attain a low cost of the wheelchair.

The accuracy of our system is **91.58%** for slope detection as calculated by the 3-axis accelerometer on a variety of slopes and **85.85%** for obstacle detection for a variety of obstacles as detected by the ultrasonic sensor. The accuracy of slope detection may decrease on a bumpy surface. Overall, the accuracy can be increased by doing 3D surrounding mapping and by GPS outdoor navigation which is a part of the future work.

We have therefore successfully targeted disabled population which accounts for up to 20 percent of the total disabled population in India. Finally, the developed prototype ensures to provide a low-cost, smart and wireless alternative to help the physically challenged, which has a tremendous impact on society.

Greater improvement and feature increments can be made to upgrade client experience and reliability, for instance, by incorporating with EEG signal or EOG signal, finger gesture, 3D surrounding mapping, and so on. GPS module can also be included for tracking and outdoor path navigation. The range for obstacle detection can be improved by incorporating the SONAR sensor.

***Abstract*: Home automation is a very important part of "The Internet of Things" popularly called as IoT. IoT provides a solution for seamless control over all the appliances at home. Home automation exists since many decades for controlling basic equipments of home like the lights and simple appliances. Present Technology expects the world to be interconnected with a touch of fingerprints or simple voice commands. The aim of it is to design and construct a home automation system which will switch on or off any household devices that are connected to it, using microcontroller, mobile or Alexa with the help of Wi-Fi. It is socially relevant and its implementation is cost effective. In our project controlling of appliances or equipment is through Alexa or mobile. We have also included an important aspect that is home security by making provisions for door (open and close), movement, fire and gas leak detection. The controllers used here are Node MCU and Arduino mini for automation and security respectively. We are using solar panels as the source of power for the equipments. It has a charging unit and a smart power management unit.**

Keywords: Microcontroller, Alexa, Arduino mini, Node MCU, Solar panels

I. INTRODUCTION

In the 21st Century of Computer age, many tasks are automated. Automation makes every task easier, safer, faster, and cost effective covering a variety of technological capabilities which can be easily installed in our home. It includes controlling the home remotely through a computer or phone by programming the gadgets so that they respond to the variable conditions. All the appliances at home can be centralized too. This new features of home automation not only makes it efficient and easier to operate, but also help in maintaining well. Device can be activity monitored which gives us live updates about the action to be taken. For example, a monitoring furnace reminds us about the cleaning to be done, AC reporting about changing the filters. A lot of countries around the world are using fossil fuels to generate electricity. They are depleting resources and also cause a lot of pollution to the environment. Although it is cheap to use fossil fuels to now, it will eventually cost a lot when the world's fossil fuel starts depleting. That is why more studies and researches have to be done on renewable energy such as solar energy, wind energy, and more as they will be the best source of energy when fossil fuel are depleted.

We in our project are introducing a smart power management system; the solar energy is harvested and used to supply power to carry out the automation and security of the home. We are calling it smart power system because it can switch between solar power and main power based on the availability of the harvested power. The paper demonstrates the complete home automation which is IoT based. Section 2 discusses the overview of the home automation system, section 3 discusses the complete description of the system used to have a home automation system with security. Section 4 and 5 discusses the BLYNK and ALEXA app and their usage in IoT communication and voice controlling respectively. Section 6 discusses the validation of the complete system.

II. OVERVIEW OF THE SYSTEM

In this home automation system, the commands are given through either Alexa or mobile to the Node MCU controller. It is processed in the controller and relayed thus the appliances are controlled. If the person who wants to operate is inside the house then he can use Alexa to give commands, if the person is somewhere else he can control the appliances through mobile phone using the Alexa app.

The home security is taken care with the help of various sensors like door sensor, PIR sensor, gas sensor, fire sensor and glass break sensor (vibration sensor) to detect open/close of the door, movement, gas leak, fire and glass break respectively [1]. The sensed data is given to the Arduino and a signaling message is sent to the mobile through the GSM module. To provide power to all these devices we are implementing a smart power management system. The power from the solar panel is given to the charging unit which consists of a regulator to regulate the voltage level and an indicator which indicates the battery level. The status of the battery level, duration of the battery and the consumption of power will be given to the user. If the battery level that is the stored solar power is getting exhausted then the devices will be powered by the main power. Thus switching between the main power and the solar power will take place.

III. BLOCK DIAGRAM OF THE ENTIRE SYSTEM

The controller receives command from the Alexa or mobile and relays it to the respective device and thus operates it [2,3]. Also the sensors collect data and send it to the controller which is sent to the mobile as an alert

message. The power supply to perform automation and security is given by the harvested solar power. It is a smart power system which switches between solar power and main power based on the availability of the solar power [4].

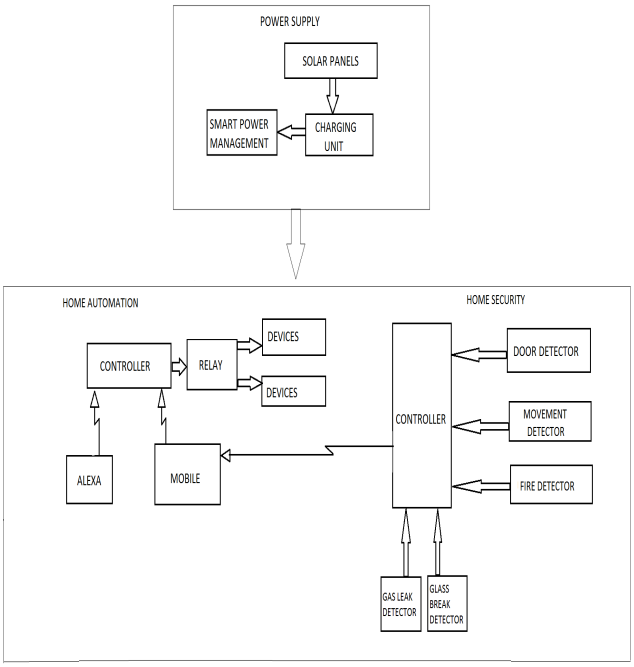

Fig.1: Block diagram of home automation and security system

The solar panel used here gives an output of 21v,30w since the battery used here is of 12v we cannot directly use the 21v output therefore the output is given to the solar charge controller to step down the voltage and making it suitable to use [5].

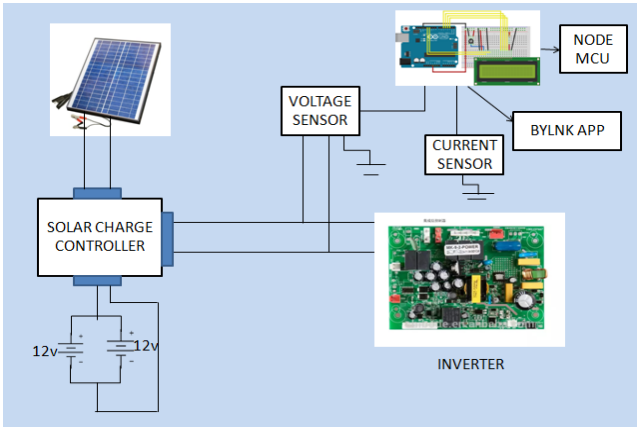

Fig.2: Block diagram of solar power harvesting

The voltage sensor and the battery is parallelly connected to the inverter.The voltage and current are read by the arduino through the voltage sensor and current sensor as they are connected to the respective pins in the arduino. The readings are displayed in the BYLNK app to the user. This solar panel provides a back up power for 6 hours.

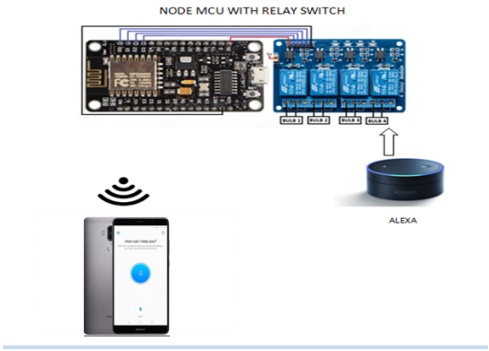

Fig.3: Block diagram of home automation system

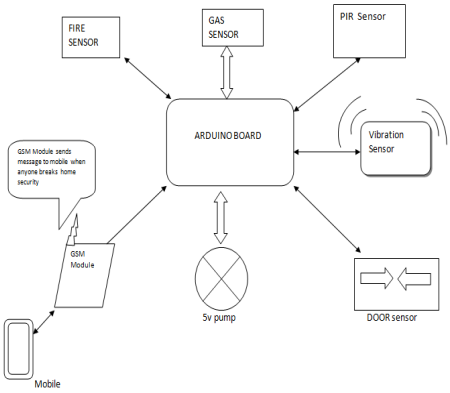

Fig.4: Block diagram of home security system

IV. BYLNK APP

The Blynk app is designed for the IoT. This app can control hardware components remotely, it can also display the sensor data, store it and visualize it. Here the components will communicate with each other to build a fully functional IoT application that can be controlled from anywhere through a preconfigured connectivity type.

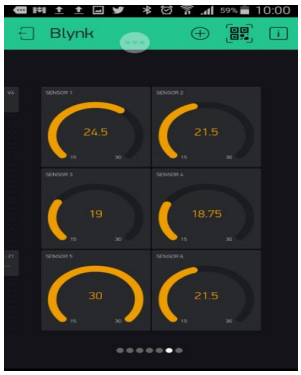

Fig.5: Preview of Blynk App

We can control our hardware from the Blynk app running on our mobile device through the Blynk Cloud or Blynk's personal server. It will work the same in the opposite direction by sending rows of processed data from hardware to your Blynk app. This app has a send on release option, that is, when you move joystick widget, commands are streamed to the hardware, and during a single joystick move you can send dozens of commands. There are use-cases where it's needed, however creating such a load may lead to hardware overload and reset. **Send On Release** is a recommended setting for majority of applications.

There are different types of widgets that control the app. Widgets are interface modules. Each of them performs a specific input/ output function when communicating with the hardware.

The types of Widgets are:

- **Controllers** - used to send commands that control your hardware
- **Displays** - used for data visualization from sensors and other sources
- **Notifications** - send messages and notifications;
- **Interface** - widgets to perform certain GUI functions

V. ALEXA APP

In this proposed work on home automation, ALEXA palys a major role by giving commands through alexa to control the devices when the user is at home. When the user is not at home then with the help of alexa app he can give commands to control the devices. Smart speakers are like gateway devices helping in easy controlling of the smart home.

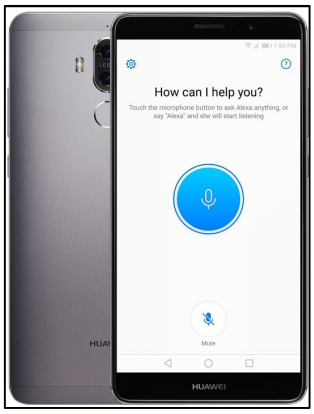

Fig.6: Preview of Alexa App

It gets easier to set up single command groups which can help in controlling multiple lights, plugs and many other devices. Hence, a single command is sufficient to control everything at a time. We can add different devices and rename the devices accordingly.

VI. RESULTS AND DISCUSSIONS

The main aim of the project is to design a system in such a way that by using solar energy we had to control all the devices and we could successfully harvest power from the solar panels which gives us a backup power up to 6 hours as shown in Fig.7 and Fig.8.

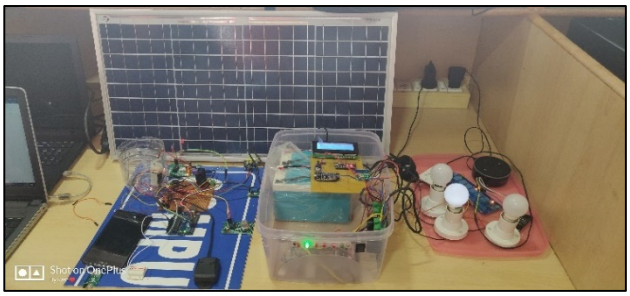

Fig.7: Complete Set-Up of the Project

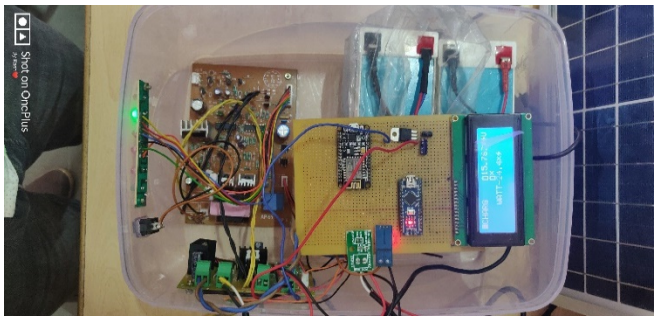

Fig.8: Set-Up of Power Harvesting

We could control the devices at home through alexa and through alexa app and thus we could implement home automation successfully. Refer to Fig.9.

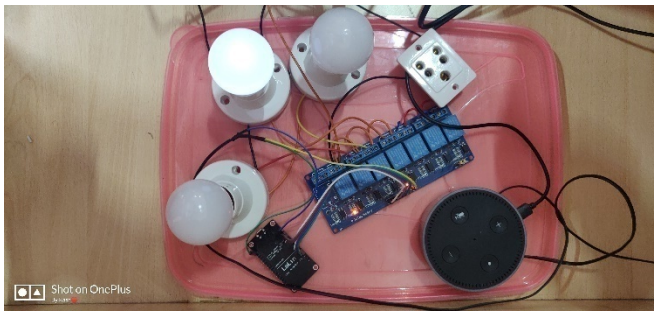

Fig.9: Set-Up of Home Automation

As shown in the Fig.10, the last part of our project is home security where we have deployed all the necessary sensors for various purposes like smoke and flame detection, unusual movement detection, and door and glass break detection. And if there any senses of violation we were successfully able to get messages through GSM module to the mobile phone through an app called BLYNK.

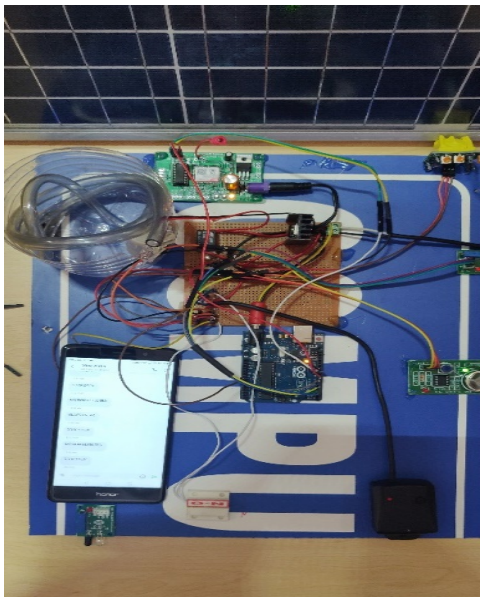

Fig.8: Set-Up of Home Security

VII. CONCLUSION AND FUTURE WORK

Future homes will be capable of offering almost all required services, for example, communication, energy, medical, utility and entertainment. The dream is future in where the data will be communicated between humans and devices without depending on a manual input of individual bytes. Computers can automatically mine data from the database that use the commanded data in changing aspects of home environment.

In future the healthcare service providers will definitely consider automation for effective way to provide remote healthcare services; mainly helping elderly and disabled. As technologies continue to advance, home automation will be a trending technology.

Ultra Wide Band Symmetric Slots Antenna for Wearable Applications

Swetha Amit[1], T R Ramya[2], Vandana S[3], Pooja C R[4]
[1]Assistant Professor, Telecommunication Engineering, Ramaiah Institute of Technology, Bangalore
[2,3,4]UG Student, Telecommunication Engineering, Ramaiah Institute of Technology, Bangalore

ABSTRACT: **A low profile antenna for wearable applications is presented. Due to the miniature and low profile compact and flexible property of the antenna, it is well suited for Wearable applications. Moreover, the antenna is completely embedded in a jean material which is used as a substrate. The substrate chosen gives a good robust against external disturbances and also a good flexibility. A circular antenna with symmetrical slots has been built in HFSS and characterized. It is seen that introducing slots in the circular patch antenna enhances the gain. In this paper, the antenna is analyzed for parameters like, bandwidth, VSWR, return loss, gain, impedance matching. The gain of the wearable antenna is 5.8101. The return loss and VSWR are -21dB and 1.1809 respectively.**

Keywords: Symmetric slots, wearable antenna, HFSS, low profile.

I. INTRODUCTION

Microstrip antenna in circular shape are highly recommended antennas for wideband and it is becoming popular with portable devices. It is very easy to manufacture, low cost, low volume. These reasons make the antenna very feasible to be used in wearable applications. Wearable systems are used to monitor the health of people by sensing, processing, actuating and communicating. A wearable antenna acts is the integrated element between cloth and the communication systems, making electronic device less obtrusive.

In this paper, a circular patch antenna is designed at 2.4GHz. The substrate chosen is a textile material; Jeans with a dielectric constant of 1.4 and height of 1.6mm. The antenna is designed on Ansys HFSS v19, which works on the principle of Finite Element Method (FEM). This technique uses a triangular shaped meshes for surface meshing, tetrahedron shape for volumetric meshing. These structures are chosen for two dimensional and three dimensional analyzing structures respectively.

II. DESIGN OF THE SLOTTED CIRCULAR ANTENNA

Since only one parameter of the circular patch antenna is needed ie., the radius of the circular patch, it is very easy to design the antenna. This makes the antenna having only one degree of freedom. The structure of the antenna is as shown in fig 1. The design considerations include knowing the dielectric constant (ε_r) of the antenna, the operating frequency (fr) and the height of the substrate (h). The radius of the antenna can be calculated by the following equation 1 [1];

$$a = \frac{F}{\left\{1+\frac{2h}{\pi\varepsilon_r F}\left[\ln\left(\frac{\pi F}{2h}\right)+1.7726\right]\right\}^{1/2}} \qquad (1)$$

$$\text{Where, } F = \frac{8.791 * 10^9}{f_r\sqrt{\varepsilon_r}}$$

For the wearable application, we have chosen substrate as "Jeans" of dimensions 38mm*25mm with thickness of 1.6mm which satisfies robustness and flexible functionality. The antenna is designed based on frequency which is taken as 3.9GHz. The circular antenna is as shown in fig 1.

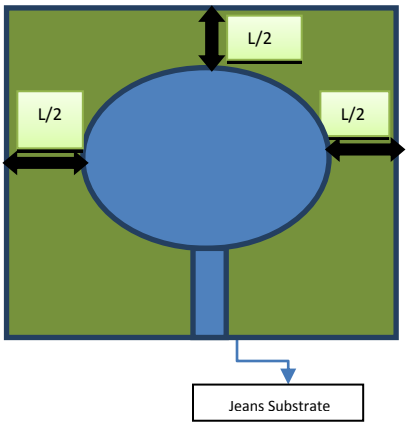

Fig 1: Circular patch antenna

Table 1 shows the dimensions of circular patch antenna with symmetrical slots. The first rectangular slot is chosen to be of dimension 1*19 mm. Further, three iterations are made to the rectangular slot with their dimensions to be 1/3rd the first rectangular slot. Hence the second slot has the dimension of 1*4mm, third rectangular slot has 1*1.3mm and the last slot is of dimension 1*0.4mm. Therefore, for the circular patch antenna, 4 Koch iterations are made so as to enhance the gain of the antenna. Adding slots to the antenna induces capacitance or inductance value which tends to increase the gain of the antenna.

Table 1: Proposed antenna parameters

Parameters	Dimension
Substrate thickness (h)	1
Relative Permittivity (ε_r)	1.4
Ground dimension (mm)	38*25
Patch Radius (mm)	10
First rectangular slot dimension (mm)	1 * 19
Second rectangular slot dimension (mm)	1* 4
Third rectangular slot dimension (mm)	1* 1.3
Fourth rectangular slot dimension (mm)	1*0.4

III. RESULTS AND DISCUSSION

According to the frequency of operation, the designed antenna is calculated at a frequency of 2.9GHz. The antenna was analysed for various parameters like VSWR, S-parameters, Gain, Current distribution. Following figures validates the antenna performance. Fig 2 shows the Symmetric Slotted circular patch antenna with its radiation boundary which tells the near field and far field zone give by the following equation 2.

$$R = \frac{2*a^2}{\lambda} \qquad (2)$$

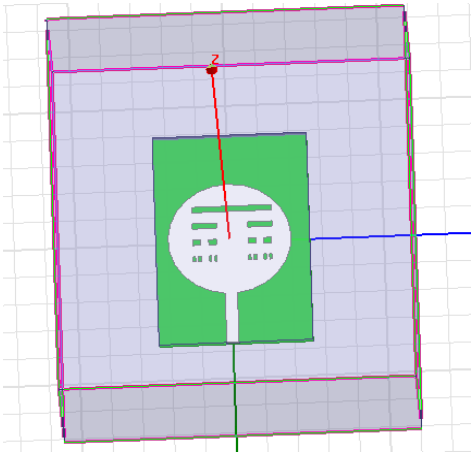

Fig 2: Symmetric Slotted circular patch antenna

Fig 3 shows the lumped port initialized and the patch antenna. The 50 ohm feed line is optimized so as to get a proper impedance matching. The dimensions of the antenna is also chosen such that the design is optimized for the designed frequency.

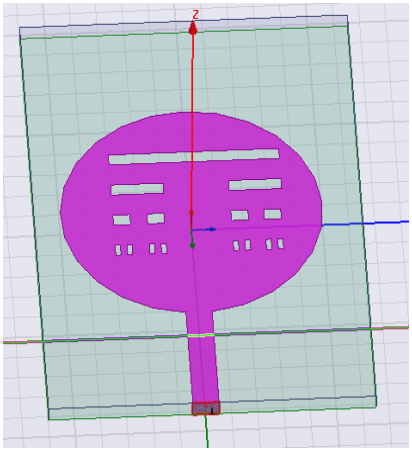

Fig 3: Lumped port initialized and the patch antenna

Fig 4 shows the current distribution in the antenna. Since it is in circular shape, the current distribution tells about the polarization. The antenna is circular polarized which can be used for applications which needs right hand and left hand circular polarized antennas.

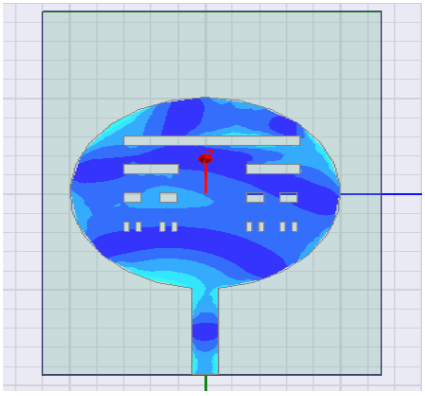

Fig 4: Current distribution in the antenna

The antenna is simulated using the software HFSS and the results were validated. The following fig shows the parameters of interest to be validated the use of antenna. Fig 5 shows return loss of -21dB at 3.9GHz with slots and -15db without slots covering a wideband from 3.5GHz to 5GHz. Fig 6 shows VSWR of antenna with and without slots are less than 2 over a wideband. Though VSWR is same for both with and without slots, we obtain better impedance matching with slots.

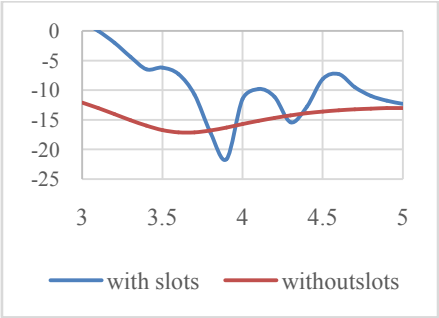

Fig 5: Return loss of -21dB at 3.9GHz with slots and -15dB without slots

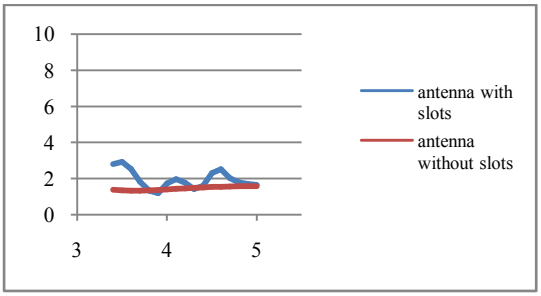

Fig 6: VSWR of antenna with and without slots 1.1809 at 3.9GHz

The bandwidth thus obtained is from 3.5GHz to 5GHz with a centre frequency of 3.9GHz. Thus the percentage bandwidth is given by,

$$Percentage\ Bandwidth = \frac{F_H - F_l}{F_C} \qquad (3)$$

Where, $F_C = Centre\ frequency$

$F_H = Highest\ frequency$

$F_L = Lowest\ Frequency$

On substituting the values, we get the bandwidth of 38.46% which validates the use of antenna as UWB.

Fig 7 shows Smith chart value: 1.080+i0.165. This implies that the antennas is matched perfectly for impedance at 3.9GHz. Fig 8 gives the 3D Radiation pattern of the antenna with a 5dB gain.

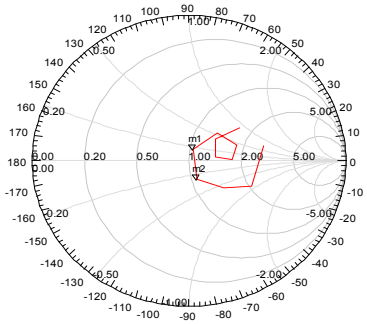

Fig 7: Smith chart value: 1.080+i0.165 at 3.9 GHz

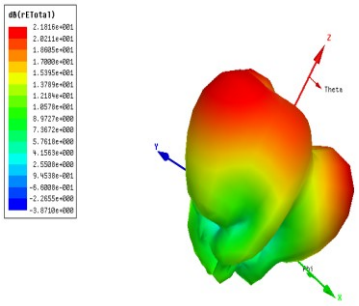

Fig 8: 3D Radiation pattern

Further, few more parameters were checked for the slotted circular patch antenna. Table 2 and 3 shows the parameters and their values at 3.9GHz. The radiation efficiency of the antenna is 86.5%. This implies that the incident power on the antenna is efficiently used since there is a good impedance matching between the feedline and the antenna.

Table 2: Antenna Parameters validated results

Quantity	Value
Max Radiation Intensity	0.201497(W/sr)
Max Directivity	5.56141
Max Gain	5.8101
Radiated Power	0.455307(W)
Accepted Power	2.53215
Incident Power	2.1902
Radiation Efficiency	0.865

Table 3: Radiation parameters

rE Field	Value	(Theta, Phi)
Total	12.3259	(0.872665, 6.10865)
X	8.68542	(0.698132, 3.14159)
Y	9.70529	(0.523599, 1.91986)
Z	9.35585	(1.0472, 6.10865)
Phi	7.63586	(0.523599, 2.26893)
Theta	12.0985	(0.872665, 3.14159)
LHCP	10.896	(0.872665, 5.93412)
RHCP	8.68715	(0.523599, 2.0944)

This circular patch wearable antenna designed on a jean substrate can be used in medical purpose for monitoring, alerting and demanding attention whenever hospital emergency is needed. Also in location based service in supplying the information that is currently needed to the user.

IV. CONCLUSION

The paper presents the design, simulation and validation of circular microstrip antenna at S band. The antenna operates with a good impedance matching. The return loss validates the result for the impedance matching between the antenna and the feeding network. The gain and directivity of the antenna are 5.81dB and 5.56dB respectively. The percentage bandwidth achieved is 38.46%. The radiation efficielcy of the antenna is 38.46% making it use for a wide band application.

In future, the antenna can be integrated with transceivers, microcontroller and sensors for human body monitoring. With the advancement in wearable technology, these devices can be worn on human body and can operate seamlessly.

***Abstract*-With the world moving so fast around us and technology evolving faster than ever, how many of us stop and take a break to cook a healthy meal or even a normal balanced diet meal? We end up going for the easy solution and stop for a burger. Our Smart Kitchen is a way to improvise this situation where the devices in the kitchen, such as, Microwave Oven, Stove, Mixer Grinder and Ingredient Dispenser are all connected by the Smart Refrigerator through a home network which makes the cooking easier as all the devices are communicating to each other controlled by the Smart Refrigerator such as temperature, timing, flavour etc., It also suggests recipes based on the available ingredients. In this paper, we are proposing the concept of Smart Kitchen which is content aware and focuses on personalization for each of its users which in the long term will help in time and waste management, restaurant type cooking and balanced diet. It is an AI driven solution aiming at resolving the problems faced by the current generation and aims at achieving a healthy lifestyle by providing restaurant type cooking in the easiest way possible using AI and ML.**

I. INTRODUCTION

The preparation of food plays a central role in human life. Rapid improvements every day in Artificial Intelligence and Machine Learning powered by Cloud computing has changed the way every household works from a Refrigerator greeting you in the morning to an Induction that reduces the work of every cook, there is a touch of AI and its improvements in every appliance we use at home.[1] The more the people realise the advantages of the integration of technology in their everyday lives, the more the demand for such products. The customers are ready and willing to explore more of it. The consumers are becoming more tech-savvy and want the next big thing in the market at their homes. A Smart Kitchen, where a smart refrigerator is connected to all the other appliances in the kitchen is both personalization and sustainability driven.[2] It has its own unique selling points and is a next-level improvement to today's existing kitchen. The traditional understanding of a refrigerator which was used to store fruits and vegetables or to keep a food cold has changed. These days, smart refrigerator is a device that is connected to the internet and cloud through a network giving it capabilities to develop data and applications focusing on making things easier in the kitchen, optimum and efficient utilization of all the items available and a healthier lifestyle.

In this proposal, we aim at developing a smart kitchen for home where the devices are connected to the Smart Refrigerator where most of the ingredients are stored. The devices are connected and communicating to each other making the routine cooking process easier with minimal supervision. The smart refrigerator also suggests recipes from the cloud database and stores the recipes tried by the user. [3]. The suggestions are personalized based on the customer's taste and requirements for future use. This smart kitchen is restaurant like cooking, personalization and sustainability driven.

Smart Kitchen when achieved will be a revolution to every kitchen making things easier and more comfortable to every user. Using these intelligent devices to bring a range of products and devices reducing the problems faced by homemakers. The smart refrigerator has an idea about all the items stored in it, different ways it can be used in a recipe and its expiration date based on which it suggests recipes to the users. Our smart kitchen proposal takes the smart refrigerator capabilities to the next level where its connected to other appliances. Smart Kitchen, when used to its full extent, will change the eating patterns of every individual leading to a lifestyle change[4].The main reason why people have adopted an unhealthy living is because of lack of time and unawareness about the importance of healthy eating and exercise, laziness and the fast-moving world which disregards the lifestyle of a person. Our smart kitchen will reduce all these problems to a greater extent where cooking

is made easier, the recipes are handed out which is all health oriented and the ability of the devices to communicate with each other about the recipe makes the process easier and the suggested recipe is based on the ingredients available which also avoids the problem of not having an ingredient while cooking. [5]

II. PRESENT SCENARIO

The idea of a smart kitchen environment at homes is not new, there are many ideas which have contributed to the concept of smart kitchen such a user interface robotic arm, sensor enabled kitchen that gives cooking suggestions or instructions through videos and audios, implementing a human behaviour recognition system which stores the actions of humans in the kitchen and suggests new ideas based on the past data etc.,[6] Although these smart kitchen ideas are implemented there are disadvantages to these ideas that are not yet addressed such as:

- The recipes suggested are not linked to the refrigerator which contains the ingredients. Therefore, the recipe suggested might not consider the availability of the ingredients in the kitchen which decreases the convenience of cooking.[7]
- In a smart kitchen, all the appliances such as oven, refrigerator, stove etc are at its best use individually but they are not connected to each other which is again a lot of work for the person cooking and does not make the work easier as much as expected. [8]
- Implementing a healthy lifestyle is an unavoidable component in today's world, these smart kitchens do not consider it as an important feature. They are just focused on making things easier and not healthier. [9]
- There is no automated way to check the progress of the food being prepared like a camera or an alert to notify the progress. Which increases the need of humans to be around all the time when that is the main thing a smart kitchen is trying to avoid to an extent.[10]

A. Problem Statement

To develop a smart kitchen where all the devices such as microwave oven, mixer grinder, stove and ingredient dispenser is controlled by the smart refrigerator through a home network for restaurant like cooking at home which is monitored through a 360-degree camera. This makes the cooking easier and tries to maintain a healthy balanced diet.

B. Objectives

This paper is intended to adapt AI and ML into the devices used in a kitchen connected by the smart refrigerator which assists the other devices in cooking a dish completely.[11] Based on the chosen recipe, the devices adapt and works around the recipe from one device to the other. Even if the user decides to cook their own recipe, the devices are adaptable and stores the information for future cooking of the same recipe. [12]

C. USP of the model

The USP of our model is the network that is developed between the appliances and the refrigerator and its ability to maintain each stage of cooking with minimal human supervision. By integrating AI and ML we are able to better understand the tastes and preferences. This AI features in the smart refrigerator not just understands the items in the refrigerator but how efficiently it can be used in a dish, it also has the ability to control other appliances which renders smooth cooking process. Its ability to adapt and register the new recipes tried by the users is a special feature and keeps the nutrients in check as per the need of the users.

III. PROPOSED MODEL

A. Smart refrigerator

The refrigerator is the centroid which connects all other kitchen appliances through a home network and manages the flow while cooking a recipe. [13] It controls the appliances such as temperature, timing etc. It is also connected to a cloud database of recipes and gives customized suggestions based on the ingredients available and the number of people to be served. [14] It also keeps in check the expiration of the product and makes suggestions based on that. The following devices can be connected to the smart refrigerator network.

1. Microwave oven

The microwave oven is connected to the smart refrigerator. It communicates about the recipe selected and the oven adjusts the temperature and the time as per the requirements.

2. Stove

The stove which is connected to the smart refrigerator also has an automatically controlled valve. Once the recipe is selected, the valve is set as per requirements at different levels and timings are controlled by the refrigerator and the cooking is taken forward from there.

3. Mixer grinder

The mixer grinder is connected to the smart refrigerator. Once the recipe is selected, the

ingredients which needs to be grinded is moved to the mixer and the speed and consistency is selected and controlled based on the recipe or needs of the user through the home network.[15]

4. Ingredient dispenser

The ingredient dispenser is connected to the smart refrigerator. Although this is not a commonly used device is every home, this device when connected to the AI based algorithm in cloud can be very efficient in a smart kitchen. The dispenser has various sections which stores different ingredients such as spices. If the recipe is directly received from the cloud database, the dispenser which has an electronic valve understands the ingredient gives the accurate amount as mentioned in the recipe. The sensors attached to the dispenser is used to check the amount of ingredients to be added.

5. 360 degree - high resolution camera

The smart refrigerator is also connected to a 360-degree high resolution camera which scans and monitors the entire working process in the kitchen. This camera checks the dish at each stage and keeps in check its cooked properly and notifies the user if something goes wrong.

B. Working process

Fig 1.1 explains the working block diagram. The process starts with the smart refrigerator analysing the ingredients in the refrigerator and suggests few recipes based on it and the user can choose one of the recipes as per the interest and feed the quantity needed to serve the number of people in the house. As per the recipe, the ingredients in the refrigerator are taken out and moved to the next step. Based on the recipe, the next needed device is shown by the smart refrigerator according to which the user can move the cooking step by step. [16] The 360-degree camera scans and monitors every step using AI and ML to check the quality, density, colour, mixture and makes sure the dish doesn't get overcooked. It notifies the user to make the necessary changes.

C. Example

In order to comprehend the application of this smart refrigerator, we were given a problem along with how we would tackle this issue.

Problem - Figure 1.2, Martin is a 35-year-old male, he decided to make a brownie for himself for the first time on a Sunday afternoon after absolutely enjoying the brownie he had last night in a restaurant. Initially he tried to bake the brownie just by following the internet recipe and doing it on his own. But he faced various problems like lack of ingredients for which he ran to go out to the store multiple times, the ingredients mix was improper, the cake was burnt due to wrong temperature and the butter and chocolate melt was inconsistent

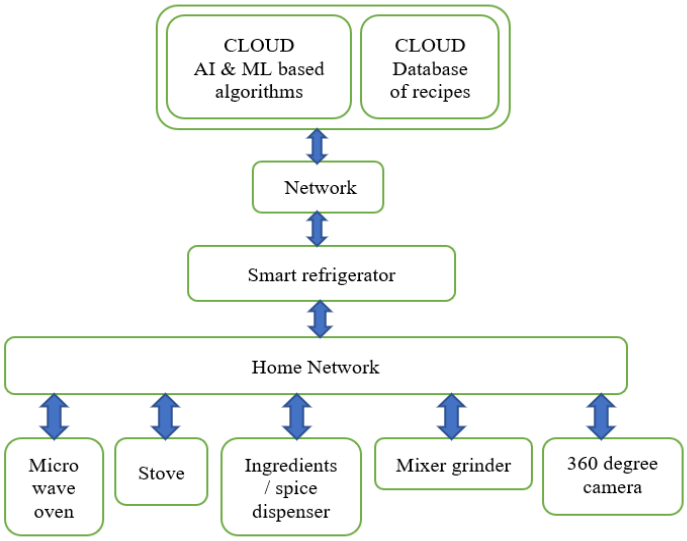

Fig 1.1 Block Diagram

Using the proposed model, he tried to bake the same with the help of a smart kitchen and the process thus went by as follows. First step, he selected the recipe from the cloud database, as per the recommendation by the smart refrigerator. The list of ingredients that was not available was suggested by the refrigerator altogether and the user can buy it in one trip to the store. After the recipe is selected and the ingredients are purchased, the next step is getting the butter and dark chocolate from the refrigerator and melting it. The stove controlled by the smart refrigerator receives the flame level to be maintained and time requirements that these items needs to be melted and adjusts its flame accordingly. Once the mix is ready, the user sets it for cooling. The 360-degree compares the progress of the food with its step-by-step database and alerts if something goes wrong. The next step will be to collect the other ingredients like sugar, flour and cocoa from the ingredient dispenser. The ratio of these items is received from the smart refrigerator and the dispenser dispenses the accurate amount of these items needed. Then the mixer grinder is used to prepare the egg and sugar mix as per the required consistency received from the smart refrigerator. Once all the ingredients are ready with the accurate amount and consistency, it is added to the brownie tin by the user and the tin is placed in the microwave oven. The timing for baking the cake is set up automatically by the smart refrigerator and the cake is ready to be served with no defects as there is a 360-degree camera monitoring the process from step one to the last and notify if something goes wrong. At the end, if the user forgets any step like adding toppings or serving it with ice-cream, the 360-degree camera understands it by comparing it with the database and alerts the user for best results and best tasting food. The use of smart kitchen for baking a

brownie is so much easier and more efficient than baking it manually without the help of the smart kitchen.

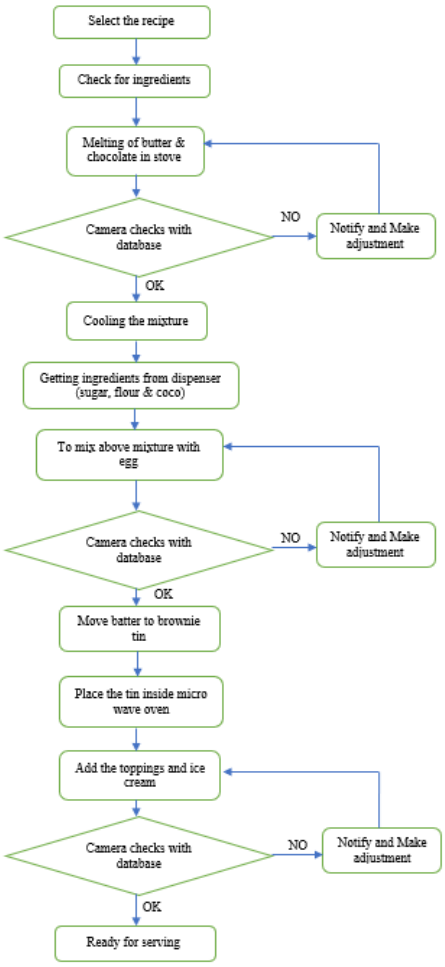

Fig 1.2 Process

D. FUTURE WORK

The future plan for our proposed model is to develop this smart kitchen into a human free kitchen set up where the need for human interaction is minimal to zero. This can be achieved by introducing a robotic arm in the kitchen which is again connected and controlled by the smart refrigerator. Once the recipe that needs to be cooked and the number of people is decided, the smart refrigerator connected to other appliances and the robotic arm takes over from there. And the 360-degree camera keeps in check and notifies if something goes wrong. When this is achieved, cooking becomes very easy and since the kitchen also provides restaurant like cooking, the need to go out and consume unhealthy food is reduced and the complete eating patterns are changed. Since our smart kitchen also provides healthy balanced diet, it is also health focused. However, people might still be interested in cooking their own food, in that case, they can temporarily deactivate the robotic arm and go on with the cooking themselves and use the robotic arm when needed. This smart kitchen makes home-made restaurant like cooking and maintaining a balanced diet very easy which is driven towards making our lives easier.

V. CONCLUSION

This concept of Smart Kitchen which is both AI and ML driven has a great advantage and desirable by the users and is bound to branch out into various other dimensions and appliances that can make the smart kitchen more presentable and automated. The smart kitchen could help the users in making the whole cooking process easy and the benefits of our smart kitchen proposal is double fold. One – Since it cooks restaurant like food, fast food consumption is controlled, packaged food which uses a lot of preservatives is reduced, dependency on the restaurant food is condensed and extra expenses are regulated which in-turn makes their lifestyle better. Two – Smart kitchen is driven towards maintaining healthy balanced diet for its users which is again a feature to attract the users as maintaining good health is a must for everyone. Our smart kitchen idea will open new opportunities and take smart kitchen appliances to a new revolutionary level.

ACKNOWLEDGMENT

We thank our colleagues from Institute of management, Christ (Deemed to be) University who provided us with insights which was a great assistance in shaping our research. We would like to express our gratitude to the faculties and colleagues of Institute of management, Christ (Deemed to be) University.

***Abstract*— In this paper, an approach to transfer data securely is proposed. First, from the sender side, the data is encrypted using Rivest-Shamir-Adleman (RSA) algorithm and then this encrypted data is hidden using Least Significant Bit image steganography concept in a image of the web page and its url is sent to the receiver. Then, at the receiving end, the encrypted data is obtained that is hidden in the image of the web page whose url is sent. This encrypted data is decrypted using the same RSA algorithm . When the sender sends the data to the receiver and incase this data is obtained by the third person or an intruder he will see a URL being sent. Then he will open the URL and he will find a webpage, and he would not find any data being hidden. Then he will try to view the source code of the webpage, and then also he would not find any data being hidden. Thus, the intruder will be assured that no data is been hidden in this and chances are more that he would not go to decode it further. Hence, the chances of doubt an intruder can get that some confidential or private data is hidden in the data being sent is reduced. And hence, the data sent by the sender to the receiver is secured.**

Keywords—RSA, Cryptography, Steganography, LSB

I. INTRODUCTION

Data security is the major issue that people face. Since, we want to make data unreadable by the third person and hide the fact from the third person that data is been sent, we are going to discuss about cryptography and steganography concept. Cryptography consists of the concept of transforming the data into a form that cannot be read by the unwanted users. In cryptography, data is converted to a form that is known only to the sender and the receiver. But it wont hide the fact that some data is being sent. In symmetric key encryption process where same keys are used for encrypting and decrypting the information. In this symmetric system only one key is used to encrypt and decrypt the data. That is, same single key is used for both encryption and decryption and this key will be known to both sender and the receiver and hence it is kept private. Since the key used here is of shorter length, data manipulation is easy here. [16] In asymmetric encryption which is also known as public key cryptography. In asymmetric encryption two keys are used, one for encryption and one for decryption. These two keys are known as the private key and the public key. Data is encrypted using public key of the receiver that can be known to everyone and decrypted using the private key of the receiver that is known only to the receiver. Hence, in this kind of systems security is more. In steganography, the fact that the data is being sent is hidden by hiding the data behind the data. The data that needs to be hidden can be anything like text, video, audio, image, web etc. And also the data that hides the data can be anything like text, video, audio, image, web etc.

The RSA algorithm uses 2 keys one public and the other private. The way in which this algorithm works is as listed in table 1. After following steps we will get public key which is e and n and private key which is d and m. We use this to encrypt and decrypt as follows. If data to be transmitted is called message, then encrypted message we get from Equation 1. And for decryption we use equation 2, LSB steganography concept uses replacement of least significant bits of pixels of the image by the data to be hidden. An example of which is given in table 2.

TABLE 1. RSA STEPS

STEPS	DESCRIPTION
1.	Choose two big prime numbers called p and q which are not equal.
2.	Find their product and call it n=p.q
3.	Let m=Totient(n)=(p-1)(q-1)
4.	Choose a small number e , co-prime to m,with GCD(m,e)=1 where 1<e<Totient(n)
5	Find d such that d mod Totient(n)=1

$$cipher = message^{e} mod\ n \dots\dots\dots\dots\dots (1)$$

$$Message = cipher^{d}\ mod\ n \dots\dots\dots\dots\dots (2)$$

TABLE 2. LSB CONCEPT

STEPS	DATA EMBEDDING USING LSB METHOD
1.	Get the pixels of the image in web page
2.	Get the data to be hidden
3.	Replace LSB of each block by a bit of the data to be hidden
4.	Send the image called stego image
STEPS	DATA EXTRACTION
1.	Extract LSB of each block of pixels and combine it to determine data.

The proceeding sections of paper discusses related work, methodology, results and conclusion respectively.

II. LITERUTURE REVIEW

A method was proposed [1] using LSB method of Steganography and RSA method of cryptography. Firstly the text that needs to be embedded in the image is converted into binary form. Now, the image in which the text should be embedded is also converted into binary form. Now, binary form of text is embedded in binary form of image using LSB image Steganography method. Now, stego image equivalent to binary form is obtained. Now, this stego image is encrypted into text form using RSA encryption algorithm. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

An alternate method was proposed [2] using LSB method of Steganography and blowfish method of cryptography. First the image in the suitable format i.e BMP format is used here is encrypted using the blowfish encryption algorithm. Now, this encrypted data is embedded in video by using LSB video Steganography method. The disadvantages of Blowfish algorithm is that it cannot assure authentication and non-repudiation as two people have same key. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

Another alternate paper[3] introduced a method where data is encrypted using RSA encryption algorithm and then this encrypted data is hidden in an image. The disadvantages of this paper is that it cannot hide large data and itt does assure integrity of the data. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

Another paper[4] proposed a method using LSB method of Steganography and blowfish method of cryptography. First the text is encrypted using the blowfish encryption algorithm. Now, this encrypted data is embedded in image by using LSB image Steganography method. The disadvantages of Blowfish algorithm is that it cannot assure authentication and non-repudiation as two people have same key. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper[5] proposed a method using discrete wavelet transforms (DWT) method of Steganography and filter bank cipher method of cryptography. First the text is encrypted using the filter bank cipher encryption algorithm. Now, this encrypted data is embedded in image by using discrete wavelet transforms (DWT) method. The drawbacks of DWT are it becomes it becomes computationaly intensive, it is less efficient and it take some energy to invest in wavelets to become able to choose the proper ones for a specific purpose, and to implement it correcly. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [6] proposed a method in which first data is encrypted using RC4 encryption algorithm and this encrypted data is embedded in 3 different images using 3 different Steganography methods. And finally comparison of theses 3 methods is done. The images used here are of BMP format. The disadvantage of this approach is RC4 is not a secure algorithm because keys used here may be weak. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [7] proposed a method in which image is encrypted first and then converted into text form. Now, this text data embedded into one more image. Now, the stego image is obtained. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [8] proposed a method using cryptography and text steganography. For cryptography, symmetric key algorithm, DES is used. Once the text message is encrypted using DES encryption algorithm, it is hidden behind another text. The text that is used to hide the secret message was created dynamically and it did not reveal the presence of any secret message. Experts have found a weakness in the design of the cipher in DES algorithm. In DES, S box creates same output with two chosen input. In DES the initial and final permutation is not exactly clear and seems confusing. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [9] proposed a method in which text is taken as the input data and it is hidden behind the video. The methods used are DCT and DWT, where, frequency domain coefficient of frames were used. The drawbacks of DCT, when the image is compressed there is a chance of data loss. So, if u need the original image for some other purpose the you have to save the original image as a backup before the DCT method is applied. The drawbacks of DWT are it becomes it becomes computationaly intensive, it is less efficient and it take some energy to invest in wavelets to become able to choose the proper ones for a specific purpose, and to implement it correcly. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [10] proposed a method where, cipher method is used for cryptography and image steganography method is used for data hiding. First, the text data is encrypted using cipher method and then this encrypted text data is hidden behind an image using LSB steganography method. The disadvantage of this approach is that block ciphers work on large amount of data and hence they need more memory. Stream ciphers do not provide integrity protection or authentication and also it is difficult to implement. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [11] proposed a method where, RSA algorithm is used for cryptography and LSB audio steganography method is used for data hiding. First, the message is encrypted using RSA algorithm and then this encrypted message is hidden in an audio using LSB audio steganography method. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [12] introduced a method message is compressed using wavelet transform technique and then this compressed data is hidden behind an image using LSB image steganography method. The drawbacks of DWT are it becomes it becomes computationaly intensive, it is less

efficient and it take some energy to invest in wavelets to become able to choose the proper ones for a specific purpose, and to implement it correcly. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [13] proposed a method in which first the message is encrypted using AES algorithm of cryptography using a key. Now, this key is hashed using SHA-1 hashing algorithm. Now, the encrypted data can be hidden in image or audio or video using LSB method of Steganography. The drawbacks of this approach is that both AES and SHA1 algorithm are difficult to implement in the approached way. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [14] proposed a method in which the original message is encrypted using encryption algorithm using key k. And the encrypted message is converted into ASCII code. After that this ASCII code is converted into binary i.e. in 0's and 1's form. A web page is taken in which data is to be hidden. Then, 4 random methods of hiding data are selected and converted binary data is hidden in a webpage. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

The paper [15] Proposed a method in which the message is encrypted through Data Encryption Standard algorithm and the message is concealed by applying LSB encoding technique in a spiral manner. Experts have found a weakness in the design of the cipher in DES algorithm. In DES, S box creates same output with two chosen input. In DES the initial and final permutation is not exactly clear and seems confusing. However, the chances of doubt an intruder can get that some data is being hidden is not reduced.

From the research we can conclude that, the cryptography and the steganography concept used above is very useful but the chances of doubt an intruder can get that some confidential or private data is hidden in the data being sent is more. In this project, the main purpose here is to fool the intruder and reduce the chances of doubt an intruder can get that some confidential or private data is hidden in the data being sent, by encrypting the data and hiding this encrypted data in the image that is used in the created webpage. Hence, to secure the data sent by the sender to the receiver. RSA algorithm of cryptography used in this approach is safe and secure for its users through the use of complex mathematics. RSA algorithm is hard to crack since it involves factorization of prime numbers which are difficult to factorize. Moreover, RSA algorithm uses the public key to encrypt data and the key is known to everyone, therefore, it is easy to share the public key. LSB method of steganography used in this approach is known for its simplicity. It embeds the bits of the message directly into the LSB plane of cover-image and many applications use this method.

III. Methodology

The data to be sent is read via GUI (Graphical User Interface) on the sender side. The data is encrypted using RSA technique and encrypted data is hidden behind the image and generates a html page with this image as content and its URL(Uniform Resource Locator) is sent to the receiver. The receiver downloads the image in the web page whose url is sent and decrypts the data hidden behind the image. If an intruder gets url he opens the web page or html source of the web page also he will not be able to guess there is hidden data. Figure 1, shows the sendor side process block diagram.

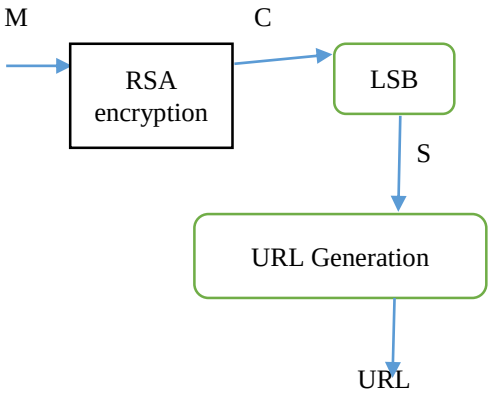

Figure 1. Sendor Side Process

Let M be the message to be sent it is fed to encryption algorithm RSA to result in cipher C. This cipher is then hidden using LSB in a image resulting into S as stego image. The resulting image is put into a web page and its url is sent to the receiver.

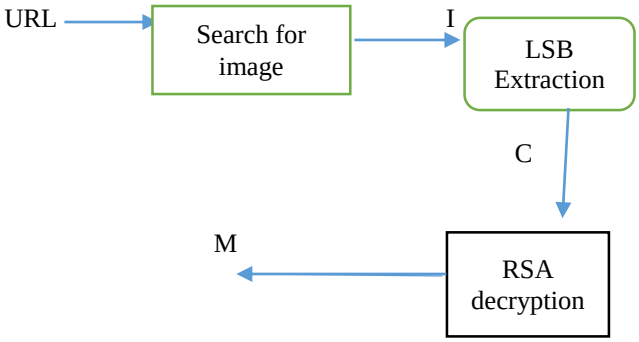

Figure 2. Receiver side process

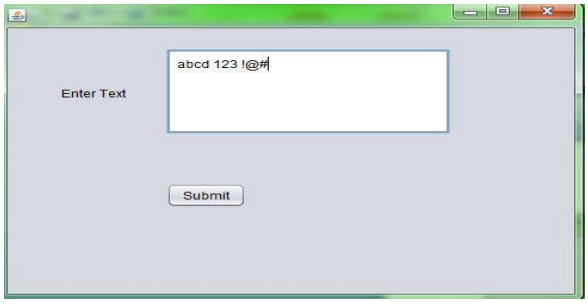
From web page whose URL is received , the image is extracted and LSB extraction is applied to get encrypted cipher C. Then RSA decryption is applied to get the message which is original.

IV. Results and Discussion

Figure 3. shows the graphical user interface for accepting message to be transmitted.



.

Figure 3. GUI to read data to be sent

Figure 4. shows encrypted message output after encryption using RSA.

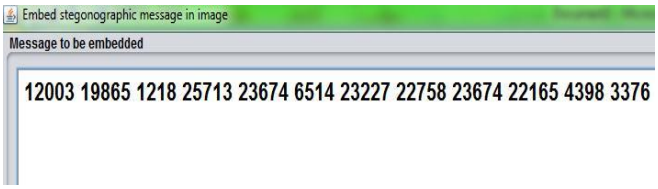


Figure 4. Sender side encrypted data

Figure 5.Shows original and embedded message image.

Figure 5. original and stego image

Figure 6. Decoding Process output

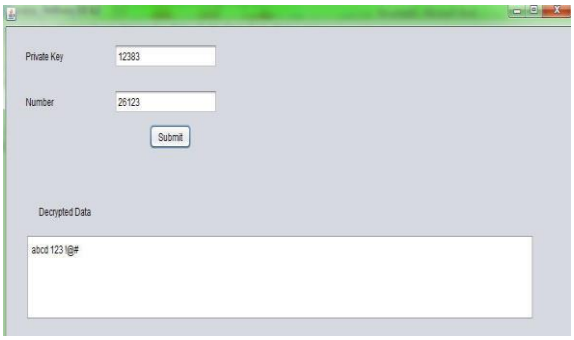

Figure 7. Decryption process output

Figure 6 shows output of decoding process and figure 7 shows decryption step. Figure 8 is the web page containing stego image whose url is sent to the receiver.

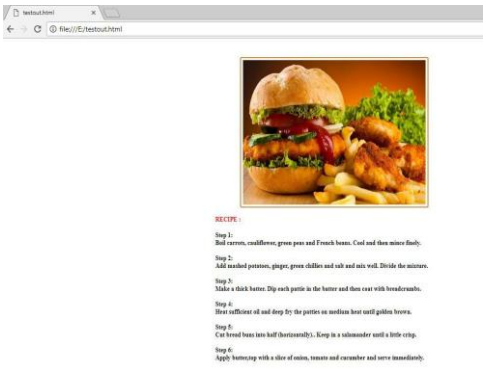

Figure 8. Web page.

When the sender sends the data to the receiver and incase this data is obtained by the third person or an intruder he will see a url being sent as shown in the Fig. 9. Then he will open the url and he will find a webpage as shown in Fig. 8, and he won't find any data being hidden. Then he will try to view the source code of the webpage, then also he won't find any data being hidden. Thus, the intruder will be assured that no data is been hidden in this and chances are more that he won't go to decode it further.

```
run:
Public Key (E,N): 14447,26123
Private Key (D,N): 12383,26123
Please find the the url: E:\testout.html
BUILD SUCCESSFUL (total time: 1 second)
```

Figure 9. Keys and URL.

V. CONCLUSION AND FUTURE SCOPE

This project gives a unique way of hiding the data apart from all other existing methods of data hiding. Hence, the chances of doubt an intruder can get that some confidential or private data is hidden in the data being sent is less when compared to the previous existing methods, since, we have encrypted and hidden the data in the image that is used in the created webpage. When the sender sends the data to the receiver and incase this data is obtained by the third person or an intruder he will see a url being sent. Then he will open the url and he will find a webpage, and he would not find any data being hidden. Then he will try to view the source code of the webpage, and then also he would not find any data being hidden. Thus, the intruder will be assured that no data is been hidden in this and chances are more that he wont go to decode it further. The chances of doubt an intruder can get that some confidential or private data is hidden in the data being sent is reduced. And hence, the data sent by the sender to the receiver is secured.

As an future enhancement some other idea can be proposed using webpage with RSA algorithm and LSB Steganography method to reduce the percentage of doubt an intruder can get that some data is being sent .Also, some work can be done using webpage with RSA algorithm and different Steganography methods and comparing the results. Also, some work can be done using webpage with different

cryptography algorithms and LSB Steganography method and comparing the results.

Abstract— Anxiety distress are excessive or continual panic of everyday circumstances causing behavioral and emotional consequences, eventually leading to diseases like heart attack, epilepsy and dyspnea. Anxiety disorders are common for people with developmental disorders like autism spectrum disorder, cerebral palsy, down syndrome. Patients suffering from these diseases have difficulties in communication and emotional recognition eventually leading to narrow interests and repetitive behavior. Sometimes their ways of communicating any symptoms may not be recognizable by the caretakers, hence building up a need of a non-invasive, continuous, real-time detection and tracking of their ECG signals for prediction of these diseases providing possible medications. Here a system framework based on unscented Kalman filter (UKF) is developed to continuously detect and track the R-R interval for anxiety prediction to make these unpredictable diseases predictable and reducing death tolls with timely treatment.

Keywords—Electrocardiography(ECG);Electroencephalogram (EEG); Unscented Kalman filter (UKF); ECG derived respiration (EDR); Hilbert—Huang transform (HHT); Intrinsic Mode functions (IMF); Respiratory Rate(RR); Heart Rate(HR), Autism Spectrum Disorder(ASD).

I. INTRODUCTION

Heart attack is a major medical emergency usually due to blood clot or thrombosis hence blocking blood flow to the heart leading to cell death. Panic attack as a cause of anxiety disorder is a major symptom of heart attack. Chronic anxiety can lead to changes in body's stress response. Anxiety causing an increase in heart rate can easily be diagnosed through electrocardiography (ECG) diagnosis where normal heart rate is 60-100 beats per minutes [20]. Major symptoms includes pain or stiffness in chest, back, arms etc. But in case of ASD the tracking system is very important as they face issues in feeling and communicating their sense of pain [17]. Apart from ECG the methods used for anxiety prediction mechanism are to study the pupil movement of eyes. People tend to have blurred vision with dilated pupil due to severe stress and anxiety since there is high adrenaline level causing pressure on eye [2] . Skin temperature can reveal the stress intensity having a rapid, short-time temperature drop in homeotherms. Stress sweat is released by the apocrine gland of our body due to our stress or anxiety response [1].Epilepsy being a neurological disease, nerve cell activities of brain is disturbed causing seizures, hence disturbing the normal brain cell communication. Seizures are abrupt electrical exertion in brain cells depending on the epileptic discharge location. They are mainly of two types, unilateral and bilateral. The discharge effects the brain cortex without losing consciousness and secondly effecting both hemispheres to lose consciousness respectively. Electroencephalogram (EEG) is the age old technique for detection, But for the early prediction mechanism, the frequency response of the EEG signal can be combined with the R-R interval for better solutions as the epileptic seizures always brings in a change in heart rate(RR).

Respiratory measurements is an important parameter for clinical diagnosis of anxiety. The normal respiratory rate is 12-20 breaths per minute [10][12]. Dyspnea is indicated as short breath or increased breath rate. Increased anxiety lead to increase in breath rate due to panic attack or increase in heart rate. The heart rate variability method is best used for the prediction mechanism to predict changes in the respiratory rate(RR). To have a non-invasive technique to predict dyspnea, an ECG signal and ECG predicted respiratory signal (EDR) analysis is done.

Electrocardiography (ECG) is the technique of recording the hearts electrical activity called heart rhythms over a time period for its functional information and hence diagnosis of complex cardiac diseases. Normal heart rate is 60-100 beats per minute. The wave characterization involves peaks and valleys with R as the main spike as shown in Fig.1. R-R intervals are taken into account to determine arrhythmia's like:1) Tachycardia referring to increase in heart rate, more than 100 beats at rest, hence a decrease in R-R interval, 2) Bradycardia referring to slow heart rate, less than 60 beats at rest hence increasing the R-R interval. Anxiety leads to an increase in heart rate, [6] shorter R-R interval, increase in breath rate hence a predictable method for detection of heart attack and dyspnea[23].The variations in R-R interval can also be used to predict epilepsy as it varies at the onset of the same. 73percentage of seizure can change up to 15 to 20 percentage of heart rate, 55 percentage changes to 20 beats per minute. This ECG is recorded using a non-invasive

external electrodes called skin electrodes. They record the heart muscles electrical activities generated as pulsating electric waves towards the skin surface. These electrodes are wet sensors and they use a conductive gel to increase conductivity between the skin and the wet electrodes.

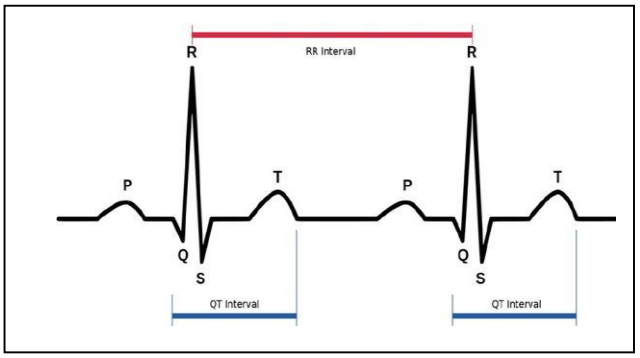

Fig 1. *ECG signal with R-R interval*

Electroencephalogram (EEG) is the test to detect brains abnormal electric activity, for the procedure small metal discs and wires are pasted on the scalp to detect the electrical charges. Mainly used to detect head injuries, brain tumors, epilepsy etc.

A non-invasive technique for tracking of ECG signal using unscented Kalman filter (UKF) technique is developed and predictions from this continual tracking are further used to predict diseases [21]. Extended Kalman filter (EKF) had a very strong disadvantage of linearizing all non-linear models and hence using the linear Kalman filtering equations thus leads to production of highly unstable filter assumption of local linearity [21]. The tracking system is very important as the advantage of a real-time tracking is much more than being subjected to test at the time of seizure or dyspnea. Prediction of such criticality is very important for ASD as they lack communication skills and to sense pain as well.

In Hilbert-Huang transform any non-stationary, non-linear signal is decomposed into intrinsic mode functions (IMF) to obtain instantaneous frequency. This is the algorithm applied to any input signal than being a theoretical tool. They are mainly divided into two parts, one being empirical mode decomposition (EMD) where the main signal is broken into various finite, small and decomposed components and the second being Hilbert spectral analysis (HAS) which examines the instantaneous frequency of above formed IMF as a time function. The section II of the paper contains system overview explaining different techniques, section III having the proposed methodology, section IV with the results and discussions and section V with the conclusions derived.

II. SYSTEM OVERVIEW

A. *Unscented Kalman Filter*

Kalman filter is the basic framework algorithm using a series of measurements with time along with statistical noise with inaccuracies. This algorithm produces estimates of the unknown variable being more accurate than the input signal measurements done by a joint probability distribution of a variable for a given time frame. The major advantages include perfect tracking of linear problem having the disadvantage being no real problems are linear. Any non-linear signals can be divided into smaller linear signals so that the linear algorithm itself can be applicable to the non-linear signal as well, hence giving rise to extended Kalman filter [15]. In this case if the initial estimate is not proper this leads to quick filter divergence hence owing to linearization proving EKF not to be an optimal estimator. The filter tend to have more noise content leading to a reasonable system but not a perfect system. The system is perfect only if the noise content is small. Improvements in EKF leads to unscented Kalman filter for non-linear signal analysis where probability density is approximated by deterministic sampling techniques using unscented transform, setting a set of minimal sample points called sigma points around any given mean. Periodically these points propagate through the non-linear signal function having a new mean and covariance [5]. UKF is the extensively used technique for tracking and evaluation because of its simplicity, robustness, less time and increased accuracy[24].

B. *Hilbert-Huang Transform*

A non-stationary, non-linear input data signal like EEG are divided into various finit, small number of components called intrinsic mode function (IMF) and hence obtain instantaneous frequency of the input signal. Other than Fourier transform, Hilbert-Huang transform algorithm can be applied to a real dataset than a theoretical tool having the advantage of having both frequency and amplitude information with respect to time. The algorithm has mainly two parts empirical mode decomposition (EMD) and Hilbert spectral analysis (HSA). In the EMD part the whole input dataset is divided into extremas i.e. maxima and minima collection over the entire domain range or given domain. There are mainly two conditions to be followed:

1. The zero-crossing must either be equal or different at most by1.
2. Mean value of envelop of local maxima and local minima is equal to 0.

To find the IMF the following procedure is called shifting:

1. Identification of local extrema of the test data
2. Connect all local maxima by interpolation to form upper envelop, repeat the same for lower

The upper and lower envelopes covers all data points between them measuring its mean as m1, having the difference between m_1 and first input component of the range h_1 as in (1).

$$X(t) - m_1 = h_1 \quad \textbf{(1)}$$

This equation must be symmetric with all maxima positive and minima negative having the IMF definition satisfied. In the upcoming shifting h_1 is considered to be the new data hence the shifting equation changes to (2). Then after repeated shifting of k times .$h_1$becomes the IMF and h_{1k} as the first IMF components gives (3).

$$h_1 - m_1 = h_{11} \quad \textbf{(2)}$$

$$h_{1(k-1)} - m_{1k} = h_{1k} \quad \textbf{(3)}$$

□□= sum of $[h_{k-1(t)} - h_{k(t)}]^2 / h^2$ **(4)**

Stoppage criteria of the shifting process: The main type used in this work is standard deviation method (4) and threshold methods. Where the shifting process stops when the deviation is less than an assumed value and in the later method where two values are set with small fluctuations [22]. Once the stoppage criteria are selected, first IMF, c_1 is obtained being the finest scale as the shortest signal component. Follow the above steps finally with residue forming in (5) with residue rn being the monotonic function hence no IMF repetition [22]. To find the instantaneous frequency, Hilbert transform is done on each IMF with u(t) as a real variable with a convolution function of (6). Having the end convolution formulae as(7):

$$X(t) = \text{sum of } (C_j + r_{n\,j}) \quad \textbf{(5)}$$

$$fn(1 \div (\pi \times t)) \quad \textbf{(6)}$$

$$H(u)(t) = 1 \div 2\pi \int_{-\infty} (u(t) \div (T - t))dT \quad \textbf{(7)}$$

C. Cubic-Spline Interpolation

Spline interpolation is one among the type of interpolations, where an interpolate behaves as a type of special piece-wise polynomial called the spline. This has the advantage of having multiple sub-functions at particular period of intervals within the function domain. The errors present are very small even though it gives accurate answer for low degree polynomials of spline. In the prescribed system Cubic-spline interpolation algorithm are used to derive ECG-Derived respiratory signal from the ECG heart rate variability mismatch to obtain a respiratory signal similar to the input ECG. (x_i, y_i):i=0,1,n is the function to interpolate between all the points (xi-1,yi-1)and (xi,yi) with the polynomial equation (8), Where i=1,2,..n.

with curve curvature y=f(x). Spline has the major advantage to minimize the bending of both y' and y" being in the knots above. Hence, only polynomials of degree three or above is the classical approach. Where the ideal case is (9):

$$Y = qi(x) \quad \textbf{(8)}$$

$$1 \le i \le n - 1 \quad \textbf{(9)}$$

$$Q_i(x_i) = q_{i+1}\, x_i \text{ and } q_i(x_i) = q x_{i+1} \quad \textbf{(10)}$$

III. METHODOLOGY

ECG obtained from physionet are filtered and processed to remove artifacts like movement artifacts, baseline wandering, muscle noise etc[19]. A low-pass and high-pass filter is cascaded to get a band pass filtering so that low frequency interference and high frequency artifacts are removed [4] [19]. From these signals R-peak detection and R-R interval detection are done using the conventional Pan Tompkins detection algorithm [4]. Algorithm consists of the following major steps as in Fig.2: low-pass filter, high-pass filter, differentiators, squaring operators, adaptive thresholding, moving window integrator and R-peak detection.

A the low pass and high pass filters are cascaded forming a band pass filter (5Hz-11Hz) having lower or high frequency interference removed for noise rejection function having a sampling rate of 200 samples/sec [11] [20].For determining the slope, derivative or differentiator block is used. In the prescribed system a 5 point derivative is used. Smoothening is done to determine the height of the wave and avoid higher peak distortion. Squaring function is to obtain the positive output and amplifies non-linearity with point-to-point squaring technique. Feature information of peaks is obtained by moving window integrator with its width N approximately equals to widest possible QRS complex [13]. The Pan Tompkins works with altering thresholds to find R-peak and other parameters periodically to adapt to changes hence reduction in false peak detection to get accurate heart rate [3]. They mainly make use of slope, amplitude and width of the ECG waves for R-R interval prediction [16][18].

As shown in the Fig.3 after the R-peak detection the major part of the project is the continuous R-R interval tracking of the system. The early existed system only traced the existence of anxiety but this is the continuous tracking system, using unscented Kalman filter (UKF) framework. These continuous tracking are used for continuous monitoring of the ECG signal for various disease prediction. UKF provides an extended range of accuracy when compared to Kalman filter at the same range of complexity. This technique has unscented transform (UT) as its fundamental component by using a set of assumed weighted points to define the mean and covariance of probability distribution.

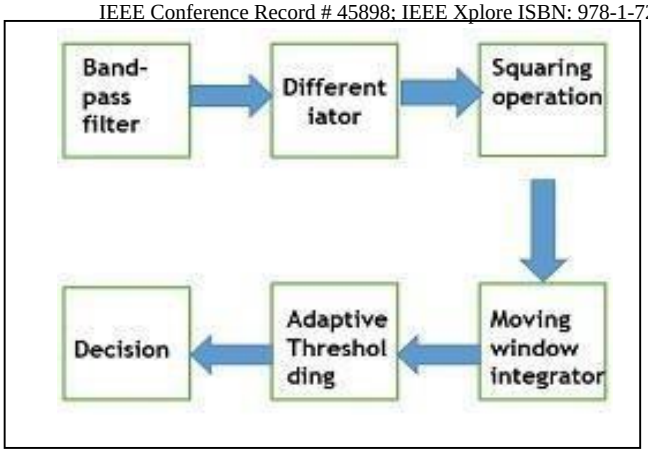

Fig 2. *Pan Tompkins block diagram*

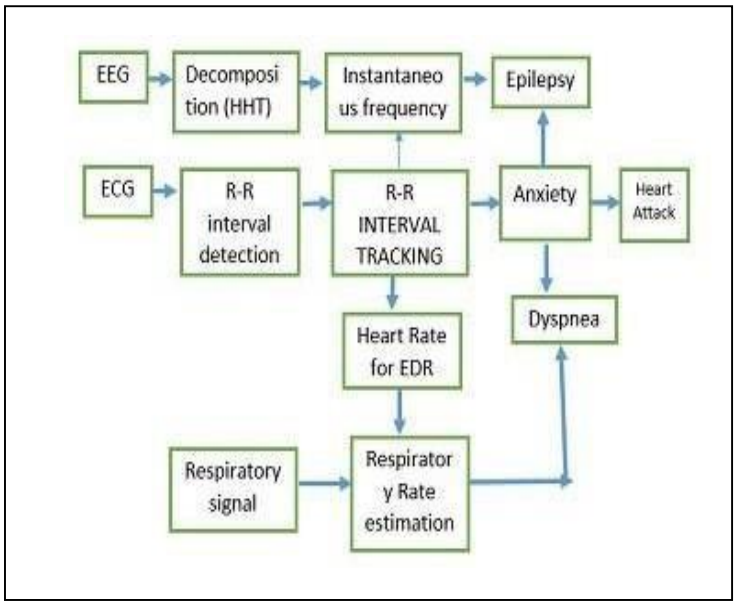

Fig 3.*Block diagram*

The transformation consists of certain steps: Predict new state and the covariance along with noise content [5].

$\hat{x}_{(k+1/k)}$ **(11)**

$P_{(k+1/k)}$ **(12)**

The system contains state-space equation model with (13) (14) governed by prediction step having the estimate of current state variable and uncertainties and updating step being updated by a weighted average having higher weight to higher uncertainties [5]. Mathematically the system equations can be denoted as:

$x_k = x_{k1} + w_k$ **(13)**

$y_k = x_k + v_k$ **(14)**

In equation (13)(14) where Xk is an ideal slow varying R-R wave with time k and wk, vk being the Gaussian noise.

$\hat{x}_{(k+1/k)} = \hat{x}_{(k/k)}$ ***(15)***

$P_{(k+1/k)} = p_{(k/k)} + Q_k$ ***(16)***

$\in_k = y_k \hat{x}_{(k-1/k)}$ ***(17)***

$G_k = P_{(k+1/k)}$ **(18)**

Equations (15) (16) are the prediction and (17) (18) are updating steps respectively. The final outlook of the state space equation is given by (19) (20)

$\hat{x}_{(k+1/k+1)} = \hat{x}_{(k+1/k)} + G_k \in_k$ **(19)**

$P_{(k+1/k+1)} = P_{(k+1/k)}\, G_k\, P_{(k+1/k)}$ **(20)**

The system works in real time as it require only the present state and just past state uncertainty matrix information rather than the past information. UKF has a deterministic sampling technique called unscented transform (UT) towards picking minimum set of points around the mean called the sigma points to propagate through non-linear function with new mean and covariance estimate. To obtain the weight to be applied we use equations having WS0,WC0,WS1 AND WC1 being the weights to be updated as in (21)(22)(23) and α, K being the control sigma points, β – the distribution as in equation (24).

$$ws0 = \frac{\lambda}{\lambda + L} \quad \textbf{(21)}$$

$$wC0 = \frac{\lambda}{\lambda + L} + (1 - \alpha^2 + \beta) \quad \textbf{(22)}$$

$$WS1 = wC1 = \frac{1}{2(\lambda + L)} \quad \textbf{(23)}$$

$$\lambda = \alpha^2 \ (L + K) - L \quad \textbf{(24)}$$

Here 2n+1 sigma points are considered for n dimensions. After R-R interval tracking, anxiety is predicted whenever there is decrease in R-R interval, normal R-R interval being 0.6 to 1.2sec hence increase in heart rate [6]. Further beyond anxiety prediction the system leads to the prediction of three main diseases which is heart attack, epilepsy and dyspnea[25].

From the available ECG, ECG-Derived respiratory signal (EDR) is obtained [7]. Whenever there is a variation in the R-R interval of the ECG there is an amplitude or heart rate variability mismatch in the signal. Hence EDR can be obtained from either of the methods. After R wave detection and RR interval calculation, Heart Rate (HR) can be calculated as (25). cubic spline interpolation and moving average operation over the particular HR value can bring about EDR.

$$HR = 60 \div \text{R-R INTERVAL} \quad \textbf{(25)}$$

To estimate the respiratory rate (RR), EDR is combined with to a reference respiratory signal as (26)

$$RR = (t_{n+1} - t_n) \div 60 \quad \textbf{(26)}$$

Where t_{n+1} is the time of occurrence of $(n+1)^{th}$ R-peak and t_n is the time for the occurrence of n^{th} R-peak. Normal being 12- 20 breath causing any abnormality to dyspnea.

Heart rate can be a bio-marker for seizure prediction as there is a change in the trend of R-R interval of the ECG wave whenever onset of seizures occur [8]. For the prediction purpose we combine the variation in R-R interval along with the instantaneous frequency of the EEG signal of the same patient through Hilbert Huang transform having two major steps for EEG decomposition mainly empirical mode decomposition (EMD) and Hilbert transform for instantaneous frequency [26]. The EEG signal obtained is decomposed into subsequent sub components called intrinsic mode function (IMF). To find IMF the steps are as follows:

1. Identify the local extremas (maxima and minima), mathematically second derivative test. So that all the intermediate data or points are covered within.
2. Connect all maxima's forming upper and all minima's forming lower envelope respectively
3. Find the mean m_1 of this data
4. Difference between the input x(t) and m1 is the first component of the IMF, h_1 i.e.: $x(t)-m_1=h_1$ being it has to be symmetric, maxima positive and minima negative respectively.
5. On next subsequent shifting $h_1-m_{11}=h_{11}$ being the next IMF component. After repeated shifting to K times the equation forms (27):

$$h_{1(k-1)} - m_{1k} = h_{1k} \quad \textbf{(27)}$$

Each IMF contains various input oscillation patterns, 1st IMF having the most and last IMF having the lowest oscillations or residues [14]. This series of IMF are then used to find the frequency using Hilbert transform algorithm [8].Where its amplitude, phase etc. are also obtained. This tool is chosen because of its versatility and its ability to extract a non-linear, non-stationary signal 's frequency component.

IV. RESULTS AND DISCUSSIONS

In the work done Pan-Tompkins algorithm is used for R-peak and R-R interval detection. The Fig.4 depicts the input ECG signal and QRS positions detection. Output are low or high frequency interference removed for noise rejection function using a band pass filter, differentiated, squared and integrated data after complete pre-processing to obtain the slope, feature information and amplitude of the input ECG signal. Threshold-array for filtered data i.e. threshold for each QRS-complex of integrated data are obtained to find the R-peak. The R-R interval obtained from the pan Tompkins algorithm is recorded in the table giving the normal and abnormal variations, where normal R-R interval being 0.6 to 0.8 second heart rate being 60 to100 beats per minute.

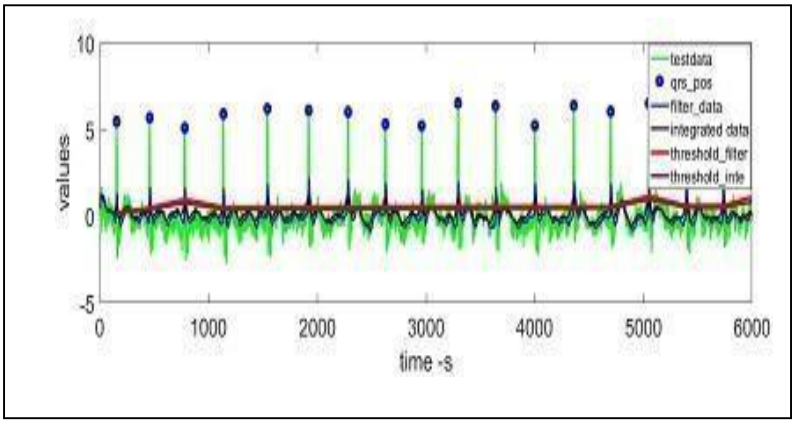

Fig 4. *R-peak detection*

This is the vital sign for a wide spectrum of healthcare strategies. If R-R interval goes beyond this limit it is an evident case of anxiety as shown in Fig.5 and proved by table1. A random signal tracking is done initially giving the results as shown in Fig.6. The figure proves that the algorithm exactly copies the input signal rather than Kalman filter for just linear tracking. The algorithm is suitable for real life tracking of any non- linear signal. For the parallel tracking of ECG-signals an unscented Kalman filter algorithm is used as shown in Fig.7. If variation in R-R interval is evident the system goes for prediction of three diseases. The cases of heart attack like Tachycardia referring to increase in heart rate, more than 100 beats at rest hence a rapid decrease in R-R interval and Bradycardia referring to slow heart rate, less than 60 beats at rest hence increasing the R-R interval. This R-R interval variation can lead to dyspnea prediction, normal being 12-20 breath where any R-R abnormality leads variation since anxiety can be a

major cause of breathlessness. The variations in R-R interval can also be used to predict epilepsy as it varies at the onset of the same. 73 percentage of seizure can change up to 15 to 20 percentage of heart rate, 55 percentage changes to 20 beats per minute.

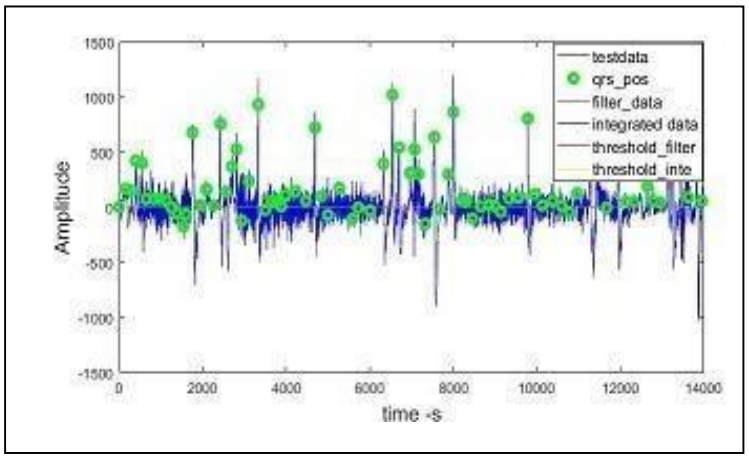

Fig 5 . *R-peak for detection for anxiety*

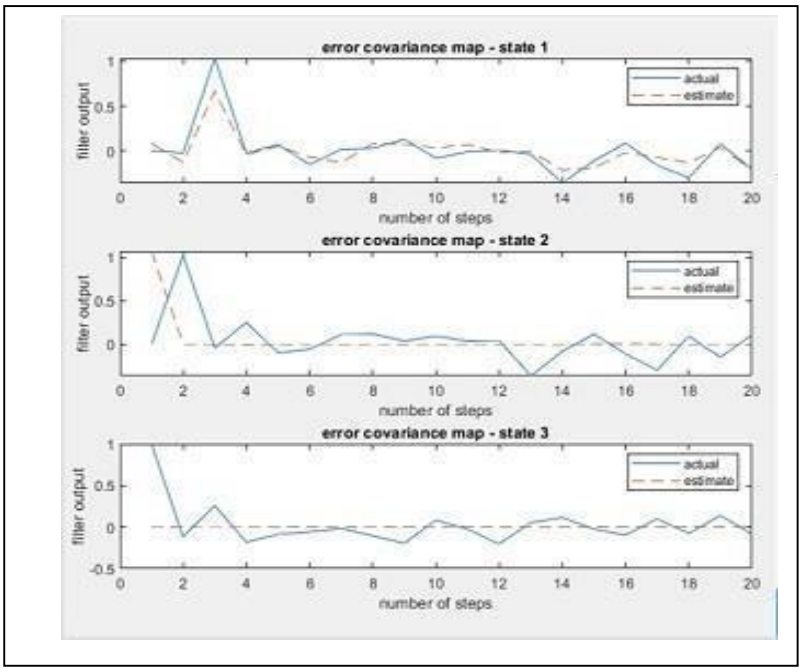

Fig 6. *Tracking of random signal*

UKF is used for tracking of abnormal ECG signals in Fig.7 as this have an advantage of tracking nonlinear signals over Kalman filter. They use deterministic technique using unscented transform setting a set of minimal sample points called sigma points around any given mean of input signal. As indicated the red line indicating sigma points ideally traced the input ECG signal. If an abnormal R-R interval is obtained. there is either heart rate or amplitude miss match as shown in table Heart rate estimation. Heart rate can be calculated from R-R interval as in table2 which is in turn cubic spline interpolated to have EDR in Fig.8. The EDR signal is compared to the respiratory signal for corresponding R-R interval as in table respiratory rate estimation of a subject for respiratory rate estimation hence dyspnea prediction**.**

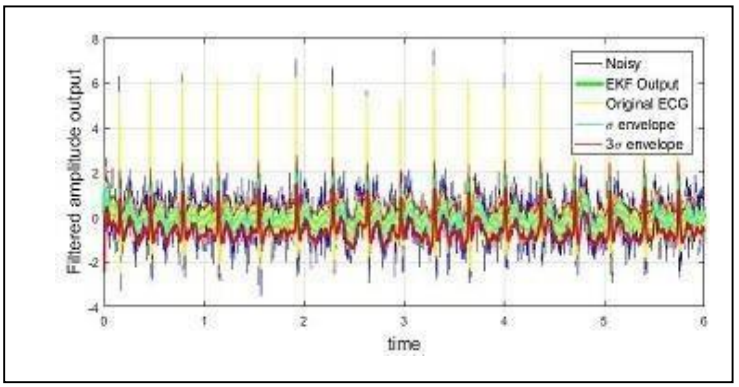

Fig 7. *Tracking of ECG signal*

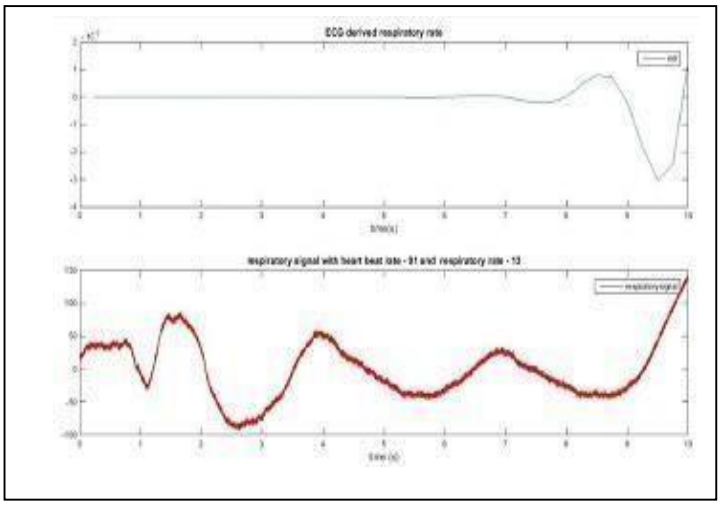

Fig 8. ECG derived respiratory signal

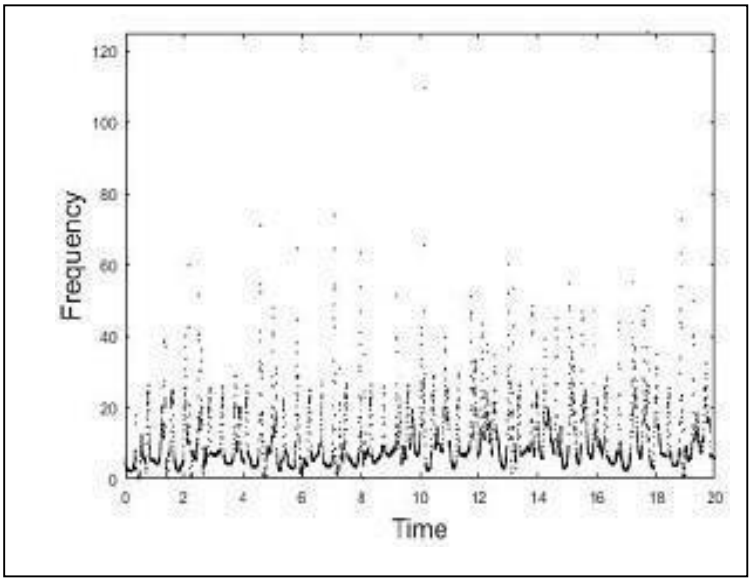

Fig 9. *Hilbert Spectrum analysis- IMF formation*

The table depicts the variation in heart rate and respiratory rate on abnormality For epilepsy prediction along with increase in R-R interval, a decrease in instantaneous frequency of EEG is also considered. In order to obtain the same Hilbert transform as in Fig.10 on input EEG signals are done where the input frequency is divided into smaller IMF and processed for instantaneous frequency by Hilbert spectrum in Fig.9. If the variation is proper this goes intact for epileptic seizure. The variation of instantaneous frequency and R-R interval is evidently plotted in Fig 11

V. CONCLUSION

The major proposal of the work is to develop an non-invasive self administered technique for anxiety related disease prediction in children with ASD. These anxiety is especially due to their growth pattern and characteristics. In such a concern, ECG signal was considered due to its bio marking capability in both cardiorespiratory for dyspnea detection and epileptic seizure detection along with heart attack. The variation in ECG during all the three case leads to a new system of parallel tracking the R-R interval and hence the heart rate variability for disease prediction. Already existed system had a Kalman filtering framework to graph the existence of anxiety. It just predicted, if anxiety existed or not, but when it comes to disease prediction the earlier existed system does not find accurate results as continuous, real-time tracking of R-R interval is absent hence there is no continuous tracking of anxiety. The newly proposed system is advancement by using UKF algorithm for real-time tracking. The prescribed system is a true application on Unscented Kalman filter framework for tracking a non-linear system. The system makes use of the deviation in ECG, while tracking to find the R-R interval variations for disease prediction. For epileptic seizure prediction the system combines the instantaneous frequency response of EEG with the variation in the R-R interval and in case of dyspnea prediction EDR is derived from ECG combines with respiratory signal to find breath rate. Hence this system provides an overall noninvasive technique, also proved in terms of its accuracy and stability to get rid of false alarm. Tachycardia referring to increase in heart rate, more than 100 beats at rest, hence a decrease in R-R interval. Bradycardia referring to slow heart rate, less than 60 beats at rest, increasing the R-R interval is noted .In case of epileptic seizure if the instantaneous frequency of EEG signal decreases and RR interval of ECG signals increases it marks its onset. Then R-R interval has a direct impact respiratory rate, as heart rate increases respiratory rate also increases leading to dyspnea. In future the system can be improved incorporating sweat sensors and image processing techniques for eye images and movements for anxiety analysis to increase the sensitivity of the system.

ACKNOWLEDGEMENT

I would like to express my gratitude to my guide, Mr. Sudheesh P for helping me progress in my project with the best possible ideas as well as my friend Miss. Krishnatulasi for the support and suggestions and Our department for giving me the opportunity to do this project on the topic Anxiety detection with all necessary software support, which also helped me in doing a lot of Research.

Abstract- **A low cost, low voltage faucet which is context-aware with a scope of water conservation. The concept propsed is capable of identifying the object in front of it and based on that it will regulate the water flow and is vital for saving water. The faucet uses an in-built sensor like Infra-red camera to identify the object in front of it using machine learning and the micro-controller will recognize the size of the object and on the bases of this it would adjust the position of the nozzle. The pressure of the faucet is determined by this and accordingly, the pressure washer pump would be turned on when the IR sensors recgonises presence of hands under the faucet the water would be sprinkled . This system is useful in large scale kitchens like restaurants, hospitals, households etc. The amount of water conserved would be vast and if implemented in homes then in the long term would be able to make a colossal impact on water conservation.**

Keywords- Micro Controller; Infra-Red camera; Motor Controlled sprinkler; Pressure water pump;Machine Learning.

I.INTRODUCTION

With a population of over 7 billion the resources have become scarce and water is one of the vital sources of survival for all of mankind. Various campaigns have been carried out for bring about awareness regarding water conservation however the impact has been comparatively less with respect to the pace in which the freshwater table is depleting. [1]The proposed faucet is aimed at providing a solution to this problem to an extent by regulating the water flow which if implemented would help to reduce water usage and also make washing and cleaning process more convenient.

The faucet may calculate the water flow required for a shower, bath or for an open faucet activity. This way an entire households water consumption can be reduced immensely and when this is view at from a larger scale i.e. a community the overall water conserved would be sufficient to stabilize the water table.[2] By identifying the content in front of the faucet it would be able to calculate the level of water that should be dispensed and based on the width and density of the object it would adjust the flow of water and would cover more area.[3]

Most of the faucets at present only serve the purpose of dispensing water the flow of water is not regulated and the faucets which have in-built sensors are unable to detect the content present in front of it and as a result, dispense water in at a fixed rate and quantity. [4]The aim of this project is to be able todetect the surface of the object on the bases of which the faucet would change the rate of flow of water and control the volume being dispensed.

Developed countries to an extent have rules and regulations to monitor and regulate water supply to households however most of the developing and third world countries with twice the population of developed countries it is high time that a solution is implemented to cut down on the water wastage. By setting up these faucets in every household would be the perfect market to target in order to tackle this issue.

It is often assumed that software and applications are restricted only to computers and mobile phones. However, the scope for integrating them to daily objects would make smart living a touch away. Implementing software to develop hardware which would help in the day to day functioning of an individual would change the game. [5]

Smart homes are becoming extremely popular and having a smart faucet is an addition to it making the living easy.[6] With the current generation heavily relying on technology, smart faucets would be a gadget that would automatically make its way into their homes.

A combination of an infra-red camera which brings in the advantage of using static overhead camera above the work area, a micro-controller with the ability to interpret the measurements of the object, a pressure pump providing water in the required volume would altogether make the washing process easier.

II.PRESENT SCENARIO AND RESEARCH GAP

The current scenario is taps and faucets are just viewed as a device to dispense water the hidden potential in this is yet to be explored. With motion sensitive and infra-red cameras becoming more common combining these with faucets would help to create smart faucets which can not only control the flow of water but also has the environmental benefit angle as well.[7]

Technology has become extremely affordable when compared to the earlier days. Almost half the world population has a smartphone which was not the case a decade ago. [8]Countries are becoming tech-savvy and the next big thing in the market is smart living. Smart faucets are an untapped market with a lot of scopes.[9]

The faucets available in the market now are mostly the normal faucets which dispense water or are the motion sensitive ones which dispense water on command.[10]

The proposed model in this paper is a novel idea which aims at bringing together different forms of technology to a faucet enabling it to be smart. Bringing home this technology would be a time saver and every homemaker's dream solution to the problem of getting the dishes done on time.[11] It can also be expanded to the bathing segment by using it in showers. Washing our hands and body properly is one of the most effective ways to avoid infection and a faucet which is able to exactly identify the measurements and provide according to it would help to implement this effectively.[12]

Faucets nowadays are equipped with in-built sensors like temperature gauges which help to control the water temperatures. The faucet proposed by us is a combination of hands-free and digital with sensors that would control the flow of water.

III.PROPOSED MODEL

A. Motor controlled sprinkler

The faucet has a 2-way motor controller nozzle which sprinkles the water. A two 2-way motor-controlled sprinkler operates on x and y-axis motion. The nozzle widens and shrinks in accordance with the object in front of it. Once the microcontroller detects the measurements of the object with the help of the infra-red camera the nozzle will adjust accordingly in order to supply water in the required quantity. For instance, if a small plastic cup was brought in front of the nozzle it would detect the width and only open the nozzles center holes for the water to flow. On the other hand, if it was a big bowl all the nozzles would be open in order to cover more area.

B. Infra-Red camera

The infra-red camera is motion sensitive and real time. It would detect motion or hand gesture and turn the faucet on. It is capable of measuring 3D surface and the measurements would then be sent to the microcontroller. This helps the smart faucet to be context-aware giving it the ability to identify what is in front of it and get its dimensions. Once a vessel comes into the washing area it would try to figure out its dimensions. And with the microcontroller, the water flow would be regulated.

The IR camera would be positioned in a manner that it would be still so that it can detect the object properly using ML[13]. Even if the faucet is being moved around the camera would be still near the tail of the faucet so that it can get the measurements easily.[14]

C. Micro Controller

The micro-controller plays a key role in the entire process as it is the deciding body which regulates the flow of the water. Once the measurements are obtained from the infra-red camera the micro-controller determines if the water flow required is high or low. Depending on the width and size of the object the water flow will be decided. If the object is big and requires high pressure then the pressure washer pump will be turned on. This is extremely useful for large scale kitchens which have huge utilizes. It would make the cleaning process a lot easier.

D. Pressure washer pump

The pressure washer pump is meant for heavy cleaning targeting large vessels or while showering or cleaning a car. Mainly when the water requirement is more and the surface area to be covered is large. The pump would get a signal from the microcontroller after which the nozzle would switch to this mode and the water flow would be wider covering the majority of the region in one go rather than having to adjust the object in accordance to the water flow. It's pretty common for people to adjust in the shower in the direction that the water comes in. this faucet would automatically adjust and cover the whole area.

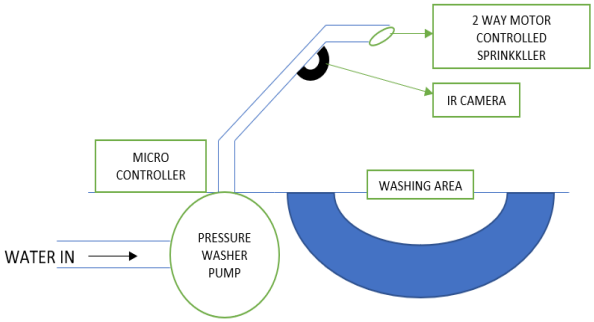

Fig 1.1 Block Diagram

E. Working Process

The models working process starts from the object coming into the washing area. Once it comes in front of the nozzle a hand gesture would indicate that the water should flow out. (Fig 1.1)This would be detected by the infra-red camera which would also check for the measurements and dimensions of the object. These readings would then be sent to the microcontroller which would decide whether to activate the pressure washer pump or not. The pressure washer pump is a high-pressure water dispensing unit which is extremely helpful to wash objects which have a huge surface. The washer would help to pump out water in large quantities so that the object can be washed in one go rather than having to keep the faucet on for a long period of time wasting most of the water. once this decision is made by the microcontroller the next step is for the 2-way motor-controlled sprinkler to adjust the nozzle in either x-axis or y-axis and let the water flow accordingly in order to cover the maximum surface in lowest possible time. This would reduce the amount of time spent on cleaning, the amount spent on electricity bill and most of all the water wastage.

- *Example*

Derek who runs a famous restaurant in the city is experiencing several issues due to the water shortage in the area and is forced to import water. He wants a long-term solution for the problem and wants to contribute to the water conservation front rather than continue wasting water. With the help of the face, he found out that the Infra-red camera sensed the object in front of it and the

Microcontroller uses this image to calculate the area of the object. (Fig 1.2) The 3D measurements obtained helps the micro-controller to combine both this information and decide what position of the nozzle would be able to cover maximum area and what should be the pressure of the water. If pressure calculated is a yes then the water is sprinkled on the object however if it requires more water and the answer is no then pressure washer pump is turned on and the water rushes in.

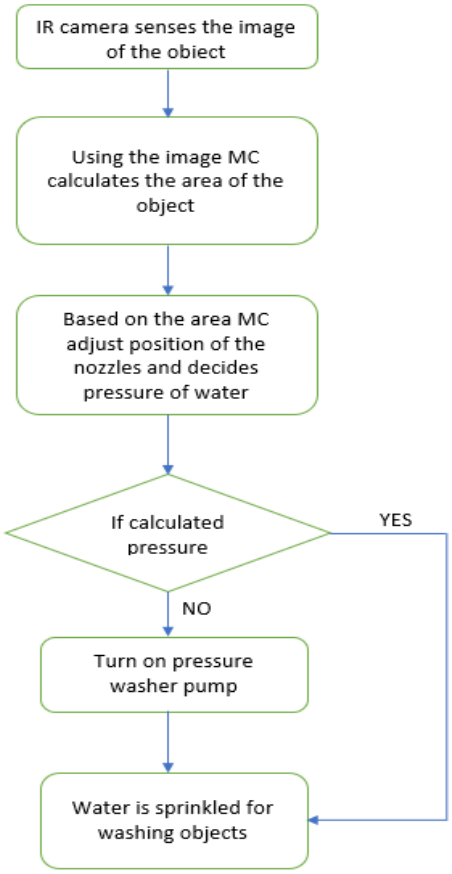

Fig 1.2 Process Flowchart

IV.FUTURE WORK

The future scope of this proposal would be to implement this on a much larger scale and not limit it to just washing utensils. But also in factory's, car washes, hospitals, restaurant and most of all in every household. By widening the scope of this faucet, it would be possible to achieve water conservation and stop having to import water in areas. The long-term aim of this project is to ensure sustainability. By having these faucets in every kitchen, bathroom possible the scope of this idea would increase immensely and the conveince as well.

V.CONCLUSION

It is high time that solutions for tackling water shortage be introduced to the public. Just how change starts at home by targeting the average household to implement this smart faucet the enormous impact it would have on water conservation is more than a first time towards handling global warming. The smart faucet would be user-friendly and the kitchen is a central part of every house starting from there would be more practical.

ACKNOWLEDGMENT

We thank our family and colleagues from the Institute of management, Christ (Deemed to be) University who provided us with insights which were great assistance in shaping our research. We would like to express our gratitude to the faculties and colleagues of Institute of management, Christ (Deemed to be) University for sharing their pearls of wisdom, reviewing our research and giving us key inputs.

***Abstract*—This project tries to transform the visual world into the audio world with the potential to inform visually challenged people the spatial locations of the objects in their vicinity. Our paper presents the development of a real-time system based on detection, classification, and position estimation of objects in an outdoor environment to provide the visually impaired individuals with a voice output-based scene perception. The system is low-cost, light weight, simple, and easily wearable. The module is integrated into the stick, and the pi-camera is used to take the picture, and a controller is provided to move the camera in the required direction. The valuable insights gained from the feedback are then used to modify the system to best suit the requirements of the user. The object detection and classification framework exploit a multi-modal fusion-based mask RCNN using motion, sharpening and blurring filters for efficient feature representation. The image recognition classifies the detected objects along with the positions of the objects. Experimental results carried out in the outdoor environment are demonstrated. These data obtained is then converted to voice, and blind people will get the visual of what the environment is around them.**

I. Introduction

Navigation of blind people is an important issue to be considered. They most commonly use sticks for obstacle detection, meanwhile memorizing all locations they are getting familiar. In a new or unfamiliar environment, they depend on individuals passing by to enquire for a certain area. In the world of sophisticated technology along with various sensors, there should be a system with the most basic innovation to make their life a bit easier. Traditional navigation aid methods such as sticks are very limited and are unable to provide a complete scene perception. For example, a stick may just provide information about the presence or absence of an obstacle. However, no information about the kind of obstacle is available. In many cases it may be important to know the obstacle type; specifically, if it is a door needed to be opened or a stair required to be climbed.

Computer vision technologies, especially the deep convolutional neural network [1], have developed rapidly in recent years. It is promising to use the state-of-art computer vision techniques to help people with vision impairment.

The utilization of computer framework advances for navigational purpose is relatively a recent technology. Commonly, the scene is perceived by extracting images/videos using vision sensors and a controller is used to adjust the camera view. The latter is discussed in relation to the recognition of the objects with the help of image processing [2] using mask RCNN [3] [4] multi-modal convolutional neural network and the usage of data that is obtained from the image recognition to identify the position of the object. The processed data is made available to the end-user through voice output and contains information regarding the class and position of the object.

In our project, we have attempted to build a real-time object detection and position estimation pipeline, with a goal to inform the user about the surrounding environment. It is possible to obtain faster results from the mask RCNN image recognition by running the process on the powerful tools. A server can be used to run the process and return the obtained results. For a smaller specifications system, the output will be obtained but the execution time may take long as RCNN requires a higher processing specifications system. So, the end-user system may be designed with low specifications which

can reduce the cost to the end-user. Its main function will be to click the image and send the image data to the server which requires less computational and processing power. The picture in the server will be processed which has a good processing and computational power to handle the RCNN and process the results faster. Once the results are obtained, they are sent back to the end user system in the form of voice output.

II. RELATED WORK

Work has been carried out by various groups in the field of object recognition using image processing techniques that are implemented for an efficient and a quicker way to recognize the object and classify them according to the class.

Mask R-CNN Object Recognition by Kaiming He, Georgia Gkioxari Piotr Dollar [5] have presented a conceptually simple, flexible and a general framework for object instance segmentation which efficiently determines the object in the image by applying the segmentation mask for each instance. They have demonstrated how simple its to train them and how it adds only a small overhead to Faster RCNN running at 5fps.They have demonstrated COCO suite of challenges, including instance segmentation, bounding-box object detection, and person key point detection. Mask R-CNN scores high against all existing, single-model entries on every task. The simple and effective approach will serve as a solid baseline and help ease future research in instance-level recognition.

An Image Matching and Object Recognition System has been developed using Webcam Robot by Sanjana Yadav and Archana Singh [6]. In this work, the image matching and recognition of the image and classification is done by tracking an object and calculating its feature points and classification with the help of trained Data Sets. They have both the manual as well as automated image matching. In the automated system, the picture is taken and uploaded to the database after which the system image matching will be performed. Black and white points of the image is first calculated, then Chamfer Matching Algorithm and 3-4 Distance Transformation with canny edge detector [6] is applied for calculating the pixel values which is used for matching the trained data sets.

pseudo Eye - Mobility Assistance for Visually Impaired Using Image Recognition by A.G.Sareeka, et al., [8] have developed a wearable device which converts the text image to the voice output through a camera click. A SoC (System on Chip) does the processing and tells the user the text thats present in the picture that will guide them through the path.

Visual Assistance for Blind using Image Processing by Deepthi Jain B, Shwetha M Thakur and K V Suresh [9] proposed a wearable model for the blind people which is capable of identifying the objects using image processing techniques and also the distance between the objects is identified using the ultrasonic sensor. Raspberry pi module is used for computation and implementing the algorithm where the modules such as the OpenCV and python language is used for the implementation. Some basic objects and overlapping images were identifiable.

Image Recognition for Visually Impaired People by sound by K.Gopla Krishna, C.M.Porkodi, and K.Kanimozhi[10] have proposed an algorithm to convert the image to the sound format to help blind people understand their surroundings. They have used a canny edge detection package which identifies the object by the edges and by comparing these values with pre- trained dimensions. It has been observed that it is working very good fors simple images but when the images are complicated like overlapping of the images they are obtaining a wrong results and yet to develop the efficient way of image processing.

Voice Assisted Navigation System for the Blind by Ananth Northey , Kishore Kumar M.[11] have designed a cheap and affordable navigators for the blind people where the ultrasonic sensors used will give a voice instruction and guide the route for the person and ground gradient is its improper they have designed an algorithm to guide the correct path for the user. They have incorporated a GPS module which can guide them the route to reach the destination n with the help of the android app which sets the destination and gives the voice output for the user to take the best path.

III. PROPOSED MODEL

The proposed model is used to overcome all the shortcomings of the aid for visually challenged people. There are in the market the sticks that have a sensor which informs whether the object is there or not. Further, there are sticks which use infrared cameras to map the surroundings but are expensive and uses a lot of processing. To address the shortcomings, a model is developed to assist the visually challenged people and read-aloud the names of the objects present in their surroundings and to give them clear estimation of how their surroundings is. To narrow down their range of estimation and to provide precise object position, a controller is given to move the camera to their required view point and then take the photo. The output is read aloud as to what objects are present in that direction.

The photo is taken by the user using joystick switch in the direction he wishes. This photo cant be processed in Raspberry PI as it takes up lot of computation. Hence, this photo is sent to the server dedicated for running the algorithm. The photo is sent through Googles Gmail REST API. Each photo has the unique name in the form of `YYYY_MM_DD_HH_MM_SS` so that there is no replacement of images.

The image is taken up by server from a dedicated Gmail link. This image is then processed using the Mask-RCNN algorithm. The server processes it as it can support multiple clients and can do it fast. The output of the algorithm consists of many parameters which are encoded and sent back to the client from which request has come.

The output from the server is taken up by client and decodes the information. This decoded information is read-Aloud clearly to the user two (2) times. Any flexibility or changes in the read-aloud can be done from provider end.

A. Architecture at the client side

At the client side using the joystick, the user moves the camera in the required position and clicks the pic, the raspberry pi

module takes the picture which is then sent to the mail (pre-coded) using the Gmail API, to make the computations fast in this project and since the raspberry pi module has limited computation al power, its functions are also limited in this project where it performs the main core functions such as uploading the picture and getting the results back and converts them into the voice format which the end user , the blind person is able to hear. The complete working of each section is discussed in detail in the upcoming sections.

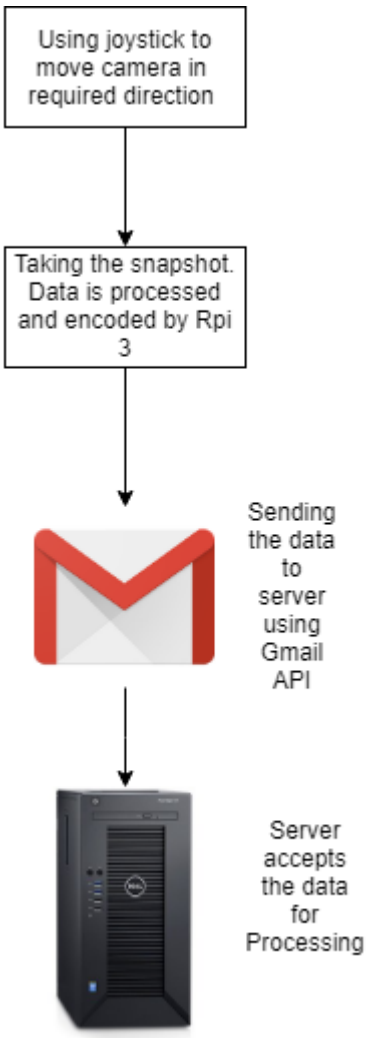

Fig1.Aritecture of the module at the client side

B. Core function of the modules

Each module used has their own core functions and responsibilities, each of the modules functions is explained in detail here.

1) Joystick module: A 2D joystick module is provided along with the push button switch where the user can use this to position the camera in the direction required and push the button. This module is powered and controlled by the Arduino Uno module which is powered by the 9V battery. The joystick provided is able to turn the camera horizontally by an angel of 180 degree and vertically 120 degree.
2) Push button: The push button is provided along with the joystick module where the user once he is done positioning the camera, he can click on the push button (press the joystick vertically) and photo is clicked.
3) Arduino Uno : The joystick along with the push button functions is handled by the Arduino Uno where the values fetched joystick module to the Arduino Uno are in the analog format since the raspberry pi does not have a ADC(Analog to Digital Convertor) Arduino plays a role where it converts the analog data to the digital format and sends the data to the raspberry-pi module which than turns the camera accordingly. Arduino also plays a important role in analyzing the push button push, once the button is pressed it takes that as an interrupt and send the signal to the raspberry pi module which in turn modifies this to take the photo.
4) Raspberry pi: Is the main core at the client side, it is powered by the power bank, it does mainly 3 things, which are.
   a) Receives the signal from the Arduino module to take the picture and once it receives the positive signal then it immediately without much delay clicks a pic and saves it.
   b) The saved picture is than sent to the mail using the Gmail API.
   c) The final results of the image processing is received by the raspberry pi which is also done by using the Gmail API. These final results are than converted into the voice format and through the jack provided the voice output is made available to be heard by the end user.
5) Pi cam: This module is a 5MP (Mega Pixel). Camera which is provided with best interface with the raspberry pi module a 8 line parallel data communication cable is provided for a high speed data transfer of the imaged to the pi module. This module just turns on when the pi send signal to take a pic and a warm up time of 5s is provided to get a clear image and returns the image back to the module

C. Architecture at the server side

The server is pre-installed with python version 3 and required packages for the image processing are also installed. Server is fully automated, and no manual intervention is required for any actions that are required concerned to the project. It is pre trained to object recognition. The Gmail API services are supported by the server. The server does all the required computations and obtains result with the minimum delay possible and max CPU usage. These results are than encoded in the csv file and sent ack to the raspberry pi module using the Gmail API. The flow and the services are explained in detail.

Once server receives the image from the client side, the image processing algorithm is applied to the image for object

recognition. The algorithm that is used is MASK R-CNN which is a robust, efficient algorithm used for object recognition. It even produces accurate results with the complicated images and overlapping images. The results obtained from this algorithm are than converted into the proper csv format which is the best way to send the data with the minimum size over the communication.

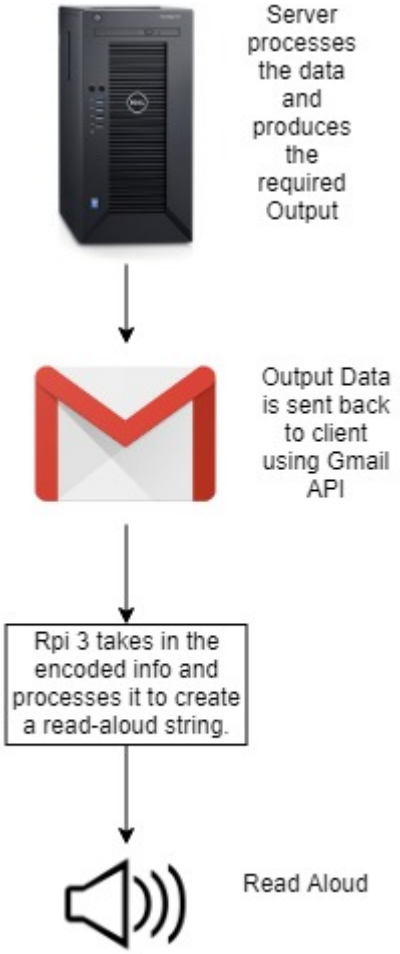

Fig 2. Architecture at the server side

The Server continuously waits for an image to be uploaded by the client. Once the client uploads an image, the authentication is done by google API. If the authentication is successful, the image is fed to object recognition algorithm. The model used by the algorithm might depend on the client's requirement. The default model might be used or the model as per client's requirement might also be used. The algorithm produces the results which are stored as a dictionary which has object as the key and its corresponding position as the value. The data is then converted into a csv format in the form of [object_id, x_left_bottom, y_left_bottom, x_right_top, y_right_top].There might be multiple IDs of this sort based on number of objects being recognized.

The csv file created is renamed the same name as the image processed to produce it to maintain uniqueness among multiple files.The csv is sent back to client through the google API.

D. Mask R-CNN

Mask R-CNN is a conceptually simple, flexible, and a general framework for object instance segmentation efficiently detects objects in an image while simultaneously generating a high-quality segmentation mask for each instance. Mask R-CNN is simple to train and adds only a small overhead to Faster R-CNN, running at 5 fps. Moreover, Mask R-CNN is easy to generalize to other tasks, e.g., allowing us to estimate human poses in the same framework. g instance segmentation, bounding-box object detection, and person key point detection. Without tricks, Mask R-CNN outperforms all existing, single-model entries on every task, including the COCO 2016 challenge winners. The Fig 3. Shows the output of the Mask R-CNN for the images which have overlapped objects, which is using the instance segmentation concept to bring up the result. Mask R-CNN structure is also trained to analyze the human pose estimation also, which means that it can identify the objects even when they are posing in the different position. Fig 4. Shows the insight of what the output would result in.

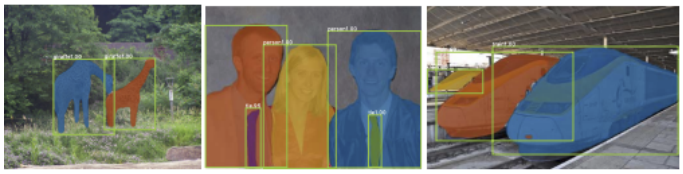

Fig 3. Mask R-CNN output for the overlapping images

E. Gmail-API

The Gmail API is a RESTful API that can be used to access Gmail mailboxes and send mail. For most web applications (including mobile apps), the Gmail API is the best choice for authorized access to a user's Gmail data. The Gmail API, like Gmail itself, is (currently) a free service from Google. The Google Fit REST API enables you to store and access user data in the fitness store from apps on any platform. The REST API provides resources and methods to create, obtain, list, and modify data sources. A data source represents a unique source of sensor data. All requests to the Gmail API must be authorized by an authenticated user. Gmail uses the OAuth 2.0 protocol for authenticating a Google account and authorizing access to user data. You can also use Google+ Sign-in to provide a "sign-in with Google" authentication method for your app. Google has doubled up the Gmail attachment size from 25MB to 50MB for incoming mails, allowing users to receive larger files of size up to 50MB. This means that user can now open file size of maximum of 50MB directly in their inbox mailbox at once.

IV. RESULTS

The fig 5 and fig 7 was sent as input by the Pi cam, the client device sends the image to server which in turn sent back the output in the form the form of fig 6 and fig 8 respectively.

Fig 5. Input Image as taken by camera

Fig 7. Image taken by Picam

7	61	429	700	765	1024
8	65	493	213	504	247
9	67	464	387	492	502
10	63	360	255	468	365
11	57	401	486	587	637

Fig 9. The form in which data is communicated

The output has n*5 fields where n is the number of object detected. Each row represents one object. The first element in each row denotes class ID. Each object has a different ID. In the above fig., the ID 6,1,3,8 represents bus, person, car and truck, respectively. The 2nd and 3rd column represents bottom left coordinates of a bounding box i.e. (x1,y1) and 4th and 5th column represents top right coordinate i.e. (x2,y2). It can be inferred that the height of the object is abs(y1-y2) and width of the object is abs(x1-x2) as seen from the camera.

For reading out the object for the visually-challenged, the center line is taken as the reference. Since the images are always 1024 * 768, center line always has x-coordinate 512. The ones having x2 $<$ 512 are in the left of the image, ones having x1 $>$ 512 are in the right of the image and the ones whose x1 $<$ 512 and x2 $>$ 512 pass through the center coordinate.

The voice output for each result would be of format ”The (number of object-name) (object-name) was/were found. One was left/right/straight of the camera, one is .... ” till all the object instances are parsed. The above is repeated for all the objects.

As indicated by Fig 9, first column of eaach row represents the class ID. 57,61,63,65,67 represents chair, table, TV, mouse, keyboard. The read aloud for Fig 9 would be of the form ”There are eleven(11) objects found. ’4 chairs were found; 1 on the left of camera, 2 in line of the camera, 1 on the right

of camera'. '1 table was found; 1 to right of camera'. '4 TV were found; 2 to the left of camera, 1 on line of camera, 1 to the right of the camera'. '1 mouse was found; 1 on the left of camera', '1 keyboard was found; 1 on line of the camera'". This output is repeated to remove ambiguities if any.

The read-aloud is such that, the number of elements in the class are told first followed by position of each. The above result is repeated to get clarity in case of ambiguity the first time.

The Round trip Time takes at max 20 seconds when being tested in the local low power server.

V. CONCLUSION

The paper presents a smart stick which is significantly better than its predecessors with ultrasonic sensors. The sticks with ultrasonic sensors are heavy and expensive. In smart stick, all the operations are done using images which reduces the infrastructure significantly.Therefore it is much cheaper than the ultrasonic ones. The algorithm when hosted on Google servers for testing yielded results in a second. It was observed that the algorithm yielded better results when trained for 30-35 epochs.The accuracy was tested for wide range of objects in various conditions The accuracy was consistently above 90%.Its easy usage combined with powerful detection algorithm makes it an obvious choice in the foreseeable future under wearable tech.

VI. FUTURE ENHANCEMENTS

1) The further goals include creation of micro-controller to perform only the required operation and thus getting rid of Raspberry Pi.
2) As the module is integrated on a stick, the module can be integrated on a cap as it is easily wearable and more portable than a stick.
3) Integrating a night vision and flash cameras for detection in extremely low light.
4) Using depth perception to read-aloud approximate distance of the object which is being recognized.

***Abstract*—This world has seen a lot many examination portals that are deployed over several servers which are used to conduct online examination for various purposes among which some may include conducting a test for entrance examinations, or olympiads at national and international level and while some portals are designed to conduct a test for placement purposes. But what we have seen is that mostly all the portals are designed to conduct tests that contain multiple choice questions. Here our aim is not to work on the technology that is already existing, rather some technology that is very rare. Here we talk of the descriptive online examination system. Multiple choice questions are easy to deal as they have a question, a few options and a field in the same question that stores the correct option in the database. While in the case of descriptive questions it is not so. It brings in or uses the concepts of Natural Language Processing or NLP to assign marks to answers. Answers are nothing but strings and the job of the model is to do some operations on the answer string such that it can assign the correct marks to answers written by the examinee. The data is basically collected from a descriptive online examination system. Further, it is analyzed and the designed model assigns accurate marks to the answers for the question. The back-end is written in Python where the web framework used is Django, the library used for Natural Language Processing includes NLTK and for database purpose, SQLite version 3 is used, while for the front-end HTML version-5, CSS version-3, Bootstrap and Javascript is used.**

Keywords—Exam System; SQLite3; Django; Descriptive System; Natural Language Processing; NLP; Python; NLTK

I. INTRODUCTION

We come to hear news from around the globe that a particular exam was conducted for a job or for a college or examination in schools and the result was published after some time, while this is a good way to conduct an exam but it is inefficient with respect to the current world where automation is the future. The examination system relies on manual work from printing to transporting the paper to the examination hall, then invigilation and the most tedious task of checking the answer sheets which is a huge mess for any examiner which sometimes leads to resource loss. Also, we hear news about paper leaks and answer sheet being lost in the transporting process. The manual checking process will always have that human error based on certain factors like biasing, the mood of the examiner, target completion and much more such factors. Also if we take account of all the paper wastage and the stationary waste which harms our environment leading to do more bad then good as the enormous amount of trees being chopped off across the world for the process. This helps us understand that the offline examination system is not cost effective or time efficient, resources are also wasted in the process and moreover we all know that resources are scarce in nature and we need to utilize it efficiently to get the maximum output of it.

While the offline examination system has a big disadvantage but are not getting replaced at a bigger scale because new online examination system features only multiple choice type of question's while most of the exams contain descriptive question for which multiple choice answers do not work and hence they are not that compatible and efficient to replace it at a larger level. We all know that if we have to remove a universally accepted system, the new system should not be just good, rather it should be able to make a quality difference so that the organizations accept it. While there are some examination system and they are good at evaluating the answers but they have little to no scope for the descriptive ones and the analysis is not well implemented to get meaningful results. Even most famous of them just have a simple system of storing the correct options in the database and just matching the correct option with it to calculate the result.

In the proposed model we are taking the online examination system to a new level by enabling the examinee to write descriptive answers which will get evaluated on their own i.e automating the entire offline examination system with the efficiency of computing having no human error involved, this can be done using NLP or Natural Language Processing. The evaluated answers will be stored in the database and they can be viewed anytime and a particular student profile will be maintained for better evaluation of the student.

This will be a huge boost to the online examination system as this will allow it to overcome its biggest con and it will also help the online examination system to stretch its paw even in the half-yearly or annual examination conducted by schools or college for evaluating the profile of the student. This will have instant benefits like the system will relieve the burden of the teachers and professors of checking copies and in return they can be more productive with their time in teaching things, this will also eliminate biasing in answer script checking and will have leased space for any human error as copies would not be scanned and the entire marks

will be allotted according to the way answers are written by the examinee while he was on and there will be little to no space for acquisition, it will help in resource management as this will cut corners on stationery products, it will also have greater efficiency with respect to time as it will produce instantaneous results and will be more secure and reliable.

Talking about the technology used in order to build such a model for evaluating descriptive answers, NLP or Natural Language Processing is has a great role to play. NLP can do a lot of innovative jobs like predicting if a message or an email is a spam or a ham, the quality search that we can do on shopping websites like www.amazon.in and www.flipkart.com in order to search for different categories of items that include kitchen utensils, electronics gadget, apparels, food items and much more such products that are available online. The basic idea was that did anyone ever think of knowing how these search bars or how these ham-spam classifications work? The answer to this question is that rarest of the rare people have tried getting into this and tried to know what the mechanism or the back-end work in order to give such powerful search results and such predictive classification techniques. For those who are not aware of the mechanism behind this, it's all just about playing with strings of characters, numbers and special characters or what we call as string manipulations to arrive at such results.

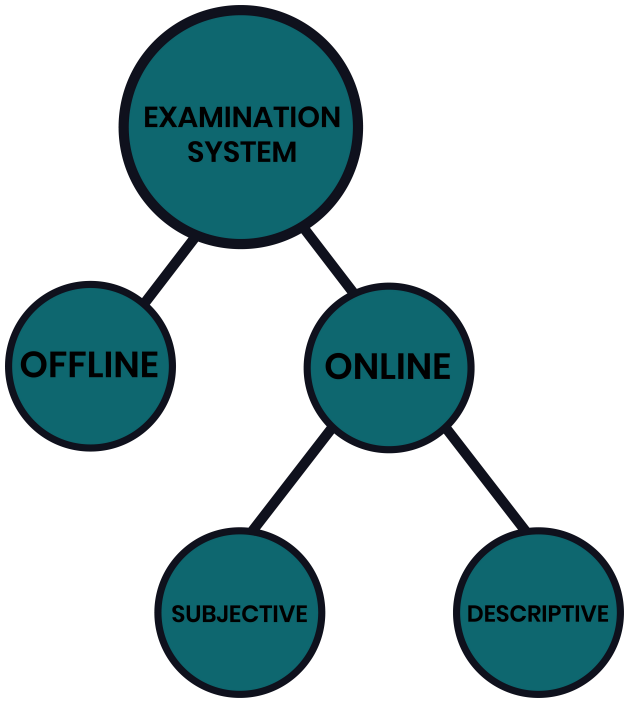

Fig. 1. Types of an examination system

For example when a product is stored in the database of the online shopping website, what happens is that additional keywords are stored for them such that they can be searched using those keywords. The string input by the customer in the search bar contains keywords using which products are searched and displayed on the customer dashboard. Even the back-end for such applications contains quality search algorithms that are out of the scope of this paper's discussion which is on the model of the descriptive online examination system. Similarly, the scenario is quite the same here for evaluating answers for questions that are descriptive in nature. Keywords are stored for every question and on the basis their occurrence in the answer string, the examinee is allotted marks. In order to perform this in Python language, there exists a library that makes it a little easier for the algorithm developers to perform string manipulations. The name of the library used is NLTK which is specifically designed for python to work on NLP. It is discussed in detail in the section where the algorithm is discussed.

In the below section as we can see is critical analysis in the field of Natural Language Processing and online examinations system. Its speaks about the works in the same field by other researchers and what they have done in order to develop such a system. The section below covers all the fields in order to develop and derive such a system out of the demerits of the other systems that are currently in use.

II. State Of The Art

The main aim of such a system is so that human effort can be reduced by introducing proficient computing technologies. Below, there is a discussion by some critical study on the existing technologies and algorithms for Natural Language Processing and examination systems that are already in use. It is by the help of these research papers that we could construct such an algorithm for conducting online descriptive examinations system.

Jayakodi et al.[1] had proposed a concept in the year 2015 to assign weights to questions for a test or basically their end semester question papers. There are multiple educational taxonomies that can be used to assess and assign weights to questions. So they use a taxonomy learning to function the above weight assignment. Here also they are using NLTK which is a library for working with Natural Language Processing along with the Wordnet package using Bloom's taxonomy.

In the year 2010 Ishikawa et al.[2], conceptualized a paper using Natural Language Processing. The idea was to detect users having multiple accounts over a community site. They had to solve this and hence they did some experimental analysis over the messages passed over Yahoo. The users who have multiple user accounts discourage other users in retrieving quality records and hence the credibility of the community site gets decreased.

Kaur et al.[3] in the year 2017 presented and introduced a paper keyword extraction from text. It uses the concepts of data mining along with Natural Language Processing in order to extract keywords. The sub-concepts used to extract keywords from the text include text mining, web mining, graph mining, temporal data mining, sequence mining, spatial data mining, multimedia mining and distributed data mining.

In the year 2009, Futrelle et al.[4] proposed a paper on NLP-NG which a new NLP system for biomedical text analysis. In this system there exist three subsystems depending on which NLP-NG works. The three components include NG-CORE which is used for language processing, NG-DB which is used for the management of the database, and finally NG-SEE that is used for active visualization. Normalization is being used to generate schema which can be used to detect domain-specific text from the main script or the text. The basic advantage of this system is that it can detect domain-specific text from a large variety of text scripts as it uses a 300 million word BioMed Central corpus.

In the year 2017, Revathy et al.[5] introduced a paper for feature extraction from text using NLP. The basic disadvantage of having an LDA system or Latent Dirichlet Allocation process was that it had a very high time complexity. In order to decrease time complexity, they used NLP or Natural Language Processing in order to do the same. LDA uses a generative statistical model that uses an unobserved group of data to explain observations for which time complexity reduces. NLP is faster as compared to LDA because it uses techniques of pattern generation and then ranks documents according to the patterns generated. What exactly happens is that documents related to the existing documents are found and further a cluster of documents are formed. Then an advanced ranking technique is applied to generate an author community so that they can communicate between them.

Nei et al.[6] in the year 2013 gave an emerging concept of simulation training which could improve the response time and could enhance the safety of the system in the real time, which would help to recreate a smart examination system. Also, the interface module works with the communication module which is connected to other modules. The analysis of data can improve the operational steps which will restore those steps and provide a base for further reports.

In the year 2009, Zhang et al.[7] introduced a SQL based online exam system which could show objective questions as well as the SQL questions but this had larger limitations that apart from the SQL questions. There is no way of showing subjective questions and also that time constraints and security could be improved to a greater extent. The system primarily focused on the processing of query statements and process of DML statements which are then compiled and the basic functions of account management and test management could be implemented in the code.

Zhai et al.[8] focussed on the online system with keeping an eye on the security and improving the performance of the system, the system basically which included the addition of the question modules storing the answers in the database, the paper also compared the traditional access methods like the MAC (Mandatory Access Control), DAC and many more such access techniques. The paper is experimenting with the basic concepts and then showing the test results on the access methods, the basic question module interacts with the test module is less reliable.

Luo et al.[9] in the year 2009 differentiated between a normal test and sequenced test and the paper focuses on order and dependency. It goes a step ahead in showing that where the executor can give executing permission or can deny it, it can also set the examinee-set which will lead to the questions module preparation and the exam system is automated as when permission is given to the executor it can start evaluating the sequence test and will generate the result, it combines the traditional model to make an automated system but the lack of security and have no scope for subjective answers is a disadvantage in the system.

Yang et al.[10] in the year 2012 gave an examination system which had a lot of features including the paper generation, to a better mix-up of library system to keep the papers and then arrange them accordingly and another automatic exam generating system which was there for the generation for the exam, the system being good for a hybrid platform for exam system has a little scope for subjective questions, even adding the feature will lead to system being check by an examiner as opposite to the automated system works, though it has new features of difficulty coefficient and also analysis of the paper but this does not use the full potential of automated online exam system.

In the year 2013, Treenantharath et al.[11] also talked about the online examination system with the use of the thin client i.e less connection need in compare to the fat client where we need a centralized server in respect to controlling the online activity also the fat client server typically exist with the client server architecture which is quite heavy to load, using thin client will provide solution to the described problem but it has little to no scope for the descriptive answers to be taken into consideration and thus the scope is only limited to the online multiple choice questions.

As discussed by Atoum et al.[12], the approach taken by the authors was a bit different in this paper as it was supposed to be a monitored online examination system as opposite to the offline center where the invigilator will have a close eye on the examinee there was an online system created to handle that problem by using the webcam and the microphone which will search for any kind of the anomaly and according to that actions will be taken if any kind of malpractice is detected while this system is better but it has loopholes where the above condition will fail, also the system will only have the MCQ based examination which leave us with little to no way for the descriptive answers to be evaluated

III. Algorithm of Online Descriptive Answer Marking System

As discussed earlier it is seen that there exist two types of examination portal or systems that include an offline examination system and an online examination system. Further, the online examination system can be grouped into two examination systems wherein one subjective questions exist while in the other descriptive questions exist. Subjective questions are those in which there exists a question for which a set of multiple choice options are provided such that the examinee has to select one of them. But then it may also happen that there may be multiple answers to a question, then, in that case, multiple check-boxes can be selected. While in the case of the descriptive examination system, a question exists for which the examinee writes an answer that is stored as a string and further marks are assigned to the answer according to the quality and correctness of the answer. Basically, keywords are stored in for the particular question by the teacher who uploads the test and its questions on the portal. The answer's correctness is judged by matching the answer with the keywords i.e basically the words of the answer with the keywords. Further, a sparse matrix is formed and hence it shows the count of each and every keyword in the answer string. Then there occurs some mathematical operation on it so as to count the actual accurate marks for the answer written.

As Python is used in order to code out the algorithm, a module or as we say a library named NLTK is used. This is the library in python that helps out to perform Natural Language Processing. It makes it easier for the algorithm developer to work with NLP. It consists of a list of common words such as prepositions and articles like a, an and the which have no use in the final answer evaluation, so they are removed. These common words are known as "stop-words".

After they are been removed, the keyword existence in the answer is calculated using a sparse matrix. For keyword that exits as a word in the answer string, we put 1 in the cell and go to the next keyword. If the keyword is not present as a word in the list of words in the answer string, then 0 is placed in the cell. This way the sparse matrix is formed. Further with the keyword existence count in the string, marks to be allotted to the answer is calculated.

There are some terms that are important while working on NLP and they are stated below, consider two strings as "Red Pen" and "Blue Pen". Here the keywords that can be obtained are "Red", "Blue", and "Pen". So, the keyword vector can be calculated in the format (Red, Blue, Pen) as,

$$A = (1, 0, 1) \quad (1)$$

$$B = (0, 1, 1) \quad (2)$$

Using this information we can calculate the similarity index between two strings by applying Cosine Similarity on Vectors.

$$sim\ (A, B) = \cos\theta = A \,.\, B / ||\ A\ ||\ ||\ B\ || \quad (3)$$

The next term is Term Frequency which is nothing but frequency of a term 't' in a document 'd'.

$$TF(d,t) = \#\ of\ occurrence\ of\ term\ 't'\ in\ a\ document\ 'd' \quad (4)$$

where,

$$t = The\ term$$

$$d = The\ document$$

Another term to be introduced is Inverse Document Frequency which is nothing but the importance of the term in the corpus.

$$IDF(t) = log\ (D / t) \quad (5)$$

where,

$$t = \#\ of\ documents\ with\ the\ term$$

$$D = \#\ of\ total\ documents$$

The final term to be introduced is TF-IDF. It gives the word count along with a notation of how important a word is in a document or a list of documents.

$$W_{x,y} = tf_{x,y}\ log\ (N / df_x) \quad (6)$$

where,

$$tf_{x,y} = frequency\ of\ term\ x\ in\ document\ y$$

$$df_x = \#\ of\ documents\ containing\ term\ x$$

$$N = \#\ of\ total\ documents$$

Without these terms, NLP is not no possible. Before working on NLP, one should know the meaning of these terms, what they are and how they can be used.

Below we discuss the algorithm used to work the descriptive answer marking system in detail. The merits and demerits of this system are also discussed in detail in the further sections. As we move on through the further sections, we can detect them.

Algorithm for Online Descriptive Answer Marking System

In the below algorithm, variables named KEYWORD and ANSWER are used to store the keywords from the database for the question and answer string input by examinee respectively. While variables NK is used to store number of keywords for the question with which answer string is to be checked, NY is the number of keyword columns for an answer string for which 1 is stored in the cell, MM is the maximum marks assigned to the question and MA is the marks assigned to the student for his answer. Below is the equation used to calculate the marks assigned to the student,

$$MA = (NY / NK) * MM \quad (7)$$

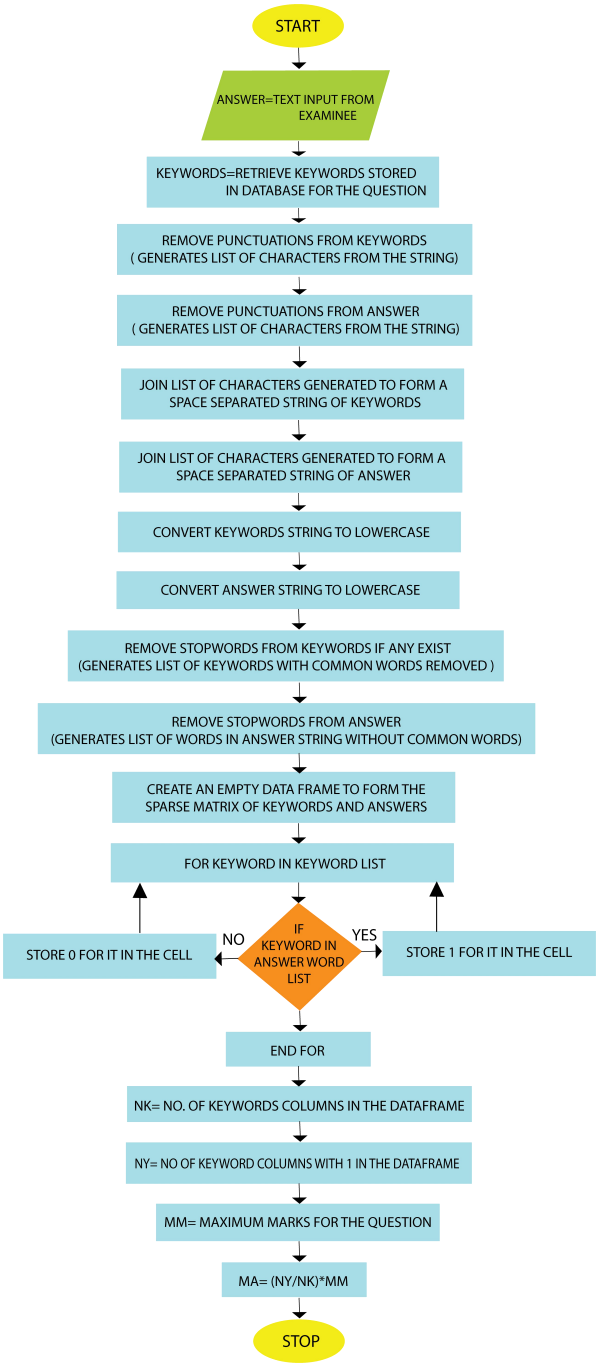

Fig. 3. Algorithm for Online Descriptive Answer Marking System

Now we would take an example of how the algorithm is working. Consider a question as "What is Data Preprocessing ?" for this question the keywords could be

KEYWORD = "data, preprocessing, mining, machine, learning, gathering, range, values, combinations, missing". Now consider the input answer to be ANSWER = "Data preprocessing is an important step in the data mining process. Data gathering methods are often loosely controlled, resulting in out of range values, impossible data combinations, missing values, etc.".

After applying all the string manipulations that include removing punctuation from KEYWORD and ANSWER, then converting the list of characters in KEYWORD and ANSWER into a string and then converting KEYWORD and ANSWER string into lowercase and then on removing stop-words or the common words from KEYWORD and ANSWER and finally after calculating keyword presence in ANSWER, it can be seen that the sparse matrix returned in the form of data-frame looks something like the figure below.

	Answer	data	preprocessing	mining	machine	learning	gathering	range	values	combinations	missing	Marks
0	Data preprocessing is an important step in the...	1	1	1	0	0	1	1	1	1	1	4.0

Fig. 2. Sparse Matrix formed on checking the presence of keywords in the answer string

Further, from here it can be seen that NY = 8, NK = 10, and let MM = 5 marks assigned to the question. Then, marks assigned would be MA = 4.0 using equation (7). Figure (2) shows the algorithm for Online Descriptive Answer Marking System.

IV. Results

The data that we received had the algorithm for online descriptive answer marking system applied to it. Below in figure (4) the sparse matrix for five students who answered the question " What is Data Pre-Processing? " can be seen.

	Name	What is Data Pre-processing?	Answer Words List	data	preprocessing	mining	machine	learning	gathering	range	values	combinations	missing	Marks

Fig. 4. Applied algorithm of the online descriptive answer marking system on answer generated by five students

In the above figure, it can be clearly seen that there are five rows with students naming Lipika, Adarsh, Bharat, Kashyap and Krishnanshu. Further, there are 14 columns among which the first column contains the Name of the student, answer to the question " What is Data Pre-Processing? ", Answer Word List which contains the keywords generated from the answer generated by the students and then come to the columns which are mandatory keywords that need to exist in the answer and the last column is Marks that consists of the marks obtained by the student.

It can be clearly seen from the algorithm in figure (3) that how the marks are being calculated from the keyword existence in the answer.

Here we have a small data for explaining the instance, while in practical situations when the number of students is huge i.e approximately in the range of 500-1000 or above than that, then quality analytics can be applied to know about the trend of the marks by plotting out some graphs by Python's visualization libraries that include Matplotlib and Seaborn. Below is a histogram showing the frequency of the marks obtained by the number of students.

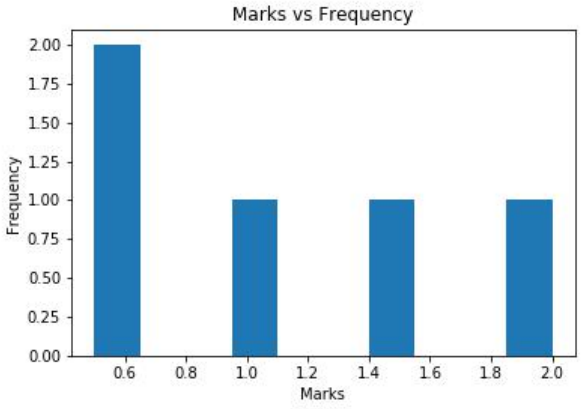

Fig. 5. Histogram for determining frequency of students marks

In the histogram, it can be clearly seen that two students have got the same marks who are Adarsh and Krishnanshu which is 0.5 marks. Further Lipika has got 1.5 marks as three of the keywords match with the answer string input by her. Similarly marks obtained by Bharat is 2.0 and by Kashyap is 1.5. Such histograms are beneficial to know the trend in the marks obtained by students.

V. Conclusion

It can be seen by conducting tests using such an algorithm at regular intervals that one can determine the trend in the marks obtained by different students and we can give them an analyzed report on the different subjects they need to focus on for which they are weak. With the existing data, we can also implement a predictive machine learning model on the data so that it can predict marks that the students will score in the future. It is observed that students mainly study those subjects that are placement oriented or which are required for placement purpose only. While students neglect the subjects of their core domain. Deep knowledge in the domain is required as it is of no use to study if you do not have a core domain knowledge. So it can help students get quality knowledge as everything will be digital and there will be no cumbersome process of conducting a pen-paper test. Also, answers are evaluated at that moment itself and the student can see the solutions and can correct the mistakes or errors committed while appearing for the exam.

The algorithm is also efficient as the faculty conducting the test can himself set the question along with the desired keywords he is expecting in one's answer. With this, there is a generalized model using which such answer marking systems can be developed and all the tests can be conducted over an easy to use dashboard oriented user login portal.

Also, talking about the future works on it, it can be tracked using the system that which student has cheated from any other student. This will again use the concepts of Machine Learning and Data Science to work upon these.

Abstract— **Recently , power electronic devices are widely used in various applications; because of this the shape of input current is greatly affected. Generally, the boost PFC converter provides satisfactory operation for current shaping but for some high voltage application it is not appropriate. In this proposed work a hybrid transformer-less PFC boost converter is introduced. This converter will function in DCM i.e. discontinuous conduction mode to shape current waveform at the input and to obtain a high voltage at output without the need of operating at high duty ratio. The converter uses a minimum number of devices which will enhance the power density and minimizes the cost. Furthermore, power switches voltage stress is decreased leading to low power loss in power switches and therefore making the circuit more cost effective. Finally, simulated results confirm the theoretical analysis and the competence of the presented converter.**

Keywords – PFC converter, Hybrid Boost converter, DCM(Discontinuous conduction mode)

I. INTRODUCTION

With the advancement of technology the use of power electronic devices increased at a rapid rate. Laptops, computers, workstation and power station etc. need of ac- dc power supplies which in turn enhances the use of rectifiers i.e. AC-DC converters inside these power supplies. The problem with conventional rectifier is that being a non-linear device they draw a non-sinusoidal input current which will greatly affect the input current and distort its shape, this on the other hand leads to the deterioration of power factor. In order to accomplish the requirement of high efficiency, many power factor correction technologies have been implemented to shape the current waveform at input. Most of the power factor correction technologies have implemented boost PFC converters owing to its excellent current shaping ability and high performance in terms of efficiency and power factor [1]-[2]. However, the problem with the conventional boost PFC converter displayed Fig .1. is that it is not appropriate for high voltage gain applications required in various biomedical and industrial equipment[3]. Owing, to the limitations of semiconductor devices it is not advisable to use the boost PFC converter at high duty ratio however, to achieve high step up voltage gain the boost PFC converter operates at extremely high duty ratio which leads to deterioration of power factor and increased losses. Also, boost PFC suffers from the problems of low efficiency, high THD at low input voltage and switch voltage stress is relatively high which will lead to increased power loss.

A family of high voltage gain single phase hybrid PFC rectifier suitable for application that require rectification with unity power factor is introduced[4].In [5] a single stage non-isolated switched capacitor AC-DC converter for PFC is proposed that commutes sub harmonics. Unidirectional step up AC-DC converter topologies with voltage multiplier in their output is proposed in [6].In [7] a hybrid switched capacitor voltage double SEPIC power factor correction rectifier to increase the voltage gain is proposed. Other examples of SEPIC PFC converters for universal input applications given in [8],[9],[11].The voltage gain can be improved by using the DC-Dc multilevel boost converter[10],[12].

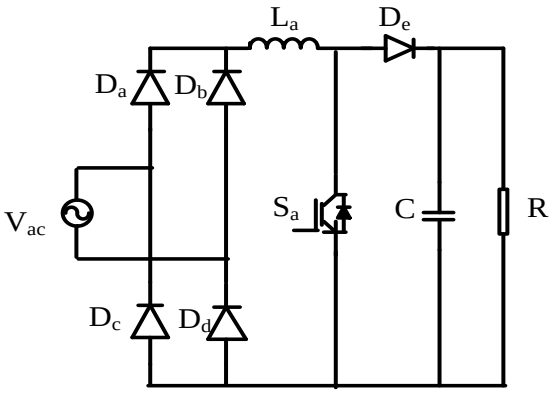

Fig .1. Conventional PFC boost rectifier

This paper presents a boost PFC converter based on hybrid transformer-less boost converter which utilizes a switching topology to replace the inductor of conventional boost converter [13]. This topology helps in reducing the number of switches of the switched inductor PFC boost converter [14] .The proposed converter displayed in Fig.2.has excellent input current shaping ability and reduces the harmonics present in the input current with the help of LC filter present at the input. This converter operates in DCM mode, thereby offering advantage of simple control techniques, soft turn on of switches and low diode reverse recovery loss. The converter uses a minimum number of devices which will enhance the power density and minimizes the cost. Furthermore, the voltage stress of the power switches is decreased so low voltage rating power switches can be used leading to low power loss and therefore making the circuit cost effective.

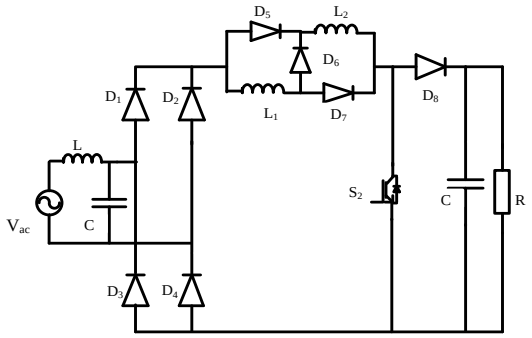

Fig.2. Proposed PFC converter

The section I of this paper includes the introduction of the proposed Hybrid Transformer-less PFC boost converter. The operating principles of the boost converter and its theoretical analysis are presented in section II and III. Finally the simulation result and conclusion is presented in section IV and V.

II. OPERATING PRINCIPLES OF BOOST PFC CONVERTER

The hybrid transformer-less boost PFC converter presented in this paper operates in DCM mode. For the simplification of mathematical calculation of the proposed topology certain assumptions are made as follows:

- Within single switching period the voltage at the input is taken as constant.
- The converter is considered as lossless thereby the power at the input and output can be assumed same.
- The load is taken as resistive.

The different key waveforms of the hybrid boost PFC converter during three distinct states of DCM mode are displayed in Fig.3.

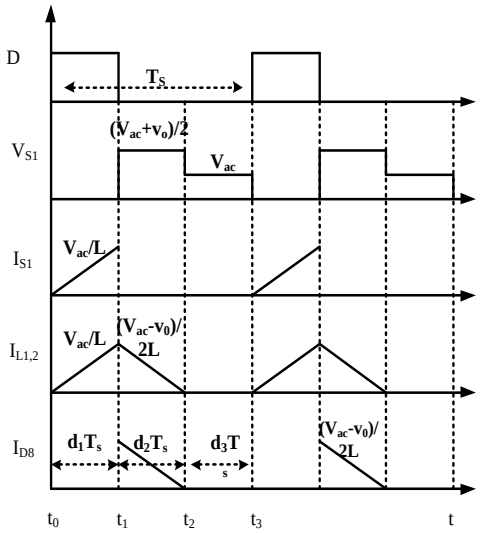

Fig.3. Boost PFC converter key waveforms in DCM mode

Operating in DCM mode, the boost PFC converter has three states during single switching period as represented in Fig.4.

State 1(Fig.4 (a)): During this state the power switch S_1 is turned on and the diode D_8 is off which will charge the two equivalent inductors L_1 and L_2 by the voltage at input which is AC in nature i.e. Vac through the path provided by the diodes D_5 and D_7 respectively. Simultaneously the power is supplied to the load by the bulk capacitor C at the output.

The equation for the current through the inductor and voltage at the output can be derived as:

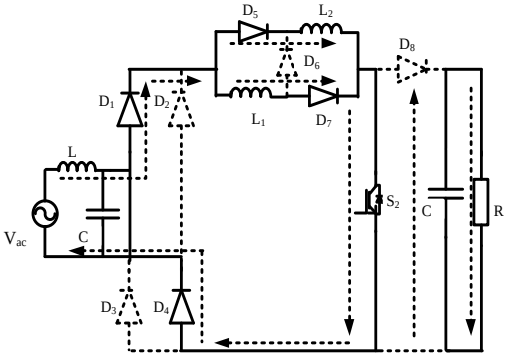
$$V_{ac} = L_{eq}\frac{d(i_{l1}+i_{l2})}{dt} \quad (1)$$

$$\frac{dv_o}{dt} = \frac{-v_0}{RC} \quad (2)$$

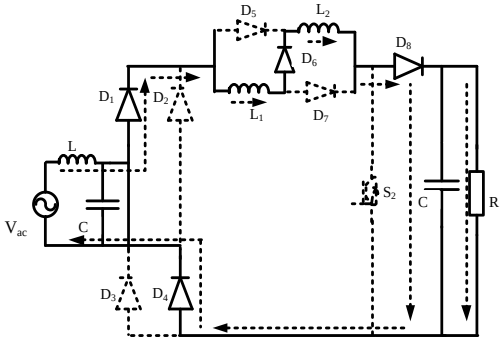
State2(Fig.4 (b)) : During this mode switch S_1 is turned off and diode D_8 is off , the power is supplied to load and the output capacitor from the input AC voltage source following the path made by the inductor L_1, diode D_6 ,inductor L_2 and diode D_8. The inductor current is given by:

$$\frac{V_{ac}-v_o}{2} = L_{eq}\frac{di_{L1}}{dt} \quad (3)$$

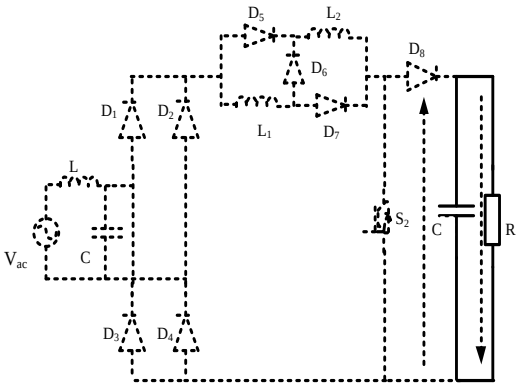
State 3 (Fig.4(c)): In the last state the power is supplied to the load by the energy that is stored in the bulk capacitor.



(a)



(b)



(c)

Fig.4. Different modes of boost PFC converter in DCM mode

III. THEORITICAL ANALYSIS

A. *Hybrid Boost Converter*

The hybrid boost converter is acquired when input inductor of a classical boost converter is replaced by the two inductor of the switching structure represented in Fig.5.

The different switching topologies of basic switching step up structure are represented in Fig.6. The two inductors represented as L_1 and L_2 charged in parallel during topology t_{on} and discharged in series during t_{off}.

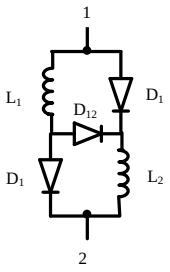


Fig.5. Basic step-up switching structure

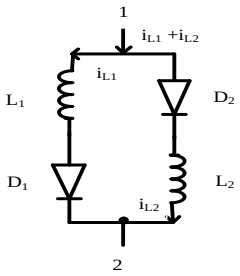
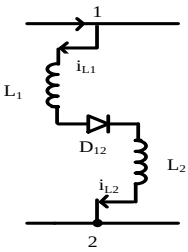


(a) t_{on}



(b) t_{off}

Fig.6. Different switching topologies during t_{on} and t_{off}

B. *Voltage conversion ratio, M*

The voltage conversion ratio of the conventional boost converter is represented as:

$$M = \frac{v_o}{V_{in}} = \frac{1}{1-D} \qquad (4)$$

However, after application of voltage second balance for the inductors L1 and L2 of the hybrid boost converter the voltage conversion ratio can be derived as:

$$v_o = \frac{1+D}{1-D} V_{in} \quad (5)$$

$$M = \frac{v_o}{V_{in}} = \frac{1+D}{1-D} \quad (6)$$

Thus, the voltage conversion ratio is (1+D) times greater than the conventional boost converter.

C. Control technique

The power factor correction converter presented in this paper has excellent input current shaping ability while operating in DCM mode. The control technique for this converter as described in Fig5. Comprises of a simple voltage loop which control the voltage at the output by comparing it with desired reference voltage and the difference between them is overcome with the help of PI controller to acquire the required output voltage.

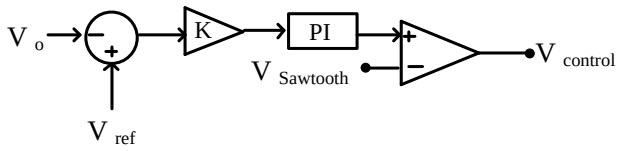


Fig.7. PI Controller

D. Power factor of high gain PFC converters

The PFC converter presented here operates at nearly unity power factor. The power factor can be evaluated by calculating the cosine of the phase difference between the current at the input and voltage at the output.

IV. Simulation and Validation of the PFC Converter

Here MATLAB simulation result is presented. The basic circuit parameters are :

- V_{ac} = 220 V_{rms}
- L_1 & L_2 = 0.4mH
- C = 470 uF
- Switching frequency ,f_s = 20KHz

Fig.8 shows the switching waveform of the switch used in the PFC converters. This switching waveform help to control the on and off timings of the converter. Here, it is noted that the switch duty cycle is very small and therefore, the voltage stress of the switch is minimized.

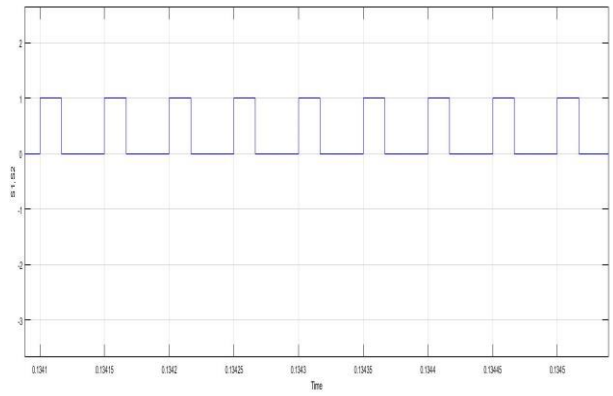

Fig 8. Switching Waveform

Fig.9. Represents the waveforms of voltage and current at the input at V_{rms} = 220V.The figure depicts that the input current waveform approximates to sinusoidal shape showing that the non-linearity and harmonics are reduced. Also, it can be depicted that the waveforms of the voltage and current at the input are approximately in phase showing that the power factor is nearly unity.

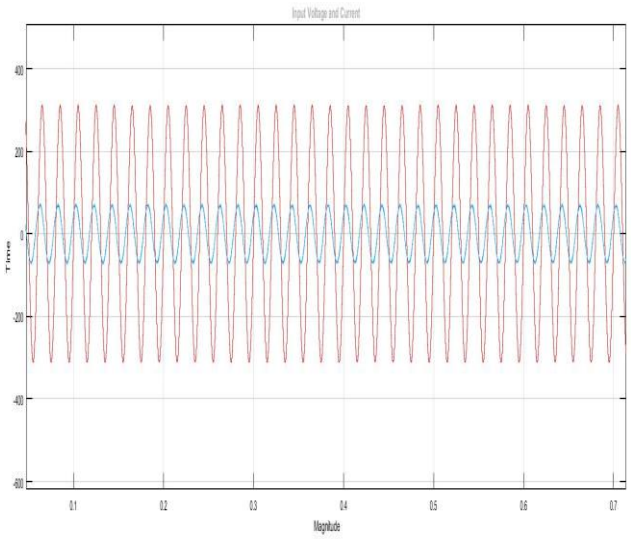

Fig 9. Waveforms of Voltage and Current at the input at V= 220 V_{rms}

The basic simulated key waveforms of the PFC converter presented in this paper are displayed in Fig 10. These waveforms are close to the theoretical waveform and thus prove the effectiveness of converter.

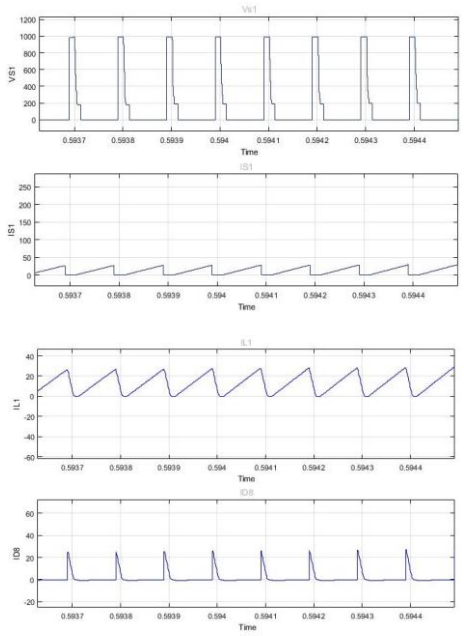

Fig 10. Simulated key waveforms

Fig.11. displays the THD analysis of input current waveform and it clearly depicts that the total harmonic distortion of the proposed converter has reduced to great extent in contrast to the traditional boost PFC converter.

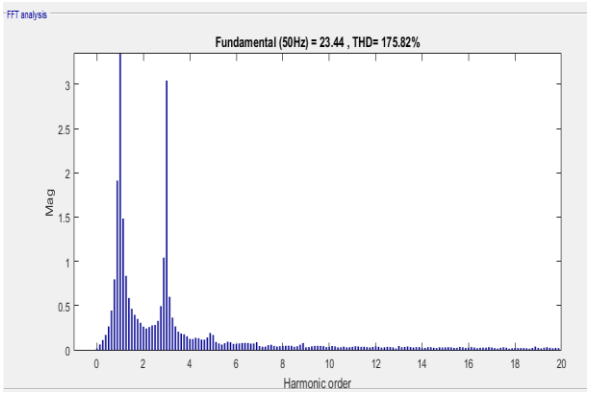

Fig.11 (a) THD analysis of current at input of conventional PFC converter

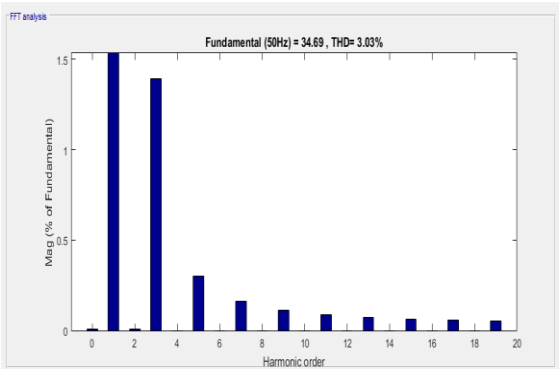

Fig .11 (b) . THD analysis of current at input of proposed PFC converter

Fig.12. represents the voltage at output of the converter which approximates to a constant value of 600 V.

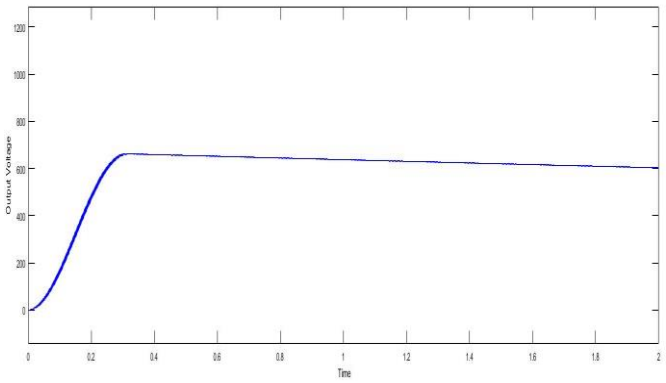

Fig .12. Output voltage

V. CONCLUSION

A hybrid transformer-less PFC boost converter based on the switching topology which replaces the inductor of the standard boost - converter thereby reducing the switching devices is proposed. The converter has input current waveform which follows sine wave i.e. it has excellent current shaping ability .Also, waveforms of voltage and current are approximately in phase i.e. power factor is close to unity. It operates in DCM mode and uses minimal number of devices which has less voltage stresses making the converter cost effective for practical application. The future scope of the proposed converter is it can be analyzed by use of other controller like fuzzy controller in place of PI controller and also it can be analyzed for different load applications.

***Abstract*—** Sensor nodes are geographically placed randomly in the environment. Sensor nodes are limited in capacities like computation power, memory, and processing speed. They collect sensitive information and send to the central base station. A novel TNVS is proposed that identifies certain nodes as authenticator nodes that have relatively high capability in storage, computation and power compared to the regular sensor nodes. These nodes are used for verifying new nodes that are being added into the network, thereby eliminating the entry of malicious nodes into the network. The master key that is shared by all the nodes of the network is renewed periodically to avoid node capture attack. Simulation and results show that in addition to providing authentication TNVS also requires less number of keys when compared to the existing key management schemes there by reducing the burden on memory requirement of the network.

Keywords— ***Authentication, node verification, Key exchange, Key Management, ECDSA, ECDH, Wireless Sensor Networks.***

I. INTRODUCTION

Sensor networks have many applications such as smart home security, military, environment monitoring, healthcare [5]. A wireless sensor network (WSN) consists of sensor nodes that are randomly distributed. Sensor nodes have less battery power, computation power, and storage [8]. They collect the monitor data and communicate with other sensor nodes or base station in the communication range. The proposed approach uses heterogeneous sensor networks (HSNs) that have different capabilities in terms of storage, computation, energy, and communication [9]. Security is a major issue in wireless sensor networks when deployed in an adverse environment. Many key management schemes for WSN were proposed on the security requirements of these environments [7].

It is important to ensure that any new node that enters into a network is properly verified. There is a high chance that it may turn out to be a malicious node if not properly verified. Hence authentication plays a very important role in security of WSN's. Digital signatures are the very best way to authenticate any given node. However, because of the resource constraint environment of WSN's few algorithms like ECDSA [16] are suitable for sensor nodes. The sensor nodes can use an ECDSA algorithm to generate a digital signature for authentication. Tree based node verification key management scheme (TNVS) proposed in this paper will use an ECDSA to authenticate the sensor nodes within the network effectively. The rest of the paper is organized as follows. Section II explains the related work. Section III briefs upon the existing tree-based protocol [12] for key management scheme in wireless sensor networks. Section IV presents the proposed TNVS approach. Section V interprets the results and Section VI is the conclusion of this paper.

II. RELATED WORK

Key management is about generating the keys and updating them in wireless sensor networks. Pre-deployed key management scheme is one of the key management schemes in WSNs [2] where, some keys are stored in the sensor nodes before deploying in the environment. In Adrian Perriz et al. proposed SPINS [1] a pre-deployed key management scheme, which is a master key based key management scheme. It stores the single key in all the nodes. If one node is compromised there is a chance to compromise all the other nodes. It provides good scalability for adding nodes in network but in-efficient security if one node is compromised. Liu et al. proposed a pair-wise key management scheme [3], in this scheme every sensor node stores all pair wise keys with neighbor nodes. It occupies a lot of memory for keys storage but it provides strong security. Sencun Zhu et al. proposed LEAP [14], that establishes four kinds of keys and provides strong security and scalability but requires a huge amount of communication for key establishment and update. Eschenauer & Gligor proposed probabilistic key pre-distribution scheme [10] that is based on the probability of neighbor nodes having common keys. Every node stores only some neighbor nodes pair wise keys from the key pool where some nodes have common keys in their neighbor nodes. Neighbor node selection is based on a chosen probability of common keys. It reduces the energy and storage but if one node is compromised then the probability of the connected nodes being compromised is 0.3. Du et al. proposed a key management scheme using deployment knowledge [4], it uses probabilistic key pre-deployment with the blom's key management scheme to establish the pair wise keys in sensor nodes. It provides node to node authentication but requires a lot of energy for computation. Chan et al. proposed q composite scheme [6], in this scheme any two sensor nodes stores q number of common keys for communication, if one key compromises, they use other keys. It provides strong security but needs a lot of memory and probability of key sharing decreases because pair of nodes has to share q common keys instead of one. Messai M-L et al. proposed a tree-based protocol for key management scheme [12], where every node is pre-

deployed with three keys. One key is the master key stored in all sensor nodes. Other two keys are used for communication between sensor node to base station and vice versa.Also, parent and child nodes compute their pair wise keys for their communication. It is resilient against node capture attack and is energy efficient and also has good scalability but requires storing more number of keys. In a tree-based scheme, new nodes are not verified before adding into the network. If not verfied, it may work as a malicious node in the network and then other nodes may also compromise. So, before adding new nodes into the network, it has to verify its authenticity. In the proposed TNVS approach some sensor nodes are taken as high capable nodes, which are called as authenticator nodes. These authenticator nodes verify the new nodes before adding into the network.

III. TREE-BASED PROTOCOL FOR KEY MANAGEMENT IN WIRELESS SENSOR NETWORKS [12]

Tree-based protocol scheme works as follows.

In tree-based protocol, the base station initiates the tree construction. The base station acts as a root node at level 0 and monitors all the sensor nodes in the network. The base station broadcasts the hello message then sensor nodes that are there in the communication range receive the hello message and respond back. All such sensor nodes are added as children to base station at level 1. Then level 1 nodes broadcast the hello message to next level nodes, and nodes that are there in communication range respond back to received hello message. These nodes will be added in level 2 and so on until the tree formation is completed. Both parent and child calculates their pair wise key and communicates using this key. Nodes send hello messages using the symmetric master key that is there in all the nodes prior deployment.

This tree-based protocol is proposed as a solution for secure node-to-node and node-to-base station communications. Tree based protocol is resistant to node capture attack. Each sensor node's identifier, its level and its parent identifier is calculated to authenticate the sender and the receiver. Hence, a sensor node cannot play a role of other nodes. So, Sybil node creation is not allowed in the network. Hello flood attack is also not allowed in the network until the master key is not known to an attacker.

However, whenever new nodes are added in the network, it has to be verified otherwise it may work as a malicious node in the network leading other nodes to compromise. In tree-based protocol new node verification is not available.

New node verification is implemented in the proposed TNVS approach. Verification is done by some nodes called as authenticator nodes. That has more capability in terms of power, memory, and computation. These authenticator nodes use ECDSA algorithm to verify new nodes.

IV. TREE BASED NODE VERIFICATION KEY MANAGEMENT SCHEME

A novel approach named TNVS is proposed to verify new nodes before adding into the network. The proposed approach is explained in three phases.

1. Key generation.
2. Tree construction.
3. Key renewal.

The following assumptions and notations are used in the proposed approach.

Assumptions

- A root node is a base station that initiates the key management process.
- Authenticator nodes have more capability than the sensor nodes in terms of storage, computation, and power.
- Only authenticator nodes can add the sensor nodes as children.
- In tree organization, internal nodes are authenticator nodes and leaf nodes are called sensor nodes.

Notations:

BS : Base Station id.
BS^{pr} : Base Station private key.
BS^{Pu} : Base Station public key.
$BS_{sign}{}^{Pr}$: Base Station digital signature using its private key.
AN_i : Authenticator node id i.
AN^{Pr} : Authenticator node private key.
AN^{Pu} : Authenticator node public key.
$AN_{i\text{-}sign}{}^{Pr}$: Authenticator node i's digital signature using its private key.
S^{Pr} : Sensor node private key.
S^{Pu} : Sensor node public key.
$S_{sign}{}^{Pr}$: Sensor node digital signature using its private key.
S_n : New sensor node
$S_n{}^{Pr}$: New sensor node private key.
$S_n{}^{Pu}$: New sensor node public key
$S_{n\text{-}Sign}{}^{Pr}$: New Sensor node digital signature using its private key.
K_M : Symmetric master key stored in all sensor nodes.
r_{AN_i} : A random number of AN_i node.
r_{S_n} : A random number of S_n sensor node.
n : n is the total number of nodes in the network.
A : A is the total number of authenticator nodes.

A. Key Generation :

Let $p > 3$ is a prime. The elliptic curve $y^2 = x^3 + ax + b$ over F_p, is the set of solutions $(x,y) \in F_p \times F_p$ to the congruence $y^2 = x^3 + ax + b \pmod p$ where $a,b \in F_p$ are constants such that $4a^3 + 27b^2 \neq 0 \pmod p$, together with a special point O called the point at infinity[13]. A sensor node private Key S^{Pr} is randomly selected from the F_p. B is a generator point on the curve. Sensor node public key $S^{Pu} = S^{Pr}.B$. [15]

B. Tree construction:

The base station is taken as a root node at level 0 and its parent is NULL. Nodes that are there in the communication range of level 0 are called level 1 nodes. In level 1 all nodes are taken as authenticator nodes. First, the base station

broadcast the hello message within the communication range. Authenticator nodes send hello message response to the base station. The base station connects the authenticator nodes as children in level 1.Authenticator nodes are identified by its ID. Level 1 authenticator nodes broadcast the hello message. In level 2, authenticator nodes and sensor nodes that are there in the communication range receive hello message and send hello message response to authenticator nodes of level 1. In this way, sensor nodes and authenticator nodes will form a tree structure until n numbers of sensor nodes in the network are completed.

Sensor nodes in each level collect the monitoring information and send it to their parent. The authenticator nodes collect the same data from the various sensors nodes and send it to the base station. However, the base station communicates with all sensor nodes in the network when key renewal is being performed to avoid communication overhead.

Base Station Node broadcast a Hello Message as follows.

$BS \rightarrow * :$
$\{HELLO\text{-}MSG, BS^{Pu}, BS, 0, NULL, BS_{Sign}^{Pr}(BS, 0, NULL)\}K_M$

Authenticator Nodes decrypt the hello message received from the base station with a symmetric master key and verify the hello message. After verifying, authenticator nodes send hello message response to the base station as follows.

$AN_i \rightarrow BS :$
$\{HELLO\text{-}RESP, AN_i^{Pu} AN_i, 1, BS, AN_{i\text{-}Sign}^{Pr}(AN_i, 1, BS)\}K_M$

BS decrypt the hello message response received from authenticator nodes with a symmetric master key and verifies the hello message response.BS adds authenticator nodes as children at level 1 after verifying hello response.

New node verification:

The next level of nodes broadcast JOIN message in communication range as follows.

$$S_n \rightarrow * :\{ JOIN, S_n, r_{S_n}, S_n^{Pu}, S_{n\text{-}Sign}^{Pr}(S_n, r_{S_n})\}K_M$$

Authenticator Nodes decrypt the JOIN message received from the new sensor nodes with a symmetric master key and verify the hello message. The authenticator nodes verify JOIN message with S_n Signature. After verifying, authenticator nodes send response to the new sensor nodes with received random number and sensor node id as follows.

$$AN_i \rightarrow S_n : \{ r_{AN_i}, AN_i, AN^{Pu}, AN_{i\text{-}Sign}^{Pr}(r_{S_n}, S_n) \}K_M .$$

New sensor nodes decrypt the received message from the authenticator node with a symmetric master key and verify the message. Sensor nodes verify the message with $AN_{i\text{-}Sign}$ signature. After verifying, sensor nodes send a response to the authenticator node with received random number and authenticator node id as follows.

$$S_n \rightarrow AN_i : \{ S_{n\text{-}Sign}^{Pr}(r_{AN_i}, AN_i) \}K_M .$$

Authenticator Nodes decrypt the message received from the new sensor node with a symmetric master key and verify the message. The authenticator nodes verify the message with S_n signature. After verifying, authenticator nodes send a response to the new sensor node with JOIN acknowledgement message as follows.

$AN_i \rightarrow S_n :$
$\{Join\text{-}Ack, AN_i, Level_i, AN_j, AN_{i\text{-}Sign}^{Pr}(AN_i, Level_i, AN_j)\}K_M$

New sensor node decrypts the received message from the authenticator node with a symmetric master key and verifies the message. The sensor nodes verify the message with $AN_{i\text{-}Sign}$ Signature. After verifying, sensor nodes are added to the authenticator nodes

C. Key renewals

It will be necessary to renew the encryption keys because using the same encryption key for extended periods may incur a cryptanalytic risk In order to accomplish the renewal of the sensor keys, the base stations generate the new master key and send the new master key to the authenticator nodes. The master key that is shared by all the nodes of the network is renewed periodically to avoid node capture attack. Authenticator nodes then send the new master key to sensor nodes. This phase first involves calculating a pair wise key between base station and authenticator nodes. Later new master key is shared to authenticator nodes from base station.

Pair wise key calculation between base station and authenticator nodes using ECDH is tabulated as follows:

A base station and Authenticator node shares their public keys.

TABLE I. PAIR WISE KEY CALCULATION BETWEEN BS AND AN_I

BS	**AN_i**
AN_i public key = AN^{Pu}	BS public key = BS^{Pu}
BS Private Key = BS^{Pr}	AN_i Private Key = AN^{Pr}
Public Base Point = B	Public Base Point = B
BS Public key(BS^{Pu}) = BS^{Pr}.B	AN_i Public Key(AN^{Pu}) = AN^{Pr}.B
Pair wise Key ($K_{BS\text{-}AN_i}$) = BS^{Pr}. AN^{Pu} = BS^{Pr}.AN^{Pr}. B $K_{BS\text{-}AN_i}$ = BS^{Pr}.AN^{Pr}. B	Pair wise Key ($K_{AN_i\text{-}BS}$) = AN^{Pr}. BS^{Pu} = AN^{Pr}. BS^{Pr} .B = BS^{Pr}.AN^{Pr}. B $K_{AN_i\text{-}BS}$ = BS^{Pr}.AN^{Pr}. B

After calculating a pair wise key between base station and authenticator node, base station now updates new master key K'_M is updated as follows:

$$K'_{M=} \text{ New-}K_M$$

The base station sends new master key in an update message to authenticator nodes using their pair wise key as below.

$BS \rightarrow AN_i :$
$\{Update, BS, K'_M, NULL, BS_{sign}^{Pr}(BS, K'_M, NULL)\} K_{BS\text{-}An_i}$

Pair wise Key calculation between Authenticator nodes and sensor nodes using ECDH is tabulated as below:

TABLE II. PAIR WISE KEY CALCULATION BETWEEN AN_I AND S_I

AN_i	S_i
S_i public key = S_i^{Pu}	AN_i public key = AN_i^{Pu}
AN_i Private Key = AN_i^{Pr}	S_i Private Key = S_i^{Pr}
Public Base Point = B	Public Base Point = B
AN_i Public key(AN_i^{Pu}) = AN_i^{Pr}.B	S_i Public Key(S_i^{Pu}) = S_i^{Pr}.B
Pair wise Key($K_{AN_i\text{-}S_i}$) = $AN_i^{Pr}.S_i^{Pu}$ = $AN_i^{Pr}.S_i^{Pr}.B$ $K_{AN_i\text{-}S_i}$ = $AN_i^{Pr}.S_i^{Pr}.B$	Pair wise Key($K_{S_i\text{-}AN_i}$) = $S_i^{Pr}.AN_i^{Pu}$ = $S_i^{Pr}.AN_i^{Pr}.B$ = $AN_i^{Pr}.S_i^{Pr}.B$ $K_{S_i\text{-}AN_i}$ = $AN_i^{Pr}.S_i^{Pr}.B$

Authenticator nodes decrypt the update message with pair wise key and verify the update message. After verification, it updates its master key and deletes the old master key. Authenticator nodes then send an updated master key to sensor nodes, after calculating pair wise key between authenticator nodes and sensor nodes.

Authenticator nodes sends new master key in updated message to sensor nodes using their pair wise keys as below:
If parent is BS:

$AN_i \rightarrow S_i$:
$\{Update, AN_i, K'_M, BS, AN_{i\text{-}sign}^{Pr}(AN_i, K'_M, BS)\}K_{AN_i\text{-}S_i}$

If parent is Authenticator node:

$AN_j \rightarrow S_i$:
$\{Update, AN_j, K'_M, AN_i, AN_{j\text{-}sign}^{Pr}(AN_j, K'_M, AN_i)\}K_{AN_j\text{-}S_i}$

Sensor nodes decrypt the message with pair wise key and verify the message. After verification, it updates the master key.

V. SIMULATION AND RESULTS

TNVS is simulated and analyzed in NS2.The NS2 simulation environment set up parameters are as follows.

A. Simulation Environment Setup :

TABLE III. *SIMULATION PARAMETERS*

Parameters	Values
Number of nodes	1020
Area size (m^2)	1200 × 1200
Simulation duration (sec)	300
Agent	UDP
Mobility speed (mb/s)	AN = 10,SN =2
Radio range (m)	AN = 250,SN = 100
Number of AN	25 percent of nodes

In simulation run the experiments for 21 nodes to 69 nodes.

B. Sensor nodes Tree Formation :

Base Station adds the first level of authenticator nodes. Authenticator nodes then verify the sensor nodes and add in each level until tree formation is completed in the network. Tree organization for set of 37 nodes is simulated in the Fig. 1.

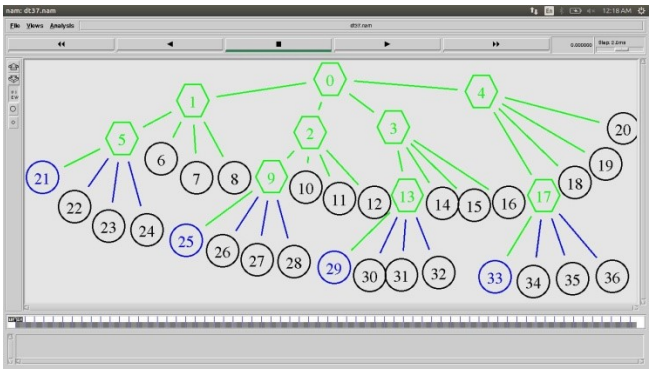

Fig. 1. Tree organization in TNVS.

C. Node verification using ECDSA

Consider n_0 as a root node and n_1 as authenticator node. n_0 node broadcast the hello message. n_1 node verifies the hello message received from base station n_0.In above Fig. 2, it can be seen that n_1 node is verifying the message with ECDSA parameters.

Fig. 2. Authenticator node verification.

D. Total number of keys:

In tree based node verification key management scheme approach sensor nodes are pre-deployed with its own private key, public key, and the symmetric master key. Authenticator nodes stores the parent and child nodes pair wise keys, public keys, one symmetric master key, its own private key, and public key. In the proposed approach d is the degree of the node.
In TNVS we have 3 sensor nodes and one authenticator node as children and one parent node resulting in d=5.Total Keys = A*(2d+3) +3*S. Total number of keys required for various existing schemes are analyzed and compared.
In table IV, m is the key pool size, H is the cluster head sensor nodes, C is the number of children assumed for tree

IEEE Conference Record # 45198; IEEE Xplore ISBN Number: 978-1-7281-1261-9

protocol and in TNVS scheme, CC-4 is able to recover the encrypted message without knowing the neighbor nodes pair wise keys. Assume each cluster head is associated with 50 sensor nodes i.e. in 204 nodes 200 nodes are taken as sensor nodes and 4 nodes are taken as cluster heads.

TABLE IV. TOTAL KEYS COMPARISON

Approach	Number of Keys	Sensor Nodes				
		204 S=200 H=4	**408** S=400 H=8	**612** S=600 H=12	**816** S=800 H=16	**1020** S=1000 H=20
Tree Based[12]	S(3+C)	1428	2856	4284	5712	7140
ECC Distributed[17]	(H+2)S+3H	1212	4024	8436	14,448	22,060
EG Scheme[11]	m(H+S)	m=30	m=60	m=90	m=120	m=150
		6120	24,480	55,080	97920	153000
		k=4	k=8	k=12	k=16	k=20
SPINS[1]	S(5+ k)	1836	5304	10404	17136	25500
LEAP[14]	S[(3*k)+2+ k]	3672	13872	30600	53856	83640
TNVS	A*(2d+3)+ 3*S	A=51 S=153	A=102 S=306	A=153 S=459	A=204 S=612	A=255 S=765
		1122	2244	3366	4488	5610

The total numbers of keys required for proposed scheme are compared with the existing schemes for 204,408,612,816 and 1020 sensor nodes. Total number of keys calculated is shown in table IV. A graphical representation of the same depicted in Fig. 3.

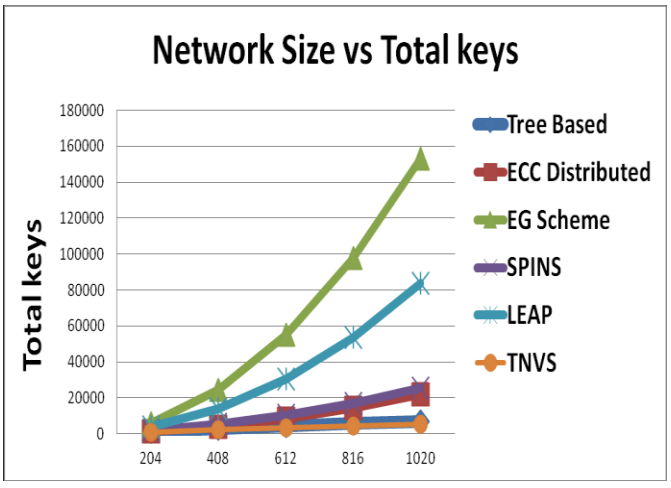

Fig. 3. Network size vs Total keys

The total numbers of keys are less compared to other schemes. In this scheme, new nodes are verified by authenticator nodes using ECDSA algorithm and total numbers of keys are better than existing pre-deployed key management schemes. Proposed scheme reduces the memory required for storing keys and as well provides authentication for new nodes that are being added in the network using ECDSA algorithm.

E. Security Analysis:

In this scheme, assume master key K_M is not known to the attacker then nodes cannot compromise until the pair wise key is calculated in the network. The attacker will not be able to recover the encrypted message without knowing the master key.

Hello Flood Attack: In the TNVS approach, sensor nodes broadcast the hello message that is encrypted using master key for tree construction. An attacker without knowing K_M could not send Hello Flood Attack. Hello message is verified by the authenticator nodes using the ECDSA algorithm.

Node Capture Attack: Every pair of nodes calculate unique pair wise key using ECDH. If one node is compromised attacker can get only one sensor nodes keys. The attacker can't get other sensor nodes keys as base point B is secret and private keys are unique for each sensor node. No matter any number of sensor nodes are compromised other nodes can securely communicate using ECDSA algorithm.

VI. CONCLUSIONS

In this paper a novel tree based node verification key management scheme is proposed for key management scheme in wireless sensor networks. New nodes that are being added in the network are verified by the authenticator nodes using ECDSA. Results shows that TNVS scheme reduces the memory requirement for storing keys and the periodical master key renewal makes the scheme resistant to node capture attack. This approach can be extended for node verification in multi-hop communication.

Abstract - **Object detection using stereovision is a process to identify a specific object in a sequence of different images. In many years it receives much more attention due to a huge number of applications like navigation, automated inspection, wildlife analysis, etc. The detection of an actual object with different shapes is a difficult task; due to some issues like the external environment, fast movement of an object, shadows, noises, etc., so there is a requirement to choose appropriate methods/algorithms with respect to it. So, this paper specifies depth analysis with stereo vision using an appropriate algorithm.**

Keywords- Deapth,Stereo,Camera,Checkerboard,Calibration.

I. INTRODUCTION

The depth analysis is a predominant tool to investigate various parameters like object detection, distance, size, shape, and many other dimensions. Stereovision is the most versatile and flexible application which used in many applications such as detection, navigation, security, wildlife analysis, etc. Stereo vision systems can be ordinarily used in object detection whereas it generates depth information which detects very small objects with accurate measurement of size and distance. The Stereovision system can be implemented using two cameras that provide a disparity between two objects. Object detection can be achieved by using various traditional methods like Background subtraction, frame differentiation, etc. [1][2][3][4] But due to some limitations, they are not satisfactory for real-time applications. The camera calibration is a primarily important step that uses 3D computer vision to extract metric information for 2D images for object detection, which can be achieved by using various methods. Checkerboard method with black and white square pattern is one of the efficient and accurate methods. It can be used for camera calibration. [8] Firstly the camera initiates too many distortions in the image. Tangential and radial are the major distortions. In a checkerboard image, the lines have appeared as curved due to radial distortion whereas tangential distortion arises due to parallel misalignment of image plane and image. These distortions can be corrected by using appropriate scaling formulas. Another parameter such as intrinsic and extrinsic parameters which include focal length, optical centers, rotational and translational vectors, etc. can be found using sample images of the checkerboard pattern. Distance, size and other dimensions can be estimated using various equations.

The overall idea of this work is, using two cameras the distance between the desired object in frame and the camera is calculated. For this purpose, using camera calibration the distortions are corrected and depth map is generated. After that using regression the depth is calculated.

This paper describes first the related work in that various surveys are considered, after that the detailed explanation about the proposed work is given. In next

II. RELATED WORK

A. Literature survey based on calibration methods

1. Traditional camera calibration method

The traditional camera method is suitable for every type of camera which has high precision calibration which gives high accuracy. The given calibration of the reference object is known in shape and size. The internal and external parameters of the camera are determined by the mathematical transformations. But the algorithm of this method is comparatively complex than other calibration methods.

2. Camera self-calibration method

The camera calibration is done only by comparing the relationship between the images of the surrounding environment during the movement of the camera. Here the 'Kruppa' equations are introduced which determines internal and external parameters. The equations of Kruppa equations are complicated to solve and this method is unstable for the camera calibration. [5]

3. Linear calibration method

The typical calibration method or direct linear transformation method was proposed by 'Abdul-Aziz' & 'Karara' in 1971. Here the parameters are defined while internal and external parameters of the camera should be determined by linear equations without any iterative calculations. The precision in this method is inaccurate. [6]

4. *Tsai two-step calibration method*

This method was proposed in 1987, there was radial distort although directly solving Kruppa equations can get internal and external parameters of the camera. The matrix transform method was used first to determine camera parameters and then achieved as the parameter's initial value, the distortion factor and the use of optimization method improve the calibration and accuracy. Due to high calibration accuracy, it reduces space dimension parameters. This method is not suitable for simplified calibration and it is difficult to obtain noncoplanar 3D points. [10]

5. Zhang calibration method

'Zang' calibration or 'planer pattern method' uses 2D checkerboard to calibrate camera without expensive calibration target. This requires a shoot and calibrate template from more than two images with a different angle. It doesn't need a specific position and displacement information of the planer template movement. The calibration process is complex. [7]

The outcome from all this survey is that the planer pattern method is preferable for the stereo vision than any other method. It gives a better result and accuracy. In this method process of calibration is complex, but still, this method gives a stable result.

B. Literature survey based on camera

1. Logitech C170

The Logitech C170 is a basic camera with a 5 megapixel with a frame rate of 30 fps with resolutions of 1024 X 768 Pixels. It is easy to interface with applications. Passive 3D depth estimation is one of the limitations of this camera. The limitation of the logitechC170 is that, its poor resolution.

2. Logitech C270

The Logitech C270 offers relatively high grade and HD quality image. The maximum resolution 1280 X 720 image capture. The USB 2.0 webcam provides the image. Among this, it yields parameters setting such as white balance, exposure, brightness, gain, and contrast. [8][9]

3. IDS UI-1646 USB

It is a 1.3 MP colored pixel camera with a compact and robust design. The camera can be easily mounted with a various number of applications without any interfacing issue. It is a board level camera that supports the use of M12 S-mount lenses. The maximum resolutions are 1280 by 1024 with the ability of 25 frames/ sec. [12]

4. PB-MV13

PB-MV13 is a 1.3 MP camera, whose frame rate is 500 frames/second. The resolution of the camera is 1280 X 1024micrometer. 12 X 12 micrometer is pixel size. The power consumption of this camera is high and it is also very expensive. [13] [14] [15]

5.HDCS-2020

It is a CMOS structured with very high resolution and less consuming power, which is available in two different types VGA and CIF. Pixel size is 7.4 X7.4 micrometers. Storage is comparatively high around 6 GB. [11]

The LogitechC270 has a high resolution and it fulfills all the featured and technical requirements. It provides high image quality and better accuracy, so it is preferable for a stereo vision system.

III. PROPOSED WORK

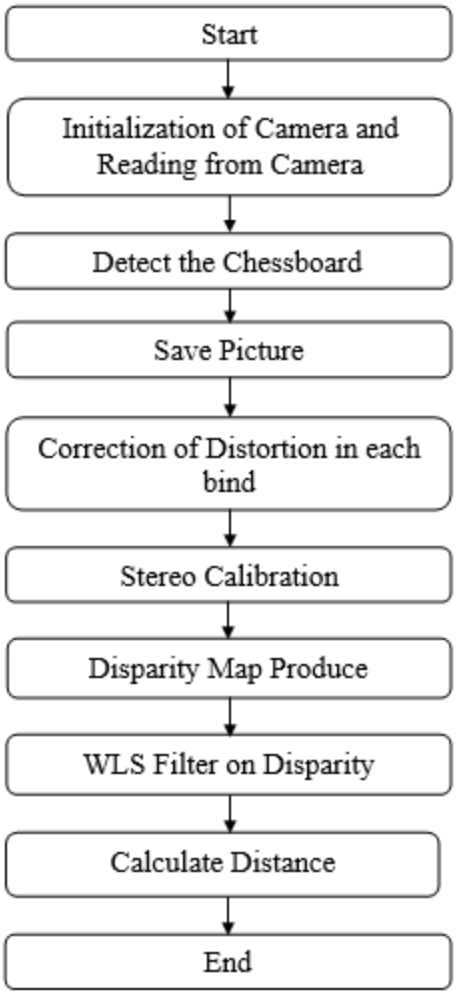

Fig (a). Flow chart of the proposed system

The flow chart consists of several processes. The processes are divided into two parts. The first part determines about images of checkerboard for calibration and the second part describes how the camera calibration is used for depth calculation.

Part I

A.Initialization of camera

Firstly, initiates both cameras which are right and left cameras, after reading the captured video it stores the frames in two variables named frames 'R' & frame 'L'. Convert the captured frames in grey for further operations and computations. [17] [18]

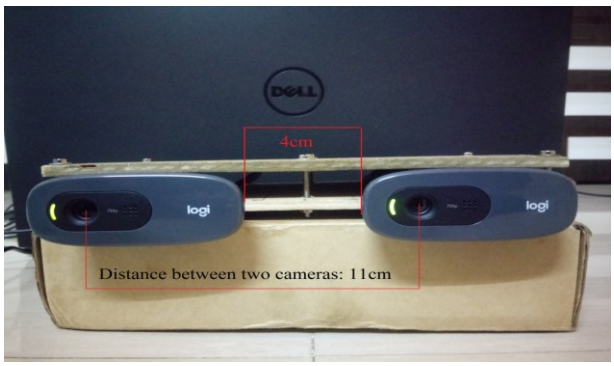

Fig (b). Camera C270 setup and initialization of camera

B. Detect checkerboard

Take Chessboard of either 8x8 blocks (Playing Chessboard) or 10x7 blocks, and find the positions of internal corners of the chessboard. If chessboard corners are detected in both the cameras, 'cv2.cornerSubPix' instruction defines the corner locations. 'cv2.drawChessboardCorners' represents the detected chessboard corners. [17] [18]

Fig (c). Cameras detecting chessboard corners

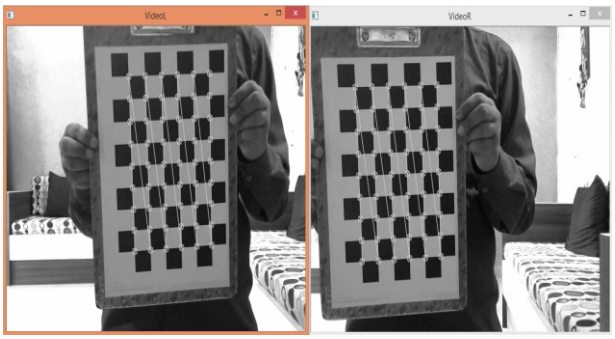

Fig (c). Detection of chessboard pattern

C. Save pictures

The detected images are saved by pressing 's' on the keyboard. Minimum 200 images of the checkerboard are required for calibration (left-100 & right-100). The maximum number of images gives a better result of calibration. [17] [18]

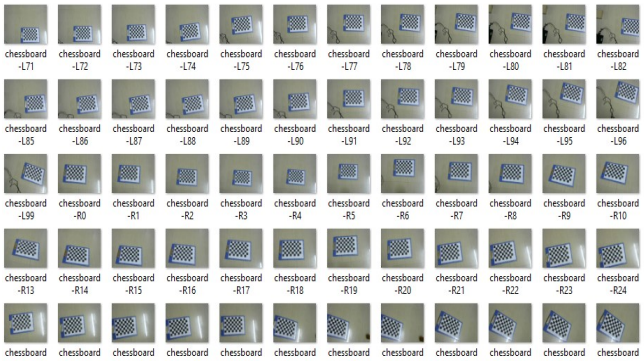

Fig (e). Database of the detected checkerboard

Part II

A. Stereo calibration

With the stored database of Checkerboard images, stereo camera calibration is initiated and the locations of corners are again calculated. The function 'cv.calibrateCamera' determines the camera's intrinsic and extrinsic parameters from several views of a calibration pattern which determines various factors like camera matrices, the distortion coefficient, and translation vector. Calibrate stereo cameras use the function 'cv2.stereoCalibrate', this function estimates transformation between two cameras making a stereo pair. 'cv2.stereoRectify' calculates rectification transforms for each head of a calibrated stereo camera, where this function calculates the rotation matrix for both cameras (right, left), which makes image planes the same (virtually). The function takes the matrices computed by 'cv2.stereoCalibrate' as input and provides 2 rotational and 2 projection matrices as an output with new coordinates. To get horizontal stereo, both the cameras (left and right) shifted to each other along the 'X' axis. In the rectified images, the corresponding 'epipolar' lines in the left and right cameras are horizontal and have the same y-coordinate. 'cv2.initUndistortRectifyMap'corrects the

distortion and rectifies the transformation maps and represents the result in terms of the map. 'StereoSGBM' used to obtain a correlation between the left and right camera. 'cv2.ximgproc.createRightMatcher' (stereo) creates another stereo for right, but the result of this function is difficult to detect the edge of the object because of noise. To remove this WLS filter is used. [18]

B. WLS filters on the disparity

First, set a filter in initialization mode. It consists of a lambda value, which can typically set at 8000, But if it is set at 80,000 it gives a better result. Another stereo object is created with 'cv2.ximgproc.createRightMatcher( )' function. These two cases are used in WLS (Waited least square filter) to generate a disparity map. So, after starting both the cameras, read and store the frames and then applied 'cv2.remap' function to generate a geometric transformation of the images. The result of 'cv2.remap' is then converted into a grey image. Then grey images are converted into a stereo image with the help of WLS filter. The values that come out from the WLS filter are normalized with the help of 'cv2.normalize()' function. In disparity, the value contains too much noise which can be removed by using a morphological filter. The 'cv2.applyColorMap ()' is used to convert a grey scale image into the 'color Image'. To identify the farther and nearer objects, the color map command is used. The nearer object is specified by white ocean color and farther object is specified by dark blue color which shown in fig (f). [18] [19]

Fig (f). Disparity map image using stereo images

C. Calculation of Distance

Once the disparity generated, the distance must be calculated. To determine appropriate distance, there is a need to satisfy the relation between distance and disparity, this can be achieved by 'regression'. In the regression, the disparity values are experimentally measured at several points which finally determine distance.

IV. RESULT ANALYSIS

As discussed in a proposed algorithm, the ocean color shades are used for object representation. The lighter color is used for nearer object and a darker color for the farther objects or background. When a particular object is clicked, then the distance between the 'selected' or 'clicked' object and camera is determined by the algorithm. Fig. (g) shows an ocean colored image, where lighter color is an object and darker part is the background scene. When we click the object in frame, it gives an appropriate distance between camera and object in 'mm' or 'cm'.

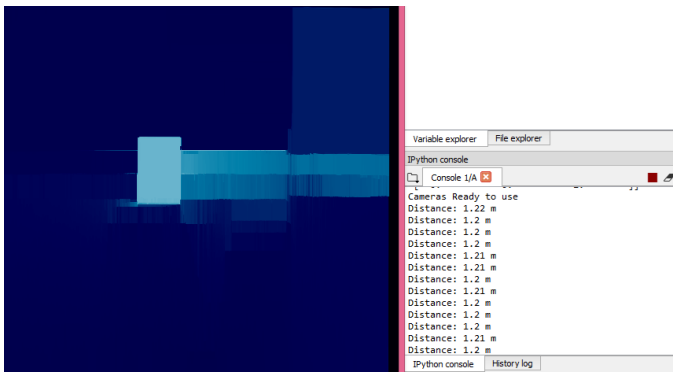

Fig (g). Result: Disparity map and computed distance

After a generation of disparity map, the distance has been calculated. The range of working of this algorithm in our case is around 2 to 3 meters. The min to max values in 10x7 and 8x8 checkerboard is 65 to 200 meters and 68 to 207 meters respectively. The following tables (Fig(h) and Fig(i)) are the result tables that consist of actual distance, computed distance and error for 10x7 and 8x8 checkerboard. Here, the random 10 readings are taken into account. The computed distance is measured with the help of disparity algorithms. According to it, the actual distance is measured manually with the help of scale; where it gives an error range from '+3 to -3'. So here, there is a variation in two different readings with some errors, which will possibly be removed by using a good quality of the camera.

Sr No.	Computed Distance (cm)	Actual Distance (cm)	Error
1	65	68	3
2	70	73	3
3	76	76	0
4	82	84	2
5	90	91	1
6	137	137	0
7	174	173	-1
8	184	182	-1
9	190	192	2
10	200	203	3

Fig (h). Result of a 10x7 checkerboard

Sr No.	Computed Distance (cm)	Actual Distance (cm)	Error
1	68	70	2
2	73	75	3
3	78	80.4	2.4
4	87	84	-3
5	113	113	0
6	142	144	2
7	175	172	-3
8	189	189	0
9	1.94	1.93	-1
10	207	207	0

Fig (i). Result with 8x8 checkerboard pattern

Limitations

- A large number of captured images (database) may lag down the system.
- Less number of captured images may affect accuracy.
- With the use of Logitech C270, its work range is around 2 to 3 meters. With the use of a better quality camera range can be extended.
- The precision of measurement is around +/- 3cm.

V. Conclusion

In this work the various camera calibration methods and various types of cameras are surveyed. Like a human eye, in the proposed system, the stereo vision with calibration algorithm has achieved the depth perception using a two camera, and also achieved calculation of the distance between object and camera without any disturbance. The proposed stereo vision system can detect a selected object and calculates its distance with the precision of +/-3cm in a range of 2 to 3 meters. The performance of this system will be enhanced by using a good quality of the camera and a high-power image processor.

***Abstract*—Due to rising fuel prices, shortage of fuels and increasing air pollution there is more demand for electric vehicles. But in India the main concern is we do not have enough charging stations to recharge electric vehicles during emergency. So, we cannot use e-bikes for longer range. The hybrid powertrain is used to solve this problem. The primary drive of the powertrain is electric motor and secondary drive uses an IC engine. The power train consists of free wheels and fixed sprocket which allows to operate motorcycle on electric motor as well as IC engine. The use of hybrid powertrain improves overall range of motorcycles.**

Keywords—Hybrid powertrain, freewheels, fixed sprocket, electric vehicles, range, hybrid motorcycle

I. INTRODUCTION

The development in the trends of internal combustion engine vehicles has brought various improvements in automobile sector having great impact on society by satisfying the needs in day to day life, [1]. However, the use large number of automobiles causes large amount of air pollution which has hazardous effects on human life. The combustion products such as nitrogen oxides (NO_x), carbon monoxide (CO) and unburned hydrocarbons (HC) are toxic to human health. Also, carbon dioxide released in atmosphere is responsible for global warming and increasing earth's temperature, [2]-[3]. These are the main reasons for increasing demand of electric and hybrid vehicles. A hybrid vehicle has at least two energy sources, most commonly used energy sources are IC engine and electric motor, [4]. Many researches and studies have been developed in the field of hybrid powertrain to develop the sufficient power to meet the demands of vehicle performance, obtain the sufficient range, improve efficiency and emit few environmental pollutants. The electric vehicles are mainly classified as Plugin electric vehicles (PEV) and Hybrid electric vehicles (HEV), [5]. The various configurations of hybrid vehicle developed are series hybrid, parallel hybrid, series-parallel hybrid, mild hybrid and complex hybrid, [6]-[9].

In India there is demand for electric bikes and cars due to increasing fuel prices, shortage of fossil fuels and rising air pollution. But the electric vehicles have limited mileage per charge, charging of batteries is a time-consuming process. So, it becomes difficult for e-bikes to cover a range of 100-120 kms with limited capacity of battery pack. This paper is aimed to solve the range problem by using hybrid powertrain for bikes. The hybrid motorcycle consists of two power sources. The parallel combination of motor and IC engine is used driving the motorcycle. The hybrid powertrain is designed in such a way that both the power sources are in frontal part of the motorcycle. The motor is used as primary device for driving the bike with a moto of reducing air pollution. The motor used satisfies the performance characteristics of motorcycle i.e. top speed, gradeability, acceleration etc. The engine will be used as a secondary device to drive the bike to improve the range of vehicle. So that even for longer distances 110-130 kms we can use motor for initial 48-50 kms and then use IC engine to cover extra distance. It will also help to reduce air pollution. The throttle of engine and motor is given in right hand only for normal driving experience. The shift from IC engine to electric mode is done by using switch. This design enables us to drive the bike using motor in cities and shift to IC engine for driving on highways.

The paper organization is as follows: In Sect. II the concept of hybrid powertrain is explained along with its CAD model. In Sect. III the working of powertrain is explained. Then in Sect. IV engine selected and its specifications are given. Sect V gives the motor selection and specifications. Sect. VI gives the battery specifications. Sect. VII includes modified frame design for motorcycle. Sect VIII has the powertrain specifications and selected drive ratio. Sect. IX has the observations taken by testing of bike at various speeds. Sect. X consist of graph comparing cost and distance in petrol and hybrid bikes. At last, Sect. XI consists of actual pictures of powertrain developed. Conclusive remarks close the paper.

II. CONCEPT OF HYBRID POWERTRAIN

In two-wheeler segment, the hybridization is usually done by using hub motors as front wheel and engine drives the rear wheel, [10]. But this configuration has very less torque and neglects the driving experience by enabling both wheel drive in two wheelers. To overcome this problem, we have used BLDC motor with gear reduction and by providing drive only to rear wheel. The hybrid powertrain consists of an intermediate shaft present between the power sources and the rear wheel. The direct transmission in bikes is divided in two stages. The length of the intermediate shaft is 300mm. The shaft is supported by the bearings on both the sides such that it has purely rotational motion. One of the freewheels is connected to

engine with chain drive and the other freewheel is connected to motor with chain drive. The fixed sprocket is used for continues power transmission on any of the running mode.

The number of teeth is as follows: -

i. Fixed Chain wheel on motor shaft t_1– 12 teeth
ii. Free wheel (connected to motor) t_2- 18 teeth
iii. Fixed Chain wheel on engine shaft t_3- 14 teeth
iv. Free wheel (connected to engine) t_4 – 22 teeth
v. Rigid chain wheel t_5 – 18 teeth

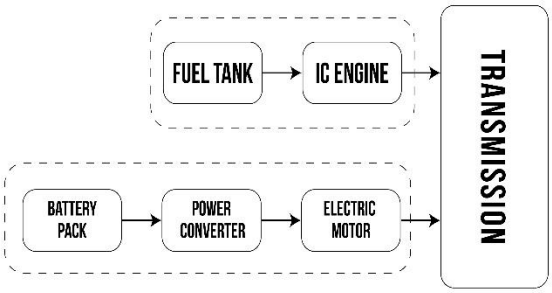

Fig. 1. Concept of Parallel Powertrain

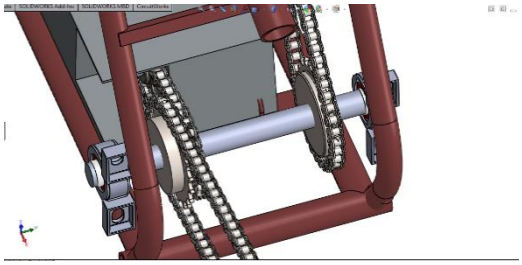

Fig. 2. CAD Model of hybrid powertrain

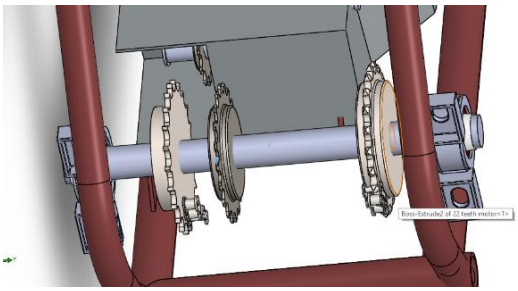

Fig. 3. CAD Model of hybrid powertrain

Fig 1. Shows the basic working of parallel powertrain in which the vehicle can be driven by either electric motor or IC engine or by both. Fig 2. And Fig 3. Shows the design on the powertrain by using counter shaft, 2 freewheels and one rigid sprocket. The freewheel to the extreme right is connected to motor via chain and the centre freewheel is connected to IC engine. And the rigid sprocket to the extreme left is used for providing the final drive continuously. In Fig 3 the centre freewheel is slightly shifted to right for better view of powertrain.

III. WORKING

The hybrid powertrain works on the principle of operation of freewheel. As the freewheel has rachet and pawl mechanism it can transmit power in one direction and not other. This application of freewheel is used to generate hybrid drive.

A. Working on electric mode-

When the electric switch is turned on and the throttle is increased the motor rotates in clockwise direction. The freewheel can transmit power in only one direction, in opposite direction it rotates freely without transmitting power. When the motor freewheel is driven by chain the counter shaft rotates, and the fixed sprocket transmit power to the rear wheel and the vehicle moves. At this condition the engine remains in neutral position or the engine sprocket does not rotate because the freewheel connected to engine does not rotate even though the shaft rotates, it will only rotate when it is driven by chain via engine.

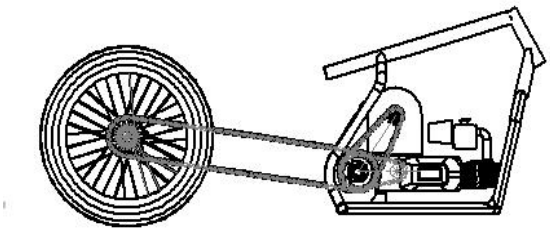

Fig. 4. Working on electric mode

B. Working on engine mode-

While running on engine mode the motor switch is turned off. The operation of freewheel and the sprocket is same. When the engine shaft rotates it transmits power to free wheel via chain drive and the shaft rotates. The fixed sprocket transmits power to the rear wheel and the vehicle moves. At this time the motor freewheel does not rotate and remains in neutral position.

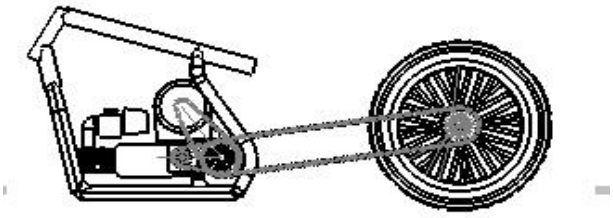

Fig. 5. Working on engine mode

IV. ENGINE SPECIFICATIONS

We have selected Hero splendor's engine which has a horizontal mounting oriented in horizontal plane which enables us more space for mounting of motor and transmission. The engine is used to cover the extra range in hybrid drive mode.

i. Capacity:- 100cc (splendor)

ii. Power:- 8.2 bhp @ 5000 rpm

iii. Torque:- 8Nm @ 5000 rpm

V. MOTOR SPECIFICATIONS: -

We have used BLDC motor as it has higher efficiency and better performance and torque speed characteristics as compared to PMDC motors and HUB motors, [11].

Type- BLDC spindle motor

Nominal Voltage – 48 V

Rated Power – 2000 Watt

Rated torque -9 Nm @3000 rpm

As the motor is primary device and has to satisfy all the performance characteristics of bike the selection of motor is done by calculating power at various driving conditions by using equations. Table 1. gives the theoretical calculated values for various driving conditions.

TABLE 1. TRACTIVE EFFORT AND POWER AT VARIOUS SPEEDS

Case	Vehicle speed (kmph)	Acceleration (m/s^2)	Gradient (Degree)	Tractive effort (N)	Power (KW)
1	40	0	0	39	0.43
2	80	0	0	75	1.66
3	20	0	5	210	1.16
4	15	0	7	281	1.56
5	40	1.2	0	227	2.2
6	20	0.5	5	315	1.75

VI. BATTERY SPECIFICATIONS

Lithium ion Battery pack of capacity 25Ah is required. As the Li on battery pack is smaller in size and lighter in weight compared to lead acid batteries. Lithium ion battery pack has higher charge density than Lead acid batteries, [12].

VII. CHASSIS AND FRAME STRUCTURE

We have used Discover 125 ST for our prototype. There are slight modifications in the frame of the bike. We have designed the frontal part of frame as per requirement which makes it easy for mounting of engine and motor and provides space for mounting shaft. The length of chassis is increased by 4 cm.

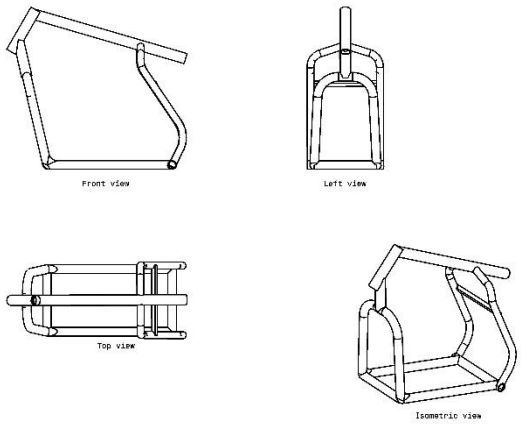

Fig. 6. Views of Frame Modified

VIII. POWERTRAIN SPECIFICATIONS

Fig. 7. Shows the sprocket and drive ratio selection for hybrid powertrain. The powertrain allows the parallel use of IC engine and electric motor for transmission. By using intermediate shaft, the overall drive ratio is obtained in two stages. The selection of drive ratio is done by calculations satisfying maximum torque & maximum speed for the vehicle to satisfy the performance characteristics of the vehicle. Sprockets are selected according to the market availability to maintain overall drive ratio which is 3.165 for electrical drive and 3.31 for IC engine drive. The overall drive ratio for IC engine drive is made constant as per standard vehicle. The first stage reduction for motor is 1.5 and for IC engine is 1.57. The second stage reduction is 2.11.

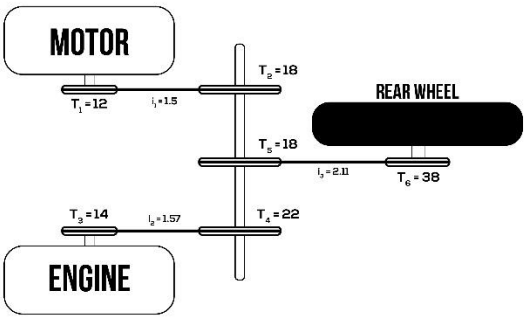

Fig. 7. Sprocket Selection and drive ratio

IX. OBSERVATIONS

A. *Test for current consumption ,mileage covered and cost.*

We have tested the bike for running more than 150 kms using both the power sources with various road conditions. The following are the observations while driving on electric mode. The total load on motor is 210 kg.

TABLE 2. CURRENT CONSUPTION AT VARIOUS SPEEDS

Speed (kph)	Current (A)	Duration For 25Ah capacity (hrs)	Distance (km)
20	10	2.5	50
30	16	1.56	46.8
40	21	1.19	47.6
45	24	1.04	46.8

Following are the observations by keeping the cost parameter constant.

The price of fuel per litre is 78 Rs which is kept constant and range is analysed in case of petrol bikes and hybrid bikes. For petrol bikes the distance covered is 70 kms in one litre of petrol. i.e. 1.11 Rs per km travel. For hybrid motorcycle the average 48 km cost 6 Rs on electric mode. The further distance is covered in engine mode. Thus, range of 112 kms is obtained in 78 Rs. i.e. 0.696 Rs per km travel. If it used for 48-50 kms daily, then motor can be used to cover the whole distance. In this case the cost per km travel is 0.12Rs. This will help to save the money and will benefit common people. For 70 kms of travel using hybrid mode it takes 30.5 Rs. If a bike travels 11000 kms in one year the cost of fuel is 12210 Rs but in case of hybrid bike the cost of travel is 7656 Rs. Thus, we can save fuel of 4554 Rs in one year.

B. *Test for speed and time parameters at normal driving conditions.*

The speed and time parameters are determined while driving bike in petrol mode as well as hybrid mode. The test is conducted as follows: -

i. For petrol mode the bike is accelerated from 0 to 45kmph at normal riding conditions and time is noted down.

ii. For hybrid drive the vehicle is propelled on ICE from 0 kmph to 15-20 kmph approximate to achieve initial momentum and reduce initial high current drain due to high torque required to move the vehicle from stationary position. Although motor provides performance similar to ICE drive but to improve efficiency of overall powertrain by reducing the high current consumption at start the bike initially propelled on ICE then it switched to electrical drive after attaining certain momentum. Time Elapsed in Hybrid mode = ICE engine time (0-15kmph) + Idle time (Switching from ICE to Electrical) + Electrical Drive time (15-45kmph).

Table 3. gives the speed time parameters for both petrol and hybrid mode for the speed up to 45 kmph.

TABLE 3. SPEED TIME PARAMETERS

Test no	ICE Drive (time in seconds)	Hybrid Drive (time in seconds)
1	14.96	26.66
2	18.58	25.28
3	15.04	23.98
4	16.52	23.06
5	16.70	22.24
Mean Time	16.36	24.244

X. GRAPH

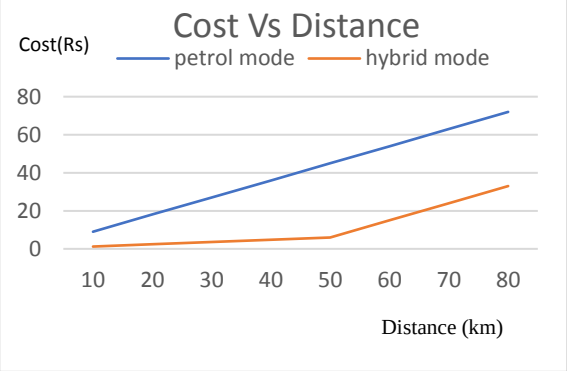

Fig. 8. Graph of Cost VS Distance of a petrol bike and hybrid bike

Fig. 8. shows the comparison of cost and distance travelled in petrol bikes and hybrid bike where the distance covered is 80 km in both cases. In hybrid mode the first 50 kms covered using electric mode.

XI. PROTOTYPE OF HYBRID BIKE WITH PARALLEL CONFIGURATION FOR TRANSMISSION

Fig. 9. Prototype of hybrid powertrain- motor side

Fig. 10. Prototype of hybrid powertrain- engine side

Fig. 9 and Fig. 10 shows the actual hybrid powertrain developed and used in Discover 125 ST.

XII. CONCLUSION

The use of hybrid electric powertrain for motorcycles helps to reduce the fuel crises and reduce the amount of air pollution. The hybrid drive will also reduce the cost of fuel per km travel and will significantly improve the range of bike. It can be used for travelling longer distances and will mainly benefit middle class people. Thus, hybrid drive proves to be more economical, cost effective than conventional petrol bikes. We have designed a powertrain which can be improved in future as the innovation is in its first stage. Researchers can go for automation in the project increasing range and performance of the bike. We can think on manufacturing kits of hybrid vehicle which can turn a petrol bike into hybrid on with small amount of fabrication. The highlighted points for future scope are reduction in weight, regenerative braking, use of solar cell to charge the batteries, ergonomics of hybrid bike, automation, IOT and smart vehicle.

***Abstract*— The trending technology Power over Ethernet (PoE) is a widespread way to send power along with data in a single Ethernet. It uses standard balanced twisted pair cable to send power in an existing Ethernet cable. Devices powered using this technology are Voice-over-Internet (VoIP) telephones, surveillance cameras, wireless access points etc. The technology is more cost effective and can be easily implemented. This paper describes the overview of Power over Ethernet, its methodology, advantages and factors in selecting cable. The paper also gives the factors which influence the performance of PoE system. The PoE using Category 3 or Category 5 cable for power transmission is described.**

Keywords— balanced twisted pair cable, Category 3 cable, Category 5 cable

I. INTRODUCTION

PoE has many industrial applications and is now popularly used everywhere. Because of its compatibility and low cost installation it is the best option for supplying power to existing Internet Protocol (IP) devices .

PoE supplies DC power and supports 10 Mb to 100 Mb Ethernet without installing additional electrical infrastructure. The company named PowerDSine took initiation to standardize the PoE in 1998. The promoting companies were Intel, 3Com, National Semiconductor, Mitel and Novtel Networks. On 12 June 2003 IEEE finally validated PoE standard. PoE provides inline power which reduces the number of power lines to be installed in the network. The two important devices used in a PoE are - the Powered device (PD) and the Power Source Equipment (PSE).Where, the PD accepts the power provided by PSE. The maximum power offered by PoE PSE is 15.4 watts 48vDC. The maximum power offered by PoE+ PSE is 30 watts at 48vDC. The maximum power offered by a Hi-PoE+ PSE is 100 watts. The IEEE standards require 4 pair cable. CAT-5 cable has 4 twisted pairs; in that, two of the pairs out of four are used for data transmission. The specification permits for the spare pairs to send the power. Power over Ethernet (POE) technology carries electrical power through existing network cables.

As an example, a digital surveillance camera generally needs two connections for its installation.

First a network connection, which is used for video recording and display gadget. Second a power connection, which is used to supply the electric power for the camera to function.

In this case, if the digital camera was POE-enabled, only one network cable would be sufficient for transmitting both power and data. This is shown in figure 1.

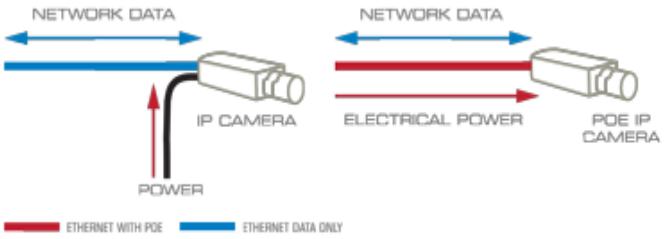

Figure 1: PoE enabled camera

II. RELATED WORKS

The CAT5 cable has four pair; by using all the pairs effectively power delivery to the destination that is power device can be increased [1]. In paper [2] author describes about the architecture present in the power sourcing equipment. The paper [3] and [4] gives specifications for PSE and PD and the power used by the devices. PoE implementation using Endspan insertion and Midspan insertion is given in paper [5]. Different communication protocol used by PoE is mentioned in paper [6] and [7]. The paper [8] and [9] explains the basic principles of a PoE system are explained along with benefits of PoE. Alternative A and Alternative B are the types of implementing PoE which are explained in paper [10].

III.BENEFITS OF POE

1. Time and cost savings

Time and cost is reduced by using PoE. By means of decreasing the time and price of getting electrical cabling established. Network cables can be installed by anyone easily, and can be placed anywhere.

2. Flexibility

PoE allows many devices to connect to it. Without calling to an electrical outlet, gadgets including wireless access points and IP cameras may be placed wherever they are wished most, and repositioned effortlessly if required.

3. Safety

POE delivery is smart, and designed to shield network device from overload, incorrect installation or under powering.

4. Reliability

POE power comes from a significant and universally well matched source, in preference to a set of distributed wall adapters. it could be subsidized-up by an uninterruptible energy deliver, or managed to easily disable or reset gadgets.

5. Scalability

Having electricity available on the network that set up the distribution of network connections straightforward and effective.

6. Enhanced productivity

PoE is capable of collecting data effectively and since it uses same cable for power and data it provides increased productivity to the devices which uses it.

IV.DEVICES SUPPORTED BY POE

PoE has many applications like VoIP phones, IP cameras. Every device can be powered using PoE by estimating how much power the device needs. Any PoE product can be integrated to the design. The figure 2 shows the devices that are PoE enabled.

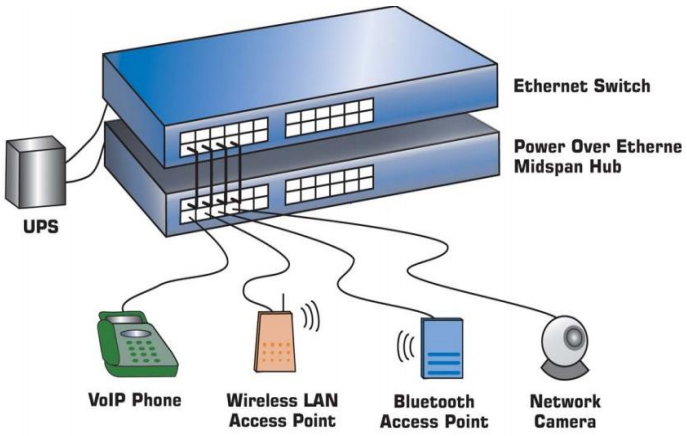

Figure 2: Devices enabled using PoE

Silvertel manufactures a many PoE modules at wattages appropriate for a large number of designs. Table 2 below gives the number of PoE wattages supplied with the aid of Silvertel and examples of a number of the products customer may power with them. Using Silvertel products the selection of PoE enabled devices is less time consuming and less challenging. Different devices require different amount of power to operate is also shown in the table 1.

Table 1: Devices supported by PoE

13W	30W	60W	100W	200W
IP Cameras	IP Telephones	Door Access Systems	Digital Signage Displays	Larger TVs
VoiP Phones	WiMAX Access Points	Video Phones	Point-of-Sale Systems	Larger Displays
Wireless Access Point	PTZ Cameras	Thin Clients	LCD TVs	Larger Monitors
Networked Audio	Remote Computer Terminals		Computer Monitors	Laptops

V. POWER OVER ETHERNET (POE) STANDARDS

The IEEE standards for PoE are 802.3af, 802.3at and 802.3bt.

Type 1 PoE

IEEE 802.3af-2003 was the first PoE standard which IEEE developed. The power given by this type is 15.4 watts at 48vDC with 12.95 watts of power to be assured to devices. Per pair maximum current rating is 350mA. Uses Category 3 cable or higher rate cable.

Type 2 PoE +

IEEE 802.3at-2009 was the second PoE standard developed by IEEE to provide more power. The power given by this type is 30 watts at 48vDC with 25.5 watts of powe.r to be assured to devices. Per pair maximum current rating is 600mA. Uses Category 5e cable or higher rate cable.

Type 3 PoE ++

IEEE 802.3bt-2018 Type 3 provides more power than 802.3at. Provides 90-100 watts at 48 volts DC.

VI. FACTORS IN SELECTING CABLE TYPE AND DIFFERENT CABLE STANDARDS

There are numerous factors that have to be considered while selecting the cable type used to make PoE application. The first one is the quantity of power the PoE device requires for its operation. This power required will dictate which IEEE standard to be selected, and ultimately the minimum class category cabling that can be used .

Other factors have to be taken into consideration for most effective performance of the network. They are heat dissipation, voltage drop and data transmission performance. Voltage drop gives how much of the transmitted power reaches the other end at receiving device. The power that is lost over the length of the cable line transforms to heat and is known as heat dissipation. More heat constructed can add growth in attenuation and also the aging of the cabling jacket.

Another aspect to which is to be considered is the data transmission requirement (e.g., 10GBASE-T, 1000BASE-T) of the device being used. Devices consisting of megapixel IP cameras can also require higher grade cabling if you want to deliver the video signal along with required power. Ethernet uses Modbus/TCP protocol for transmitting and receiving data.

There are 4 standards of twisted pair cabling given by the Telecommunications Industry Association (TIA) which is used mainly for Ethernet application. Those consist of Category 3, Category 5e, Category 6A and Category 6. Based on their power performance characteristics the different cable categories are selected.

As given in the table 1 below, Category 3 cabling makes use of a 24 AWG copper conductor and has a highest bandwidth of 16MHz. Category 3 cabling is permitted for 802.3af devices that require low energy. When compared to other cable Category 6A cable has a maximum bandwidth of 500 MHz and makes use of a 23 AWG copper conductor. The bigger conductor used in Category 6 and 6A cabling is preferred for PoE packages because of its less voltage drop over the cable. Even among all gauge sizes, slight differences in real conductor diameter will have measurable consequences on machine's overall performance. PoE application is also dependent on cable distance.

The table 2 gives the cabling standards, voltage drop and their Approved PoE Applications.

Table 2: Cabling standards and corresponding Approved PoE Applications.

Category	Nominal Conductor Size AWG	TIA Maximum Bandwidth MHz	Common Ethernet Applications	Approved PoE Application(s)	Voltage Drop* volts	Temperature Rise at 500 mA** °C (°F)
Superior Essex Category 3	24	16	10BASE-T	802.3af	1.58	n/a
Superior Essex Marathon LAN® Category 5e	24	100	1000BASE-T	802.3af, 802.3at	1.52	7.2 (12.96)
Superior Essex Cobra Category 5e+	24	100	1000BASE-T	802.3af, 802.3at	1.41	6.95 (12.51)
Superior Essex DataGain® Category 6	23	250	1000BASE-T	802.3af, 802.3at	0.85	6.7 (12.06)
Superior Essex NextGain® Category 6+	23	250	1000BASE-T	802.3af, 802.3at	0.85	6.7 (12.06)
Superior Essex 10Gain® Category 6A	23	500	10GBASE-T	802.3af, 802.3at	0.81	5.1 (9.8)

VII. PRINCIPLE OF POE

An Ethernet cable does not carry power to the devices but Power over Ethernet (PoE) has a only one cable for both data connection and electric power to the devices. The figure 3 explains the principle of PoE. The PoE equipment combines the data and power together into a single cable and is given to the access point.

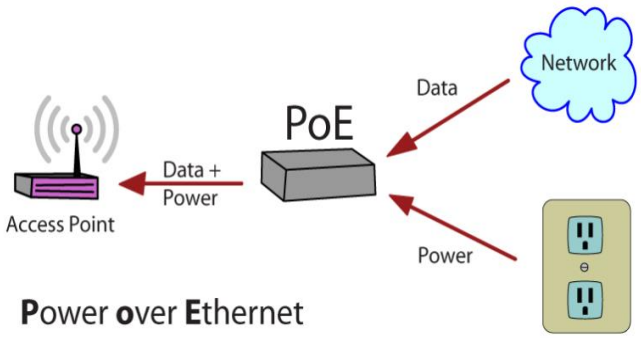

Figure 3: Principle of PoE

Power is "injected" into the cable using "end-span" WAN/LAN switches which include power deliver circuitry. As an alternative, in case user don't need to update existing LAN switches, or simply needs to power a few parts, "mid-span" power injectors may be connected in between the switch and the PD. The end PDs should work with PoE. Power management feature is also supported by many PoE switches so that devices attached to it are power cycled. The PoE power devices turns on telling the endspan or midspan switch that it can receive the power coming through cable.

The figure 4 shows the direct connection using End-Span power source and intermediate source using Mid-Span power injector.

A fully complaint IEEE PoE PD can receive energy over the unused pins or data lines. In this vicinity network administrators should be careful because a few PD's claiming compliancy with the IEEE PoE requirements are constrained to the usage of mid-span power resources using the unused pairs. Mid span injectors does not always verify the end devices hence sometimes it can cause damage to other non PD devices.

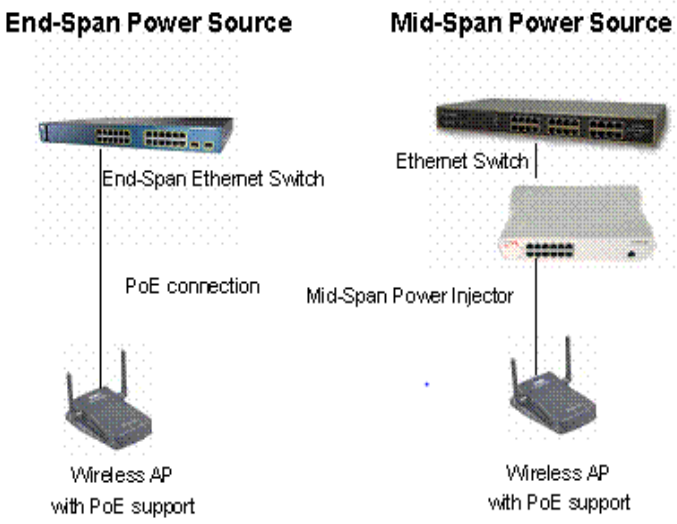

Figure 4: End-Span and Mid-Span Power Injector

To protect the power devices from incoming currents that could occur at some stage in powering up, it is necessary that the PD have inbuilt inrush current safety. The PD having this protection starts with a low current usage stage to prevent the power sourcing equipment (PSE) from getting damaged and then switches to a excessive current level permitting the PD to use its required power of maximum 100 watts.

Fiber extenders are used to extend cable distances up to 100 Miles or 160 km, without the loss of information due to long distance copper cables. LAN extenders increase network distances till 6 miles or 10 km, however if the distance crosses 328 feet cable can have drastically less data speeds. Instead of a 100 Mb/s, the information will decrease lower rate as 2.3 Mb/s. Also, security is provided by fiber cable. Electromagnetic emission is not generated by it so it is very

difficult to detect. Cable is extremely reliable as it is not vulnerable to electrical interferences, or information loss due to temperature, pressure or atmospheric conditions, cable is extremely reliable.

Fiber runs from a present data to a place with power access. A PoE Media Converter is powered by means of either AC or DC electricity. The media converter is hooked up between the power deliver and the fiber cable. In copper cable (STP or UTP) Ethernet can be provided up to 100 meters to the power device. The PoE Media Converter converts the data from fiber to copper, adding power and then transmitting it to the power device.

If Ethernet service has to be extended more than mentioned limits of IEEE 802.3 of 328ft / 100m, Ethernet Extenders are the used. These Ethernet Extenders increase Ethernet connections throughout copper wires. Uses single twisted pair (Category 5/6/7), any copper wiring formerly used in alarm circuits, E1/T1 circuits, RS-232, RS-422, RS-485, CATV and CCTV applications. A PoE Ethernet Extender can operate both as PSE or PD.

VIII. METHODOLOGY [9] [10]

Ethernet is usually transmitted using unshielded twisted pair (UTP) cable which has four pairs. Only two of the pair out of four pairs is used for 10 Mbps and 100 MBps Ethernet. There are two connections used with PoE, namely Alternative A and Alternative B. is In Alternative A, the power is transferred simultaneously along with data over the pairs 1 and 2, 3 and 6. That is the DC+ of 48V is delivered as an industry standard on data pin 1 and pin 2 with DC- data given to pin 3 and pin 6. The figure 5 shows the type 1 Alternative A PoE here spare pairs are used for data transfer and signal pairs are used for power transmission

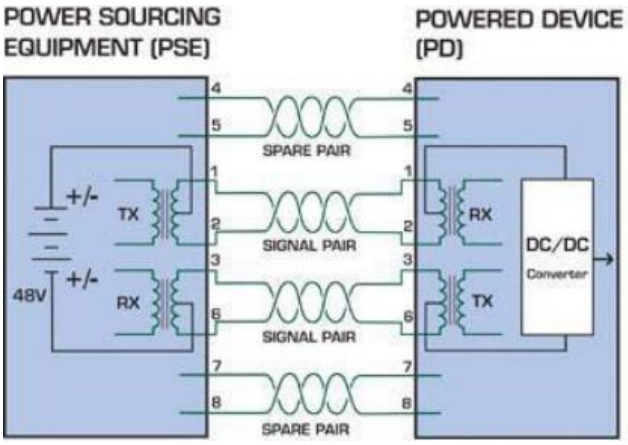

Figure 5: Type 1 Alternative A PoE

In Alternative B, the power is transfered over spare pairs 4 and 5, 7 and 8. That is the DC+ is delivered to unused pin 4 and pin 5 with DC- on pin 7 and pin 8. With PoE data/power interfacing between the two-Ethernet elements is served by LAN cable. The figure 6 shows the type 1 Alternative B PoE it is vice versa of the Alternative A PoE.

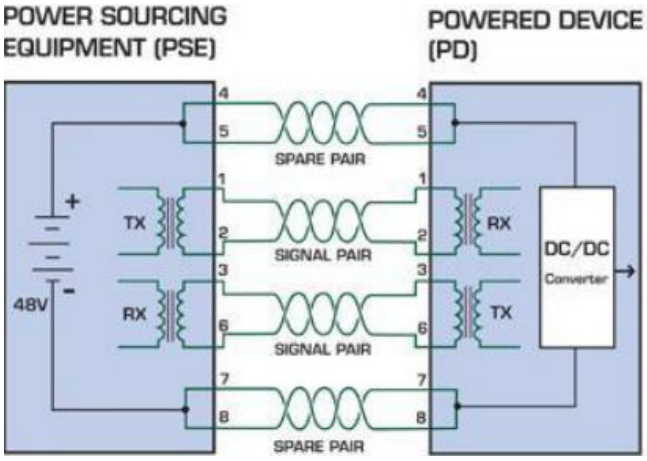

Figure 6: Type 1 Alternative B PoE

Most commonly used is Alternative B by PoE. In Alternative B, the 48V DC power is sent over the cables which are connected to pins 4, 5, 7, and 8 which Base 10/100 networks do not use. The figure 7 shows the Alternative B wiring, there are 8 pins available for the connection.

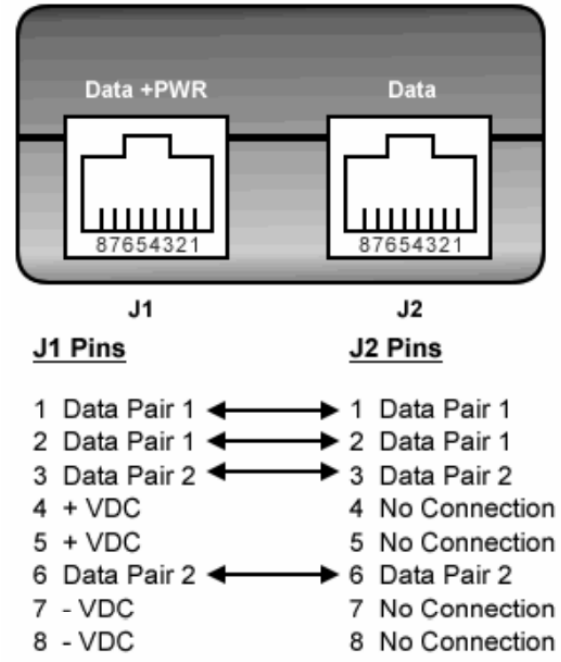

Figure 7: Alternative B wiring

CONCLUSION

Power over Ethernet allows the devices such as VoIP phones, security cameras, Printers; sensors etc transmit data and power on a single Ethernet connection. Deploying PoE technology in the network eliminates the need for installing separate cable for power and data transmission. The PoE deployment is flexible and cost effective while upgrading the Ethernet switch. PoE finds the great scope in almost every field in future as it is cost effective.

ACKNOWLEDGMENT

I acknowledge with immense pleasure the guidance and support extended by Dr. Nagamani K, Professor, Department of Telecommunication Engineering, R. V. College of Engineering, Bengaluru. Her timely suggestions have contributed in successful completion of the paper.

***Abstract*—This paper presents an improved Vivaldi antenna design for Through Wall Radar Imaging (TWRI). It is one of the most emerging radar technologies that has different applications in real-life situations. Radar uses EM waves to penetrate through the wall, and then detects the objects behind the wall. Antenna plays a very important role in TWRI system. Vivaldi antenna can be used as an ideal candidate for this system. The antenna presented here operates from the frequency 2.5 GHz to 11.3 GHz and shows a constant radiation pattern in the operating bandwidth. The gain obtained is around 6 dBi. The effect of various antenna parameters are also studied in this paper. Furthermore, corrugations and grating elements are added to analyze the effects on gain and bandwidth. With the above enhancements in design, a bandwidth of 8.8 GHz and an improved gain of around 9.6 dBi has been achieved.**

***Index Terms*—Vivaldi, Through Wall Radar Imaging, Grating elements, Corrugations.**

I. INTRODUCTION

The main objective of TWRI is to use electromagnetic (EM) waves to sense and image moving and stationary objects through visually opaque obstacles such as walls[6]. It is a unique application of UWB technology. UWB radio technology has a bandwidth greater than 500 MHz or 20% of the center frequency according to Federal Communications Commission (FCC)[1]. Many existing UWB antennas can be considered for TWRI applications. The choice of the specific antenna depends on the wall material as well. The wall attenuation is comparatively higher at high microwave frequencies. Among the various UWB antenna designs implemented for TWRI application, most of the antennas operate at a higher UWB frequency range (8-12 GHz). Here, we have chosen concrete walls of thickness 19.45 cm for which the optimum range of operating frequency is 2-6 GHz[6]. Hence, designing a UWB antenna for this frequency range (2-6 GHz) remains a challenge.[1-4] represent various UWB antennas that can be used for TWRI application. Among these, Vivaldi and Horn antennas are most suitable antennas which satisfy the TWRI specifications[1,2].

This paper includes the design of UWB Vivaldi antenna for Through Wall applications. Vivaldi antenna is a tapered slot antenna that is based on the principle of travelling wave antenna[5]. Vivaldi antenna was first proposed by P. J. Gibson in 1979[7]. The antenna has an exponentially tapered profile, which provides wide bandwidth and end-fire radiation pattern.

II. DESIRED CHARACTERISTICS OF TWRI ANTENNAS

A. TWRI Antenna Constraints

One of the important characteristics of a TWRI antenna is that, it should be compact and light weight for portability[10]. The antenna should have a gain that is sufficient for the signal to penetrate through the wall and detect the target behind the wall. The return loss should be less than -10 dB so that impedance matching is obtained in the desired frequency range. The antenna must have better transmission and radiation performance with minimum number of side-lobes and back-lobes[6]. The antenna should radiate short transient pulses with minimum distortion[6,10].

B. Antenna in TWRI system

The main elements of the TWRI system are UWB antenna, RF transceiver, duplexer, signal generator and image processing and display unit. Transmission and reception of electromagnetic waves is carried out by the antenna in a TWRI system. In a monostatic radar configuration a duplexer is required to switch between the transmission and reception of signals by the common antenna. The signal generator produces UWB pulses that is transmitted through the wall. The signal after penetrating through the wall is reflected by the target and reaches the antenna in receiver mode. The image of the target is then processed using a focussing algorithm. The main parameters that influence the quality of image produced are cross range and down range resolutions[11]. The Fig 1. shows the configuration of TWRI system components.

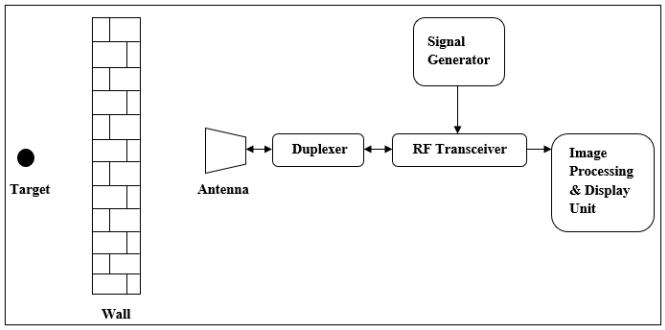

Fig. 1. Monostatic configuration of TWRI system

C. Link Budget Equation

The performance of a communication system depends on the signal-to-noise ratio (SNR) at the receiver. The link budget is generally used to predict the received power in a communication system. For TWRI, the gain required for the receiver antenna is estimated using Link Budget equation[12]:

$$R^4 = \frac{P_t G_t G_r \lambda^2 \sigma}{10(4\pi)^3 K T B L_s L_w^2} \tag{1}$$

where, R is the range, σ is Radar Cross-section(RCS), L_s is system loss, λ is the wavelength of signal transmitted, P_t is the power of the transmitted signal, L_w is the wall attenuation, B is the IF Bandwidth.
Typical values assumed for the above mentioned parameters, in our proposed design are, SNR= 10 dBi, R = 20 m, λ = 0.075 m, σ = 100 cm x 100 cm, P_t = 15 mW, L_s = 10 dBi, B = 10 kHz and concrete wall losses L_w = 15 dBi.
Gain obtained after substituting these values in equation 1 is G=6 dBi. Hence, we need to design a UWB antenna that has a minimum gain of 6 dBi.

D. Vivaldi for TWRI System

Vivaldi antenna is a wide band antenna that has a two-dimensional structure. Being light-weight and planar, the antenna could be mounted on a portable device, thus making it suitable for through wall imaging. Compared to other UWB antennas, Vivaldi antennas show minimum distortion in the shape of the transmitted UWB pulses[6]. The antenna has a constant moderate gain over the wide band of operation. Hence, Vivaldi antenna has been chosen as it satisfies most of the constraints of a TWRI system.

III. DESIGN CONSIDERATIONS

A. Structure Explanation

The designed vivaldi antenna for TWRI is shown in Fig. 2 and Fig. 3. The antenna consists of three layers. The top layer act as the ground plane. The middle layer is composed of substrate. The feeding technique used is microstrip to slotline transition. It forms the bottom layer.

1) Substrate: : The antenna is designed on FR4 material of 0.8 mm thickness that has a permittivity(ϵ_r) of 4.3.

2) Ground plane: : It consist of a uniform rectangular slot that is connected to an exponentially tapered slot. Circular cavity is attached at one end of slot and the other end of the slot is exponentially tapered. The shape of flaring of taper and the cavity determines most of the antenna performance. The slot width affects the highest frequency of operation and the width of antenna affects the lowest frequency[5].

3) Feeding Technique: : The cavity-stub model is used for designing wide band Vivaldi antenna. Micro strip and slot line crosses at right angle to each other to form cross junction. At the cross junction, micro strip line behaves as short circuit, since radial stub is open circuited at the end which is approximately $\lambda/4$ in length[1] and the short circuited slot line behaves as an open circuit. Energy is coupled from microstripline to slotline, which is then radiated from the exponential slot to give an end-fire radiation pattern.

B. Equations

The tapered profile of the antenna is given as,

$$y(x) = \pm ce^{rx} \tag{2}$$

where, constant c is given by,

$$c = \frac{s}{2} \tag{3}$$

$$r = \frac{1}{L}\ln(\frac{W}{s}) \tag{4}$$

where, L, W, r and s are the antenna length, antenna width, opening rate and width of slot at origin[8].

C. Simulated Structure in CST Microwave Studio

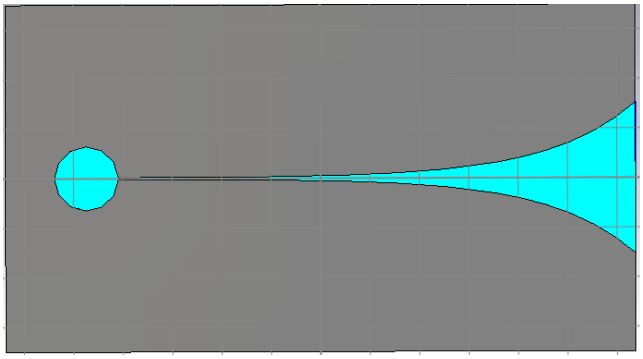

Fig. 2. Vivaldi antenna- top view

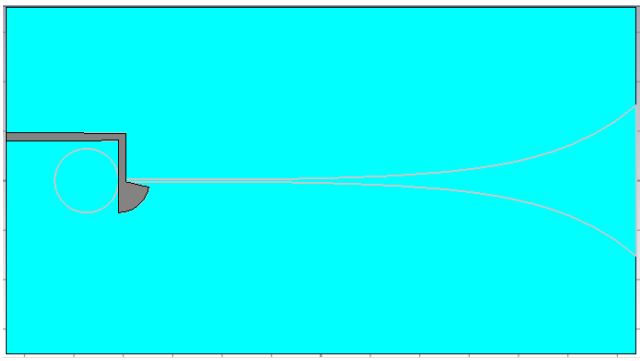

Fig. 3. Vivaldi antenna- bottom view

The values we have chosen for our vivaldi construction are mentioned in Table 1[9].

IV. SIMULATION RESULTS

The proposed vivaldi antenna was simulated in CST simulation tool and results were obtained as follows:-

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

TABLE I
CALCULATED ANTENNA PARAMETERS

Parameters	Dimensions(mm)
Antenna length	128
Antenna Width	70
Taper length	80
Taper width	31
Slot width	0.5
Slot length	25
Taper rate	0.057
Stub angle	80
Substrate thickness	0.8
Circular cavity radius	6.46
Radial stub radius	6.46

A. *Reflection coefficient*

The variations in reflection coefficient with frequency are shown in Fig. 4 for FR4 substrate with ϵ_r=4.3. It is observed that the reflection coefficient is below -10 dB for 2.5-11.3 GHz. The fractional bandwidth for the simulated antenna is 127.5. The antenna has an operating bandwidth of around 8.8 GHz.

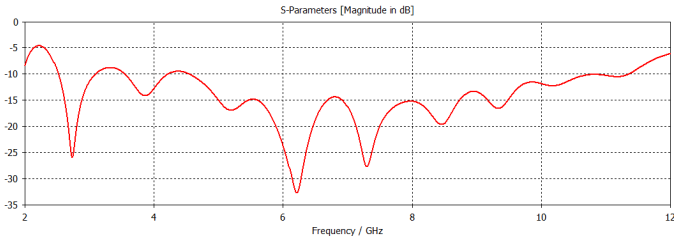

Fig. 4. Variation in reflection coefficient with frequency

B. *VSWR*

The voltage standing wave ratio for the designed antenna is shown in Fig. 5. The value is found to be less than 2 for 2.5-11.3 GHz.

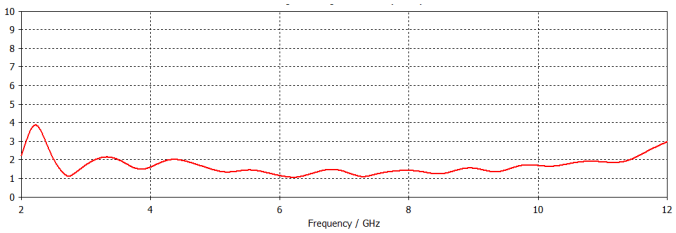

Fig. 5. VSWR Plot

C. *Gain*

It is found that maximum gain of the antenna is always greater than 5 dB in operating frequency range. The far-field directivity of the antenna at 4.5 GHz is shown in Fig. 6. The gain obtained is around 6.6 dBi. The main lobe is directed at 90° and has 3dB angular width of 52°. Further enhancement in gain can be obtained if grating elements and corrugations are added.

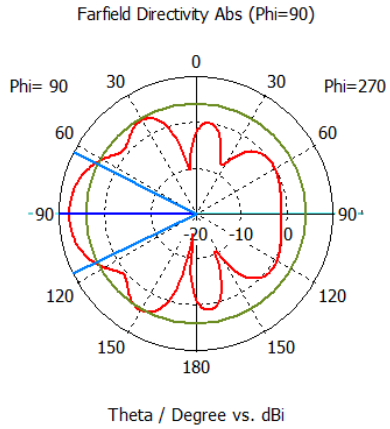

Fig. 6. Far-field Directivity at 4.5 GHz

D. *Effect of adding Grating Elements*

Grating elements were added at the opening end of the exponential slot as shown in Fig. 7. It is observed that as the number of grating elements increased, gain started to increase from a particular point from the radiating region. The side-lobe level also reduced, thus favouring the TWRI application. The length of the grating element was chosen to be 14 mm. Fig. 8 shows the return loss plot of the antenna with grating elements.

When the number of grating elements added was 4, the gain at 4.5 GHz was found to be 7.82 dBi with a reduced amount of side-lobes as shown in Fig. 9. The 3 dB angular width also reduced to 47°, giving a narrow and directive beam suitable for TWRI application.

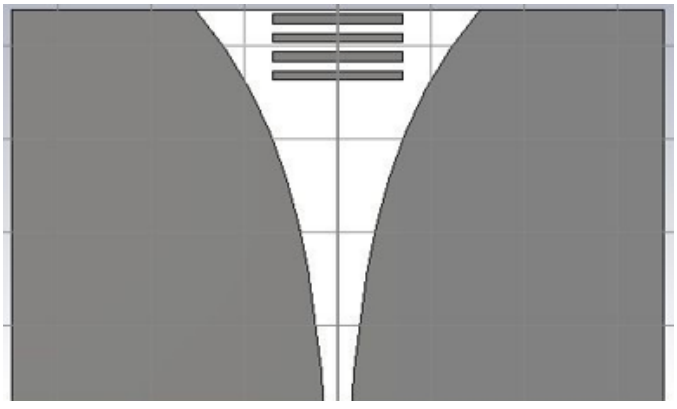

Fig. 7. Vivaldi antenna with Grating elements

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

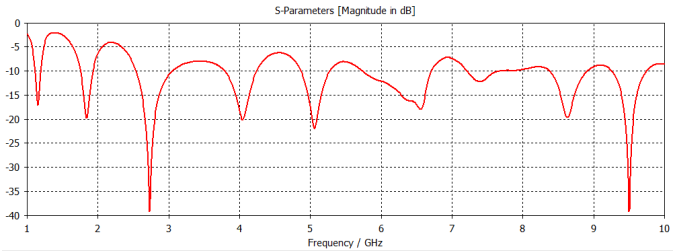

Fig. 8. Return Loss of Vivaldi antenna with Grating

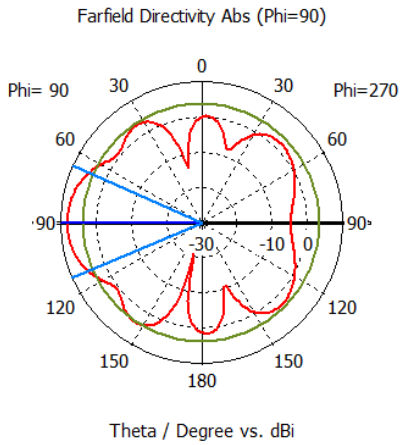

Fig. 9. Directivity of Vivaldi antenna with gratings at 4.5 GHz

E. Effect of adding Corrugations

Corrugations were added along the taper as shown in Fig. 10.As the number of corrugations increased, the gain improved. Eight corrugations each on both sides were added. The width of the corrugation was chosen to be 5mm, maintaining a gap of 1.5 mm between the corrugations. The rate of decrease of corrugation length was fixed to 1.5 mm. Fig. 11 and Fig. 12 show the results of adding 8 corrugations to Vivaldi antenna. The gain obained was 9.6 dBi with a satisfactory side-lobe level. The 3 dB angular width is 63°.

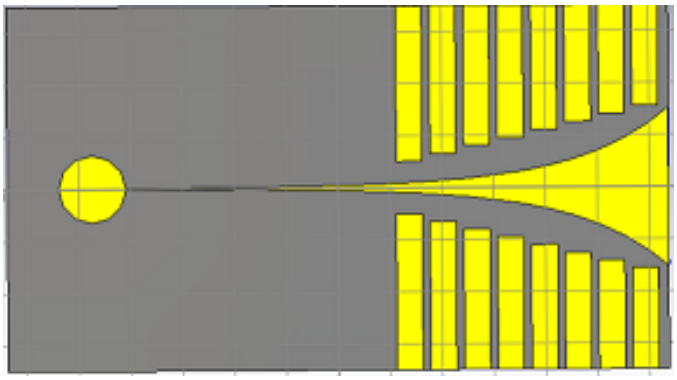

Fig. 10. Vivaldi antenna with 8 corrugations

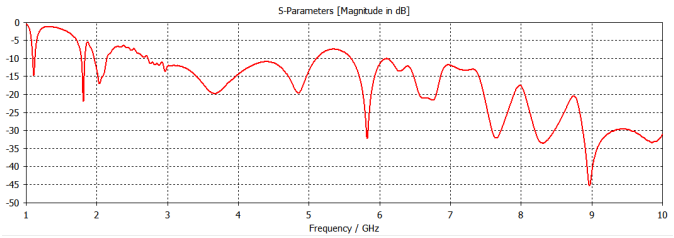

Fig. 11. Return Loss of Vivaldi antenna with corrugations

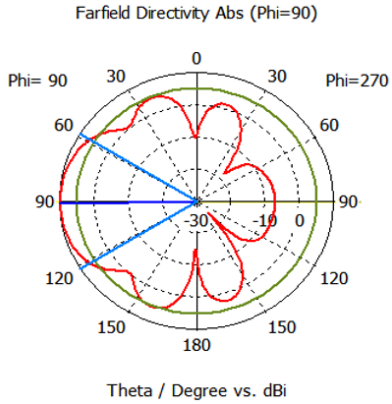

Fig. 12. Directivity of Vivaldi antenna with corrugations at 4.5 GHz

V. Conclusion

This paper presents the design of vivaldi antenna on FR4 substrate suitable for TWRI application.The proposed antenna is developed to operate in the frequency range of 2.5 GHz to 11.3 GHz with a gain greater than 5 dBi. CST microwave suite was used to simulate the antenna. The antenna has return loss less than -10 dB with VSWR value less than 2. Since TWRI system requires a moderate gain, gain enhancement techniques have been introduced in the antenna design. Addition of grating elements and corrugations improved the gain upto 9 dBi with satisfactory return loss for the frequency range 2.5 GHz to 11.3 GHz which can be considered as wide band. The gain obtained is greater than the minimum 6 dBi gain required for the TWRI system.

VI. Future Scope

Array of Vivaldi antenna elements can be implemented to improve the gain. Performance analysis using different feeding techniques like stripline to slotline transition, co-axial to slotline etc could also be considered for vivaldi antenna .

Abstract: Cloud computing furnish services such as storage, database, software and many more and are accessed through cloud service platform via internet. As cloud computing is a most widely used technology there are plenty of user who uses the cloud for their computation and inquire about exercises in the field of information the board. To handle this increased data cloud data storage is the best technology. Keeping data in the cloud more reliable than maintain in the local machine. But providing security for data which is stored in cloud is big issue.it is more important to maintain privacy of the user data if the data is loss it affects the user cloud service. By using some encryption method, we can assure privacy for a certain level in the cloud. There is no complete privacy preservation system is available. This is a survey on different privacy preservation schemes in cloud.

Keywords: Cloud Computing, Two Factor Authentication, RSA, Two-layer encryption.

INTRODUCTION

Cloud computing is most widely used technology and there will be a greater as for number of users because of more user more data will be produced and handling such a huge data in a real world is difficult task so solution for this is cloud. There are different service and deployment models [1] service models are as follows

1. SaaS: it gives feature to use any application through cloud platform. Software as a Service Applications is used by the user from anywhere in the world by internet through web browser. The user need not to have any cloud infrastructure like network, OS, servers, Storage component or even application. it is not applicable for the application that requires real time response such as email and banking related application.

2. PaaS: it gives a user to a platform to run their application for which can't handle the large software and hardware platform. Platform as a Service with help of programming languages, it provides user to put user-developed or acquired applications and tools supported by the provider. PaaS provides application for software development where user will collaborate, deployment and testing services should be automated, PaaS is not suitable if user expecting for portable application and user want to improve performance by some customization.

3. IaaS: it's a delivery model which contains licensed software's based on user needs they

will pay and uses the services. Infrastructure as a Service it is also termed as on-demand services. User will access these services by using browser. Most of the organisation pay for the services for which they need instead buying the software's. Some applications which is provided by SaaS is office software, database software, development software, communication software.

The different deployment models are as follows Public, Private, Community and Hybrid clouds [6]. To store large amount of data storing devises which are high expensive, requires more space and maintenance should be done. Cloud computing provides to store any huge size proportion of information at various limit area and they are dealt with autonomous way. The information stockpiles are taken care of by the CSP. The CSP act as an intermediate which provides different services to the customer such as network, infrastructure and business applications in cloud.

Obligation of the cloud organization is to re-appropriated information with reasonable stage model. The virtual machine official will put the data into any managed Virtual Machine (VM) districts. These virtual machines are made and kept up by the Virtual Machine Manager (VMM). with the assistance of cloud, we can store data in cloud as much we required instead of putting away in local machine yet giving security to the data in cloud is important task. Privacy first important thing to provide privacy for customer data in cloud if the privacy is lost it affects promises to provide good service mainly it affects to the public clouds because data is in unencrypted form present in servers which are handled by cloud service provider. Customer cannot completely trust on CSP for providing privacy for their data for all 3 models priorities of privacy are different.

Privacy Issues in Cloud

Guideline speaking, assurance alludes to the condition or state of concealing the nearness or view. There is a need to achieve this state in the spots where the private things are utilized, for example, information and documents. data of cloud need to be had privacy of client personality and controls leaking of privacy leads to major failure of the framework to keep up information security, it workable for fruitful organization and use of any administration. cloud data storages are disturbed in limited place.it is the responsibility of the CSP to maintain safety of the user data. On the off chance that appropriate security instrument is executed the security is disregarded at the storage service.

Only owner will be able to access data in cloud sometimes CSP can peruse user data for his own benefits' might be sell the user information for some organizations for the sake of money. There might be confidential data which related to the Government records and examination records which might be require for some businessmen's and some organizations can offer personal data of the reputed persons of society such as prime minister, sportsman and actors' personal data can be used for the crime. Using client data is offense some of attackers might change the data of cloud storage.

Dangers malignant programming is acquainted with this stockpiling for getting access and increase knowledge about the information. Privacy manages the availability and accessibility of delicate data to the expected beneficiaries. Re- appropriated information got to and changed just only by clients with suitable access benefits. assume an association has arranged and re-appropriated their information in the cloud. The redistributed information substance is given to the administrator to put in the cloud. It is recommended to guarantee that the administrator can't see or alter the information substance. After record

redistributing, nobody including specialist community can see or alter the substance. If a specialist organization or neighborhood manager is endeavoring to examine the record substance, it must not be done. Protection safeguarding manages the sort of security in redistributed data. This could be guaranteed by utilizing Cryptographic techniques.

Related Works

One of the main solutions for providing privacy in cloud by using different encryption and decryption techniques.

RSA Algorithm RSA [2] algorithm asymmetric block cipher [2], it uses variable size of block. Algorithm is mainly used encrypting and decrypting of data files. The idea of RSA is since it is hard to partition an enormous number open key is a mix of two numbers where one is augmentation of two huge prime numbers.in a similar way private key is gotten from an equivalent two prime numbers. If anyone divides substantial number, the private key is undermined. The encryption depends on key size as key size increases strength of the encryption also increases usually RSA keys are 1024 0r 2048-bit lengths but 1024-bit length key is easy to break than 2048 bit key. But till now it seems to be an infeasible task. An example of asymmetric cryptography

1. A client sends its public key to the server and solicitations for certain information. 2. The server scrambles the information utilizing client's public key and sends the encoded information. 3. Client gets this information and decodes it. There will be two keys public and private where these keys are used respectively to encrypt and decrypt message. The RSA consists of encryption and decryption keys can be calculated by the mathematical operations then it is possible to get cipher text and the plain text by using formula.

$$C = ME \bmod (n)$$
$$P = ME \bmod (n)$$

Q. Xiong and L.T. Yang [3] these authors proposed an authority-based SAPA it is termed as privacy-preserving authentication protocol [4]. this show accomplished shared access master by unapproved access sorting out an instrument with assurance and security thought in this paper principally examined on the following properties 1. Shared access authority is accomplished by anonymous access solicitation coordinating system 2. Attribute-Based Access Control (ABAC) is embraced with the goal that a client can just access to its own information 3. Proxy re-encryption applies to give information to different clients.

In this paper author mainly focused mainly focused on authentication so that user access their data on remotely from cloud model. There will be a different group are there in cloud where each group has its own user which can access data. A supplier makes a request to access information fields, however it isn't ensuring that carrier will permit its access demand. In case the bearer decays its solicitation, the provider's entrance will be uncovered close-by nothing picked up towards the ideal information fields. The supplier may not send the passage solicitation or disadvantage the unaccepted requesting from the get-go if it consistently comprehends that its sales will be denied by the transporter. It is ridiculous to inside and out reveal the provider's private data with no privacy contemplations. A BGKM proposed to overcome the shortcoming of using same key for both encryption and decryption in a public cloud model. It is No longer important that purchaser rely on the public key cryptography. One can select the symmetric keys significantly toward the crowning glory of decryption. A pleasant-primarily based get admission to manage technique used to achieve customer who is having the persona properties can decrypt the substance the creator assuming that a more ultra-modern protection the trouble is seen to perform sharing of prolateness- safeguarding access expert. Through the wrapped traits transmission statistics unsure great is executed. Session

identifiers are utilized for anticipating the session association.

M. H. Au and X. Huang [4] Proposed a model it is based on web-based class computing service [4]. Major problem to provide security for class service is authentication. User received to login to access the class service by using traditional username and password-based system, but it has two problems. Username and password-based system for privacy preserving. Usually computers are shared by different people at that time it is easy for hacker to install spyware to tell details of username and password. To overcome these issue two-factor authentication (2FA) method is used. It is common in most of the web-based services in addition username/password as OTP (one-time password) is received to a service like mobile user needs to enter to complete login process. To provide more security to 2FA a protocol is proposed for web-based service computing service using a lightweight service is having 2 properties It performs some computation also i.e., having exponents. It is tempered i.e.., no one can break to get secrets. With this service protocol proxies 2FA security first the user security key is received.

Services are connected to the computer to authenticate user to access cloud services. User receives both invoked to access security key can't be uses another device belong to other for the access. This design supports a fine-grained attribute-based access control. For the actual abrogation of public keys mediated cryptography was structured. Immediate revocations of public keys are intended for mediated cryptography. A Security Mediator (SEM) model is prepared issue to this cryptography. Regardless, it gives a weight that this SEM dependably continue to be to play out any exchanges. A modified variant of this model planned as protection interceded testament less cryptography. In this framework, the patron has a thriller key, open key, character, and marking calculation. Mystery key & SEM model will be required furthermore required. It takes care of the disavowal issues. Client is mysterious to this model which causes security issue. with short term signature using cryptography added key we can store large haul keys to the protected gadget and unbound gadgets. A Security Mediator (SEM) version is deliberate reliant in this cryptography. It requires a smaller range of prerequisites. Performance analysis and protection evaluation are carried out. It enables a safety framework model to give privateness backing to the data. It normally calls for the gadget to guarantee privacy. Along those lines, it isn't convincing beneath various cloud administrations storage mechanism.

E.Bertino and M. Kantarcioglu [5] has proposed A great grained get admission to manage with first-class grained encryption technique for cloud records [7]. there are many models which are proposed by different authors for outsourcing data which provides encryption. But one problem with these models is that there will be an overhead of computation and communication.so to overcome this issue a Two Layer Encryption (TLE) technique is addressd.in this model at both client side and server-side encryption will be performed that is two-layer encryption and fine-grained encryption respectively. there is a one problem with this model where it can't disintegration Of Access Control Policies (ACPs) at time of TLE.So, in -layer encryption over scrambled information fine grained access control is connected and Various symmetric keys are utilized for correspondence these keys will influences connection between records things. By acting unmarried layer encryption, we will confine the troubles by means of the speak key management plans. customer can access content by using the fine-grained access control using some methodologies this task is done. There are two models in access control push and draw based models. In this way, it is hard to keep up the key mystery in a dynamic information

Sharing framework. Redistribution of the key is struggling besides the assistance of expressive get admission to manage techniques isn't always maintained. Power based totally models required the statistics distributer to live online to furnish get right of entry to. Such works ensures this, using untouchable garage administrations.it is the responsibility of the owner to provide the client privacy and control policies from data publisher. There are six phases are used for Two-layer encryption technique.

TLE perform the encryptions by gathering group key approach to guarantee the security on re-appropriated information It has such overhead on computation on the server facet and inside the get entry to control strategies. Accomplishment of the model is based on the attribute-primarily based keys, access manage strategies.

B.Justus and D.Loehr[7] to provide security for cloud and local administrators authors has designed a model called privacy preservation Mainly provides privacy for data storage provider is needed when we are outsourcing the sensitive data. This data can be leaked this make to build which provides security for both internal and external. In this model, the data is main thing we need to provide security more for that, so all data storage encrypted as backup data should be performed by cloud service. Data backup is automated for encryption proxies. Encryption proxies means which allows third parties to allow cipher text which has been encrypted for one party so that it may be decrypted by another. So, data decryption keys are exchange across secure channel by compressing PCR value we can achieve integrity. If both encryption proxies have same state, then exchange of key matrix take place. For example, when a request is made for data then a new request is designed by developer and sends to an editor, so editor integrates the request and set up access rights for the new request after setting file is signed and sends to next editor and he checks like after that he write sign file. Now encryption proxy access file on condition files is signed by two editors all their signatures are good access if changes rejects the file. The technologies which are used in this model are XML, XML-Encryption, XML Signature and Trusted Platform Module (TPA).

Larry and Ray [8] Propose An algorithm for nameless sharing of private data amongst N parties is evolved [6]. This approach is used to assign nodes ID numbers ranging from 1 to N. The received ID is not known to the other members of the group. If private communication channels used, then collision will not occur. It is likewise tested that there's no collision in personal verbal exchange channels use. This is sent without the use of a relied on crucial authority. The more recent algorithms are developed over a comfortable sum records mining operation the use of Newton ‘s identities and Sturm ‘s theorem. Markov chain technique is used to understand the data on the desired wide variety of iterations.

The pc algebra gives the outcomes towards the finishing touch fees. Author discovered that some cloud primarily based tools used for website control are providing get admission to for a server to saw the traveler moves on a website. For network nodes, such programs are there for requiring dynamic particular ID. This ID is required in sensor community services for administration sports or for protection to the man or woman nodes. It isn't an anonymous community, the contributors acknowledged and identifiable by way of each other’s. Suppose that a set of hospitals with man or woman databases wish to compute and share best the common of a records item, which include the number of clinic acquired infections, without revealing the cost of this facts item for any member of the organization. Thus, N nodes n1. N2, nN have statistics items d1, d2….DN, and desire to compute and share simplest the overall price T=d1+d2+…..+dN A at ease sum algorithm lets in the sum to be amassed with a few guarantees of anonymity T.Secur sum algorithm used for transmitting data securely.

An set of rules for sharing simple integer information on pinnacle of relaxed sum is construct. This is used with the nameless ID

challenge (AIDA) set of rules. It calls for a big range and various iterations. The writer prescribing a evaluate on at ease sum, precise technique of transmitting easy facts with strength sum, sharing complex statistics with an AIDA, and how to discover an AIDA. Comparison of numerous AIDA like Slot selection AIDA, Prime modulus AIDA, Sturm ‘s Theorem AIDA are discussed. Communications Requirements of AIDA methods are defined. Author concluding that the usage of newton identities reduces the communication overhead greatly. So the use of many slots with less number of rounds is needed. The polynomial solution may be avoided by way of making use of strum’s theorem. The non-cryptographic algorithms are simulated. The requirements are based totally best on the secure algorithm chosen.

COMPARIOSN TABLE

Table: Comparison table of different privacy preserving schemes

Comparison Factor / Paper	Q. Xiong and L.T. Yang	M. H. Au and X. Huang	Larry and Ray	E.Bertino and M. Kantarcioglu	B.Justus and D.Loehr
Access Control	Attribute based	Fine grained	No	Fine grained Course grained	Fine grained
Encryption	Proxy re encryption	yes	No	Two layer encryption	XML Encryption
Key management	Broadcast group	yes	No	Group key	No
Policy	No	Two factor authentication	Anonymous ID management	Group key management policy	XACML Policy
proxy	Re encryption	No	No	No	Encryption Proxy
Security person	No	No	No	No	No
Signature	No	yes	No	No	XML signature
Central authority	No	No	No	No	Trusted platform module

Over View of Privacy Preservation

From the relative investigation of existing privacy preservation models, there are different methods and techniques are used different authors but the motive of the all authors is to provide privacy for outsourced data. There some mechanisms which provides access control user and what part of data can be used. These models provide depending on client roles, attribute, policy and group-based access control schemes. to scramble the user data encryption will be performed on a document. different techniques are used to encrypt the data such as single level and multilevel encryption are performed. Some specific parameters are used at the time of access to verify the authenticate user.

providing security for the static files is easier it is difficult for such file where data will be updating and deleting for every time.in such case re-encrypt should be performed on whole file this will be an extra task. For user’s proxy server credentials are given so that user no need to there every time. If the credentials are leaked or meets failure at that time, there is possible of effects of wholeframework. Encryption methods will not support for all the operations of cloud data. homomorphism encryption will not support for analytics operation of data. There is no any scheme is proposed which provides complete security and privacy.

CONCLUSION

Cloud computing more useful for digital data access which provides different services on cloud. There are a greater number of users ofcloud, so it is increasing data storage and retrieval daily.so it is essential to provide security of user data it is priority to provide privacy for client information while storing and retrieving. Different encryption techniques and privacy preserving schemes are used to secure the data. With help of hash functions and signature key privacy is preserved there are some models which provides data recovery techniques. These

models are designed to secure the data of cloud. In destiny with the aid of the result of this audit a consolidated a model of cloud safety framework is planned to guarantee all protection organizations.

Optimization Of Vehicle Using Monitoring Systems

Sasvanth Narayan R, Loganathan V, Prateek Lakkar, Suganthan B
Department of Mechanical Engineering
Sri Krishna College of Technology
Coimbatore, India
sasvanth123@gmail.com

***Abstract*— In recent years, vehicle monitoring systems helped riders in gathering real-time information about their vehicles. This paper puts forward, the advancements which can be done using the data's gathered from the monitoring systems and optimize the vehicle. The monitoring system comprises of the following units processing unit, sensors unit, storage unit and a communication unit. The processing unit, communication unit and sensors unit has standard sensors and modules like weight sensor, global positioning module, real-time clock module, speed measuring module, etc. In the storage unit, the data's are stored in the built-in storage module as well as in the cloud. Ishikawa diagram helped to analyze the root causes of the problems faced by the riders. Then by considering those causes, the following solutions current fuel price display, audio communication of the customized details, fingerprint unlocking, mileage indication, automatic maintenance updater and economic travel assistant has been put forward. Towards the end of this paper, a survey related to the research has been described.**

Keywords—vehicle monitoring systems; Ishikawa diagram

I. INTRODUCTION

Road transport is one of the most sophisticated means of carrying around people and things for our day to day life until different problems related to our vehicle maintenance and fuel economy steps in. The present vehicles do not have proper maintenance scheduling or they are integrated with offline data storing methods that are used only for feedback purposes. The development of a unique integrated procedure to find a perfect solution for complete vehicle maintenance including track of fuel usage, tracing of non-economic activities and damage of vehicle parts and performance. Recording and implementing simple technology along with Microcontrollers that can be integrated with numerous cloud and virtual storage devices that are not only secure but also dynamic and provide real-time monitoring. The procedure must be user-friendly and easy to install such that the common man doesn't feel it as a burden but as a pride to have it. "Fig. 1," represents the Ishikawa diagram, also called as fishbone diagram which describes the root cause of the problem. The final problem can be solved by deriving solution for each root causes.

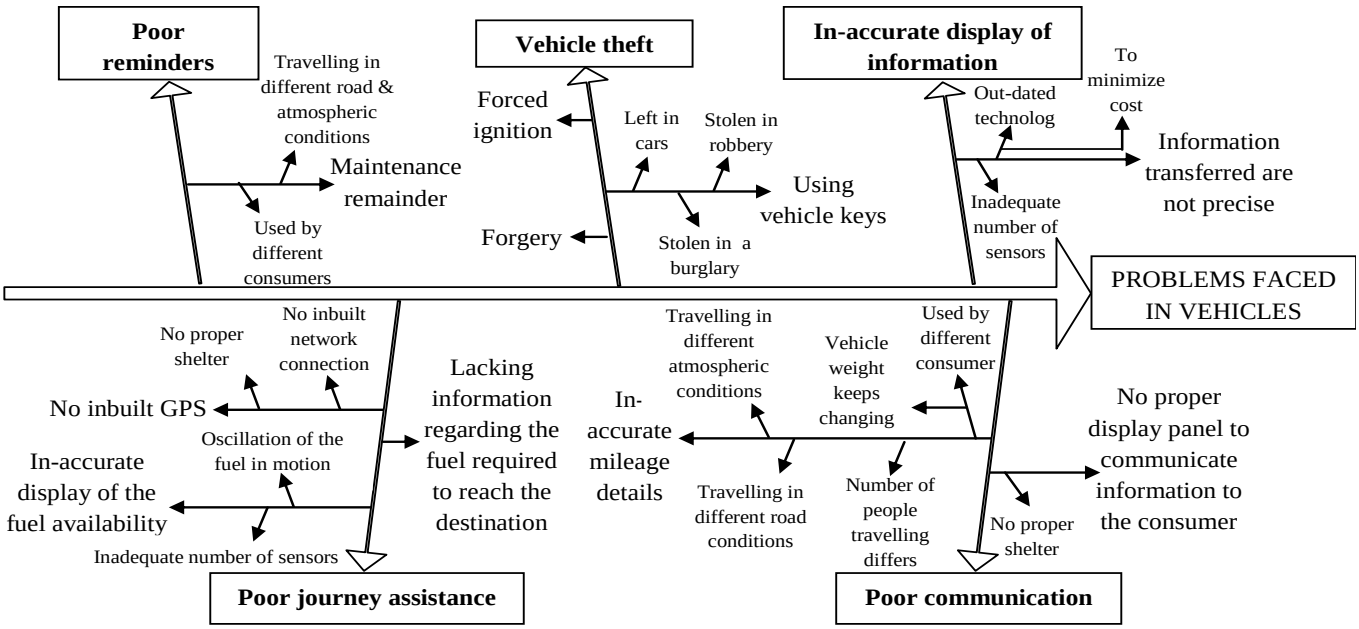

Fig. 1. Ishikawa diagram

II. Proposed Solution For The Causes

A. Maintenance Updater

Vehicles need maintenance at different interval of time, based on the driving conditions, fuel type, etc. So, with maintenance updater, it is possible to time the maintenance according to our daily travel and vehicle conditions, finally alert the consumer that the vehicle needs maintenance. In addition, it suggests the best nearby maintenance station based on the consumer's customization. For predicting the future maintenance schedule we need old maintenance schedule history, along with predetermined calculations. For better communication, we required some of the external parameters like current location, nearby maintenance stations, particular vehicle model details, etc. For updating or calculating maintenance time we need total distance traveled by vehicle between particular intervals as well.

TABLE I. Case Study of Maintenance Updater

Case 1	
From: 02/15/2018	To: 05/15/2018
Initial distance travelled: 0 km	Final distance travelled: 4000 km
Total distance travelled: 15000 km	Total distance travelled: 19000 km
Case 2	
From : 05/16/2018	To: 07/16/2018
Initial distance travelled: 0 km	Final distance travelled: 4000 km
Total distance travelled: 19000 km	Total distance travelled:23000km
Case 3	
From : 07/17/2018	To: 11/17/2018
Initial distance travelled: 0 km	Final distance travelled: 4000 km
Total distance travelled: 23000 km	Total distance travelled: 27000km

[a.] Date format: MM/DD/YYYY

With reference to "TABLE I," if the final distance travel reached a preloaded value say 4000 km, it stores the data using the storage module and sends an alert message to the rider.

B. Fuel Price Diplay

It's difficult for the consumers to keep in trace of the fuel price because of their fluctuating nature. Fuel price display updates the current fuel price on a daily basis with the help of the internet or intranet, respect to location and customized categories, in accordance with the third-party API and electronic device. The customized category indicates selection of fuel type by the customer whether it may be petrol, diesel, bio-fuel, hydrogen fuel, etc. individually or all data can be displayed at the same time if required.

C. Fuel Economy Assistance

Fuel economy assistance helps to make the travel safer, secured and preplanned. It will update the accurate fuel available in the vehicle and analyzes the riding quality based on the past rider's data and suggests the best fuel economic conditions. With the help of this, the future traveling schedule is created by itself. To implement this, we need to access the vehicle speed rate, calculate the distance to be traveled based on the destination location, riders weight and mileage rate based on the previous riding condition. Having these parameters, the fuel economy can be calculated and also suggests the additional fuel to be filled to reach the destination. "TABLE II" implies the case study of fuel economic assistant.

TABLE II. Case Study of Fuel Economic Assistant

Parameters	**Case 1**	**Case 2**	**Case 3**
No. of riders	1	1	2
Riders weight (kg)	60	60	60,60
Avg. speed (km/ liter)	40	60	40
Fuel price (Rs/ liter)	73	73	73
Total distance travelled (km)	10	10	10
Avg. mileage gained (km/ liter)	40	35	30
Fuel economy (Rs/ km)	1.825	2.086	2.433

D. Vehicle Analyzer

Vehicle analyzer gathers information about the vehicle riding route with riding environment and it is integrated with third-party WebPages and APIs for collecting other related information. Once the process is done, it stores all the information in the cloud when the internet is available. If the rider wants to know data between two destinations, the AI matches the current inputs with existing results, finally, it displays the results with its customized predictions. "TABLE III," explains the different parameters necessary for vehicle analyzer.

TABLE III. Case Study of Fuel Vehicle Analyzer

Working condition	**Case 1**	**Case 2**	**Case 3**
No of riders	1	1	2
Weight of the riders (kg)	90	88	120
Model of the vehicle	A001345	A001399	A002005
Mileage of the vehicle (km/ liter)	40	40	35
Speed limit (km/ hr)	60	60	50
Riding method	Continuous	Continuous	Moderate
Environmental conditions	Good	Good	Bad
Result	More efficiency	More efficiency	Less efficiency

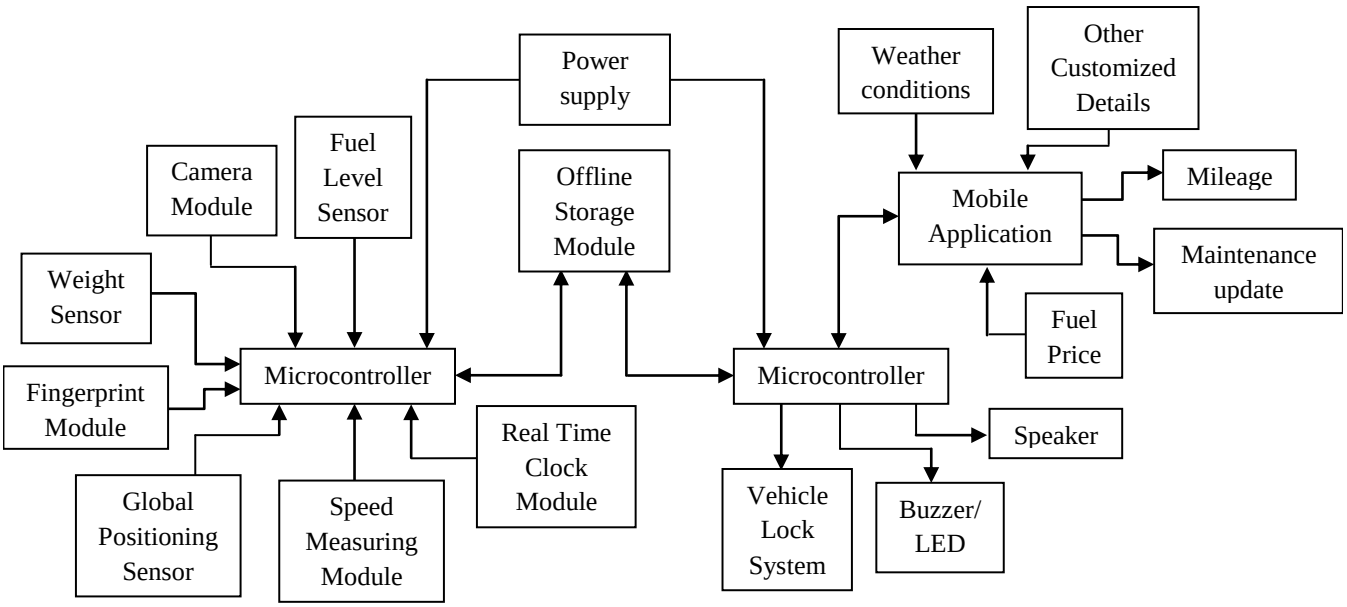

Fig. 2. Block Diagram of the Vehicle Monitoring System.

III. WORKING

With reference to the "Fig. 2," the working of vehicle monitoring system are as follows. Initially, when the rider covers their face and tries to start the vehicle, they get a failed response as the Identification module function was restricted by the rider. Then the rider is authorized by Authentication module by using his/her fingerprint, he/she can switch on the vehicle, and the fuel status will be informed to the customer through Customer communication module by using both audio and visuals after which the rider can start his journey. The Display module projects the economical and fast path using GPS for choosing the best route. The fuel level is displayed and notified regularly by Fuel level indication module so that the driver can refill with the nearest fuel station, fuel price is also projected according to the categories of fuel available in the station with price label by using cloud access module. The rider's weight is found using a weight measuring module, which helps to calculate the mileage of the vehicle preciously. The rider is notified if the vehicle wants maintenance through the maintenance updater in advance by receiving data from the speed measuring module and all the data of the devices which were stored with inbuilt storage system in the form of Offline storage module. With the help of all these modules, we can easily increase the efficiency of customer service.

IV. MOBILE APPLICATION

The first page of the application for the rider is to login to his access for the first level security. Generally, the login details are generated from the riders driving license details and the password is set while installing in the service center. Thus the system is completely secure. "Fig. 3" represents the home page and there are buttons to represent the notification page which displays the warnings and alerts of the vehicle. Separate display page of each button is set in the application. All kinds of notification and warnings based on the location and activities of the vehicle are also displayed for better security in a small map and the vehicle speed and economic speed values are displayed in separate meters. The user can access it by pressing either the notification or the warning button. The application has numerous functions and buttons such that it helps the user to have virtual connect with the vehicle. For example, if the vehicle has changed the route and is not moving towards the destination, notification or warning message will be delivered based on the severity of the problem. If the user finds that his vehicle gets disturbed or being theft or any kind of undesirable change he will get a notification and the warning button is highlighted. If the user finds that his vehicle is being used even after attaining the maintenance period, he will receive a call from the service centers which will help improve vehicle life. The cloud interacts with the customer based on real-time values and provides various facilities. The customer can get timely updates of the location of the vehicle, it can provide the change in the cost of fuel, create maintenance schedules, provide direct contact with the service centers and live navigation.

Fig. 3. Sample mobile application format

V. Survey Report

To evaluate how far our research would be beneficial for the end uses, we took a survey with individuals who are the consumers of the automobile vehicles. The data collection tool which we used is Survey Monkey and the data analysis is done using Microsoft Excel.

From the "Fig. 4," the majority of our survey population are between the age of 20 to 25 years old. Since these age category people are the potential internet users, and survey monkey being an online survey tool, it happened to have a higher proportion of people in this category. This doesn't have any correlation for the number of people who are riding vehicles in that particular age category.

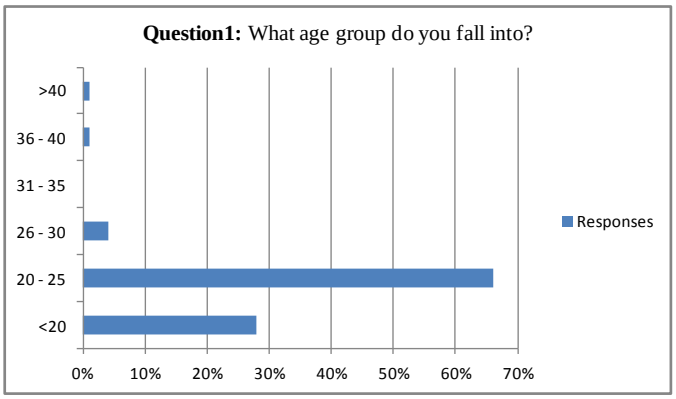

Fig. 4. Survey responders age category

It is a well-known fact that more people use bikes over cars and buses. That replicated in our survey results as well. The population distribution of individuals on their primary mode of transportation is shown in "Fig. 5".

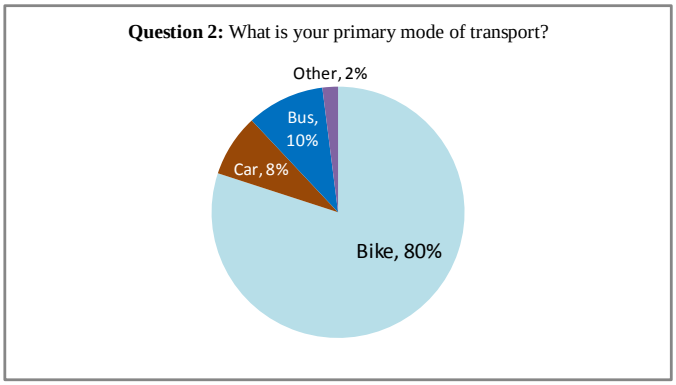

Fig. 5. Survey responders primary mode of transportation

"Fig. 6" shows that, most people in our survey population are the once who ride vehicles every day, this happened to be an advantage for the survey because only the people who use vehicles quite often know the difficulties associated with the vehicle.

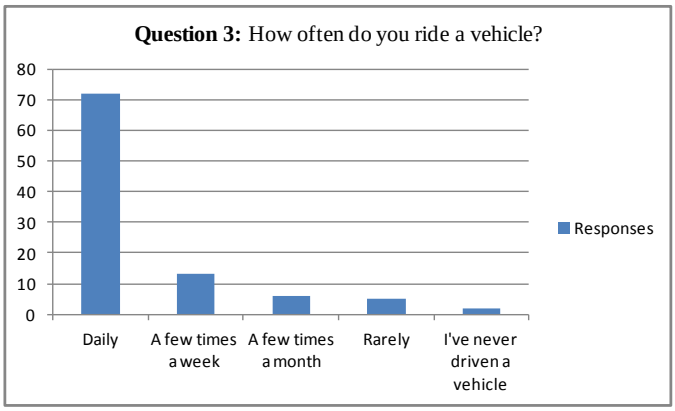

Fig. 6. Survey responders frequency of travel

It has been a mixed response for the advancements which we have proposed in this paper. From "Fig. 7," it is evident that the percentage range between economic travel assistance and current fuel price display (which happened to be the highest and the lowest response) is just 6%. This low variation between each proposed advancements makes it clear that how each advancement contributes value to their vehicle.

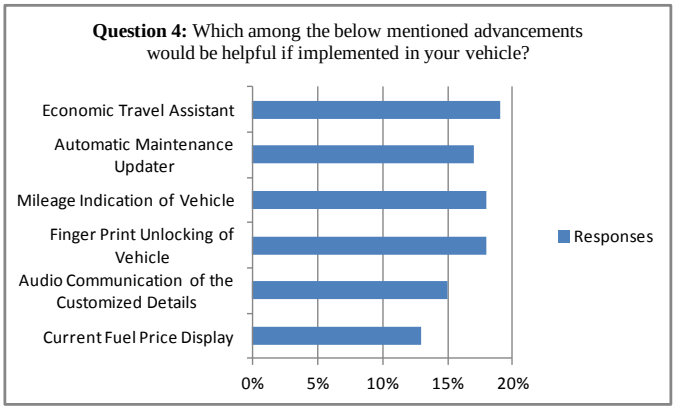

Fig. 7. Survey responders efficaciousness on the proposed advancements

The majority of the survey responders felt that the proposed advancements will be helpful if implemented on the bike. "Fig. 8" gives the evidence for it.

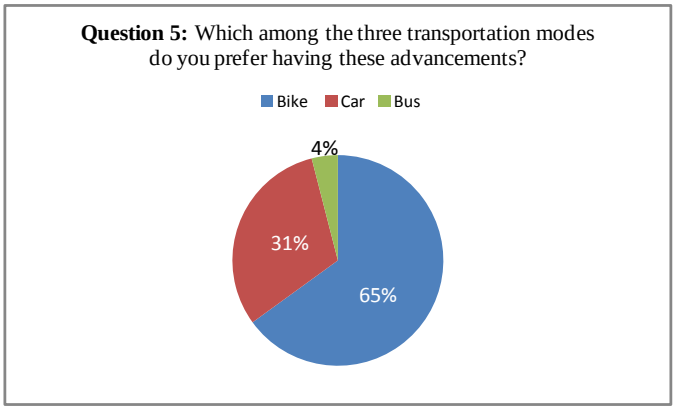

Fig. 8. Survey responders predilection in implementing the advancements

VI. Conclusion

This paper describes solutions for the problems which are being faced by the vehicle riders, using monitoring system technologies. The gathered real-time data's gives the riders the required information to utilize their vehicle optimally which thereby decreases the transportation cost. The proposed solutions also help the manufactures to provide value-added services to their consumers. With the survey results, it's evident that, implementing monitoring system in bikes has far better scope over car. But implementing in bikes leads to other complications, which needs crucial examination.

VII. Future Scope

Apart from the day to day monitoring of the vehicle the people and government organization give higher preference to safety and control. Thus the future scope lies in the fact of implementing various safety methods along with this technology. The suggested methods are alcohol detection, helmet detection, accident detection, and control by sending messages to family, friends and nearby ambulance service.

The future also lies in the concept of Connecting vehicles for better movement on faster platforms without any confusion to cause accidents and to contact nearby workshops and fuel stations for help during the breakdown and guidance. The installation of a GPS based smart route finder to find the best route without traffic and save time and fuel consumption.

If block chain concept is to be implemented successfully in future, we may be able to achieve the secure transfer of data from the vehicles to the OEMs and manufacturing companies along with secure payment methods in fuel station by default setup of encryptions in the vehicle to transfer money without any risk of the breach of our privacy and hacking.

Making all the sensor, microcontrollers and actuators resistant to wear and tear in an open vehicle is a difficult task. Maybe in the future, the shape and design of the vehicle will be modified to provide a secure and resistant atmosphere for the Electronic devices to work effectively.

The manual process of monitoring the vehicle is automated in this project but the vehicle is still to be manually driven by the user and the system provides useful data to the user which is to be analyzed by the user and take necessary actions by himself. In the near future, we can be assured that Artificial Intelligence and Machine learning will be a guiding member and make this also automated. We will be able to develop autonomous driving vehicles that drive on its own and maintains itself on its own.

***Abstract*:**
Indian economy mostly depends upon agriculture. More than 60% people of India depends on farming. Farmer has to go through huge losses due to use of historic techniques in agriculture. Most of the activities are done manually by farmers, which consumes time, energy and manpower. So, there is a need to develop an equipment which will reduce efforts of the farmer. Through this project our attempt is to fabricate such a system to automate all the agricultural processes including seeding, ploughing, fertilization and irrigation. As soon as the program is loaded in the PLC, bot starts working.
System has embedded smart technologies like IoT to inform the farmer about the weather conditions. Also the bot is provided with theft security. System has motor-sensor assembly to collect the real field data and according to the data further processes takes place. The dimensions of the field decide the trajectory of the AGROBOT. HMI is used to provide interface between the user and the machine.
***Keywords*-Agricultural robots, Automation, Agriculturalautomation, PLC, HMI, IOT.**

I. INTRODUCTION:

Farming requires a lot of efforts to perform various activities such as seeding, ploughing, irrigation, fertilization. Hence robotics must be implemented to overcome difficulties during farming .But still implementation of robotics in agricultural field is challenging for engineers. Advanced technology helps us to water and fertilize precisely, this results in good quality of food. The idea of applying robotics technology in agriculture is unique.
For this system Programmable Logic Controller is central oriented.

PLC:

PLC is an industrial computer which is rigid, and adapted for the control of processes like assembly lines, robotic devices, etc. It has high reliability control, ease of programming, process fault diagnosis[4]. PLC is an example of hard real time system in which output must be produced in response to input conditions. It consists of input modules, processor, memory, output modules and power supply[4]. PLC receives the information from connected sensors processes the data and produces output based on programming parameters. PLC's are adaptable to almost any application. Various output devices with different voltage ranges can be connected to PLC. Ladder logic is the traditional programming language of PLC[4]. It is usually written on the computer and then downloaded to PLC using serial communication.

HMI:

In order to interact with the PLC users need an HMI. These operator interfaces can be simple displays, keypad, or large touch screen panels .They enable users to review and input information to the PLC in real time. HMI communicates with PLC and sensors to get and display information for users to view [6]. HMI's are used to optimize an industrial process by digitizing data for a viewer. By using HMI operators can see important information like graphs, charts or digital dash board and alarms and can connect with SCADA systems[6].

MOTORS:

- **Stepper Motor**

Stepper motor is used to divide a complete rotation into number of steps. In this project stepper motor is used for seeding and fertilization purpose[8].

- **DC Motor**

This motor coverts electrical energy into mechanical energy. One of the advantage of dc motor is its speed can be controlled over a wide range. In this project DC motor is used in motor sensor and plougher assembly[7].

- **Square Geared Motor**

These motors equipped with gear boxes for providing a great balanced between speed and torque according to requirement. Generally, it provides high torque.In this project, these motors are used to drive the bot on its given trajectory[7].

INVERTER:

Inverters are needed where it is impossible to get AC supply from the mains. An inverter circuit is used to convert DC to AC .here in this project inverter is used to convert 12V DC to 230 V AC, which is given to PLC. Inverter work on the idea to produce oscillations from DC and applying these oscillations to step up transformer to amplify the current.

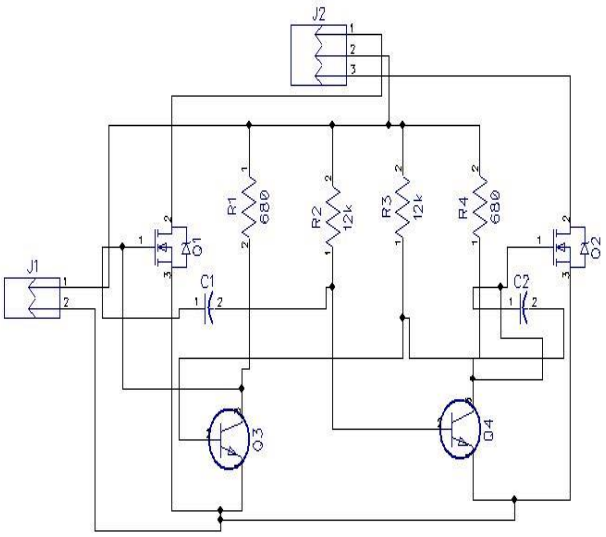

Fig 1.1

II. LITERATURE REVIEW:

Agriculture is the backbone of Indian economy. It supports17% of world population. Nowadays most of us have come across the atomization in various fields which leads great development in industrial products which made our life easier than before. Development of new technologies in agriculture has helped for growing countries. The survival of those people is improved which are totally dependent on agriculture[3]. According to this paper engineers has to make a great efforts for advancement in agriculture complex machinery has to be developed in order to reduce work load of farmers with good quality of food. These equipments are mostly very complex as they are implemented on basics of operation. As these devices are made taking the present scenario in the field of agriculture. The basic objective of developing such a system which detects moisture and PH of field is according the present moisture of soil the irrigation will be carried out in the field which will definitely give a proper way of using water as well as PH will to detect acidity of soil which will turn helpful to fertilize only required nutrients to soil which will help to less damage on soil[1]. The results shows that the robot will successfully work as per physically outlined it will also met the economic and time constraints that it was able to drive up and back along the tracks in the field.

A. Durmus et al.(2015)

In 2015 this team comes with the agrobot term they defined it as a multipurpose robot. They completed their work as per they have divided it was designing team and cloud based service providing team[3]. They built their robot in-house under 2000$ budget using only their available tools, equipment. It was not just a complete mobile robot but also was connected with farmers wirelessly through cloud computing through the farmers mobile devices. But unfortunately implementation of this idea was not completed.

B *Amer et al(2015)*

This team comes up with the prototype of multipurpose robot that is agrobot to perform various agricultural tasks. It has ability to perform various agricultural activities such as harvesting, and weeding. But there was a limitation of this robot was dependency on Wi-Fi.In this work there was impractical to introduce Wi-Fi connections in the open fields, as Wi-Fi routers and cables would be exposed to elements,power and maintenance cost would be high[3].

PROBLEM STAEMENT:

New technologies are introduced in agriculture but question remains the same are they capable to produce good food quality, help farmers, sustain us? According to UN it is needed to gain 3 billion metric tons of food this is very big. Hence for this reason it is necessary to develop a system which will do all work without interference of human to reduce human error. The problem is to make a robot which will be able to do all these work including IoT in it which causes to have all information with farmers. This will reduce the work load of farmers by using smart ways, also will turn helpful for improving food quality by reducing adequate use of fertilizers and maintaining use of water. These will reduce all problems regarding to agriculture and farming will become ease for the farmers as the whole thing will be automated. Thus, the whole process gets automated which isof greater need to the society as well as to the farmers so that they can also enjoy the fruit of life. This technique is definitely going to change the phase of the modern farming in the near future.

OBJECTIVES:

1. Human efforts will be reduced.

2. Just a brief description is more than enough to control the whole system.

3. Efficient use of technology.

4. To design a PLC based more advanced automotive irrigation robot.

5. Efficient use of resources such as water & time.

6. To preserve quality of soil.

III . PROPOSED METHOD:

A complete prototype of agrobot is presented here will first collect weather data to check that all weather conditions are ok that means there is no possibility of raining. The agrobot will start its working as shown in fig 2.

BLOCK DIAGRAM:

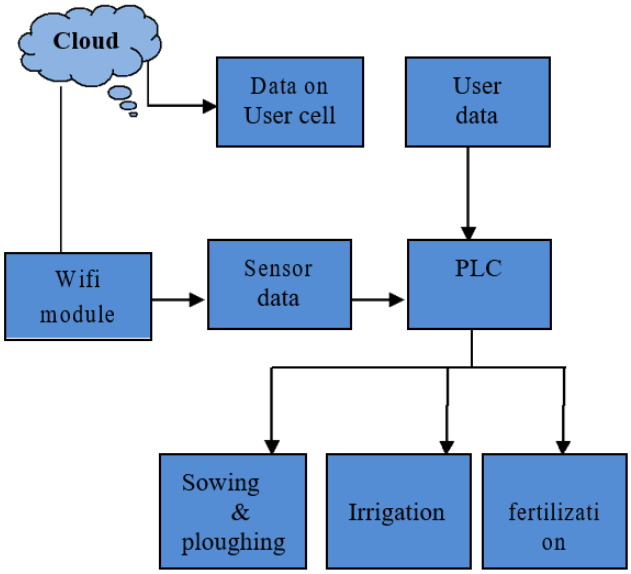

Fig.3.1

Soil fertility testing and weather forecasting:

The land will be suitable for agricultural purpose only if the soil over there is fertile. So the very first task performed by the robot will be testing the fertility of soil as well the weather conditions via IOT as shown in fig 2. Only if the soil is fertile, the further process will be carried on else, message will be given to the farmer about the infertility of the soil.

Sowing and Ploughing:

As shown in fig 2 after checking the fertility of the soil and the weather conditions, and if the soil is fertile, PLC will allow the machine to sow and plough simultaneously. The robot contains a plough, hopper and a container to which a valve is attached. The plough will be connected at the end of the machine and after getting the signal from the PLC, robot moves and thus the ploughing process starts. The only thing that the user has to do is to fill the container with seeds. The level of seeds in the container will be continuously monitored by the robot using a level sensor and thus the PLC, if the level of seeds in the container drops below a specific value, message will be given to the farmer about the shortage of the seeds. As soon as the level of seeds in the container falls below a specific value the PLC will give a signal to the robot to stop so that the container can be filled again with the seeds. The sowing process will again resume by pressing the resume push button on the machine. Thus the ploughing and sowing process will take place. Messagewill be given to the farmer about the completion of the process.

Moisture detection and water supply management:

The robot is at rest after completing both the above Processes. The next task taken into account by the robot is moisture detection. The PLC is being provided with inputs from the moisture sensor. Depending upon the concentration of the moisture present in the soil and after performing the desired calculations in the PLC, the PLC will be able to control the amount of water given to the sprinkler pipes. As the moisture is not even everywhere in the field so the PLC would receive the inputs from the moisture sensors at different stages. Depending upon the data received by the PLC in fig 2 flow rate through the sprinkler is going to vary by actuating a control valve. So the main function of the robot here is to just send the data from different locations to the PLC which will control the flow rate through the pipe. This would save water to a great extent. Again, as per the norms, the message for completion of water supply will provided to the farmer.

Fertilization:

After collecting the data from different locations the robot is at rest. After finishing the above process the next process taken into consideration is the fertilization. Before this if the container contains the seeds the PLC will give an indication to remove the seeds for the farmer by using a bypass valve. The same container will then be filled with the fertilizers. After getting the signal from the farmer to start the fertilization process the PLC will cause the valve to open, thus causing to fertilize the whole field area. As the process gets completed message for the completion of the whole process will be given to the farmer as shown in fig 2.

Overview of the system:

A complete prototype of the agro-bot which will do all the above said processes such as sowing , ploughing , watering, etc. which will be controlled by the heart of the system which in this case is the PLC refer fig 3. The objective of the whole project is to make an automated robot that would be able to do all the work that is done by the farmer. The very first thing done by the agro-bot is to check the fertility of the soil as well as the weather conditions of the field. The weather conditions will be determined by the IOT based technology that would display the real data on the screen of the bot and provide an idea to the farmer that whether the farming is suitable for the present day. If positive signal is given by the farmer the PLC will give the signal to the hopper valve so that it will start sowing seeds within its bounds and plough simultaneously as shown in fig 3. This will tend to reduce the time consumed by the farmer and he will be able to do some productive work during this slot. If level of the seeds in the container drops below a specific value the PLC will cause the agro-bot to stop and at the same instant reduce the time consumed by the farmer and he will be able to do some productive work during this slot. If level of the seeds in the container drops below a specific value the PLC will cause the agro-bot to stop and at thesame instant message

will be given to the farmer about the shortage of seeds.Again after getting the input from the farmer/user the Robot will start the same process further andploughsimultaneously. At last the plough will be lifted up and the hopper valve will close.

FLOW CHART:

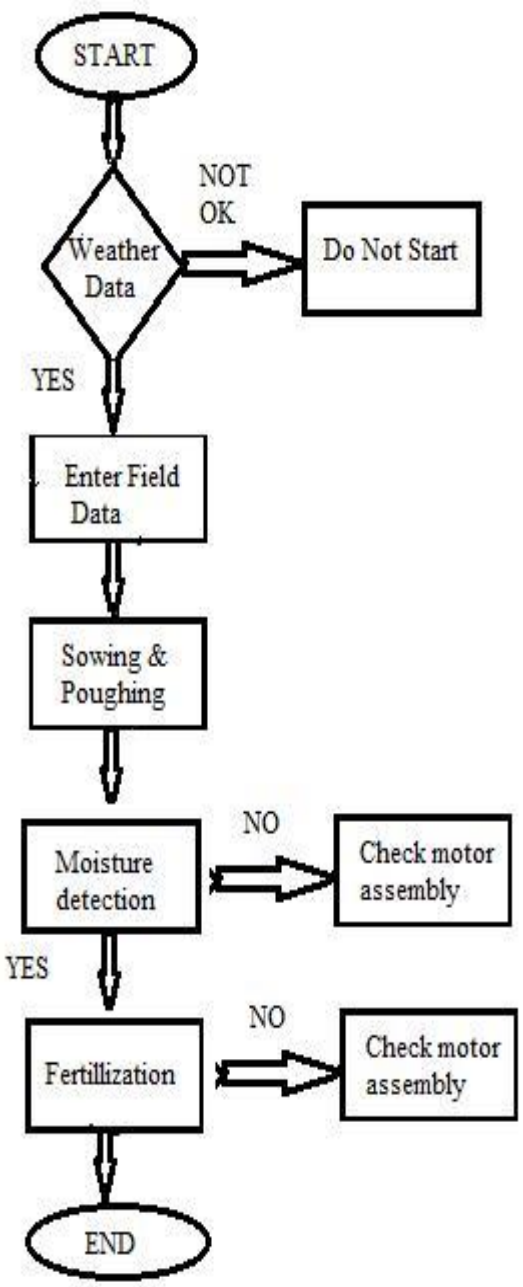

Fig 3.2

System outcomes:

1. Reduced human efforts.
2. Smart use of technology.
3. Visualization of each process is available.
4. Effective time usage.
5. Energy consumption mitigation.

IV. IMPLEMENTATION:

PLC Program:

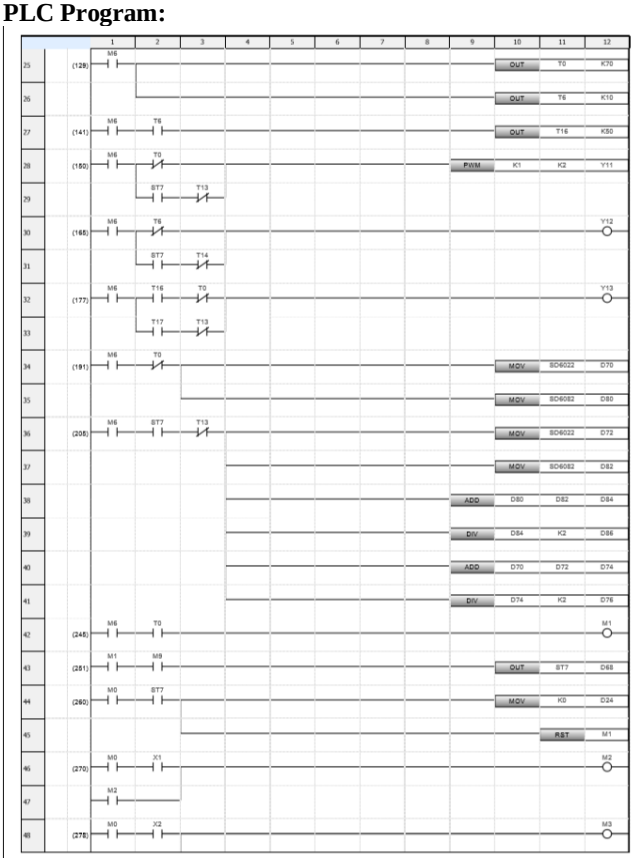

Fig.4.1

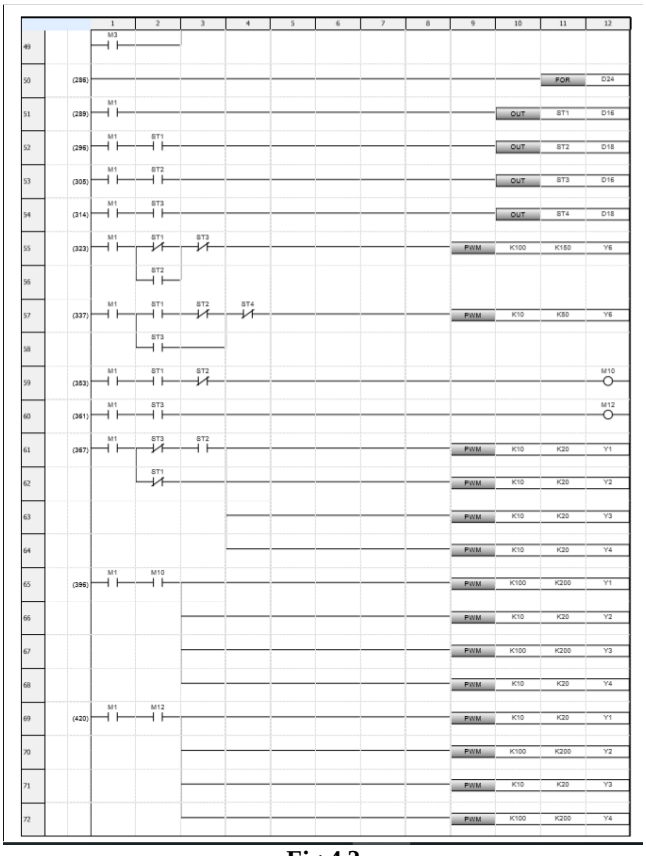

Fig.4.2

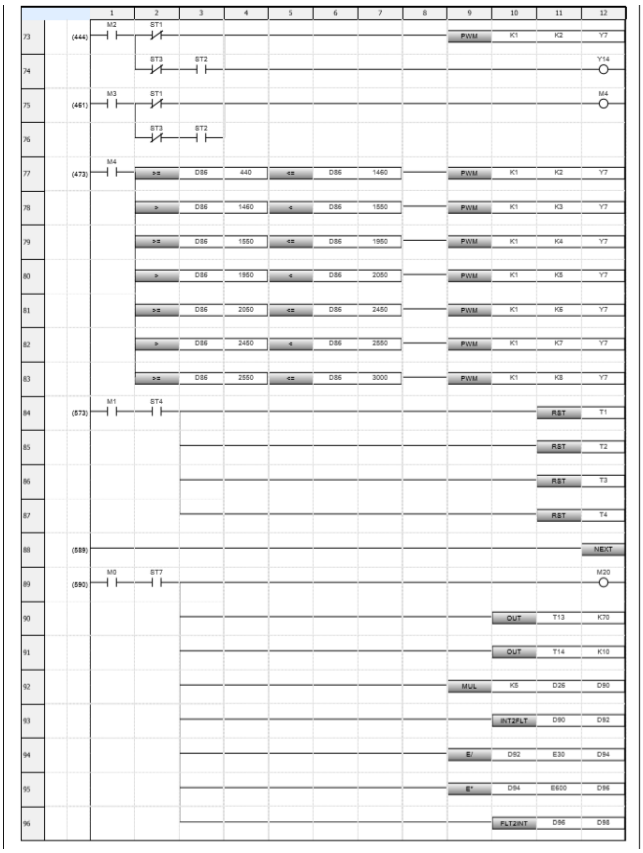

Fig 4.3

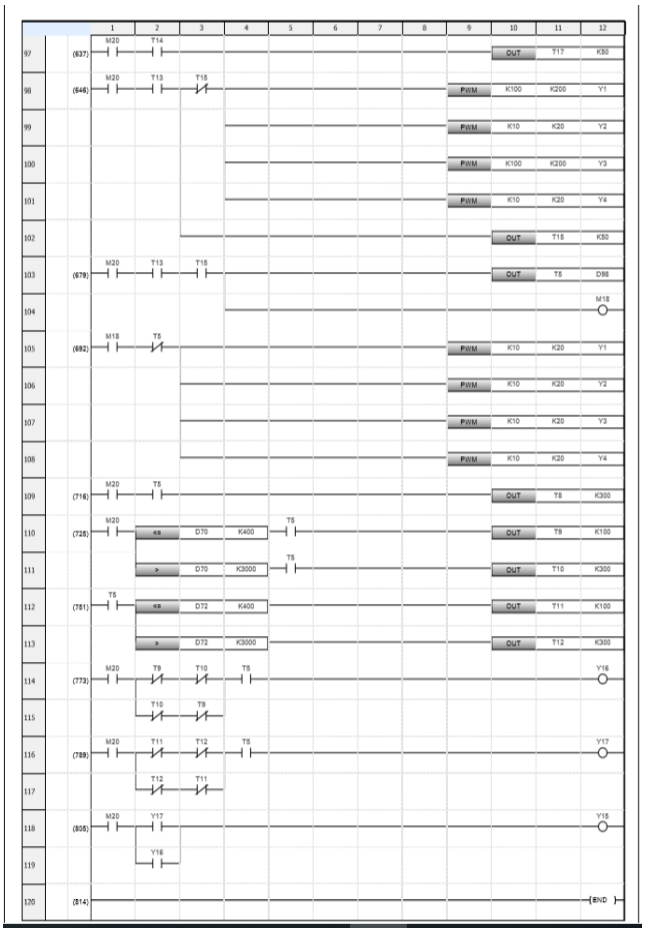

Fig 4.4

HMI Screens:

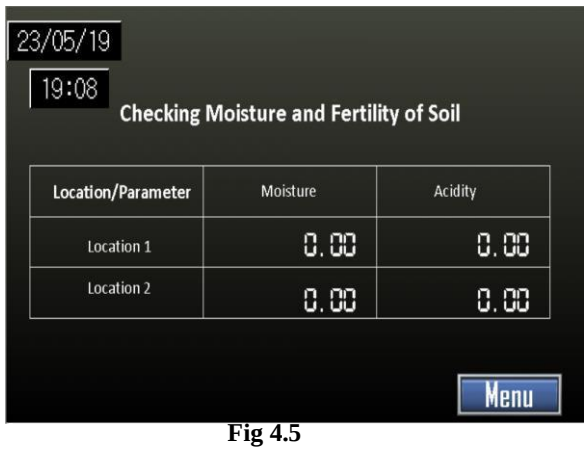

Fig 4.5

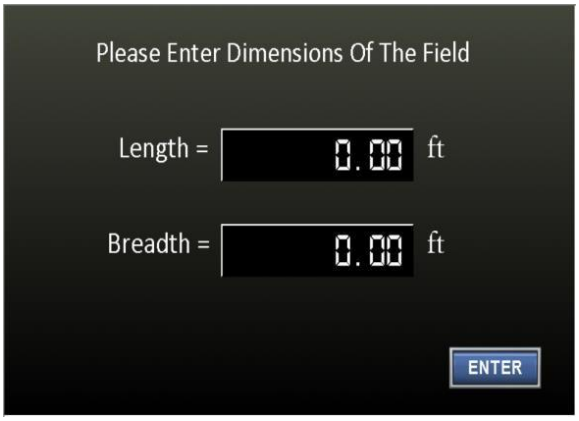

Fig 4.6

Orthogonal view:

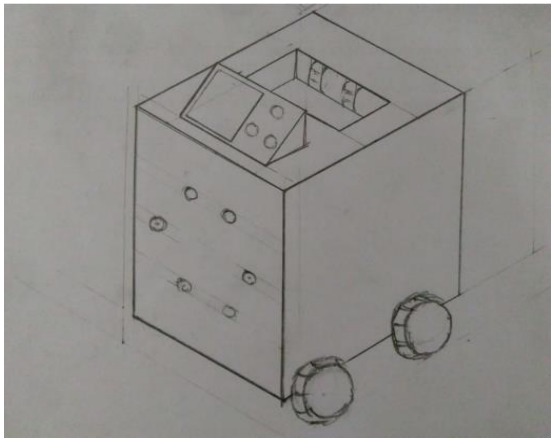

Fig4.7

Fig 11

Result:

1. The bot takes the data from field and the controller and take the respective action depends on the measured values.
2. Speed of bot is fixed so controller can adjust its timing for various dimensions of field given by farmer.
3. Robot will work according to the selection of process user want to do.
4. Fertilizers will be provided in proportion according to acidity of the soil.
5. In irrigation process amount of water provide to field is being control using current moisture data and rain data.

V . CONCLUSION

Through this paper such above mentioned efforts madeto reduce problems in agriculture. The prices of food
grains, fuels, cloths and other things are increasing hencelabors are requesting more wages from owners. This
paper shows that agriculture robots need a supportinfrastructure. This provides wireless connectivity for
the robots in the field.Implementing suchinfrastructure
is challenging the cost of such a robot could be prohibitive. The key to implementing agriculture robots is to find a novel, practical and a reliable approach to implementing the support infrastructure it needs.

Abstract -- In the field of image processing application such as medical diagnosis, crime prevention, publishing or advertising, historical research a common image retrieval technique is used. Simple browsing can easily identify images in a small collection of images but for large and different collection of images identification of image becomes critical issue. In this paper for image retrieval four different features are extracted using DDBTC technique. The first two features such as Color Co-occurrence Features (CCF) and Color Histogram Features (CHF) are obtained using color quantizers, Bit Pattern Feature (BPF) and Bit Histogram Feature (BHF) are obtained using Bitmap image. In order to remove the false counter problem and blocking effect different error diffusion kernels are employed. The results shows better accuracy.

Keywords— Average Recall Rate Average Precision Rate, Bit pattern feature, color co-occurrence feature color histogram feature, Dot diffused block truncation coding.

I. INTRODUCTION

Content based Image Retrieval application of computer vision technique to minimize the problem of image retrieval.In annotated based method we have to annote every image based on information of metadata or keywords. In this process the system is not able to capture the exact keywords to represent The images and it becomes time consuming. In CBIR system search of images is based on visual contents rather than metadata. Here "content" is information of texture, shape, or color obtained from images. In 1979 [1] Mitchell and Delp introduces first Block Truncation Coding (BTC). Udpikar and Raina [2] describe the overhead statistical information using source encoding of a block truncation coding. (BTC). Author uses the vector quantization which reduces the bit up to 1.5 bit/ pixel. Yiyan Wu [3] derives Blo for image retrieval. BTC generates the vector quantized bitmap which are then decomposed into a set of vectors. It achieves the compression ratio up to 10:1. G. Qiu [4] uses BTC technique for feature extraction. N. Jhanwara [5] uses motif co-occurrence matrix (MCM) for content based image retrieval. The MCM is similar to the color co-occurrence matrix (CCM), but MCM performs the retrieval task better than the CCM. Experiment shows the MCM improves the retrieval performance as compared to CCM. In [7-10] author uses dot diffusion block truncation coding for image retrieval. To measure the performance of image retrieval various distance metrics are employed.

I.SYSTEM DESIGN

System design flow is mentioned in fig.1

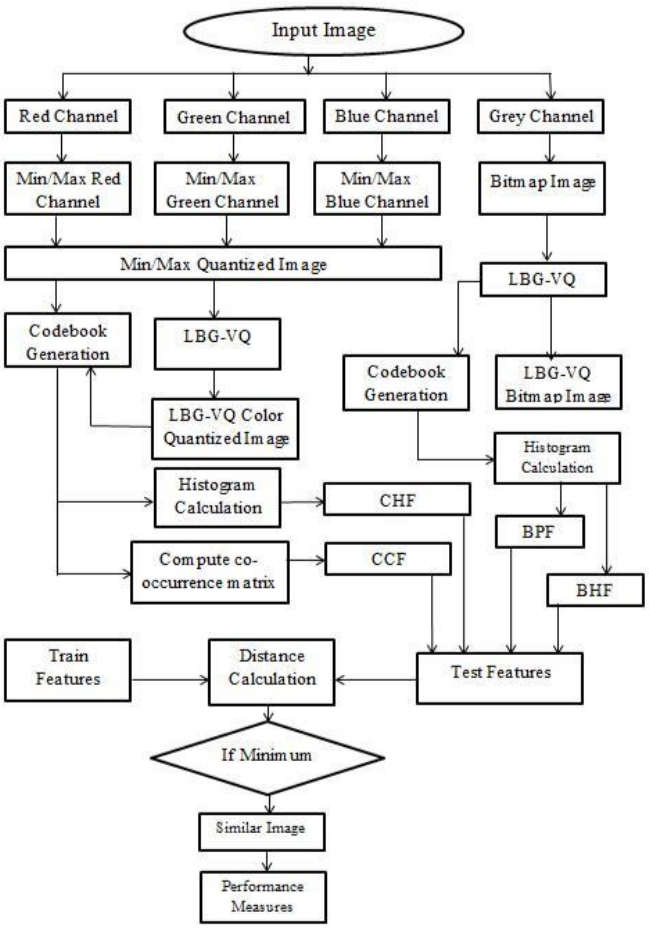

Fig. 1. System Design

A. *Dot Diffused Block Truncation Coding :*

A sample image is used to derive the minimum and maximum quantizers. In this assume at position (i, j) an f (i, j) be the image block. The color images are in RGB color space.

$$Q_{min} = \{\min f_R(x, y), \min f_G(x, y), \min f_B(x, y)\} \quad (1)$$

$$Q_{max} = \{\max f_R(x,y), \max f_G(x,y), \max f_B(x,y)\} \quad (2)$$

In this Red, Green and blue color are represented by R, G and B. The color image is converted into grey image using:

$$f\hat{}(x,y)=1/3[f_R(x,y)+f_G(x,y)+f_B(x,y)] \quad (3)$$

The Bitmap image is also computed using:

$$b_m=1; \text{ if, } f\hat{}(x, y) \ f(i, j) \quad (4)$$

$$0; \text{ if } f\hat{}(x, y) < f(i, j)$$

II.FEATURE EXTRACTION

1.Color Histogram Feature (CHF) :

The Process of CHF is shown in Fig 2.

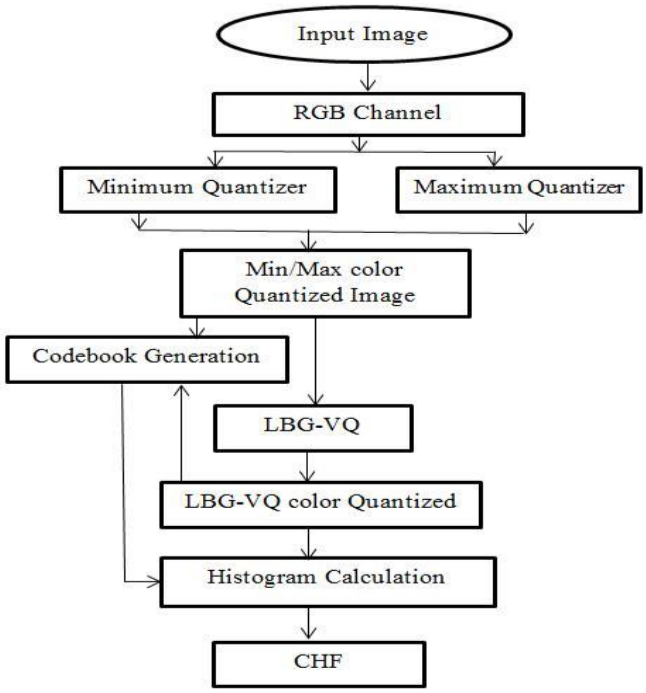

Fig. 2. Design flow of CHF

2. Color Co Occurrence Feature (CCF):

The Process of CCF is shown in Fig 3.

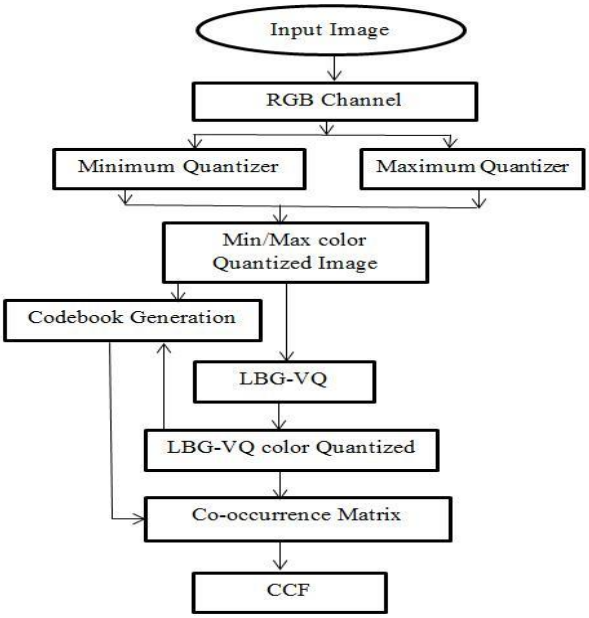

Fig. 3. Design flow of CCF

3. Bitmap Pattern Feature (BPF):

The Process of BPF is shown in Fig 4.

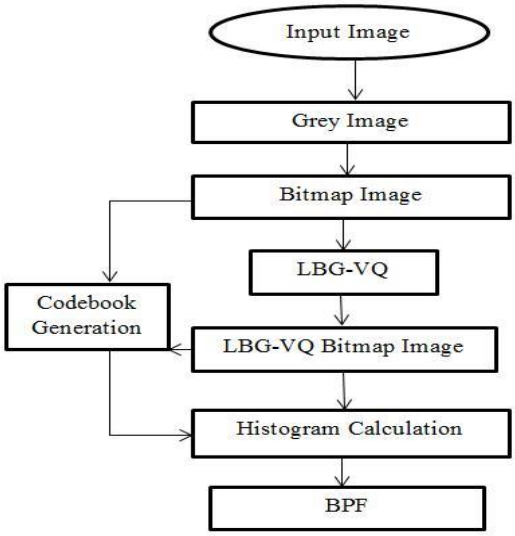

Fig. 4. Design flow of BPF

4. Bit Histogram Feature (BHF):

The Process of BHF is shown in Fig 5.

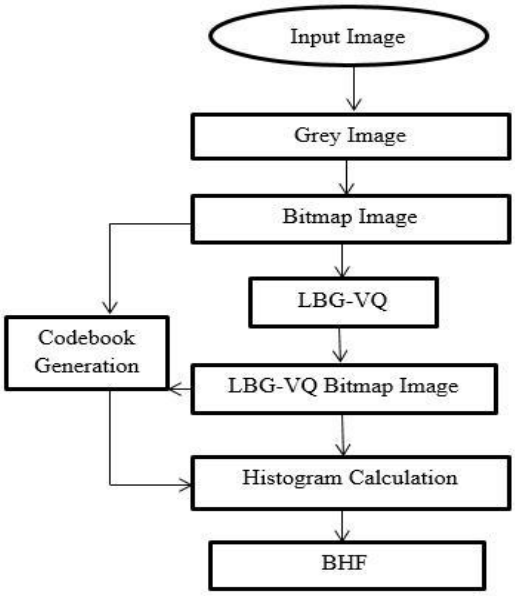

Fig. 5. Design flow of BHF

B. Distance Metrics :

The different distance metrics are given by:

1.L_1 distance

$$\delta(query, target) = a_1 \sum_{k=1}^{Nmin} | CHF_{min}^{query}(k) - CHF_{min}^{target}(k)| + a_2 \sum_{k=1}^{Nmax} | CHF_{min}^{query}(k)\, CHF_{min}^{target}(k)| + a_3 \sum_{k=1}^{Nb} | BPF^{query}(k) - BPF^{target}(k)| \quad (5)$$

2.L_2 distance

$$\delta(query, target) = [\, a_1 \sum_{k=1}^{Nmin} (CHF_{min}^{query}(k) - CHF_{min}^{target}(k))^2 + a_2 \sum_{k=1}^{Nmax} (CHF_{min}^{query}(k) - CHF_{min}^{target}(k))^2 + a_3 \sum_{k=1}^{Nb} (BPF^{query}(k) - BPF^{target}(k))^2]^{1/2} \quad (6)$$

3.x^2 Distance

$$\delta(query, target) = \alpha_1 \sum_{k=1}^{N_{min}} \left(\frac{CHF_{min}^{query}(k) - CHF_{min}^{target}(k)}{CHF_{min}^{query}(k) + CHF_{min}^{target}(k) + \varepsilon} \right)^2 + \alpha_2 \sum_{k=1}^{N_{max}} \left(\frac{CHF_{max}^{query}(k) - CHF_{max}^{target}(k)}{CHF_{max}^{query}(k) + CHF_{max}^{target}(k) + \varepsilon} \right)^2 + \alpha_3 \sum_{k=1}^{N_b} \left(\frac{BPF^{query}(k) - BPF^{target}(k)}{BPF^{query}(k) + BPF^{target}(k) + \varepsilon} \right)^2$$

4. Fu Distance:

$$\delta(query, target) = \frac{L_2 distance}{|CHF_{min}| + |CHF_{max}| + |BPF|}$$

5. Modified Canberra distance

$$\delta(query, target) = a_1 \sum_{k=1}^{Nmin} \frac{|CHF_{min}^{query}(k) - CHF_{min}^{target}(k)|}{CHF_{min}^{query}(k) + CHF_{min}^{target}(k) + \varepsilon} + a_2 \sum_{k=1}^{Nmax} \frac{|CHF_{max}^{query}(k) - CHF_{max}^{target}(k)|}{CHF_{max}^{query}(k) + CHF_{max}^{target}(k) + \varepsilon} + a_3 \sum_{k=1}^{Nb} \frac{|BPF^{query}(k) - BPF^{target}(k)|}{BPF^{query}(k) + BPF^{target}(k) + \varepsilon} \quad (7)$$

C. System Performance:

System performance determined using:

$$APR = \frac{1}{Nt\,L} \sum_{q=1}^{Nt} Nq(L) \quad (8)$$

$$ARR = \frac{1}{Nt\,Nr} \sum_{q=1}^{Nt} Nq(Nr) \quad (9)$$

D. Error Diffusion Kernels:

Here we can mention various Error Diffusion kernels in order to generate the Bitmap images. The advantage of Error diffusion kernels is that it can achieves better image quality as compared to Block Truncation Coding technique. The image compression using BTC and EDBTC and BTC also used in [3, 4, 6]. Here we mention the six different error diffusion kernels.

$$\left(\frac{1}{16}\right)\begin{bmatrix} & * & 7 \\ 3 & 5 & 1 \end{bmatrix} \quad \left(\frac{1}{42}\right)\begin{bmatrix} & & * & 8 & 4 \\ 2 & 4 & 8 & 4 & 2 \\ 1 & 2 & 4 & 2 & 1 \end{bmatrix} \quad \left(\frac{1}{32}\right)\begin{bmatrix} & & * & 5 & 3 \\ 2 & 4 & 5 & 4 & 2 \\ 0 & 2 & 3 & 2 & 0 \end{bmatrix}$$

(a) (b) (c)

$$\left(\frac{1}{32}\right)\begin{bmatrix} & & * & 8 & 4 \\ 2 & 4 & 8 & 4 & 2 \end{bmatrix} \quad \left(\frac{1}{48}\right)\begin{bmatrix} & & * & 7 & 5 \\ 3 & 5 & 7 & 5 & 3 \\ 1 & 3 & 5 & 3 & 1 \end{bmatrix} \quad \left(\frac{1}{200}\right)\begin{bmatrix} & & & * & & 32 & \\ 12 & & 26 & & 30 & & 16 \\ & 12 & & 26 & & 12 & \\ 5 & & 12 & & 12 & & 5 \end{bmatrix}$$

(d) (e) (f)

Error diffusion kernel: (a) Floyd-Steinberg (b) Stucki [62], (c) Sierra (d) Burkers (e) Jarvis and (f) Stevenson filter

Generally while using BTC technique many problems are occurred such as blocking effect and false counter problems. Due to this the image quality can be degraded. In order to overcome such problems various error diffusion kernels are employed

III. EXPERIMENTAL RESULTS

E. Experimental Setup:

Fig.6. Corel Image Dataset

The Fig.6.shows sample images from Corel 1000 Dataset. The Corel 1000 dataset having 10 different Classes. For our image retrieval task we can select 20 images from each class, so that the dataset.

Fig.7. Input color image

Input color image is selected as shown in Fig.7.The Fig.8. is obtained using quantization process From Gray color image Bitmap image obtained as shown in fig.9.

Average	**0.5268**	**0.5951**	**0.7175**	**0.7788**	**0.9125**

In paper [2] author uses the Error Diffusion Block Truncation Coding and derives the two features which achieves the Precision Rate as 0.797 under Corel 1000.

CONCLUSION

To perform the Experiment DDBTC method and four number of image features are used. The bit pattern feature (BPF) and Bit Histogram Feature (BPH) recognize the contents of image. The color co-occurrence feature (CCF) and color histogram feature (CHF) represents color distribution and image brightness. The simulated results shows better average recall rate and average precision rate. The Error diffusion kernels are employed to minimize the problem of blocking effect and false contour problem. The Modified Canberra distance shows better accuracy as compared to other similarity distance. In the future work, we can increase the size of dataset and computational time for image retrieval can also reduce.

***Abstract*—This paper addresses comparative analysis between three basic converters i.e. Buck, Boost and Buck-Boost converter to interface with a rooftop domestic Photo-Voltaic (PV) system to track maximum power point (MPP) effectively in normal conditions and in partial shading conditions. With partial shading, variable atmospheric conditions and variable load, the working value of impedance at MPP (Z_{MPP}) may vary widely. The MPPT algorithm should force the PV system work very near to Z_{MPP} with the help of power electronic interface for varying load and atmospheric conditions in order to make the system work at MPP. The effectiveness of the MPPT algorithm and the power electronic interface can be inferred from this obligation. Although all the three mentioned DC-DC converters can be used as interface between PV source and desired load, the simulation study verifies that the performance of each converter is different. Here the effect of diverse load having different value than Z_{MPP} on tracking MPP for both with and without partial shading condition is analyzed and it is deduced that Buck-Boost converter successfully tracks MPP for varying loading effect and atmospheric condition most efficiently.**

I. INTRODUCTION

Increase in global warming demands to increase the use of renewable and pollution free energy sources for an environment well suited for human and other living beings. Solar energy can be an ideal energy source which is inexhaustible, having zero carbon emission and completely free. Solar energy is natural source of light and heat. As electricity can be converted into all other form comparatively easily, photovoltaic (PV) technology, which converts solar irradiation (light energy) directly into electricity by photovoltaic effect is more popularly used. Still there are several problems are associated with PV modules such as

a) The electricity generated by PV cell is highly variable with environmental conditions.

b) Efficiency of PV cells to convert energy is very low (12-18%), (although cells over 30% have been fabricated in lab, they are not cost-effective) [1]. Due to low efficiency, it is important to control PV system in such a way to extract maximum power possible.

c) Also practically the V-P curve is highly non-linear, especially due to partial shading there are multiple local maxima on V-P curve, which makes it difficult to track maximum power point.

To get maximum power from PV system for most advantageous utilization, it is utmost important to have a control mechanism to track MPP. However among multiple local maxima, to find the global MPP,frequently usedmaximum power point tracking (MPPT) algorithms like Incremental Conductance (IC) algorithm [2] andPerturb and Observe (P&O) algorithm [3] fail to perform well. So different optimization techniques are used to find the global maximum.

For the variation in solar irradiation, temperature and loading condition, the MPPT algorithm controls the parameters of power electronic interface so that PV system has to work at MPP. Most researchers investigate new methods of MPPT algorithms. Nevertheless performance of DC-DC converters also needed to be scrutinized in different circumstances to build a PV system with an appropriate converter topology.

The presented work includes the modelling of PV system and tracking the MPP using three popular topologies of DC-DC converters i.e. Buck, Boost and Buck-Boost DC-DC converters without partial shading condition and also taking account for partial shading effect. Here Particle Swarm Optimization (PSO) technique is used to get global maximum point for different partial shading condition.

II. PV MODULE MODELLING

Here the relation between output current and voltage (I-V) of a practical PV module is given by equation (1) and the equivalent circuit for an ideal PV cell and practical PV device is given in fig. 1.

$$I = I_{PV} - I_0[\exp(\frac{V+RsI}{V_t\alpha})-1] - \frac{V+RsI}{R_P} \qquad (1)$$

Where I_{pv}= photovoltaic (PV) current, I_0 = reverse saturation current, $V_t = N_s kT/q$ = thermal voltage, k= Boltzman's constant, T= working temperature, q= charge of electron, N_S = no. of series connected cells. If array consists of Np no. of parallel cells, then $I_{pv} = I_{pv,cell}N_p$, $I_0 = I_{0,cell}$ Np. In equation (1), R_s and Rp are intrinsic series and shunt

equivalent resistances respectively. Rp is very large compared to Rs.

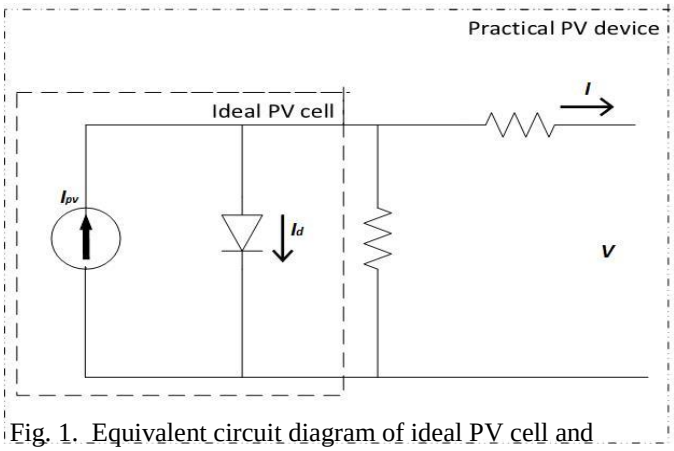

Fig. 1. Equivalent circuit diagram of ideal PV cell and practical PV device

The Bosch Solar Module designation M245 3BB has been successfully modelled from the following mathematical equations. [4]

$$I_0 = \frac{I_{SC,n} + K_I \Delta T}{\exp\left(\frac{V_{OC,n} + K_V \Delta T}{\alpha V_t}\right) - 1} \quad (2)$$

$$I_{PV} = (I_{PV,n} + K_I \Delta T)\frac{G}{G_n} \quad (3)$$

Where,
Vocn = Nominal open-circuit voltage
Imp = Output current at maximum power
Iscn= Nominal short-circuit current
Vmp= Output voltage at maximum power
Pmax_e = Maximum output power = Vmp*Imp
Kv = Temperature coefficient of voltage (%/K)
Ki = Temperature coefficient of current (%/K)
Ns = Number of cells connected in series
G = Solar irradiation
G_n = Nominal solar irradiation
ΔT = (T- 25°C)

List I: Electrical Characteristics of Bosch Solar PV Module c-Si M 60 EU30117 designation M245 3BB

Vocn= 37.7 V
Imp = 8.2 A
Iscn = 8.7 A
Vmp = 30.1 V
Pmax_e = Vmp*Imp = 245 W
Kv= - 0.32 %V/K
Ki = 0.0387 %A/K
Ns = 54
Above list gives the electrical specifications of Bosch Solar Module M2453BB [5] at STC (i.e. irradiation of 1000 W/m^2(=G_n), temperature at 25°C), which is taken as reference in this paper.

III. MAXIMUM POWER POINT TRACKING (MPPT)

(a) Without Partial Shading

Without shading effect the PV panel gets full insolation to generate electricity. Here the P-V curve has only one point where power becomes maximum as shown in fig 2(b). In the simulation here incremental conductance (IC) MPPT algorithm is used [6]. It states that at maximum power, differentiation of power w.r.t. voltage is 0 (zero).

Mathematically,

$$\frac{dP}{dV} = 0 \Rightarrow \frac{dP}{dV} + \frac{I}{V} = 0, \text{ at MPP} \quad (4)$$

$$\frac{dP}{dV} > 0 \Rightarrow \frac{dP}{dV} + \frac{I}{V} > 0, \text{ left of MPP} \quad (5)$$

$$\frac{dP}{dV} < 0 \Rightarrow \frac{dP}{dV} + \frac{I}{V} < 0, \text{ right of MPP} \quad (6)$$

The flow chart of IC algorithm is presented in fig 3. This calculate change in voltage and current and also change in current w.r.t voltage to calculate required duty cycle (D). If equation (6) is satisfied 'D' is increased if (5) is satisfied 'D' is decreased and for equation (4) no change in 'D'. Therefore, by varying duty cycle it will reach at MPP by checking the change in current value w.r.t change in voltage.

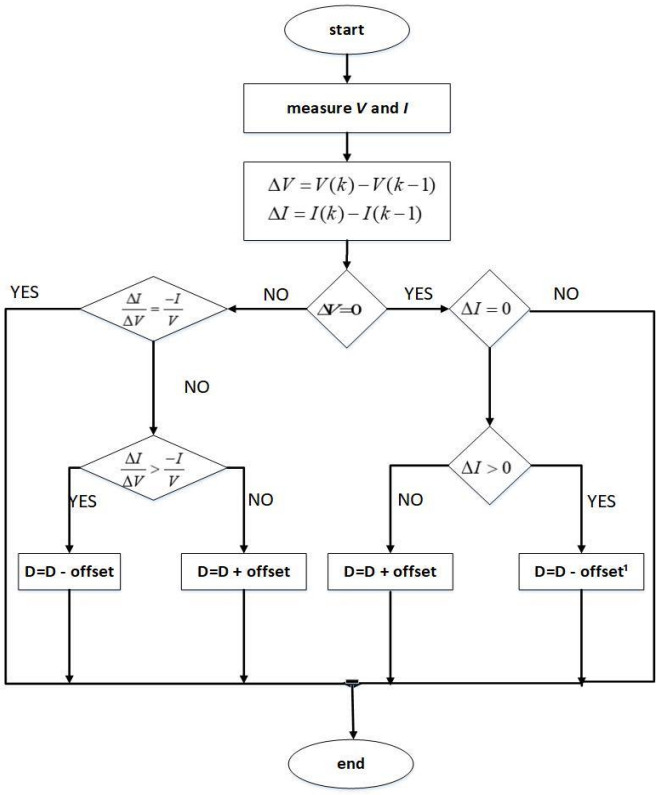

Fig. 3. Flow chart for Incremental conductance MPPT Algorithm

(b) With Partial Shading (effect of shading)

When different parts of a PV panel (shaded cells) get different irradiation than other parts of PV panel (illuminated cells), the generated current by shaded cells is less than that of illuminated cells. Due to this mismatch of current, photodiodes of shaded cells become reverse biased, due to which power loss happens in shaded cells, which in turn leads to hotspot problem.This can damage the PV module permanently[7]. To eliminate this problem, diodes are connected with PV cells in parallel as bypass diodes [8]. These bypass diodes conduct only during shading condition

so that no current can flow through shaded cells. To simulate shading effect in PV module, each group of the PV module is connected to an antiparallel diode and here three groups (connected in series) are used with different insolation given to each group.

Due to bypass diode and mismatch of current P-V characteristics of different PV cells, PV panel has multiple local maxima. Hence MPPT algorithm like IC, P&O may stuck at local MPP and fail to track global MPP. Here to track global MPP particle swarm optimization (PSO) technique [9] is used.

Steps to implement PSO:

1. Create a swarm (i.e. population) of particles (here Duty cycle 'D')uniformly distributed over 0 to 1.
2. Calculatethe objective function(here it is power 'P') for each particle (D).
3. If current position of a particle is betterthan its previous best position, according to the value of corresponding objective function (i.e. $P_{new}>P_{old}$)then update it to new position as its local best.
4. Calculate the best particle position from the total population for global best value.
5. Update the velocity of each particle:

$V_{i+1} = V_i + c_1 * U1 * (pBest - p_i) + c_2 * U2 * (gBest - p_i)$

Where

- P_i: particle's current position
- V_i: current path direction or particle velocity
- c_1: weight of the local bestinfluence
- c_2: weight of the global best influence
- *pBest*: local best position of each particle
- *gBest*: global best position of whole swarm
- *U1 and U2*: random variables

6. Update each particle's new positions:$p = p + V$
7. Go to step 2 until the below criteria is satisfied i.e. $(P_{PV,\,new} - P_{PV,\,old})/\,P_{PV,\,old} < 10^{-4}$

IV. DC-DC CONVERTERS

To maintain the operating point of PV system at MPP, we need a power electronic interface [10] between PV module and load, so that its circuit parameters can be controlled. For PV system DC-DC converters are popularly used for this purpose. The output voltage of DC-DC converter as well as current drawn from the source can be controlled, which in turn controls the input impedance of DC-DC converter by manipulating duty cycle (D). Pulse width modulation (PWM) technique [11] is used here to control duty cycle. Value of 'D' can be obtained by any MPPT algorithm.

For the PV module, both connected load and DC-DC converter (and inverter for ac loads) act as load. Thus by varying input impedance of the converter via duty cycle, slope of load line for the PV source can be manipulated to achieve MPP. Fig. 3 shows operating point of PV module, which is the intersection point between I-V characteristics and the load line (w.r.t PV system the impedance is resistive in nature as the source is dc).

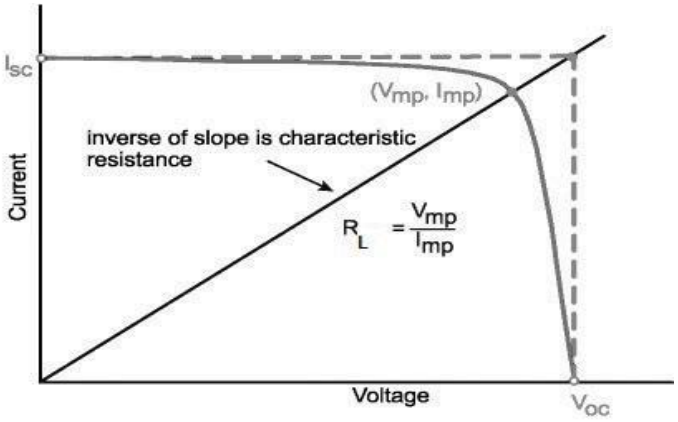

Fig. 3. Operating point for a PV system (V_{MP}, I_{MP})

Fig.4. shows circuit diagram of the Buck, Boost and Buck-Boost converters and the performance characteristics of buck, boost and buck-boost [12] converter are given in table-I

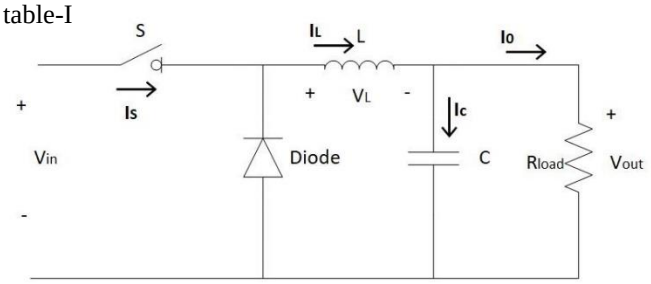

Fig. 4(a). Buck converter circuit diagram

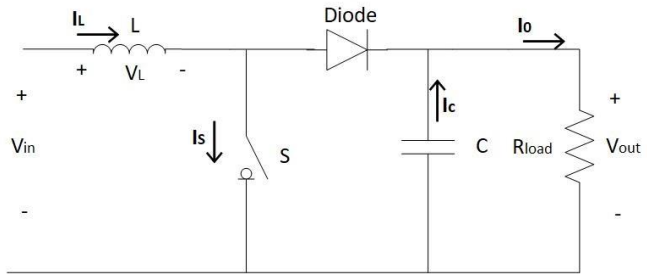

Fig. 4(b). Boost converter circuit diagram

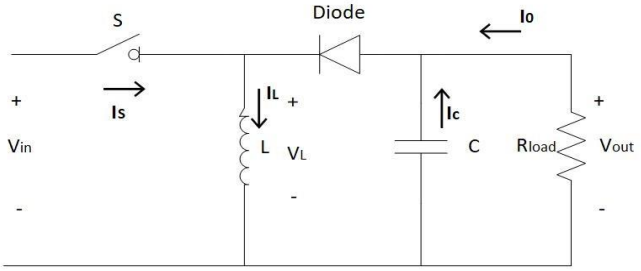

Fig. 4(c). Buck-Boost converter circuit diagram

It can be seen from the table as duty cycle varies from 0 to 1, the impedance reflected by input side of the converter (Z_{in}) also varies differently in each case. This acts as a critical factor which influences tracking ability of MPPT algorithm for any given converter topology for diverse load and atmospheric condition.

Variation of input impedance (Z_{in}) of each converter as D varies from 1 to 0 will be (a) Buck Converter : R_L to ∞ i.e. R_L to open circuit impedance, (b) Boost Converter : 0 to R_L i.e. short circuit impedance to R_L, (c) Buck-Boost

converter : 0 to ∞ i.e. any value of impedance between short circuit and open circuit impedance.

Table- I : Converters performance characteristics

Name of Converters	Gain in voltage	Gain in current	Input impedance (Z_{in})
Buck	D	1/D	$R_L\left(\frac{1}{D}\right)^2$
Boost	$\left(\frac{1}{1-D}\right)$	$(1-D)$	$R_L(1-D)^2$
Buck-Boost	$\left(\frac{D}{1-D}\right)$	$\left(\frac{1-D}{D}\right)$	$R_L\left(\frac{1-D}{D}\right)^2$

If impedance associated with MPP (Z_{MPP}) and Z_{in} have different value due to restrictions of converter topology, then any MPPT algorithm will fail to track global MPP. So for Buck converter if Z_{MPP} is less than R_L, then Z_{in} can never achieve the value of Z_{MPP} and MPPT algorithm will fail to track MPP, for Boost converter if Z_{MPP} is more than R_L, then MPPT algorithm will fail, but for Buck-Boost converter, as Z_{in} can be any value from 0 to ∞, for any load tracking efficiency only depends on MPPT algorithm.

V. Simulation and Results

To show the ability of tracking MPP, here 3.95 KW (~4KW) solar PV array is taken, where 4 modules are connected in parallel and 4 are in series. Each module can provide maximum power 246.82 W at STC. All simulations are done in MATLAB R2016a.

(a) Without Partial Shading

Simulation has been done for three atmospheric condition (i) 500W/m^2 irradiation and 25^{o}C temperature (ii) 800W/m^2 irradiation and 30^{o}C temperature and (iii) 200W/m^2 irradiation and 20^{o}C temperature, for 1st 10 sec, 5 sec, 5 sec respectively i.e. total simulation time is 20 sec.

Table- II : Required operating point parameters for different environmental condition

Sl No.	Atmospheric Condition Irr (W/m^2) T (^{o}C)	P_{max} (KW)	V_{MPP} (V)	I_{MPP} (A)	Z_{MPP} (Ω)= V_{MPP}/ I_{MPP}
1.	Irr=800, T=30	3.119	118.2	26.39	4.478
2.	Irr=500, T=25	2.002	122.7	16.32	7.51
3.	Irr=200, T=20	0.812	122.5	6.583	18.6

Table II shows the impedance value corresponds to MPP from the simulation results with different solar irradiation (I_{rr}) and temperature (T). From simulation it is quite clear that, Z_{MPP} value decrease with increase in irradiation. For domestic load at 220 V ac, heavy load (10.75 KW i.e. 4.5 Ω), medium load (4 KW i.e. 12.1, 1KW i.e. 48.4 Ω) and light load (400W i.e. 121 Ω) are taken for simulation.

The extra power demand of load can be supplied by battery bank. Here it can be observed for variation in irradiation from 200 W/m^2 to 800 W/m^2, Z_{MPP} varies from 4.67 Ω to 18.6 Ω

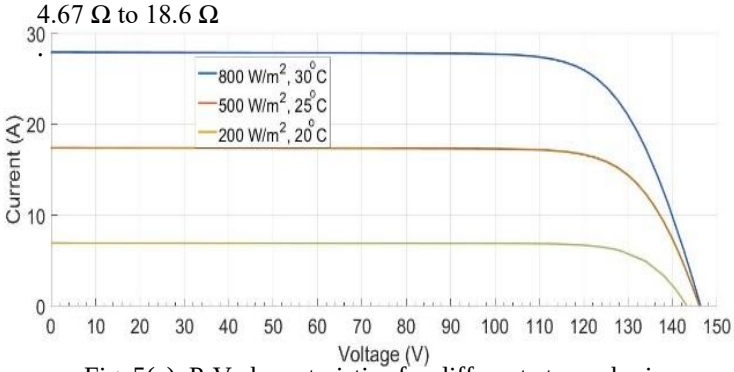

Fig. 5(a). P-V characteristics for different atmospheric condition

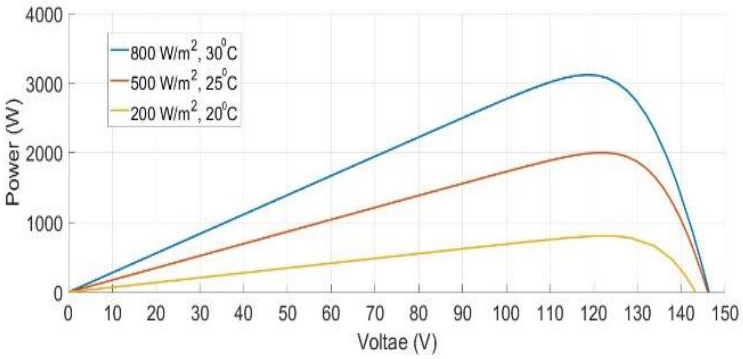

Fig. 5(b). I-V characteristics for different atmospheric condition

As shown in result fig.6, Buck converter tracks properly when load impedance seen by the converter is less than Z_{MPP} i.e. for only very heavy loads (for 4.5 Ω, P=) and for low irradiation level, but for domestic loads it will happen very less time duration in a day. Because generally peak load happens during mid-day when irradiance is very high. So most of the cases it may fail to track MPP.

Boost converter tracks MPP properly when load impedance seen by the converter is more than Z_{MPP} i.e. except for only very heavy loads at low irradiation level. But for high irradiation due to the value of Z_{MPP} is low, at peak load period boost converter may track properly as it happens around mid-day. For medium and light load, it generally can track MPP properly (as sown in fig. 7)

As Z_{in} of Buck-Boost converter can vary from 0 to ∞, so it can track MPP for all values of load impedance and for any irradiation value greater than the threshold value (from fig.8)

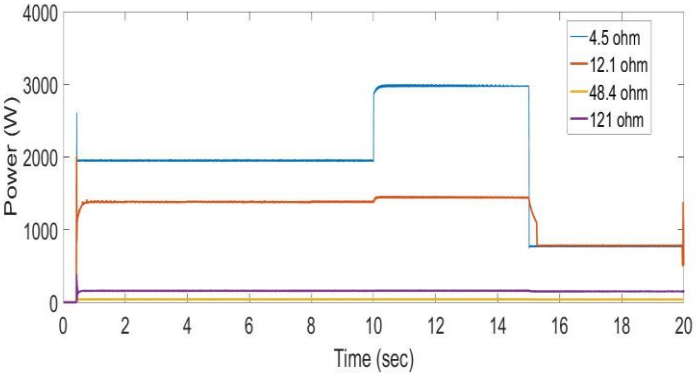

Fig. 6. Tracking of MPP for Buck converter for load resistance 4.5Ω, 12.1Ω, 48.4Ω, 121Ω

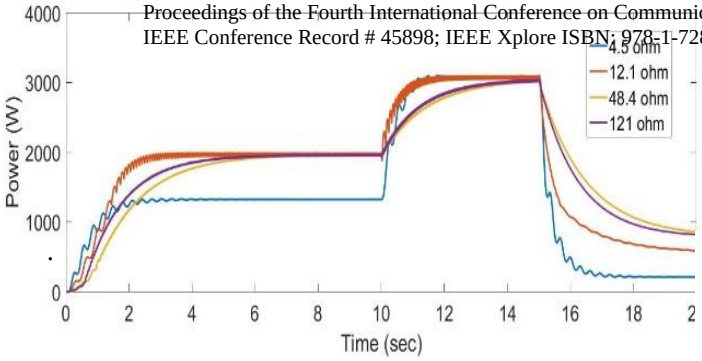

Fig. 7. Tracking of MPP for Boost converter for load resistance 4.5Ω, 12.1Ω, 48.4Ω, 121Ω

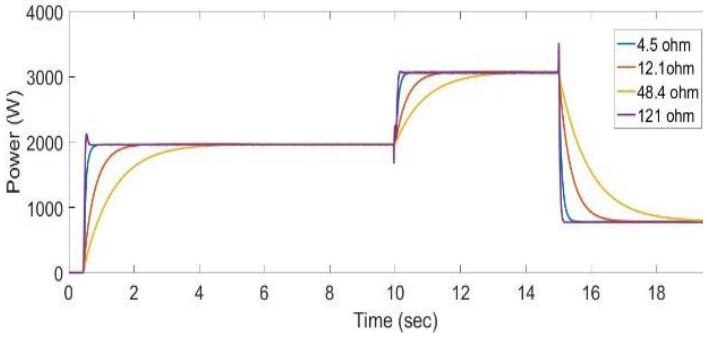

Fig. 8. Tracking of MPP for Buck-Boost converter for load resistance 4.5Ω, 12.1Ω, 48.4Ω, 121Ω

Table III: Output Power produced by different converters without partial shading

Sl. No.	Atmospheric Condition Irr (W/m^2) T (^{o}C)	Load Resistance (in Ω)	Power (KW) produced by PV system (in KW) (for different converters)		
			Buck	Boost	Buck-Boost
1	Irr = 500, T=25	4.5	1.968	1.323	1.97
		12.1	1.393	1.945	1.975
		48.4	0.156	1.973	1.972
		121	0.0404	1.99	1.98
2	Irr = 800, T=30	4.5	3.001	3.044	3.072
		12.1	1.447	3.094	3.078
		48.4	0.157	3.039	3.075
		121	0.041	3.065	3.082
3	Irr = 200, T=20	4.5	793.9	210.7	0.782
		12.1	789.4	589.7	0.797
		48.4	148.5	819.3	0.798
		121	0.038	857.2	0.8

(b) With Partial Shading

Here two partial shading conditions are taken for simulation. All these values are given in below table. After simulation of PV modules also Z_{MPP} values are also given for respective shading condition. Among the four series connected PV modules we provide 3 different irradiation to simulate partial shading condition having the maximum I_{rr} = 800 W/m^2. Here two shading conditions are simulated each for 10 sec.

When partial shading is taken into consideration, for a definite weather condition, Z_{MPP} can vary very widely according to the shading. So even if at the time of peak load sufficient irradiation is available for partial shading, boost converter may not track MPP.

In previous case (without partial shading) for I_{rr}= 800 W/m^2, boost converter tracks MPP properly. But due to different partial shading scenario as presented here Z_{MPP} varies, so boost converter also fails to track MPP for maximum available I_{rr} = 800 W/m^2 and T= 30^{o}C. Similarly for the same reason sometimes buck converter can also track MPP accurately for high irradiation value as Z_{MPP} vary widely for same maximum irradiation available to PV cells.

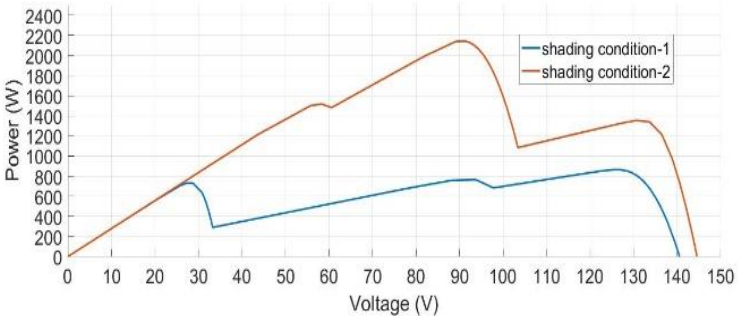

Fig. 8(a). P-V curve for partial shading condition

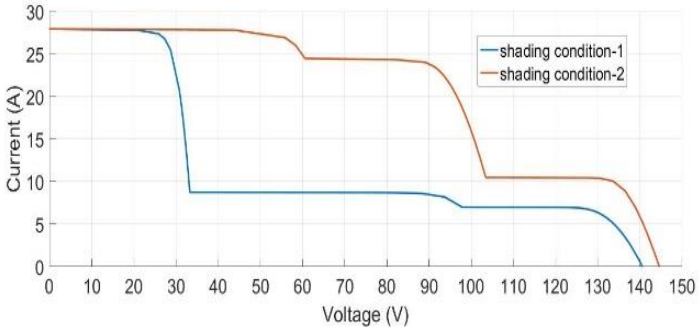

Fig. 8(b). I-V curve for partial shading condition

Table IV: Required operating point parameters for different shading conditions

Sl No.	Series connected Module No.	Irr values (W/m^2)	P_{MPP} (KW)	V_{MPP} (V)	I_{MPP} (A)	Z_{MPP} (Ω)
1. (0 to 10 sec)	Module 1 & 2	250	0.8646	125.6	6.88	18.24
	Module 3	800				
	Module 4	200				
2. (10 to 20 sec)	Module 1 & 2	800	2.143	91.34	23.46	3.893
	Module 3	700				
	Module 4	300				

As from result it is clear that buck converter failed to track MPP in light load condition but successful for high load for first shading condition. For second shading condition it failed to track MPP. Boost converter works

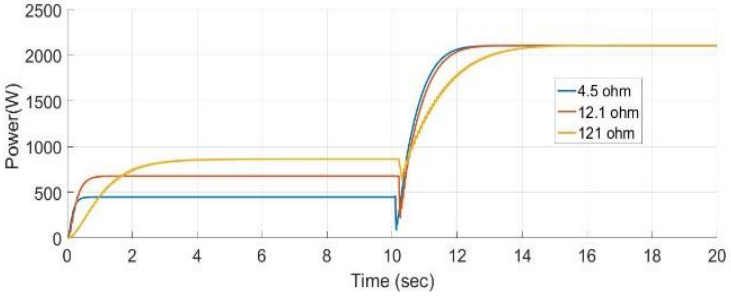

Fig. 8.Tracking of MPP for Buck converter for load resistance 4.5Ω, 12.1Ω, 121Ω with partial shading

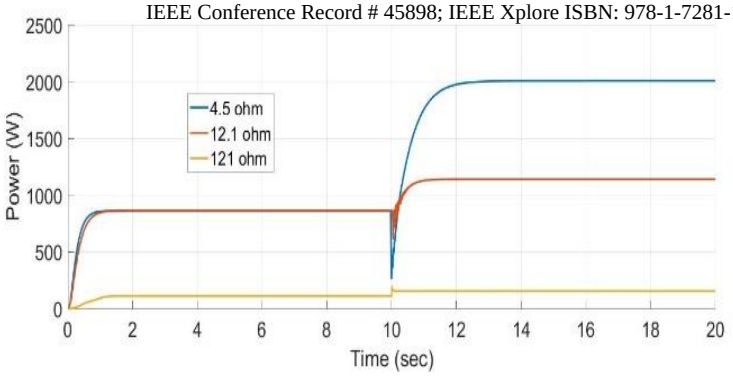

Fig. 9.Tracking of MPP for Boost converter for load resistance 4.5Ω, 12.1Ω, 121Ω with partial shading

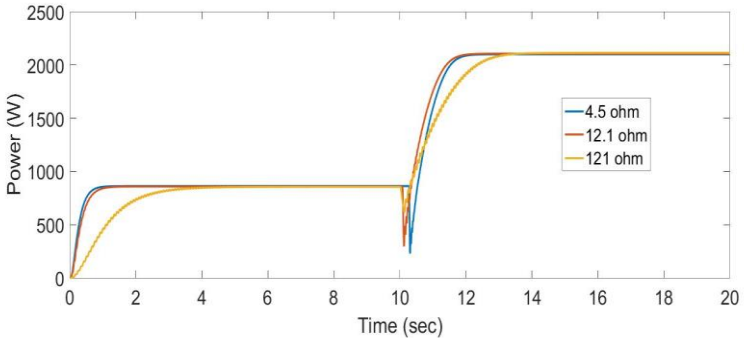

Fig. 10.Tracking of MPP for Buck-Boost converter for loadresistance 4.5Ω, 12.1Ω, 121Ω with partial shading

Table V: Power produced by converters in partial shading

Name of Conver-ters	Power (KW) produced by PV system (for different load)					
	Shading condition-1			Shading condition-2		
	Load Resistance			Load Resistance		
	4.5Ω	12.1Ω	121 Ω	4.5Ω	12.1Ω	121 Ω
Buck	0.854	0.858	0.110	1.97	1.31	0.155
Boost	0.650	0.658	0.861	2.12	2.122	2.123
Buck-Boost	0.860	0.859	0.857	2.12	2.125	2.132

successfully for second shading condition but for first shading condition it failed. But in each case Buck-Boost converter tracks MPP successfully as sown in table-V.

VI. CONCLUSION

If partial shading is ignored, boost converter can track properly for most of the time. But for shading condition as the value of Z_{MPP} is totally unexpected (for a given weather condition), neither Boost nor Buck converter can able to track MPP all the time as each has its own restriction to have required Z_{in} value for all loading conditions. This limitation can be overcome by buck-boost converter. As during lower irradiation and temperature which corresponds to higher value of Z_{MPP}, the converter works in buck mode (for D = 0 to 0.5) and during higher irradiation and temperature which corresponds to lower value of Z_{MPP}, the converter works in boost mode (for D = 0.5 to 1) to adjust the value of Z_{in} of the work near Z_{MPP}. Hence the ability to track MPP gets improved by buck-boost Converter.

Further work in this area may use other converter topologies and also with inverter topologies to show how compatible it is with MPPT algorithm and various loads i.e. industrial loads, medical equipment etc. for less size, cost and reduced ripples in output voltage and current.

ABSTRACT— In this paper fault detection and classification scheme using K nearest neighbor (KNN) has been presented for AC/DC transmission line with DFIG (doubly fed induction generator). The power system model consist of 1000 MW synchronous generator, 510 MW wind far, three phase transmission line of 500 kV and 30km length and HVDC line of 1000 MW. The model has been implemented with the corresponding parameters in MATLAB and simulated for different scenario. The raw current and voltage acquired for the sensors have been processed by performing discrete wavelet transform to the derive the discriminatory attributes with maximum disparity between the healthy and faulty cases. Following feature extraction, the required tasks of fault detection and classification scheme in AC and HVDC lines have been achieved using KNN. Further, the efficacy of the proposed KNN based scheme has been validated for varying fault scenarios pertaining to wide variation in fault resistance, inception angle of fault and fault location. For all tested cases, the proposed scheme is able to achieve a fault detection and classification accuracy of 100%.

Keywords- Doubly Fed Induction Generator Windfarm, HVDC, K-nearest neighbor classifier, Discrete Wavelet Transform Fault Detection, Fault Classification

I. INTRODUCTION

In the present era, countries all over the world are trying to enhance their economic conditions by improving industry which demands more energy. It motivates the power system to improve by combining both conventional source of energy and renewable source of Energy. Among renewable sources, wind energy is aggrandized because of its all day wind availability. But most of the wind farms are developed in offshore area. So it is difficult to route wind power to mainland grid efficiently. As HVDC transmission line is more efficient of transferring bulk amount power over long distances due to continuous technical improvement in power electronics [1]. However, the integration of a DFIG Based Windfarm into AC/HVDC system will influence the fault level and network topologies of the power system. These fault levels are intermittent in nature and existing protection schemes may fail to operate because of their pre-set condition. Therefore, the design and selection of a proper protection scheme is essential for reliable control and operation of renewable integrated power systems. Reliability of AC/HVDC system increase by addition of DFIG based windfarm which is possible by improvement of the propensity of its protection scheme. However, the inclusion of windfarm affects the existing protection schemes of AC/HVDC System because of variable speed of wind turbine and its different power rating and others threshold parameters which make the system protection task quite difficult [3]. In AC transmission line two types of fault can occur i.e. shunt fault and series fault. Further, shunt faults are differentiated into asymmetrical fault (LG, LL, LLG) and symmetrical fault (LLL, LLLG). In HVDC line, the DC pole-to-Ground fault and pole-to-pole fault on dc-link can occur. The successful and reliable operation of any transmission network is closely related to the accuracy of the associated fault detection and classification scheme. An accurate scheme minimizes the damage post fault and also helps in attaining the pre-fault condition at the earliest.

Currently, distance relays are used as primary protection for AC lines. In addition, other dominant schemes are based on rate of change of voltage and travelling wave, with under-voltage protection and current differential protection engaged for backup protection schemes. The notable schemes for fault detection/ classification in HVDC lines can be found in [4-9]. A directional pilot protection based on travelling wave has been reported in [4]. Related to fault transient voltage, a non unit dc line protection Approach is published in [5]. In [6], fault detection using power frequency current has been reported. In [7], linear distribution of low frequency voltage signals is utilized to implement distance protection. The unbalance in the current magnitude has been used to incorporate differential protection on the distributed-parameter transmission-line model is presented in [8]. For fault identification and fault pole selection criterion, in this paper the compensated current of the common mode and the differential mode are used. Earlier applications of KNN in power system protection include development of a detection and classification module in [9]. However all the above mentioned protection scheme developed for HVDC line did not consider the impact of integration of a DFIG based wind farm into HVDC system.

The global search capability of heuristic dynamic programming has been exploited for developing an adaptive modulation approach for AC/DC power system in [10]. The

fast power routing capability of HVDC has been analyzed in [11], by interfacing a DFIG wind farm with LCC-HVDC system. Some new protection scheme also developed for multi terminal HVDC connected offshore Windfarm [13]. For microgrid connection extreme learning machine is also developed in [15]

The KNN based scheme for AC/DC network [12, 14] uses the standard deviation of approximate coefficients of current and voltage signals measured at relaying bus (Bus-2). The scheme has been extensive validated for different faults in both the AC and DC line.

II. DFIG WIND FARM BASED AC/HVDC SYSTEM UNDER STUDY

The single line diagram of benchmark power system used in this paper is shown in Fig.1. The model comprises of two sources i.e. a 600 MW wind farm and a 1000 MW synchronous generator, integrated with HVDC transmission line, controlled by two thyristor based converters [10]. A monopolar HVDC transmission line with the earth as a return path which connects two AC systems of different frequencies is considered. The power generated from the sources are transmitted to the grid via a HVDC line of 300 km. Rectifier and inverter are connected on both side of the HVDC link. The raw time domain current and voltage signals acquired from the sensors at the relaying busses are utilized for the development of the fault detection and classification modules.

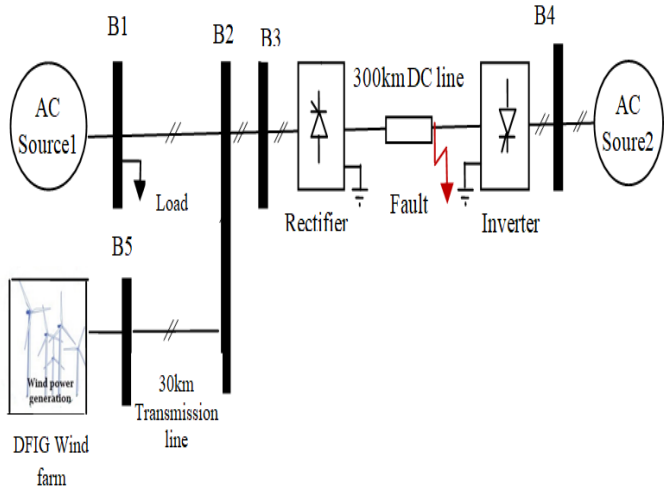

Fig-1 single line diagram of AC/HVDC transmission line with DFIG Windfarm

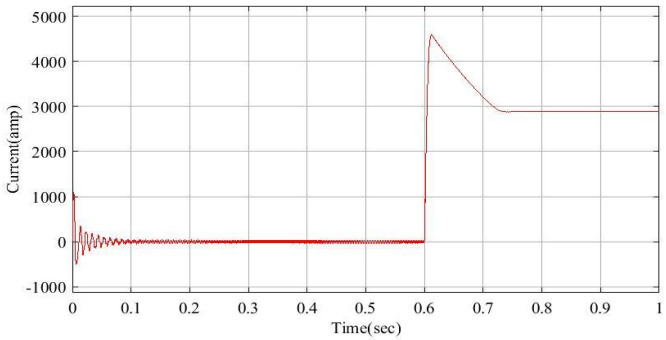
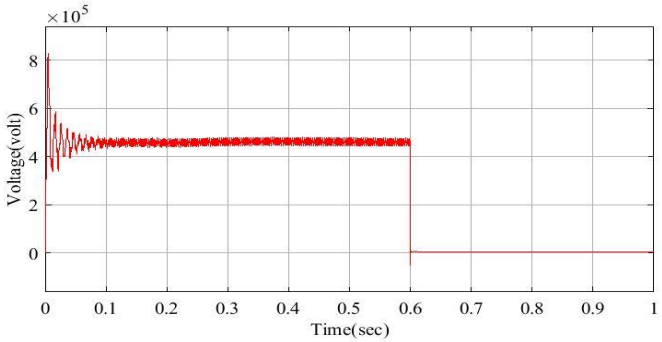
III. Analysis of Fault

To develop an accurate protection scheme for the HVDC system, fault analysis in terms of variation in the voltage and current profile post-fault has been carried out. In order to depict DC fault, a pole to ground fault has been simulated at 150 km from the relaying point and corresponding voltage and current waveforms are depicted in Fig.2.

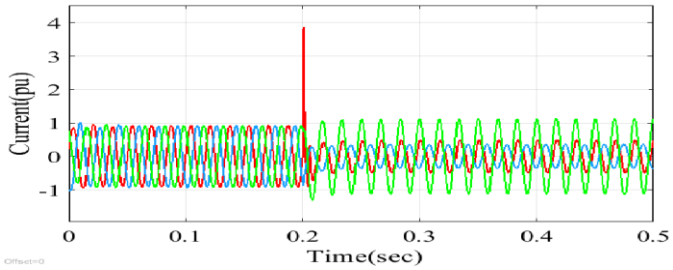


a

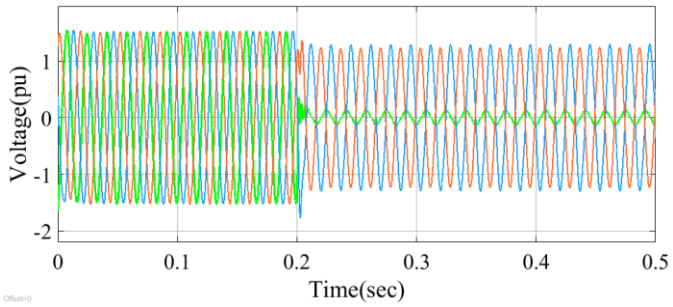


b

Fig-2 (a) Current (b) Voltage in HVDC transmission line during a pole to ground fault at 0.6 sec.



a



b

Fig-3 (a) Current (b) Voltage of Bus B2 during a AG fault in AC transmission line at 0.2 sec.

Similarly, in the AC a single line to ground fault section between Bus-2 and Bus- 5 has been simulated at 10 km with inception angle of fault(Φ_i) = 0 ° and resistance of fault (R_f)=

20 Ω from relaying point. In fig-3, the corresponding current and voltage waveforms are depicted.

From Fig 2 and Fig. 3, it is confirmed that the magnitude of current signals increases while there is decrement in the voltage signals in both the fault conditions (i.e. fault in HVDC and AC LINES). Thus current and voltage signals are the best indicative of fault conditions.

IV. KNN BASED FAULT DETECTOR AND FAULT CLASSIFIER

A. Pre-processing and Feature Extraction Process

Pre-processing of signals and extraction of discriminatory attributes is useful operation to obtain the suitable feature which can represent the present condition of the line effectively. The time domain instantaneous current and voltage signals are obtained at bus-2 by simulating the power system model under different fault scenarios. Following this, in the proposed scheme, the approximate coefficients are derived from the raw current and voltage signals collected from bus-2 is processed through Discrete wavelet transform (DWT). The attraction of DWT toward protection schemes is due to its both time and frequency domain Delineation. As compared to the more widely used DFT approach, DWT provides a better description since it is not just a single transform, but rather a set of transforms, each with a different set of wavelet basis functions. In this protection scheme, for feature extraction from instantaneous values of voltage and currents and voltages signal DWT technique is utilized. After obtaining the approximate coefficients, the standard deviation of approximate cofficients are then estimated which is fed as inputs to present KNN based fault detector and classifier.

Consider different fault scenarios, six numbers of input features are obtained for the presented KNN based fault protector. Features are

1- Standard deviation of approximate coefficient of voltage signal (σV_a, σV_b, σV_c) of phases a, b and c at Bus -2.
2- Standard deviation of approximate coefficient of current signal (σI_a, σI_b, σI_c) of phases a, b and c at Bus- 2.
3- The detailed description of variation in fault parameters considered in the proposed scheme is deal in Table 1.

Table-I

Fault Simulation Parameter

Simulation Parameters	Parameters Details	Number
Types of feature	Voltage, Current	2
Numbers of Features	Va,Vb,Vc,Ia,Ib,Ic	6
Types of fault	LG,LL,LLG,LLL, DC Pole to ground	12
Fault Resistance (Ω)	0,15,30,50	4
Inception Angles(Degree)	0°,90°	2
Number of Sections	S1,S2,S3	3
Measurement Point	B2	1

3. KNN BASED CLASSIFIER PROTECTION SCHEME

As mentioned in section 1, the inclusion of DFIG windfarm in the HVDC system may affect the conventional protection schemes and demands a new protection strategy which protects both AC and HVDC Transmission Line. For this purpose, KNN based protection method has been developed in the present work. The flowchart detailing the different stages of the algorithm is depicted in Fig. 4.

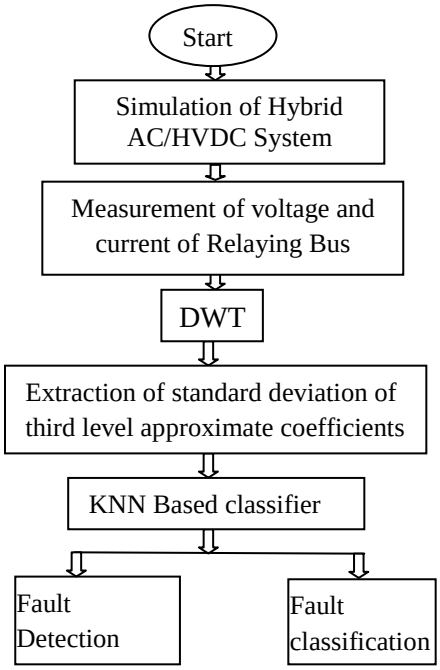


Fig-4 Flowchart of proposed scheme

K-Nearest Neighbour is a supervised learning based classifier, where K is the numbers of classes nearest neighbour to a test case. The value of k varies between 3 to10. The KNN classifier predicts the class of test point. For the protection of the power system model under study, a total of two KNN have been developed. The first KNN will identify the internal fault (fault in HVDC line), external fault (fault in three phase line) and no fault case. Thus for fault detection module has three target values i.e. 1, 2 and 0 representing fault in HVDC line, three phase line and no fault condition. Following detection of fault, KNN-2 classifies the type of faults in AC line. For three phase line the total possible faults are 11 (a-g, b-g, c-g, a-b, b-c, c-a, a-b-g, b-c-g, c-a-g, a-b-c-g). Thus, in case of classification task there are total eleven outputs representing each type of shunt faults in three phase lines. Thus KNN-1 supplies the details idea about the presence of fault and also differentiates between AC and DC faults while KNN-2 classifies shunt faults in AC line.

4. PERFORMANCE EVALUTION OF PROPOSED SCHEME

Following the improvement of the KNN based fault protection technique, testing of proposed KNN is accomplished for a variety of fault conditions to analyze the relay performance. The network was tested using different shunt faults in AC lines and DC faults in DC line with varying fault locations, resistance of fault and inception angles of fault.

A. *Evaluation for varying fault locations*

The appropriateness of the scheme has been evaluated by conducting extensive simulations on both the AC and HVDC line. The exhibition of the suggested scheme for the tested cses are depicted in Table II.

Table II

Test results for different fault detection with varying fault types in AC line

Fault type		Fault Location	Outputs of KNN1 based fault detector/classifier
Fault in AC line	a-g	5 km away from relaying point in AC line	2
	b-g		2
	c-g		2
	a-b-g		2
	b-c-g		2
	a-c-g		2
	a-b		2
	b-c		2
	a-b-c-g		2
Fault in DC line	p-g	150 km away from relay point HVDC line	1
	p-g		1
	p-g		1
	p-g		1
No fault			0

From the test results illustrated in Table II, it is confirmed that the suggested scheme detects AC and DC faults correctly with 100% accuracy.

B. *Evaluation for varying fault locations*

To validate the robustness of the proposed KNN-based detector/classifier, faults of varying types have been simulated at different locations of both the AC and DC lines, with different fault parameters. The different scenarios pertaining to fault resistance of 50 Ω and inception angle of 0°) are detailed in Table III. From the table, it is clear that the proposed network gives accurate results and perfectly identifies the fault. Further, the response of the KNN scheme also tested for fault cases (pole to ground fault) occurring at HVDC line at different locations form the relaying point. The test results detailed in the Table IV confirms that the proposed KNN based detector correctly detects the fault at different locations. Therefore, the proposed KNN based protection strategy is insensitive to the changes in the location of faults.

Table III

Test results for several shunt faults with varying fault locations (L_a) in AC line

Fault location (km)	Fault type	Outputs of KNN2 based fault detector/classifier
1	a-g	1
3	b-g	2
5	c-g	3
10	a-b-g	4
12	b-c-g	5
16	a-c-g	6
22	a-b	7
24	b-c	8
26	a-b-c	9
29	a-b-c-g	10

C. *Evaluation for varying fault resistance*

Any reliable protection scheme needs to validate for different resistance of shunt faults. Achieving robustness against fault variation is a challenge. In this context, the proposed KNN based fault detector and classifier has been gauged for fault resistance varying from 0 Ω to 50 Ω and inception angle of fault varying from 0˚ to 360˚. Results of some test cases are stated in Table III. Fault cases are simulated at fixed fault location (La=15km). From the test clearly that the proposed scheme is immune to fault variation and gives accurate result and perfectly identifies the faulty phases.

Table IV

Test results for DC faults with varying fault locations (L_a) in HVDC line

Fault location (km)	Fault type	Outputs of KNN based fault detector/classifier
1	P_1	1
50	P_1	1
90	P_1	1
150	P_1	1
200	P_1	1

Table V

Test Results for Different Shunt faults with several fault inception angle (Φ=0°) and fault resistance (Ω) at L_a = 15 Km

Fault resistances (Ω)	Inception angle of fault	Type of fault	Outputs of KNN based fault detector/classifier
0.01	0˚	a-g	1
		b-g	2
		c-g	3
50	90˚	a-b-g	4
		b-c-g	5
		a-c-g	6
100	180˚	a-b	7
		b-c	8
		a-b-c	9

.

5. CONCLUSION

In this paper, the feature space to classification output mapping capability of KNN classifier has been utilized to develop a accurate and reliable fault protector (detector and classifier) for AC/DC transmission line. The proposed scheme is able to detect faults of varying types in both the AC and DC sections of the line. Further, the proposed scheme also identify the line (AC or DC) in which fault has occurred. The scheme was extensively validated for faults occurring at various locations with different fault resistance and inception angles .The test results depict that the proposed ANN based protection technique is accurate in detecting and classifying all types of faults in both AC as well as HVDC line.

***Abstract*— Now-a-days, a lot of clinical data are used for utilizing the intellectual advancements of clinical basis leadership. In the area of health sector, the need for improving the nature of patient's lives and decreasing the expenses as well as measures the work engaged with their everyday medicinal services condition is very important. An Electronic health record (EHRs) is a data record set which resides patient diagnostic lab records with different parameters, physician/consultants' histories, also in the accounts of different sections of the hospital. Earlier, in the case of heart disease prediction, we have attained a bulk unorganized set of data since the time series of the EHR system. By dividing and taking out these time-sensitive EHRs information, we can distinguish/perceive the aggregate factors among all the obtained set of clinical data for our research purpose. Despite the fact that it is troublesome undertaking to utilize the current EHR information legitimately, on the grounds that they might be repetitive, not in a standardized structure, and some of the data missed/blanked. Consequently, this paper has been proposed a viable and solid design of the Dynamic LSTM model for coronary illness forecast. The main aim of doing this paper has been used to predict heart sickness utilizing an alternate information mining arrangement system. In this paper, we have designed a Dynamic LSTM using classification techniques and generated a training and test model which produce a more accurate result as compare to previously LSTM risk algorithm. One of the advantages of the proposed algorithm is it can work on dynamic dataset records and capable to produce a more efficient classified result for heart disease prediction.**

Keywords—Electronic health record, Deep learning, Dynamic LSTM

I. INTRODUCTION

Heart disease/ Coronary illness is a popular term that implies that the heart isn't used regularly. Children can be brought into the world with heart-related problems. This is called inherent heart disorder [1]. Many of the heart/coronary related diseases can be acquired. Coronary illness, which incorporates ischemic coronary illness, coronary heart disappointment and different sicknesses of the heart, is the main source of all around. It represents the greater part of all s because of cardiovascular illness.

Coronary illness can cause angina (chest torment), heart assaults (myocardial localized necrosis) and unexpected heart failure. A heart assault is typically the principal indication of coronary illness. A Heart disease ordered into three classes:

- Coronary artery disease – This disease occurs when veins are not passing on blood properly in the heart.
- Congestive heart failure – This disease occurs when a heart is not pumping properly.
- Bad heart rhythms – This is a very rare heart disease. This disease defines the electronic pulse like the movement of the heart.

CVDs are the number 1 explanation behind at around the globe. A bigger number of individuals die every year from CVDs than any other reason. A normal 17.9 million people passed on from CVDs in 2016, addressing 31% of each and every overall demise. Of these deaths, 85% is a result of heart strike and stroke. Out of the 17 million startling misfortunes (more youthful than 70) on account of non-transmittable diseases in 2015, 82% are in low-and focus pay countries, and 37% are realized by CVDs. Most cardiovascular ailments can be evaded by keeping an eye on social danger factors, for instance, tobacco use, bothersome eating routine and weight, physical inaction and destructive use of alcohol using people wide philosophies [5][6].

Peoples/Individuals with a cardiovascular ailment or who are at high cardiovascular hazard (because of the nearness of at least one hazard factors, for example, hypertension, diabetes, hyperlipidemia or officially settled malady) need early identification and the board utilizing directing and prescriptions, as fitting. Coronary illness and stroke together added to 28·1% of all-out deaths in India year 2016 — contrasted and 15·2% in 1990. Coronary illness added 17·8% of all-out deaths and stroke contributed 7·1% of complete deaths. The extent of deaths and incapacity from coronary illness was essentially higher in men than in ladies, however, was comparable among people for stroke. Death due to cardiovascular diseases increases from 13 lakh in 1990 to 28 lakhs in the year 2016.

So, diagnoses & prediction of heart disease earlier is compulsory and treatments for individuals/peoples who are probably going to have a coronary illness and help them have a longer life.

A favored technique to determine the issues of precise finding and the conveyance of focused treatments is the continuous execution of complete physical assessments [4]. Be that as it may, total and continuous physical assessments would prompt information over-burden. So, in this paper, we design a novel approach namely Dynamic LSTM model with classification techniques. The main purpose of this algorithm to produce accurate results for finding out heart disease prediction.

A Data mining alludes to extricating or mining information from a lot of information. As it were, Data mining is the science, workmanship, and innovation of finding huge and complex assemblages of information so as to find helpful examples. To accomplish an objective, the proposed calculation deals with information mining characterization strategies. Characterization is an established issue in AI and information mining [1][23]. In other words, the order issue is worried about producing a portrayal or a model for each class from the given informational index. "Characterization" is a standout amongst the most vital information mining strategies. It is utilized to foresee bunch/class enrollment for information cases.

The remainder of the paper is broken down into six sections. Section II gives a review of the previous work in this area and its different aspects. The Background and related work covered in this section. Section III identifies the problems with the existing approach and Section IV presents proposed work. The experimental results define in Section V. This paper concludes with Section VI, which contains a summary and future work for further research.

II. BACKGROUND AND RELATED WORK

Ji.Zhang et.al [1]design a bagging based troupe display is used to anticipate the patient's condition one day ahead of time for creating the last suggestion. A blend of three classifiers artificial neural network, least squares-support vector machine, and naïve Bayes are utilized to develop a group structure. This proposed framework is a promising device for examining time arrangement medicinal information and giving precise and solid suggestions to patients experiencing endless heart infections.

Fen Miao et.al [2] proposed an improved RSF (iRSF) with a novel split standard and a halting basis for distinguishing progressively exact indicators that can isolate survivors and non-survivors and, in this way, improve segregation capacity. Initial, a weighted log-rank test was utilized to part the hub and can be connected to non-relative risk circumstances to improve the test for a scope of elective theories.

Afef Mdhaffar et.al [4] presents a novel wellbeing examination approach for heart failure prediction/ expectation. It depends on the utilization of complex occasion preparing (CEP) innovation, joined with measurable methodologies. A CEP motor procedure approaching wellbeing information by executing edge-based investigation rules. Rather than having to physically set up limits, our novel factual calculation naturally figures and updates edges as indicated by recorded chronicled information.

Chrysa et.al [5] The heart phonocardiogram is breaking down by utilizing Ensemble Empirical Mode Decomposition (EEMD) joined with kurtosis highlights to find the proximity of S1, S2 and concentrate them from the recorded information, framing proposed HSS conspire, to be specific HSS-EEMD/K.

Bo Jin et.al [3] proposes a successful and strong design for heart disease prediction. The primary commitment of paper is to anticipate heart failure(attack) by utilizing a neural network (i.e., to foresee the likelihood of cardiovascular sickness dependent on patient's electronic restorative data). Specifically, they utilized one-hot encoding and word vectors to demonstrate the analysis occasions and anticipated heart disappointment occasions utilizing the fundamental standards of a long short-term memory model.

Assessments dependent on a genuine informational collection show the promising utility and adequacy of the proposed engineering in the expectation of the danger of heart disappointment.

III. PROBLEMS WITH THE EXISTING APPROACH

Coronary illness or CVDs are the number 1 reason for at around the world for death. A bigger number of people die every year from CVDs than from some other reason.

In our proposed approach we have increased the accuracy and efficiency by replacing the static LSTM which was used in the traditional approaches by dynamic LSTM. Our results clearly depict that the dynamic LSTM have higher accuracy than static LSTM. A few investigations/studies in the writing have been led utilizing outfit approaches, with some achievement, in the medicinal area [1][4]. However, none of them drew closer or tackled the issue that we manage in our examination to give exact suggestions to coronary illness persons to take or cure further medical test in for coming days.

IV. PROPOSED ALGORITHM

We contrast to the above-mentioned problems with the existing approach, we develop a classification technique with dynamic LSTM Model framework for heart disease prediction earlier stage. Our proposed model working on the basic LSTM model [3].
To handle Electronic health records data, we proposed a new algorithm namely Dynamic LSTM model (Long Short-

Term Memory Model). In our algorithm we use a training data set and test data set. This algorithm gives better result compare to the above mention algorithms [1]. We are shown details of the algorithm in this section.

We utilize Classification methods of data mining. Classification is the handling of finding a lot of models (or capacities) those define and recognize information classes. A classification technique has two types of data set namely training and test data. First, one is used to implement a model or classifier and the second dataset is used for testing of implemented model. There are some popular classification methods like:

A. CART :

CART represents Classification and Regression Trees. CART is one of the famous techniques for structure choice tree in the AI people group [13][28]. It was created by [Breiman and his team. At 1984] and is portrayed by the way that it develops binary trees, specifically every interior hub/node must be precisely 2 active edges, every one of which presently endeavors to part in a similar way as the root hub/node. The parts are chosen to utilize the Gini index.

B. Bayesian classifier:

A Bayesian classifier is a measurable classifier. This classifier is used for prediction with probabilities.

C. Fuzzy logic:

Fuzzy logic is a set of the rule-based classification system. It improves all the problems of crisp and rule-based classifiers.

D. Association rule mining :

This is an imperative & active field of data mining researcher. One strategy for association rule mining, called associative classification/characterization, comprises of two stages. In the primary advance, affiliation guidelines are produced utilizing an adjusted form of the standard affiliation rule mining calculation known as A prior. The second step builds a classifier dependent on the affiliation rules found.

E. LSTM Model:

Hochreiter and his team design an LSTM model demonstration. It's a unique RNN method. To fulfill a requirement of long-term memory, the RNN capture of condition/situation of the current concealed layer. The result of the calculation comes in the form of an exponential increment and it shows time, cost of a model. That is a reason RNN is not applicable for long term memory calculations.

F. Dynamic LSTM Model:

A collaborative approach is an effective model, which combines all the multiple parent classifiers to solve a problem and increasing performance of every base classifiers. The working principle is taken from LSTM model and deep learning. There are two different datasets namely training data set and test data set. This model is also in working condition if data varies [3].

V. RESULT ANALYSIS

We used a real-life data collection "HEART-DISEASE dataset" occupied from UCI repository. This data composed from four following different locations: Cardiology University Hospital. The characteristics of the multivariate attributes of the dataset are shown in Table 1.

TABLE I. MULTIVARIATE ATTRIBUTES OF DATASET

Attribute name	Attribute type
Age	Numeric
Sex	Binary
Cp	Numeric
Trestbps	Numeric
Chol	Numeric
Fbs	Binary
Restecg	Binary
Thalach	Numeric
Exang	Numeric
Oldpeak	Numeric
Slope	Numeric
Ca	Numeric
Thal	Numeric
Target	Numeric
Bglf	Numeric
Bgl pp	Numeric
Bglr	Numeric

A property of this dataset is that it is a multivariate and generally used for classification purpose. This dataset contains categorical, integer and real attributes. Basically, there are 14 different attributes that were used earlier and 3 more attributes namely Bglf (blood glucose level fasting), Bgl pp (blood glucose level PP) and Bglr (blood glucose level regular) are added to find accurate results.

Table III clearly shows that when dynamic LSTM model is chosen with numerous classification techniques such as LR, KNN, CART, NB and SVM gave the better results. Graphs are plotted in between the Baseline and the prediction values. The corresponding graphs are as given below.

VI. Conclusion & Future work

In this section, we conclude the paper with overall findings as well as suggestions for future research work. The paper proposes a design of original methodology for finding accurate result and helps in earlier diagnoses of heart disease predictions. The proposed model gives more efficient and accurate result as compare to previous diagnoses models and algorithms. This classifier varies according to the different data records. One of the advantages of this model is that it can

work on a real, numerical and categorical dataset. In future work, this model can be used in diagnosing of different diseases prediction.

***Abstract*— In this paper, we propose a hybrid approach for wireless sensor networks which can reduce the total energy consumption of network operation therefore improving network lifetime along with complete coverage of remote monitoring field. The proposed method named as Hybrid Weight based Coverage Enhancing Protocol (H-WCEP) helps to select appropriate cluster heads and their respective cluster members by using weighted sum method and subsequent routing path by genetic algorithm. The network lifetime and coverage lifetime are computed by implementing this approach to achieve continuously monitoring of remote monitoring areas. The results of H-WCEP outperform as compared to other existing protocols. The network lifetime and full coverage lifetime of H-WCEP increase by 48 percentage and 42 percentage approximately respectively.**

Keywords—wireless sensor networkS; network lifetime; full coverage lifetime.

I. INTRODUCTION

Recently, remote sensing systems have received significant attention in electronic and computer science applications. In wireless Sensor Networks (WSNs), tiny component known as sensors are perform sensing and on-board processing, communication and storage facilities. The WSN provides remarkable benefits for a number of real world problems such as military surveillance, agricultural monitoring and oil pipelining monitoring [1] etc. The WSN has come to stay as one of the highly advanced technologies that can immediately respond against the rapid change in sensed data and send this to data analysis center in areas which could not be connected through cabling. Various applications of WSN are discussed in [2].

In order to tackle design challenges of WSNs, clustering algorithms play a very significant role. The clustering algorithms in WSN can greatly contribute to lifetime, energy efficiency and scalable issues of network [3]. The large number of sensors is deployed in remote monitoring field. In clustering, the sensor nodes are grouped into clusters. Each group/cluster of sensors is managed by a specific sensor called as Cluster Head (CH) and other group/cluster members in cluster are known as Cluster Members (CMs). The CMs monitor or sense the specific environment periodically. The CMs process the

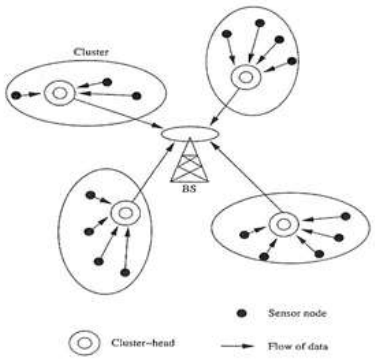

Fig. 1. Cluster based WSN

sensed data and transmit to their respective CH. The CHs aggregate data from their respective CMs and then transmits it to BS. In this way, clustering reduces the energy consumption and numbers of messages communicated to BS decreased. Moreover, data at BS can be encrypted in efficient manner before further transmission to any data centre[4].Thus, clustering achieves prolonged network lifetime [5].The measurements of various performance metrics viz. total energy consumption, network lifetime, number of CHs selected in each round, number of alive nodes in each round, and QoS support like coverage etc. are used to determines the performance of clustered based WSNs.Fig.1 indicates the clustered based network WSN architecture.

The prime objective of this paper is to present an energy efficient clustering protocol which is suitable for remote military area surveillance for achieving prolonged lifetime. Recently, proposed algorithm Weight based Coverage Enhancing Protocol (WCEP)[6] provides the full coverage for longer time as compared to existing clustering protocols. The WCEP works on the basis of weighted sum theory and it increases the lifetime and full coverage by minimizing the energy consumption during cluster formation. But, unable to minimize the energy consumption during inter cluster communication phase.

In this paper, Hybrid-WCEP (H-WCEP) is proposed to decrease energy consumption of the network by using Genetic Algorithm (GA) during data transmission of WCEP. A hybrid approach of weight based method for clusters formation and GA for data transmission is opted to achieve the objective of prolonged full coverage. The cluster head nodes (CHs) and cluster member nodes (CMs) are selected on the basis of coverage governing parameters. The coverage governing parameters taken for this selection procedure are; network remaining total energy, overlapping, node density and degree of sensor node. To conserve the energy consumption, weighted sum method is used. In this method, different weight values are assigned to governing parameters. The optimal set of CHs and alive nodes (as Cluster Member nodes CMs) are selected. Since simple evolutionary optimized algorithm GA has more capability to determine optimal path from CHs to Sink, this GA adopted in inter cluster communication of data transmission in order to conserve the energy consumption.

The rest of the paper is organized as follows. Section II discusses the literature review. Section III discusses the proposed H-WCEP. In Section IV, experimental results are discussed and finally in Section V, the paper is concluded.

II. LITERTURE REVIEW

In literature review, we studied different approaches to optimized energy usage to improve Quality of Service (QoS) in WSNs. The cluster based protocols mimic remote sensing in real time situations. Generally, these protocols are criticized for energy efficiency that involves limited QoS in WSNs. The brief description of related literature is as follows:

[7]proposed distributed cluster based routing protocol namely Low Energy Adaptive Clustering Hierarchy (LEACH) protocol for micro-sensor networks. LEACH improved the network life time, latency and application perceived quality in micro sensor network. However, the study does not investigate good distribution of CHs in the network and sink is assumed only one hop far away from other nodes/ CHs which is not feasible in geographically large network. The work had been extended further based on centralized approach, namely LEACH-C protocol. Still, it cannot solve the limitation of scalability in network. To extend network life time by uniformly CH distribution across the network and load balancing, the amalgamated concept for CH selection, [8] introduced a Hybrid Energy Efficient Distributed Clustering (HEED) protocol. The HEED incorporates two parameters: residual energy of node and node's proximity to its neighbors. However, the rise in iterations involved in cluster formation can lead to overhead cost.

[9] Proposed Distributed Weight-based Energy-efficient Hierarchical Clustering protocol (DWEHC) that designs multi-level structure in intra-cluster communication and limits a number of children of parent node. The author introduced the idea to select CH by calculating weight based on its residual energy and distance to its neighbors. This newly proposed technique improves HEED protocol by developing balanced size clusters and optimizes intra-cluster communication using location

In [10], the authors proposed a protocol incorporating residual energy and other metrics like distance to aggregation point, node reliability, and mobility for CH selection by using evolutionary computing method with purpose of maximizing network life time.

The CHs election techniques called as Coverage Preserving Clustering Protocol (CPCP) was proposed with aim of coverage preservation [11]. The CPCP is based on four coverage aware cost metrics which selects CH, active nodes and routing nodes from densely deployed sensors respectively. The CPCP integrates problem of coverage and energy consumption in network. But these cost metrics cause a large computational burden on sensor nodes. The CPCP is also unable to minimize redundantly covered area in each round.

In [12], the authors described a multi-function based on two factors i.e. choosing optimal CHs locations and minimizing transmission distance. In this protocol, topology of network is designed with three level hierarchical levels. Two CHs at level 2, One CH at level 1and sensor for collecting data placed at level 0. The BS knows the position of all nodes. Thus achieves the minimum distance for transmission.

A GA-based adaptive clustering protocol was proposed by [13] to achieve good performance in network life time in WSNs. Additional information was updates before beginning of first round. In this phase, role of node as sensor or CH, node identifications and geographical position are send to BSs. GA finds an optimal probability of nodes being CHs by minimizing the total energy consumption in one round. The optimal probability was determined by an evolutionary optimization process. This process incorporated non-deterministic rules in probabilistic transitions for prolonging the network life time.

The Distributed Energy Efficient Clustering Algorithm with Improved Coverage (DEECIC) was implemented to increase network lifetime and coverage using average number of clusters in scheme [14]. In this, CH is opted from a crowded area with more remaining energy and more degree of sensor.

Coverage aware Unequal Clustering Algorithm (CUCA) is distributed scheme to prevent hot spot issue and achieves energy efficient coverage preservation in WSNs [15]. The CUCA targets to obtain network load distribution uniformly. The CUCA necessitates overburden of control packets in routing purposes. As a result, unnecessary consumption of energy in each stage takes place that is unacceptable.

The WCEP is an energy efficient full coverage protocol [6]. The WCEP reduces computation burden of sensors and attains pro-longed full coverage with improvement in scalability. The WCEP incorporate the concept of clustering and sleep scheduling efficiently[16]. The WCEP is based on weight values which are assigned to certain governing parameters viz. network remaining total energy, overlapping degree, node density and degree of sensor node. These governing parameters affect the energy and coverage issues magnificently. However, main focus of WCEP is optimal selection of CHs and CMs, whereas energy consumption during data transmission is ignored.

The CPCP [11] and WCEP [6], both primarily focuses on cluster formation process but there is significantly less

importance given to energy consumption during data transmission phase of clustering. Therefore, motivation behind this proposes work is reduction in energy consumption during data transmission phase of WCEP. This has led to more conservation of residual energy and helps in more coverage.

III. PROPOSED WORK

The proposed work presents a hybrid approach using weighted sum method and evolutionary method to achieve coverage of remote and harsh environment for longer period of time. The proposed work is based on Weight based Coverage Enhancing Protocol (WCEP) for clustering and Genetic Algorithm (GA) for transmitting the data to end user controller. In clustering, CHs and CMs are selected in appropriate number for maintaining full coverage in each communication round. The process of clustering considers assigning weight merits to remaining total network energy, overlapping, node density and degree of sensor. The weighted sum method helps in conserving energy using different weight merits to respective governing parameters depending upon situational requirements. Further, GA based optimization procedure performed with each communication round to conserve the energy. The proposed hybrid approach is named as Hybrid -Weight-based Coverage Enhancing protocol using Genetic Algorithm (H-WCEP). The stepwise procedure of H-WCEP is discussed below:

A. *Information Update*

We assume that 'N' sensors are deployed in squared remote monitoring field in uniformly random manner. The deployment of sensors is such that they confirm the 100% coverage at the start of network procedure. The sensors are assumed stationary after deployment and each sensor is awared its own location and BS. The BS is placed at fixed point. The wireless communication channel is symmetric which means monitoring and communicating range is same. The range of sensor and transmission range is modeled as disk sensing model [8]. The transmission range is considered at least double the sensor's range. The network considered for proposed work is homogeneous i.e. all sensors have same computing and communication capacity.

B. *Network Model*

In this step, four coverage observing parameters are incorporated to assign a value to each sensor. These governing parameters are residual/remaining total network energy, overlapping, node density and degree of sensor. At each communication round, sensor dissipates part of their limited energy. As a result, remaining energy is called as residual energy of sensor need to be update periodically. The other governing parameters are node density, degree of sensor and overlapping degree are calculated only once at the start of network procedure. For each sensor, energy dissipation in transmitting and receiving 'L' bit information by each sensor is measured using simple radio model [6], [7], [11]. Equation (1) represents energy consumed by transmitter for performing transmits circuitry operation and Equation (2) indicates receiver's energy consumed due to receiver circuitry when it is receiving data.

$$E_{Tx}(L,d) = L\,E_{elec} + L \in d^{\alpha} \quad \text{where } \alpha=2 \text{ or } 4$$
$$\begin{cases} L\,E_{elec} + L\,\epsilon_{fs}\,d^2 & d < d_0 \\ L\,E_{elec} + L\,\epsilon_{fmp}\,d^4 & d \geq d_0 \end{cases} \quad (1)$$

And Equation [7] indicates formula for energy consumption in receiving L-bit packet.

$$E_{Rx}(L) = L\,E_{elec} \quad (2)$$

In equations (1) and (2),

L=Length of transmitted/ receiving packet,
d=Distance between transmitter and receiver,
d_0=Threshold distance (d_0) calculated from Equation (3):

$$do = \sqrt{\frac{\epsilon_{fs}}{\epsilon_{fmp}}} \quad (3)$$

The electronics energy E_{elec} controlled by digital coding, modulation of signal, filtering of packets, and spreading of the signal.

If $d < d_0$, then free space model is used. It means =2, and amplifier energy becomes $\epsilon_{fs}\,d^2$. Otherwise, $d \geq d_0$ multipath fading channel model is applied which means $\alpha = 4$ and amplifier energy becomes $\epsilon_{fs}\,d^4$.

With each communication round, residual energy is given by Equation (4):

$$E(residual) = E(initial) - E_{Tx} \text{ or } E_{Rx} \quad (4)$$

The other governing parameters such as node density can be calculated by obtaining number of sensors within its cluster range. The degree of sensor is determined by number of covered points in its range. The overlapping degree is number of sensors which produces overlapping area in the monitoring field. Higher the values of these governing parameters (residual energy ($E_{residual}$), overlapping degree ($O_{lapping}$) , node density (ND) and degree of sensor(D_s) for particular sensor make that eligible to become live sensor. The weight w_1, w_2, w_3 and w_4 are assigned to governing parameters using weighted sum method in order to calculate the weight value of each sensor. Equation (5) represents the formulation to compute sensor weight.

For a specific covered point, higher the weight of sensor, higher the chance to become live, otherwise idle or sleep.

$$Sensor.wt = E_{residual}.w_1 + O_{lapping}.w_2 + D_s.w_3 + ND.w_4 \quad (5)$$

Equation (6) is used to obtain CH role for a sensor in terms of CH weight.

$$CH.wt = Sensor.wt + (\text{distance between Sensor and Sink}) \quad (6)$$

C. Clustering Method

In the clustering method, set of sensor nodes are selected as CMs/ CHs which will be active and rest will be in sleep mode for a particular communication round. The proposed clustering algorithm comprises of two phases: cluster formation phase and data transmission phase.

- Cluster Formation Phase:

  The cluster formation phase of proposed algorithm uses a weight based method along with sleep scheduling mechanism to conserve energy while maintaining prolong full coverage of the monitoring field. The total weight of each sensor is calculated on the basis of governing parameters $E_{residual}$, $O_{lapping}$, ND and D_s. The selection of sensor as live sensor is based on maximum value of total weight of sensor for specific covered point. The total weight of sensor and distance from sink determines the CHs. These selected CHs find live sensor as part of cluster and termed as CMs within its cluster radius. These appropriate numbers of specific CMs and CHs are selected repeatedly that maintains the coverage in each communication round.

- Data Transmission Phase:

  In the data transmission phase, intra and inter cluster communication ensures that live sensors communicate to their respective CH directly using single hop method during intra cluster communication. The CHs transmits data to sink via multi hop method. The data transmission phase is optimized using energy and distance parameters using GA. The GA helps to determine path with minimum energy consumption to transfer all data from sensor CHs to sink. To find out an optimum path, the GA generates all possible paths for each of CH. Then, each path is evaluated to determine fitness value using fitness function of GA. The best chromosome is selected among number of generations by means of minimum energy consumption and minimum distance during data transmission. The data transmission phase of WCEGA is further elaborated in Algorithm 1, as follows:

  Algorithm 1: Data Transmission using GA

  D= cumulative distance between sensor and Sink
  w1=weight for residual energy

IV. RESULTS AND ANALYSIS

In this section, the impact of governing parameters on performance metrics for remote WSNs has been investigated. The results of WCEGA protocol is compared with common coverage aware clustering protocol (CPCP) and Weight based Coverage Enhancing Protocol (WCEP). The CPCP discussed four coverage aware cost metrics i.e. energy-aware (Cea), minimum-weight (Cmw), weighted sum (Cws) and coverage redundancy (Ccc). The CPCP (Cmw) focuses longer 100% coverage of monitoring field. Therefore, out of four CPCP cost metrics, CPCP (Cmw) is taken for comparison in these simulations. Generally, coverage related clustering protocols are compared with coverage, lifetime and energy consumption of the network.

In simulations 200 nodes, each with initial energy 1J are taken into monitoring field. The sensors are distributed randomly across 100x100 square units monitoring field. The implementation of WCEGA is iterated based on lifetime of network i.e. energy level of sensors become equal to threshold energy of sensor. The threshold level of energy is assumed zero in this paper. In all communication rounds of network operation, live sensors are selected to collect the sensing data and transmit them to their CHs using single hop communication. Once CH obtained data from its cluster then it transmits the data further to sink using multi-hop communication by GA method. The sink is located at (50,50) co-ordinates. The radius of each sensor is 15m and their communication radius is 30m. The parameters of proposed model are given Table I and parameters for GA approach are listed in Table II.

TABLE I. SIMULATION PARAMETERS

Parameters	***Value***
Initial Energy (E_{int})	1 J
Transmission/Receiving electronics circuitry constant [7]	50 10^{-9}J/bit
Amplifier circuitry constant [7]	10 $^{-12}$J/bit/m^2
Size of Data Packet [7]	240bits
Sensing Range (Rs) [7]	15m
Cluster Radius(Rc) [7]	30m
Transmission Range	40m

TABLE II. SIMULATION PARAMETERS

Parameters	***Value***
Population Size	20
Generation	10
Crossover	0.05
Mutation	0.01
Weight1 for distance factor	0.3
Weight 2 for energy factor	0.7

A. Coverage lifetime Energy Consumption Comparison

The H-WCEP outperforms in comparison to other similar protocols i.e. CPCP and WCEP. By decreasing the consumption of energy during data transmission, it increases the coverage of network. The Fig. 2 depicts comparison of coverage of network in H-WCEP with WCEP and CPCP (Cmw) with time.

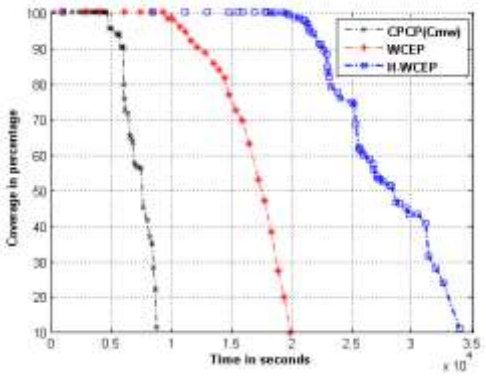

Fig. 2. Comparison of Coverage lifetime with Time for WCEP, CPCP (Cmw) and H-WCEP

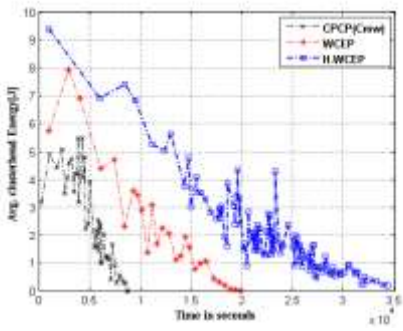

Fig. 3. Average CHs energy with Time for H-WCEP in comparison to CPCP (Cmw) and WCEP

The Fig. 3 indicates higher value of average residual energy of CHs in H-WCEP in comparison to WCEP and CPCP (Cmw) with time.

On the other hand, an important criterion to evaluate energy consumption of WSNs is the average number of CHs with time. If the Number of CHs are high, energy consumption increases. Fig. 4shows that H-WCEP has relatively low number of CHs as compared to CPCP(Cmw) and WCEP.

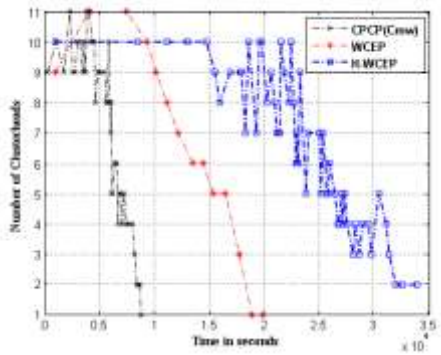

Fig. 4. Comparison of number of Cluster Heads Vs Time for H-WCEP, CPCP (Cmw) and WCEP

B. Lifetime comparison

Network lifetime is defined as start of specific WSNs to death of first sensor. Generally, lifetime of WSN is determined by time taken by First Node Dead (FND), Half Node Dead (HND), Last Node Dead (LND) and these are considered for evaluate performance of cluster based WSNs [11]. Further, FND indicates start of network operation to death of First sensor Node Died. The HND indicates start of network operation to death of Half sensor Node Died. The LND indicates start of network operation to death of Last sensor Node Died. The Fig. 5 represents that H-WCEP exhibits better results than other considered protocols.

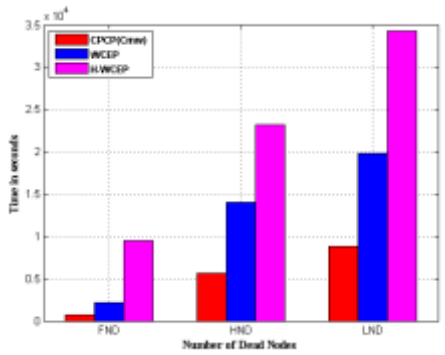

Fig. 5. Lifetime of WCEP, CPCP (Cmw) and H-WCEP in terms of FND, HND and LND

V. CONCULSION

In this paper, an evolutionary based method has proposed to improve longer full coverage in energy efficient clustering protocol. The proposed hybrid method helps in determining efficient optimal path for effective set of CHs and its members. The H-WCEP uses genetic algorithm based routing method that consider distance between cluster head and sink and sensor node's residual energy. Therefore H-WCEP achieves increase in network lifetime and full coverage lifetime. Thus, our hybrid approach uses network energy in effective manner for enhancing the full coverage lifetime in WSNs.

In our future work, we can extend this work by incorporating mobility of sink and pre-determined sensor deployment to enhance the coverage lifetime.

***Abstract*— Electric bicycles or e-bikes are gaining momentum in the market as they are offering a smooth, noise less and pollution free option for individual transportation in cities as well as in countryside. E-bikes are usually with a battery powered electric motor drive with an additional option for pedaling. In this work a low cost e-bike was designed and developed with a brushless DC hub motor with controllers. For smart control, smartphone was used a console and the e-bike can be controlled using a mobile application which was connected to the e-bike through Bluetooth. The controller will pick the gradient of the terrain and will control the power of the motor, which results in energy saving. Predicted range of the e-bike, speed, acceleration and total distance covered were displayed in the console along with the geographical position on the map and throttle control options. The bike with the proposed control tested and the results were giving a reduction in current drawn from the battery.**

Keywords*— *Electric bicycle, E-mobility, Range prediction, Intelligent control, Terrain intelligence.

I. INTRODUCTION

Electric bicycles generally known as e-bikes are the bicycles integrated with electric motors for propulsion. These e-bikes are battery powered with either pedal assist provision or with throttle control to ride through different terrains. E-bikes offer more comfort and less noisy operation than usual pedal powered bicycles, so the market for e-bikes is growing all over the world. Increase in fuel prices and polices by various countries to reduce emissions are also driving the market for e-bikes. Riding bicycles is a healthy and eco-friendly practice and e-bikes with pedalling option is adding comfort and efficiency to that. Global opportunity and industrial forecast report by Allied Market research shows that the market of e-bikes expected to grow annually at a rate of 5 % to a total value of 23.83 billion USD in 2025 from the total value of around 20 billion USD in 2018. Market analysis also indicates that countries with higher population density are having higher demand for e-bikes and the Asian countries are leading the trend [1]. Also the development in Lithium-ion battery technologies after the year 2012 and the availability of low cost, efficient and light vehicles are also offer better prospects for the market for e-bikes.

Since e-bikes offer a pollution free and comfortable drive, lot of research and developments are happening in the technological area which offer better solutions in mobility as well as in sports goods category. Multiple fuel options, hybrid vehicle and improved efficiency are the major areas of many of these researches [2]. E-bikes are mainly of two types; a pure electrical powered one with electrical motor which is controlled through a throttle by the user to obtain different power depending on the intention of the user and the second one is a pedal assisted one or a pedelec, in which the power is supplied by both the electric motor as well as pedalling power together. In any e-bike the range of the bike is determined by the battery capacity, motor power, driving terrain, human load and the control mechanism [3]. Pedelecs need pedalling to actuate the motor operation and the comfort level is less compared to a fully battery powered one, but will be having higher range per charge. There were some studies conducted on optimization of power in pedelecs [4].

Fully battery powered e-bikes with BLDC hub motor offer more comfort and can replace conventional fuel based two wheelers in populated cities, especially for short distance commutation. Lower distance per charge and throttle control are the main drawbacks of such vehicles [5]. There were few techniques adopted to improve the efficiency of the vehicle and thus the battery backup, like the regeneration during the slowing down regimes [5]. The regeneration techniques were improved with the help of bi-directional controllers [6] and with EMC compatible controllers [7]. The BLDC motor based e-bikes can additionally save power during when the power demand is less, like in the case of climbing down the hill. Since the controller is feeding the supply to the BLDC motor based on the rotor position, there is an option to save power depending on the road conditions [8, 9].

In this work, we designed and developed a battery powered e-bike with a BLDC hub motor. The rider can control the e-bike using a hand controlled throttle. To improve the efficiency and the range, a gradient senor based controller is provided, which help in suitably giving the throttle based on the gradient of the road in the auto run mode. The rider's mobile phone is used as the console for the e-bike, which will display the predicted range, speed, acceleration as well as the total distance covered. The bike tested in different terrains and the results showed improved power efficiency as well as longer range per charge.

This paper is organised as follows; in section II the design of the e-bike is described, controller details are given in section III. The gradient based control mechanism is described in section IV, integrated e-bike with controllers is presented in section V, results and discussion are given in Section VI and conclusion is given in section VII.

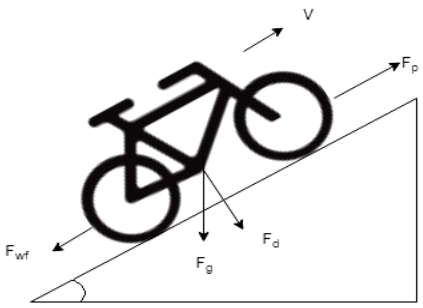

Fig. 1. Forces acting on a bike, while climbing a slope

II. DESIGN OF THE E-BIKE

A single rider bike with some minor additional load carrying capacity which can run for a medium trip length of 50 km is explored. To obtain better comfort and easier mobility, a fully electric powered bike is preferred over pedelecs. If the rider needs to shift to pedalling mode, the motor can be switched off and run as a normal bicycle. The design starts with the propulsion motor, the specification of which depends on the weight of the rider and the other loads on the bike apart from the traction force. There are few options available for the motor type, but a BLDC can provide more torque, stability, higher efficiency as well as lower noise compared to DC motors. Even though the control circuit of the BLDC is complex, lack of commutators and smaller size will give BLDC motors an edge over its competitors.

The following values were selected for the selection of motor power. Mass of bike frame and accessories – 12 kg, battery and controller – 3 kg, cyclist – 80 kg, load – 5 kg. So total weight – 100 kg. As given in Fig. 1, the bike is climbing a slope with an inclination of θ, the traction force F_p has to overcome the normal component of weight F_d and the friction and windage force F_{wf}. If the linear speed of the vehicle V is assumed as 20 km/h. An additional aerodynamic load of 20W is assumed when riding at V km/h [10]. The power is calculated as 260 W and a 36V, 250 W, 250 rpm BLDC hub motor with a maximum torque 32Nm selected to fix on the rear wheel hub.

III. BLDC MOTOR CONTROLLER

BLDC motors offer higher torque over a range of speed with higher efficiency than DC motors. The motor use a set of MOSFET bridge to energize the phase windings according to the position of the rotor with respect to the stator. The position of the rotor is sensed through a set of Hall Effect sensors. In three phase wound motor, three set of Hall Effect sensors are used to precisely locate the position and these signal output from the sensor will be used as the feedback for speed control. For the e-bike speed control, a throttle is connected on the handle, where the rider can adjust it with hand or fingers. Similarly braking and ON-OFF control signals are also fed to the controller through cables. Fig. 2 shows the outline of the controller. In addition to the power control, the controller should be capable of protecting against abnormal voltage and current values. So over voltage and over current protections are also incorporated in the controller.

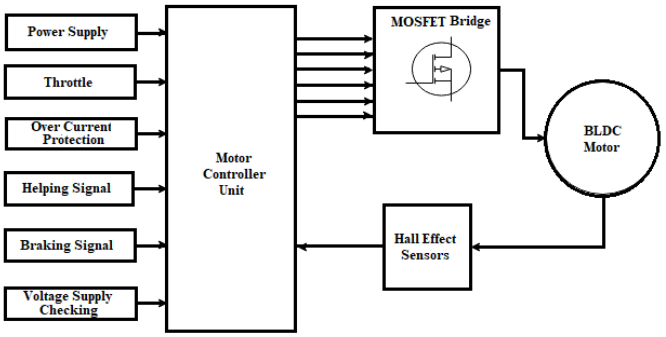

Fig. 2. Block diagram of BLDC motor controller

IV. GRADIENT BASED CONTROL MECHANISM

The gradient of the road is measured by a gradient sensor; the sensor will feed different voltages based on the gradient of the track. If the gradient is negative, the sensor will feed zero and with increasing positive slope, it will give positive voltages. This voltage values are augmented by the throttle output voltage values in the auto run mode. In negative slopes, the motor will be switched off and in positive slopes the motor will be powered based on the voltage values fed by the sensor and processed by the microcontroller.

The rider can opt for normal riding mode or auto run mode. As shown in Fig. 3, the modes are selected based on the relay selection. In auto run mode, the gradient sensor will give voltage values, which the microcontroller will process and categorize into five different levels. For negative slopes it will give zero voltage and for the positive slopes between 10^0 and 50^0 it will a voltage between 3.4V-6.6V and which is calibrated as comparing with the throttle voltage values. While climbing down the slope, the motor will supply with zero power and at higher positive slope motor will be running at highest power. This control scheme is based on the terrain intelligence and which was implemented to improve the power efficiency and thus to improve the range of the bike [11]. The system is compatible with the pedalling mode also, where with the help of a switch; we can totally disconnect the motor from the battery. In case of the battery charge is exhausted the rider can shift to pedalling mode just with toggling the switch.

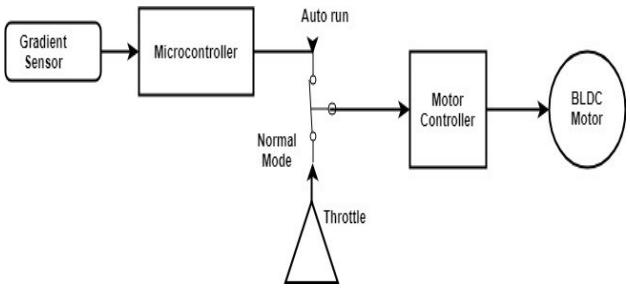

Fig. 3. Gradient sensor based auto run mode

V. E-BIKE INTEGRATED WITH CONTROLLERS

A normal pedal bicycle was converted into the e-bike by fixing a 250W, 36V BLDC hub wheel motor in the hub of rear wheel of the bike. Modifications were done on the wheel holder as well as chassis to accommodate the motor in the hub. The tire size was 66 cm and with a frame size of 45.7 cm. The brake levers are replaced with hybrid brake levers which are capable of controlling mechanically, also capable of producing braking signals for the motor controller [12]. A 5V electric thumb throttle was fixed on the right hand side of the handle to control the acceleration. The throttle was provided with a key to switch ON or OFF the electric motor mode.

The power for the motor is provided with a 37V, 10.4 Ah Li-ion battery packs. It was a custom designed pack with 40 numbers of 3.7V, 2800 mAh batteries connected as 10 in series and 4 such units connected in parallel. The batteries are with 2C rating and suitable for faster charging. A battery pack is provided with charge controllers and protective circuits. Total weight of the battery pack is around 3kgs and a metal holder is provided on the chassis for fixing it comfortably on the bike.

To monitor the State of Charge (SoC) of the battery a voltage sensor and a current sensor were included in the power circuit. The voltage sensor was connected across a high resistance potential divider circuit to reduce power losses and to obtain more reliable readings. The voltage and current sensor output were fed to a Arduino Uno microcontroller and SoC calculations are done there. The current sensor output is used to monitor the current values and to provide protection in case of abnormal operations. These sensor values are also used to calculate the instantaneous power consumption. The Hall Effect sensor outputs were used for speed measurement. Fig. 4 shows the outline of the microcontroller part.

Fig. 5 shows the actual view of the e-bike integrated with the battery pack, motor controller and sensors. The components added to the e-bike were placed carefully to reduce the aerodynamic resistance as well as to improve the comfort of the rider. The controller and the microcontroller circuits were provided with an enclosure to ensure safety and to have a better appearance.

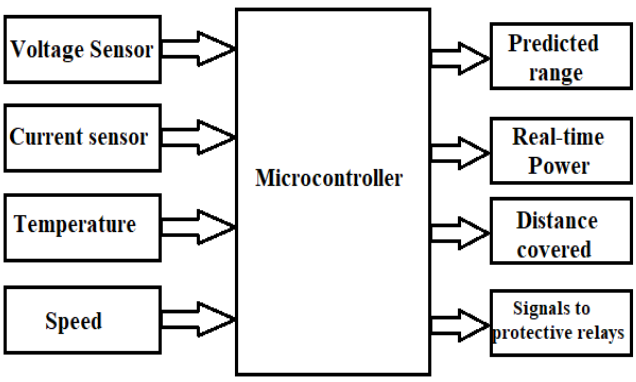

Fig. 4. Outline of the Microcontroller circuit

Fig. 5. The e-bike integrated with controllers and sensors

Terrain intelligence of the e-bike was provided with a set of gradient sensors. These sensors were calibrated to measure the gradient of the road whether it is positive or negative. These sensors will provide voltage signals based on the slope of the road and for better accuracy these sensors were fixed on the horizontal part of the frame. These signals were fed to the microcontroller, which will give a voltage signal output calibrated with the throttle signal values. When the bike is climbing down the hill, the voltage signal output will be zero from the microcontroller and the motor will be disconnected from battery.

Fig. 6 shows the various modes of operation of the e-bike. The rider can select the pedalling mode with the help of the 'kill switch' provided. In normal mode, the rider has to apply the throttle based on the slope of the road. If the rider opts for the 'auto-run' mode, the motor will be driven automatically by providing appropriate power calculated based on the gradient sensors.

Modern e-bikes are provided with consoles to display the measurements like speed, time etc. But such consoles are costly and not suitable for low cost e-bikes. In this project we had developed a mobile phone application which will help the rider to use own smart phone as a console while riding. The mobile application will fetch the predicted range, total distance covered and the instantaneous power consumption of the motor in addition to the current taken from the supply through Bluetooth from the microcontroller unit. Presently the mobile phone application is developed for Android platforms, but can be easily modified to make compatible for other platforms also. A simple holder for the smart phone was provided on the frame of the bike to safely hold the phone.

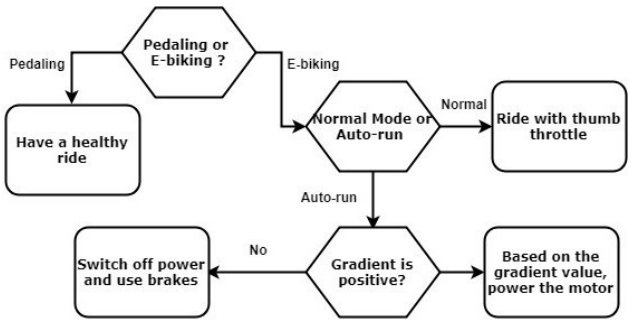

Fig. 6. Flow chart for various modes of operation of the e-bike

VI. RESULTS AND DISCUSSION

The 36V, 250W, BLDC hub motor was tested for the performance using a mechanical loading with spring dials. The motor shown very good speed regulation with a maximum speed of 275 rpm at very light load and with a minimum speed recorded during the test was 224 rpm during the test. The motor was capable of producing a maximum torque of 19.08 Nm. The maximum efficiency of the motor was found to be 81.54% which shows it is much superior to a DC motor. The maximum efficiency recorded at around the half full load and the efficiency at higher loads found to be in close range of maximum efficiency. The load test values are tabulated in Table I. Fig. 7 shows the variation of torque with the output power. Fig. 8 and Fig. 9 show the variation of speed and efficiency with the output power respectively. The vibration of the e-bike with the BLDC was found to be very small even at higher motor speeds.

6	37.2	2.82	2.675	257	72.02	68.65
7	37.2	3.65	3.86	254	102.71	75.65
8	37.2	4.48	4.86	252	128.30	76.99
9	37.2	5.28	5.92	248	153.81	78.31
10	37.2	6.11	7.024	245	180.28	79.32
11	37.2	7.09	8.426	243	214.50	81.33
12	37.2	8.21	9.864	241	249.04	81.54
13	37.2	9.54	11.048	238	275.46	77.62
14	37.2	10.52	12.98	234	318.20	81.31
15	37.2	11.86	14.42	232	350.47	79.44
16	37.2	12.98	16.02	230	386.01	79.94
17	37.2	14.44	17.88	228	427.08	79.51
18	37.2	15.9	19.08	224	447.74	75.70

The integrated e-bike was tested on different terrains and found to be with easily controllable with thumb throttle. At higher slope the motor takes higher current to supply the higher power requirement. Noise and vibrations were less compared to a normal pedal bicycle. The maximum speed recorded with a rider weighing 80 kg was 25 km/h. The battery pack was capable of providing around 1.5 hours of back up with a single charge. Around 40 km range with a single charge make it a good choice for usual scenarios like urban travel, countryside commutation, in tourism and in sports.

The terrain intelligence system was introduced only in auto-run mode. In auto-run mode no throttle control is required and only braking signal to be applied whenever required. In auto-run mode, the gradient sensor output was used to generate the signal corresponds to throttle signal. In usual throttle control, the throttle voltage signal was varying from 3.4V to 6.6V. In auto-run mode also the voltage signal is calibrated to these levels using the microcontroller

TABLE II PERFORMANCE OF 250W, 36 V BLDC MOTOR

Slope of the terrain (Degrees)	Voltage output from microcontroller (V)
Less than -5	0
-5 to 10	2.4
10-20	2.8
20-30	3.2
30-40	3.5
More than 40	3.66 (max)

program. Only four levels of voltage signals were provided in the terrain intelligent system. In Table II the levels used were consolidated. Presently only a rule based algorithm was used to control the motor power. A more complex intelligent algorithm can be used to control the motor.

The terrain intelligence system was capable of saving power consumed by the motor. In normal thumb throttle controlled mode, the throttle was applied based on the assessment of the rider based on his comfort and the road conditions. Most of the time the perception of the rider will be fuzzy in nature and there will be definitely some scope for optimization in throttle control. To verify the power savings in the terrain intelligent control mode, the currents taken by the motor in throttle control mode and terrain intelligent mode were compared. Since the power consumed by the motor is directly proportional to the current drawn from a constant DC voltage supply, the reduction in current while riding in same terrain with different modes can be seen as the difference in power. The e-bike was tested under some known slopes in different operating modes and the results are tabulated in Table III. The reduction in current is evident in terrain intelligent mode. The percentage power savings can be better if the e-bike run in a complex track with varying slopes.

A mobile phone application was developed for Android platform and the current, predicted range, speed and instantaneous power consumption were displayed on it. The microcontroller fixed on the chassis is acquiring the voltage of battery, current drawn from the power circuit and calculating the above parameters and will send to the mobile application through the Bluetooth module. Fig. 10 shows the display of mobile application. The rider can select the mode and drive accordingly. The predicted range is calibrated to give the minimum distance the bike will run before recharging the battery

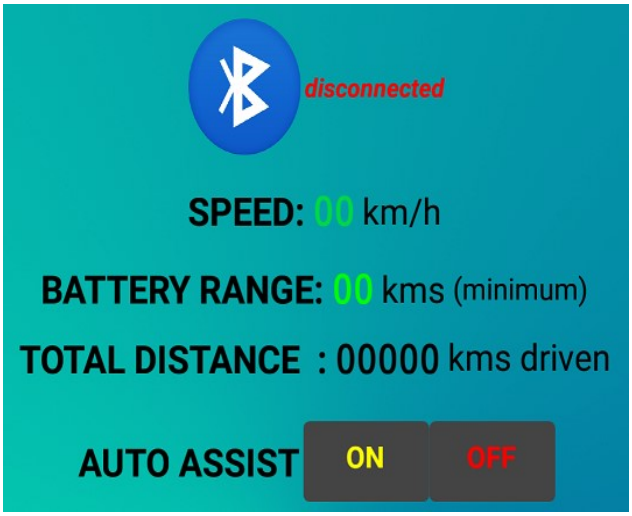

Fig. 10. Display of the mobile application

TABLE III POWER SAVINGS IN TERRAIN INTELLIGENT MODE

Slope of the terrain (Degrees)	Current (A) Thumb throttle mode	Current (A) Auto-run Mode	Power saving (%)
Less than -5	0	0	0.00
-5 to 10	3.4	3.3	3.03

I. CONCLUSION

E-bikes are gaining popularity especially in populated cities. Riding comfort, long range per charge of battery and capital cost are the major considerations while people selecting e-bikes in present market. In this work a BLDC rear hub motor powered e-bike was developed and tested in various terrains. A gradient sensor based throttle control provided in the auto-run mode was making it terrain intelligent by providing throttle equivalent signals to the motor. The results showed that the terrain intelligent control is capable of saving power consumed by the motor while riding under different slope conditions. A mobile phone application developed and which can display the current, predicted range, instantaneous power of the motor can serve as a console for the e-bike, thus the cost of the e-bike can be reduced. Presently only a rule based terrain intelligent system was employed but a better algorithm can be tried to improve the power savings. Regeneration and charging of battery while pedaling are the future works to be added to the project.

ACKNOWLEDGMENT

The authors acknowledge the facilities provided by the E-mobility Research & Development Facility at Faculty of Engineering, CHRIST (Deemed to be University), Bangalore for the successful completion of this work.

Abstract **-- This paper designs a flying lifeguard drone accessory which will deliver an automatic inflating vest to the drowning victim. It is observed that 40% of beach deaths are occurring every year according to statistics due to unavailability of the rescuer on time. There is a need for a system which can increase the victim's survival time. In this project a wrist band is used by the swimmer which has an emergency button. This is suitable for people who go deep into beaches. If a person gets pulled into the sea by the waves, they can press the button on the device, a drone will detect the location of the person using GPS and Zigbee and will go to the victim and drop a life jacket. After which the coast guard can save the drowning victim. There will be many drones present at the beach for the rescue process, but only one drone should be selected for the rescue process for there a GUI is created with the help of Visual C where in the life guard can select the drone for the rescue mission.**

Keywords- global positioning system(GPS), life-ring, Zigbee, Arduino, pixhawk, visual c, servo motor.

I. INTRODUCTION

The drone technology has been used by different organizations and hobbyists. However, the advantages of this technology extends beyond these applications. The use of drone leads to safe, cost-effective solutions ranging from data collection to delivery. In the present scenario where autonomy and collision avoidance technologies improve, so does the drone's ability to perform complex tasks increase [7]. This project presents the design of the ring buoy Delivery Drone System, which delivers ring buoy to the drowning victims before the lifeguard reaches [6]. Once the victim has a ring buoy, he/she can survive until the lifeguard reaches him/her. Lifeguards and rescue crews around the world are now considering drones to be life-saving equipment. These drones can quickly deliver flotation devices to the drowning victims, saving time and reducing panic. Drones could soon become a standard life-saving accessory for lifeguards and rescue teams.

Even just a few seconds in the water can make a difference between life and death, and these drones can fly much faster than people can swim. A drone carries a payload of inflatable ring buoy and can fly to the drowning victim. Upon arrival of the drone above the swimmer, it releases the ring buoy. The whole process is completed within 60 seconds. The swimmer wears a notification device which is like a strap band which fits on the wrist of the swimmer, that can send GPS signals to the drone [1][12].

II. SYSTEM MODEL

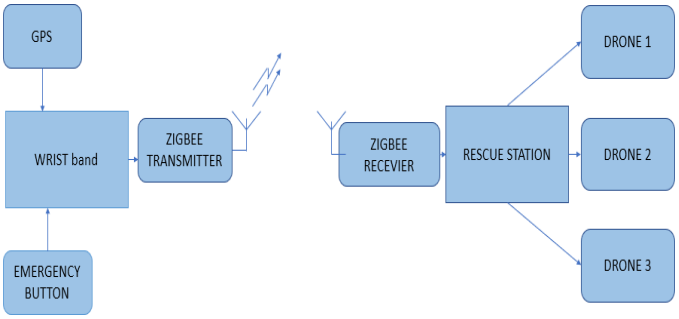

Fig 1. System block diagram

The lifeguard process and the drone system are not dependent on each other, that is if the lifeguard due to some reason is not able to reach the drowning victim in time, the drone will still continue and drop the ring buoy.

The drone process will start and simultaneously the lifeguard has to swim to the drowning victim. This victim is positioned on the rip current and is trying to escape.

As shown in fig(1), with the help of an emergency button on the wrist band the swimmer will be sending GPS signals to the drone with the help of the ZigBee transmitter [1][2].

As shown in fig (5), the rescue station receives the location of the victim with the help of ZigBee receiver and finds the exact spot and coordinates with the victim. The rescue station [5] is where the life guard will select which drone will be selected for the flight. The rescue station will plan the mission for the drone [3]. The rescue station will then command the drone to lift-off. The drone leaves the home point to the given coordinates.

The drone will then detect the exact location of the drowning victim and start hovering towards the drowning victim. When the drone reaches the victim in time, it will drop the ring buoy near the drowning victim. The victim grabs it, and then the drone returns back to its home point [6]. This will increase the victim's survival time. Lifeguard has identified the zone of the victim and is prepared for rescue process.

Working

Let's consider a swimmer named 'X' has gone deep into the sea. Then 'X' is attacked by rip currents in the sea. 'X' has worn the wrist band ,with an emergency button on it. Now when the 'X' feels it can't resist the rip currents it will press the button on the wrist band.

When this button is pressed this sends an SOS signal to the rescue station, fig5 which shows the GUI of rescue station. The rescue station has an option of alarm which turns red whenever the button is pressed. The SOS message consists of the GPS location of 'X'.

This alerts the lifeguard that the swimmer is in in danger. The lifeguard at the rescue station selects the alarm button which has turned red and this creates a notepad.

This updated notepad is uploaded in the mission planner software as shown in fig3. By selecting "do action" in the mission planner software the Pixhawk present on the drone receives the signal and follows the waypoint and drops the ring buoy and saves the swimmer 'X'.

After the drone has dropped the ring buoy the lifeguard will also swim to 'X'.

Hardware used:

1.*Emergency Button* :- It is placed on the wrist band used by the victim. It has a ZigBee module present in the band. This module is used to send GPS co-ordinates to the drone. Whenever the emergency button is triggered the ZigBee module sends GPS co-ordinate to the drone [4].

2.*Zigbee*:- It is used to transmit and receive GPS coordinates. The transmission of the GPS coordinates is done by the wrist band and the reception is done by the rescue station [1][2].

3.*Rescue station* :- It consists of computer hub where the ZigBee receiver will receive the GPS coordinates from the victim and then select the drone which will be sent for the rescue mission[3].

4.*Servo Clamp* :- A servo clamp is used to hold and drop the life ring. The clamp is connected to the pixhawk which instructs when to release the life ring.

5.*Pixhawk:*- This is a flight controller which manages the motion of the drone by setting appropriate speeds for the BLDC motors. It receives commands from on board/off board computer via MAV Link protocol and takes action according to them. [8]

6.*GPS:*- NEO-8m model is used for mapping the GPS co-ordinates.

7.*Arduino Mega:*- The Arduino mega board is used to build the wrist band. On this board is mounted GPS and Zigbee in transmitter mode.

Software Used

1.*Arduino IDE*:- Is the software used to program the GPS module in order to receive the real time coordinates.

As shown in fig 4 are the GPS coordinates that were received from the drowning victim. These coordinates were received via a ZigBee module. The ZigBee module was configured only as a transmitter using the XCTU software. Using this software the ZigBee module was programmed in such a way that when the button was pressed the coordinates were transmitted.

It was also used to handle the interrupts that were generated when the switch was pressed [10].

2.*Visual C*: The GUI for the rescue station is written in visual c.

3.Mission planner: Mission Planner is used as a ground control station for the use of Plane, Copter and Rover. It can be only used with Windows. It can also be used as a configuration utility or as a dynamic control supplement for autonomous vehicles. [11]

II. DESIGN SOLUTION

Design of drone

The drone is designed in such a way that it can carry a payload of 1000g. The rpm of the motors is 980kv. The propellers used are 10inches. It can fly up to a height of 100m. The battery life of the 3s lipo cell is 4000mAH , which can work for15mins. The telemetry used by the drone to communicate with rescue

station has a range of 1000m. Weight of the quadcopter is 2kg.The motors were controlled using ESC of 30mA. The frame used for the drone is S500.

Fig 2. Drone model

Design of Wrist band

The design of the wrist band includes an arduiono mega board, GPS and zigbee. The GPS placed on the arduino board is programmed in such a way that it can take real time GPS coordinates[9]. The zigbee used is configured using XCTU software for transmission. It is also programmed in such a way that it can transmit the GPS coordinates. The arduino board also has a hardware switch which acts as an interrupt. On pressing of the switch the coordinates are transmitted.

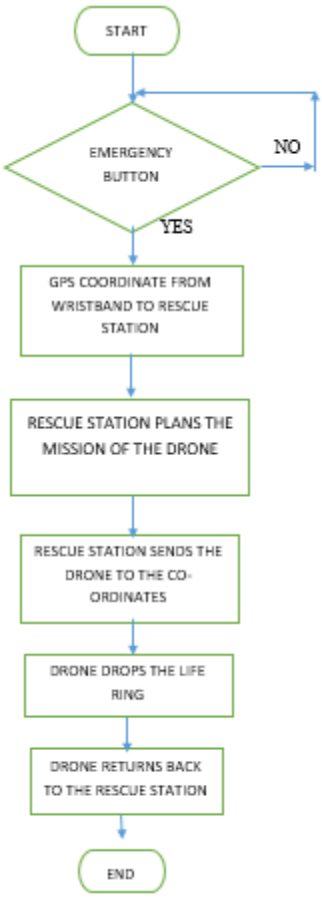

Fig 3. Flowchart of the proposed Solution

The drone rescue process proceeds as follows:

1.The system keeps on checking if the emergency button is pressed.
2.If 'yes', it will send GPS coordinates to rescue station.
3.If 'no' it will keep on checking.
4.Rescue station receives the GPS coordinates and plans the mission for the rescue.
5.Drone then reaches the GPS coordinates and drops the life ring.
6.After the mission is completed it will return back to its home location.

IV. RESULTS AND DISCUSSIONS

An .Autonomous flying of drone

As shown in the fig (4), the mission is planned by the drone to reach the drowning victim. The drone follows the path as shown in the figure. The fig (4) is the snapshot of the screen that can be viewed at the rescue station

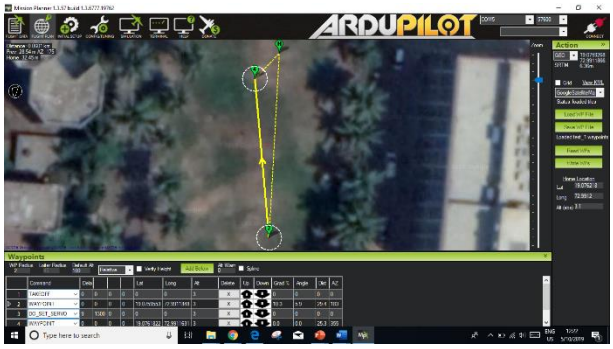

Fig 4. Autonomous settings on mission planner

Transmission of GPS coordinates

As shown in Fig (5) are the coordinates received by rescue station sent by the drowning victim. These are the latitude and longitude values. This is the snapshot seen on the Arduino ide terminal.

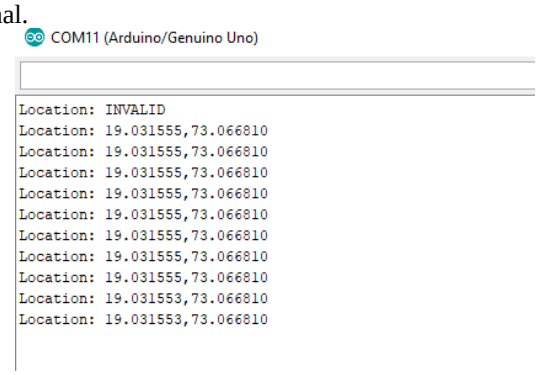

Fig 5. Receiving GPS coordinates

B.GUI of rescue station

As shown in fig. (6), is the GUI of the rescue station. From this window you can select the port from which the data is going to be transmitted to the drone. Also you can read the data that is being received by the Zigbee receiver. The required baud rate can also be selected from the drop down menu. When the send option is clicked the port status will go green when the data is transmitted. The drone selected option will show which drone is being selected.

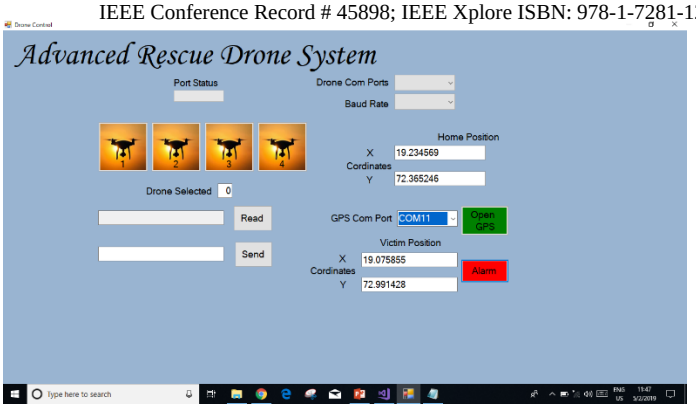

Fig 6. GUI for rescue station

C.Wrist band

As sown in fig (7) is the wrist band that has an emergency button and zigbee transmitter. Whenever the button is pressed the GPS sends the data to the rescue station.

Fig 7. Wrist band

D.Final test of drone using servo motor

As shown in Fig (8),is the drone that was tested using the drop mechanism. It is a holding a ring in the servo clamp. It drops when it reaches the drowning victim.

Fig 8. Drone using drop mechanism

V. CONCLUSION

This concept is developed in order to alert the divers at the beach. So that those drowning in the sea will be sent a life jacket using quadcopter technology before the diver arrives. The drone will reach the site by tracking the location using Global Positioning System (GPS). The proposed model can be used at various levels, for eg: drone companies, healthcare companies, government organizations.

VI. FUTURE SCOPE

1.A camera can be used that allows the lifeguards to view the current situation.
2.In future the drone can send real time video and audio feed to the rescue station for monitoring purposes.
3.Another method is to use artificial intelligence where in it can automatically detect the drowning victim without the need of pressing the hardware switch.
4.Implementing drones in medical field to deliver the medicine and first aid.

ACKNOWLEDGMENT

We express our profound gratitude to our project guide, Ms.Sreedevi Nair, in particular for patience, inspiring guidance, encouragement and freedom given to us during this project, due to which every step was shaped into a stepping stone towards success. We are highly obliged to our college and the management for providing us with best facilities and proper environment to work on our project and for all the moral support and guidance.

Abstract- **Indian Railways is the third largest rail network in the world and provide an efficient service to travelers. Tracks running well over 60,000 KM helps connect about 7500 stations, ferrying nearly 20 million people every day. One of the important problems faced by train travelers in India is to find out whether the destination station has reached or not as the schedule is not always on time. The proposed system consists of 2 sub systems. One is integrated in the train engine for reading RFID tags installed in the entry of the station platforms [1]. Another is the mobile application which works in offline mode for providing useful information regarding the destination arrival time and also offers other features to a train commuter. This system works well during emergency situations where the normal mobile network and other modes of communication fail to provide train station information to travelling commuters.**

Keywords- **Railways, RFID, Information Display Boards;**

I. INTRODUCTION

Passengers travelling in night trains usually wake up early to know which station the train currently passed by. During early morning hours or at night the visibility of outside railway station boards at stations are not clear from travelling trains. Passengers are often frustrated with wanting to know the details regarding the station. The proposed idea is to develop an information system using LED boards in coaches for providing real time information regarding the current station passed by. This cost effective approach enhances user experience by not disturbing the passenger's sleep in night trains as they need to wake up much early to avoid their destination been passed. Currently travelers rely on wakeup call service using 139 services or manually search the place using other map services using GPS. Map services by Google rely completely on availability of Internet services like 3G and above networks which is not a reliable network during train travels and consumes huge battery power and packet data.

There are number of existing online based services which give useful information regarding arrival or departure time, next stop arrival time etc. One such service offered by a private website not connected to Indian Railways is "www.etrain.info" [13]. Another service available to Indian train commuters is Rail Radar [14], a live train tracking service that runs on Google Maps. Available at http://railradar.trainenquiry.com/ the service allows you find out the exact location of a train. One of the oldest IRCTC initiatives for improving customer satisfaction is "Railways on SMS". In this service, train travelers can send an SMS to 139 to avail following services- PNR status enquiry, fare enquiry, train arrival or departure enquiry, accommodation availability, train time table enquiry etc. All of these services rely upon the existing mobile communication networks. If train commuters are travelling through mobile cell networks with low range, internet based services is of little use. Under emergency situations like flooding, earthquakes etc and in the absence of mobile networks, there is not a single service which can offer a reliable train station information details to the customers during their journey in the early morning hours or at night hours.

The proposed system employs broadcasting of station information from a unit at station to the unit in train engine wirelessly upon the entry of that train to a station. The engine unit then updates this information in the LED units at each coach in real time. The proposed system also contains a mobile application. The train code displayed in the display boards can be entered into the mobile application which in turn gives details about estimated arrival time of the destination station. The customer can also set alarms by entering the destination station name or code into the application.

Section II covers working of proposed system using RFID. In section III analysis of various feasibility issues related to integration of proposed system with the existing system is discussed. Cost effectiveness of RFID in our proposed system compared to GPS is evaluated in section IV. In section V brief discussion regarding implementation is provided.

II. PROPOSED INNOVATION

The proposed system employs Radio frequency identification wireless technology [9] and tracking system for updating railway station information from railway platform to the train engine and in turn transfers this information to the LED display boards at each coach in a wired fashion. RFID tags can be used for identifying products and objects uniquely. It contains an integrated chip, an antenna and a memory unit which stores information related to product's electronic product code [EPC]. A Radio frequency identification system consists of 3 parts: - scanning antenna, RFID reader (transceiver) for decoding data and a RFID tag (transponder) [4]. The purpose of scanning antenna part of RFID reader is to radiate RF signals to do two

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

things: One, a means of communicating with the RFID tag and two, it gives the RFID tag the necessary energy for communication.

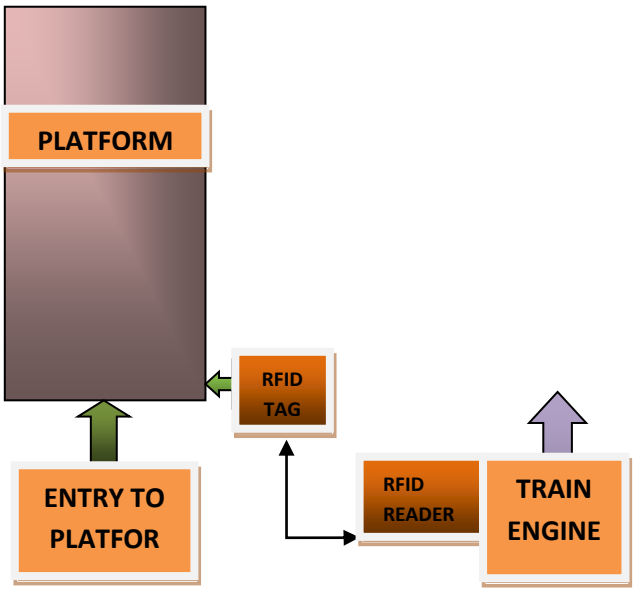

Fig-1: Basic Layout

Figure-1 shows the working our proposed system. The RFID tags installed at entry point of each station stores data related to the corresponding railway station known as "**station tags**". Station tags are the short form notation which uniquely identifies each station name similar to station notations currently used in IRCTC. The train's engine uses an RFID reader to read and track the RFID tags installed in the station. The reader then passes this station tag information to the corresponding coaches in real time. The tag installed at the stations contains details regarding the station name. The basic layout is shown in figure 1. The most optimal location to store RFID tag is at the entry of the platform as shown in figure 2.

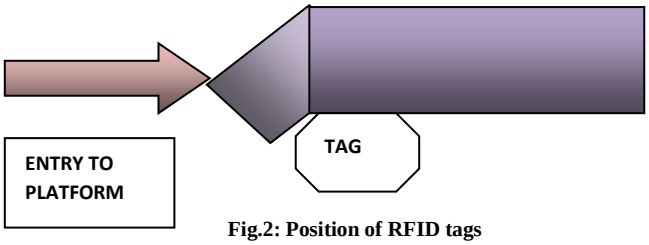

Fig.2: Position of RFID tags

The position of RFID tag (As shown in figure-2) below the entry position of platform is safe enough to protect it from rain water and it gives the optimal shortest distance to the train engine RFID reader. Figure-2 actually depicts the position of RFID tags in the entry point of each station that is below the edge of platform pavement. When the train engine approaches the platform, RFID tag passes through the field of the RFID reader's antenna and activates the RFID tag chip which in turn sends the data in its microchip to the RFID reader. The RFID tags receive their power from the magnetic field generated by the RFID reader in train engine through inductive coupling. Coupling elements of the RFID tag converts the received magnetic field and produces a current which powers the tag. The RFID reader will decode the received signal and send the decoded data to the LED boards in coaches in wired manner.

The main benefit of using RFID systems [11] is its non-contact and non line of sight nature. RFID tags works in various challenging scenarios at remarkable speeds with response time taking less than 100 milliseconds in most cases. It also functions through a variety of substances like fog, snow, paint and could be effective in other visually and environmentally challenging conditions.

WIFI hotspots within the train can provide connectivity with RFID reader so that commuters can obtain the real-time location details [1], [6]. The android application can be equipped with in-built algorithm for calculating the next station details, a machine learning algorithm for finding the expected destination time and other interesting features. Another add-on to the proposed system is using a handheld attachment connected to an android-based mobile device which gives more interesting real time information.

Passengers often wake up early in the morning in night trains due to uncertainty in knowing which railway station the train might have reached. Due to the sudden changes in the railway station it seems harder for a passenger to read a railway station board in a moving station. And passengers can't fully rely on wakeup call service 139 either due to uncertainty of waking up a person in deep sleep and other external noises.

The passenger's experience will get enhanced in trains if they can see which railway station has arrived or which one just passed by. In AC coaches [2 Tier, 3 Tier or Chair car], the visibility of railway station boards is poor in day time and much more difficult during night or early morning hours. The proposed system establishes a simple user friendly display system which gives commuters the necessary railway station details.

One of the enhancement for the proposed system is by creating an android application that can give commuters more information regarding next train information, expected destination time, next stop where food is available in addition to

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

alarm settings. For this enhancement, WIFI technology can be utilized.

III. FEASIBILITY OF IMPLEMENTATION OF THE PROPOSED INNOVATION

Radio frequency identification belongs to a family of Automatic identification and Data capture. RFID tags are simple to use and works very well even during bad weather conditions. It would be impossible to know the station details from AC coaches when it's raining. The RFID tags proposed is used in passive mode which does not require any power source like a battery and hence will remain usable for longer period of time. The power comes from induction method from the RFID reader in the train engine, i.e; the induction from RFID reader is filtered and rectified into DC for powering the tags. Once the RFID tag comes closer to RFID reader, the data in RFID tag's memory will be read by RFID reader. These RFID cards or tags costs about Rupees 50 and the size are analogous to size of a coin.

The RFID reader emits RF waves [5], [7] in ranges varying from few inches to 100 feet or more, depending upon the power output and RF used. The reader's RF waves creates electromagnetic field and if the RFID tag comes within the sphere of this field it gets activated and send the memory data to the RFID reader which in turn decode it and produces useful information.

Currently the railway employs LED display boards in coaches to display whether anyone currently occupied the toilet or not. This same system can be extended to display the current railway station just passed by. The non functional features are fully compatible with the existing system as the same type of contract can be extended to achieve this. The wiring operation can be made simpler by integrating the wiring with the connectivity mechanism already implemented from train engine to each coach for emergency braking system. The power requirement for the LED display is already implemented for toilet occupancy display board. For the start-up cost involves cost for readers, tags, software unit, wiring and display boards.

To integrate with the existing system, the RFID system should be properly tested and implemented. Hence time must be spent as a best practice approach before finalizing the kind of RFID tag to be employed. The hardware should be tested for potential pros and cons. Testing phase should utilize different types of tags after proper type of RFID reader and antenna is selected depending upon the range requirement.

Currently there is no such information system in any public transportation systems which employ RFID tagging methodology for passing station information to the commuter information boards. Presently in public buses the LED boards shows the next stop information.

IV. COST EFFECTIVENESS OF PROPOSED DESIGN

The cost of RDIF reader ranges from 300 to 1000. The setup cost involves cost for packaging the reader unit in engine, wiring to the respective coaches, LED display units per train and the control unit (software unit) which analyses and decodes the railway station information. Also it is expected that with more and more applications switching towards RFID technology both in commercial and industrial in near future the cost will reduce. The cost per unit of RFID tags will be reduced further if orders are in bulk.

GPS: GPS (Global positioning system) reader system [14] offers tracking of objects using a tracking device that obtains signals sent from GPS satellites. And these signals in turn used to view the real-time position of objects like car, busses etc and the digital screen is used for displaying the GPS data. The technology can triangulate the longitude, latitude, speed of the object and direction of movement. Nowadays GPS reading can be tracked using Internet or using mobile applications. The table [1] shows the comparison (relevant to the proposed system) of Passive RFID reading and GPS technology.

Table.1 Comparison of RFID and GPS [12]

KEY FACTORS	PASSIVE RFID TAGGING	GPS METHOD
Range	Limited	100% coverage on the planet
Power Requirement	Not power hungry	Power hungry
Cost	Cheap	Costly
Reliability	Consistency offered within the specified reading range	Accuracy not guaranteed always and may change due to obstacles like trees, buildings and extreme weather conditions
External Battery Source (During power failure)	Not required	Not always possible

The RFID technology offers so many advantages [11] compared to other information transfer systems. RFID technology provides longer operational life as it doesn't require external power source and the power is obtained in wireless mode. The usage of passive tags makes it easy to replace or maintain the tags. The cost of maintenance per passive tag is much lesser compared to active tags. The periodic maintenance can be conducted on the reader device in the train engine by checking the value read from a test RFID passive tag and

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

troubleshooting if any reading error occurs. The tags at the station can also be tested periodically by the same approach.

The main benefit of using RFID systems is its non-contact and non line of sight nature. RFID tags works in various challenging scenarios at remarkable speeds with response time taking less than 100 milliseconds in most cases. It also functions through a variety of substances like fog, snow, paint and could be effective in other visually and environmentally challenging conditions.

Few disadvantages of RFID [8] are discussed in this session. Reader collision occurs when the signals from two or more readers overlap. The tag is unable to respond to simultaneous queries. Systems must be carefully set up to avoid this problem. Few constrains anticipated during set-up phase is that the range should be properly calibrated for the proposed system by the hit and trail method. One of the constrain in using RF waves is the interference effect due to metal bodies. Tag misalignment, the presence of water in the vicinity of RFID reader system and the location selected for installing RFID tags poses some difficulties during reading phase.

V. IMPLEMENTATION

For the implementation purpose we used Raspberry Pi B processor (Fig.3), an RFID reader (based on 125 KHz frequency) and Python programming language. The proposed system can be integrated with mobile application or web based application. Another possible area of improvement is integrating with existing system of arrival or departure time prediction system. The program reads values ("Kottayam" and "Ernakulam") from 2 tags and compares with the stored database to find the station code (Fig.4). The station code can then be sent to the information boards installed in train coaches.

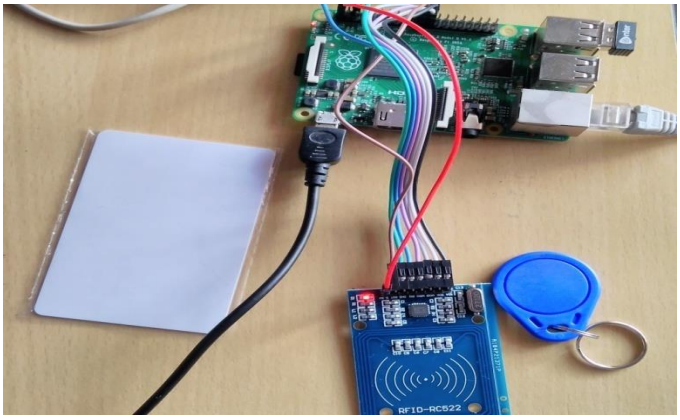

Fig. 3 Prototype: Raspberry Pi B processor with RFID reader

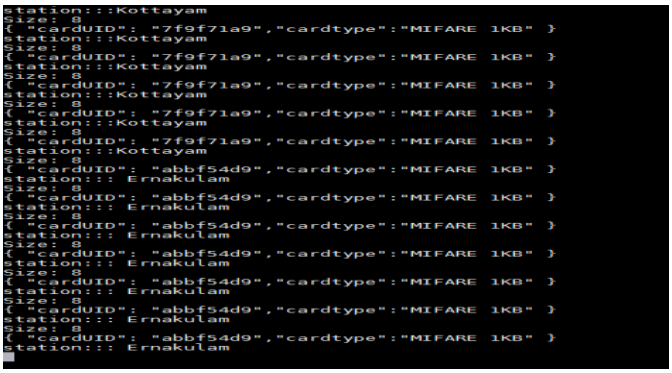

Fig. 4 RFID Reading with Python program

The proposed can be integrated with existing arrival or departure time prediction system like Rail Radar. Indian Railways has launched Rail Radar [13], a live train tracking service that runs on Google Maps. Available at http://railradar.trainenquiry.com/ the service allows you find out the exact location of a train. Trains that are running on time are displayed in blue and those running late are shown in red. Clicking on a train shows the status of the train, and also the route. [15] Active RFID tags give 100% accuracy but in our proposed system we are using Passive tags. The accuracy of Passive tags depends upon environmental factors and metallic interferences at the time of reading. In ideal or optimal reading scenarios the accuracy is 99%.

VI. CONCLUSION

There is immense opportunity for RFID technology yet to be tapped in real world applications like real-time monitoring of logistics, real-time status value extractions of wireless sensors etc. The proposed work gave us in depth insight into the possibilities of RFID technology [10] in solving one of the important problems faced among train commuters in India. The same system can be applied flawlessly in other public modes of transportation especially in tier-1 and tier-2 cities.

VII. FUTURE SCOPE

The proposed system reduces the cost of implementation in public transportation bus's location access systems. The RFID technology along with an offline mobile application can be used in tourism sector. Tourist's locations and national museums can install RFID tags and provide an application so that they will get useful information.

Acknowledgement: We thank Management, Principal and Head of the Department-CSE & IT of Adi Shankara Institute of Engineering and Technology for giving permission to access database of college's vehicle monitoring system. We would like to extend our sincere thanks to all staff coordinators of Data

***Abstract*— The newest favorable technology which supplies to the customer end data amenities at a high speed is the Worldwide Interoperability for Microwaves Access (WiMAX). By witnessing the foundation of the WiMAX physical layer a thought has been excellently attained concerning the system of WiMAX. The foundation improving the BER vs. SNR variation using the Firefly algorithm has been discussed in this paper using MATLAB (R2013b) simulator. The studies and research of the students and scholars are based on the meadow of WiMAX can use this model as a helpful reserve. The reimbursements of using Firefly algorithm in a WiMAX system have been depicted in this paper.**

Keywords— Orthogonal Frequency Division Multiplexing (OFDM), FA(Firefly Algorithm), Wide Area Ntwork(WAN).

I. INTRODUCTION

The showground of telecommunication has a blowup demand of a superior set of amenities, for instance, immediate messaging, video conferencing, or any other kind of communication provision. New technologies are settled for the attainment of high data rates with the hundreds of persons demanding to get entree at an analogous tower. WiMAX (Worldwide Interoperability for Microwave Access) is an encouraging elucidation or a technology conveying digital Broadband Wireless Access (BWA) with augmented rapidity and distance that marks it underneath the Fourth Generation (4G) of expertise [1].

Expansion of the WiMAX was completed by IEEE (Institute of Electrical and Electronics Engineers), a society that mechanisms for the educational and technical origination in innumerable castigations. IEEE 802.16 was the profitable standardization of the WiMAX family for which a group in June 2001 was molded baptized as WiMAX Forum. A wireless auxiliary to cables, DSL, and fiber providing much-advanced bandwidth over the corresponding reportage areas. Another headway in the clan of wireless communication is the forefront version of WiMAX, commonly known as WiMAX 2+ that can exert in amalgamation with LTE (Long Term Evolution) [2]. It is also from time to time termed as MAN (Metropolitan Area Network) interrelating the operators in a geographical section proposing resourceful interconnection to a Wide Area Network (WAN) [3].

Two groups of WiMAX have been volunteered to discourse the supplication of dissimilar types of access. IEEE802.16-2004 is the first version of WiMAX also designated as Fixed WiMAX intended for fixed applications from its base stations. It is centered upon the two standards specifically ETSI HiperMAN (High-Performance Radio Metropolitan Area Network) in addition to IEEE 802.16 agreeing global deployment. It encompasses the usage of 256 carriers Orthogonal Frequency Division Multiplexing (OFDM) and the profiles aimed at compliance testing. This version has its provision expanding to both line-of-sight and non-line-of-sight provinces providing a bit rate ranging from 32 Mbps to 134 Mbps. The second version or the modification i.e. IEEE 802.16e provisions mobile applications [4, 5]. This standard reinforced a lower bit rate of 15 Mbps while providing access in the non-line-of-sight domain. It enabled full nomadic besides mobile users organized with roaming and handoff [6].

In the existence of noise, WiMAX writhes from stark enactment deprivation. In the literature, plentiful approaches have been offered to correct channel noise either in the time domain otherwise in the frequency domain. In previous papers, numerous computational intelligence techniques have been used that does not deliver a better result, here the proposed technique is utilized to deliver an improved result in comparisons to already implemented intelligence technique. For such circumstances, the proposed method in this paper i.e. the firefly algorithm is appropriate wherever performance is very authoritative although the computational cost is less indispensable [7-10].

The result is amended by the application of the firefly algorithm in the MATLAB (R2013b) simulator. The numerous iterations will be evaluated and the finest possible result retains the objective of entire operation i.e. improvement of SNR and BER in CODED-OFDM based WiMAX System by the application of FA [10, 11].

Section II of the paper describes the literature survey and while section III describes problem statement and Section IV provides specifics about the system model. Section V describes the simulation results and Section VI describes the Conclusion.

II. RELATED WORK

In [1] the model construction of the WiMAX physical layer and the enactment valuation for real-time audio data communication in WiMAX using convolution coding has been discussed. BER performance of the signal communicated over the AWGN channel is improved in the WiMAX system by the use of convolution coding. In [5] authors emphases on examining significant QoS parameters in the WiMAX system. Results showed that an optimum WiMAX network should have very a small value of delay and packet plummeted, while high values of throughput. In [6] WiMAX know-how, its simple conceptions, uses, and advantages/disadvantages are studied. Operation of the WiMAX system is corroborated under numerous channels in addition to modulation systems. The graph amongst SNR and BER for performance exploration has been drawn. In [10] discussion is made about various security problems in each version of the WiMAX system. The handling of the security problems and basic evolution of the technology has also been deliberated. The various solutions to tackle such security issues have also been proposed. Basically, a light has been thrown on the security issues and related solutions in the WiMAX system. Under the security's umbrella numerous authentication, access control in addition to encryption technologies fall. After the clearance of all the problems related to security, this broadband technology plays a major role as a future technology of wireless communication. In [29] Non-linear design problems solution by utilizing the newly developed Firefly Algorithm has been shown in this paper. As compared to solutions obtained in the literature previously, FA performs better for an optimization related standard pressure vessel design optimization. Nonlinear design optimization is successfully optimized using the Firefly Algorithm. Some standard test functions were used to validate the algorithms. Unconstrained stochastic functions were solved using the FA after new test functions are designed utilizing the singularity and stochastic components.

III. PROBLEM STATEMENT

WiMAX network lacks quality service because there are hundreds of people trying to get access at the same tower accompanied by various environmental factors like distraction, diffraction, etc. due to this maintaining high SNR and low BER becomes difficult. Hence an efficient technique i.e. Firefly algorithm has been amalgamated with the WiMAX system for the improvement of signal to noise ratio (SNR), bit error rate (BER).

IV. PROPOSED ALGORITHM

The Firefly Algorithm was advanced on the foundation of the idealized behavior of the fireflies and their flashing characteristics.

As per the following three rules, the flashing characteristics are idealized as:

- Regardless of the sex, each firefly is attracted to other fireflies as all fireflies are unisex.
- For any two flashing fireflies, towards the brighter one, the less bright firefly moves since attractiveness and brightness are proportional to each other. Both attractiveness and brightness reduce as their distance upsurges as the attractiveness is proportional to the brightness. A firefly will randomly move in case of non-existence of a brighter firefly.
- The objective function's landscape helps to determine the firefly's brightness or light intensity [11-13].

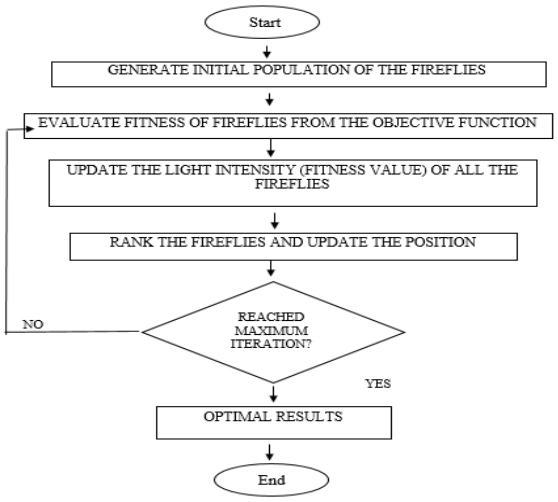

Fig. 1 Flowchart of the Proposed Algorithm

V. SYSTEM MODEL

Following are the steps to be followed in building up the system model in the MATLAB (R2013b) simulator.

A. Assumption and Configuration

Create the input environment with Length of FFT= 256, length of cyclic prefix= 256/8 =32, modulation size =64, 128, and 256, system bandwidth= 20 MHz, null subcarriers (guard and dc) =368, pilot subcarrier= 560, data subcarriers=1120, subchannels = 30, subcarrier spacing =10.93 KHz, guard time=11.4 us, symbol time= 91.4 us, OFDM symbol duration=102.8 us, number of OFDM symbols in 5ms frame=48.

B. Steps followed in model building

1) Signal generation for Transmission

Generate random data that is further passed through various processes such as interleaving, forward error correction, and modulation. Now, implement the subchannelization and frame generation process. Convert the signal to time samples and add the cyclic prefix to it.

2) Signal transmission

Now the message signals are transmitted through the AWGN channel.

3) Improved performance

Convert the signal to frequency samples and remove the cyclic prefix from it. Now the signals are demodulated and decoded. Necessary random data is now obtained. Computational

intelligence technique (i.e. firefly algorithm) is used for the improvement of signal to noise ratio and bit error rate.

4) Necessary computation and comparison

Measure the values of signal to noise ratio and bit error rate after the implementation of the Firefly algorithm using the following formulas.

- Signal to noise ratio= ratio of signal power to the noise power.
- Bit error rate= the number of bit errors divided by the total number of transferred bits throughout a studied time interval.

5) Comparison

Compare the base paper result with proposed results of performance improvement in CODED-OFDM based WiMAX system.

VI. SIMULATION RESULTS

Various results and comparison of proposed results with existing technique result in terms of SNR and BER in MATLAB (R2013b) simulator have been shown in this section.

A. Variation of BER vs. SNR using different modulation techniques

In table 1 and figure 2, it is observed that from the comparison of different modulation techniques and their performance against BER versus SNR results show that 256 QAM performs best (hence also termed as proposed results in next sub-section).

TABLE 1 shows the comparison of BER and SNR for different modulation techniques

	16-QAM		128-QAM		256-QAM	
S.NO	**BER**	**SNR**	**BER**	**SNR**	**BER**	**SNR**
1.	.000299	11.1	.000298	11.3	.000301	11.2
2.	.000296	11.76	.000295	11.8	.000299	13
3.	.000273	13.01	.000289	13.25	.000288	15.1
4.	.000262	13.7	.000278	13.86	.000267	17.2
5.	.0002557	14.0	.000257	14.9	.000250	18.7
6.	.000200	14.9	.000222	16.4	.000216	19.45
7.	.000187	15.01	.000212	16.7	.000200	19.87

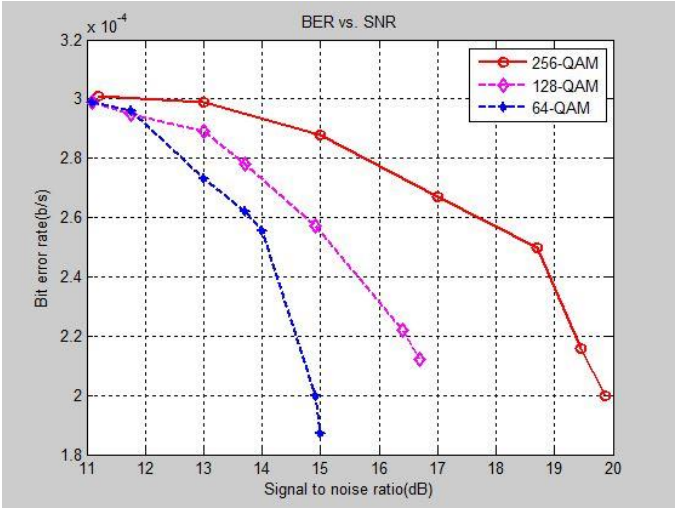

Fig. 2 Variation of BER vs. SNR for 64-QAM, 128-QAM, and 256-QAM

B. Variation of BER vs. SNR for the existing and proposed results

In table 2 and figure 3, it is observed that from the comparison of existing results and proposed results using Firefly algorithm and their performance against BER versus SNR results show that WiMAX system performs best with Firefly algorithm.

TABLE 2 shows the comparison of BER and SNR for existing and proposed results

	EXISTING-RESULTS		PROPOSED-RESULTS	
S.NO	**BER**	**SNR**	**BER**	**SNR**
1.	.000298	11.1	.000301	11.2
2.	.000289	11.76	.000299	13
3.	.000270	13.01	.000288	15.1
4.	.000254	13.7	.000267	17.2
5.	.000244	14.2	.000250	18.7
6.	.00021	14.4	.000216	19.45
7.	.00019	14.7	.000200	19.87

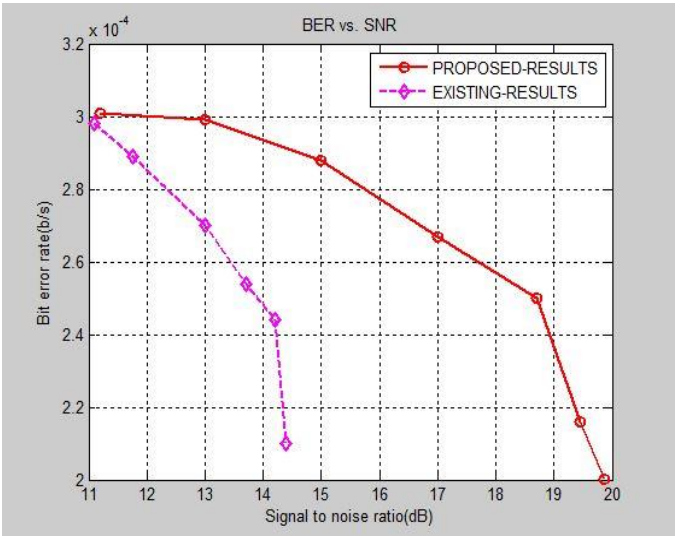

Fig. 3 Variation of BER vs. SNR for existing and proposed results

VII. CONCLUSION

In the noise presence, WiMAX wriggles from stark enactment deprivation. In the collected works, plentiful approaches have been presented to spot-on channel noise either in the time domain or else in the frequency domain. In previous papers, several computational intelligence techniques have been used that does not make available a better result, here the proposed technique is used to provide better upshot in comparisons to previously implemented intelligence technique. For the circumstances, the proposed system is appropriate wherever performance is very authoritative even though the computational cost is less vital.

The result is improved by the application of the firefly algorithm. The numerous iterations are evaluated and the best possible result preserves the objective of the entire operation i.e. improvement of SNR and BER in WiMAX System by the use of FA.

***Abstract*—Plant growth monitoring and plant protection are the key elements in the plant production industry. These factors influence the quality and productivity of the plant and its yields. Diseases are the major factor that vitiates the plant health. More often they harm plant parts like fruit, flower, leaf or stem, but quite often the severity of diseases may even result in plant death. In recent years, computer vision techniques, machine learning algorithms, and deep learning models have gained importance due to their capability of dealing with complex data with precision. These techniques are well known for pattern recognition and classification problems. Therefore in this work, a multilayer convolutional neural network is proposed for the classification of diseased plant leaf images. The real-time images of four different plants in healthy and diseased condition are collected for validating the performance of the proposed model. Results, when compared with other methods, shows the higher classification accuracy of the proposed model.**

Keywords—Computer vision, Convolutional neural network, Deep learning, Image classification, Plant pathology.

I. INTRODUCTION

The plant growth monitoring and plant protection are the key concepts for agriculture. The production from a field is completely depended on how healthy is the plant being evolved. This in turns further imitates on the quality and quantity of the plant yields. There are several factors responsible for influencing the plant health, some of them are soil type, moisture level, humidity level, nutrient content, weed, and diseases, etc. Among them, plant disease is the major factor that decreases plant production. These diseases can occur in any part of the plants including stem, flowers, fruits, leaves, stem, etc. More often a severe loss to the plants is observed when a disease is diagnosed in the plant leaves. Since leaves are the main source of producing food for the plants, therefore, entire plant life is depended on them. There is the number of factors responsible for affecting the plant health, but majorly those are categorized among two known as abiotic factors and biotic factors. The abiotic factor is the non-living entities that include temperature, humidity, climate, etc. whereas biotic factors are the living organisms that include fungus, bacteria, or virus. We cannot countermeasure the environmental factors but on the other hand, while espousing suitable mechanisms abiotic factors can be counter-measured [1]-[3].

Generally, the conventional way of diagnosing a disease from the plant is done with the help of an expert. The samples of the plant have been gathered and observations have been made based on both physical and laboratory investigations. The functional part of these systems requires an expert known to be a plant pathologist to make decisions and also physical intervention. Usually, this entire process is time-consuming and often ends up with a high cost [3], [4]. With the increasing demand for food production, it has become essential to adopt some real-time and automated measures to overcome the old-fashioned means of diagnosing plant diseases.

Computer vision methodologies have been used in the number of applications for pattern recognition, classification, object segmentation, etc. Images and image processing techniques are to the core for all the computer vision applications. They play a key role in

storing and analyzing the useful and important information from a scene. Nowadays, it has been observed that a number of methods based on Machine Learning (ML) and Deep Learning (DL) has been used for processing an image. These methods are known for their capability of handling complex images and also for their higher accuracy. Deep learning models are the subpart of machine learning well well-known for their layered structures. These networks simulate the conventional artificial neural networks that map the functional capability to simulate the thinking process of the human brain [5], [6]. These networks are unsupervised in nature generally compromised of the stack of layers over one another. Deep learning is also termed as deep neural networks or convolutional neural network having the capacity of learning from unstructured data [7], [8]. In recent years, deep neural networks have been extensively used for the purpose of classification.

Therefore, in this study, we present a deep neural network for the classification of healthy and diseased leaves images [9]. The real-time images of the leaf have been acquired for this purpose. This dataset compromises of both the healthy and diseased leaf images. The images are then labeled for their classes. Then the entire dataset is divided among training and testing datasets. Three cross fold strategy has been adopted to validate the performance of our proposed multilayer convolutional neural network. The network is first trained with the help of the training database and then the trained model is then validated with the help of testing database for its accuracy. Finally, the results of the proposed model have been compared with other methods for its classification accuracy.

The rest of the article is organized as in section 2 literature related to a disease classification using deep learning has been presented, followed by proposed work in section 3, section 4 presents the details of the multilayer convolutional neural network, followed by results in section 5, finally, section 6 concludes this article followed by references.

II. LITERATURE REVIEW

The various studies related to deep learning have been done and summarized in this part. Edna Chebet Too et al. in [1] have studied the deep learning models named as VGG 16, Inception V4, ResNet, and DenseNets for the plant disease classification. They have broadly presented the fine-tuning and evaluation methodology of these dense layer architectures. The results were validated on the images taken from plantVillage dataset. Shanwen Zhang et al. in [4] have proposed a global pooling dilated convolutional neural network (GPDCNN) for the classification of cucumber plant leaf disease. The presented model also combines the benefits of dilated convolution and global pooling. The model was validated for six different cucumber plant leaf diseases. Among DenseNets has obtained higher classification accuracy. S. Lakshmi and R. Sivakumar in [10] have worked with the artificial neural network and convolutional neural network for the classification of algae disease from the images. In [11] Yuan Yuan et al. have used the concept of transfer learning by utilizing the two-deep networks named as AlexNet and VGGNet for the classification of diseases from the plant images. Eight different kinds of crop diseases were considered for this work. The images were acquired from the plantVillage image dataset. In [12] Artzai Picon et al. have presented an adapted Deep Residual Neural Network-based algorithm for the classification of different diseases. The authors have acquired about 8178 images from the two sites located in Spain and Germany. Konstantinos P. Ferentinos in [13] has used a convolutional neural network for the classification of leaf images among healthy and diseased. For this purpose, the images were selected from the open data repository of about 87848 images with 25 different plants. Focusing on the different diseases of the Grape leave images named as Esca, Black rot and Chlorosis, P. Goncharov et al in [14] have present a deep learning architecture. This research is primarily focused on the classification of diseases and the protection of plant from those diseases.

With the help of the convolutional neural network, K. R. Aravind et al. in [15] have classified three disease form the grape leave images. For this purpose, the authors have used the AlexNet model that is validated with the help of 4063 images taken from the plantVillage dataset. Yang Lu et al. in [16] have presented a deep convolutional neural network for the classification and diagnosis of ten different diseases from the rice leaf images. For this purpose, the 500 images are acquired in the real-time conditions. The proposed work is validated for ten cross strategy for its accuracy. Qiaokang Liang et al. in [18] have proposed a deep network named as Plant Disease Diagnosis and Severity Estimation Network (PD^2SENet) for the classification of diseases from the plant leaf images. This works simultaneously for the diagnosis and

severity of the diseases occurring in the plant. A three-channel convolutional neural network (TCCNN) is proposed by Shanwen Zhang et al. in [19] for the classification of the diseases from the vegetable leaf images. Aravind Krishnaswamy Rangarajan et al. in [20] have used two deep learning models named as AlexNet and VGG16 net for the classification of leaf images among healthy and diseased. The tomato leaf images were taken from the plantVillage leaf image dataset categorized among seven classes. With the capability of learning from the unstructured data, deep learning model has proven to play a significant part in the diagnosis of the diseases from the plant images. So, in this work, we present a study for the classification of plant leaf images among diseased and healthy.

III. PROPOSED WORK

The flowchart for the proposed work is given in Figure 1. At first, our primary focus is on the acquisition of the database. This has been carried out at Shri Mata Vaishno Devi, University, Katra, 182320, India. We have acquired images of 4 different plants containing both healthy and diseased images. Then the collected images are labeled and divided among training dataset and the testing dataset in the ratio 70:30. The proposed multilayer convolutional neural network is the trained with the help of training dataset. After this, the trained MCNN model is then validated for the classification of leaves. Finally, the images are classified among diseased and non-diseased leaf images.

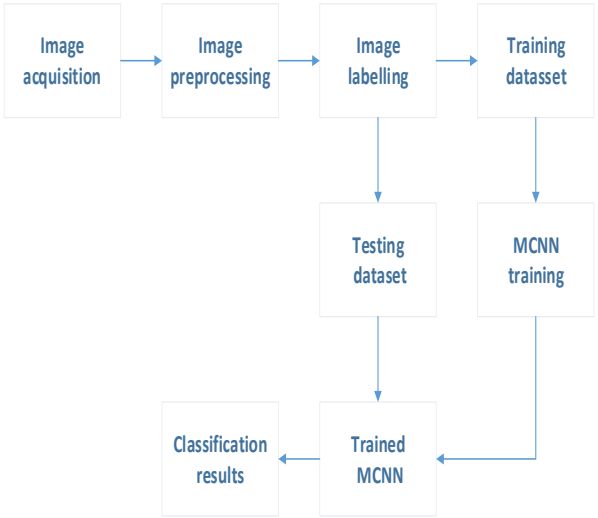

Figure 1. Flowchart for the proposed work

IV. MULTILAYER CONVOLUTIONAL NEURAL NETWORK (MCNN)

Deep learning models are similar in learning capabilities to the conventional artificial neural network. These models are well known for their capability of solving complex problems with higher accuracy. There are a number of deep learning model available like GoogLeNet, AlexNet, ResNet, VggNet etc. These models are varied based on their configuration details like the number of units, their depth, the learning algorithm, etc. These models generally have a layered architecture stacked over one another. More often depending on the complexity of the problems the number of layers namely Convolution layer, Max-pooling layer, Fully-connected layer can be varied to the desired accuracy of the result. This is an important feature of the deep learning model. However, the deeper is structure the more complex is to handle it. This also increases the computational overhead of the network. Deep models are also known for their requirement of a high amount of data to give superior results [9].

For this work, we have proposed a simple convolutional neural network that is inspired by the AlexNet model. The figure 2 shows the architecture of our proposed network. It consists of 6 convolutional layers each followed by ReLU, 3 Max-pooling layers, a flatten, and 2 fully-connected layer, where the last layer acts as an output layer consist of the Softmax activation function. The training of CNN has been performed with the help of BPA or SGD [9]. The various configuration details of the model have been illustrated in Table I.

TABLE I. MCNN CONFIGURATION DETAILS

No. of Convolutional layers	6 with 3×3 filter
No of Max-pooling layers	3 with 2×2 filter
No. of Fully-connected layers	2
Dropout rate	0.2 to 0.5

V. RESULTS

The training was accomplished on the GPU of an NVIDIA GTX1080 card using the CUDA platform. This process has been completed in about two and a half days. The proposed model has validated on about 1345 images collected for four different plants. Some of the sample images are given in Figure 3. The entire collected images are being first labeled and then divided among two sets in the ratio 70:30. The class labeling for different plant images is given in Table II. The network is trained for three cross-validations i.e. first to classify the given image is of plant leaf or not, second is to classify the given image is the healthy image, and third is to classify the image is the diseased image. The training is accomplished using the 70% images of the database. The result was evaluated using the classification accuracy for the training of the network as well. The average training accuracy of the proposed model is found to be 98.58%. Then the trained network is tested for its accuracy using the testing database. The testing of the network is completed in within six minutes. The classification results of the proposed model are also compared with the other methods. Table III shows the higher classification accuracy of the proposed network.

TABLE II. LABELLING OF IMAGES

Plant name	Healthy class	Diseases class
Arjun	P00	P10
Alstonia	P01	P11
Mango	P02	P12
Sukh chain	P03	P13

Figure 3. Samples images of Arjun, Alstonia, Mango, and Sukh chain plants

TABLE III. RESULTS FOR DIFFERENT METHODS

Algorithms	PSO	SVM	RBFNN	MCNN
Accuracy	87.96	91.57	95.21	98.24
Missing report rate	12.04	8.43	4.79	1.76
False report rate	8.23	5.54	2.36	0

Finally, for the proposed work a number of challenges have been encountered. Most of them are related to the acquisition of the database. The images, when captured in the real environment, are appeared with the number of noises with them. Some of them

include the illumination, temperature, overlapping of leaves, and background details. The proposed CNN performs better under such unavoidable conditions. But, in the future, the model can be more deepen to further overcome the vulnerabilities present in the images.

VI. CONCLUSION AND FUTURE WORK

Plants are important for nature and as well as equally important for the living being. They are the essential part as they provide us with food, shelter, medicine and many more. Plants are also get affected by the diseases and the disorders as the human being does. So in this regard, some appropriate, timely, and accurate methods are to be adopted for suitable plant growth monitoring and plant protection. Therefore in this work, we have proposed a multilayer convolutional neural network for the classification of diseased plant leaf images. The results were validated on the database acquired for four different plant leave images categorized among healthy and diseased. The proposed model with 98.24% achieves higher classification accuracy when compared with the other state of the methods. In the future, the presented model can be further enhanced for the classification of different plant leave and diseases.

***Abstract*—Cooperative communication in MANETs has grow to be an interesting area, as it perk up system efficiency but still lacks system design. Cooperative routing method includes route discovery, reply, enhancement and data forwarding resulting in mobility conflict and path enhancement. Hosts are typically battery operated, path selection method takes keen on energy utilization, harvesting ability and link break probability to establish suitable path across the network . Using data stored in Cooperative Table and Relay Table we suggest a new Trusted Constructive-Relay-based Cooperative Routing (TCRCPR) protocol with trust inference framework, which provides trust assessment along with results in novel TCRCPR . A new path selection method incorporate route metric value from MAC layer as remaining energy, EH(energy harvest) ability and generally entire network performance is enhanced comparatively and appreciably. Network layer frame unambiguously cover cooperative trusted path discovery, trusted path reply, trusted path improvement and trusted data forwarding. Hence this structure results in efficient throughput lower packet delay ratio, packet control, less energy consumption and secured data transmission and hence can be incorporated by means of existing lower layer mechanisms and can provided great efficiency in performance of MANETs.**

Index Terms—cooperative communication, trust based routing protocol, trust framework, reliability, mobile ad hoc network

I. INTRODUCTION

Mobile ad hoc networks (MANETs) were designed for environment which are co operative and are self-configuring, infrastructure-less network connected wirelessly having features such as frequent change in topology, weak physical protection, no centralized administration, limited bandwidth, limited operating range and high dependence on intrinsic node cooperation which exchange information while there is no central authority and fixed infrastructure. The lack of communications in MANETs makes reliability an issue and data transmission over multi-hop in the occurrence of malicious hosts. Few more issues faced by MANETs are repeated link breaks caused due to mobility along with fast tiredness of energy cause of restricted battery also impacting on the flexibility in MANETs. MANETs are mainly vulnerable to various kinds of routing attack occurred internally [13].It also faces some intrinsic challenge when compared with traditional wireless networks. Earlier proposed routing protocols for ad-hoc networks were ineffective handling attacks.

In paper work, a novel routing protocol called "CRCPR" based on cooperative communication is studied further to support MANETs. By exploring cooperative communication through trust evaluation and available information, energy consumption during transmission is bargained and decreased. Further implementing relay theory based on a Relay Table, [6] TCRCPR introduced offer huge efficiency by providing secure data transmission, trusted path discovered and great robustness adjacent to node mobility by inducing link breaks. Route selecting method selects new route and make use of Route matrix value from Physical/MAC layer as remaining energy [7], EH capability and determine ultimate route by link break probability significantly affect network performance. CRCPR proposes to select new route for assortment mechanism considering energy consumption, energy harvesting, and link break probability that helps determining an appropriate route across a network.

Even after having so many advantages of cooperative communication, there are still some issues in systematically designing in this routing scheme include route discovery, reply, enhancement of path, data forwarding, mobility resistance facilitated, and path selection both effecting energy factors and has less efficiency and performance is also less. TCRCPR remove the mobility concern via self supervision, relay data forwarding and provides secure trusted communicating path between source and destination .There is legacy on association amid participant to attain desired functionalities, with above proposed concept we propose a novel objective that is trust inference structure, which performs assessment plus prediction. The procedure of host trust evaluation based on nodes previous behaviors. To

increase the reliability of data delivery trust establishment scheme which is in Hermes[1], which allow source node to direct data under "trustworthy" with midway nodes. In this design, every host will be assigned"trustworthiness" [3] to its neighbor hosts based over how data is forwarded by analyzing continuous observations. The theory of trust-worthiness runs on conception of "opinion" which hosts in a network have on one other. Then using trusted data sequence info the SCGM (1, 1)-weighted Markov stochastic chain measure predicts trust for upcoming decisions [3]. In this paper we propose a fresh trusted routing protocol with CRCPR to increase the trust, performance, security and efficiency. All simulation result from ns2 tool are shown in the result section. Also a final point, investigational outcome are subjected to convince presented idea via concluding routing valuations.

II.RELATED WORK

A. Energy Efficient Cooperative Routing

Recently, research interest on cooperative communication for efficiency has increased in [11]. Author address orderly approach for evaluating obtainable scheme in cooperative communication. To deal with this concern, the existing routing algorithm for energy efficient cooperative routing algorithm is proposed. Focusing on the transmit set collection strategy, that has huge impact on energy reduction and performance of schemes compared and notional investigation and obtain three theorems to initiate energy efficient cooperative routing.

In paper,[12] a study on cooperative routing for complementary the division of energy amid nodes done. By introduce new method for routing cooperative relay hosts are assigned power for transmission and equilibrium the left over energy amid adjoining nodes to make the most of the lifetime of the set of connections. Targets the systematically cooperative scheme [10] finding the best multiple hop transmission strategy in such a network where we determine hosts implicated in each hop, is a extremely significant trouble to overcome this problem control observation are available at each and every node which describe information organization[11].

In [6] study, the intellect light-weight trust-based routing protocol Intrusion Detection System (IDS) use trust each host posses for other, restricted computational supply needed. In paper,[14] proposed has light weight proactive source routing (PSR) protocol maintaining additional network data compared to distance vector (DV) routes to starting place routing, though it have minor operating cost compared with conventional protocols.

B .Trust Efficiency

In (MANETs), basic start node always depends on supplementary nodes for promoting data packets scheduled multi-hop path to sink. Security with reliability is big issue addressed in ad hoc atmosphere. In this research paper proposed a scheme for trust establishment in MANETs aim provide trustworthiness of data packet forwarded over multiple hop route [1]. Using a Bayesian framework, every node are provided a "trustworthiness" value to neighbor node forming opinion for packet forwarding behavior by direct observation based on trustworthiness value evaluated in network. Opinion metric is implemented to ad hoc routing protocols for getting dependable packet liberation later presented consequences reveal the efficiency of the trust concern design. Many schemes for security are proposed in MANETs to identifying malicious nodes with mean behaviors like packet reducing, alteration, and misrouting on cooperation amongst the host .In paper, [5]proposed defines trust-based detection algorithm factoring in a node's status for MANETs. The algorithm provides less communication overhead with node distributed.

III. TRUST BASED COPERATIVE ROUTING

TCRCPR is a routing protocol which is similar to cooperative protocol that is reactive in nature to built path during transmission and does not maintain any table but proactive routing maintain local table for each data transmission and any modification in network topology updates for betterment.

From a variety of routing scheme for MANETs dynamically routing having been discussed in [2] such as cooperative communication and dynamic routing for energy saving CRCPR[2] is over looked again for betterment of routing with mobility of nodes to decreased energy consumption provide reliability and increase performance.

TCRCPR provides efficient cooperative routing with trust format includes cooperative trusted route discovery, route reply, trusted path enhancement, trusted path selection, and trusted cooperative data forwarding. Further, finds a novel path on basis of energy utilization, EH, and link break probability therefore contributes for cost-effectiveness, energy consumption and **b**etter performance ensuing since mobility-induced frequent link break.

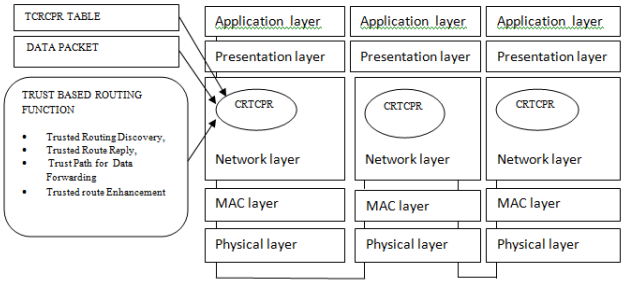

Fig. 1. TCRCPR Structure

Fig. 1 illustrate Cooperative trust frame. It is one tiny sub layer acting without affecting inside the network layer .
It support regular IP traffic, one hop and multi hop ad hoc mobile communication. TCRCPR framework is similar to that of CRCPR frame work its just that trust inference is added to improve efficiency. TCRCPR has three parts:

1) CRCPR tables: the COP Table(cooperative table) with trust, Relay Table, and Cooperative trusted Neighbor Table.
2) Control packets: Trusted Cooperative Hello packet, Trusted Cooperative Route Request Packet, Trusted Cooperative Route Reply Packet, and Trusted Cooperative Confirm Packet.
3) Trust Routing function: Trusted Route Discovery, Trusted Route Reply, Trusted Path Enhancement, and Cooperative Data Forwarding.

A. Neighbor detection

Neighbor discovery is the major role in routing data packet. Many protocols for adhoc networks, includes localization and routing. When neighbor discovery fails, protocols performance decreases. In networks there will be 'N ' no of nodes in which malicious nodes will also be present which can bring down the entire network.

In paper,[2] we present Trust Based Multicast Routing protocol used in network where each node acts as smart agent. Also each agent poses capability of estimate neighbor node trust and select one trusted path for routing of packets.

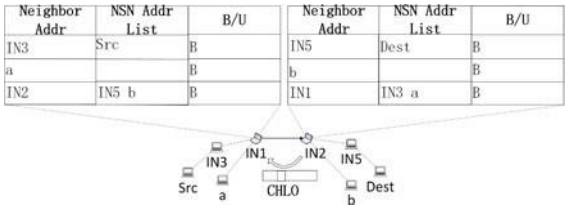

Fig. 2. Cooperative Trusted Neighbor Table Creation.

But once the frame work start working and network established neighbor address tables are created intelligently using algorithm COP possibility detection [2].By using data transformation info as shown in Fig.2 cooperative neighbor table is built with new column added NSN Addr List field and Broadcast/Unicast field[2].

For a topology with more than four nodes Fig.3 it is very difficult for the algorithm to generate and preserve topology but performance will be promising in terms of reduced frequent link break and saving energy but creation and maintenances of algorithm of this kind of topology is very complex. In dynamic MANETs designing and accomplishment of such algorithm is not realistic.

Further, easy results in easy understanding of subordinate layer means for cooperative communication and frame management challenges are studied fully for cooperative communication. Besides, COP topologies know how to coexist with the MANET's .This provide chance to increase performance and save energy, results in forcefulness. Here each node forward data by selecting a trustable entry by broadcasting data packet to there neighbor node and observing time interval of data transmission. The main idea is to detect if any malicious node found in the topology. Ratio of no of packet correctly forwarded to that of number of packets expected in a given time interval[9]defines historical observation .Behavior of node during forwarding of packets are monitored which is required to follow hence consistently data forwarding takes place and the packet are received by the intended node. When a node performs suspiciously value of attributes reduces.

Hence causes packet loss or packet tampering and noted as there was a malicious behavior in the network and mark its entry in COP table.

In detail Host in the network initially receive first data packet is considered as source which has been initialized to value 1 and the intermediary Nodes (INs) will be allotted in table with traveling time from previous node. In the beginning before trusted COP source forwards data, it selects appropriate route by referring to trust attribute value from built COP Table list and packets are placed. Then these packets are sent to all available neighbor routes soon after notifying them to be ready to transmit data via Cooperative (C) nodes. Then, once COP Table is established across the topology data starts forwarding with genuine routes.

Cooperative Network also includes some participants who remain quite are never disturbed until triggered using the COP Table once data is c onfirmed.

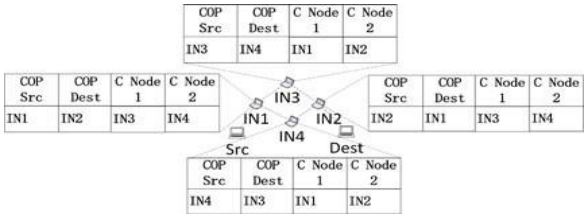

Fig. 3. COP table creation.

Relay Table Creation: As soon as the table Fig.3 is rationalized by the packet, every IN runs the COP algorithm [2] new fill in takes place in COP table and all the reliable entries are obtained and rest entries are deleted as invalid entries. If the neighbor still remains even after the entry in the table is deleted relay table is built. If the entry is deleted but path still stay in the topology then its referred as malicious.

B. Trust-Based Route Discovery and Reply

During data transmission a node is required to route packets to a target, therefore it broadcast demanded packet for search for a path across MANETs. A novel request handling idea of trust based path handling has been implemented and intended to let cooperative topology info to route packets toward destination.This handling is similar to AODV topology. In this COP topology, intermediate node once receives a request packet it immediately finds upstream host of previous hop performs "last hop replacement," where to get closer to COP Des and to decrease the sum hops in the absolute route it replace previous hops IP address through its own IP address within packet IP list. Further with the help of C nodes final route in the topology is selected and this outcome effective point-to-point association of link transversely contained by the COP topology. This not only throw in to saving energy but also improve the robustness cause even if any C host (node) go far from COP topology, a Relay Table is preserved association among

Source and Sink. Additional COP topologies draw, in the ultimate path, then it will lead to huge robustness and increase energy savings. Elaborating more with trusted route discovery and route reply to confirm genuine route:

1.The new fields are added with packets called RPT-Reverse Path Trust RT-Required trust. RPT is calculated using path trust equation [3] .The minimum value of trust flow between the intermediate nodes to reach destination is used and as source does not have any previous node its value is fixed and initialized to one.

2.In Packet Forwarding Strategy ahead getting a data packet from host .The later hop neighbor say 'x' check if it has no route to the previous node then route entry is created stored node ID for backward tracing .

3. Trust value calculated between 'x' and previous node. If obtained RPT value is greater than RT then it's kept in wait state else packet will be discarded. Nodes keep checking if the packets received are same by the receiver if yes understood as lower hop count else goes into wait state in the mean time 'x' node may receive other copies if values as well from other nodes where again step 3 is conceded out . If host 'x' have suitable path to recipient(s) in the table it created and unicast packet to previous nodes else again step 2 carried out. 3. New Fields added here additional fields introduced control package.

1.The Forward Path Trust (FPT) field indicates minimum constant item for consumption of trust data has conceded in the path reply time, also initialized to value 1.

2. The recently added field Required Trust (RT) has the similar denotation.

3. The Reverse Path Trust (RPT) field position to min value obtains from packets and last hop indicated to the multicast receiver.

Once data reached multicast receiver Table Packet Forwarding Strategy is done by intermediate nodes which includes once after packet reaches multicast receiver it calculates trust value previous hop(s). A broadcast packet table created to its neighbors. Intermediate node say '*xm'* receive packet from node 'x*n'*, next node ID is cross checked to see whether its entries matches with its own ID if not from backward learning node recognizes it is malicious.

Now FTP assessment over written to minimum and if this value satisfy the trust condition then host '*xm*' broadcasts its matched entries in the table. If packet forwarding crowd receive numerous packet entries with dissimilar FPT ideals minimum FPT value is selected by the source from packet received. This procedure constructs two-way trusted path starting sources to receivers and vice versa hence trusted packet delivery done.

C. Trusted Path

Path trust represent data will be forwarded from routing path which is used.

$$PathTrust_{sd} = \min_{\substack{s \le m \le d-1 \\ k=m+1}} \{ \bar{TV}_{mk} \}$$

Where *xs* represents a sender, *XD* receiver, *xm* and *xk* are two neighboring nodes on path, and x_m-> x_k indicates that x_k is the next hop of x_m. When control packet are received node tend to, update essential routing records in routing table accordingly.

1. Path Trust Update: Here PTU includes Source Address address of source node, Update Address includes node ID with trust estimation of a given node, Change Address a node with behavior change recorded here and Update Trust Value in control packet. Consider x_k as next node of x_j, then trust of node x_k evaluated by x_j over two succeeding time intervals is bigger or equivalent to the trust revise threshold ζ, host x_j generate PTU. If observed host ought to be no lesser than trust constraint for packet broadcast.

First of all, node x_j looks route set '*X' in* i.e considered as next hop for node there now x_j becomes x_k next node becomes transmitting node where as next node that x_k is not the node needed this info is updated there for trust is node and its path.

Subsequent, PTU data is put on air by x_j for one hop to save energy. Further whichever node getting this data look in favor of the path set 'Y' where later hop x_j, and next hop of x_j is x_k in routing table. Appropriate neighbors update routing info. After execution source node refreshed by node x_j it unicasts a PTU packet using packet table forwarding. Finally route reliance (trust) updated and decided either to employ the novel trail is not.

2. Path Hand-off Procedure is a way to find alternate route when trust value of an exacting node becomes inferior to needed trust constraint for packet broadcast. Initially, host x_m following confirm that host x_k is a unfriendly host , its takes care of path hand-off procedure and informs the downstream node x_j should stop forwarding packets to node x_k then routing entries are also deleted from routing table. Routing entries of x_k is deleted by x_m and again re-transmission takes place for next neighbor node.

Once after receiving packet, again each neighbor will build and unicasts packet to its next. If no route is known packets simple broad casting and specify there is no next hop available and malicious. This is entered in table and flag set done. Until a new efficient trusted path is recognize this redundancy is enough to set up alternate trusted route.

D. Route Enhancement

In this section we discuss about those routing path which do exist in routing table but not in neighbor table this kind of route are deleted. C nodes created between the source and destination nodes will enhance the routing of packets where neighbor association among C host in COP Table along with the Relay Table is enhanced by the unicast scheme when some unwanted routes not present in neighbor table are removed. Therefore both broadcast and unicast are considered valid. Both this casting confirms subsequently hop legitimacy. And hence increase chance of finding valid reliable route. This unicast design flows as follows when a host receive a data from its C hosts it unicasts this to further C host or spread to neighbor. To make use of improved neighbor connections in communication of packets increases overall path robustness.

E. Data Forwarding

Once after final path for data transmission refer Fig.5 is confirmed before data is about to send there are three ways contributing in trust based constructive data forwarding normal manner is executed only when next hop address matches of its own, cooperative manner C nodes starts sending data cooperatively with trust to destination which is alike the "Usual form for Cooperative Communication"[10].

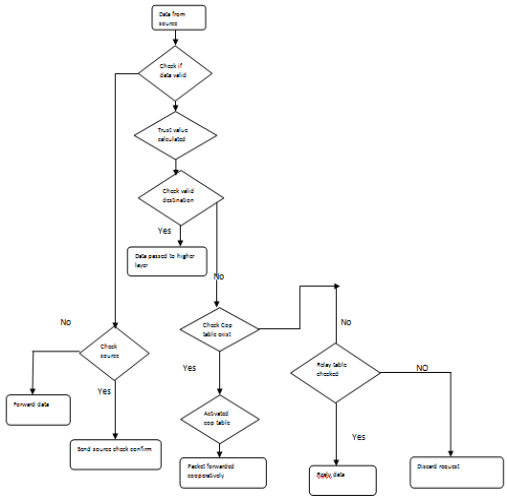

Fig. 4. Flowchart of data forwarding in TCRCPR.

F. Route Selection Criteria

In TCRCPR, to obtain the ultimate path with maximum performance coefficient *Q*, we require info distinct in [2].

1) Energy Harvest Degree*:*

$$H_i = C_e\left(-e^{\frac{-K_1}{n}}+1\right). \qquad (1)$$

From (1), Node *i* has energy harvest degree with stable values of '*n'* associated to energy translation effectiveness C_e and energy harvest involvement K_i, where K_i is determined by battery capability C_{ai}.

Generally it's fixed for all devices. R_i as energy accumulation rate is different.

$$K_i = \frac{R_i}{C_{a_i}}. \qquad (2)$$

2) Real-Time Residual Energy Degree

$$E_i = \left(-e^{-E_i^r(1+H_i)/n_1}+1\right)^{n_2}. \qquad (3)$$

$E_{r\,real}$- time remaining energy of node *i* and $E_r \geq 0$.

H_i Energy harvests degree. n_1 and n_2 are the stable ideals.

Equation (3) guarantee Ei is contained by the range [0, 1].

3) Energy Drain Rate Coefficient

Reveal the power consuming rate of each host. Even if single host has outstanding energy, its life span will be extended even if it has more energy intense rate.

$$a_i = \begin{cases} 1, & \frac{R_i}{E_i} < R_{\text{thr}} \\ 0.1, & \frac{R_i}{E_i} \geq R_{\text{thr}} \end{cases} \qquad (4)$$

$$R_i = \frac{1}{N-1}\sum_{k=i-N+1}^{l} R_k(t). \qquad (5)$$

Therefore, a_i (energy drain rate coefficient) used in ultimate path selection scheme eliminate node with high energy drain rate.

4) Link Break Degree Li make use of reflected stability of each connection, which is evaluated using.

$$L_i = \frac{1}{\left(1+e^{-10(p_i-p_0)}\right)} \qquad (6)$$

where p_i is the diverse link probabilities in TCRCPR, selected factors makes our ultimate chosen path more secure.

5) Link Break Probability for TCRCPR, p_i has of three diverse link break probabilities a normal link p_n two host converse with every one other directly, COP link p_c (i.e., a link between IN1 and IN2) an separate COP link p_{nc} (i.e., a link do not survive among IN1 and IN2). Where *pn=p (7)*

$$P(L_{dotted}) = 1-(1-pn)\,2 = 2p-p2 \qquad (8)$$
$$P(L_{solid}) = pn = p \qquad (9)$$
$$P(L_{dashed}) = 1-(1-pn)\,2 = 2p-p2 \qquad (10)$$

Here the dotted "link" for unconnected COP link L_{dotted}, solid "link" L_{solid} and also dashed "link" L_{dashed}.

IV. SIMULATION RESULTS WITH COMPARISION

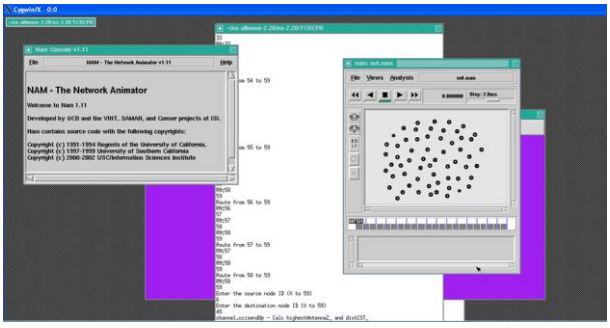

Fig. 5. Topology of MANET nodes

According to the experiment, several advantages of the design have been proved in this result. First, with Trusted Cooperative Neighbor Table, COP Table, and Relay Table stored in the help of topological data structure has helped to improve the performance of the CRCPR greatly. Second, security issue also has solve to great extend with the help of building trust among the neighbor which has reduced control overhead by detecting malicious node with the trust value and excluding them without affecting overall network performance while routing the packets and packet loss also reduced with genuine node transformation and resulted in higher through

put comparatively . Third, the liveliness factor (EH and ER) when choosing the finishing path, the network duration is extended actually.

V. Conclusion and Future Work

In this work, we focus on a routing protocol called "CRCPR" based on cooperative communication to supports MANETs which are dynamically reconfigurable. By exploring this communication more adoptable by using information structure, energy utilization during transmissions can be radically decreased. Further introduced CRCPR [07] deals with node mobility issue robustness is providing flexibility from induced link breaks by using relay principle but still lacks in efficiency. This paper presents Trust based Routing Protocol in MANETs which takes trust idea to provide trusted routing protocol. The concept CRCPR incorporates with Trust to increase the efficiency of energy consumption providing effectiveness by allowing nodes to act as smart agent. Where agent has the ability to estimate the trust of neighbor and selects a trusted route for data transmission with trust assessment and hence achieving reliability, robustness and increase in performance and lower energy consumption with TCRCPR. In future work, deep study on trusted strategy can be done majorly focusing on security levels that can be provided to make the topology more secure and in turn enhance performance.

Abstract— following research paper presents hybrid photovoltaic array (PVA), Solid oxide fuel cell (SOFC) and generation network having some related to MPPT, Availability of Sun irradiance, PV String failure & Shadow effect on PV Panel. Solid Oxide Fuel Cell [SOFC] generates electricity directly by electro chemical process. Here SOFC model will generate electricity whenever Solar power fails to generate electricity according to grid code due to switching harmonics. This proposed system increases the Reliability of local distribution system. This proposed hybrid Solar plus SOFC model will sure help in Smart grid implementation. In this paper we have implemented complete three -phase PV with IC MPPT Controller SOFC hybrid generating power system in MATLAB Software.

Keywords— Maximum power point tracking (MPPT), PV, Solid oxide fuel cell (SOFC), Power quality (PQ), Total voltage harmonic distortion (THD).

I. INTRODUCTION

Recent research and development towards finding alternate generation sources has encouraged exploration of non-conventional energy sources in order to meet growing load demand, decentralised generation has remarkable advantages duo to locally available non-conventional sources of energy[1,4]. Electricity can be obtained explicitly by PV system. Aside these energy sources like PV and wind are stochastic in back up unit to assure uninterrupted power supply. Current harmonics, unbalanced liner loads, reactive power and excessive neutral current are among the sole factors responsible for power quality at distribution end [6].

PV cell is one unit of PV array. Several PV cells can be connected in series or parallel combination to develop PV module as shown in Fig.1. They may be assembled to make panels[2,13]. BP MSX 60 PV Module having two parallel string with 18 cells in one string is used as basic unit of model. PV panel modelling describe in section II with Boost converter and Incremental conductance MPPT [3].

It is feasible to employ PV in coordination with fuel cell to meet variable load demands for either utility or stand-alone application [10, 14]. Non-linear power electronic (PE) loads insert high harmonic components in figure of non-sinusoidal current/voltage and need to be forced to improve supply quality at user end actively.

Together as a hybrid power supply system as solar ia intermittent in nature, SOFC and battery will provide back up when solar generation is reduced. In this way combined operation of sources will improve the reliability of supply to consumers. These sources provide DC power output, which may be converted in to AC supply for AC loads. This conversion is done by PWM inverters at particular frequency power System.

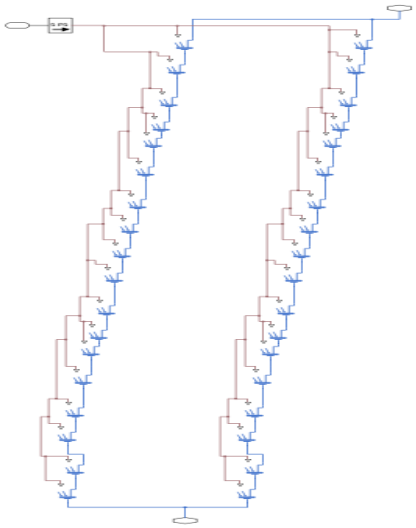

Fig. 1. Photovoltaic panels

Further Solid oxide fuel cell mathematical modelling [9,11,12], MATLAB Simulink model is described in section-III. In the section-IV Hybrid PV & SOFC Simulink Model is proposed, whose schematic is depicted in Fig.2. The Simulink output load voltage waveform with time reference shows the reliability of proposed system. Three phase filter, pulse width modulation (PWM) based voltage source inverter (VSI) [8, 15], SOFC and incremental conductance (IC) MPPT based Controller are the main highlights of the proposed system.

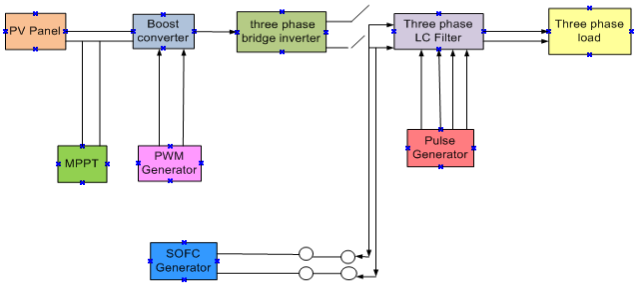

Fig. 2. Block diagram of three phase isolated (PV+SOFC) hybrid generating power system.

II. SOLID OXIDE FUEL CELL MODELLING

PV panel output depends upon the irradiations received on its surface. Sun light is not available equally and moreover different environmental condition may break the

process of PV panel, hence voltage output is not fully guaranteed. This makes the system unreliable in terms of output voltage available at boost converter end. Thus, to enhance the reliability of the system SOFC is added here. Assumptions in SOFC modelling are all gases having deal state, temperature invariant so that Nernst's equation applies. Simulink architecture is shown in Fig. 3.

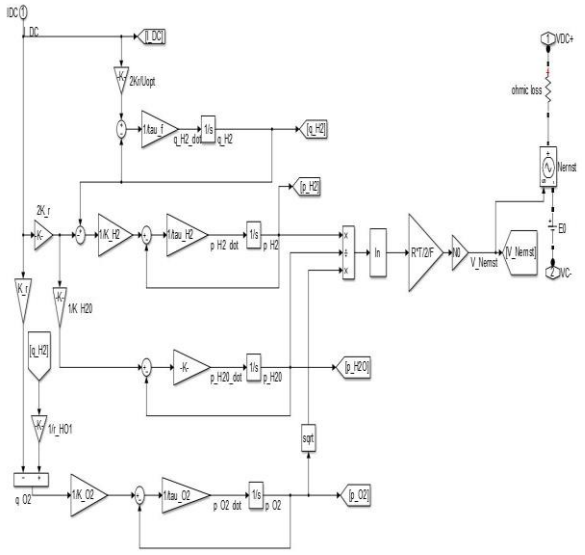

Fig. 3. Simulink model of solid oxide fuel cell (SOFC)

SOFC is based on electro-chemical properties and Nernst Equation (9) which is described from equation (4) to (6).

$$E = N_o\left\{E_o + \frac{RT}{2F}\ln\left(\frac{P_{H_2}\sqrt{po_2}}{p_{H_2o}}\right)\right\} \quad (1)$$

$$P_{H_2}(s) = \frac{1/K_{H_2}}{1+\tau_{H_2}s}\left(q_{H_2}^{in} - 2K_r I_{fc}\right) \quad (2)$$

$$P_{H_2}(s) = \frac{1/K_{H_2o}}{1+\tau_{H_2o}s}\left(2K_r I_{fc}\right) \quad (3)$$

$$P_{o_2}(s) = \frac{1/K_{H_2o}}{1+\tau_{o_2}s}\left(q_{o_2}^{in} - 2K_r I_{fc}\right) \quad (4)$$

$$sq_{H_2}(s) = \left(q_{H_2}^{out} - q_{H_2}^{in}\right)\frac{1}{\tau f} \quad (5)$$

$$q_{H_2}^{in} = \frac{q^r H_2}{uf} = \frac{2K_r Ifc}{uf} \quad (6)$$

Where :-

U_f =fuel uutilization factor

q_r = Molar flow rate

Kr = No/4F is constant

$r_{OH} = \frac{q_{H_2}^{in}}{q_{O_2}^{in}}$ = Hhydrogen to oxygen flow rate

I_{fc} = Fuel cell stack current

$p_{H_2}, p_{H_2O}, p_{O_2}$ = Hydrogen, Water & Oxygen pressure

The SOFC mathematical model parameters values used in MATLAB is illustrated in Table 1.

TABLE 1 SOFC parameters details

Parameter	Detail	Value
T	Absolute Temperature	1273 K
I_FC_0	Primary Current	100 A
F	Faraday Constant	96.487e-6
R	Universal Gas Constant	8314
Eo	Standard Potential	1.18 V
No	Series Cells	525
Umax	Maximum Utilization Factor	0.9
Umin	Minimum Utilization Factor	0.8
Uf	Utilization Factor	0.85
K_{H2}	Hydrogen valve Molar Constant	8.43 e-4
K_{H2O}	Water Valve Molar Constant	2.81 e-4
K_{O2}	Oxygen Valve Molar Constant	2.52 e-3
τ_{H2}	Hydrogen Response Time	26.1 sec
τ_{H2O}	Water Response Time	78.3 sec
τ_{O2}	Oxygen Response Time	2.91 sec
R_{ohm}	Ohmic Loss Per Cell	3.2813e-4
τ_e	Electrical Response Time	5 sec
r_{HO}	Hydrogen to Oxygen Ratio	1.145

III. SOLAR INVERTER MODELLING

Equivalent circuit of the PV cell contains a current source, diode, shunt resistance and a series resistance. Solar cell equivalent circuit is shown in Fig. 4.

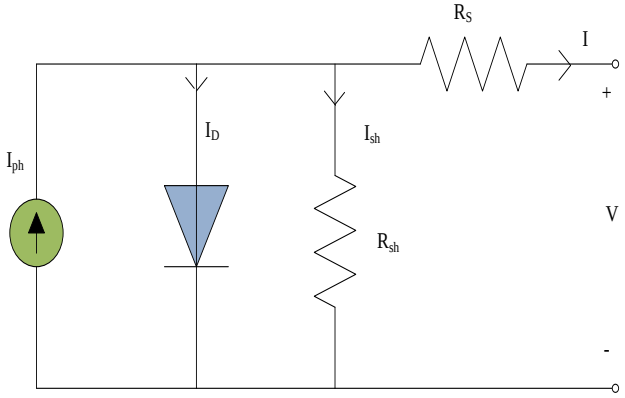

Fig. 4. PV cell network.

$$I = I_{pv,cell} - I_{0,cell}[\exp\left(\frac{qv}{\alpha kT}\right) - 1] \quad (7)$$

Where,

$I_{pv,\,cell}$ = Iincident light current

I_d = Shockley diode equation

$I_{o,\,cell}$ = Reverse saturation current

q = Electron charge

k = Boltzmann constant

T = Temperature

R_p = P-N junction resistance due to leakage current

R_s = Contact resistance of semi-conductor layers

In Two stage Solar inverter, PV power produced by PV Panel here is optimized by IC MPPT with boost controller which work on basis of switch duty cycle, boost converter amplifies applied input PV array voltage. To obtain maximum power, duty cycle of switch is controlled by MPPT in proposed work. Calculations for inductor and capacitor value are calculated as follows:

$$L = \frac{Edc\alpha}{Fs\nabla I} \quad (8)$$

$$C \geq \frac{Eo\alpha}{Fs\nabla V} \quad (9)$$

$$\alpha = \frac{Eo - Edc}{Eo} \quad (10)$$

IV. THREE-PHASE INVERTER

The three-phase VSI square wave inverter as described can be applied to create balanced three-phase AC voltages with fundamental supply frequency.

However 5^{th}, 7^{th} and other odd multiples fundamental frequency voltages distort the output voltage not desirable at all. VSI based on MOSFETs switch is explained in Fig.5.

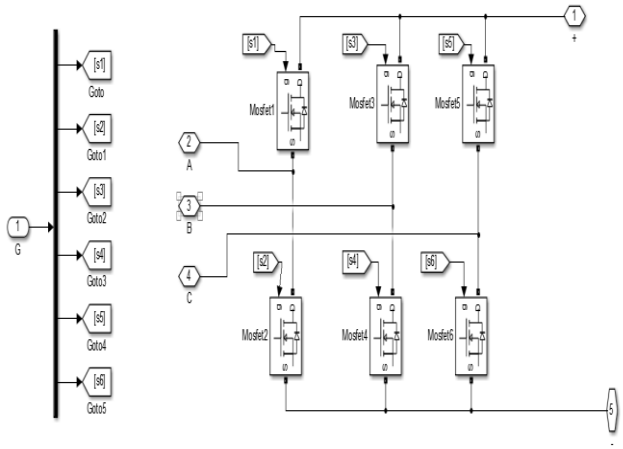

Fig. 5. Basic diagram of three phase VSI invertrer.

Distributed generation is now utilized more and more in world with aim to integrate renewable electrical energy sources into traditional electrical energy power system.

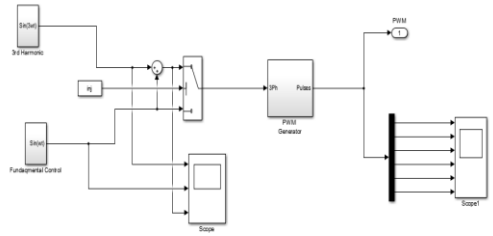

Fig. 6. Three phase PWM inverter module.

Normally, energy sources utilized in DG are linked to a DC-bus, while utility grids work with alternating current (AC). Therefore to merge such energy into grid it is needed to use power electronic converters (PEC), it is applied to step-up the alternative energies voltage, convert DC to AC and for synchronization with utility grid. So, VSI is mostly applied to convert DC-AC signal.

Passive filter system is applied to manage priority of power quality improvement using L_C filter. This system is given away in Fig.7.

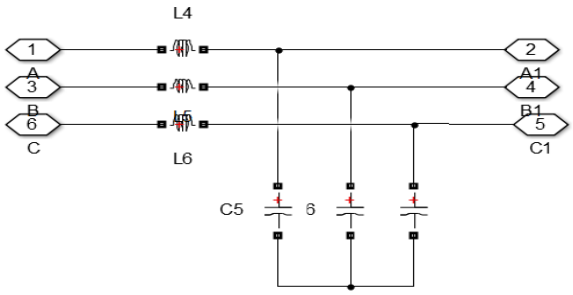

Fig. 7. Performance of three phase filter.

V. PROPOSED THREE PHASE HYBRID MODEL

Here our main aim is reliable power system for smart grid implementation which is realized by means of high speed DC circuit breaker. Operation of these circuit breaker is based on time signal. Through above methodology we connect solar inverter and SOFC in hybrid mode to overcome deficiencies of solar power. Generally, to get connection with grid it requires filter. Thus most common exercised passive filters are inductor (L), capacitor(C) and pi (π) LCL filter.

Active power filter(APF) is also a solution for harmonics. It detects electric current/voltage of nonlinear load and injects a compensation of electrical signal to compensate components that feds to grid.

The filter voltage, current, frequency and overall power handling are affected by designing of particular device or circuitry. The variable DC signal output of a photovoltaic (PV) panel is converted into a fundamental frequency alternating current (AC) using solar inverter.

The proposed hybrid Simulink model of single phase isolated (PV+SOFC) generating power system is examined in Fig.8.

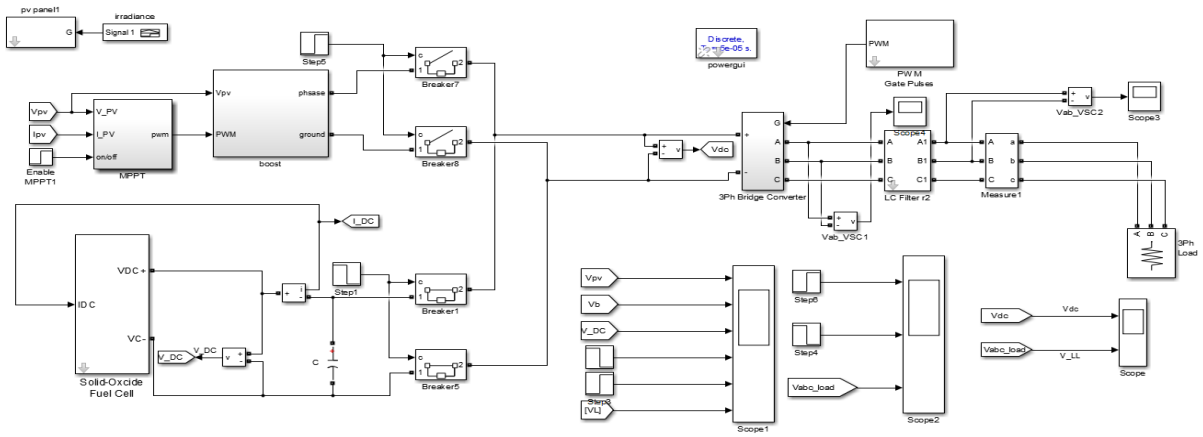

Fig. 8. Matlab Schematic 1 of Proposed 3-Phase Isolated (PV+SOFC) Hybrid Generating Power System.

VI. SIMULINK RESULTS

As per parameters describe in Table 1 results are obtained with Simulink model PV+SOFC for supply quality in distribution system energy sources. These are illustrated Fig. 9 to Fig.14.

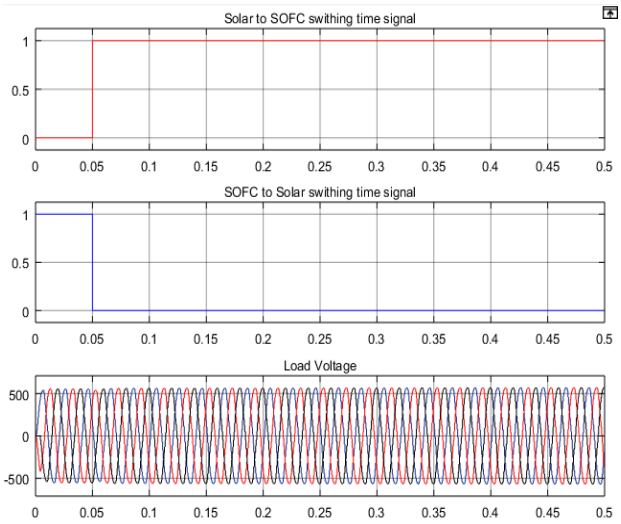

Fig. 9. System load voltage waveform with time signal of three phase isolated (PV+SOFC) hybrid generating power.

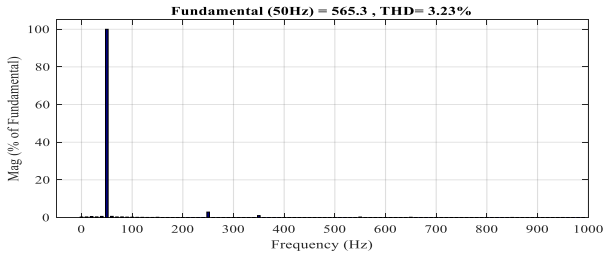

Fig. 10. THD_v (Total voltage harmonic distortion) with LC filter

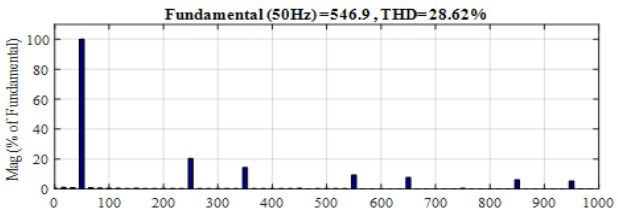

Fig. 11. THD (Total voltage harmonic distortion) without LC filter.

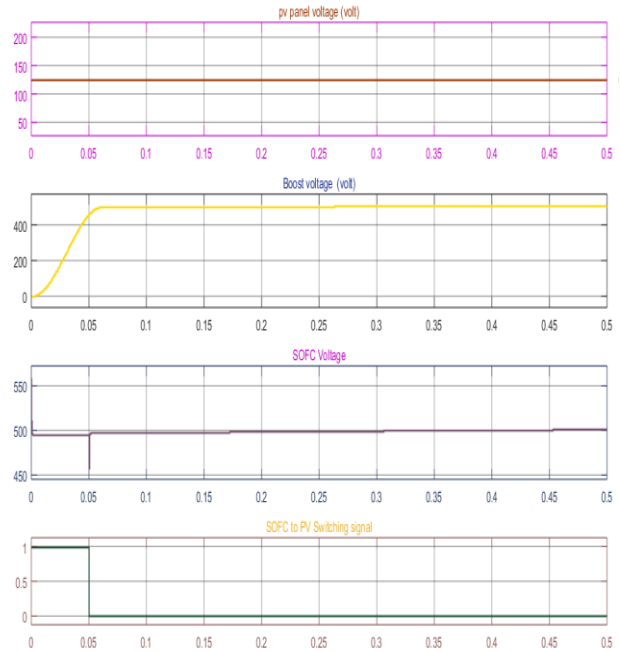

Fig. 12. Voltages at different stages of model and switching signal.

Load voltage waveform and time signals having simulation time period 0.2 second above model is shown in Fig.4. From simulated waveforms it is clear that we has achieved a reliable three-phase hybrid PV+ SOFC generating power system.

VII. CONCLUSION

Hybrid PV+SOFC (photo voltaic + solid oxide fuel cell) three phase isolated power system model is implemented in MATLAB 2015 Simulink software. Complete load waveform shows improved reliability of distribution system. The implemented hybrid model practically suitable for local distribution system, agriculture, multi buildings societies etc. Total voltage harmonic distortion with LC filter at fundamental frequency (50Hz) with level of voltage 565.3V is 3.23% and without LC filter is 28.62%. Pulse width modulation is including and filtering is also include performance analysis three phase PV (photovoltaic) and MPPT (maximum power point tracking) Controller.

***Abstract*—Automatic emotion recognition using computer vision is significant for many real-world applications like photo-journalism, virtual reality, sign language recognition, and Human Robot Interaction (HRI) etc., Psychological research findings advocate that humans depend on the collective visual conduits of face and body to comprehend human emotional behaviour. Plethora of studies have been done to analyse human emotions using facial expressions, EEG signals and speech etc., Most of the work done was based on single modality. Our objective is to efficiently integrate emotions recognized from facial expressions and upper body pose of humans using images. Our work on bimodal emotion recognition provides the benefits of the accuracy of both the modalities.**

Keywords—facial emotion recognition, body gestures,bimodal emotion recognition,feature-level, hog feature, SVM.

I. INTRODUCTION

The world of computing has changed over last 40 years. In the recent years technology has developed where 3D gestures are used in television, smartphones and PC for Human Computer Interaction (HCI). Universal gesture recognition market size is increasing at a fast pace and global annual rate is predicted to expand at 22.2% by 2025 [1].

In the present-day context of interactive and intelligent computing, an efficient HCI is of utmost importance. Emotion and gesture recognition can be coined as an approach in this direction.

Emotions are conscious expressions categorized by powerful cerebral activity and a firm intensity of pleasure or displeasure. Humans direct their emotional state through several conduits: facial expression, speech, and body gesticulations etc., The process of identifying emotions from facial expressions is called Facial Emotion Recognition (FER). There are 7 basic emotions: disgust, anger, fear, neutral, surprise, sad, and happy.

Gestures can be described as any non-verbal communication that is expressed to communicate a particular message. In the epoch of gesture recognition, a gesture is well-described as any corporal body movement, that can be understood by a motion sensor. Recognizing gesture is the capability of a computer to comprehend gestures and accomplish commands based on those gestures. Gesture recognition systems finds applications in several interesting areas: Lie detection, Distance learning, photojournalism, tutoring system and biometrics etc.,

In this work, a feature-level fused bimodal emotion recognition model is proposed based on two different modalities: facial expressions and upper body gestures.

The remaining sections of the paper are systematized as follows: Section 2 brief the literature surveyed for this work. In Section 3 dataset description is specified. Phases in emotion recognition are detailed in Section 4. In Section 5, experiment and results are discussed. Finally, the last section includes conclusion and future works.

II. LITERATURE REVIEW

For human behavior understanding and HCI, facial emotion recognition has gained interest of several researchers. Emotion recognition has attracted researchers in computer vision from mid 1970s. Several methods for emotion recognition from images and videos have been proposed by researchers since 1990. Recognition of emotion from facial expression is researched thoroughly in past few decades but emotion recognition from body gesture is a challenging task. An emotion recognition system has 3 main components: face/body detection, feature extraction and classification. The literature survey focuses on the several methods that have been developed for the aforementioned modules.

According to [2] the admixture of facial expression and body gesture overpower all other channels in making judgements about human expressive behavior. This work reflects the combination of the two channels at feature and output level to achieve better recognition rate. For extracting facial features, skin segmentation and histogram equalization are applied followed by feature extraction for body using segmentation and bounding box methods. 94.02 % accuracy was achieved by using BayesNet classification algorithm for feature-level fusion.
Some of the works support the fusion of more than one channel and better results are obtained as compared to single channel. In [3], speech, gestures, and facial expressions are used and overall performance of 78.3% was achieved at feature-level fusion. For feature extraction from facial expression, and body gesture, MPEG 4 FAPs and EyeWeb platform are used respectively. Intensity, pitch, silence length, and MFCC are the features extracted from speech.

Other modalities are facial expressions and physiological signals. For facial expressions, features are extracted using Lucas-Kanade algorithm and 5 physiological signals are extracted using PROCOMP Infiniti system [4]. SVM classifier has been used. A novel fusion of depth and inertial sensor data for hand gesture recognition has been proposed in [5]. The authors have used Kinect SDK and wireless inertial sensor for data collection and Hidden Markov Model (HMM) for classification. Overall recognition of 93% was achieved.

There are various existing technologies for gesture recognition like radar, and image-based gesture recognition etc., [6]. The authors in [7] presented a detailed survey on techniques used in image based emotional body gesture recognition. A survey of gesture recognition illustrating numerous methods and tools for gesture recognition like HMM, FSM, soft computing and connectionist approach are discussed in [8].

Hand gestures can be recognized using accelerometer and IMU [9]. A real-time emotion recognition using Raspberry Pi is illustrated in [10] where emotions are recognized using active appearance model and Adaboost classifier for embedded system applications. The authors in [11] proposed real-time FER using images with pose, age variations, and illumination using CMU-MultiPIE database and an in-house developed Amrita Emotion Database (AED). Apart from images, emotions can be recognized from videos using several techniques and

Fig. 1 shows some of the images from Amrita Emotion Dataset-2

authors [12] proposed method for the same using curves and surface normal.

In all the above previous works, it is shown that the fusing two modalities or data from two modalities results in improved accuracy. Combination of upper half of body and facial expressions in emotion recognition is an emerging area of research and we have proposed a method for the same. The two modalities will complement each other and are expected to provide efficient recognition of emotions in case of ambiguity or if the subject is not expressive in one of the modalities.

III. DATASET

Several databases are available for emotion recognition from facial expressions like CMU-MultiPIE, BU3DFE, BU4DFE, and CK+ [13-15]. Databases for emotion recognition using both body gestures and facial expressions are not openly available. So, we developed an in-house "Amrita Emotion Database-2" (AED-2). The age group of the subjects are 20-25. There are 3 females and 6 males posed for 7 basic emotions (disgust, anger,

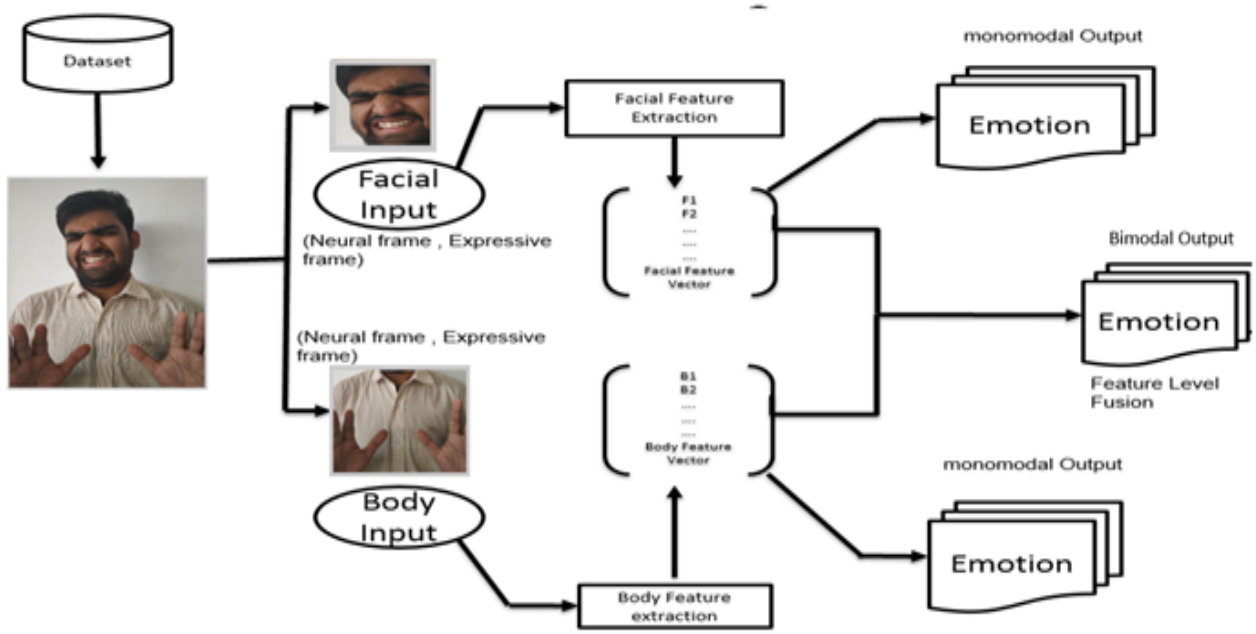

Fig.2 Overview of the proposed method.

happy, fear, sad, neutral and surprise). Fig.1. shows sample of images from AED-2. The dataset contains a total of 100 images.

IV. Implementation

A. Proposed Method

In this work, we have proposed 2 approaches for emotion recognition. An overview of the proposed method is shown in fig.2. In the first approach, emotions are recognized from facial expressions and upper body gesticulations independently. In the second approach the extracted features from facial part and upper body part are combined together to recognize emotion.

The rationale in proposing two approaches is to evaluate and analyse the accuracies of both the approaches and to choose the optimal emotion recognized in case of ambiguities in the expressions in any of the modalities. The ambiguity may arise when the subject express different emotions using facial expression and upper body part. For example, facial expression may give happy and body parts may express surprise. In this case, the combined feature extraction approach will recognize correct emotion. In other cases, the emotion recognized will be the same using first approach.

The basic steps in emotion recognition are image pre-processing, feature extraction & selection and classification. All these phases are discussed in detail in this section.

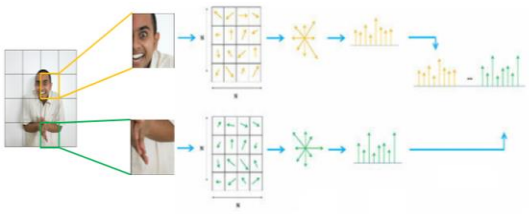

Fig. 4: Process of HOG features extraction: image is divide in cells of siz N x N pixels. The orientation of all pixels is computed and accumulated an M-bins histogram of orientations. Finally, all cell histograms a concatenated in order to construct the final features vector. The examp reports a cell size of 4 pixels and 8 orientation bins for the cell histograms

1) Image Preprocessing

The images in AED-2 are of size3456 X 3456. So, we pre-processed the image by cropping it to 512 X 512 to include only the key region (face and body) in the image.

2) Face and Body Detection

Detecting face and body in an image is a vital step in emotion recognition system. For an optimal detection of face and body separately, the image is segregated into two parts: face image and body image as shown in fig.3(a). Detection of face is done by Voila-Jones face detector [16]. Detection of torso, hands and shoulder are done by using K-means segmentation. Using K-means clustering we segmented the image into two regions,

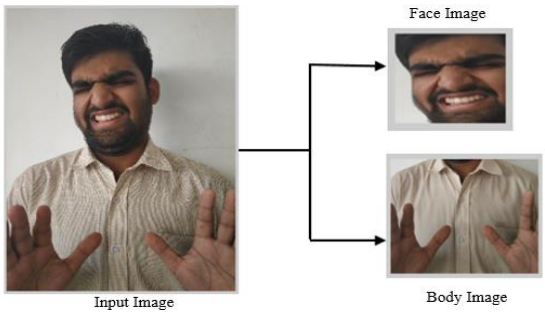

Fig.3(a)Detecting face and body in the image

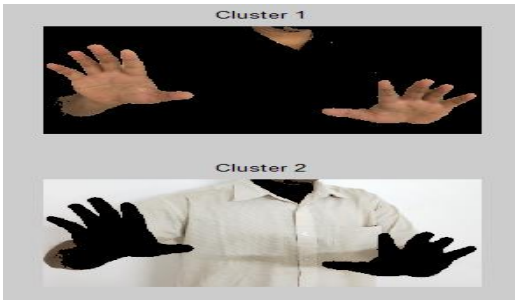

Fig.3(b) K-means segmentation

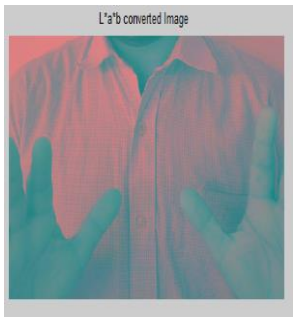

Fig.3(c) CIELAB (L*a*b) converted

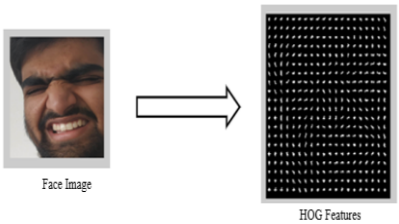

Fig.3(d) HOG features for face

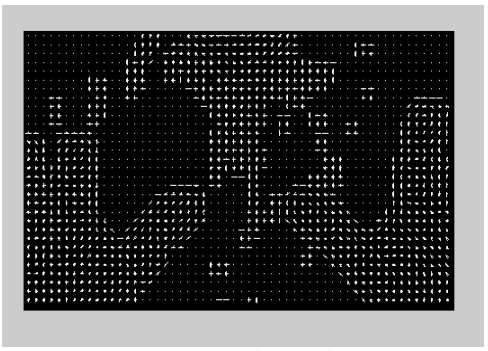

Fig.3(e) HOG features for Body

differentiating the body part from background as given in fig.3(b). The goal of K-means clustering is to classify set of patterns, points or objects into given number of clusters. Each pixel of image (with rgb values) is treated as a feature point taking a position in space. The standard K-means algorithm then randomly pinpoints, the various cluster midpoints in multidimensional space. Each point is then allocated to the group or cluster having closest random mean vector. The process is repeated until there is no noteworthy modification in the position of cluster mean vectors between two consecutive repetitions. K-means clustering [17] is an unsupervised approach and is used in several areas like data mining, image analysis, pattern recognition, face detection, and image segmentation etc.,

3) Feature Extraction

Detecting face/body in the image is the first step of extracting feature in emotion recognition system. The subsequent step is to ensure normalized color and so cropped body images are converted in CIELAB color space, as shown in fig.3(c).

In this work, Histogram of Oriented Gradients (HOG) method is applied which is illustrated in fig.3(d) and 3(e). The HOG has been discovered as an effective technique for detecting face as well as for FER [18, 19]. The elementary notion of HOG features is to map the local object shape and appearance by scattering of edge directions or local intensity gradients. This orientation study is robust to illumination variations. The very initial step behind building the histogram is evaluation of gradient values. Generally, this technique filters the intensity data or color of the picture using filter kernels given below:

$$[-1, 0, 1] \; and \; [-1, 0, 1]^T.$$

The next step is to form histograms. The image is divided into number of cells and each cell covers group of pixels. Based on the gradient values calculated, each and every pixel in the cell have power to casts a vote for an orientation-based histogram mode. Extraction process using HOG method is illustrated in fig.4.

4) Feature Fusion

Feature-level fusion is a critical phase in the approach 2. There are plenty of feature-level fusion procedures such as concatenation, mutual information results, and Principal Component Analysis (PCA) etc., A description of feature-level fusion methods is discussed in [4]. The corpus used in this work is locally created and is small in size and so concatenating the features from two different modalities is the best approach to achieve improved accuracy.

5) Classification

Most of the surveyed literature have used Artificial Neural Network, Support Vector Machine (SVM), and HMM as a classifier [3], [4], [7], [8], [20]. SVM is extensively cast-off in many fields like image classification, text & hypertext categorization, face detection, protein fold and remote homology detection, bioinformatics, and handwriting recognition etc., MATLAB software is used for evaluation and *svmtrain* & *svmclassify* are the inbuilt functions in MATLAB.

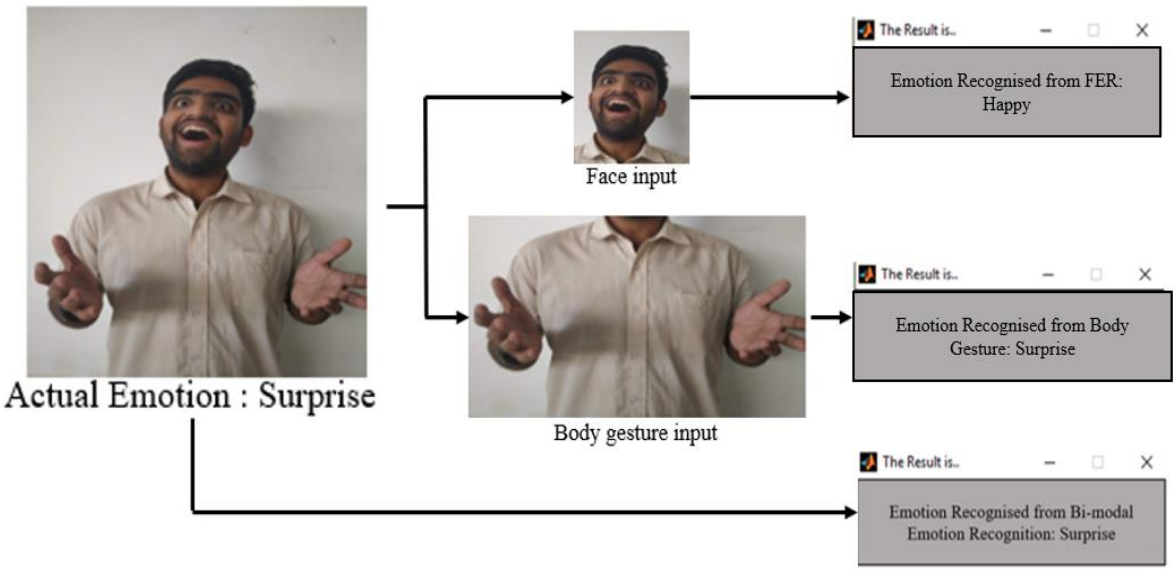

Fig.5 Emotion recognized using two modalities for the same input image

TABLE 2 Emotion-wise accuracy (%) for approach 1 and 2 for 7 emotions

Approach	Modality	Anger	Fear	Happy	Disgust	Neutral	Sad	Surprise
Approach 1	Facial Expression	92	85	85	95	85	85	75
	Body Gesture	80	90	90	80	75	90	80
Approach 2	Bimodal (facial expression and body gesture)	95	91	95	96	95	94	93

We have developed an algorithm *multiSVM* classifier for classification of seven emotions. *MutliSVM* is described as follows:

- Initially SVM is trained for dataset AED-2 for 7 different emotions using *svmtrain*. It will generate train data containing classes with their feature set.
- For each class *i*, where *i*<=*n* (where *n* =number of emotions, i.e. 7)
- Execute *svmclassify*.
  The extracted features are classified using the procedure described and results

V. EXPERIMENT AND RESULTS

Out of 100 images, 70% and 30 % of the images are taken for training and testing respectively. Table 1 represents the overall average accuracy using both approaches for 7 emotions. It shows that fusion of two modalities at feature–level results in better recognition rate as compared to any of the single modality. Inclusively, we have identified that fusion at feature-level of two channels delivers noteworthy enhancements in emotion recognition. Proposed method proves that when we combine two modalities it can achieve better accuracy.

Emotion wise accuracy for approach 1 and 2 are discussed in Table 2. It illustrates that 'disgust' and 'anger ‘are well expressed by facial expressions whereas 'happy' and 'surprise' are recognized better by body gesture. Expressions like 'happy' and 'surprise' are confusing and are often misinterpreted as one another. In fig.5 the input image expressing 'surprise' emotion, is recognized as 'happy' by facial expression because the facial features for 'happy' and 'surprise' emotion are quite similar (eye wide open or wrinkle around the corner of the eyes mouth open). Fusion of features from two modality brings out the best of two different modalities and helps to overcome the drawback of any of the modality. For example, in fig.5 when the feature from both modalities is combined then correct emotion is recognized. Merging different modalities are beneficial in case of missing and unreliable feature due to noisy environmental conditions and corruption of signals during transmission. Approach 2 delivers better result for 'anger', 'happy', 'disgust', 'neutral' and 'sad’. It proves that merging two modalities significantly improve the recognition rate for emotions like happiness, surprise, fear, sad and neutral as shown in Table 2.

TABLE 1 Overall average accuracy for approach 1 and 2 for 7 emotions

Modality	Accuracy (%)
Facial Expression	86
Body Gesture	83.57
Bimodal (facial expression and body gesture)	94

VI. CONCLUSION

In this paper, we have presented a bimodal emotion recognition system constructed on face expressions and upper body gestures. We have proposed two approaches: In the first approach, emotions are recognized from upper body gesticulations and facial expressions independently. In the second approach the extracted features from facial part and upper body parts are combined together to recognize emotion.

We have found that approach 2 achieves higher recognition rate than approach 1. This shows that combination of two modalities will provide the benefit of achieving better accuracy than uni-modal approach.

In future, this work can be extended using deep learning and for images with pose & illumination variations. More number of subjects will be added to the database.

***Abstract*— Cloud computing these days, may be an elementary amendment happening within the space of data technology. It plays a vital role in terms of information storing and reducing the value to entrepreneurs. However, knowledge security continues to be one in all the highest issues for cloud computing. To produce the secure knowledge storage and retrieval, several techniques are projected however the bulk of them face some drawbacks that diminish the practicality of Cloud Computing. This work scrutinizes a hybrid cloud approach for efficient data storage and security. The aim is to propose a model to identify duplication and prevent it thereby using the cloud storage efficiently.**

***Keywords*—Hybrid cloud, security, deduplication, authentication, tokenization**

I. INTRODUCTION

Moving ahead with time, we are all becoming smart and thus making the things we use smarter too. We are developing more and more devices and complicating the device by giving it various tasks to perform and making our own lives simpler because all the tasks that we are to do is done by the devices that we invented over time. For example, a coffee maker, its only supposed to make coffee upon putting the ingredients to make coffee in it. But now we have made it a smart coffee maker. So, it not only makes the coffee but also before leaving home intimates the user that his coffee is ready. Another example is of a smart home. Earlier one should have to remember to turn off all the lights and fans before leaving home. Else they would be running till they get back home in the evening. But now, since we have a smart home, we don't need to remember and turn off all the lights and fans before leaving home. After 20 minutes the fans and lights are automatically turned off if no one is in the house because it's a smart home. One more such example is a smart watch. Earlier the watch was just a device to give information about what time of the day it is. But now since it's a smart watch, the watch gives many more details such as 'xyz' number of steps have been walked by the user, 'abc' number of calories have been burned, what is the rate at which the heart is beating or the user hasn't moved from his place for more than an hour. So, what is the understanding is that, by making devices smart we are not only saving energy in doing the tasks that have to be done but also do much more work in the same time. There are many advantages in devices being smart and helping mankind do their daily routine much faster and in a much more efficient manner. Hence the more and more the devices becomes smart, the more and more time is available to do various other tasks but at the same time important and sensitive data is being shared over the internet which is some food for thought. After all, with every boon comes a bane!

Another example is of the photo gallery in a smartphone. What's new in the market these days is an app called the 'Google Photos' instead of the traditional 'Photo Gallery' which used a fixed storage space in the smartphone. Whereas the 'Google Photos' is a cloud where the photos are uploaded when taken. The cloud is linked with a Gmail account and since it's a big cloud there is no need to worry about how many photographs are there in our phones. And there is absolutely no need to worry about what we'd do with the photos on our old phone in case we buy a new mobile phone. The account that is linked to cloud does all the backing up and transferring of the photos and videos to the new phone as well. The photographs are so well backed up that years down the memory lane, Google reminds us where we were, with whom we were and what we were doing back then. To add to the nostalgia, it also gives us an option of viewing more photographs from that month of that particular year and be in the fantasy of it forgetting about where we are now and what we are currently doing. Probably one major reason for us to miss our old friends, college life, bunking, chit-chatting, etc. Also, if we find a particular snap very interesting, we take a screenshot of that and put it as our status on WhatsApp. Now this screenshot could be a snapshot of the original pic or of another snapshot too. After taking this snapshot, since it's a new photograph in our smartphone, 'Google Photos' backs up this new snapshot too. Now an interesting thing to notice about this is that there are repeated pictures being saved in the cloud. Taking undue advantage of the storage space that is available and being offered we load everything in this huge cloud. Food for thought here is that while taking a snapshot of the original picture or snapshot of the snapshot if Google had told us that, that particular picture already exists in the cloud, it'd save us lot more space and avoid a duplication called deduplication. This is the current problem faced by majority of the organizations using cloud for various purposes. A deduplication [13] check could be done at various levels. For example, file level, where it checks if the filename is the same, or block level, where it checks if the content of the files is the same, etc. The following literature survey shows the research work done in this field to know what are the solutions fund till date to address this problem. Hence, having enormous space to save the files is not just enough but to use this space efficiently is of paramount importance in the present scenario. Also being safe with what data is shared is also very crucial. Afterall its better to be safe than sorry! The later sections elaborate on the proposed solution to this emerging problem and the future scope as to what else could be added to the current research work.

II. RELATED WORK

In [1] Cloud based attacks and vulnerabilities are collected and classified with respect to their cloud models. It also presents a taxonomy of cloud security attacks [12] and potential mitigation strategies with the aim of providing an in-depth understanding of security requirements in the cloud environment. [1] For example, the Authentication Attack, Password Reset Attack, Man-In-the-Middle Attack and Cloud Malware-Injection Attack. They also [1] highlighted the importance of intrusion detection and prevention as a service. [2] The outsourced cloud storage is not fully trustworthy; it raises security concerns. [2] Specifically, aim at achieving both data integrity and deduplication in cloud by proposing two secure systems, namely SecCloud and SecCloud+. [2] SecCloud introduces an auditing entity which helps clients generate data tags before uploading as well as audit the integrity of data having been stored in cloud. [2] SecCloud+ is designed motivated by the fact that customers always want to encrypt their data before uploading, and enables integrity auditing and secure deduplication on encrypted data. [3] Implementing cloud computing empowers numerous paths for Web-based service offerings to meet diverse needs. [3] Loss of sensitive data has increased users' anxiety and reduces the adoptability of cloud computing in many fields, such as the financial industry and governmental agencies. The proposed approach in [3] divides the file and separately stores the data in the distributed cloud servers. [3] The proposed scheme is entitled 'Security-Aware Efficient Distributed Storage (SA-EDS) model', which is mainly supported by proposed algorithms, including 'Alternative Data Distribution (AD2) Algorithm', 'Secure Efficient Data Distributions (SED2) Algorithm' and 'Efficient Data Conflation (EDCon) Algorithm'. [4] To protect the confidentiality of sensitive data while supporting deduplication, the convergent encryption technique has been proposed to encrypt the data before outsourcing. [4] To better protect data security, this paper [4] makes the first attempt to formally address the problem of authorized data deduplication. [4] Different from traditional deduplication systems, the differential privileges of users are further considered in duplicate check besides the data itself. [4] Security analysis demonstrates that our scheme is secure in terms of the definitions specified in the proposed security model. [4] This model shows authorized duplicate check scheme incurs minimal overhead compared to normal operations. [5] Gives details of the vulnerabilities in cloud computing [14]. It's a survey paper which surveyed on the various techniques used till date for cloud computing, what are the issues in doing so, how they can be combated, etc. [6] Talks about an efficient deep learning model proposed to predict the overload on the cloud. they also work on virtual machines on the cloud. results obtained show that there is a good prediction and it's a good learning model which can be used by the industries. [7] For data security a hashing algorithm is used to generate an immediate cipher txt which will be combined with other offline cipher texts to get the actual cipher text. The proposed work proves data integrity without any doubt. [8] Is a survey paper giving insights about what exactly is cloud computing, how exactly things work in cloud computing [11], how are these various computations done, what are the risks involved in doing so, etc. [9] in this paper they have made use of amazon web services- EC2 for their computations and study the services the cloud can offer. [10] In this paper the problems of data not being in encrypted form in cloud is studied.

III. PROPOSED SYSTEM

This is an approach to avoid duplication of data in the cloud called 'deduplication'. In this approach, the deduplication check happens at different levels. One such level is the 'file level', where it checks if the file of the same name is being uploaded as it is in the cloud already. For example, if user A uploads a file called 'document.jpg', and another user or the same user also wants to upload 'document.jpg' to the cloud again. Due to deduplication, the attempt to upload the same file to the cloud is stopped, i.e., deduplication is efficiently checked at the file level by saying 'file with this filename already exists. Try uploading a different file.' Another such level is the 'block level', where it checks if the file uploaded and the file to be uploaded have the same file contents or not. For example, if a user A uploads a file 'document.jpg' with a scanned copy of the heart and another user or the same user also wants to upload 'heart.jpg' also having a scanned copy of the heart to the cloud again. Due to deduplication, the attempt to upload the file contents to the cloud is stopped, i.e., deduplication is efficiently checked at the block level by saying 'File contents of this file is already present in the cloud. Try uploading a different file.' These are examples of how exactly the deduplication is being checked in the proposed model. How exactly this works is by making use of an open private server to maintain private cloud data, user, private cloud, public cloud and a hybrid cloud. The unique encryption technique used is that of the AES (Advanced Encryption Scheme) algorithm to secure the data shared. Dropbox is used to upload the encrypted file to the cloud. each time a trusted user wants to upload the file a unique ID (identification key) is given to upload. The user is identified as trusted or not by first registering with the cloud. Then using the user credentials, he can upload files which are encrypted to the cloud. To better protect data security, this paper [1] makes the first attempt to formally address the problem of authorized data deduplication. Different from traditional deduplication systems, the differential privileges of users are further considered in duplicate check besides the data itself. In this research work [2], Cloud based attacks and vulnerabilities are collected and classify with respect to their cloud models. The proposed approach [3] divides the file and separately stores the data in the distributed cloud servers. Propose two secure systems, namely SecCloud and SecCloud+. [4] SecCloud introduces an auditing entity which helps clients generate data tags before uploading as well as audit the integrity of data having been stored in cloud. [5] Results indicated that the projected model achieves a better coaching efficiency and employment prediction accuracy. The contents above summarize in detail about each research paper that was studied in order to carry out the work proposed in this report. An exhaustive research was carried out in order to successfully achieve the results shown.

IV. IMPLEMENTATION

This is an approach to avoid duplication of data in the cloud called 'deduplication'. In this approach, the deduplication check happens at different levels. One such level is the 'file level', where it checks if the file of the same name is being uploaded as it is in the cloud already. For example, if user A uploads a file called 'document.jpg', and another user or the same user also wants to upload 'document.jpg' to the cloud again. Due to deduplication, the attempt to upload the same file to the cloud is stopped, i.e., deduplication is efficiently checked at the file level by saying 'file with this filename already exists. Try uploading a different file.' Another such level is the 'block level', where it checks if the file uploaded and the file to be uploaded have the same file contents or not. For example, if a user A uploads a file 'document.jpg' with a scanned copy of the heart and another user or the same user also wants to upload 'heart.jpg' also having a scanned copy of the heart to the cloud again. Due to deduplication, the attempt to upload the file contents to the cloud is stopped, i.e., deduplication is efficiently checked at the block level by saying 'File contents of this file is already present in the cloud. Try uploading a different file.' These are examples of how exactly the deduplication is being checked in the proposed model. How exactly this works is by making use of an open private server to maintain private cloud data, user, private cloud, public cloud and a hybrid cloud.

The unique encryption technique used is that of the AES (Advanced Encryption Scheme) algorithm to secure the data shared. Dropbox is used to upload the encrypted file to the cloud. each time a trusted user wants to upload the file a unique ID (identification key) is given to upload. The user is identified as trusted or not by first registering with the cloud. Then using the user credentials, he can upload files which are encrypted to the cloud.

So, to begin with first the user has to open the private server and run all the services. He then has to navigate to eclipse and run the code. Upon running the code, the credentials are asked. If a trusted user, credentials are entered and now a unique access ID is generated. He now has access to the drop box. He uploads whichever file he wants and if another user wants to upload the same file, i.e., file with the same name or the same file content, be it a file of any file format, the cloud says 'No. I already have this file. Please upload a new file'. The python code is run to show this message. Hence, an integration of java and python is made use of to execute the proposed system. The system architecture of the proposed system is as shown in the figure below.

A deduplication [13] check could be done at various levels. For example, file level, where it checks if the filename is the same, or block level, where it checks if the content of the files is the same, etc. The following literature survey shows the research work done in this field to know what are the solutions fund till date to address this problem. Hence, having enormous space to save the files is not just enough but to use this space efficiently is of paramount importance in the present scenario. Also being safe with what data is shared is also very crucial. Afterall it's better to be safe than sorry! The later sections elaborate on the proposed solution to this emerging problem and the future scope as to what else could be added to the current research work.

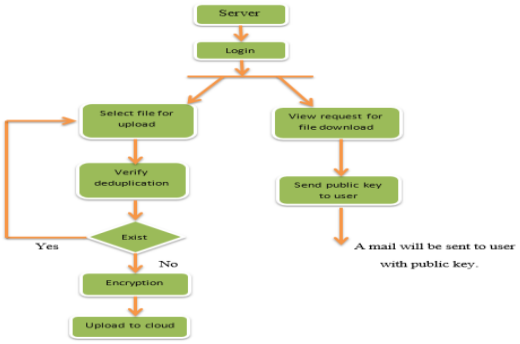

Fig. 1 System architecture

The above figure shows the system architecture of the proposed system where the server allows to login. Further after logging in, either user needs to choose the files to be uploaded or view request for file download. If viewed request for downloading file, then the public key will be sent to the user via mail. If user chooses files needed to be uploaded, the deduplication verification happens. If it exists then user is asked to choose another file to upload to cloud else the file chosen is encrypted using AES algorithm and uploaded to cloud. the below figure is a flowchart showing the user flow.

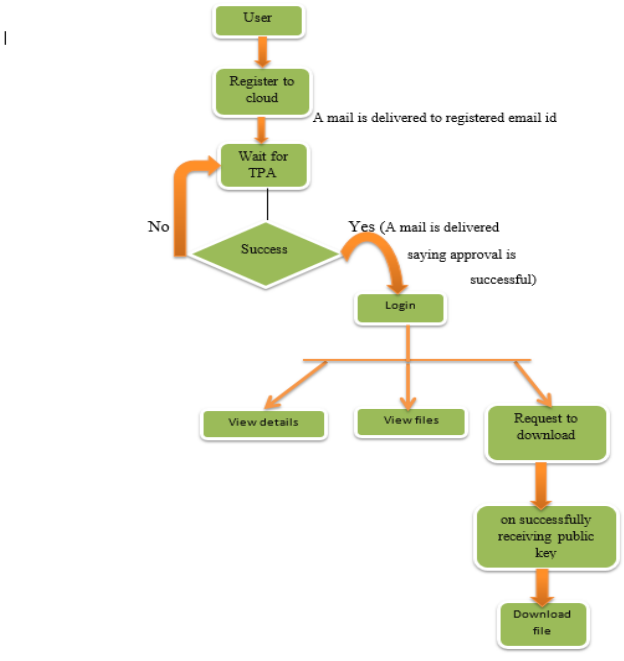

Fig. 2 (a) User flow

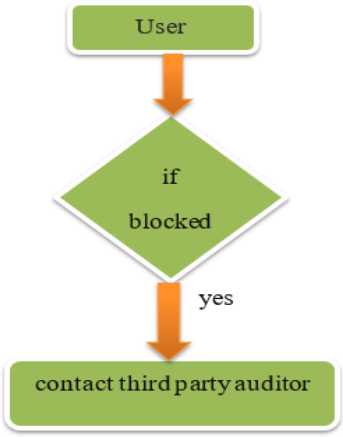

Fig. 2 (b) User flow confirmation

The above figure shows the steps the user has to follow to upload a file to the cloud. Fig. 2 (a) shows that the user has to register to the cloud and then a mail will be sent to the registered email id. The user should then wait for the TPA (Third Party Auditor). If received, then the mail is received that there is a successful login, else continue to wait for the TPA. Upon logging in, the user can view files or view details or request to download. Further, on successfully receiving the public key, the file can be downloaded. The below figure shows details of the TPA work flow.

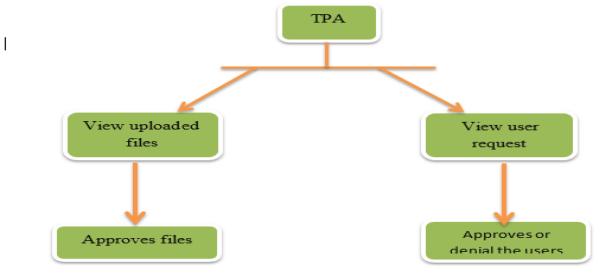

Fig. 3 TPA work flow

The above figure shows details of the TPA work flow. This has a broad classification as either to view the uploaded files or view the user request. If chosen to view the uploaded files, files can only be approved. If chosen to view the user requests, users can be approved or denied. This is how the proposed model exactly works. The next section deals with the results obtained upon implementing the proposed work.

V. RESULT ANALYSIS

The proposed model was implemented successfully. Deduplication was checked efficiently and only the files being uploaded to cloud are encrypted. Hence the data is completely safe in the cloud because its in the encrypted form. So, any search operation done would be on the encrypted data. The below screenshots give details of the results obtained on implementing this proposed model.

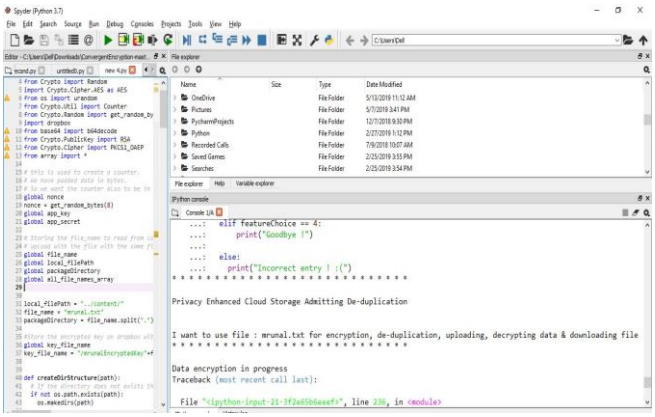

Fig. 4 Python code screenshot

The above figure shows the python code screenshot. This code when run checks for deduplication of files selected to be uploaded to cloud. the below figure shows details of how exactly the cloud looks when a file is uploaded to it.

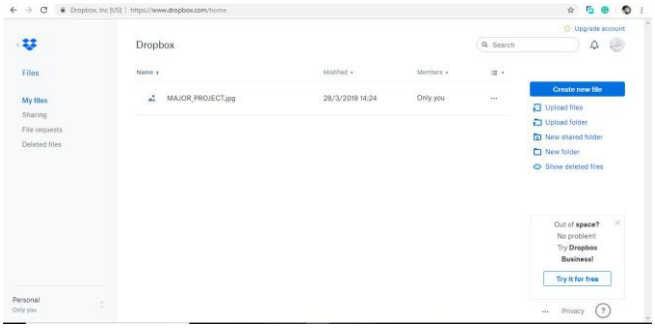

Fig. 5 Screenshot of files in Dropbox

The above figure shows details of the files uploaded in drop box. Before uploading to drop box, the user has login with the credentials provided. If logged in, file chosen is first checked for deduplication. If it exists the user is asked to choose another file to upload, if not the chosen file is encrypted and uploaded to cloud.

VI. CONCLUSION

We did an investigative study on the available techniques of avoiding duplication of data saved in different names/file formats called deduplication in the cloud. The available techniques just allow to upload any type of files to a private cloud or public cloud. No one has tried to read the data that has been uploaded to the cloud and save it from additional storage space by allowing multiple uploads of the same contents of the file in just different file formats. Hence after an elaborate and exhaustive research, we conclude that the cloud is now free from deduplication of data and there is an efficient utilization of storage space in the cloud. The cloud can now restrict the user from uploading the same file contents saved in a different file name or file format to the cloud. Thus, utilizing the storage space it has also in a much

better and efficient manner. Also, the data uploaded is secure. Hence proving no multiple files with same file contents uploading to cloud, efficient utilization of storage space and secure way to share data over the internet. The future work includes to further improve the efficiency of medical data security even more. It also aims to provide deduplication for image, PDF, etc. and reducing to delay required to send public key with automatic servers. Another important future enhancement includes to use the private server itself as a cloud.

Smart Sugar Cane Grower Inquiry and Plotting Using Android Application

Apoorv Kansal and Pradeep Kumar
Department of Electronics & Communication Engineering
Amity University Uttar Pradesh, Noida, India
appuavi2012@gmail.com, pkumar4@amity.edu

***Abstract*— This paper presents the development of Sugarcane Grower Enquiry and Survey Application(Android) that would be a Grower Enquiry Mobile Application so that the Growers could know about their Basic Quota, Cane Area, Survey, Purchy, Calendar, Weighment , Payment, Loan Details and Bank Details of their Sugarcane crop produced and provided to Sugarcane Factories. The proposed Paper would also serve to show the plots of each Growers via Google Map. Moreover there will be 8 Main Options which contain 10 Activities/ Screens.**

Keywords*— *Android, Grower Enquiry, Sugarcane factories, SOAP API, XML Pull Parsing, Android Studio.

I. INTRODUCTION

In recent years, researchers have developed applications and systems for precision agriculture based on current resources and future possibilities to improve profitability [1-5]. The concept of smart farming using IoT and advanced sensors has been also developed [6-8]. A novel methodology for the monitoring of the agricultural production process based on wireless sensor networks has been proposed [9]. Wireless sensor networks for agriculture: The state-of-the-art in practice and future challenges and Nb-IoT system for M2M communication were developed [10-11]. Optimized algorithm of sensor node deployment for intelligent agricultural monitoring has been described [12]. Some websites are created by different IT Companies so that farmers could view the details of their sugarcane crops produced and delivered to different sugarcane factories. By visiting these websites and logging in to their accounts, they are able to view the quality of crops produced by them, the status and variety of their crops. They get to know about the details of the amount of money they have taken as loan from the sugarcane factories to grow the required amount of sugarcane, the amount of money they have been paid in return by the sugarcane factories for the quantity of sugarcane delivered to the factories. Up till now in India the entire data of the Farmers' sugarcane fields and crops are updated on Computer Systems only. Describing the process and the data that is displayed on these websites, basically what happens is that factories provide welfare schemes such as pesticides, urea, seeds etc. on loan. If a grower requests for some initial money as a loan to grow crops or to buy seeds as per his requirement, then sugarcane factories come forward to provide the necessities to the farmers. Eventually, the factories want good quality of sugarcane to be produced by the farmer in return so that they can produce sugar out of them. Some factories even have research labs to produce and invent Sugarcane seeds of new types and quality so that more amount of cane could be produced at minimum cost and minimum amount of land is required by the farmers. Modern types of seeds are distributed to the farmers. By doing this, quantity of crop produced could be increased by such loans and sugar would be produced more. So loans for producing new variety of sugarcane crops from the seeds are given to the farmers. In this way, Sugarcane factories and farmers both are at profit. It is noticed that by distributing modern seeds, quantity of sugarcane produced was doubled. In this proposed paper, we have focused on helping the farmers with advancement in Technology to modify and optimize the way Farmers and Sugarcane Industries are used to deal with their data. Since the advancement of Android Application Development, some IT Companies related to Sugarcane Industries are trying to fulfill the need of farmers and sugarcane factories to develop user friendly Android Applications so that farmers don't require to go to Cyber Cafes for viewing the details of their crop field plots. With the proposed Paper a user-friendly Android App has been developed for the farmers keeping in mind their need of viewing their credentials and details. Hindi Language is used for displaying the different options and details so that the famers and local people working in Sugarcane Factories could easily access it accordingly. Each farmer has some sugarcane plots which produce thousands of quintals of sugarcane crop. So one can easily estimate the use of this Application such that this Application would serve to thousands of farmers at the same time very easily. The main purpose of this App is to run 8 options for the farmers. They are : Grower Enquiry, Loan Details, Grower Account Details, Survey, Calendar ,Cane Payment, Weighment , Purchy Details.

The organization of this paper is as follows: This section presents the brief introduction of sugar cane smart farming and precision agriculture using various techniques. Section 2 gives the overview of the android application description. Section 3 gives the details description of the android application implementation and results. Conclusion is given in section 4. At last related references are given.

II. ANDROID APPLICATION DESCRIPTION

The Application requires a proper co-ordination between the Web-Service which takes the data from the main Server and retrieves the required data in key-value pairs back to Android App End. The Android App is developed in Android Studio

Software using Java Programming. Further, the App is divided into 2 sections: Front End and Back End developed using XML files and Java classes respectively. The primary goal of developing this Android Application is to provide relief to the farmers and local staff of Sugarcane factories so that they don't require to go to the cyber cafes to look for their credentials and details related to any plot. Therefore, keeping this in mind we are developing such Application which could run on every smart phone whether it is an old one consisting of Android Jellybean or even the Latest Oreo 8.1. The App is compatible to every Android SDK Versions. That's why minimum SDK Version taken is 15. The App is made user-friendly in the sense that the default language of all the options, buttons and menu are set in Hindi to connect to those people as well who are not much educated.

Moreover, the Application's Main Menu consists of 9 items or options. The Main Page Activity basically consists of Grid View Layout which internally consists of 9 items. Each item or option is linked with subsequent image. The image describes the option name so that a farmer could easily know what the option is all about. So the images would help the farmers to use the App easily. The Front End is developed in such a way that the App looks easy to access and the farmers shouldn't find any difficulty while using it. The UI has a theme consisting of 2 colors: green and white to make it look simple and sober. Green color signifies agriculture basically Sugarcane crops. Each farmer is associated with a farmer code and its village with a village code. Every factory is allotted a unit code. When the application is run by any user, a Splash Screen is shown first reflecting the name of the company and the image depicting sugarcane. Then a Screen arises which asks the user to select any 1 of the 10 sugarcane factories. After choosing the concerned factory, next screen is the Main Page Activity screen where the grower is asked to write his Village Code and Grower Code. Only them he could use the provided 9 Options that are Grower Enquiry, Loan Details, Grower Account Details, Survey, Calendar ,Cane Payment, Weighment, Purchy Details and Log Out. Actually, the Android Application needs Year, Unit Code, Grower Code and Village Code so that these values are taken by Web Service and then the Web Service connects with the Server and checks for the credibility of these 4 codes. If the codes are accepted by the Server, then subsequent method is called and then the Web Service returns the details that need to be displayed on the Screen. This Web Service is called via Soap API i.e using ksoap2. Every Item or Option is connected with some Method which is created at the back end of Web Service. The particular method returns the data as the key-value pairs to the Web Service which in turn connects with the Android Backend and Frontend to display the required details on the Screen of the Grower in tabular form. Grower Enquiry details option includes farmer's name, father's name, village name, centre name, mobile number, total land, average yield, mode of cane delivery, crushing year and society. Loan Details option consists of Loan Type, Loan Description, Loan Amount, Received Amount, Balance Loan and Loan Date. Grower Account Details option includes Bank Name, Bank Branch Name and Grower Account Number. Survey Option includes details like Is Survey, Plot Serial, Plant/Tree type, Village Name, Variety Name, Latitudes and Longitudes of North-East, North-West, South-East, South-West Directions, Plot Area of each of the plots of every farmer, Cane Type. Moreover one can see any plot on Google Maps. Plots are drawn as polygons via Google Map API. Calendar Option consists of the crop details of every farmer. Calendar displays 12 Fortnights. Each Fortnight has 15 days. So as a whole Calendar represents the Purchy(Indent) Details of sugarcane produced and delivered to the respected Sugar Mills in 180 Days of an year. Cane Payment Option includes details like Payment Date, Purchy No., Final Weight, Due Amount, Deducted Amount, Paid Amount, Bank Name, Branch Name, Account Number, Payment Sheet Number. Weighment Option includes details like Mill Purchy Number, Tare Date, Gross Weight, Tare Weight, Net Amount, Indent Slip Number and Mode. Purchy Details(Indent) option includes details like Mill Purchy Number, Fortnight, Day of Fortnight, Variety, Delivery Mode Name, Purchy Issue Date and state of purchy.

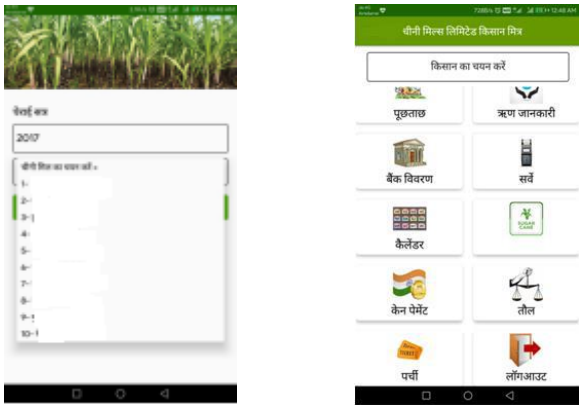
III. ANDROID APPLICATION IMPLEMENTATION AND RESULTS

The aim is to not to store any kind of information inside this Application as a local storage. So "SQLite" is not used so that in case a Virus or a Hacker tries to hack the Application, he would not find any private information related to any farmer since this Application gets the details of Bank, Aadhar Card Number etc from the Server which is accessible by the registered devices only. The splash screen of the developed android application is shown in figure 1.

Fig. 1: Splash Screen(First Screen)

Constraints include doing Research in handling SOAP WEB API i.e "ksoap2". Soap API is a connecter which calls the Web Service. Soap API gives the Unit Code, Grower Code, village code and Year to the Web Service to check for the credibility of the data entered by the user. This data is sent to the Server by the Web Service and then the Server responds the appropriate messages back to the Web Service. The Web Service returns the message back to the Soap Calling into the variable declared as "message". This variable could contain entire table. Soap Objects are created which stores the result sent by the Server. When the Soap API is ready with the required data that is asked by the Grower, then comes the role of Parsing. Xml Parsing includes different tags. Each Tag represents a Column of the table. When Server sends back the data, it sends the entire table of the corresponding method

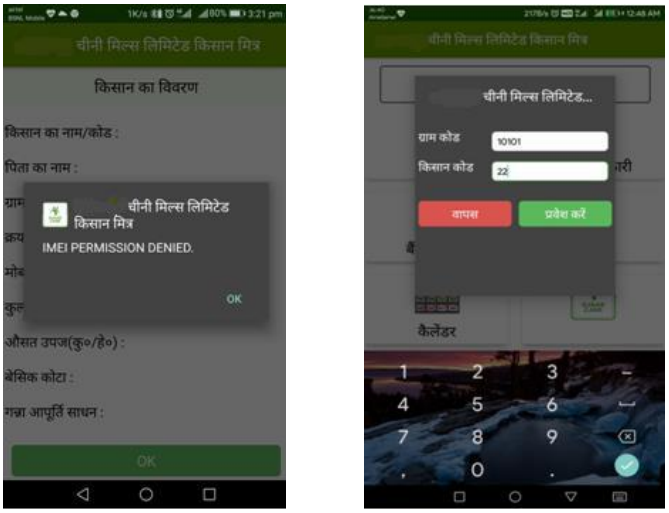
which is created on the Server. Each Activity is connected to its corresponding separate method on Server. So if the grower wants to have a look on it Grower Enquiry Details, so Soap API would have to connect with the Web Service and retrieves the data from "getGrowerDetailsEnquiry" method created at the WebService Backend Database. The data is send back to the Soap call and stored in “message” object. So only then XML Pull Parsing comes into force and different columns are extracted in terms of different tags.



(a) (b)

Fig. 2: (a) Main Activity depicting Spinner, (b) Main Page Activity

Under “MainPage” Activity shown in figure 2, one of the most important task performed is getting the IMEI NUMBER given in figure 3 of the device on which the app is running. This is done for security purposes, as only those devices which get registered on the Server are allowed to use this app. That means if the non-registered device tries to access this app, then it won’t run on the suspected device.



(a) (b)

Fig.3: (a) IMEI Permission Denial, (b) Bootstrap Dialogue Box

The 8 Options are Grower Enquiry Activity shown in figure 4, Loan Details, Grower Account Details, Survey Activity, Calendar Activity, Cane Payment Activity, Weighment Activity and Indent(Purchy) Activity. Last Option is Log Out.

A. Grower Enquiry Details

In Grower Enquiry Activity, details include Grower Name, Father’s name, Village name, center name, mobile number, total land, average yield, mode of cane delivery, crushing year and society name are displayed for the farmers.

Fig.4: Grower Enquiry Activity

B. Loan Details

Loan Details Activity shown in figure 5 includes Loan Type, Loan Description, Loan Amount, Received Amount, Balance Loan and Loan Date. Moreover, Loan Amount in Loan Details activity denotes the amount of money taken in advanced by the grower from the sugarcane factory for buying pesticides or urea or may be seeds. Received Amount tells about the amount of money received by the grower when he supplied the sugarcane factory with the sugarcane. Deducted amount is the difference of the final amount to be received by the farmers and the loan that farmer took from sugarcane factories.

Fig.5: Loan Details Activity

C. Grower Account Details

Fig.6: Grower Account Details Activity

Grower Account Details given in figure 6 include village name, grower name, father's name, center name, bank name, bank branch name and bank account number. Method of the web service published to which this Activity is connected to is "getGrowerDetailsEnquiry",

D. Weighment Activity

Weighment Option shown in figure 7 includes details like Mill Purchy Number, Tare Date, Gross Weight, Tare Weight, Net Amount, Indent Slip Number and Mode. Method of the web service published to which this Activity is connected to is "getWeighmentDetails".

Fig. 7: Weighment Details

E. Survey Activity

Survey Option shown in figure 8 & 9 includes details like Is Survey, Plot Serial, Plant/Tree type, Village Name, Variety Name, Latitudes and Longitudes of North-East, North-West, South-East, South-West Directions, Plot Area of each of the plots of every farmer, Cane Type. Moreover one can see any plot on Google Maps. Plots are drawn as polygons via Google Map API.

Fig. 8: Survey Activity (first half of the screen)

Fig. 9: Survey Activity (second half of the screen)

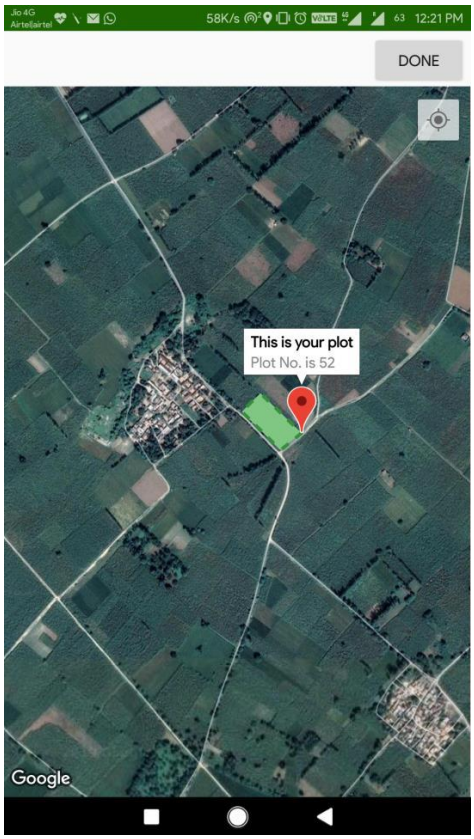


Fig. 10: First Plot of a farmer shown on Google Maps via Google API

Each plot is drawn shown in figure 10 as a polygon and its boundaries are marked accordingly by taking the co-ordinates of latitude longitude of each of its 4 corners. Each crop field plot of sugarcane is shown on the map (figure 11) when the farmer taps on "Yes" TextView box corresponding to each plot. 2 "Bean Classes" are used to use the concept of encapsulating many objects into a single object. Method of the web service published to which this Activity is connected to is "getGrowerSurveyDetails". A bean class implements Serialization concept and has public getters and setters methods. One of the bean classes created is "PlotLatLng" class and other one is "SurveyData" class.

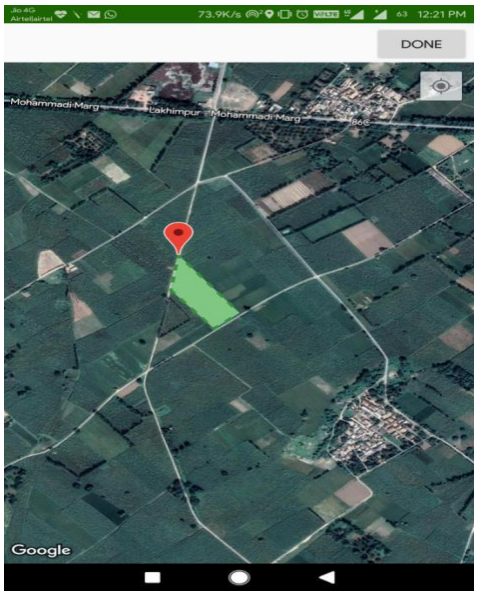

Fig. 11: Second Plot of a farmer shown on Google Maps via Google API

Map Activity Class is opened along with sending "plotLatLng" object in the bundle as serialized and also the plot serial number of each plot of the farmer is also sent with the bundle as well (figure 12).

Fig. 12: All plots of a farmer shown on 1 screen of Google Maps along with the required information of each plot

To see all the plots of the farmer, All Plots Activity Screen is executed from Survey New Activity. "SurveyData" bean class is used.

F. Calendar Activity

Calendar Option shown in figure 13 consists of the crop details of every farmer. Calendar displays 12 Fortnights. Each Fortnight has 15 days. So as a whole Calendar represents the Purchy(Indent) Details of sugarcane produced and delivered to the respected Sugar Mills in 180 Days of an year. Method of the Web Service published to which this Activity is connected to is "getCalenderDetails". "showSummary" function is called and executed. "LayoutParams" attribute of "TableRow" layout is used to draw and map the table.

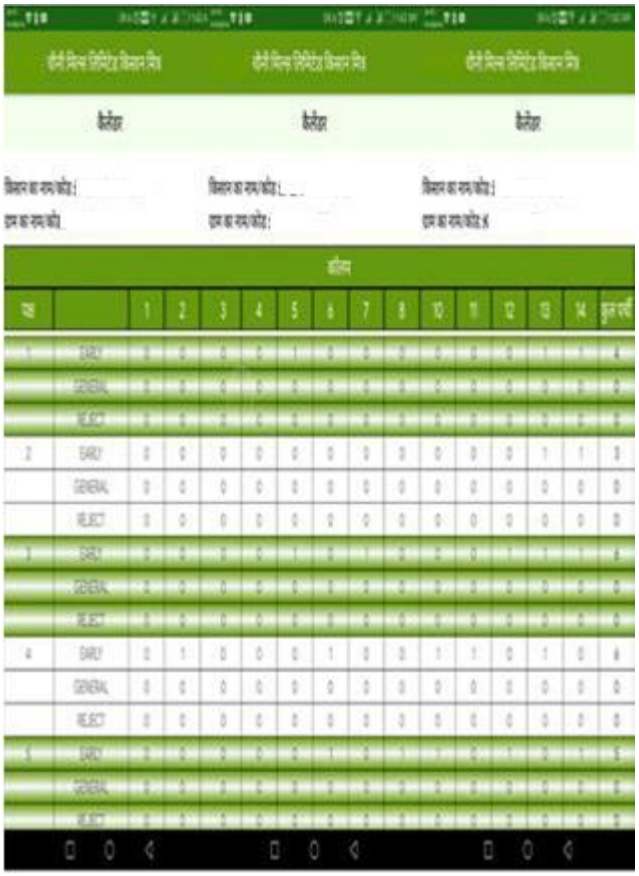

Fig.13: Calendar Activity for 12 Fortnights

G. Payment Activity

Cane Payment Option shown in figure 14 includes details like Payment Date, Purchy No., Final Weight, Due Amount, Deducted Amount, Paid Amount, Bank Name, Branch Name, Account Number, Payment Sheet Number. Method of the Web Service published to which this Activity is connected to is "getPaymentDetails".

Fig.14: Payment Activity for 12 Fortnights consisting a total of 168 days of an year

H. Indent Activity

Purchy Details(Indent) shown in figure 15 option includes details like Mill Purchy Number, Fortnight, Day of Fortnight, Variety, Delivery Mode Name, Purchy Issue Date and state of purchy. Method of the Web Service published to which this Activity is connected to is "getPurchyDetails"

IV. CONCLUSION

In this paper, we have focused on helping the farmers with advancement in technology to modify and optimize the way of farming and Sugarcane Industries are used to deal with their data. With the proposed paper a user-friendly Android App for the farmers has been developed, keeping in mind their need of viewing their credentials and details. Hindi Language is used for displaying the different options and details so that the famers and local people working in Sugarcane Factories could easily access it accordingly.

Abstract--- Landslide is a natural hazard, which badly affects people's safety and property. Continuous monitoring of such a disaster may lead to reducing of losses of human lives. With this aim, in this paper, we have proposed a surveillance system for real time landslide monitoring using computer vision algorithms. Here we have used a video camera to acquire live view of landslide site and a small computer board 'raspberry Pi' to run the algorithm we will introduce here. When landslide is detected SMS text messages are transmitted using a GSM modem. Due to video camera and Raspberry Pi, this method is inexpensive yet efficient and also requires low power, therefore this method can be used in any region. We have used median filtering to remove noise present in the detection algorithm. Here we have also proposed a new implementation method for median filtering using a linked list and parallel processing which is very time efficient.

Keywords—computer vision, camera, raspberry pi, motion detection, background subtraction, video, entropy, landslide, median filtering, image processing, artificial intelligence

I. INTRODUCTION

The term landslide describes gravitational movements of soil or rock down slopes. Landslide is a geological disaster which is the major cause of damage to life, human settlements, and public utility [1]. Landslide is a serious problem in mountainous terrain like Himalayan states of India [2]. Therefore in these regions, there is an urgent requirement to establish a system for landslide monitoring to save human lives and properties. There is a need to establish landslide monitoring and detection systems which can provide alarms at the moment when a landslide occurred. These systems may save human life and property by generating alarms at critical moments [3].

Several measurement methods have been developed for slope instability and landslide risk estimation [4]. For example map analysis and remote sensing are used for landslide risk estimation based on terrain information and geological information. But these methods are costly, labor intensive and highly subjective.

One approach for landslide monitoring is by installing various geotechnical instruments such as inclinometers, extensometers or piezometers on the slop. Various geotechnical instruments based landslide monitoring systems have been discussed [5]. But these types of systems are very costly and require continuous maintenance.

In this work, we have introduced a low cost and low power consumption system for landslide detection and monitoring. For this work, we have used a web camera, and a single board computer raspberry pi to detect landslide events using motion detection technique and median filtering.

Landslide detection in a video stream can be thought about detecting moving objects in a video. There are various techniques existing for detecting moving objects in a video. One of them is temporal differencing which uses pixel wise difference between 2 consecutive frames in a video. This method is sensitive to noise, cannot handle complex background and still object detection [6].

The second method is Optical flow [7] which is very complex and time inefficient therefore cannot be used in real time application. Gaussian mixture model based background subtraction is another method for moving object detection [8]. However, this method cannot handle multimodal background.

In this work, we have used Visual Background Extractor (ViBe) [9]. This method has high accuracy, requires less memory space and is time efficient. The Vibe can handle complex background and small camera movement.

Median filter is used to reduce impulse noise. Various methods have been discussed in the literature [10] [11] for conventional median filtering. In [12] various algorithms have been proposed for fast median filtering with time complexity from $O(n^2)$ to $O(n \log n)$. Here we have used linked list and parallel processing to reduce time complexity.

We have used entropy threshold technique [13] as an index to determine down slope motion of large area i.e. landslide or small object's motion.

The research paper is divided as follows. In Section **II** we present a system diagram and give an overview of hardware components used in the proposed landslide detection system. In Section **III** we shortly describe the methodology and about the developed algorithm for landslide detection. In Section **IV** we present the achieved experimental results. Finally, in section **V** we conclude the research paper and discuss about the future work.

II. Proposed system

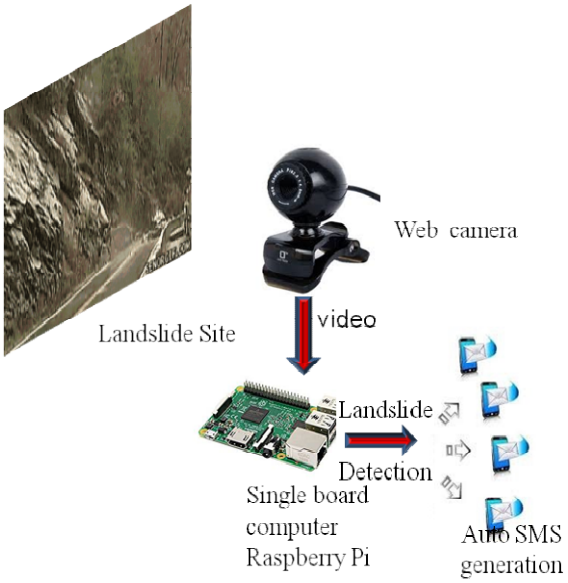

Figure 1: System Diagram

System diagram of the proposed system is given in figure 1. Following hardware components are used:

- Video camera: a digital video camera is used to capture live view of landslide vulnerable site. Video camera feed is basic input to our system. OpenCV library is used by single board computer raspberry PI to capture video from web cam and accessing video frames.
- Raspberry Pi: Raspberry Pi is a low cost, powerful and portable computer board having dimension of a credit card, developed by the Raspberry Pi Foundation. Raspberry pi is a central processing unit of our landslide detection system. We have used a third generation the Raspberry Pi 3model B and raspbian operating system. The selected Raspberry Pi 3 model B includes 64 bit Quad Core 1.2GHz Broadcom BCM2837 processor and 1GB RAM.
- GSM modem: GSM modem is a wireless modem that uses a SIM card and operates over a cellular network. GSM modem is connected to raspberry PI through a serial cable. GSM modem is programmed using AT commands for Automatic SMS generation to send an alert message when a landslide occurs. Here GSM modem is programmed to send a landslide alert message as Flash SMS.

III. METHODOLOGY

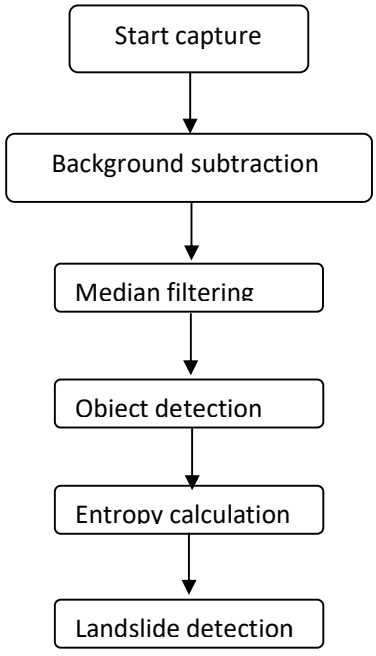

Figure 2: Flow diagram of methodology

A. Background Subtraction

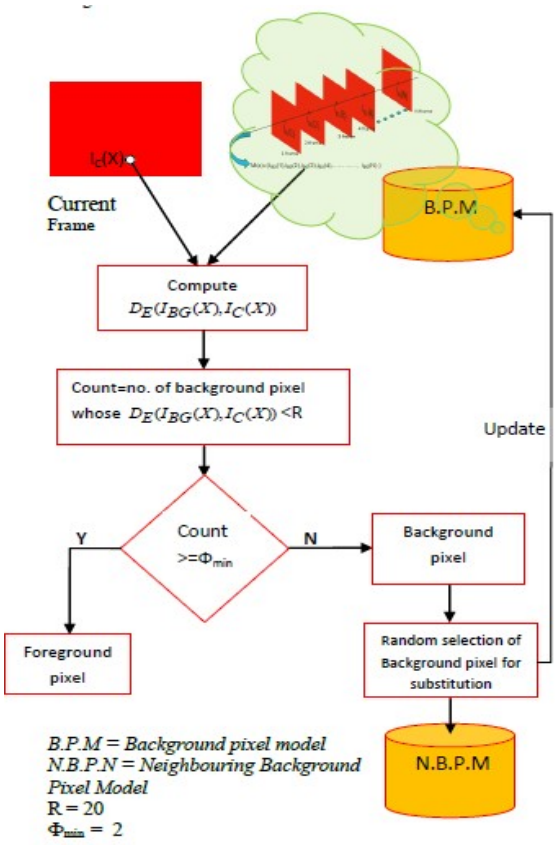

Figure 3: Flow Diagram of Visual Background Extractor

Background subtraction is the second step of the flow diagram of methodology shown in figure 2. Background subtraction detects moving objects from static cameras. Here we have used Visual Background Extractor (ViBe) [9]. This method, has high accuracy, requires less memory space and is time efficient. The Flow diagram of Visual Background Extractor (Vibe) is shown in Figure. 3. The ViBe is pixel based background subtraction approach. Here each background pixel model is set of previously observed background pixel values instead of estimating probability density function like in GMM based approach. Each pixel value is compared to closest value of its background pixel model. Background pixel models are initialized by a single frame using pixel values of their spatial neighborhood. Consequently Vibe starts background subtraction from second frames. The Vibe can handle sudden illumination changes. Vibe has a unique property of spatial diffusion where each background pixel updates one of its spatial neighbouring background pixel model chosen randomly. This feature makes Vibe to handle small camera movement and slowly evolving structure.

Each background pixel model is updated with each new incoming frame by using a conservative update policy. This update policy has 3 important properties

1) Memory less update policy
2) Random time sub sampling
3) Spatial temporal update policy

B. Median Filtering

Outcomes of visual Background extractor are binary images which contain salt and pepper type noise. This type of noise can be effectively removed by using a median filtering . We propose a fast median filtering algorithm for smoothing the output of background subtraction. The median filter is the well known method in image processing for reducing the impulsive noise. However, it has a problem that execution speed is slow because it uses a sorting algorithm to obtain the median value. So, a fast median filtering algorithms has been discussed here for real time landslide detection.

Median filter is a nonlinear filter which replaces value of each pixel by median, of all pixel values in its spatial neighbourhood. For computation of median filtering, pixel values covered by kernel, are sorted. If the kernel size is odd, then the median is just the middle value of a sorted array. For even size kernel, median is average of two middle values. There are various sorting algorithms like quick sort and heap sort whose time complexity can have significant variations, depending on the kernel size and can increase with the kernel size. Each time, kernel is moved to cover new pixel values and old values from kernel are discarded. Now new pixel values in the kernel are sorted into numerical order to compute median value. This process is repeated until whole image is covered. This is very time inefficient.

We have proposed a new implementation of median filtering where we never have to re-sort the running kernel; the operations are designed so that the array will remain sorted after each deletion and addition. All pixel values of the window are not discarded and also sorting algorithms are not used in every time. Pseudo code of the proposed median filtering algorithm is shown in **Algorithm: proposed median filtering algorithm** for kernel slide horizontally. Since insertion and deletion operation of pixel values are fast in a linked list, therefore we have used linked list data structure.

Here we have used parallel processing to compute median filtering. Since our used raspberry pi 3 model B has 4 cores, video frames are subdivided into 4 equal segments. We divide the 340x480 frame size into 4 equal parts and each of 4 segments is given to each core. Each core performs median filtering simultaneously to reduce time complexity. Now the output of all core are recombined to get final result. For median filtering computation, the following steps are followed:

- First time, linked list is sorted using pixel values in the kernel.
- In next time (window slides to the next location), from the sorted linked list, delete node corresponding to the first row or first column depending on whether video frame is scanned horizontally or vertically as shown in figure 4 and figure 5.
- For all new value in the window to be added, use a linear search to find their position in the sorted array. Add the new values in those positions.
- Note that the linked list is still sorted. The median will be in the middle of the linked list (assuming window size is odd) or the average of two median values (window size is even).

Algorithm: proposed median filtering algorithm

Input: Image X of size M×N, kernel size n
Output: Image Y of the same size as X
Initialize Linked list L with special neighbourhood of $X_{1,1}$
for i= 1 to M do
for j= 1to N do
for k= -n/2 to n/2 do
Remove $X_{i+k,j-n/2}$ from Linked list L
Add $X_{i+k,j+n/2}$ to L using lenear search
end for
$Y_{i,j}$ ← median (L)
end for
end for

In a brute-force way, the time complexity per pixel is $O(n^2 \log n)$ when applying a quick sort to a median filter with a window size of n. As shown in pseudo code of our proposed algorithm, for kernel size of **n×n**, n addition and n deletion are required to update the linked list. So our proposed method has time complexity of $O(n)$ and also space complexity of $O(n)$ per pixel for kernel size **n×n**. This method is easy to implement in hardware

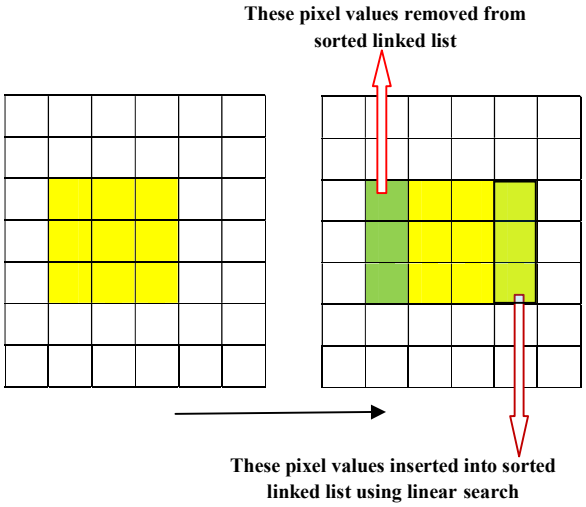

Figure 4: Removal of linked list node when window slide horizontally

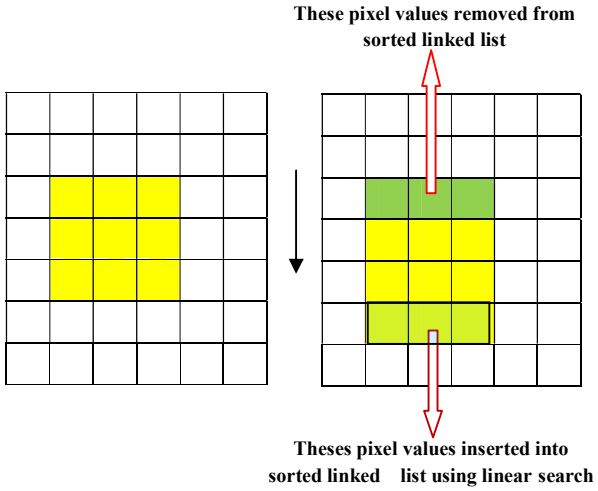

Figure 5: Removal of linked list node when window slide vertically

.

C. Object Detection

Result of median filtering is a binary image where all white pixels belong to the moving objects. These white pixels can be grouped by using pixel connectivity process where pixels having similar intensity values and connected in some way to each other form a group. Now these groups can be labeled by assigning grey values to each group.This labeling technique is called connected component labeling. There are various proposed algorithms for connected component labeling. For this work we have chosen one pass algorithm because it requires

less computational time. Now these labeled groups belong to moving objects.

D. Entropy Calculation

After background subtraction and noise removal using median filtering, landslide detection is possible but still there is need of a threshold to determine whether it is down slope motion of large area i.e. landslide or small object's motion. Entropy [14] is used to measure the amount of disorder or randomness in a frame. As shown in figure 6 (a), the frame is perfectly ordered so its entropy is zero. Figure 6(b) shows a disordered frame so its entropy is higher than figure 6 (a). Finally frame in figure 6(c) is highly disordered so its entropy is highest. Consequently entropy thresholding can be used to find landslide movement. The Entropy of a frame can be calculated by the following formula

$$H = -\sum_{k=1}^{n} P_k \log_2(P_k)$$

k is no. of gray levels and P_k is probability of gray level k. For our work, this entropy threshold is set to 0.8.

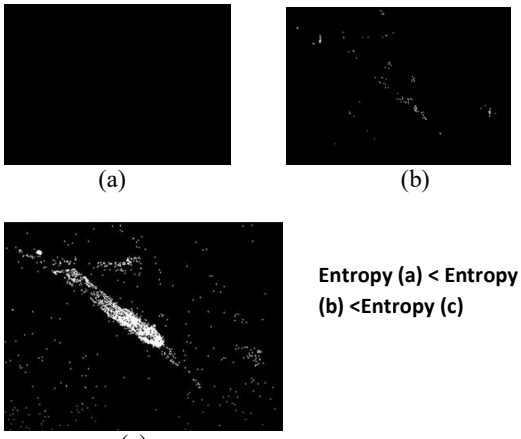

Figure 6: Illustration of Entropy in different frame

IV. RESULTS

All the operations, we have discussed in the methodology section, are applied on each individual frame of a video stream. Here we have used openCV library for accessing video frames and for changing frame rate. We have developed a GUI for this work whose screenshot is shown in figure 7. There are two fields in GUI first is ROI (region of interest) and second is window size of median filtering. ROI is used to select a portion of live view on which the proposed algorithm is performed. ROI is can be defined by regular polygon or freestyle.

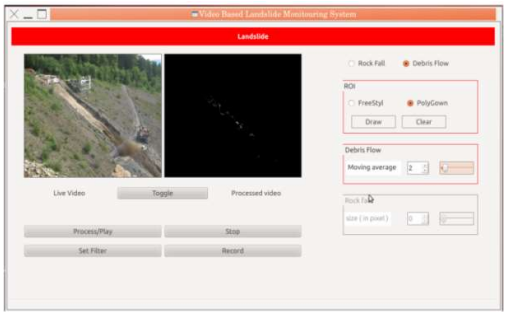

Figure 7: Snapshot of developed GUI

We have tested our proposed algorithm on prerecorded footage of debris flow landslide. The footage is of 52 seconds and frame size is 340x480. Actual landslide occurs after 7 second and our proposed landslide detection system detects it at 7 second and generates an alarm message. Our proposed algorithm works similar on the video if frame rate of the video increases upto 40 fr/seconds. This algorithm will work the same in case of live streaming from the web cam.

Result of the proposed algorithm is shown in fig 8. As a landslide occurs, a message "LANDSLIDE DETECTION" is flashed in red colour at top most window and test SMS is sent to the local authority.

For this result, we have selected a third generation of Raspberry Pi 3 model B and raspbian operating system. Raspberry Pi 3 model B includes 64 bit Quad Core 1.2GHz Broadcom BCM2837 processor and 1GB RAM. Above mentioned raspberry Pi with a USB web-camera of 5MP and a GSM modem is hardware components used in the proposed system.

Figure 8: Result of developed algorithm

V. CONCLUSION & FETURE WORK

The research work has been introduced a landslide monitoring and detection system which detect landslide in real time. Hare, we have used a Raspberry Pi 3 B and webcam which requires less power and is very economical therefore it is suitable to use in remote areas. Our proposed

system provides an innovative and economical system for landslide detection. When landslide occurs our system can detect the event and can inform concerned authority by real time SMS text message. Concerned authority can take necessary steps to divert the traffic and to protect property and lives living in landslide vulnerable areas. We have proposed a fast implementation method for median filtering using linked list data structure which has time complexity of $O(\sqrt{n})$. In the future, we can incorporate deep learning and convolution neural network to detect landslide.

Abstract- Crowd analysis is an essential topic of research in artificial intelligence. There are several applications on crowd analysis, such as, environmental management, urban planning and public safety. This paper presents review of different methodologies those have been implemented for estimating crowd. This paper covers several methods of crowd density estimation, such as, image processing techniques, machine learning and deep learning based technique, and smartphone based technique.

Keywords—Image processing methods, direct method, indirect method, location based smartphones for crowd counting, machine learning and deep learning based crowd classification.

I. INTRODUCTION

With the increase in human population, crowd gathering takes place at many public places such as rail, maglev, metro, stadium, marathon etc. So there is a risk of stampedes. Various incidents took place because of overcrowd such as in 2005, more than 640 people died in Religious procession at Baghdad, In 2013, 115 people died in Hindu Festival at Datia District, in 2014, during Dussehra festival in India around 32 people died and in 2017, 23 people died at Elphinston Road Mumbai [1], [2]. Due to such incidents, there is a requirement of some efficient and effective crowd density estimation and crowd management techniques. Estimating crowd density is of great importance, as it can prevent stampede. Traditionally, human operators were required for continuously monitoring the CCTV cameras installed for identifying any suspicious or unusual action of the crowd. Analyzing and observing such huge information originating from different view-points and various angles is critical job for the human operators and would be costly. Also, if a very small team is appointed for crowd monitoring task then it may lead to improper analysis and they may miss any unusual event within the crowd. For better accuracy of crowd density estimation advanced computer vision techniques are being deployed recently to automate crowd monitoring system. This would reduce the need of human operator significantly and hence the cost involved in employing the security persons would also reduce. Various methods adopted for crowd density estimation are reviewed in this paper.

Conventional Image Processing have been widely used for crowd density estimation is studied in this paper. It involves two approaches first is direct approach which is also known as detection based method in which individuals are directly segmented from the crowded scene and then number of people are detected. The other approach is indirect based which is also knows as feature based method in which features are learned by using some learning algorithm. The other method is by using location based smartphone for people counting is reviewed in this paper. One more method is by using Machine Learning and Deep Learning algorithm to classify images as low crowd, high crowd, moderate crowd, extremely dense crowd. In deep learning, various algorithms are available such as Artificial Neural Network (ANN), Convolutional Neural Network (CNN), and Recurrent Neural Network (RNN).

II. RELATED WORK

[1] proposed two approaches direct based and indirect based. Both approaches have some limitations. Various methods have been proposed by many researchers for crowd counting in public areas. [17] proposed ROI (Region of Interest) based crowd counting This method is based on human detection or any regression method. The main important step in this method is background subtraction and then mapping the foreground shape with the human shape. This method is not suitable for highly dense crowd or in occluded area. Various other researchers implemented

Markov Random Field (MRF) for foreground subtraction [28]. Recently computer vision techniques are adopted for crowd analysis.

III. Crowd density estimation using Conventional Image Processing Techniques

Crowd density estimation using conventional image processing technique is categorized as: Direct and indirect approaches [1].

A. Direct approach for crowd density estimation

Direct approach aims to estimate number of people by segmenting each individual from images and it also locate their position. This method is applicable only in low crowd scene. In high crowd scenario or in high occlusion scene, detecting each individual is difficult task. This approach is further improved by using part based detection such as head detector and omega shape detector which is formed by head and shoulder, pedestrian detector. However, this part based detection is not suitable for very high crowd. Further Direct approach is of two types Model based approach and Trajectory based approach [1].

In model based method each individual is segmented and counted with the help of some model or appearance of human shape. This method is used for counting problem. In trajectory based approach, every pedestrians motion is tracked using interest based points. After detecting peoples position counting can be carried out.

B. Indirect approach for crowd density estimation

Indirect approach aims to extract local and global features from images. As detecting features is much easier task then detecting people in high crowd situations. In the literature foreground and background subtraction technique were used to estimate crowd and edge based features was extracted for crowd analysis. However, foreground and background subtraction is very difficult in highly crowded areas are the limitations of this approach. Edges like features are incorrect in complicated background and occluded areas. [1], [15]. To overcome such problems more methods are proposed and they are discussed in the succeeding subsections.

a. Pixel Based Method

Pixel based method [1] extract very local features to estimate crowd. The first step in pixel based is to remove background by using some background subtraction techniques; the next step is to extract features by using edge detection method. These features are the input to back propagation neural network. This method is 100% accurate in very low to low crowd situations. However, due to high occlusion false information could be captured by this pixel based method.

b. Texture based method

Texture feature extraction is proposed by many researchers as it is highly efficient method for feature extraction which is used for many image processing applications. Texture gives the detailed information about all the regions of an image. Texture extraction is more robust than pixel based method. Marana proposed images of low crowd exhibit coarse pattern while images of high crowd exhibit fine pattern. In their work, researchers proposed Gray-Level Co-occurrence Matrix (GLCM) features for crowd density estimation. Four GLCM features, such as, Contrast, Energy, Homogeneity, and Entropy for estimating crowd were extracted. These features were applied to the input of neural network for crowd classification. However, this method needs more time for crowd classification. The other recent methods are based on Local Binary Pattern (LBP) and Gabor Features [4], [10].

1. Local Binary Pattern

LBPs are texture descriptor proposed by Ojala et al [5] It simply describes the local information. The calculation of LBP involves the subsequent steps. The first step is to convert the color image into the gray scale image. Then the gray scaled pixels are computed for 8 neighborhood pixels with the central pixel. [3], [4]. If the intensity of the pixel to be converted to grayscale is greater or equal to its neighbour's pixel value than it is set 1 or else, it is set to 0. A similar procedure is done for all the pixels in the image to generate a gray image.

LBP is defined as follows: [4]

$$\text{LBP} = \sum_{i=0}^{P-1} s(P^i - P^c)\, 2^i \qquad (1)$$

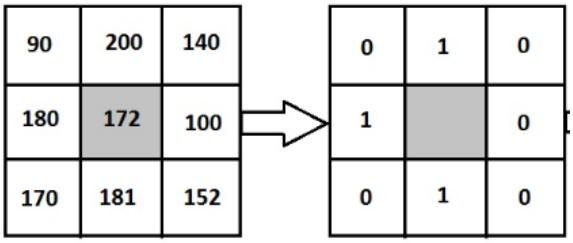

Fig. 1. Converting into a gray scale image in LBP [5]

where P is the number of neighbors; P^C denotes the central pixel; P^I denotes the other pixel around P^C. S(x) is defined as:[6]

$$S(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases} \quad (2)$$

The next step in calculation of LBP is to take any neighbourhood pixel value and traversing the LBP code in clockwise or anticlockwise. This will result into 8-bit binary pattern, [7]

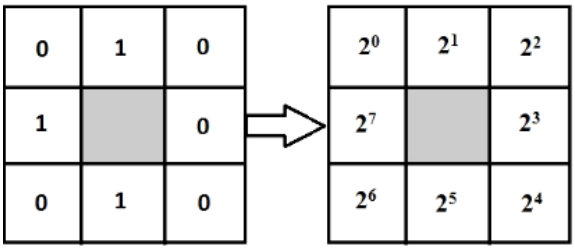

Fig. 2. Converting grayscale into decimal representation in LBP [5]

The final step in LBP is converting the binary into decimal number. This value is stored in output array.

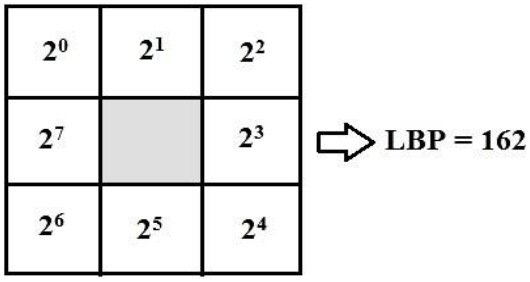

Fig. 3. Converting binary to decimal and storing the LBP value in output array [5]

The process of converting to grayscale and obtaining the output decimal value in the LBP array is repeated for each pixel in the image. Fig. 4 shows the LBP of an image.

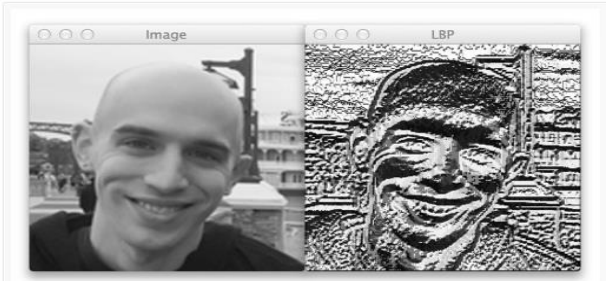

Fig. 4. Original image (left) and its LBP (right) [5]

Finally, the histogram is computed from the output array. The patterns obtained from a 3 x 3 neighbourhood are 2 ^ 8 = 256. Thus the final feature vector is 256 bin histogram of LBP 2D array. The advantage of using LBP in image processing technique is that it provides detailed information of the images.

2. Gabor Features

Gabor features find their uses in image classification, image segmentation. Gabor features are represented by using different scale and different orientations. Gabor filter are set of linear filter which are efficiently employed for edge detection and texture feature extraction. Gabor filters are those filters which allows certain range of frequencies and rejects the unwanted frequencies. The images are filtered by gabor filter with a specific frequency and orientation and feature vector is created. This feature vector is input to segmentation or classification problem. A 2D gabor filter is a sinusoidal Gaussian filter with a preferred frequency and orientation. Two-Dimensional gabor filter is as given in the Fig. 5.

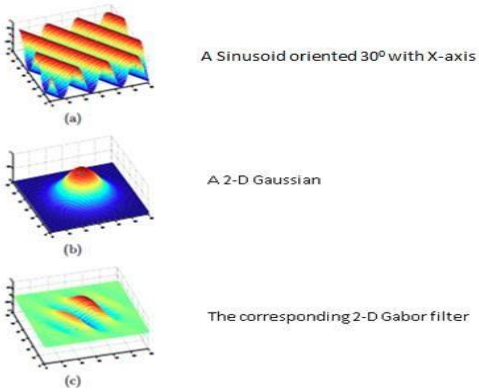

Fig. 5. Two-Dimensional Gabor filter

Two-dimensional Log-Gabor filter involves radial and angular filter components. The frequency

response of a 2-D Log-Gabor filter is given in eq.(3)[9]

$$G(r,\theta) = \exp\left(\frac{-[\ln(\frac{r}{f_o})]^2}{2[\ln(\frac{\sigma_r}{f_o})]^2}\right) \exp\left(\frac{-(\theta-\theta_0)^2}{2{\sigma_\theta}^2}\right) \quad (3)$$

where (r, θ) represents the polar coordinates, the central frequency of the filter is given by f_0, the orientation of filter is denoted by θ_0. σ_r and σ_θ are the scale and angular bandwidths respectively. By using different values of frequency and orientation, a bank of Gabor filter is created. Then each feature is convolved with discrete time Fourier transform of the input image. The two features are extracted using Gabor are:

Local Energy = $\sum i \sum j |G(i,j)|2$ (4)
Mean Amplitude = $\sum i \sum j |G(i,j)|$ (5)

List of different Gabor filters are obtained by using different values of frequency and orientations.

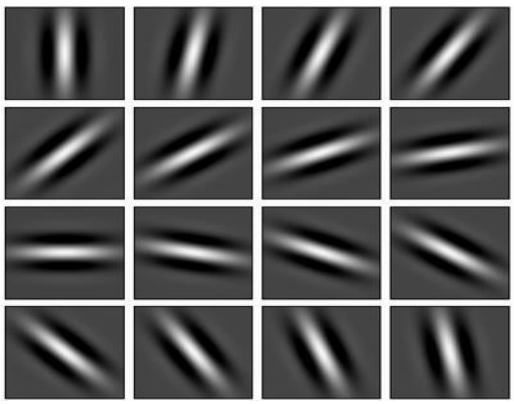

Fig. 6 A bank of 16 Gabor filter [8]

3. Gray Level Co-occurrence Matrix

GLCM is a mathematical and statistical tool for image texture feature analysis. It gives the relationship between the adjacent pixels. The main image texture features used for crowd density estimation are contrast, energy, entropy, homogeneity. GLCM takes the relation between two pixels reference pixel and neighbour pixels. GLCM is prepared by using Gray pixel values and it will calculate how often the pixel occurs horizontally, vertically, and diagonally. The GLCM example is given below [11], [12], [13].

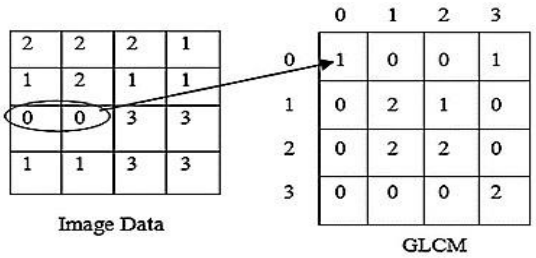

Fig.7. GLCM example

The four important features are given by the equations (3) to (6) [11]

Contrast: Contrast estimates the magnitude of intensity between a pixel and its neighboring pixel for the entire image.

The formula for contrast is gives below:

Contrast = $-\sum_i\sum_j (i-j)^2 P[i,j]$ (6)

Energy: restores the addition of squared components in the GLCM.

The formula for Energy is given below:

Energy = $-\sum_i\sum_j P^2[i,j]$ (7)

Entropy: Entropy provides the necessary information of images which are requires for various image compression techniques.

The formula is given as:

Entropy = $-\sum_i\sum_j P[i,j] log P[i,j]$ (8)

Homogeneity: Gives the value which provides the information of closeness distribution of all elements of GLCM with the GLCM diagonal elements The formula is given below:

Homogeneity = $\sum_i \sum_j \frac{P[i,j]}{1+(i-j)^2}$ (9)

IV. Crowd Monitoring Through Location Based Smart phones Wi-Fi Probes

In this method sensing approach is proposed using phones in which people will participate and share their location. This method proposed the moving speed of individuals in the crowd is the main important factor for crowd density estimation. To determine the crowd, the exact location of people is an important issue. There are two main approaches for obtaining the location of smartphones In-network localization and In-phone localization. In-network localization method explains the fact that at every time the smart phone is

connected to the base station in the network. The entire information about which phone is connected to which base station is stored in the database and automatically it updates the databases. As the location of all the base stations are known, estimation of position of smart phone can be localized and hence location of people can be obtained. From this information people count can be estimated [26] [27] [28].

The other method is by using Wi-Fi signals. With the growing technology, Wi-Fi enabled smartphones are used by every individual. Smartphones send request periodically for connecting to the existing network. This method is applied for counting number of individuals by counting the devices who share the network.

V. Crowd density estimation using Machine Learning and Deep Learning

Machine Learning and Deep Learning are recent techniques for crowd density estimation. They involve the following steps shown in fig.8. The first step is to acquire features for various density levels using several feature extraction algorithms and the next step is use classifier for classification into various density levels such as low crowd, high crowd, moderate crowd and extremely dense crowd.

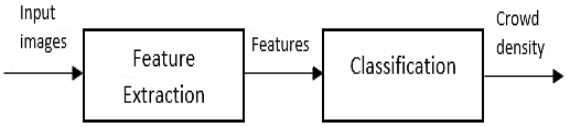

Fig. 8. Machine Learning Architecture

In Deep Learning feature extraction is carried out by hidden layer and it compute feature vector. This feature vector will help to compute classification. Convolutional Neural Network is popular Deep Learning algorithm for many image processing applications. CNN consist of input layer, output layer, and many hidden layers as shown in the Figure 9. CNN receives data through input layers and sends the data to hidden layers. Each hidden layer consists of neurons. The final output layer is a dense layer also known as fully-connected layer which performs deep learning classification task. Thus, the network calculates output by adjusting weights and bias. Hidden layers are Convolution Layer, Pooling layer and many nonlinear layers,

Each convolution layer contains many kernels and these kernels are convolved with input images and generate corresponding feature map.

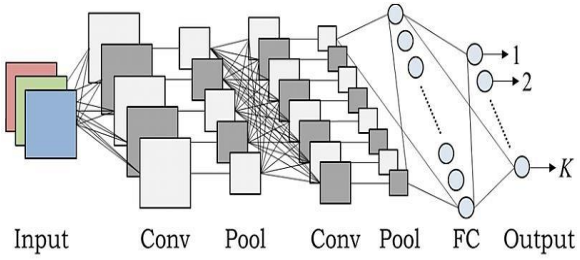

Fig. 9. Deep Learning Architecture [16]

Assume the input I is (*n x n)* matrix, convolution kernel k is a (*k x k)* matrix, bias is b_1, then we could get a (*n-k+1*) *x* (*n-k+1*) feature map after convolution. The computation is shown in Equation [14].

$$F_{ij} = S(\sum_{i=1}^{k} \sum_{j=1}^{k} (I_{ij} K_{ij} + b_1)) \qquad (10)$$

where F_{ij} is feature matrix and S is motivation function. In convolution, input images are passed through a set of convolutional filters from which various features are calculated.
Consider the following (5x5) image matrix whose pixel values are only 0 and 1

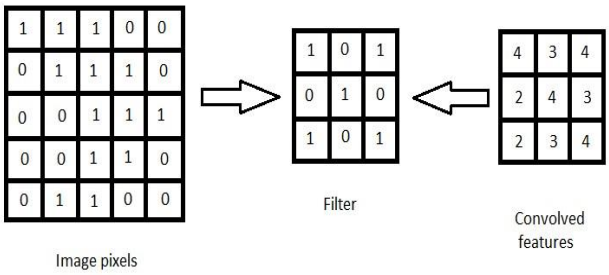

Fig.10. Convolution Example

To detect patterns, compute the dot product by sliding matrix over the image.

In CNN architecture, the Pooling layer is placed between two successive convolutions. Pooling layer reduces the dimensions of the features of input images. It is of two types: One is Max pooling and other is average Pooling. In Max Pooling operation it accepts the largest value from the region and in average Pooling, it takes the average of the region.

The last layer is Fully Connected layer. In this layer, the neurons have complete connection to all the activations from the previous layers. The output of

Fully Connected layer is K vector in which K represents the number of classes depending upon the classification task.

VI. Comparison Of Various Methods For Crowd Density Estimation [1].

Various methods for crowd density estimation have been compared in Table I.

TABLE I. DIFFERENT METHODS FOR CROWD DENSITY ESTIMATION

Methods	Objective	Limitation
Direct Method		
Model based method	Segmenting people from crowded scene using some model or appearance of human shape and counting them.	Accurate results in low or moderate crowd but less accurate in dense crowd situation
Trajectory based method	Individual's position is tracked using some interest point and counting is carried out.	It gives good results in sparse crowd but when the crowd is occluded then this method is not reliable.
Indirect Method		
Pixel based method	Determination of foreground pixels	It is simple but gives false result in highly occluded and cluttered areas. Sensitive to light changes
Texture based method	Explores detailed information of the image patches.	Detecting individual in crowded scene is easier in this method but detecting texture based features is time consuming
Smartphone based approach	Counting is carried out by detecting smartphones position or by localizing wi-fi signals.	This method is not suitable when the peoples cell phones are not working or it are switched off.
Deep Learning and Machine Learning based approach	It is neural networks training based approach and is data dependent.	Accurate but time consuming when the dataset required is too large.

VII. Conclusion And Future Scope

Crowd analysis such as crowd management, people counting and estimating crowd density is an important problem for public security. Different computer vision techniques or methodologies that are recently adopted for crowd density estimation are reviewed in this paper. Different methods used for crowd density estimation are an image processing based technique that is further classified into Direct method based on model and trajectory and Indirect method based on pixel counting and texture based analysis. Machine Learning and Deep Learning based methods are based on training of neural network models those are accurate but needs exhaustive training on data. Smartphone based method needs the cell phones of the people in the crowd active so as to be detected by Wi-Fi signal. Crowd density estimation on public gathering is demanding task to prevent stampede. By estimating crowd any unusual and abnormal activity or action within the crowd can be identified. These techniques of crowd monitoring can be used to estimate the number of people in railway compartments so that the people on the platform will come to know about the crowd density in the compartment before the train arrives. This would help the passengers to board the suitable low or medium crowd compartment.

***Abstract*— The project aims to model implementation of an advanced Smart City system that consists of Smart Home equipped with security features, Smart Waste Management System and automated street lights. Because of the increasing instance of gun violence in the country as well as abroad, we have added the feature of detecting guns outdoors using neural networks, image classifier and object detection. The system is designed by merging the concept of the Internet of Things that control various components of the Smart City ranging from energy efficient Smart Home along with its security measures to identifying a gun from closed-circuit television (CCTV) footage to detect danger on streets of the city achieved by creating an image classifier by training a neural network. As there is no sensor currently available that can detect the presence of an object in a photo, an image classifier is used to detect guns in the photos taken by the CCTV camera.**

***Keywords*— Internet of Things (IoT), Deep Leaning, Smart City, Smart Home, Smart Waste Management System, Smart Streets, Intelligent CCTV, Object Detection, Neural Network, Supervised Learning, PyTorch.**

I. INTRODUCTION

Presently, even though devices can communicate to different machines by the power of IoT, they still don't natively have the ability to detect an object from the images captures by a camera (CCTV in case of Smart City) that can have a vast number of applications. The proposed system has the capability to detect a gun from an image acquired from closed-circuit television by processing it using a trained neural network as the implementation of deep learning and generate an alert to notify of potential gun violence. The paper attempts to fill the gap in IoT enabled devices and Object Detection, allowing more room for new possibilities and applications [20]. The implementation of Smart City [17] will contain three major components. First, one is the Smart Home that includes automated lighting that is configured in conjunction with light sensors (LDR, that is, light dependent resistor) and can also be controlled via a mobile application. Aside from lighting, the smart home monitors humidity and temperature and automatically switches on an air conditioner to regulate and maintain the preferred temperature conditions as per the user's needs.

Due to the rapid development of deep learning, a variety of research areas have achieved remarkable results that are accompanied by the continuous improvement of neural networks, their architectures, algorithms, computer vision has arrived at a new peak [3]. IoT has gained importance and popularity in recent years. But there is no sensor available that can directly detect an object in an environment. Object detection can play a vital role in this task and act as a sensor replacement. Object detection as one of the important applications in the field of computer vision has been the focus of research, and convolution neural network has made great progress in object detection. Object detection is developing from the single object recognition to multi-object recognition [13]. On the other hand, IoT plays the role of raising a high-risk alert. The smart home is also equipped with security features that can detect the presence of an intruder, take a photograph and send it via email to the owner as well as nearest concerned authorities. The second component is the Smart Waste Management System which enables Municipal Corporation to track waste, the location of bins, the release of any toxic gas and monitors waste better. The third feature of the smart city is Smart Streets that have efficient street lights which are integrated with an autonomous system that can help control traffic flow by sensing the traffic density. Along with the above-mentioned functionalities, motion sensors are also calibrated to turn on the street lights for a duration in the surrounding sectors on detecting motion in presence of low natural light, thereby resulting in a more efficient and energy-saving environment [16].

II. RELATED WORK

The Internet of Things (IoT) has acquired popularity in recent years and progresses towards becoming part of our everyday life in the near future. It contains objects of day-to-day life that are able to communicate closely with one another and users by equipping them with sensors and the ability to exploit the vast domain provided by the Internet [1]. They are optimized by specially configured protocols that make the communication process efficient and reduces the overall latency. By enabling access to a wide bouquet of devices such as, home appliances, smart wearables, surveillance cameras, healthcare systems, monitoring sensors, actuators, displays, vehicles, and many more.

Machine Learning is a method of teaching computer something by feeding a large amount of data into it. Image classifier is basically an algorithm created using neural network and deep learning to detect features and objects in images and classify them into categories accordingly. We can teach our computer to see things using image classifier. We first train it on images whose category is known and then export the trained classifier as an application. To ensure the classifier is good at generalization and detecting objects in images it hasn't previously encountered, image augmentation and dropout are used. A more robust classifier is created by training it on flipped, cropped and rotated images. In this project, we are integrating Image Classifier with IoT to create a Smart City Management System with features for gun detection and violence control. With the increasing instances of gun-related violence in the country and abroad, it is important to detect such mishaps before they can take place. For that, it is important that the usual delay involved in manual surveillance is eliminated. That can be done by replacing human eyes with artificial intelligence. As soon as an image is captured by the CCTV surveillance camera, it is sent to the image classifier which determines whether or not the image contains a gun. If it does, a high alert is sent to the authority. Otherwise, the image is discarded.

Some of the Convolutional Neural Network models are AlexNet, ResNet, and Vgg etc. These models are several layers deep and the pre-trained models can be suited to any given project by simply replacing its classifier or last layer. Then,

instead of training the whole network, only the classifier needs to be trained. The parameters of the classier are chosen to best suit the needs of the application. This type of learning is called "Transfer Learning" as a trained model is used to detect features and those features are then used to train the classifier. Extensive research has been done in the field of deep learning, object detection and computer vision. It ranges from detecting anomalies in red blood cells to detecting the species of flower via a mobile phone using a simple app. The level of training and testing done is according to its application. Deep Learning and Home/City automation have never been combined at a large scale even though they are perfectly suited for each other. A large amount of manual labour is employed currently that can be utilized more efficiently in other areas, for example in actual gun control, if the detection part is automated.

Clement et al. (2017) [23] in their Service-Oriented Reference for Smart City discusses the trends of shifting existing cities into IoT enabled smart cities with the objective of creating an autonomous and integrated system by bringing together the technology of different domains. They also mention the extensiveness of cities and propose a service-oriented architecture that binds different aspects of the smart city such as intelligent traffic management, smart grids and autonomous vehicles managed by smarter versions. It further highlights the critical integration between environmental factors, logistics, infrastructure and the human layer to provide a concrete platform.

Betis et al. (2018) [15] mentions the expected increasing number and type of services provided for citizens so as to achieve goals such as energy saving, sustainability and quality of life. It suggests that upgrading a city's organization doesn't merely include infrastructure, it rather requires drastic changes and large-scale implementable innovations that include relevant new technologies. It addresses the issues of smart/sustainable energy systems (smart grids), e-health, social factors and general involvement of citizens. It supports the argument that smart city paradigm can be achieved with local government, industrial developers and non-governmental organizations (NGOs) working together towards a common goal.

Li et al. (2012) [11] describes the principle and framework by suggesting the use of IoT protocols for Machine-to-Machine (M2M) communication in coordination with sensor network that can include infrared sensors, GPS, Radio Frequency Identification (RFID) and other devices by connecting them to the internet or mobile telecom network. It proposes a multi-layer framework that consists of a sensing layer, network layer and application layer.

The sensing layer mainly realizes physical information collection from the real-world which is then converted to digital information that can further be used to process and analyse data. Since objects themselves do not have the capability to communicate, sensors, executors and intelligent devices through RFID can interchange information utilizing communication module in the communication sub-layer. The network layer includes a variety of wireless networks and cable-connected gateway providing access to the core network and mainly realizing bidirectional transmission, route and control of sensor layer data and relevant information. The application layer provides support for sub-layers and kinds of practical IoT applications with the ability to interface between industrial and public domains having a vast number of applications.

Brand et al. (2018) [22] briefed that a smart city should be an open platform where the city is willing to share experience and resources are planned or available in an efficient manner. The smart city initiative can be served as a collaboration platform for the global community of professionals, academia and local government to overcome the challenges associated with IoT, big data and related technologies. It presents the use of smarter protocols for communication and the pressing social and ethical issues regarding the development of Artificial Intelligence and Autonomous Systems. The IEEE can provide solutions for both technical and ethical standards that transcend technology of different domains such as Big Data, IoT, Cyber Security, Deep Learning and many such more into an integrated system where devices can closely communicate in real-time.

Darbari et al. (2015) [10] in their Intelligent Traffic Monitoring Using Internet of Things (IoT) with Semantic Web describes the need for an intelligent traffic monitoring system due to the sudden rise in vehicle demand and population resulting in heavy traffic especially on certain routes and hence, the need to control them. It suggests that this objective can be achieved by Hierarchical Cluster Analysis based on the assumption that every object in the entire universe is associated with some information that can be used to help in forming clusters. Web services can be used as a medium to communicate between heterogeneous environments. XML can be customized accommodating special tags for spatial locations and sensor networks. Fuzzy logic can be used to implement the decision-making aspect of traffic monitoring by Fuzzy Inference System to dynamically allocate traffic light timers to manage the flow of the same more effectively thereby resulting in smarter management of streets in the smart city and significant reduction in heavy traffic that has increased over recent years.

Zhao et al. (2017) [12] in their Object Detection with Deep Learning mentions the close relationship of object detection with image understanding and video analysis which has attracted research attention in recent years. The traditional object detection methods are based on selective and limited features that have relatively rigid architecture thereby not being flexible enough to be able to learn new semantic. Deep learning can be used to train the neural networks that permit detection of deeper features using classifiers and usage of more powerful tools. The focus on generic object detection architectures with some modifications to improve the performance of detection classifiers is also suggested. It has several relevant applications

such as facial detection and recognition by cross-referencing the image with the pre-configured dataset. It demonstrates the progress in the development of neural network algorithms and their impact on object detection techniques that can be considered as learning systems.

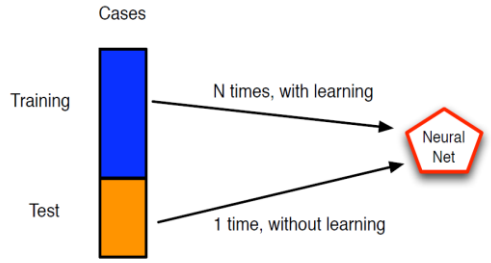

Fig. 1 The essence of the Backpropagation Algorithm [19]

Tang et al. (2017) [21] describes the most typical methods used nowadays in object detection via deep learning. It not only discusses the difference between classical methods and deep learning methods in object detection but also the challenges faced in object detection based on deep learning along with proposing some solutions. It focuses on the framework design and the working principle of models as well as the analysis of performance in real-time and accuracy of detection by keeping track of false acceptance rate (FAR) and false rejection rate (FRR). It highlights the faster recognition rates obtained by using deep neural networks (DNN) and demonstrates the effective object detection even after the crop and warp operations. The classifier can be trained by using an appropriate dataset that can then be further optimized by adjusting the weights and following the approach of supervised learning to achieve the target goal.

Alex Krizhevsky et al. (2014) [24] devised a new method of training a convolution neural network by parallelizing it over various GPUs. This method scales much better than any other method when applied to modern convolution network that is deeply layered. Convolution Neural Networks are big networks that are trained on a large amount of data. The parallelizing of their training can be done in two ways:

1. Different workers train different part of the model (Model parallelism)
2. Different workers train on different data examples (Data Parallelism)

In model parallelism, the input and output of different parts must synchronize. In data parallelism, the model parameters must synchronize to ensure the trained model is consistent. Ideally, both type of parallelism should be exploited as none is better than the other. Model parallelism is more efficient in case of high computation per neuron. Data parallelism is more efficient in the case of higher computation per weight. Batch size is another factor that affects the preference.

There are two types of layers in modern convolution neural networks:

1. Convolution layers: contain 95% of computations but only 5% of parameters, have large representation.
2. Fully-connected layers: contain 5-10% of the computation but 95% of the parameters, have small representation.

A different way of parallelizing looks more attractive for the two types of layers. Data Parallelism suits convolution layers better whereas model parallelism suits fully connected layers better. This is what Alex Krizhevsky proposed in the paper.

One way of doing this is that each worker is assigned a certain amount of data in the beginning when they are training the convolution layers. The workers use this data to train the layers using data parallelism. They must also synchronize the weights. When the time comes to train the fully connected layers, the workers switch to model parallelism.

The backpropagation depends on which of the method was used in feed-forwarding. Previously, the neural networks were trained on a GPU cluster. The network was locally connected but not convolutional. The workers were distributed spatially across the image and only neuron activation near the edges of workers area of responsibility needed to be communicated. In case of using this scheme in convolution networks, the weight needed to be synchronized as well. It would require synchronization at every convolution level. Also, with eight or more workers, the area of responsibility of each worker will be very small making computations inefficient. The scheme proposed by Alex Krizhevsky seemed like a better way of parallelizing the training of neural networks as it even works on architecture that has not been adapted to multi- GPU setting.

Shuiwang et al. (2013) [25] developed a 3D CNN model to detect human action in surveillance videos. This kind of analysis finds its application in domains like intelligent video surveillance, customer behaviour analysis etc. An accurate and precise analysis is difficult due to cluttered backgrounds, viewpoint variation etc. Most of the models employed formerly made certain assumptions about the condition in which the video was taken. Also, they followed a two-step approach: in the first step, the features were computed from raw data frames. In the second step, the detected features were used to train a classifier. However, this method was not practical as features are rarely important in detecting human actions as they may appear drastically different in terms of their appearance and motion patterns. Convolutional neural networks can work directly on raw data, hence not needing to build classifiers based on complex handcrafted features. Deep learning is more efficient at learning as it builds high-level features from low-level ones and can be trained using supervised or unsupervised learning methods and they have been shown to give an excellent result in domains like natural language processing, image restoration, human tracking etc. CNN's have been shown to be unaffected by variations such as poses, lightening and surrounding clutter.

CNN models, however, are currently limited to handling 2D inputs (images). Here they developed a novel 3D model for action recognition in videos that extracts information from both: the spatial dimension as well as the temporal dimension, by performing 3D convolutions. A simpler approach would have been to recognize action at every single frame, failing to

recognize the motion information encoded in a series of frames. It captures the motion information encoded in a series of frames. Multiple channels of information are created from the input frames and the final representation combines information from each channel. By performing multiple distinct convolution operation at a single frame, different types of information can be extracted. Regularization of output and combining the output from various models is done to further boost the performance.

This model was used in a practical situation of analysing airport surveillance videos and it achieved better performance than formerly employed methods. The model was evaluated on TRECVID data, which consists of data from surveillance video footage at London Gatwick Airport. The model achieved the best performance at all the specified categories. It also achieved competitive performance on the KTH data. Key contributions of their work are:

1. Proposal for applying 3D convolution to extract multiple information (both spatial as well as temporal features).
2. 3D convolution architecture developed based on the 3D convolution feature extractors.
3. Auxiliary outputs computed at high-level motion features used to augment the output of the model.
4. The 3D model evaluated.

Kalchbrenner et al. (2014) [26] proposed DCNN (Dynamic Convolution Neural Network) that has the ability to accurately represent sentences. It is adapted for the semantic modelling of sentences for purpose of classification or generalization. The sentence modelling problem is the core of many tasks involving a degree of natural language comprehension including sentiment analysis, paraphrase detection etc. Individual sentences are rarely observed. A sentence must hence be represented in terms of frequently observed n-grams in the sentence and features.

The model employs a global pooling operation over linear sequences called k-Max Pooling. Long- and short-range relations is explicitly captured. The network does no use a parse tree and hence can be easily applied to any language. The model performs significantly better than the strongest baselines in domains like small case binary and multi-class sentiment predictions, six-way question classification and twitter sentiment predictions.

The gap in the literature and proposed model is bridged by integration between the IoT aspects of project and the trained neural network that is used to classify whether image captured from the PiCamera (acting as CCTV) contains a gun leading to potential high-risk activity that could lead to violence thereby generating an alert as well as providing pathway to analyse the gun-related violence rates in the city. Image Classifier can be successfully integrated with IoT to create a system that detects guns (or any other object) in the surrounding and create an alert for it. Other cases for which this system can be applied are accidents, unaccounted baggage, missing kids, stray trash etc. With the growing need for automation and data-centric computations, IoT and Deep Learning can complement each other and fill in the gaps wherever needed.

III. Proposed Work

The smart city comprises of three major components, smart homes that come with special features, smart waste management system and smart streets equipped with intelligent CCTV. Various sensors are placed inside smart homes to detect motion and lighting conditions. Cameras are placed for security purposes. Following are key features of the proposed system:

- The lighting of Smart Home can be controlled remotely via smartphone, and if a room is vacant for a relatively long time then lights are automatically switched off to save energy. Ambient light has also been added.
- Humidity and temperature sensors are used to monitor environmental conditions inside the house. Temperature is regulated by the use of an air conditioner.
- Flame sensor senses if there is a fire outbreak and sends a signal to sound alarms and alert to Smart Home owner's mobile phone in case of a critical condition.
- If an intruder is detected, the image is captured and a copy of it is sent to the owner's email address as well as to the authorities with an alert message.
- Smart Waste Management is implemented in the smart city. The system will keep track of completely filled trash/waste bins that can be used by the State Municipality. Their real-time status can be seen via web-page on the internal server for efficient route planning.
- The streets are made smart as well. The street lights are switched on for specified duration upon detection of motion in its proximity only if natural light is less than threshold and motion is detected in the neighbouring area.
- The PiCamera is used as a CCTV on the streets to capture images at regular intervals along with the location. The images are then sent to an image classifier to detect the presence of guns in them.

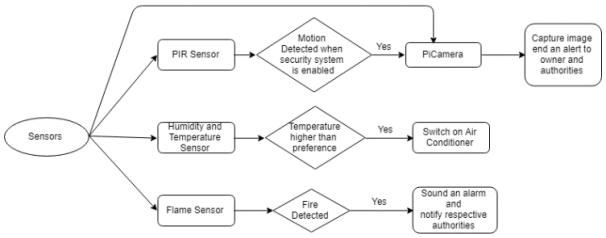

Fig. 2 Control Flow of Smart Home

The control flow of the Smart Home is illustrated in figure 2. It outlines the basic data flow of how aside from smart lighting and control of various components of the smart home, the humidity and temperature inside the house is monitored using the DHT11 sensor and autonomously triggers an action to switch on the air-conditioner if the temperature is higher than the preferred preset. The smart home also has safety and security features. The intrusion detection system uses motion sensors and camera to detect an intruder, take a photograph and

send it to the owner as well as nearest authority alongside generating an alert on the resident's mobile phone [18].

In the presence of natural light is below the threshold, the system checks for the detection of motion. Upon satisfaction of both the conditions, the street lights in the neighbouring area are switched on. After a particular duration, the conditions are checked again and if they are not fulfilled then the lights are switched off to save energy.

Convolutional Neural Networks (CNN's) have a vast number of applications in computer vision, image and video recognition and natural language processing. However, the basic concept at its core remains the same and can be applied to other use-cases as well. CNN's are made up of neurons, like neural networks, and are learnable by adjustable weights and biases. Each neuron receives multiple inputs, performs a weighted sum over them which is then passed through an activation function to obtain an output. However, unlike neural networks, the input in CNN is a multi-channelled image instead of traditional vector input. It can be said that CNN's operate over volumes. The convolutional layer contains a set of independent filters where each of them is independently convolved with an image. These filters are initialized randomly and become our parameters which will be learnt by the network.

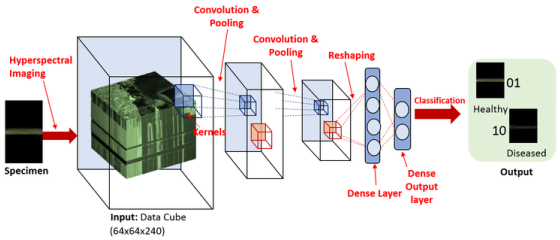

Fig. 3 Architecture of 3D Convolutional Neural Network [27]

The architecture for said Convolutional Neural Network is illustrated in figure 3. The function of Pooling Layer is to progressively reduce the spatial size of representation to thereby reduce the number of parameters and amount of computation. Pooling layer operates on each feature map autonomously. Max Pooling is the most common approach used in pooling.

The Images classifier is built using pre-trained neural networks with a custom classifier layer. The classifier is trained on a dataset comprising of images with the known output by using PyTorch. The working of classifier comprises of following steps:

1. The dataset is divided into training and testing dataset.
2. Data augmentation is done so that the trained classifier performs better at generalizing. The model is tested on the testing dataset.
3. Sufficient accuracy is reached by tweaking network training parameters like learning rate.
4. The network attributes are saved.
5. The classifier used to detect the presence of guns in images sent by the CCTV.
6. If a gun is detected in an image, a high-risk alert is created for that location and is sent to the authorities.

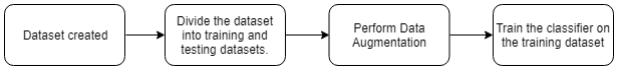

Fig. 4 Training Image Classifier

The classifier training by using a neural network is demonstrated in figure 4. The supervised learning [14] approach is used for training the classifier. It is attained by using the training dataset to present positives and negatives for the target object in the object detection algorithm. After the successful training of the neural network, the test dataset is used to determine if desired results are achieved [4]. If the result of test data is not satisfactory then the training process is repeated for adjusted weights and classifier is thus obtained.

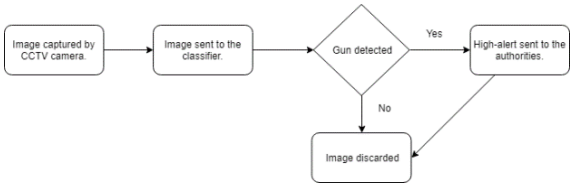

Fig. 5 Detecting High-Risk using Image Classification

As demonstrated in figure 5, the classifier is used to detect gun from an image acquired from CCTV. The classifier checks for the presence of a gun in the image. If a gun is detected, then a high-risk alert is generated and sent to authorities with the location of the potential incident, otherwise, the image is discarded after a preset time span.

Fig. 6 Model of Smart City

The model of Smart City equipped with various sensors is demonstrated in figure 6, having major components as Smart Home, Smart Street Lights and Smart Waste System.

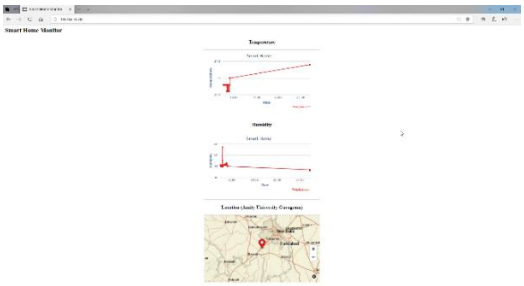

Fig. 7 Web page to monitor humidity and temperature of Smart Home

As represented in figure 7, the web page that can be accessed by the local server which displays a graph for temperature and humidity that is updated in real-time at regular intervals along with the location of Smart Home.

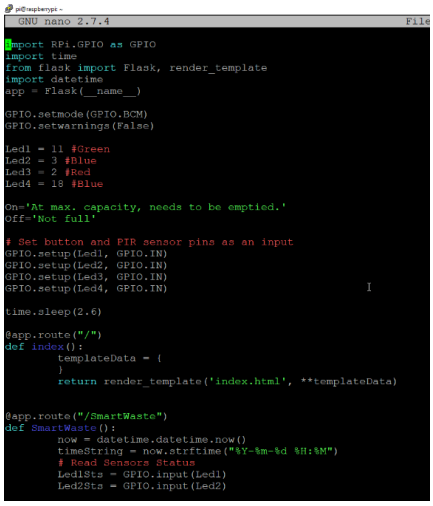

Fig. 8 Flask server

As shown in figure 8, the Flask Server has been used to provide dynamic web-functionalities such as real-time Smart Home monitor and live Smart Waste Management. It is based on Python and allows users to define dedicated functions to handle the web-page requests.

Fig. 9 Example of an image in training and testing dataset

A sample of images that were used to train and test the Image Classifier as demonstrated in figure 9 and were taken from the PiCamera.

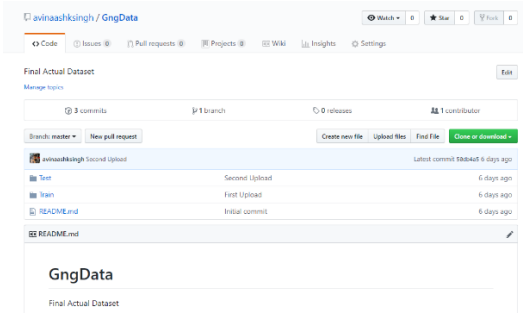

Fig. 10 Dataset on GitHub

As illustrated in figure 10, since files cannot be directly loaded into google Colab, there are certain code snippets available to include files either from a local machine or from Google Drive. These code snippets temporarily load the file. The files get deleted at the end of every session. To go around this problem, the dataset is first organized and then uploaded on GitHub. Then the GitHub repository is cloned in the colab project file. This way, the dataset is cloned in every session whenever the command is run.

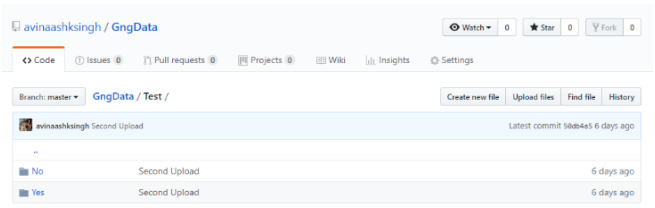

Fig. 11 Organized Dataset

As demonstrated in figure 11, the pre-trained models require the dataset to be organized in a definite structure. The root folder must contain the Training and the Testing set in separate folders. These folders then contain the folders for different categories. While training and testing, the labels are derived from the name of these folders. The pathname of every directory is passed while creating the testing and training dataset.

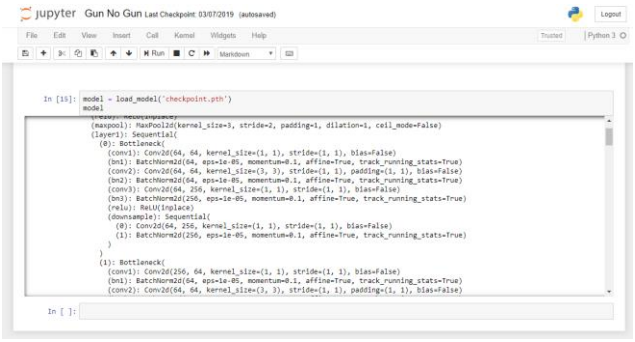

Fig. 12 Convolutional Layers

As shown in figure 12, after loading the pre-trained model from the checkpoint, the model architecture can be displayed. Even though the various layers are beyond the understanding of a newbie, but it is still fascinating to see the amount of work that goes into feature detection and analysis.

IV. Result Analysis

Upon powering the project, Raspbian OS is booted up. The Python scripts for various components are executed at start-up. The calibrated sensors become active, constantly sensing for trigger action. The cloud-based services such as Flask and Blynk are initiated. The integration and resolution of dependencies among the vast number of sensors has been done so they don't conflict when accessing the same GPIO pin. Ideal delays have been introduced for appropriate calibration of sensors to achieve proper functioning. The lighting of Smart Home can be controlled via mobile application. Ambient light

is switched on automatically in the presence of low natural light. The flame sensor constantly checks for a fire outbreak. In case of fire, an alarm is sounded along with a generation of push notification on a mobile phone. Humidity and temperature conditions are monitored whose status and location can also be viewed from a web-page on an internal server. The room's light is switched on for specified time on detection of motion. Aside from the above, the Smart Home also has an intruder detection system. The PiCamera is used to capture an image when the house is vacant and protocol is activated from the remote control. The image is then sent to the owner's email address along with an alert message. The street's lighting is automated to switch them on for specified time upon detection of motion under low natural light. Smart Waste Management System consists of Smart Bins which have a notification light that switches on if the bin is at near-full capacity. The status of bins can be viewed from a remote location by accessing the web-page on the internal server, thereby allowing efficient route planning for cleaning municipality.

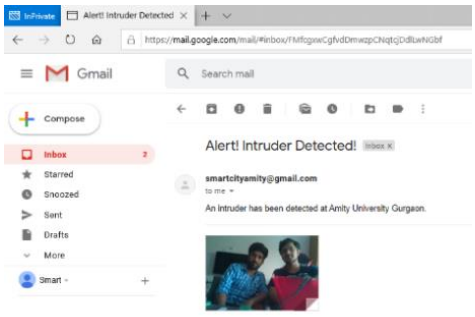

Fig. 13 Email with an image captured by camera upon detection of Intruder

As shown in figure 13, the functioning of the Intruder Protocol. Upon detection on the intruder, an image is captured by PiCamera and emailed to the user with an alert message. It can also be configured to inform authorities about the intruder break-in.

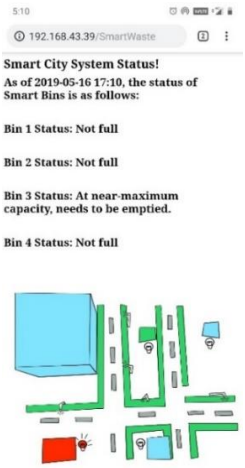

Fig. 14 Webpage for status of Smart Bins in various sectors across the City

As illustrated in figure 14, the web page displays the current date and time along with the status of the Smart Bins location in different sectors of the Smart City. It allows the Municipal Corporation responsible for cleaning the trash to view in advance which bins are close to max capacity and hence, the driver can plan the route accordingly thereby providing better waste management facility.

The PiCamera (acting as CCTV) takes images of the surrounding at regular interval. The images are sent to the image classifier where they are analyzed whether they contain a gun. Whenever the shooter/gun is in its field of vision, an alert is created and sent to the authority (in this case, to the email). The model is full-proof because it gave 86% accuracy during testing. The model was tested during the training phase and also after its final implementation.

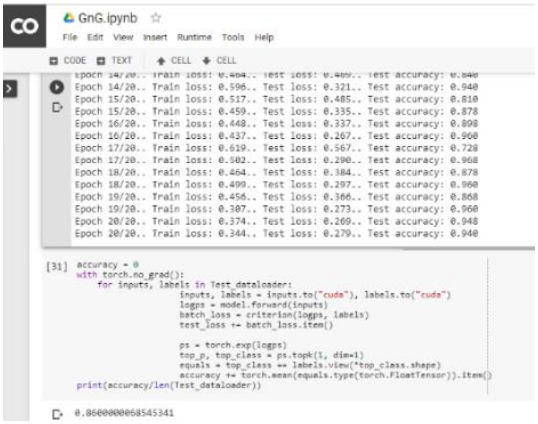

Fig. 15 Training of network

As demonstrated in figure 15, epochs at the time of training the neural network on the created dataset. The network processes and detects features from all the images once in every epoch. The number of images in the network is parsed at one time depending on the batch size. The final training accuracy obtained was 94% and the final testing accuracy was approximately 87%.

Fig. 16 Python script for Gun Detection

The python code for detecting the presence of a gun in the image is demonstrated in figure 16. The normalizing parameters for the classifier based on a neural network used in the system can also be seen. PyTorch, Numpy and TorchVision have been used for the implementation of the classifier as a python script.

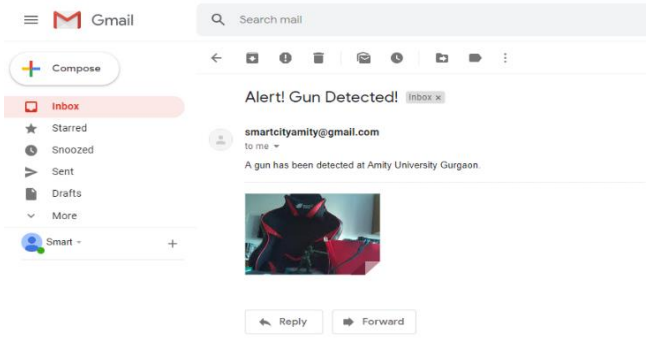

Fig. 17 Alert created by Image Classifier

As shown in figure 17, the alert that is sent to the authority once a gun is detected. The mini-soldier has been used as a gun for training the classifier. The alert is sent in the form of an email with the image attached.

V. Conclusion

It can be concluded that Smart City envisions a far more integrated, autonomous and efficient system than the traditional cities. The smart home provides a much more convenient residential environment that allows residents to possess massively more control than the conventional ones. Other than basic monitoring and control systems, the integration between safety and security module provides better peace of mind to the people of the city. The smart streets can allow the city to be energy efficient, monitor and regulate the traffic to avoid heavy traffic density on common routes. The object detection integrated with IoT is the highlight as presently, no standalone sensor is capable of detecting a target object (gun in this case). Due to the rise in gun-violence rate over recent years, it is an essential feature to be included in the smart city. The system is designed by merging the concept of the Internet of Things that controls several components of Smart City with an image classifier developed by training a neural network. Large-Scale implementation of the proposed work can hence aid in a more energy-efficient ecosystem along with providing some necessary security features.

Microcontroller rooted collaborative functioning system in Vehicles

P. Tarun, T. Pradeep Chandra, G. Anil Kumar and Sudha Yadav

***Abstract*— Automobile industry is growing vast throughout the world. The cost of the vehicles are also moderate. There are a large number of personal vehicles. Due to the surge, road accidents are the major problem. It is not only the duty of the person who drives, but also of the vehicle's manufacturer to ensure more preventive systems suitable for our daily routine. Automobile industry had been taking a few safety steps over the last two decades. Few more safety measures are being added to make the system more versatile. There is a large void in post-accident emergency facilities. If emergency services with definite accident location are provided in time, many lives can be hoarded. In this paper, a novel approach is proposed for this issue and adds some safety measures. Our system will not allow drunken people to drive the vehicle; A help request is sent to helpline Centre with accident location when an accident happens; Vehicle stops automatically if there is any leakage of fuel gas; Driver will be alerted if he/she is in drowsiness state and stops the vehicle if continues to drive in drowsiness state.**

***Index Terms*— Real time accident detection system, road accidents, Prevention of accident, Immediate rescue system, Gas leakage detection, Drowsiness detection.**

I. INTRODUCTION

In the introduction, It is briefed about the accidents and the statistics of the deaths in the past decades. And about, how are accidents happening, what are the major causes of the accidents, what plays the major role in saving a life. Later, we will be comparing our system with the previous, existing and proposed systems. In the next part, It would be described about the sensors used in our system along with their working and some sensor description. In this part, we can find the block diagram of the system and its working. And the next part shows us the flowcharts and gives a brief about the algorithm. Followed by a demo of the system in the pictures and the sample outputs. Lastly the results initiated and the conclusion followed with the references for the whole system.

According to world health organization (WHO) "Global status report on road safety", approximately a million people is losing their valuable life's and 20-30 million people are being injured due to road accidents every year. Among these, 30% of deaths are due to delay in contact with emergency services and 17% of deaths are due to drunken driving [1,6].

In general, when an accident occurs, one has to manually contact the emergency services. Sometimes no one voluntarily comes forward neither to help nor to inform helpline services and wait for others to do, that leads in loss of time which eventually leads to a death of the victim. Many times we do not find any automated systems that could directly intimate helpline services or our close members. Now a days some systems have an option called SOS (Save Our Souls), which also has to be functioned by a person manually.

Chances are evidently high, for those who drink and drive in making an accident. Alcohol slows down one's brain and body responses, which leads to impair our vision and hearing, make one loose his concentration and feel drowsy. A medical report says, for those who drink and drive, night vison will be reduced by 25%. Blood Alcohol Concentration (BAC) is the measure of amount of alcohol present in 100ml of blood. The permissible alcohol limit is 30 mg/100 ml of blood. Right now, There is not any system present in vehicles which prevents drunken people to drive.

As our future is about to be completely on electric cars, LPG and LNG fueled cars. The government of India has announced plans to set up 10,000 CNG distribution stations by 2030 to decrease the usage of diesel and petrol. The risk for LPG and LNG leakage is very high. There is not any system present in vehicles which detects the leakage of LNG/LPG and take preventive measures accordingly. There had been many cases registered over the LPG leakage in cars. LPG is a propane or a butane. LPG leakage results in explosion either in household goods or in vehicles, they also causes irritation when comes in contact with eyes and skin. When LPG leakage occurs, the smell is due to a stench of other chemical called Ethyl Mercaptan, which when inhaled causes dizziness, light headedness, coma and death. They are also hazardous to liver and kidneys. The most dangerous property of this Ethyl mercaptan is Highly inflammable [3].

Sleep deprivation, the term used to mention the drowsiness, is one of the highest risk factor for the car accidents. A survey

Sudha Yadav, Assistant Professor, Department of Electrical & Electronics Engineering, Amrita School of Engineering, Bengaluru, Amrita Vishwa Vidyapeetham, India, sy_sudha@blr.amrita.edu

in United States says, about 20% of the car accidents are due to sleep deprivation. As night rides are more often to the transport vehicles containing heavy goods, the after effects of an accident are very devastating, resulting mostly in on spot deaths and in these cases sleep deprivation plays a major role. Here, delay in immediate interaction with helpline services also costs a life.

To overcome these, a few rescue systems exist whose responses are partly delayed from the emergency services and are less effective in safety and preventive measures. Our model is made in consideration with various causes of accidents. So we came up with a real time alternative which upgrades the safety in the system and decreases the delay in responses.

II. RELATED WORKS

The literature survey for the work is discussed in this section. Accidents are being detected by piezo electric sensors [6]. Based on the impact, a corresponding voltage is generated between plates, which is read by micro controller. There is a chance that piezo electric sensor doesn't detect the accident, for example it is difficult for piezo electric sensor to detect a sideswipe collision. Some set of EEG signals from brain are taken and studied to detect whether driver had alcohol [4]. Gas sensor MQ6 is used for detecting any leakage of LPG gas from the gas cylinders in home and turns off the regulator if system detects any LPG [3]. Eye blink sensor is used in controlling home appliances [5].

In our proposed system, we used an eye blink sensor for detecting drowsiness based on the eye blink length, Vibration sensor SW420 for detecting accident, MQ3 gas sensor for alcohol level detection, MQ6 gas sensor for detection of leakage of fuel gasses.

III. SYSTEM DESCRIPTION AND DESIGN

Our system uses Arduino MEGA 2560 as micro controller, gas sensor MQ3 for detecting the alcohol content, vibration sensor SW420 to detect an accident, H bridge for controlling the motor drive. Eye blink sensor for detecting drowsiness. MQ6 for detecting any leakage of LPG fuel or any smoke. GPS module to get the co-ordinates of a place where accident occurred and a GSM module for sending a help request to emergency services.

A. Arduino MEGA 2560

Arduino MEGA has following :
Operating Voltage – 5v
Input Voltage (recommended) 7-12v
Digital I/O Pins – 54
Analog Input pins – 16
DC current per I/O pin – 40 mA
Flash Memory 256 KB
SRAM – 8 KB
Clock Speed – 16MHz
UART'S – 4

The Arduino ATMEGA 2560 is powered using USB or with an external constant DC power supply. External supply should be constant DC of 7-12 V. It can be supplied by using an AC-DC adapter or by using a DC battery. Arduino ATMEGA 2560 has a 2.1 mm power jack. If we use constant battery The positive terminal is connected to Vin pin of Arduino and the ground to GND pin of Arduino. The input supply to Arduino should not exceed 12V, if exceeds the regulator overheats and damages the board. If input supply is less than 7V, the board becomes unstable. The Arduino ATMEGA 2560 differs from other Arduino boards in, it do not use the FTDI USB to serial drive chip instead, it uses an ATMEGA8U2 as a USB to Serial converter.

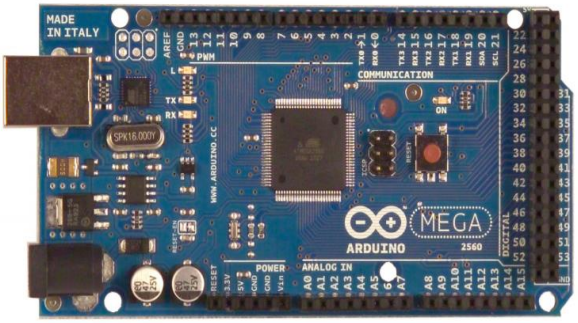

Fig 1. Arduino ATMEGA 2560.

Communication of Arduino ATMEGA 2560 with other modules like computers, micro controllers, etc.… can be done in different ways. It has a total of four UART's (Universal Asynchronous Receiver Transmitter) for TTL (transistor-transistor logic) serial communication. The Arduino software contains a serial monitor which makes the simple textual data from the board. The Receiver and Transmitter pin LED's will be flashing when the data is being transmitted via the ATMEGA8U2 chip and a USB connection to the computer. Arduino ATMEGA 2560 has a reset button on board. The Arduino ATMEGA 2560 is designed such that reset can be done by running in software of a connected computer. Each time when we connect Arduino ATMEGA 2560, it resets the data that is present in the micro controller.

B. Gas sensor MQ3 & Vibration Sensor SW-420

This sensor contains a sensitive material that is less conductive in nature. The sensor's conductivity increases as the concentration of the alcohol gas in air increases. The output signal strength depends on the concentration of the gas with the help of a simple electro circuit. This MQ-3 gas sensor has high sensitivity to alcohol, and has a good resistance against the disturbance of gasoline, smoke and vapour. This sensor is used to detect the alcohol at different concentrations and it is cost effective too and also suitable for various applications.

Fig 2. MQ-3 gas sensor.

It has high sensitivity and fast response time. Sensor provides an analog resistive output based on alcohol concentration.

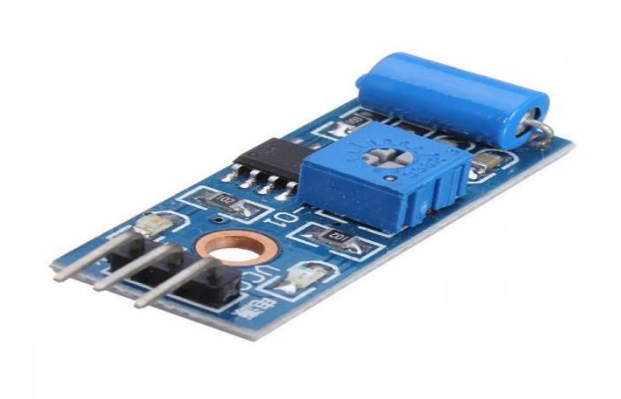

Fig 3. Vibration sensor SW420.

It is a highly sensitive non-directional vibration sensor. It's working can be described as, if the module is stable, the circuit is turned on and the output will be high. If some vibration or any movement occurs in the module, the circuit will be disconnected and the output will be low. Advantage of this module or sensor is that, the sensitivity of the module can be adjusted accordingly to our own needs. The working bias of the circuit is between 3.3V to 5V DC.

C. H- Bridge L298N

It is defined as a bridge circuit built of four switches, which can be used to control the flow of current to the load. It is interfaced with Arduino and controlled using Control pins. Based on the digital values given to the control pins, operation varies.

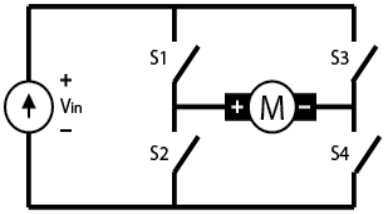

Fig 4. H-bridge circuit.

- If switches S1 and S4 are closed, then the current will flow from the left to the right and results in forward operation of the motor.
- The current in the circuit will flow from the source, through switch S1, and then through the load, then through switch S4.

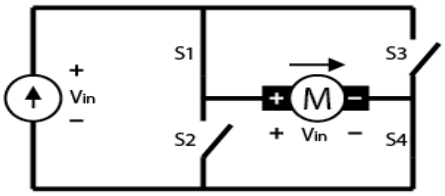

Fig 5. Forward operation.

- If switches S2 and S3 are closed, then the current will flow from the right to the left and results in reverse operation of the motor.
- The current will flow from the source, through the switch S3, and then through the load, then through switch S2.

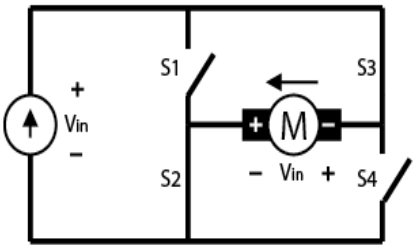

Fig 6. Reverse operation.

It is very cautious that when working with the H-bridges, check carefully while switching, short circuiting should never happen so that, it may damage the load and results in burning of the bridge circuit.
The below case is seen when switch S1 and switch S2 (or) switch S3 and switch S4 are closed.

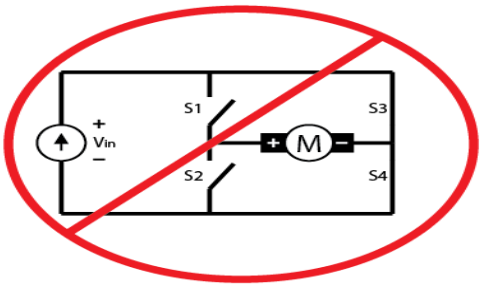

Fig 7. Cautious operation.

D. GSM and GPS module

The SIM800 is a quad band GSM module which can be implanted straightforwardly by the user. AT stands for ATTENTION. Attention commands are used for setting UP and controlling the module. There are some Attention commands in making a phone call and delivering a message.

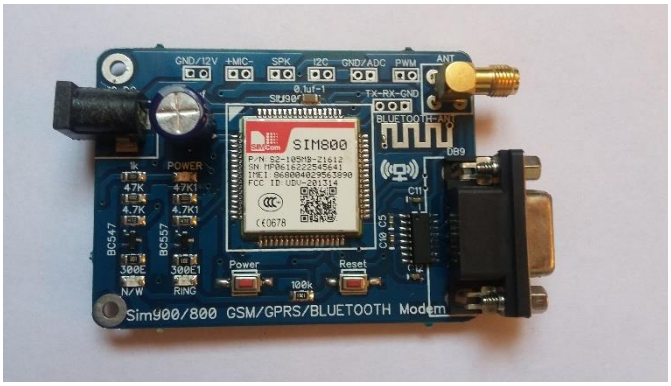

Fig 8. GSM SIM800 module

The NEO-6M GPS module is a well dressed GPS receiver with an integrated 25 x 25 x 4mm ceramic antenna, which gives a robust satellite tv for pc search capability. With the power and signal indicators, it could extol the clever working of the module. The facts backup battery, the module can store the facts, if the main energy gets shut downed accidentally.

Fig 9. NEO 6M GPS module

E. Eye blink sensor

The eye is irradiated by an IR led, that is powered with a +5V DC from the energy supply and the reflected light is detected by an IR photo diode. The variant throughout the eye will vary as per the eye blink. The precise functionality relies significantly upon the arrangement and the aiming of emitter and detector with the eye. If the eye is shuttered, then the output is high and if not, the output is low. This is to check whether the attention is downing or in establishing the position. This output is given to common sense circuit (logic circuit) to indicate the alarm.

Fig 10. Eye blink sensor

F. Block diagram

The block diagram represents the overall system. The sensors involved in the system are Gas sensor MQ3, Vibration sensor SW420, Gas sensor MQ6 and an eye blink sensor. For controlling the motor we used the H-bridge. For communicating an accident occurred, we used a GSM 800C and for getting the accident co-ordinates we used a NEO-6M module. The micro controller we used in this system is Arduino ATMEGA 2560.

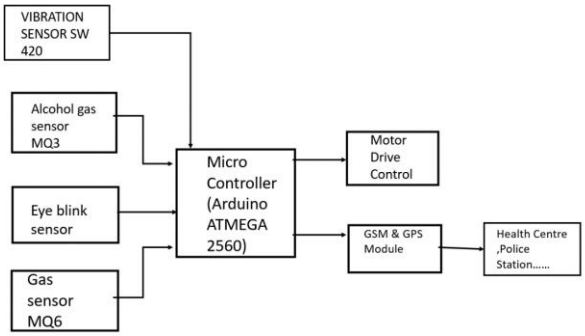

Fig. 11. Block diagram

MQ3 gas sensor gets the alcohol content that is present in the driver's body and compares it to the threshold value. If it exceeds the threshold value, vehicle engine will not start. If the alcohol content is within the prescribed limits, the vehicle starts. Once the vehicle is started, it continuously checks for the eye blink length from the eye blink sensor. In general, the closing eye blink length is 300-500 milli seconds. We kept a threshold value for eye blink length as one second. If it exceeds, buzzer turns ON and count will get incremented by one. If the count equals five, the buzzer will turn on and the vehicle stops. There may be chances for the driver closing eyes for more than one second if there is any dust or if he/she gets some dust irritation. To overcome this issue, we used this count command as mentioned.

There are two interrupts present in our system, one is when an accident occurs and the other is when there is any leakage in the LNG /LPG in the engine cabin. System continuously checks for the eye blink length but if any interrupt comes, it stops checking the eye blink length and proceeds further for the required actions on the necessity of the interrupts.

If MQ6 gas sensor detects any leakage of LNG/LPG in the engine cabin, then the interrupt comes in and stops the main

program. The required action, if there is any leakage of LPG/LNG in the engine cabin, is to turn on the buzzer and further stopping the vehicle.

If an accident occurs, Vibration sensor SW 420 detects and asks for an interrupt service routine. The main program is stopped and required action for the accident is proceeded. It checks for the accident and then the Arduino gets the geo coordinates from NEO 6M module and a help message is sent to help Centre with the location coordinates (latitude and longitude) link.

IV. FLOW CHART

The below schematic flow charts will explain the work flow process of the system. Interrupt occurs in two ways, one when an accident occurs and other when there is any leakage of LPG/CNG fuel gas. Main program always checks for drowsiness detection. The below flowchart is the main program work flow.

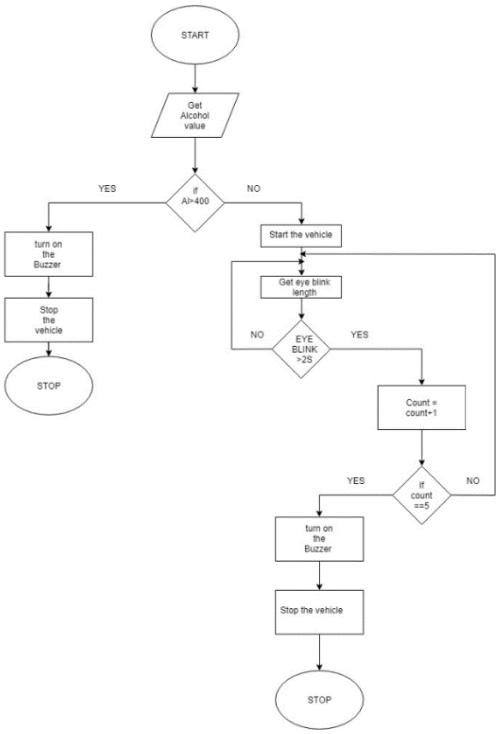

Fig 12. Main program flow chart

When driver starts the vehicle, MQ3 sensor will activate. The MQ3 gas sensor gets the value of the alcohol content that is present in the driver's body by the exhaled air in the driver's cabin and transfer that data to micro controller Arduino ATMEGA 2560.

The value is compared with the threshold value, if it exceeds the vehicle will not start and the buzzer gets turned ON indicating that driver is drunken and not allowing him to drive the vehicle. If the value is present within the limits, the vehicle starts, and eye blink sensor activates. The eye blink length is continuously checked with the threshold value. If it exceeds, a buzzer will turn ON and sounds with low pitch to help driver to get rid of drowsiness and a count will get incremented every time when it exceeds. If the count exceeds the threshold value then the buzzer turns ON and sounds with high pitch and stops the vehicle.

In our system we used a motor instead of an engine. So, for turning ON of engine is turning ON of motor and vice versa. H-bridge is used to control the motor. H - bridge can be interfaced with Arduino ATMEGA 2560. It can be controlled using control pins of H-bridge.

The below flowchart (fig 13) shows the work flow process, whenever an accident occurs, an interrupt service routine comes and pauses the main program. Accident is detected by the vibration sensor SW420. When an accident occurs, vehicle will have heavy vibrations at the colliding instant. Whenever there is a massive vibration, the SW 420 sensor senses it and asks for interrupt service routine. Whenever interrupt comes in, the main program is kept on hold and required action takes place for the accident. The location coordinates of the accident are given to the micro controller through the GPS NEO 6M module. Using GSM 800 module, a help message is forwarded to the helpline center's with the accident location coordinates.

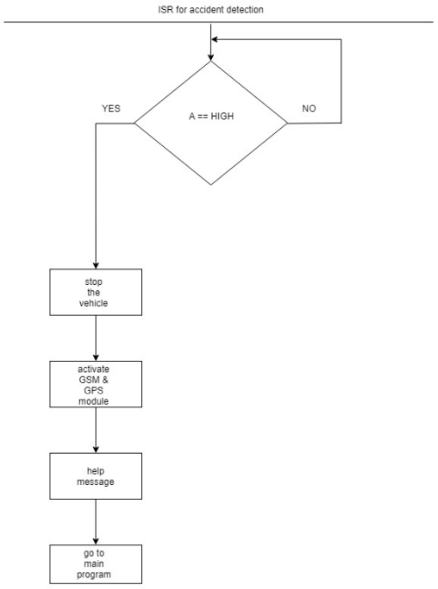

Fig 13. Accident detection interrupt flow chart.

The below flowchart (fig 14) is the work flow process when there is any leakage in the fuel gas. MQ6 gas sensor is used for detecting any fuel gas (LPG/LNG) in the engine cabin. If it detects any leakage gas, it calls for an interrupt service routine. The main program is paused and required interrupt function executes. The vehicle shut downs, buzzer will turn ON, LED turns on indicating there is a leakage of fuel in the vehicle.

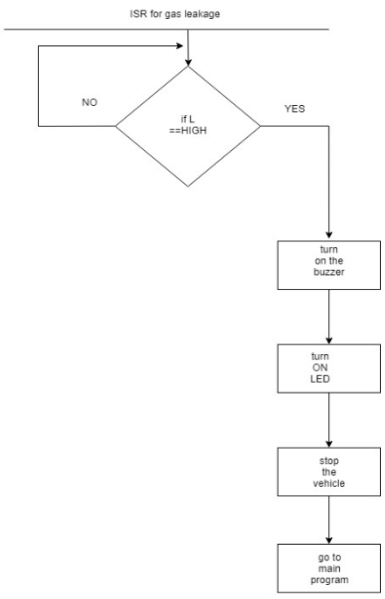

Fig 14. Gas leakage interrupt flowchart.

The flowchart in (fig 15) shows the representation of the entire work flow process of the system. Whenever an accident occurs, corresponding action takes place. The system uses interrupts for accident and gas leakage detection. Eye blink rate is continuously assessed in the main program. If any interrupt comes, required action takes place. The interrupt flowcharts and main program flow chart are explained in detail in the above sections.

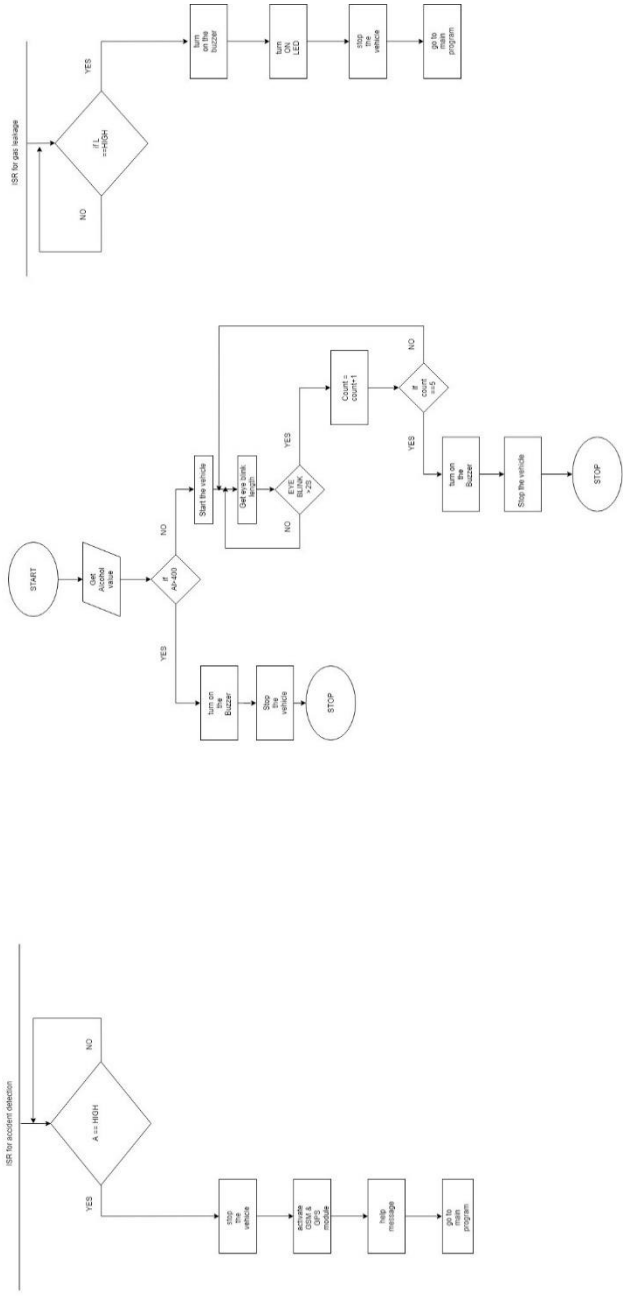

Fig 15. Entire flow chart.

V. HARDWARE SETUP AND RESULT

Connecting our system accordingly with the vehicle's central Electronic Control Unit(ECU), so that it co-ordinates with the unit adaptively.

Main burden arises in positioning of the sensors i.e., as of our knowledge:

a)Alcohol detection sensor is placed at the nearest point to the driver's face.

b)Gas detection sensor is placed in the exhaust chamber near the engine.

c)Vibration sensor is located at a stable position, where minute vibrations cannot disturb the sensor's output. And the remaining

module of it is hoarded with the Arduino near the ECU.
d)Eye blink sensor is located in the glasses, These has to be worn by the driver only while driving.
e) A buzzer has to be located on the dashboard.

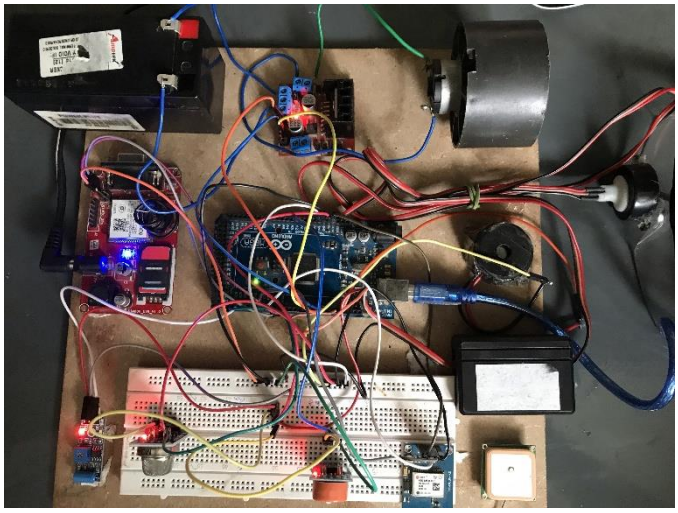

Fig 16. Entire setup

The above picture is the entire set up of our system. We connected the sensors : MQ3 gas sensor, MQ6 gas sensor on bread board and vibration sensor on bottom left. A buzzer which is present beside the motor turns ON when driver goes to drowsiness state or if the driver is in alcoholic state. Motor stops resulting in stopping the vehicle, when there is a leakage of LPG in the system.

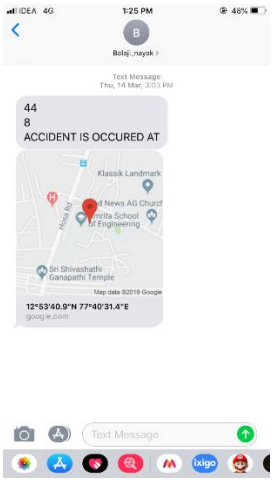

Fig 17. Help request message.

The above figure is the help request that is sent automatically by our system when an accident occurred. The help request will be having the co-ordinates of the accident's location.

Fig 18. Location coordinates of the accident.

The above figure is the location coordinates of the accident occurred. The red pin mark indicates the accident location and the blue mark indicates our location. The request message sent with the location co-ordinates of the accident helps to fasten the rescue process.

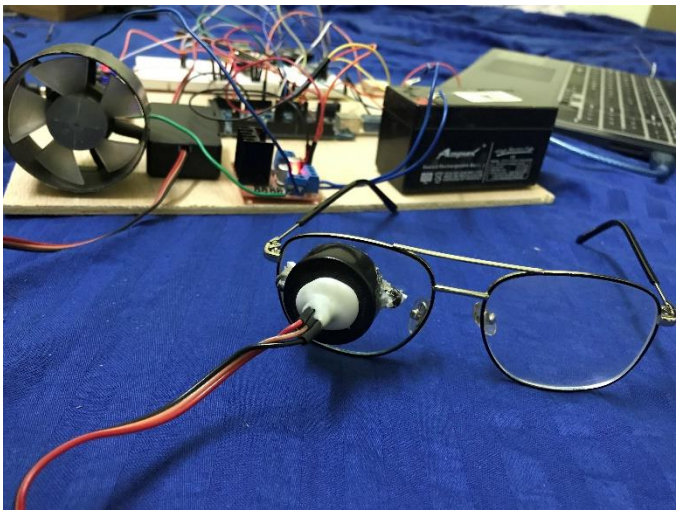

Fig 18. Eye blink sensor.

The entire setup with eye blink sensor. The eye blink length is continuously cross checked with the microcontroller. If any mismatch occurs (drowsiness), it buzzes for one second duration and if it continues, vehicle (motor) stops and a buzzer with high pitch sounds.

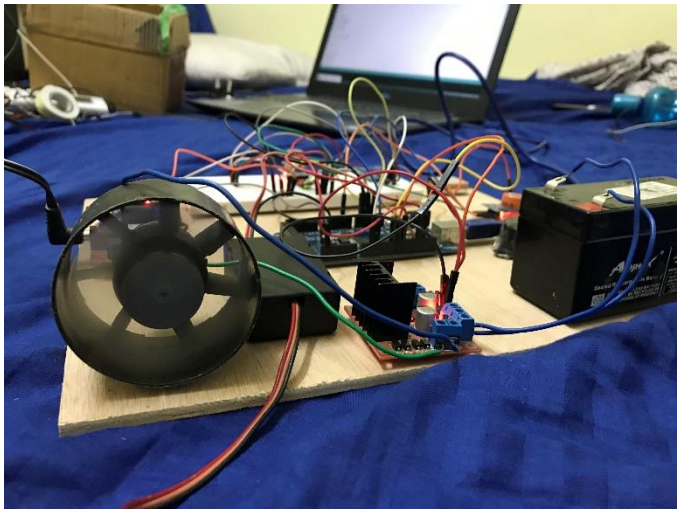

Fig 19. Normal condition.

From the above image we can observe the motor is in ON condition indicates everything is normal which includes

- Driver is not drunken.
- No leakage of fuel gas.
- Driver is not in drowsiness state.
- No accident occurred.

The entire setup ensures a faster rescue operation for accidents and also warns the driver on certain stances such as over speeding, while going to drowsiness state and if any leakage of LPG in the system.

On a whole, this system helps in a better and a faster way of rescue in lone stances, this helps in reducing the risk of losing lives by establishing some rescue in a minimal time.

VI. OBJECTIVES ACHEIVED

Our prototype is aimed to be designed and implemented by the automobile manufacturers in the vehicles. As it locates an accident and prevents the driver in undergoing an accident at typical times. The objectives achieved from the proposed model are summarized below:

- Mediate the Sensor information and locate the accident location using GPS for help and rescue.
- In case of any gas leakage(LPG) , it alerts the driver.
- In case of any drowsiness, it alerts the driver as a threatening call (vibration /Buzzer).

VII. CONCLUSION

The Proposed system makes use of various sensors to detect an accident, leakage of fuel gas, level of alcohol present and drowsiness. prevents drunken people to drive the vehicle, Alerts driver when he/she goes to drowsiness state, Stops the vehicle when it detects any leakage of CNG/LPG in the engine cabin and detects an accident on real time system and inform the supervisory with the accident location.

As a further extension, the Drowsiness of the driver can be precisely detected using image processing and based on the state of drowsiness, command will be initiated with an alert and the vehicle will automatically slows down and stops. Fire Extinguishers will be automatically sprayed if there is any fire in the vehicle. Accident detection can be linked directly to the air bag system in vehicles, It makes more simpler reducing the complexity.

Abstract - Over the last few years, WSNs has attracted tangible involvement in many real time applications. They are composed of small, low cost sensor nodes and these nodes having limited power. After consumption of power, sensor nodes become dead and the life period of WSNs depends on life of sensor nodes present in the network. Sensor nodes are generally deployed in remote area where recharging or replacement of battery is not possible. Hence, it is compulsory to develop some the techniques to improve the life of the nodes and life-time of the network. Clustering protocol is used to increase the lifetime of the wireless sensor networks and for long distance data transmission; Multi hop roughing protocol are preferred. MH technique reduced the energy cost of every node which lies in path. This paper describes various inter cluster multi hop routing protocols in WSNs.

Keywords - ***Wireless Sensor Network, cluster, multi-hop and energy efficient routing protocols.***

I. Introduction

Wireless sensor networks are formed by small, compact, low energy, low cost, multifunctional sensor nodes which are placed in the wanted region. Each node can sense the physical condition of environment surrounding it and also can transmit and receive the data. Currently, WSNs have been broadly used for the tracking and surveillance, environmental monitoring, medical care, infrastructure management, and many other areas [1]. WSNs are usually used in military operations [2]. However, sensor nodes are generally spread out in the precipitous and hostile domain where it is tough to reach and power availability is restricted. Therefore, sensor nodes may be faulty and unreliable. Generally, hardware fault and software fault are the two types of fault mainly occurring in WSN. The fault in hardware is usually due to damage of sensor nodes or due to low energy, and then those nodes cannot collect and transmit the data. Hence, energy is the major issue in the WSNs. Efficient use of nodes' available energy can solve low energy problem in WSNs. By using routing process in the network, we can utilize the available energy of node efficiently. Hence, all researchers target the energy-efficient and reliable routing protocol.

According to structure of network, all the routing techniques in WSN mainly divided into two categories: 1) hierarchical routing, 2) flat routing [3]. Architecture of hierarchical routing technique helps to get high scalability and efficiency in the network. In this routing all nodes perform different works. Entire area of network is portioned into different clusters and every cluster contains member nodes and cluster head. In flat routing protocols, same type of work is performed by all the nodes in the network.

Data transmission between nodes and base station can transmit in mainly two ways: 1) Direct transmission, 2) Multi-hop transmission [4] [5]. In direct transmission, each sensor nodes transmit sensed data to base station without using any intermediate nodes. So, it use large amount of energy to transmit the data for the far nodes. To solve this issue, we use MH transmission. In this, all nodes work cooperatively to relay data to the base station; as a result the total distance is divided into small distances. Also multi-hop technique uniformly distributed the energy cost of network between the all nodes but it is not guaranteed that overall energy consumption along the path is minimized. So, it may possible that total cost in multi-hop transmission is greater than direct transmission.

Clustering is used to improve the life duration of the WSN and Multi-Hop (MH) techniques are preferred in long distance transmission reduce the energy cost every node which lies in path. So, for long distance, multi-hop communication is adopted among CHs. Figure 1 shows the multi-hop routing among CHs of clusters. This paper provides a review on different multi-hop routing techniques in clustering protocol.

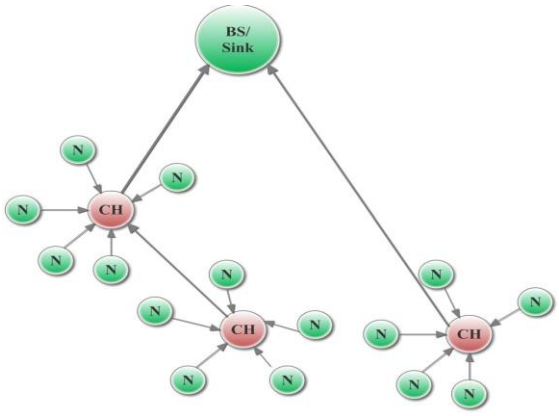

Fig. 1: Multi-hop in clustering protocol

II. Inter-cluster multi-hop routing protocols

1) Multi-hop-LEACH

In WSNs energy consumption is determine by radio energy model. According to this, energy consumption depends on

the distance from cluster head to base station. If distance between it is more than a threshold value, then energy consumption is directly proportional to d^4 (d=distance). In large area of network, distance between base station and some cluster heads are greater than threshold value. So, these cluster head dissipate their energy very rapidly and become dead. Such type of problem cannot be handles by basic LEACH. So, we use MH LEACH [6] which handles such type of problem. This routing technique improves the performance of network by choosing MH communication between base station and cluster heads. In multi hop leach protocol, set-up stage is same as to the LEACH protocol but in steady stage, CHs which distance is greater than threshold value are selected as hoping nodes via which transmitted data goes to the destination or BS. The CHs which distance is less than threshold distance from the BS, they transmit their information directly (single hop communication) to base station.

Multi-hop LEACH is scalable and energy efficient but it is more complex and it increase network overhead because of MH transmission via relay nodes.

2) Energy-LEACH

E-LEACH [7] technique is based upon the residual or remaining energy of nodes. Cluster head selection is in this technique is depending upon the energy left in the nodes but working principal of it is same like LEACH. In this technique, any node become a CH in first round because initially all nodes have same energy, so each nodes have the same probability select as a CH in the first round. Randomly, $N_{CH} = p$ x N_t number of nodes are chosen as the cluster heads. Where N_{CH} denotes the number of CHs in the 1st round and other notations are as usual. In 1st round each node consume different amount of energy, so energy left in each nodes are different after finishing of 1st round. So, the nodes in which left energy (residual energy) have more, that nodes have more probability to select as cluster heads and remaining are member nodes.

In E LEACH protocol, always higher energy nodes are selected as cluster heads in every round that improved the overall life of the WSNs. This protocol only worried about the residual energy of the nodes it is not worries about optimal path. By selecting optimal path, more energy can be saved. So, this protocol is not overall energy efficient.

3) WST LEACH

WST LEACH [8] protocol is solving the following two problem of basic LEACH, first is, cluster head selection and second is, in which way CHs and base station communicate. In this protocol, CH selection process is different for forming a weighted spanning tree. For this protocol, a new modified $T(n)$ formula is given by equation 1 for CH selection. In Equation 1, the coefficients are denoted by c_1, c_2 and c_3, node n residual energy is denoted by *'e'*, initial energy is denoted by 'E_0', '*Nb'* denotes the *n* neighbor's node, '*N'* denotes the total nodes present in the WSN, *'d'* denotes the distance and probability of node n selected as CH is denoted by '*p'*.

$$T(n) = \frac{P}{1 - P * (r \; mod(\frac{1}{p}))} * \left[c_1 * \left(\frac{e}{E_0}\right) + c_2 * \frac{Nb}{p * N}\right) + c_3 * (1/d)] \quad (1)$$

In this protocol, CHs communicates with base station by multi-hop communication. Each CH assigned with some weight. According to this weight spanning tree is formed. Weight formula is given by equation 2.

$$W(j,k) = \frac{e(j)}{E_0} * \frac{N}{M(j)} * \frac{1}{d(j,k)^i} \quad (2)$$

Where, 'W (j,k)' is weight of j^{th} and k^{th} cluster head and whichever is higher magnitude between *i* and *j* cluster heads that include in the spanning tree. '*e(j)'* denotes remaining energy of j^{th} cluster heads. CHs having highest weight are joining spanning tree.

By using WST LEACH protocol, communication path is optimized. So, it is more energy efficient and also it can improve the life of the network but it has some issues of scalability and control packets overheads.

4) Multi-hop Routing-LEACH

The target of MHR-LEACH [9] is to reduce the power utilization by the network and increase the life of network. In this protocol, the entire areas are divided into many layers and make sequence of various layers of clusters and all these clusters having equal size in every layer. It means that any member nodes of cluster transmit their information to base station in same no. of hops. By the help of TDMA scheduling, base station allot a time slot for each cluster head and according to it, each cluster heads allot a time slot for own cluster member . In this protocol, the node having highest residual energy can select as a cluster head.

MHR-LEACH protocol is increase the life of the network and it is highly scalable but hotspot problem the main issue with it.

5) LEACH D

LEACH-D [10] protocol is used to achieve better network lifetime. It is achieved in the three ways. 1st approach is CHs selection. It is depend upon energy left in the nodes and the nodes density distribution. In this protocol, nodes which located in high density and having more remaining energy are chosen as cluster head. Second approach is based upon distance to base station and degree of connectivity. In this cluster head decide and calculate the cluster radius. Cluster is form by nodes join the CH according to distance from the CH to the BS and energy of cluster head. The cluster head reduces energy consumption by adopting this approach. In third approach, multi-hop transmission is uses among CHs to send information from member nodes to base station.

In LEACH D, CH is selected by threshold value which is calculated by help of energy and connectivity density factor. This technique increases the scalability and energy efficiency of the network but hotspot problem arises in it.

6) C-LEACH

In Cell LEACH [11] protocol, total area is divided into some hexagonal cells and each cell having some sensor nodes. A cluster is formed by seven nearby cells. A special node is present among the nodes present in the cells which called cell head and other nodes are called as member nodes and every cluster having a cluster head and they are changing randomly in each round. According to TDMA, time slice is allotted by cell head to the cell members and the data transmission by cell member during its allotted time slice. In this protocol, when member nodes transmit their information to cell heads, all other nodes are off, after that cell head send the all received information to own cluster head and then cluster head send it to base station by choosing the smallest path between them.

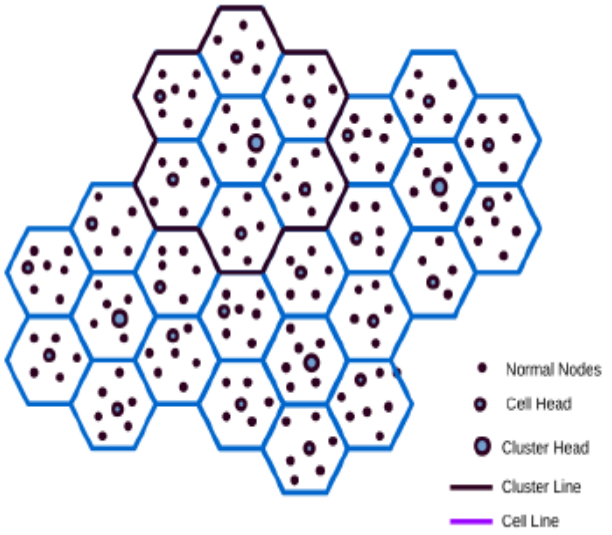

Fig. 2: Cells and Cluster.

Figure 2 shows the cells and clusters which form by seven cells.

C LEACH improves scalability and energy efficiency and it provide very good network coverage but overhead and complexity are increased.

7) Enhanced-LEACH

In E-LEACH [12] protocol, sufficient number nodes selected as cluster heads and round time is varied in each round to improve the life of network and distribute energy equally. To calculate the power used, this protocol add the power consume by each node of the network to send the data. In this protocol, two conditions are there for the selection cluster head and these conditions are following in every round. 1st is energy left in the nodes and 2nd is amount of energy required to send information to base station. The main benefit of following these two conditions is that energy distribution in the network is uniformly distributed. In this protocol, CH selection is depending upon remaining energy of node and power required to transmit information from cluster head to base station.

The E-LEACH protocol is energy efficient and highly scalable but packet overhead and delay in the transmission are the issue with it.

8) EEMH-LEACH

EEMH-LEACH [13] protocol is use to minimize the problem of direct communication between cluster head to base station and selection of cluster head in basic LEACH. Three different approaches have been used in this protocol. First one is average energy remaining energy are used for the selection of cluster heads, second one is finding a path between cluster head and base station for communication and in this path energy cost should be minimum, third one is direct communication between base station and nodes which are nearer to it. For selection of cluster head, we have required to calculate the a threshold value *TH*(*n*) similar to LEACH. But it have one extra parameter which is energy remaining. It is denoted by *E(Re)*. New threshold *TH*(*n*) and *E(Re)* are given by eq. 3 and 4.

$$TH(n) = \begin{cases} \dfrac{P}{1 - P * (r \bmod (\frac{1}{P}))} * E(Re) & : if\ n \epsilon G \\ 0 & : otherwise \end{cases} \quad (3)$$

$$E(Re) = \begin{cases} \dfrac{E_{res} - E_{avg}}{E_{res}} & : if\ E_{res} > E_{res} \\ 1 - E_{avg} & : otherwise \end{cases} \quad (4)$$

When cluster head receives CH message from the cluster head or base station they computes communication cost matrix *b* and it is calculated by help of eq. 5.

$$b = \begin{cases} C(m) + d_{mn}^4 & : d_{mn} \geq d_0 \\ C(m) + d_{mn}^2 & : d_{mn} < d_0 \end{cases} \quad (5)$$

Where *C*(*m*) denotes the communication cost matrix of node *m* & d_{mn} denotes the displacement between nodes *m* & *n*. using equation 5 and 6 we can calculate the cost metric of node *n*.

$$C(n) = \min(C(n), c) \quad (6)$$

Using cost matrix of *m* we can find data sending path between cluster head and base station.

EEMH-LEACH technique uses multi-hop and single hop to send data between clusters and BS. So, it saves significant energy and also good in packet delivery but delay in the packets transmission is increased.

9) Orphan-LEACH

In WSNs some nodes are there for which no cluster head are assigned. These nodes are called orphan nodes which are consider in O-LEACH [14]. This protocol is discussed in two situations. In 1st situation, a member nodes work like a gateway of orphan nodes and the orphan nodes transmit own information to the gateway by joining it. After that, it collects the information and transmits them to base station. In 2nd situation, nodes which lie in an unclosed region are called orphan nodes and they create a sub cluster. Cluster head selection is based upon the distance from gateway nodes.

This protocol is use to get large coverage area rate of connectivity. It is more energy efficient and scalable. The issue with it is searching of orphan nodes and knowledge about it.

.

10) Cross Layer-LEACH

Cross layer method is used in CL-LEACH [15] to increase life of network. Entire function of CL-LEACH is partition in four different parts. First one is making of cluster, in which every node in the cluster choose own cluster head according distance between cluster head and base station and energy. In second part, routing process achieve in two steps: (i) distance calculation and (ii) route discovery. Distance between two nodes is calculated by eq. 7.

$$D = \sqrt{(p_2 - p_1)^2 + (q_2 - q_1)^2} \qquad (7)$$

Where, (p_1, q_1) is coordinates of first node and (p_2 , q_2) is coordinates of second node. In the route discovery, first node always checks the cache in the route before transmitting the information to next node, if any route cache present in the path then information is not transmitted otherwise transmitted. In CL-MAC model if remaining energy of node is more than threshold value then this node works like a relay node in MH communication. Brocken link along the path is detected by route maintenance and they are maintaining by adding new paths line in pre-existing path.

CL-MAC protocol is energy efficient, it has low message cost and live nodes present in the network are more, although it have complexity and message overhead.

11) DHL-LEACH

DHL-LEACH [16] technique resolves the problem which created due to double hop transmission structure. The sensor node nearer to base station lives in lower most layer of network. According to consumption of power, entire area is portioned in some layers. In data sending period, nodes present in the lower most layers measure their distance from cluster head and base station and compare it. If BS distance is shorter than to CH then that nodes directly transmit their sensed information to base station else they transmit them to cluster head. So, the nodes which lies away from base station, they transmit their information to cluster head, after that cluster head transmit them to base station.

DHL LEACH technique is better in terms of power utilization but in large scale networks it is suffers from short node lifespan problem.

12) Improved MHT-LEACH

In IMHT-LEACH [17] divides the all cluster heads into many levels, instead of dividing in only two levels like in MHT-LEACH. This protocol gives a different way to route the information to BS via different the levels. It reduces the data transmission cost when network area is large. In this protocol, all the cluster heads are separated into levels according to distance from the base station and *do/2* is the length of each level. This protocol has four stages to set a route between cluster head and base station: (i) Setup phase (ii) Announcement Phase (iii) Routing Phase and (iv) Redundancy Phase.

IMHT-LEACH technique improves the life of the network, stability and throughput WSNs.

13) EACBM

The basic operation of EACBM [18] is clustering and multi-hoping. It has three level heterogeneous clusters and three types of sensor nodes (SNs): (i) normal sensor nodes, (ii) intermediate sensor nodes and (iii) advance sensor nodes. These all nodes randomly deployed in the network area. In this technique, selection of cluster head is depend upon the probabilistic equation and its count is fixed. In this protocol, the nodes which are not attach to any cluster head or they not comes under the sensing range of cluster head are created a sub cluster because it is compulsory to gather information from every nodes of network. Cluster head gather information from member node and transmit them to base station by MH communication. Working diagram of EACBM shown by figure 3.

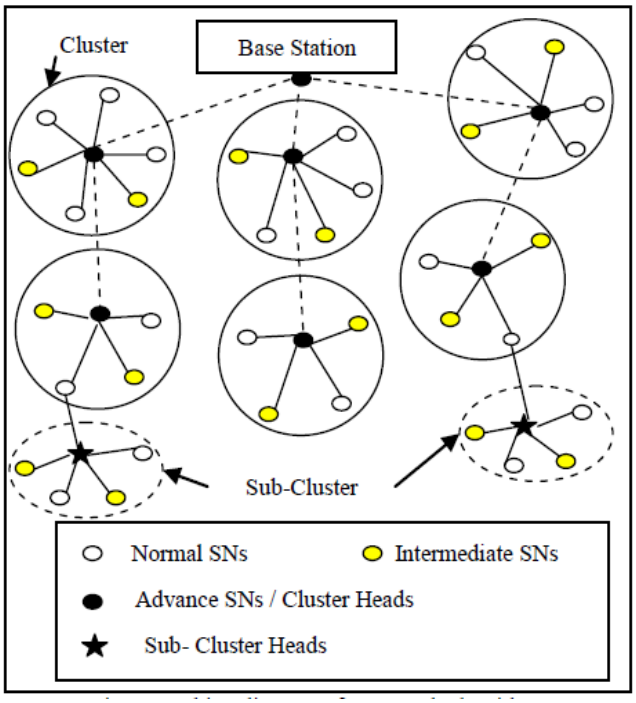

Fig. 3: Working diagram of EACBM protocol

EACBM protocol increase stability and life of the network and provide a stabilized model for WSNs.

14) ECMR

ECMR [20] is very new technique on cluster bases which improved the energy efficiency successfully by using multi hop routing protocol. This technique combines the two different technique which are clustering and Dijkstra routing technique. The total left energy of each CH along with total transmit power is used to calculate the weight load. CHs which have highest remaining energy and lower transition power having high probability to join the shortest path communication. Dijkstra algorithm use weight factor

to find the shortest path between source node to sink node or BS in ECMR.

Out of ECMR and LEACH protocols, the performance of ECMR is good in terms of life time of network and packet received at target node or BS.

III. Comparison between different Inter-cluster multi-hop routing protocols

The comparison of different inter cluster multi hop routing in clustering protocol is presented in Table 1. The comparison is done on the basis of their energy efficiency, scalability, complexity, overhead and delay.

.

Table 1: Comparison of different inter-cluster multi-hop routing techniques.

Routing protocols	Energy Efficiency	Scalability	Complexity	Overhead	Delay
Multi-hop LEACH	High	High	High	Moderate	High
Energy LEACH	High	High	High	Moderate	High
WST LEACH	Very high	High	Moderate	High	Small
MHR LEACH	High	High	High	High	High
LEACH D	Very high	Very high	Very high	High	Low
CELL LEACH	Moderate	Very high	Very high	Very high	Moderate
E LEACH	High	Very high	High	High	High
EEMH LEACH	Very high	Moderate	Very high	High	Small
O LEACH	High	High	High	High	High
CL LEACH	High	Moderate	High	High	High
DHL LEACH	High	High	Low	Moderate	Moderate
IMHT LEACH	Very high	Very high	High	Moderate	Moderate
EACBM	High	Very high	High	Moderate	Moderate
ECMR	Very high	High	Very high	Moderate	High

IV. Conclusions

In this paper, the several inter cluster multi-hop routing protocols are discussed in which IMHT LEACH and EACBM protocol are better in term of scalability, LEACH-D have low delay and the ECMR routing technique is better than other protocol in terms of energy efficiency. It is also good in terms of overhead but it is more complex. All discussed protocols mainly consider the problem of energy consumption and at some extent they overcome it. By balancing the load of nodes, we can save the energy consume by the nodes and increase the life of the network.

***Abstract*—In this paper, Structural optimization based microstrip bandpass filter design is discussed. Conventional optimization mainly focuses on the dimensional optimization of the filter. Here, the focus is to design a bandpass filter using rectangular patch-based resonator. The obtained result is then optimized using Genetic Algorithm which is part of Evolutionary algorithm. In order to obtain an optimized result, we define a fitness function in terms of S_{11} (dB) and S_{21}(dB) parameters. The final design of the filter will possess maximum transmission co-efficient and minimum reflection co-efficient.**

***Index Terms*—Microstrip bandpass filter, genetic optimization, narrow band frequency response, patch resonator.**

I. Introduction

In wireless technologies, bandpass filters are widely used in transmitters and receivers. These filters are main components at the front end of these devices. It plays an important role in limiting the bandwidth of the output signal to the minimum of transfer information at desired speed. Narrowband microwave bandpass filters with high performance are the most preferred ones for the modern wireless communication systems [1]. A balanced patch type resonator has the advantage of having high resistance to outside noise compared to the unbalanced structures [2]- [4]. Evolutionary algorithm can be used to obtain optimum solution by selection and evaluation of various designs [5]- [6]. The patch based resonator is a good contender for the bandpass filter because it is easy to remove cells from the patch to reduce insertion loss and thus improve transmission [7] - [9].

In this paper, the genetic algorithm(GA) has been used to design bandpass filter with higher performance. We propose a GA-optimization method which introduces a fitness function estimating the S-parameters in a passband. The fitness function is defined in a way that increases transmission coefficient and decreases reflection coefficient. The GA-optimization method used here involves the following processes Representation, crossover and mutation. Finally, the best solution is returned as the final output.

II. OPTIMIZATION DESIGN

Fig.1. shows a design of microstrip bandpass filter. It consists of a substrate with dielectric constant ϵr = 10.2. The substrate used in this analysis is Rogers RT/Duroid 6010. The dimensions of the substrate are length L_1=15mm, width W_1 = 12mm and thickness H_1 = 1.27mm. The dimension of the conductor are L_2 = 9mm, L_3 = 2.7mm, W_2 = 0.6mm, W_3 = 8.4mm. The dimensions of each cell of the square patch resonator are length P = 1mm and width Q = 1mm.

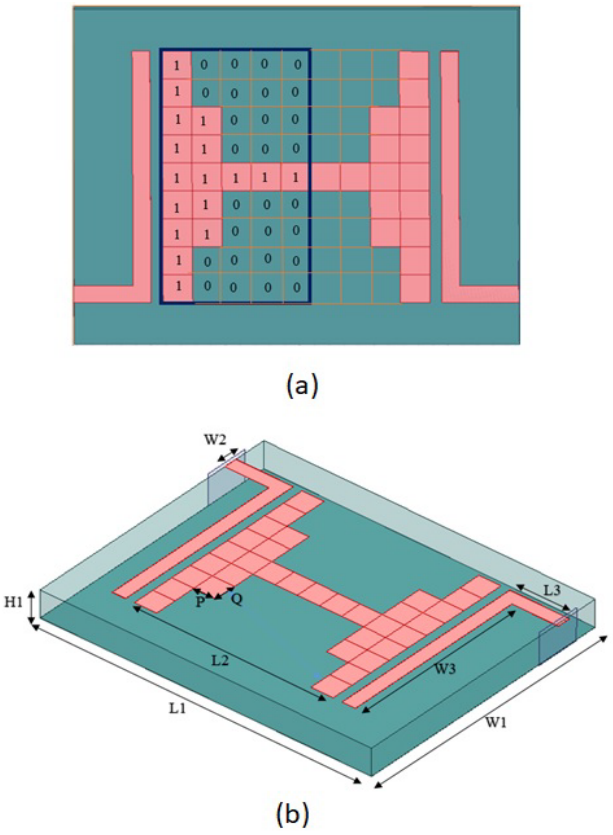

Fig. 1. GA optimized filter (a) top view and (b) Bird view

In the GA, the circuit is described by binary code as the conducting cells of the square patch resonator are 1 and other cells are 0.The geometry of the circuit is organized in such a way that it is symmetrical about y axis. The input and output ports are placed at inverted L shaped feed lines.

A. Fitness Function

The fitness function used for reflection coefficient and transmission co-efficient are taken into consideration. It is expressed as follows:

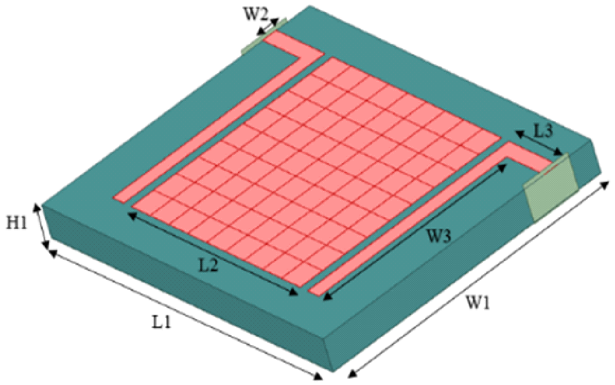

Fig. 2. Initial structure of filter

$$F = \{S_{21}(dB)/S_{11}(dB)\}\ at\ 2.5GHz \leqslant f \leqslant 4.5GHz \quad (1)$$

Reflection coefficient (S_{11}) of the filter was chosen because it describes the impedance matching which in turn shows how well the filter is capable of making use of the input power that is being provided from the feed. Transmission coefficient (S_{21}) of the filter was chosen because it shows how well the input power is being transmitted to the output port without getting attenuated. The transmission co-efficient has to be maximized and the reflection co-efficient has to be minimized. Thus the fitness function is maximized in the passband to obtain an optimal solution.

III. Filter Design

Fig.2. shows the initial design of the bandpass filter using patch resonator. Using GA, the cells are removed uniformly from the resonator. The initial population is created randomly with symmetry along the y axis. The fitness function of the initial population is calculated and stored

A. Crossover

The crossover is designed in such a way that it combines the genetic information into two parents to generate new off springs. The crossover population is generated from the initial population. Two parents (initial matrix) are taken at a time and are combined together to produce a progeny (crossover matrix).

B. Mutation

The crossover population is mutated to obtain a new set of pro-genies. Mutation is more powerful in the sense that it has the capability to give birth to a more distinct variety of children.

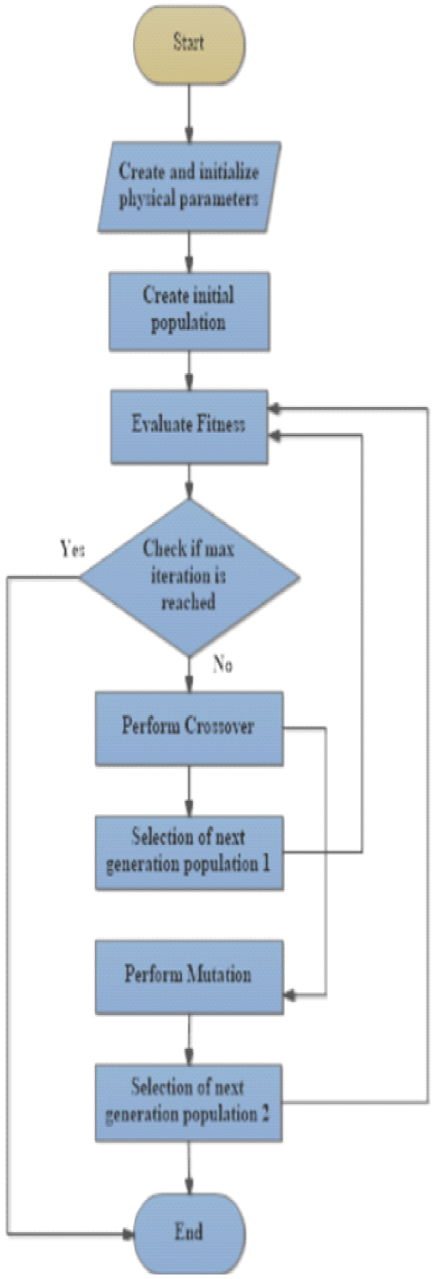

Fig. 3. Flowchart of algorithm

IV. Result and Discussion

A. Selection

The fitness function of the initial population, crossover population and mutated population are calculated. These fitness function values are compared to obtain the best population set. This set is stored as the initial population for the next generation. This process is repeated for the given number of iterations. After the final iteration, the best solution (Fig.1.) is obtained.

The initial design (Fig.2.) has the passband centre frequency

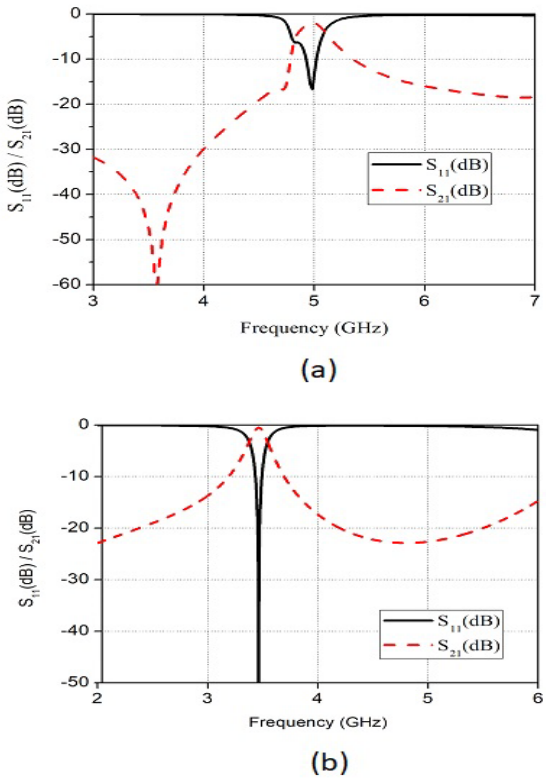

Fig. 4. (a) S parameters Vs Frequency for Fig. 2 (b) S parameters Vs Frequency for Fig. 1

located at 5GHz.The S-parameter values obtained at the centre frequency are S_{11}= -16.12(dB) and S_{21}= -1.92(dB). The GA-optimized design (Fig.1.) has improved transmission performance with lesser S_{11} and higher S_{21}.The passband centre frequency is shifted to 3.3GHz and the values of S-parameters are S_{11}= -25.13(dB) and S_{21}= -0.52(dB).

V. CONCLUSION

In this paper, the Bandpass filter has been structurally optimized using evolutionary algorithm. From the generation of the initial population to performing the genetic operations on subsequent population, measures were taken to ensure that genetic diversity was maintained. The output of the evolutionary algorithm iterations is quite satisfactory. The added advantage of the structurally optimized designs is that the area occupied by the optimized designs is much lesser than the base design. Transmission performance has been improved to a greater extent in the passband.

***Abstract*— Determining the gender of a person has a prominent role in many social interactions. Recognition of gender will be beneficial in certain applications like interaction of human and computer, scrutinizing systems, Demographic research. Identification of gender can be made by using different sources such as through voice, facial expressions and gait. Due to the distinctive advantages of gender perception based on gait, such as non-invasive, non-contact and obtained easily at a distance, there is an increase in the interest of researchers in the classification of gender-based on gait. In the proposed work, there are 2 stages of methodology. The first stage consists of determining Gait energy image projection model(GPM) which is our new proposed descriptor for gender perception and in the second stage; the proposed descriptors are merged with the better existing ones such as GEI, Gait Entropy Images, Dynamic Gait Energy Image (D-GEI), Gradient Gait Energy Image (GGEI) to enhance the performance. Finally ,for classification, SVM classifier is given to the proposed descriptors for determining the gender. The OU-ISIR database and CASIA datasets are considered for the gender evaluation and comparison of different performance metrics like Accuracy, Precision, Recall and Error rate.**

Keywords*— *Gait Energy Image Projection Model (GPM), Gait Analysis, Gender recognition

I. INTRODUCTION

The recognition of gender has an eminent role in social communication. Many biological features were applied for gender identification such as footprints, sound, face and gait. Perception at a great distance can be handled with gait when compared with voice (or) face[1]. Nonaggression, accessible collection and non-contact are some of the advantages of gait. Due to this, gait has an incomparable place in gender recognition. Biometric systems, surveillance systems are some examples to explain the benefits of gait.

Generally, for the confirmation of a person, reliable person recognition schemes are required. The key role of such recognition systems is to confirm that, the services are done only by the authorized users and not by any other persons. Accessing of computers, laptops, ATMs are the familiar examples for the secure access.

With the advancements of biometrics, it is easy for the establishment of person's identity based on "who he/she is" rather than " what he/she possess". In the 19th century beginning, biometrics are used for the criminal identification. Later, biometrics extended its applications from forensics, convicts and prisoners identification to person identification in many civilian applications.

Gait is an essential way of human locomotion [2]. In the present days, there are two significant categories of gait approaches. They are Model dependent approaches and Silhouette dependent approaches. To obtain the static and dynamic parameters in series, we will go with the model-based methods which establish a mathematical model that represents dynamic changes in walking. In the silhouette based method, to recognise the gender, the silhouettes of gait sequence characteristics are considered because of their low computational complexity and noise reduction.

Estimating human gender at a farther distance has several applications and also found solutions for face-based approaches disadvantages. Hence, in present paper, the highlighted concepts are different gender features on human gait which cited some great work dealing with gender classification based on gait at the beginning[3]. For the underscore of the relevant gender gait features, we introduce the proposed descriptor. As the estimation of gender by gait is a tough job, the idea of fusion is introduced that can improve recognition performance. Many of the recent works in the fusion of information explained that the several features fusion achieves better performance and robustness. It overcomes the individual feature based identification method in many applications. The experimentation also showed that the descriptors fusion had given splendid results when compared with the individual features recognition rate.

The preceding of paper is described as below; In section II, the work that is performed in previous research is described. In Section III, procedural steps of the identification method is described. Next, the methodology of proposed work and different features is described for gender recognition is given. In the former part of the paper, the fusion of descriptors is explained. Based on highly populated OULP database [4] and CASIA B database, the experimental study and results analysis of our proposed descriptor is presented in Section VI. A relative study of the put forth descriptor with the existing features and fusion of descriptors regarding performance like the Correct Classification Rate (CCR) along with the precision, recall and Error rate is presented. Finally, the conclusion of current paper is described in section VII.

II. RELATED WORK IN GAIT ANALYSIS

Basically, humans have the capability of determining the age and gender on seeing a person. But , there are some cases, where the person is not clearly seen (or) observed through the human eyes. For example, in scrutinizing systems (or) in monitoring systems , a person is observed and captured through a camera. When the resolution of the captured image is low, then the person's details like gender (or) age can't be identified easily. To resolve this problem, we come across the gait analysis.

Gait has two modes of approaches for performing the analysis in recognizing a person's features. They are Model independent and Model dependent approaches. In the Model independent approach, pre-defined model will be absent. There are no assumptions on the description of model. Moving on to the model dependent approaches, the assumptions are made on the past research work and modelling of model is done based on the assumptions. Generally, model independent approaches are highly preferable than the model dependent approaches.

In the past days, by using the face features such as shape of the individual's face, its geometry and its appearance, the age and gender can be determined. In one of the research work , based on the face based features, age and gender is determined. Gender and age estimation can be done by observing the eyebrows, the way of clothing, the hair style and body shape. Static body features[5] and Dynamic body feature are the most appropriate features for the determination of gender of a person. Many research works are done[6] based on these features and gained good accuracy in gender recognition[7].

In the case of age prediction, the images of the faces that are taken at low resolution are not that suitable and analysis of such images is also not possible. Hence, the approaches using gait came into existence for determining both the age and gender of person as it is best suited for analysing low resolution images. As gait is referred to as the human walking, many of the age and gender related parameters like stride length, cadence speed will be different for different persons.

There are some research works done by researchers in the literature. For the calculation of contour-based information for the extraction of gait features,[8] showed age classification by using the descriptors such as FED, HMM[9] which gave some improvement in the recognition. A work is done in the age and gender classification for the finding of gait differences. For the extraction of gait features, silhouette is used and it is described in frequency domain. Depending on this work, many parameters in connection to gait are clearly demonstrated which differentiate the younger and elder.

The research work is also done based on the apparel features of a person for age and gender prediction by using footwear and clothing conditions and obtained better outcomes in gender prediction. There are some other features for this work such as Gait energy image which is generally used in age and gender perception and gave splendid results in its performance. Many research works are done based on GEI which is obtained from silhouettes to extract the spatial information and temporal information. But, there are some failures in using the GEI , that is, there is some unwanted information which occupies more amount of storage space.

Some of the authors suggested a new approach using the Gabor filters for the feature extraction which is suited for orienting the body shapes of the silhouettes. Many research works are performed based on the silhouettes, which is the important tool required for extracting any feature based on the applications.

In the gait analysis, determining age and gender is a complicated task. To overcome this problem, the concept of fusion is introduced. With the fusion of different gait features, the accuracy is enhanced and performance of the descriptors will also be increased. So, the concept of fusion is introduced for the proposed and existing descriptors.

Research works are done on biological features for identifying the gender and age of a person. By analysing the biological features such as speech given by person, based on fingerprints, based on the voice, the determination of a person is done. But, the biological features are noise sensitive and the information may be corrupted. As a result, the results produced from this noisy information may not be correct. So, gait analysis is considered as the best suitable solution for the age and gender prediction.

III. OVERVIEW OF THE METHOD

In the framework of the gender detection, there is some sequence of steps that have to be implemented and the same demonstrated in Fig.1

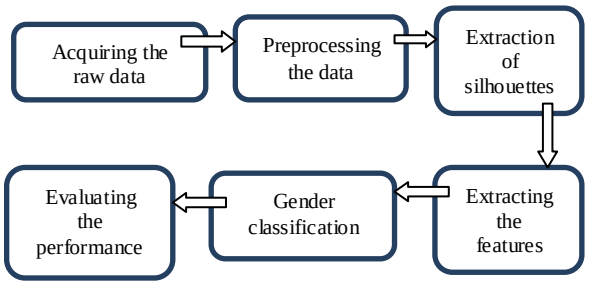

Fig 1. Gender classification taxonomy

IV. METHODOLOGY OF PROPOSED WORK

In the proposed work, two stages have to be implemented to classify the gender. In the first step, the Gait Energy Image Projection Model (GPM) is introduced which presents the vital gender-related parameters such as body size, head pitch, arm swing and stride length variations that characterise the gender in the respective gait cycle shown in Fig 2.

Two projections are present in GPM. They are Gait Energy Image longitudinal projection (GLP) and Gait Energy Image transverse projection (GTP). The GLP explains the stride length and body size whereas the GTP

gives the details regarding the head pitch, hunched posture and arm swing of the GEI image sequences given in Fig. 3.

In this paper, by using GLP and GTP, a new method is proposed and in parallel, we are highlighting the gender-related gait features. GPM combines both GLP and GTP by the use of the concatenation technique

$$GPM=\{GLP_{cycle}\ U\ GTP_{cycle}\} \quad (1)$$

Mathematically, GLP_{cycle} is defined as equation(2)

$$GLPcycle = \frac{1}{M}\sum_{i=1}^{M} GLPi \quad (2)$$

Here, M defines number of frames ; GLP_i defines *i*th frame vector of GLP.
And GTP_{cycle} is defined as equation(3)

$$GTPcycle = \frac{1}{M}\sum_{i=1}^{M} GTPi \quad (3)$$

M defines number of frames ; GTP_i defines *i*th frame vector of GLP.

Gait energy images (GEI): GEI represents the spatiotemporal information of silhouette images from entire gait cycle. Averaging the silhouette from the entire gait cycle gives energy image.

The D(x,y) represents GEI and calculated by using equation (4)

$$D(x,y) = \frac{1}{N}\sum_{t=1}^{N} Bt(x,y) \quad (4)$$

Where N defines number of gait cycle images; x and y are the coordinates of every image B.

Gait entropy images (GEnI): It is obtained from normalised silhouettes. From gait cycle, the calculation of Shannon entropy is performed for individual pixels of silhouette images.

Uncertainty associated with any random variable is given by Shannon entropy. With the use of Shannon entropy, the randmoness of the pixel is evaluated.

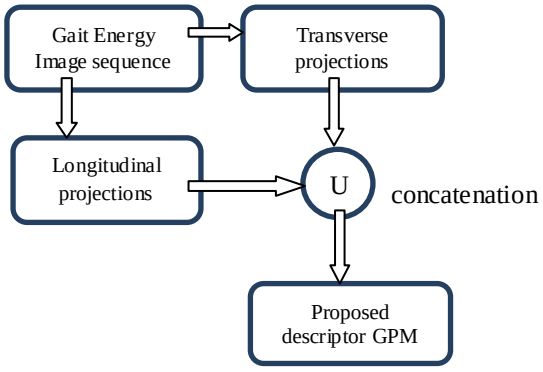

Fig .2 Proposed descriptor

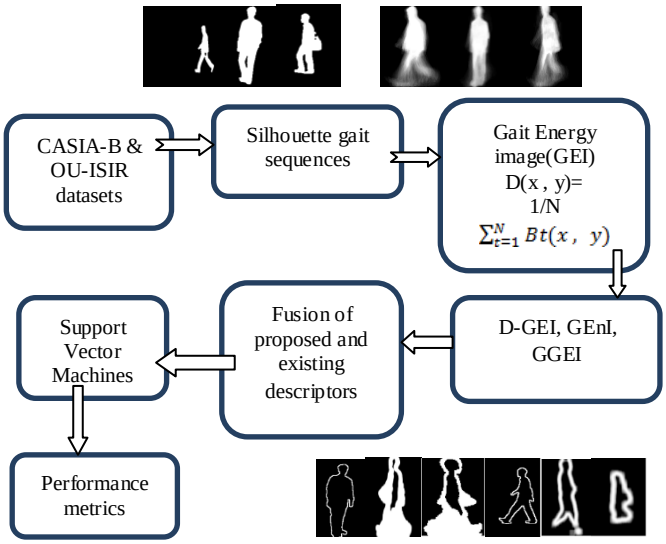

Fig. 6 Flow chart of the proposed methodology

The entropy of the fixed pixel location intensity value from a gait cycle is given by

$$H(x,y) = -\sum_{k=1}^{K} pk(x,y)\log 2pk(x,y) \quad (5)$$

Where x, y defines pixel coordinates & p_k (x, y) gives the probability that the pixel considers kth value.
Here, silhouettes represents binary images and hence K=2.
Then, using scaling operation and discretising operation for H(x,y), the obtained gait entropy image G(x, y) is as

$$G(x,y)=\frac{(H(x,y)-Hmin)*255}{(Hmax-Hmin)} \quad (6)$$

Where $Hmin=\min(H(x,y))$ and
$Hmax=\max(H(x,y))$

Dynamic Gait Energy image (D-GEI): There are three steps in the extraction of D-GEI.
The first step is to get GEI dynamic region,

$$I'gei(x,y)=\begin{cases}0 & \text{if } Igei(x,y) > 220\\ 1 & \text{if } Igei(x,y) \cong 0\end{cases} \quad (7)$$

The second step is logical 'and' operation is present with a dynamic part of GEI to the dynamic area of the frame.

$$F'(x,y) = F(x,y) * I'gei(x,y) \quad (8)$$

Where I'gei(x, y) defines dynamic part of GEI
F(x, y) gives frame in the gait cycle; F'(x, y) defines dynamic region of the frame.
Gradient Gait Energy Image (GGEI): GGEI is obtained by applying the computation procedure called neighbourhood gradient computation procedure which results in the subtraction of each of the pixel to the next 3*3 area from the centre pixel.

V. DESCRIPTORS FUSION

Identifying the gender automatically is a crucial task. Hence, an approach is proposed called the descriptors fusion approach to address the gender estimation problem. Recent advances proved that multiple features fusion [10], [11] achieves better performance and robustness and gives the recognition rate when compared to a single-feature recognition rate.

Generally, gender-related parameters are complementary and overlap. Hence, by the fusion of gait features, gender classification performance can be improved. Therefore, GPM, GEI, GEnI, D-GEI and GGEI should be merged.

$$GGGDG=\{GPM \cup GEI \cup GEnI \cup D\text{-}GEI \cup GGEI\} \quad (9)$$

Then, the features that are computed for the considered datasets are given to the classification algorithm for the gender recognition which is represented in Fig .6

VI. EXPERIMENTS AND ANALYSIS

A. Classifier

Gender identification is a binary case. So, for the classification process, SVM algorithm [12], [13] is suitable which separates data points in each class by the use of the best hyperplane. Different kernels for example polynomial, linear are applied for classification purpose and among the kernels; linear function gave the better results when compared to other kernels as our data is separable in a linear manner to discriminate male and a female.

B. Experiments and Results

The experimental study is conducted on two datasets namely CASIA B [14] and OULP datasets shown in Table 1.

Firstly, we test the performance of the descriptors individually. Secondly, we test the fused descriptors performance to illustrate the performance.

TABLE 1. DATASETS USED IN PROPOSED METHODOLOGY

Type of dataset	Number of persons	Number of image sequences	Variations
CASIA B dataset	124 persons	13640 image sequences	11 view angles
OULP dataset	4007 persons	2135 men 1872 women	1 to 94 years of variation

Here, we designed a test protocol for five cross-validations. We considered an equal number of persons for gender classification because it is a two-class problem. For the experiments, we selected 30 subjects (15 female and 15 male) randomly for the training phase. Next, 60 persons (30 male and 30 female) are selected for the testing phase.

TABLE 2. THE RESULTS OF INDIVIDUAL DESCRIPTORS OF CASIA B DATASET

Descriptor	Recall (%)		Precision (%)		CCR (%)
	Male	Female	Male	Female	
GPM	**99.89**	**89.47**	33.33	**99.92**	**90**
GEI	85.71	78.26	54.54	94.73	80
GEnI	66.66	80.95	60	85	76.6
D-GEI	83.33	71.42	55.55	90.9	75
GGEI	72.72	73.68	**61.53**	82.35	73.3

For every individual descriptor extracted from the GEI images, different number of subjects are considered for evaluating the performance and for the fused descriptors, another set of images are taken from the training phase for evaluation and the results are tabulated.

TABLE 3. THE RESULTS OF INDIVIDUAL DESCRIPTORS OF OULP DATASET

Descriptor	Recall (%)		Precision (%)		CCR (%)
	Male	Female	Male	Female	
GPM	**99.92**	**94.44**	66.66	**99.89**	**95**
GEI	99.89	84.21	25.00	**99.89**	85
GEnI	75	88.88	**81.81**	84.21	83.33
D-GEI	75	83.33	75	83.33	80
GGEI	75	77.27	54.54	89.47	76.66

TABLE 4. THE RESULTS OF FUSED DESCRIPTORS OF CASIA B AND OULP DATASETS

Fused descriptors	Accuracy (%)	
	CASIA B	**OULP**
GPM U GEI U GEnI U D-GEI U GGEI	**96**	**98**
GPM U GEI U D-GEI U GEnI	94.33	95.66
GPM U GEI U D-GEI U GGEI	93.01	94.85
GPM U GEI U D-GEI	91	93.48
GPM U GEI	90	92.81

C. Analysis

From Table 2 and 3, it is clearly shown that the put forth descriptor GPM has given better results when compared to that of the existing descriptors. In the proposed descriptor, we consider the longitudinal projections and transverse projections of an image, and hence, the gender-based parameters can be easily observed and hence the discrimination rate is enhanced to that of the existing ones. The results are highlighted in Table 2, 3 for both CASIA B and OULP datasets.

It is observed through Table 4 that, fusion of different descriptors performs better when compared with the individual descriptors performance. The features fusion is the union of different frames and the features that are not highlighted in any of the images can be observed in the fused frames. Hence, the classification performance will be high and hence the recognition performance will be better when compared to individual descriptors performance. The OULP large population set gives better performance when compared to that of the CASIA B sets which gives 95% accuracy because of its excellent gender balance and it is useful for all tests. The error rate is also reduced in OULP dataset when compared to CASIA dataset. The 90^0, 180^0 and 0^0 view angles gave the best outcomes in contrast to the other view angles in CASIA B dataset for all 124 persons with all the three variations like cloth , bag and normal walking.

GPM descriptor gave the best results in contrast with other existing descriptors because in GPM descriptor, both the transverse projection and the longitudinal projection which highlight the critical parameters for gender recognition whereas, in other features, the static and dynamic information is only represented. Some gender-related parameters [15] are not seen clearly in some existing descriptors which reduce the prediction accuracy.

There are some constraints to this method. Such as precision value is less in some cases for males. Because the trunk component and head component for the slim and fat persons can't be easily identified especially for female and male cases, the hairstyle is outstanding dissimilarity for male and female. So, precision is less for a male in very few cases. We obtained optimal outcomes only in three view angles for 0^0, 90^0 and 180^0 in CASIA B dataset.

VII. CONCLUSION

Gait based gender perception is a peculiar and fascinating topic of present days. The put forth method gives good results and accuracy is also higher when compared with features that are generally used for gender identification. As a result, it proved that gait analysis is best suited for gender perception at a greater distance.

In our prescribed method, both the temporal and static features are used for the classification of gender and their fusion is performed and achieved better results when compared to individual features. In future, we will try to classify the gender using the different classifiers and also other factors that affect the gender classification to determine cross-gender classification using the different descriptors and their combinations.

ACKNOWLEDGEMENT

The authors are sincerely thanking the efforts of CASIA B dataset and OULP dataset providers to carry out our research work.

***Abstract*—With an increase in number of knee problems in patients, the demand for the rehabilitation has increased. Most of the rehabilitation trainings are expensive and time consuming. So, the need for personalized treatment in rehabilitation is increasing. The knee exoskeleton is one of such solutions to assist the patients suffering from weal knee, paraplegia and hemiplegia. These exoskeletons meet the patient's expectation in terms of assistance required and wearing comfort. These are relatively more portable than lower body exoskeletons owing to their lighter weight. These can either be used for gait rehabilitation, providing assistance during sit to stand motion, normal walking and running, for load carrying augmentation or for performing activities of daily living. In this work, a knee exoskeleton consisting of a linear actuator and surface Electromyography sensor is designed and fabricated. Experiments are performed to validate the results with those of theoretical one. The developed knee exoskeleton is found to be well suited for assisting the wearer during the rehabilitation.**

Keywords—knee exoskeleton; linear actuator; EMG sensor; four bar mechanism; rehabilitation; joint angle; joint torque.

I. INTRODUCTION

The world's population is ageing—essentially each country is experiencing growth in the number of elderly people in the population. Globally, the population aged 60 years or above is growing faster than other age groups. Figure 1 describes the ageing population trend.

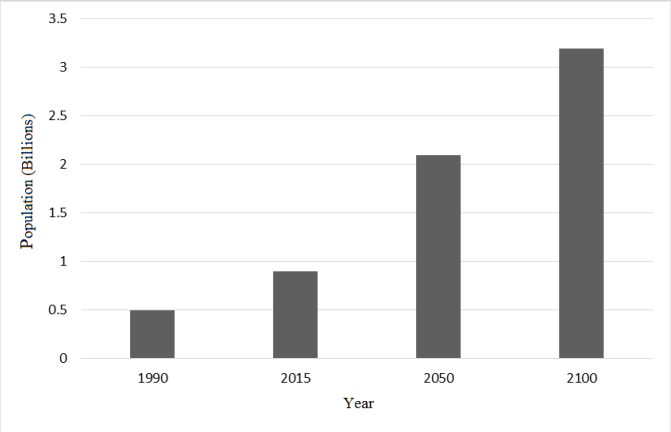

Fig.1 Projected global ageing population (60 years and above)

Owing to the aging population, large number of people suffer from neurological sicknesses such as stroke, central nervous system syndrome, spinal cord injury etc. The manual therapy for patients suffering from such diseases is very much physically demanding. To overcome such problems robotic exoskeletons have been developed. In comparison to the manual therapies, these exoskeletons are physically very less demanding.

The Exoskeleton that are used for rehabilitation could be classified into various categories. Depending on the body parts, they can be classified into full body, upper extremities such as arms and torso and lower extremity exoskeleton such as legs. The upper extremity exoskeletons could be further broken down to specific areas such as wrist, fingers, shoulders and elbow joints. Based on the input power, they can be classified into powered, passive, pseudo-passive and hybrid exoskeletons. The powered exoskeletons make use of batteries and electric cables for running the sensors. The actuators are required to be switched on every time. This is due to the fact that the device needs to maintain its shape. These exoskeletons can further be broken down to static and dynamic exoskeletons. The passive exoskeleton doesn't contain any power sources. These are generally used for weight redistribution, energy capturing, dampening and locking. The springs and locking mechanism diverts the weight of the object around the wearer's body. The spring damper exoskeletons are used to charge the batteries. The pseudo passive exoskeletons aren't meant for actuation purpose. These exoskeletons find their application in controlling a variable damper in the knee. The hybrid exoskeletons consists all the controllers and sensors of powered exoskeleton. On the basis of the mobility, exoskeletons are classified as fixed, supported and mobile. The fixed device is usually tethered, wall attached or suspended from the air by fixed hook and harness. Based on the control mechanism, the exoskeleton can be controlled using joysticks, buttons or control panel, mind controlled, using sensors or there is no control. The supported exoskeletons are normally supported by the moving frame or by a wheeled robot. With mobile robot, the user and the exoskeleton could move around freely. The joystick provides complete energy that is required for the wearer's motion. Using buttons or controlled panels, the exoskeletons operate in pre-programmed mode. Electrode skull caps are used when there is a control using signals generated by brain.

In this work, an attempt has been made to design and fabricate a knee exoskeleton. This device is based on four bar mechanism that could assist the wearer during the rehabilitation stage. A (sEMG) sensor is used to detect the user's intention. Goniometer is used to measure the joint angle and force sensitive resistor (FSR) is used to measure the force developed

by the linear actuator. A mathematical model of the exoskeleton design is presented along with the experimental results

This paper is organized in five sections. The introduction of the present work is included in Section-I. Section-II discusses the work related to the design and control of knee exoskeleton. Section-III discusses the mathematical model of the proposed knee exoskeleton design followed by the calculations for joint torque, joint angle and the experimental details. Section-1V consists of the results and discussions, followed by the Section-V which concludes the current work and discusses the scope for future work.

II. Related work

A knee exoskeleton could be remarkable for people suffering from weak knee. This is due to the fact that a human knee produces large peak torques and absorbs impact during the motion. The knee experience between 5 and 10 degrees of external rotations automatically as the leg extends [1]. A knee exoskeleton consisting of a motorized mechanism was presented [2]. The effects of different exoskeletons designed on the joint internal forces were studied [3]. An adaptive device was proposed that could assist both the translational and rotational motion of the kinematic chain. An EMG based model of the human knee that could anticipate knee movements was presented [4]. A control scheme for powered knee based device was proposed. It is based on real time estimation of EMG signals that are captured based on user's intention from the leg's muscles [5]. A tele-impedance based control strategy was stated to identify detect the user intention of motion to generate assistive torques at knee joints for performing various task [6].The human motion intention was evaluated based on electroencephalogram **(**EEG) and surface electromyography sEMG signals. The signals were used to control the knee joint and were meant for sit stand flexion extension motion of the knee [7]. A proxy sliding based controller was used to control the knee joint position. In addition, the response of the system at zero torque condition was also noted experimentally [8]. A parallel elastic exoskeleton was proposed. It consists of a clutch for disengaging the spring placed in parallel to the leg. This leads to the motion not getting restricted during the swing phase [9]. A modular knee exoskeleton where the user intention is determined by force-sensitive resistors (FSRs) which have been put on the user's foot. The torque sensor is attached to the knee joint and an encoder which is fitted inside the motor. The device is tested on standing, walking and sitting motion controls [10]. An analysis of different mechanisms based on combinations of passive and active actuators was demonstrated. A knee exoskeleton was thus proposed to support the worker's body weight during sit to stand for various seated positions [11]. A prosthetic knee that mimics the biomechanics of human knee joint was proposed [12]. The spring parameters and its effectiveness were determined in a novel knee joint exoskeleton by using dynamic study and simulations. The analysis includes forward kinematics using Lagrangian dynamics followed by simulations using ADAMS. The parameters of the hydraulic dampers used were found to satisfy the real requirements [13].

III. Proposed Knee exoskeleton Design

A knee exoskeleton consisting of linear actuator is proposed. It is based on four bar mechanism. The rigid links AE, ED, DCB and AB constitutes the four bars of the mechanism. Link AB is the fixed link, whereas the link DCB acts as a rigid binary link attached with the joints D and B in the mechanism. This planar four bar linkage is a rocker-rocker mechanism as the sum of the shortest and the longest link is greater than the sum of the length of other two links.

The schematic drawing of the proposed exoskeleton and its cad design is shown in Fig. 2 and Fig. 3, respectively.

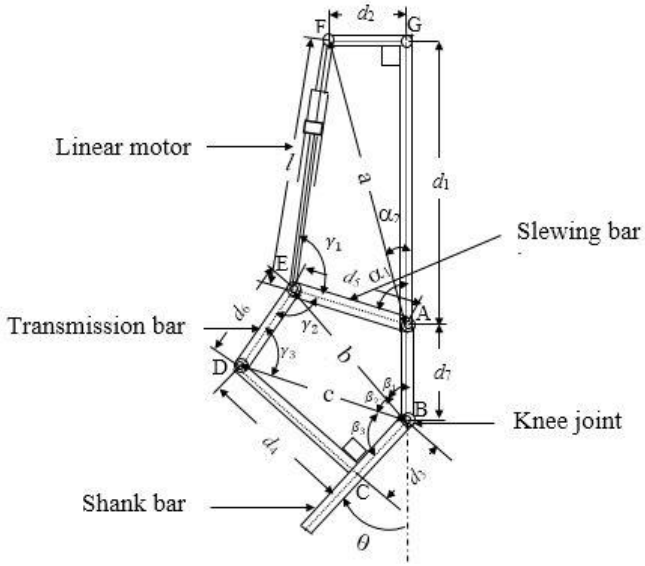

Fig. 2 Schematic drawing of the proposed design

Fig. 3 CAD model of the proposed knee exoskeleton design

A. *Mathematical Model of the proposed design*

Figure 2 depicts the schematic drawing and kinematic parameters of the knee exoskeleton. When the actuator pushes the link d_5, the force is transmitted to the shank link through the link d_6. The force generates the joint torque. The transmitted force F_3 and the torque changes with the knee joint angle. The joint angle (θ) can be expressed as

$$\theta = 180\text{-}\beta_1\text{-}\beta_2\text{-}\beta_3 \quad (1)$$

where $\beta_1 = \cos^{-1}\left(\frac{b^2+{d_7}^2-{d_5}^2}{2bd_7}\right)$, $\beta_2 = \cos^{-1}\left(\frac{b^2+{d_3}^2+{d_4}^2-{d_6}^2}{2b\sqrt{({d_3}^2+{d_4}^2)}}\right)$ and $\beta_3 = \tan^{-1}\left(\frac{d_4}{d_3}\right)$.

$$b = ({d_5}^2 + {d_7}^2 - 2d_5d_7\cos(180 - \alpha_1 - \alpha_2))^{\frac{1}{2}} \quad (2)$$

where $\alpha_1 = \tan^{-1}\left(\frac{d_4}{d_3}\right)$, $\alpha_2 = \cos^{-1}\left(\frac{{d_1}^2+{d_2}^2+{d_5}^2-l^2}{2al_5}\right)$.

The joint torque due to actuators can be derived as follows:

$$\tau_{\text{joint torque}} = F_3.\sqrt{{d_3}^2 + {d_4}^2}.\sin\gamma_3 \quad (3)$$

Where $F_3 = \frac{F_1.\sin\gamma_1}{\sin\gamma_2}$, $\gamma_1 = \cos^{-1}\left(\frac{l^2+{d_5}^2-{d_1}^2-{d_2}^2}{2ld_5}\right)$,

$\gamma_2 = \pi - \alpha_1 - \alpha_2 - \beta_1 - \beta_2 - \gamma_3$ and $\gamma_3 = \cos^{-1}\left(\frac{{d_3}^2+{d_4}^2+{d_6}^2-b^2}{2d_6\sqrt{({d_3}^2+{d_4}^2)}}\right)$.

F_3 is the transmitted force along ED and F_1 is the force developed by the linear actuator along FE.

B. Experimental setup

The aluminium bars of grade 2000 were used to build the basic four-bar structure along with the extra links to fasten and clamp the actuator. A linear actuator of 12V DC supply is mounted with the aid of cotter pins. A 7-12 V input voltage Arduino UNO microcontroller was used for the control purpose. EMG sensor was placed at three locations on the leg as shown in Fig. 4 to get the input signal from the user to initialize the actuator. The EMG sensor ensures maximum safety because it works according to the user's intentions. A force surface resistor was used to measure the force developed by the actuator. A goniometer was used to measure the joint angle rendered by the device on the subject's knee. Strapping was custom-made according to the user's need with its one strap fastening around the user's waist and thigh while the other around the subject's calf.

C. Experimentation

The values of the link lengths of the proposed design are mentioned in Table I and the calculated parameter values are stated in Table II.

TABLE I Link lengths

Parameter	Values (m)
d_1	0.3104
d_2	0.1158
d_3	0.1750
d_4	0.0200
d_5	0.1950
d_6	0.0450
d_7	0.0507
l_{max}	0.381
l_{min}	0.275

The knee exoskeleton is used for a healthy male who is free from musculoskeletal and neurological injuries. The weight of the person is 63 kg and the height is 1.6 m. Figure 4 shows the the prototype of the knee exoskeleton being wore by the subject. The control flow diagram of the knee exoskeleton prototype is shown in Fig. 5. Two batteries of 18 V and 12 V are used for the power supply. The current flows through 2 channel 5 V relay to the linear actuator. The power from the 18 V battery flows through the FSR, the controller, the 5 V channel to the actuator. Figure 7(a)-7(d) shows the images of the person's shank in flexion and extension motion at various values of joint angle. The experimentation was performed for two cycles. Each cycle comprises of the flexion and extension motion of the persons' shank.

TABLE II Design parameters

Parameters	Values for l_{max}	Values for l_{min}
$\gamma_1 = \cos^{-1}\left(\frac{l^2+{d_5}^2-{d_1}^2-{d_2}^2}{2ld_5}\right)$	52.43°	23.53°
Force along $FE, F_1 = \frac{\tau_{motor}}{d_5\,sin\gamma_1}$	87 Nm	87 Nm
$\alpha_2 = \tan^{-1}\left(\frac{d_2}{d_1}\right)$	114.27°	47°
$a = \sqrt{({d_1}^2 + {d_2}^2)}$	0.33 m	0.33 m
$\alpha_1 = \cos^{-1}\left(\frac{{d_1}^2+{d_2}^2+{d_5}^2-l^2}{2ad_5}\right)$	20.46	20.46
$b = \sqrt{{d_5}^2 + {d_7}^2 - 2d_5d_7\cos(180-\alpha_1-\alpha_2)}$	0.21 m	0.12 m
$\beta_1 = \cos^{-1}\left(\frac{b^2+{d_7}^2-{d_5}^2}{2bd_7}\right)$	103.93°	45.45°
$\beta_2 = \cos^{-1}\left(\frac{b^2+{d_3}^2+{d_4}^2-{d_6}^2}{2b\sqrt{({d_3}^2+{d_4}^2)}}\right)$	24.31°	28.93°
$\gamma_3 = \cos^{-1}\left(\frac{{d_3}^2+{d_4}^2+{d_6}^2-b^2}{2d_6\sqrt{({d_3}^2+{d_4}^2)}}\right)$	28.39°	81.87°
$\gamma_2 = 180 + (\alpha_1+\alpha_2) - (\beta_1+\beta_2) - \gamma_3$	158.08°	91.27°
$F_3 = \frac{F_1.\sin\gamma_1}{\sin\gamma_2}$	184.78 N	76.76 N
$\tau_{\text{joint torque}} = F_3.\sqrt{{d_3}^2 + {d_4}^2}.\sin\gamma_3$	10.34 Nm	8.94 Nm
$\beta_3 = \tan^{-1}\left(\frac{d_4}{d_3}\right)$	44.31°	6.52°
Joint angle$(\theta) = 180 - (\beta_1+\beta_2+\beta_3)$	7.44°	61.32°

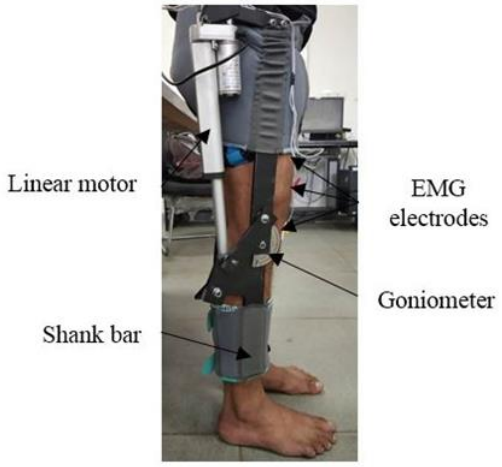

Fig. 4 Prototype of the knee exoskeleton

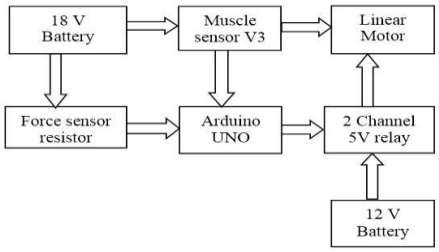

Fig. 5 Control flow diagram

Table III FSR output voltages

Force (N)	FSR resistance (kΩ)	Voltage across resistor (V)
0.2	30	1.3
1	6	3.1
10	1	4.5
100	250	4.9

The output voltage corresponding to the FSR was approximately 4.8V. It is concluded from Table III that, the force developed by the linear actuator being measured by FSR is 87 N.

Figure 6 shows the location of the FSR below the poston rod. Figure 7(a)-7(d) show the shank position at different joint angle values.

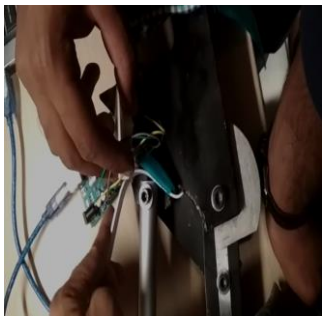

Fig. 6 FSR reading

(a) (b)

(c) (d)

Fig. 7 Shank positions at (a) θ=7.7°, (b) θ=30°, (c) θ=45° and (d) θ=62.9°

III. RESULTS AND DISCUSSIONS

The cycle starts when the person is at the standing position. The EMG sensor detects the wearer's intention by sensing the muscle activity. The contraction and the relaxation of the muscles is reponsible to drive the actuator. The muscle sensor provides signals to actuate the linear actuator.

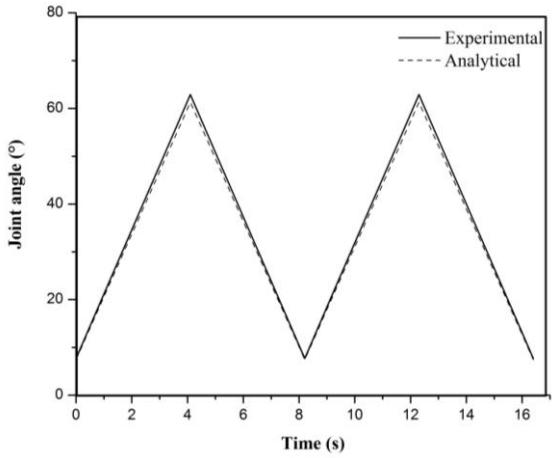

Fig. 8 Plot for joint angle with time

Figure 8 shows the variation of joint angle (θ) with time for both experimental and analytical analysis for two cycles of flexion and extension motion of shank. It is clear that, as the shank starts to flex in the clockwise direction direction, the joint angle increases and reaches to its maximum value. The maximum value of joint angle (θ) measured by the goniometer is 62.9° while the analytical value is 61.3°. The EMG sensor now detects the user intention to provide the shank's extension in the counter clockwise direction. Due to the muscle activity, when the shank starts to rotate in clockwise direction, the joint angle decreases to 7.7° experimentally. The theoritical value of the minimum joint angle (θ) is 7.4°.

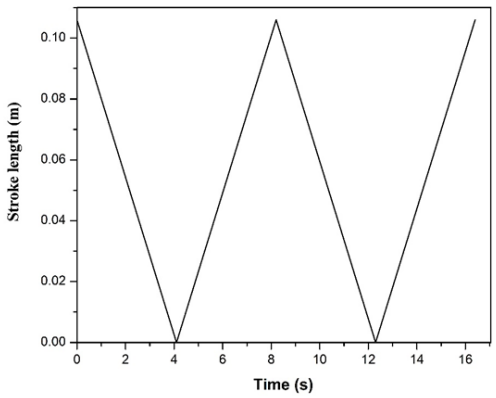

Fig. 9 Plot for stroke length with time

Figure 9 shows the measure of the piston stroke length with time. The piston stroke length is maximum and minimum at the start of flexion and extension movemen, respectively. The cycle time is approximately 8.2s.

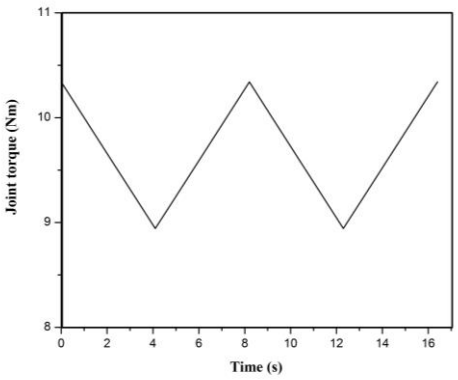

Fig. 10 Plot of joint torque with time

Figure 10 depicts the joint torque values required for performing the flexion and extension motion with time. Joint torque is the torque generated by linear actuator at point B. The value of the joint torque due to the actuator for performing flexion and extension motion is 10.34 Nm and 8.94 Nm, respectively.

Figure 11 shows the experimental and analytical values of the angular velocity of shank for the two cycles of flexion and extension motion with respect to time.The experimental value of the angular velocity of the shank is 0.235 rad/s while the analytical value is 0.229 rad/s.

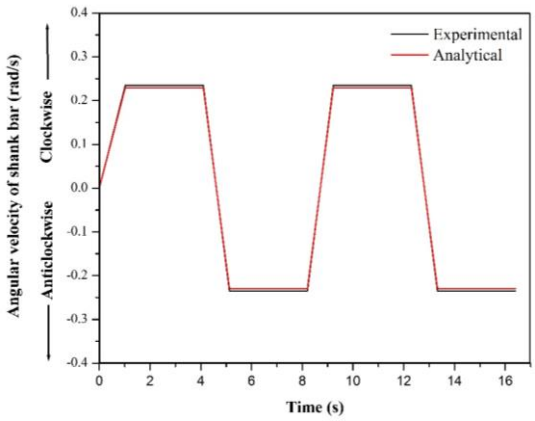

Fig. 11 Plot for shank angular velocity with time

IV. CONCLUSION

The design and fabrication of a surface electromyography sensor based knee exoskeleton consisting of a linear actuator are proposed. The prototype is fabricated and the experiments are performed. The experimental and theoretical values of the joint angle and shank's angular velocities are validated for the kinematic design of the proposed knee exoskeleton. Thus, the flexion and extension motions of the lower limb through the proposed design are well suited for the rehabilitation of the knee joint.

The future work is focused on optimizing the design parameters of the four bar mechanism in order to maximize the joint range of motion. In addition, the focus would also be on designing the exoskeleton for assisting the patients in performing the activities of daily living (ADL).

ACKNOWLEDGMENT

The project was supported by the Mechanical Engineering Department, Thapar Institute of Engineering and Technology, Patiala, India.

The author would like to express sincere thanks to the members of the Mechatronics laboratory at TIET Patiala, India who are associated with this project.

***Abstract*— Electricity is one of the basic requirements of human beings since it is very widely used for domestic, industrial and agriculture applications [1]. In most of the developing countries the energy generated is less than the requirement hence there is scarcity of energy, therefore effective utilization of energy is very important. In the existing system there is no any indication of the energy used to the consumer at regular intervals, only by the end of the month when the bill is received the consumer will come to know the energy used by him. Further the meter reading at present is also manual which needs lot of man power. In this paper a smart energy meter is proposed with which the consumer will be notified the amount of power consumed by the end of the day such that he can plan the consumption of power. Also the power consumed by the consumer will be notified to the distributor as well as consumer such that no manpower is necessary for meter reading.**

Keywords—Smart power meter, electricity, consumer, distributor, microcontroller, GSM, WIFI

I. INTRODUCTION

Electricity has become very important to human survival and progress. Along with new techniques of power generation to meet the increased demand, automation in the energy distribution is also necessary to enhance people's life standard. The manual meter reading is not that efficient and requires lot of man power hence, there is increased demand for Smart electronic meter systems which will send the meter readings to the distributor without any human interventions.

The electricity distributer has made rules in the billing system based upon the number of power units used where, the consumer will not be aware of his usage. Keeping this in consideration the smart energy meter will help in knowing the number of power units consumed and the amount that needs to be paid. If the usage is going beyond normal, consumer can control the operation of electric devices and can reduce the power consumption. The cost of power consumed will be calculated by reading the pulses generated by the meter. The calculated amount for a month is then sent to consumer and distributer and will also be displayed on the LCD to the consumer on daily basis. In existing system either an electronic energy meter or an electro-mechanical meter is fixed in the premise for measuring the usage which is capable of recording kWh units which is then have to be read by meter readers monthly. The cost for the recorded data will be generated according to the present tariff whereas, in smart electronic meter the meter reading need not be read. Both consumer and distributer will be sent the information which includes the details of their power consumption and the cost with time. Since the consumer already have prior knowledge about their usage and the cost for the power consumed they can cut down their consumption of power and save it.

This paper consists of introduction to the smart energy meter, existing energy measurement system, proposed system with additional features, Implementation of the system, block diagram, methodology, flowchart, results, conclusion, future scope and references are discussed.

II. EXISTING SYSTEM

In the existing system, a mechanical or an electronic energy meter will be fitted at every consumer point which will record the amount of power consumed by the consumer. At the end of every month a meter reader has to visit every consumer and should issue the bill, hence lot of man power is required. In this existing system there is no any alert message given to the consumer about how much power they have consumed every day so that they can plan and effectively utilize the electric appliances and cut down the electricity bill. Only at the end of the month the consumer will come to know the electricity bill. Further in the existing system if any faulty electrical appliances are consuming more power than their rated power the consumer will come to know only at the end of the month.

III. PROPOSED SYSTEM

In the proposed system along with the mechanical or electronic energy meter optocoupler, Arduino UNO microcontroller, real time clock (RTC), liquid crystal display (LCD), WIFI module and GSM module will also be connected. This smart energy meter will not only record the amount of power consumed by the consumer but also will send the alert message to the consumer through GSM about the amount of power consumed and the cost of the power consumed at regular intervals. Hence a smart consumer can plan the power consumption and can cut down the power consumption by properly using the electric appliances. Along with this since the WIFI module is connected, the bill

generated at the end of every month can be sent to the distributer as well as a copy to the consumer such that the man power required for reading the meter for generating the bill can be avoided.

IV. IMPLEMENTATION

A. Block Diagram

The Block diagram of smart energy meter is shown in Fig. 1.

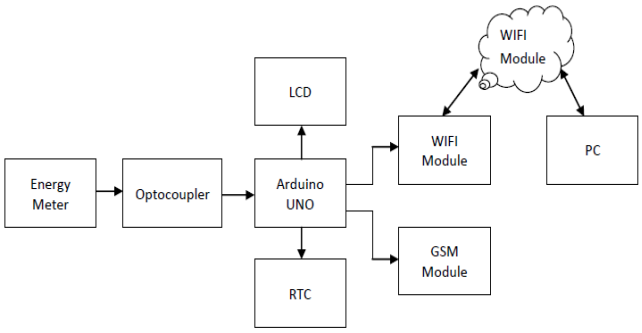

Fig. 1 Block Diagram of Smart Energy Meter

The smart energy meter consists of an electronic energy meter, optocoupler, Arduino UNO microcontroller, real time clock (RTC), liquid crystal display (LCD), WIFI module, GSM module and PC.

Energy Meter
An energy meter is a device which measures the amount of power consumed by the electrical appliances. Electric distributer uses energy meters which are installed at consumer's premises to record the power consumption for billing purposes. The calibration LED present in the energy meter will indicate the real time power consumption by the consumer and by recording the number of blinking of the LED the power consumption is calculated.

Optocoupler
The optocoupler is a light sensitive device which senses the light from the calibration LED and generates a pulse which will be applied to Arduino controller. Optocoupler is used to provide isolation.

Real Time Clock (RTC)
The RTC is used to keep track of date and time to generate bill at regular intervals, it is interfaced to Arduino to initiate the GSM and WIFI module for sending information to consumer and distributor.

Arduino UNO
Arduino UNO is a microcontroller used to interface optocoupler, LCD, RTC, WIFI module and GSM module. Arduino will count the pulses given by optocoupler which is the real time power consumption by the consumer and calculate the cost for the power consumed. The power consumed and the cost will be displayed on the LCD and at regular interval initiated by RTC the details will be sent to consumer through GSM and to the distributor using WIFI module [2] [3].

Liquid Crystal Display (LCD)
A 16×2 LCD is used to display the power consumed by the consumer and cost of the power consumed at the user end.

Global system for mobile communication (GSM):
GSM is used to send the calculated power consumed and the cost to the consumer through SMS [4].

WIFI Module
WIFI is used to connect the PC at the distributor end to the consumer point. The power consumed and the cost will be updated in the PC at the distributor end using WIFI.

B. Design

For every 1 Unit (1KWh) of power consumption the calibration LED in the energy meter will blink 3200 times which will be converted as 3200 pulses by optocoupler. These pulses will be counted by the Arduino and calculate the power as per the current tariff. At regular interval the RTC will initiate the process to send the details power consumption and the cost to the consumer and distributor.

C. Methodology

The methodology of implementation of smart energy meter is shown in Fig. 2.

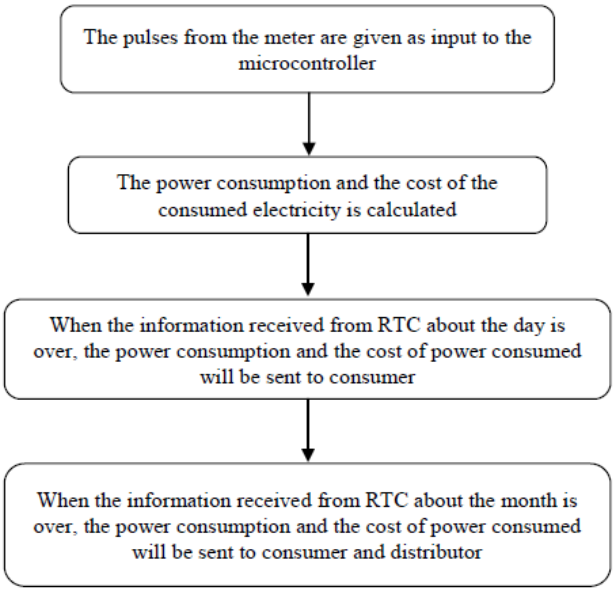

Fig. 2 Methodology of implementation of smart energy meter

The pulses generated in the energy meter as per the consumption of power by the consumer will be read by the Arduino microcontroller. The microcontroller will calculate the power consumed by the customer and the cost for the

consumed power in a day. At the end of the day the microcontroller will send the information about the power consumed and the amount for the consumed power to the customer through GSM. At the end of the month the information about the power consumed and cost of the consumed power will be sent to both consumer and distributor.

D. Flowchart

The flowchart of smart energy meter is shown in Fig. 3. The pulses are counted from the energy meter by the microcontroller and the power consumed by the consumer will be calculated by incrementing the counter. The power consumed and the cost of power consumed will be displayed on LCD. After receiving the signal from RTC about the end of the day a message will be sent to the consumer about the power consumed and amount for the consumed power. Once the RTC sends the information about end of the month message will be sent to the consumer and the distributor about the power consumed and amount for the consumed power.

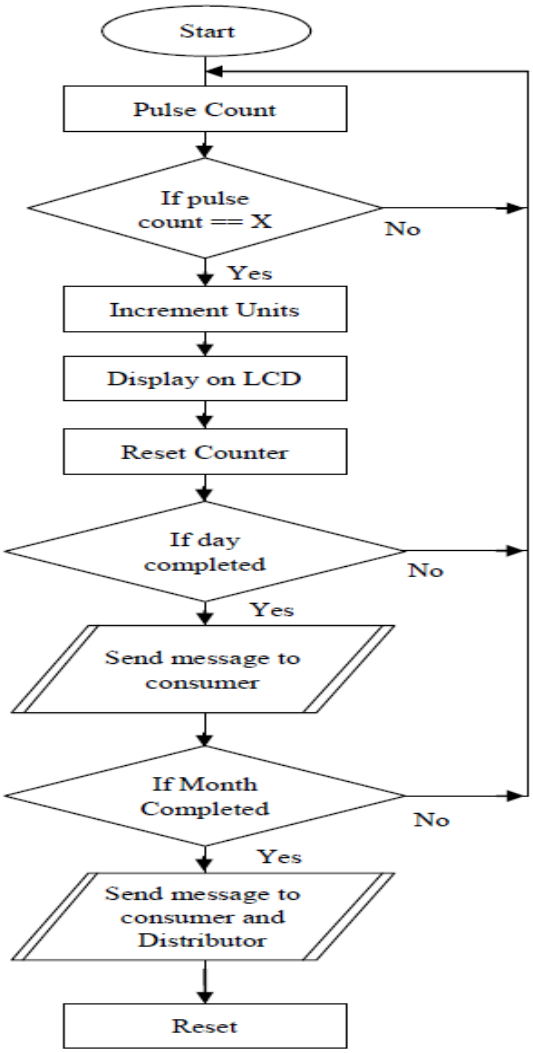

Fig. 3. Flowchart of smart energy meter

V. RESULTS AND CONCLUSION

A. Results

The working model of the smart energy meter is shown in Fig. 4.

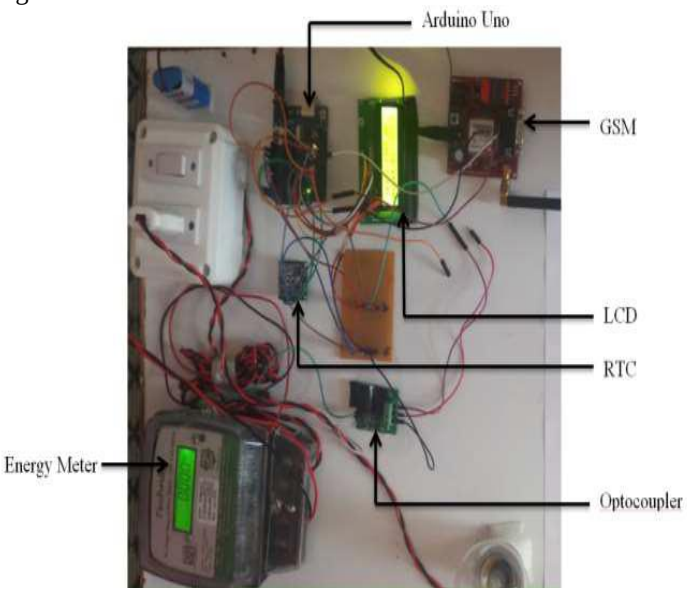

Fig. 4. Working model of smart energy meter

The display of power consumed and the amount for the power consumed on LCD is shown in Fig. 5.

Fig. 5 Display of power consumed and the amount for the power consumed on LCD

The message sent to the consumer about the power consumed and the cost of the power consumed is shown in Fig. 6.

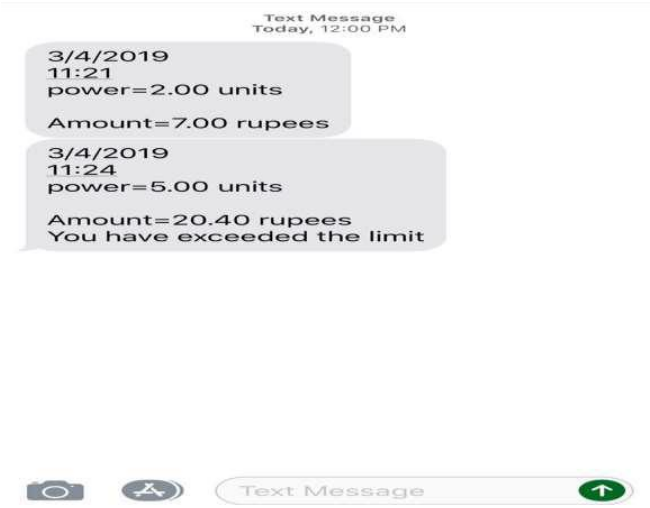

Fig. 6. Message sent to the consumer about the power consumed and the cost of the power consumed

B. Conclusion

The Smart Energy Meter is successfully designed, which sends the message of power consumption along with cost to both consumer and distributer using GSM at the end of each month. It also sends the alert message to consumer about the amount of power consumed and the cost for the power consumed at regular interval of time. The automation of billing system eliminates the human involvement hence it is more reliable. Smart Energy Meter will bring the solution of creating awareness of unnecessary usage of power and will tend to reduce the wastage of power.

C. Future Scope

The smart energy meter can be further improved by including IOT such that the database can be maintained for a long period. Further the energy meter can be made a prepaid energy meter such that when there is overdue of the bill the power can be disconnected. A mobile app can also be developed such that the consumer can contact the distributor through app for any additional power allocation required during some rare occasion or can complaint to the distributor regarding any problems he is facing.

***Abstract* – Flood and earthquake are one of the most devastating natural disasters in the world. Such natural disasters deleteriously affect the environment, lives of human, etc. which indirectly affect the economy of the country. Due to such natural disasters, there is a decline in the death rate of the human and fauna. So we should have a monitoring and observatory flood and earthquake detection system. The proposed system based on IOT technology gives a real-time analysis of flood and earthquake and so that the authority can monitor flood and earthquake affected areas. This paper highlights the Flood and earthquake Observatory System as a warning and alert system to efficiently monitor the critical flood prone and earthquake areas in real time basis baring the cost and safety measures. The proposed system also alerts the authority regarding the presence of a human in the area. It also provides backup supply for emergency situations using solar energy. Design of the proposed system includes integrating sensors to the microcontroller, RF transmitter, and receiver for long-range communication, and Thing Speak IOT platform for examining and visualizing sensor values which have been uploaded.**

***Keywords*—SmartCity, Water Quality Monitoring, WSN, LoRa, LoRaWAN, IoT, LPWAN**

I. INTRODUCTION

Natural disasters are a worldwide phenomenon. Recently hurricanes, floods, tides, etc. have illustrated along with the differences in the effects of disasters on developed compared to developing countries like India [1]. An effective solution to such natural disasters is by giving people adequate time to evacuate and protect their property. If people knew about the flood was coming, many lives and property could be saved.

Flood and earthquake are crucial disasters in the world affecting the economic status of the country in the form of natural resources, lives of human and fauna, economic properties, environment, and other infrastructure [2]. The extent of flood and earthquake damages depends on the certain measures and steps taken by the responsible authorities especially government officials during such a critical period.

Internet of things (IoT) is emerging technology that Connects anything and everything to the Internet[3]. IoT is the technology rapidly widens according to the usage. This technology brings out new technology such as natural disaster monitoring. IoT technologies in detecting the activity of natural disasters like flood and earthquake helps to rescue the lives of people

Natural disasters such as flood and earthquake that occurs in different places around the world which has become a critical problem[4]. Thus there is a need for a Flood and earthquake observatory and warning system which can save lives of human, environment, an economy of the country. Recently Kerala faced dangerous floods which resulted in deaths of human, fauna and destroyed the environment of the state which reduced the economic status of the state. To solve such issues and creating a remedy such as introducing early warning, detection, and rescue system of flood and earthquake.

Even though significant progress has been made during the last decade in the field of developing and implementing efficient flood and earthquake observatory and warning system, there are a lot of challenges faced by the researchers. There is a need for an intelligent flood and earthquake observatory and warning system which is fast, efficient, simple and accurate. Flood and earthquake observatory and warning system using IOT is a new technology to implement an efficient flood and earthquake observatory and warning system with high security and researchers are showing great interest in this technology. Also, this can develop and implement flood and earthquake observatory and warning system that will help to save lives of society, and the economy of the country.

The first section in this paper gives a general idea about the flood and earthquake detection system and its associated problems and find out a general solution to it.Second section explains about the proposed system which is explained through block diagram having pole unit and home unit. Third section explains about the technical descriptions of various modules used in the proposed system. Fourth section explains about the result analysis through proteus simulation and hardware interfacing of the proposed system. Last section includes conclusion and future scope

II. PROPOSED SYSTEM

The proposed system is a warning and alert system to monitor efficiently critical flood prone and earthquake areas in real time basis. The system includes a water level sensor (float sensor) which detects water level intensity and gives alert to house member. There are 4 types of alert given i.e.; green bulb indicates no danger, orange bulb-low level danger, blue bulb- medium danger, red bulb – high danger. Each color bulb is on in each alert. When water level increases to mid-level itself (blue bulb turns on), through hooter dangerous siren is alerted and alert the authorities by providing messages through GSM, and even nearby house member will also be alerted. The system even detects an earthquake by using a vibration sensor (accelerometer/ gyroscope) and provide alert to authorities through GSM. In such flood-prone areas, they may not be the current supply. So we provide solar energy through the solar panel to charge the whole system and provide a slot to charge our mobiles. Through RF transmitter wirelessly communicate to the pole unit section through RF receiver, a dangerous siren(hooter) is alerted in pole section indicating blue bulb on, so that other human near to pole unit can try out to help the people affected by a flood. Presence of rain can be detected by the rain sensor. The gateway here is ESP Wi-Fi module. The gateway then transmits the sensor data packets to the ThingSpeak cloud server over internet protocol and we can monitor the sensor values in ThingSpeak API and also in internet-enabled devices and through GPS(location tracking) is possible which helps them to locate and trace people who are affected by flood and earthquake.

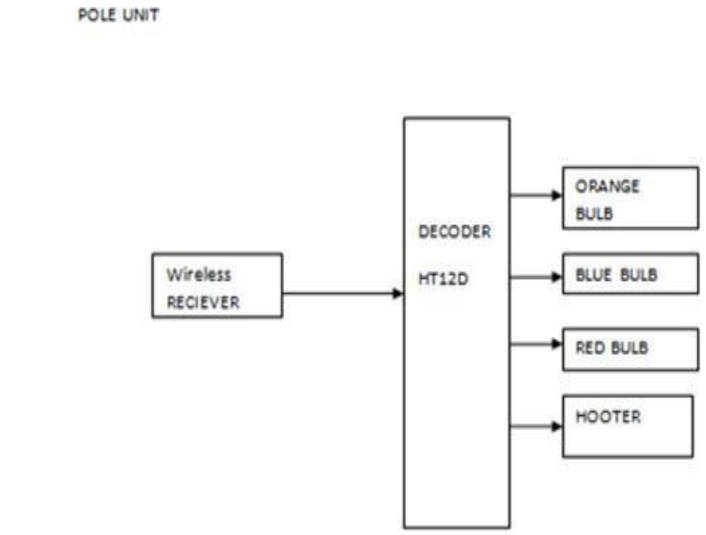

Figure 1: Pole unit of proposed system

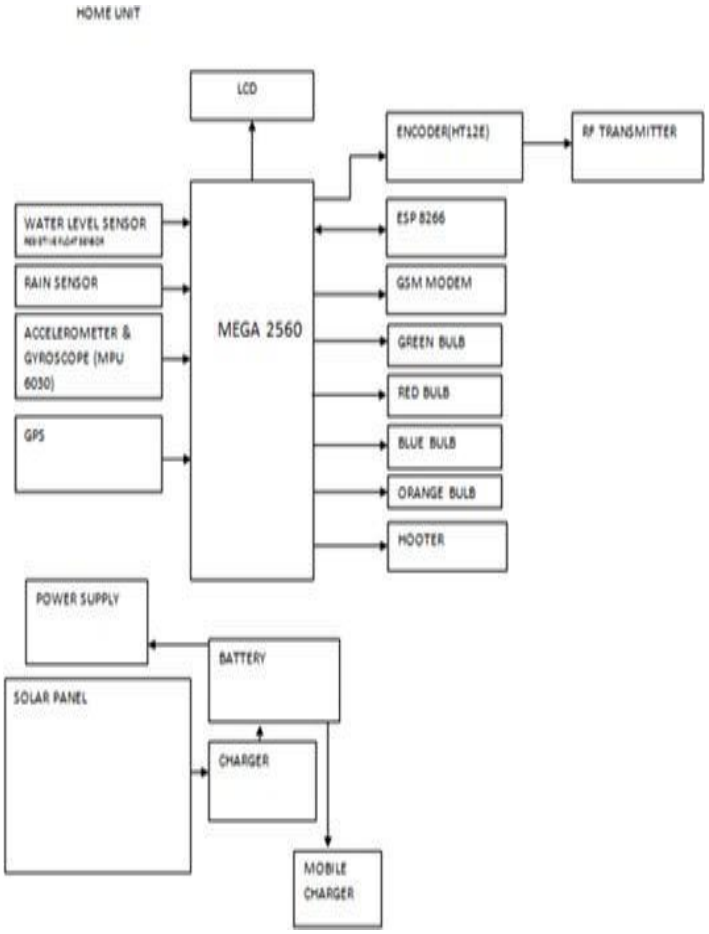

Figure 2: The Proposed Flood and earthquake detection and rescue using IOT technology Home unit

III.TECHNICAL DESCRIPTIONS

3.1. Arduino Mega2560

Arduino Mega 2560 is used for projects that contain more input/output pins, RAM (random access memory and more memory space [5]. It is used in many robotics projects. It contains 54 digital I/O pins (14 can be used as PWM outputs) and 16 analog inputs. It is programmed using Arduino software (IDE-integrated development environment) using C language. It also consists of 4 UARTS (serial ports), USB connection, a power jack, ICSP header, reset button,16MHZ crystal oscillator and can be simply connected to the computer with USB cable or power it with AC-to-DC adapter

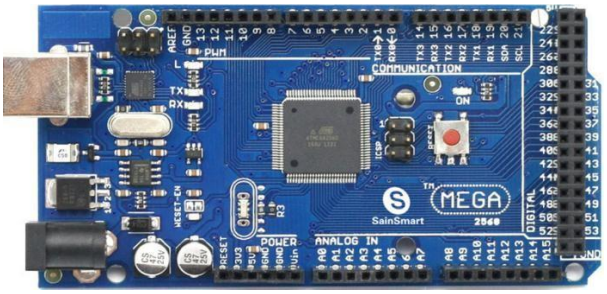

Figure 3: Arduino Mega2560

3.2. Water level sensor

Water level sensor is also known as float sensor to detect the water level increased or decreased in terms of resistance varying. It consists of float connected to potentiometer.

Figure 4: Water level sensor

3.3.Rain sensor module

Presence and intensity of rainfall are detected by the rain sensor module [6]. When raindrop falls on raining board, module act as a switch. It contains features such as potentiometer (to adjust sensitivity), LED (power indicator). Here rain board and control board are separate for convenience. It produces the analog output. The module is connected to the 5V power supply. When the induction board has no raindrop, LED turns on i.e.; Do output is high. When it has a little number of raindrops, Do output is low.

Figure 5: Rain sensor module

3.4. MPU6050 - Accelerometer and Gyroscope

Micro-Electro-Mechanical Systems (MEMS)-MPU6050 consists of a 3-axis Accelerometer and 3-axis Gyroscope inside it [7]. It measures acceleration, velocity, orientation, displacement, and other motion- related parameters .to perform complex calculation, DMP(digital motion processor) is used which is present inside the module.MPU6050 sensor can be interfaced to the microcontroller using AD0 pin.

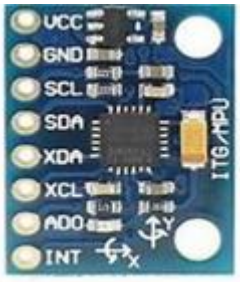

Figure 6: MPU6050-Accelerometer and Gyroscope

3.5. GPS-Global positioning system

GPS is known as global positioning system which transmits microwave signals [8]. It determines position i.e.; location in terms of latitude and longitude

Figure 7: GPS-Global positioning system

3.6. GSM Modem

A **GSM modem** performs like a mobile phone consisting of SIM card (subscriber identity module) [9].It is used for sending and receiving messages to regarding persons or authorities

Figure 8: GSM Modem

3.7. LCD-Liquid crystal display (16*2)

It is an electronic display module .These modules are preferred over seven segments.LCD's are economical and easily programmable. It can display 16 characters

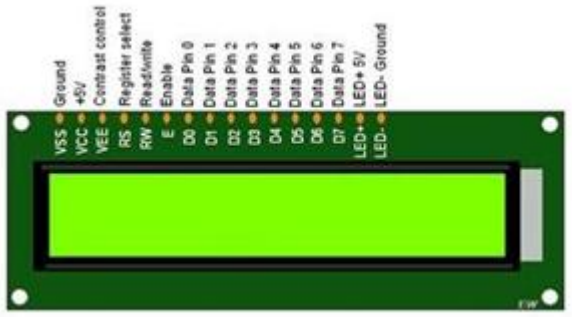

Figure 9: Liquid crystal display

3.8. RF TRANSMITTER AND RECEIVER

The RF module operates at Radio Frequency (30 kHz & 300 GHz)[10]. If there is an obstruction between transmitter & receiver, radio frequency signals can travel. Radio frequency signals are more strong and reliable than the Infrared signals. RF module consists of two devices known as RF Transmitter and RF Receiver. The transmitter/receiver (Tx/Rx) pair has an operating frequency of about 434 MHz. The RF module consists of a pair of encoder/decoder. HT12Eis used for encoding parallel data transmission while the reception is decoded by a HT12D.

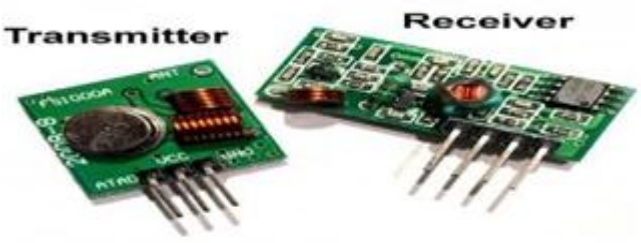

Figure 10: RF transmitter and receiver

3.9. SOLAR PANEL

Solar panels that generates power from the sun which converts sunlight to electricity [11].12-volt panel size of about 25 inches by 54 inches contains 36 cells which are wired in series connection to produce about 17 volts output

Figure 11: Solar panel

3.10. ESP8266 Module

ESP8266 is power-packed module and capable of onboard processing and storage capability that can be integrated with the sensors and other specific devices through its general purpose input/output pins with minimum development up-front and minimum loading during runtime [12].This module is pre-programmed by AT command. By simply connecting this to your arduino device and get about as much Wi-Fi ability

Figure 12: ESP8266 Module

3.11. LM317 Circuit

Solar charger circuit is used to charge lead-acid batteries or Ni-Cd using solar power. This Circuit harvests solar energy to charge a 12- volt 1. 2Ah battery for various applications. The charger circuit has voltage and current regulation cut-off facilities. While adjusting the adjustment pin, voltage and output current can be regulated

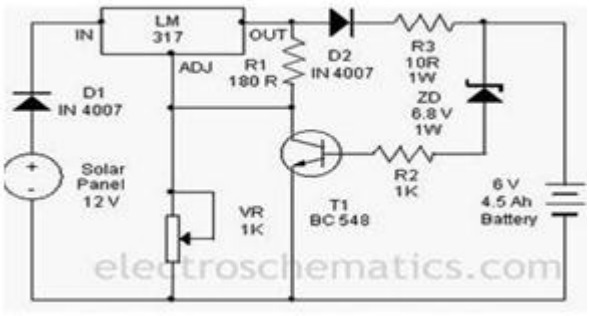

Figure 13: solar charger with current regulation and cutoff

3.12.Power supply

The input to the circuit is obtained from the regulated power supply. Normally devices work in dc supply, so here diodes are used for rectification purpose to convert incoming ac supply to dc supply and and voltage regulator (7805) is to convert incoming dc supply of 12V 12V to 5V and capacitors is used to pure dc voltage

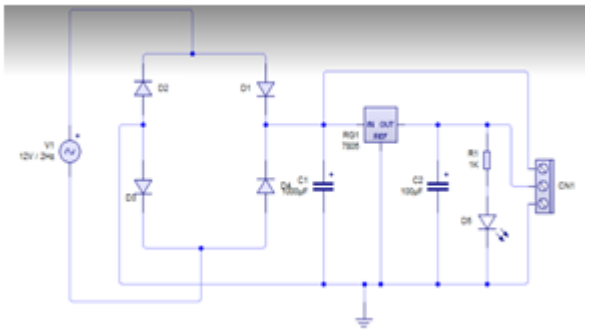

Figure 14: Power supply

IV.RESULTS AND DISCUSSIONS

The Flood and earthquake detection and rescue using IOT technology system presented a good performance. Simulation of the project is done in Proteus. The simulation result is shown in the figure 14. Accelerometer sensor, Rain sensor, and Water level sensor (Float sensor) values displaying on LCD have been included in the simulation. Messaging to authorities is done through GSM and its commands displayed on virtual window in Proteus.The PCB design of the system is done in Proteus ARES.

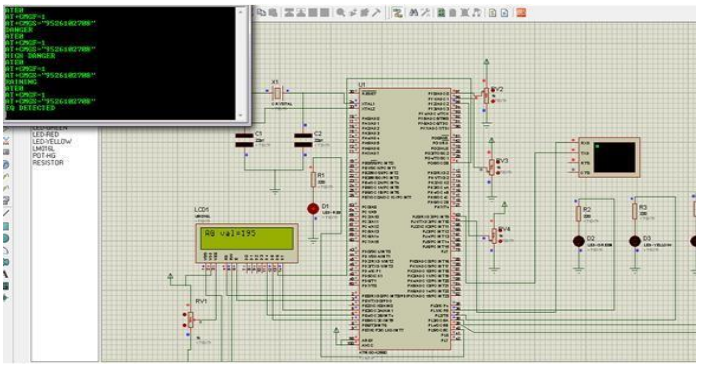

Figure 15: Simulation of the Project

In above simulation, there is also alert system showing 4 types of LED (green-normal, yellow and blue-midlevel, red-danger level) are shown in Proteus.

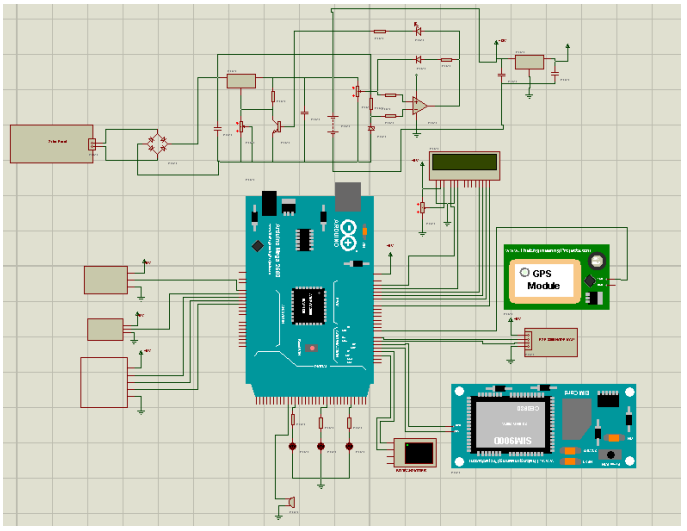

Figure 16: Schematic layout of the Project done in Proteus

Figure 17: PCB output of LM317 CIRCUIT

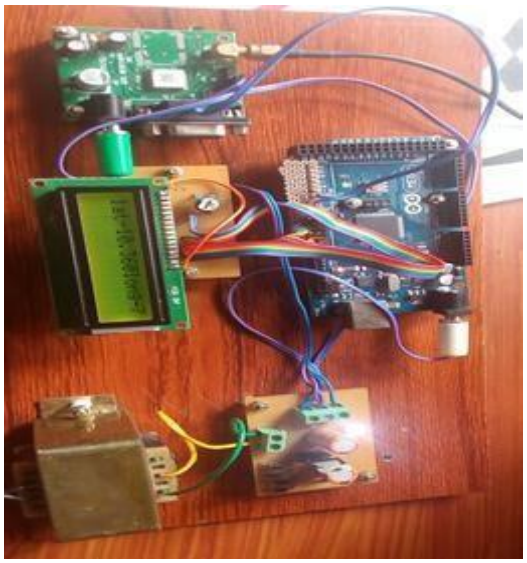

Figure 18: PCB output of GPS showing latitude and longitude

The above figure explains about GPS hardware interfacing to arduino mega 2560 microcontroller and LCD displaying latitude and longitude values

.

Figure 19: Final PCB output of Flood and earthquake detection and rescue using IOT technology

The sensor data packets from the RF receiver are picked up by the gateway ESP Wi-Fi module. Sensor nodes and the base stations (gateway) communication goes over the wireless channel utilizing the RF technology. Gateways connect to the internet and relay messages to the central network server using the standard IP protocol. Here the network server is ThingSpeak cloud-based platform. It provides live visualizations of data measured by sensors. We can send our data to be stored, to a ThingSpeak channel. Each channel can store up to 8 fields of data. We can monitor data from the phone, laptop or any other internet-enabled devices by login to ThingSpeak account.

V. CONCLUSION AND FUTURE SCOPE

Designing and implementation of Flood and earthquake detection and rescue using IOT technology is successfully completed. The system is able to monitor the water level sensor, accelerometer sensor, rain sensor to detect the presence of flood and earthquake to alert house hold members and authorities. The system performed well as per the design. By analyzing various technologies it is better understood that IOT.. The future work includes visualizing the location of flood and earthquake affected area in ThingSpeak IoT platform and monitoring those data on internet enabled devices. Also, the system can be extended to IoT based other natural disaster detection system

Dr. Nirupama Tiwari
Dept. of CSE & IT
SRCEM
Gwalior, India

Abstract*—E-mail is the secure way for the online form of communication as well as for transferring of data or messages through web. A day to day increase in the popularity, which give rapid growth to unsolicited mails in bulk amount. To filter the data, various methods present which is to detect automatically as well as eliminate such untenable messages. There are large number of technique for email spam filtering such as Clustering techniques, Learning based technique, Knowledge-based technique, Heuristic processes & many more. Given paper is on the research of spam filtering by using the feature selection through Relief feature selection technique & then classifies data by using Fuzzy support vector machine so as to deal with the factors of uncertain type. The experimental outcome illustrate that given algorithms can improve filtering rate parameters & spam filtering speed more efficiently.

Keywords— Spam, Fuzzy support vector machines, Relief feature selection, Polynomial kernel.

I. INTRODUCTION

E-mail is a major form of revolutionary which is taking place over the conventional communication systems which is because of its fast, convenient to use, easy, as well as economically cheaper to use. A key bottleneck in the E-communications is huge diffusion of emails which is unwanted & dangerous in nature so named as spam emails. A key concern is for developing of suitable filters which can capture those emails in sufficient amount and get high rate of performance. Researchers of Machine learning (ML) have developed number of approaches which is to deal with similar problem. in the machine learning framework, support vector machines (SVM) have maintained a large part to spam email filtering development . Based on SVM different scheme been designed through the approaches of text classification (TC). A major issue when we use SVM is the kernels selection as it affects openly by the partition of emails in quality space [1]. In this section figure (1) shows the brief process of filtering the spam. Here the first step is of preprocessing in which we remove redundant messages, conversion of lower case, tokenization as well as streaming is done in this step, next is feature selection & weighted feature where information gain methods we also select the feature size in this step ,next is representation of features is performed after selecting the required features, at last dataset is divided in train & test set in which learning & testing on models performed respectively, then classification is done to get the evaluated result, after this step the process ends.

Several types of researches have been performed on email filtering, some acquired good accuracy and some are still going on. Spam filtering is a process to detect unsolicited massage and prevent from entering into user's inbox. Now days, various systems have been existed to generate anti-spam technique for preventing unsolicited bulk email. Most of the anti-spam methods have some inconsistency between false negatives (missed spam) and false positives (rejecting good emails) which act as a barrier for most of the system to make successful anti spam system. Therefore, an intelligent and effective spam-filtering system is the prime demand for web users. [2]

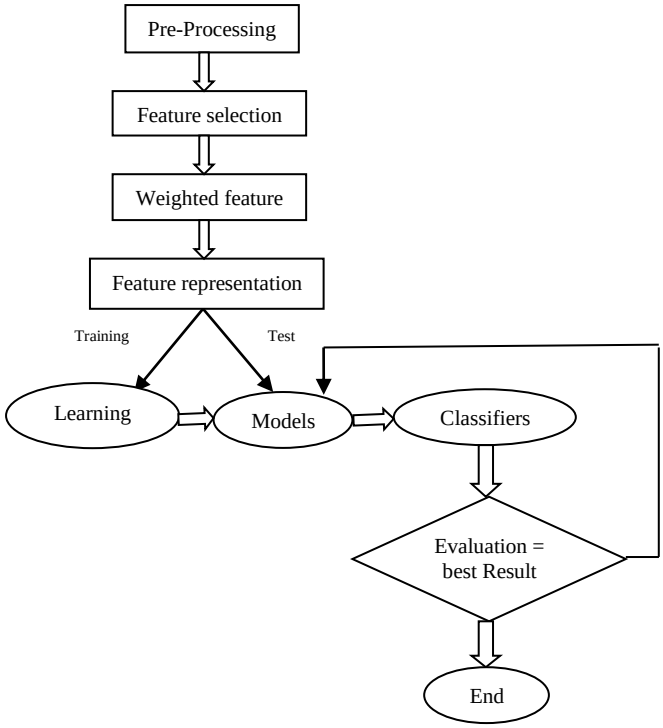

Figure 1: Process of Spam Filtering. [2]

Spam is making use of electronic messaging systems (by including the most of broadcast media, digital form of delivery systems) to transfer the unsolicited messages in bulk indiscriminately [3]. E-mail spam, also termed as e-mail in junk form / unsolicited bulk e-mail (UBE), it's a subset of spam which consist of nearly similar messages delivered to many recipients by the e-mail [4].

Several studies took place in this field and published the ways on how to get rid of spam mails , some of these are Rule Based Spam Filtering, Content Hash Based Filtering, Support Vector Machines (SVM), Machine Learning techniques, Content- Based Filtering (CBF) and many more [5]. From all above methods, CBF has been used widely as anti-spam solution because it's available in easy way with its full implementations in commercial form [6].

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

FCM is to reduce feature set at the time of training phase and the membership degree is in use at time of clustering, which is performed among data and clusters centers have been included during system training. The given degree of membership is then required as box constraint when the incorporation of training phase with fuzzy SVM based classifier. In our work, FSVM based classifier is being used in place of SVM classifier to get better performance of system at time of classification.

The rest of the paper is organized as follows. In Section 2, feature selection technique a relief feature selection algorithm been described. In Section 3 other related researches performed till yet been discussed in literature review. In Section 4 flow of work done in our research area with brief review on methods used in research is discussed. In section 5 the experimental results being discussed where results obtained on various threshold values and comparisons of our work with past research is discussed. At last the conclusion of the work is presented in section 6

II. RELIEF FEATURE SELECTION

Relief is said to be feature weight based algorithm which is inspired from the learning of instance based [researcher Aha, Kibler, Albert year 1991 & Callan, Fawcett dz & Rissland year 1991]. Here the training data denoted as §, size of sample is denoted as m, and relevancy threshold is denoted by α , Relief take only those features those are appropriate to the target concept in statistical manner. A threshold is to encode as ($0 \leq \alpha \leq 1$). We also let scale of each feature which can either be nominal (take only Boolean) else numerical (which take only integer / real) values of feature. Difference among 2 instances X & Y is used are given functional diff.

When X_k , Y_k are the nominal,

Diff (X_k and Y_k) ={0 <if X_k and Y_k are the same>

1 <if X_k and Y_k are the different >

When Xk and yk are numerical,

diff(X_k and Y_k) = (X_k and Y_k)/nu_k

where nu_k is a unit of normalization to normalize given values of diff within the interval [0, l].

Algorithm representation of Relieff Feature Selection

1. Relief(§,m, α)
2. Separate § into § + = { instances of positive type] and
   §- = (instances of negative type)
3. w = (O,O, . . . * 0)
4. For i= 1 to m
5. Select randomly the instance X € S
6. Select randomly one instance of positive type near to the X, Z+ € § +
7. Select randomly one instance of negative type near to the X, Z- € S
8. if (X will be positive form of instance)
   Then Near-hit equal to Z+; Near-miss equal to Z-
   Else Near-hit equal to Z-; Near-miss equal to Z+
9. weight updated (W, X, Near-hit, Near-miss)
10. where Relevance is (l/m)W
11. For i = 1 to p
    if the value of (relevance i ≥ t)
    then fi is feature of relevant form
    else fi is irrelevant
12. Again weight is updated
13. For i= 1 to p
    Wi = Wi – diff (xi, near-hit i)2 + diff(xi, near-miss i)2

Relief select a sample which is m composed by no: of triplets of instance X, its instance for Near-hit is 1. Relief makes use of the p-dimensional formula of Euclid distance for choosing Near-hit as well as Near-miss. Relief each time make a calls for routine which is for updating W which stands for the vector for feature weight for each triplet sample & to determine the relevance of average weight. At last, Relief selects only such features which have average weight called (**'relevance level'**) above w.r.t given value of threshold α .[7]

III.LITERATURE REVIEW

Yuksel et al. [8] [2017] use Support Vector Machine and Decision tree for spam filtering. The Decision tree used in data mining and the support vector machines as a supervised learning model which can analyze the data for spam classification. First data was divided into two sections; one is training and other is test data, then the algorithm was trained and evaluated through Microsoft Azure platform which provides tools for machine learning and compared results with decision tree and support vector machine algorithm. The result of SVM method was 97.6% and for Decision tree the result was 82.6%. The result estimate that, SVM classifier performed better than DT.

Choudhary et al. [9] [2017] presented a novel approach using machine learning classification algorithm for finding and classifying SMS spam by using Short Message Service (SMS). The first step in this approach is feature selection and for that, they work on presence of mathematical symbols: UGLs, Dots, special symbols, emotions, Lowercased words and Uppercased words, mobile number, keyword specific and the message length in the SMS. After that they created a system design and collected a dataset which contained2608 emails out of 2408 collected SMS Spam Corpus.

Verma et al. [10] [2017] proposed a method for spam detection using Support Vector Machine algorithm and feature extraction. This methodology works through several steps such as Email collections, preprocessing, feature extraction, SVM training, test classifier, top word predictors, test email and result. First they take a dataset from Apache Public corpus. In preprocessing section, they remove all special symbol, URL and HTML tags and also unnecessary alphabet. Then they mapped all word from the dictionary using Vocab file. SVM classifier applied on the training dataset. The Accuracy of the system was 98%.

Rusland et al. [11] [2017] perform the analysis using Naïve Bayes algorithm for email spam filtering on 2 datasets those are evaluated on the basis of the accuracy, recall, precision and F-measure. Naïve Bayes algorithm is a probability-based classifier and the

probability is counting frequency as well as values combination in dataset. This research performed through three phases such as pre-processing, Feature Selection, and implementation through Naïve Bayes Classifier.

Sah et al. [12] [2017] proposed a method for detecting of malicious spam through feature selection and improve the training time and accuracy of malicious spam detection system. They also showed the comparison of difference classifier as Naïve Bayes (NB) and Support Vector Machine (SVM) based on accuracy and computation time. The proposed approach completed by $f(x) = a_0 + \sum_{n=1}^{\infty} \left(a_n \cos\frac{n\pi x}{L} + b_n \sin\frac{n\pi x}{L}\right)$ steps such as preparing the text data, creating word dictionary, Feature extraction process and training the classifier.

Singh et al. [13] [2018] discussed the solution and classification process of spam filtering and presented a combining classification technique to get better spam filtering result. With the help of Data mining, they collected several information of failures of previous papers, success with recent issues of spam filtering. In this method, researchers used binary value where 1 is for spam email & 0 for ham.

Abdulhamid et al. [14] [2018] discussed a performance analysis based approach by using some classification techniques such as Bayesian Logistic Regression, Hidden Naïve Bayes, Rotation Forest, REP Tree, Naïve Bayes, Radial Basis Function (RBF) Network, Voted Perceptron, Lazy Bayesian Rule, Multilayer Perceptron, Random Tree and J48. The competence of these techniques classified through Accuracy, Precision, Recall, F-Measure, Root Mean Squared Error, Receiver Operator Characteristics Area & Root Relative Squared Error using Spam base dataset and WEKA data mining tool.

IV.PROPOSED METHODOLOGY

In our propose work spam-filtering techniques is based on the statistics which is focusing on how to improve the recognition parameters of spam, where, the recognition time of execution will depend on no of samples which are randomly selected each time and how much amount of system memory is free at the time of execution . E-mail is easy, fast and cheap method of communication, which may cause unpredictable consequences for users, if sent information is not arrive in time. This paper proposes an algorithm on fast content-based spam filtering with proposed technique of feature selection and fuzzy-SVM.

Here from large part of original data, the fixed size of training set, the fixed size of the test set is randomly selected. First, training set is being required to train classifier, and then test set is needed to test the classifier, process is required to calculate performance level of proposed classifier. With the help of precision and recall parameters. Threshold value of 70% and 50% is used to extract the relevant features or attributes and discard the rest of it with the help of feature selection technique.

As evaluation of filtering method of feature selection, Relief is use to calculates a proxy statistic for every feature (attributes in our paper) from the sample of dataset that is then used to estimate or to calculate the 'quality of feature' or 'rank' to target concept. These types of feature statistics are known to be as the feature weights is within rank (W[A] is the weight of feature 'A'), or much casually as the 'rank' of feature. When the number of attributes which are 57 multiplied by used threshold value (say 0.7) the value is generated, if the rank is greater than or equal to attribute value/ weights of feature then attribute is extracted or else it's discarded .
Here, we apply clustering algorithm fuzzy c means to get the membership degree. With the help of SVM with polynomial kernel function the required model is classified. This is generated FSVM which is suitable for the uses in which data points consist of unmodelled characteristics.[15]

After the achieved train FSVM classification model. This is suitable for non linear problems and to deal with uncertain factors. So, this paper uses the modified classification technique of SVM into FSVM through polynomial kernel and clustering algorithm fuzzy c means. The dissimilarity in both the classifier is FSVM and SVM is, in FSVM, each data sample make use of degree of membership to which dataset belongs to from 2 distinct classes. The main part of proposed technique is to find out the best possible separating hyper plane so as to segment / distribute the set of data to complete the classification.

Generating the Fuzzy Memberships

To select fuzzy memberships of appropriate type in a given condition is much easy. Firstly, the lowermost bound of the fuzzy memberships need to be defined, & secondly, we require choosing those property of data set which helps to establish the connection among set of data and fuzzy memberships function. [16]

Assume that we have to perform the sequential learning problem. Where First thing is to choose, $\boldsymbol{\sigma} > 0$ because lower bound of the membership function. In second step , we identify ,time which is the major property of given kind of situation which then make s_i stand for fuzzy membership which is a function of time t_i

$$s_i = f(t_i)$$

where $t_1 \leq \ldots \leq t_l$ *is* time the arriving time of point in system. We choose $s_t = f(t_1) = 1$, and make use of first point to be the least essential and choose $s_1 = f(t_1) = \boldsymbol{\sigma}$.

By applying conditions for boundary, we get t_l

$$s_i = f(t_i) = \frac{1-\sigma}{t_l - t_1} t_i + \frac{t_l\sigma - t_l}{t_l - t_1}$$

The polynomial kernel not only takes care of given features of i/p samples which is to know their similarity, but also combinations of these. In context of regression analysis, such type of combinations is c/d interaction features.

$$K(\vec{x}, \vec{z}) = (\vec{z}^T \vec{x}_+ C)^n$$

Where n is "order" of kernel, and C is constant which permit to trade off influence of higher order & lower order of terms. Quadratic kernels are much popular form of the Polynomial kernel, Higher order kernels be likely to "over fit" training data so, thus don't generalize well. [17]

Here we, use k no of samples which is to train then get FSVM classification model. We achieve classification o/c after placing data for characterizing the mail in the model.

In this research we have Train classification model with FSVM. The data samples for this paper is from, famous UCI Machine Learning Repository having the spam base data unit. Randomly choose 300 no: of samples of the positive (ham) and 300 samples of negative (spam), having total of 600 used samples. Now from 300 positive samples, 200 no: of samples were chosen as the training set & 100 for testing set for both category of email and similarly performed with 300 negative samples

Pseudo code of FSVM& Polynomial kernel

Step 1. Start
Step 2. Load Spam base dataset
Step 3. Select randomly 600 samples of data
Step 4. Now categorize the 600 samples as 300 ham (+) and 300 spam (-)
Step 5. Now Divide samples 200 training and 100 testing for individually ham and spam.
Step 6. Divide the training data into sets
$D_1 = \{(x_1, 1), (x_2, 1) \ldots (x_n, 1)\}$
$D_2 = \{(x_{\frac{\pi}{2}+1}, -1), (x_{\frac{\pi}{2}+2}, -1), \ldots (x_n, -1)\}$

Step 7. Apply Relief feature selection strategy on training samples and calculate w[A]
$w[A] = w[A] - \sum_{j=1}^{k} \frac{diff(A,ri,hj)}{(m,k)}$

Step 8. Apply fuzzy-c-means (on equal attributes on training & testing) to calculate membership degree s_i
Step 9. Classify obtained model using SVM
Step 10. Using Polynomial kernel function to make kernel in commutation
$$K(\vec{x}, \vec{z}) = (\vec{z}^T \vec{x}_+ C)^n$$

Step 11. Obtain the trained model of Fuzzy Support vector machine
Step 12. Result obtained (ham and spam mails)
Step 13. Process ends.

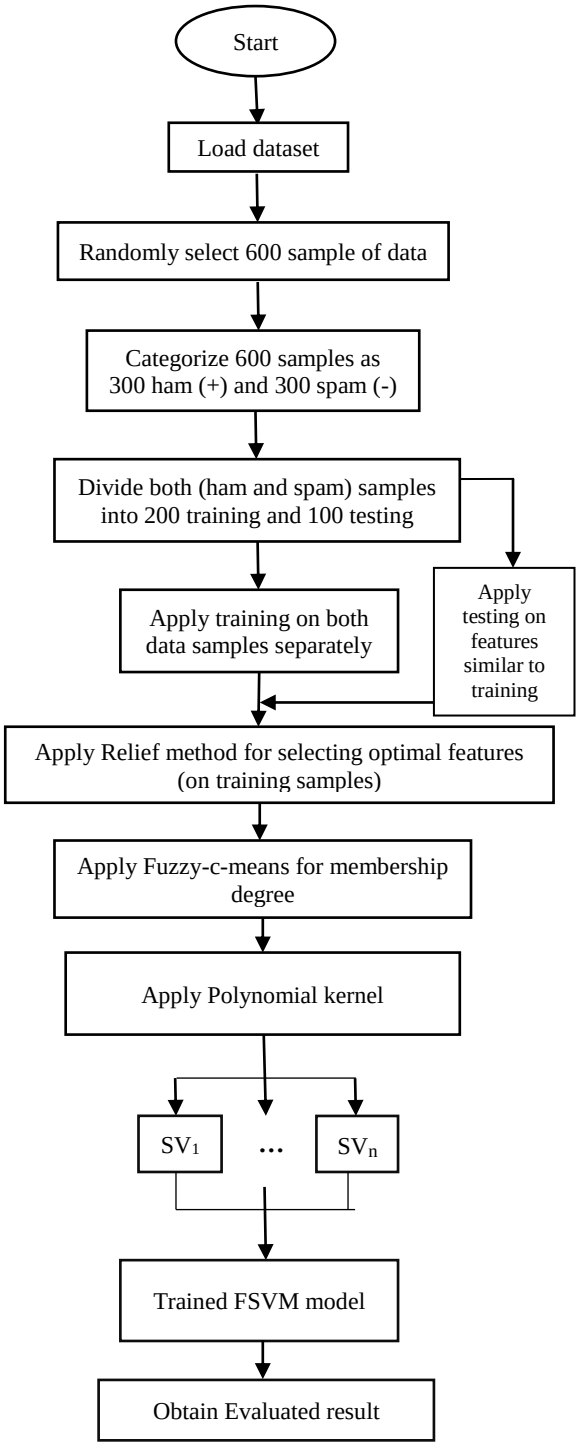

Figure 2 Flow diagram of FSVM using relief feature selection& polynomial kernel

V. EXPERIMENTS RESULTS AND DISCUSSION

The research work is implemented on MATLAB simulation tool. The given screenshot is to show the used train dataset sample from the "spam base data unit".

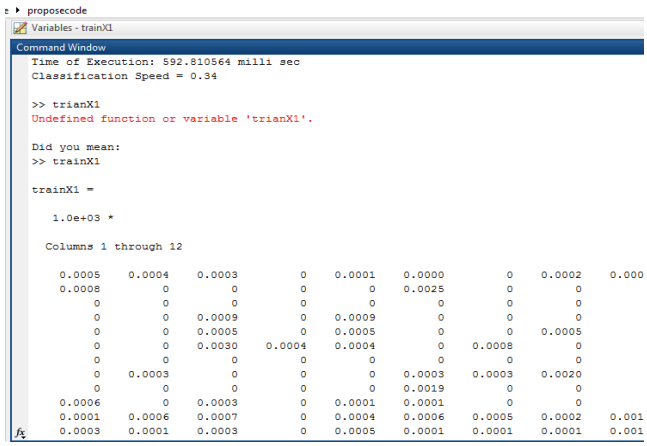

Figure 3train data set sample screenshot.

The performance of this research model is based on some specific criteria that is precision (p), recall rate (R) and speed of classification (*v*), time of execution (t). The higher is speed less is classification time taken for processing.

1) R =. $\frac{TP}{TP+FN}$, the recall rate shows discovering no of spam ability. The higher value of R, less is no: of spam evading arrest.
2) P =. $\frac{TP}{TP+FP}$, is identified as the % of real errors among all encounters that were classified as errors.
3) $v = \frac{N}{t}$, v stands for speed of classification.

Table 1: illustrate that FSVM using relief feature selection is comparatively generating better value of recall and precision on different threshold value then the FSVM using k-means clustering algorithm. Graphical representation is performed on 50% value and 70% value of threshold on a separate basis.

Table 1 Comparison of existing and proposed work with threshold value of 50% and 70%.

Algorithms	Recall		Precision	
	50%	70%	50%	70%
K-means& FSVM	85.94%	85.29%	91%	90%
Relief & FSVM	89.23%	92.59%	93%	94%

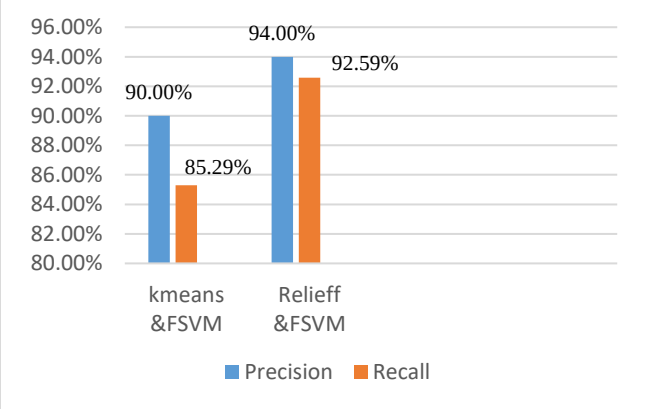

Figure 4 Recall and Precision of FSVM using k means and FSVM using Relief feature selection with threshold 70%

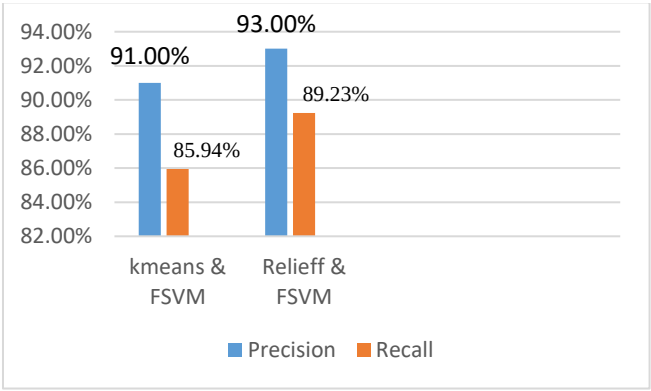

Figure 5 Recall and Precision of FSVM using k means and FSVM using Relief feature selection with threshold 50%

As shown in Table 2, the comparison of proposed method with those of other existing method is generating much better results, when comparison is performed on recall and precision values.

Figure 2 Comparison of proposed technique with other existing methods

Reference	Classifier used	Precision	Recall
Alsmadi, I [15]	NGram	83.6%	88.4%
Etaiwi, W.[16]	Naïve Bayes	51.8%	86.8%
Shengnan Wang, [17]	k-means & FSVM	90%	85.29%
Proposed method	Relief & FSVM	94%	92.59%

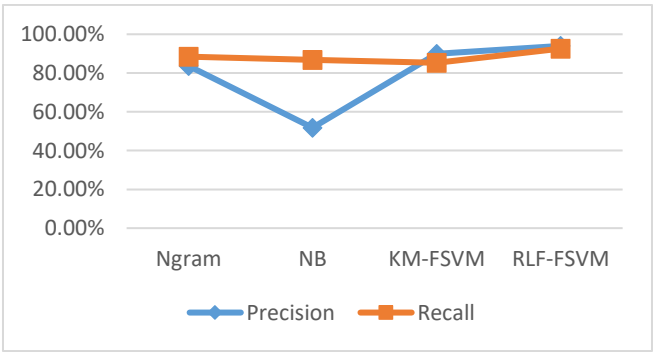

Figure 6 Graphical comparisons of various existing methods with proposed technique

As shown in Table 3, the classification speed and time of execution. The result obtained shows a huge difference between existing and proposed work. **As we are achieving high speed of classification and time of execution is reduced from the base work.** As this is the desired result so far.

Table 3 Comparison of Time spent & Speed of the classification from base work to propose work

ALGORITHMS	Base work	Propose work
	FSVM(K-means & RBF)	FSVM(Relief &Polynomial)
Classification Speed	0.71	2.21
Time of Execution	283.590212	90.629472

VI.CONCLUSION

Spam also called unsolicited bulk mails. E mail is undoubtedly a very effective, economically cheaper and also easy method of communication for ongoing time. But, as social networks and advertisers, have evolved their business worldwide with the help of emails , which contain unwanted information called spam.

This research paper is based on Fuzzy support vector machine (FSVM) classifier with Relief feature selection method which is required to extract features in form of attributes. In this research relief works on rank of the attributes, the rank is dependent on the value of threshold and number of attributes used. Here FSVM is required to train the classification model, with the help of membership degree which is to show the degree of similarity as the proposed model is much better for working on uncertain factors. Proposed experiments have shown that it is the improved form of spam filtering algorithm from other work by two aspects of reducing the time of execution & maximizing the speed of classification. How to improve filtering parameters in feature selection technique so as to achieve improved filtering results is significant topic for the future work.

***Abstract*- In proposed article comparative study and simulation of PV system connected with Z-source and conventional inverters output are analyzed. A perturb and observe MPPT technique incorporated for maximizing output power of PV panel. Inverters is used in our system are receiving power input (DC) from PV system and inverters output is controlled by various triggering by space vector pulse width modulation technique (SVPWM). Respectively output voltages of both types of inverters are compared in respect of total harmonic distortion (THD) and obtain simulation results are gives effectiveness of Z-source inverter as compare to conventional inverter. In both cases inverters are able to calculate distortion factor according to IEEE standard. Projected model is intended under MATLAB/SIMULINK platform 2016(b).**

Keywords: Space vector pulse width modulation (SVPWM), photovoltaic (PV), Z-source inverter (ZSI),total harmonic distortion (THD).

I. INTRODUCTION

Electricity utilization is growing day by day. The use of renewable energy is become trendy because of lower availability in fossil fuel. Also conventional power generation methods are harmful for environment as compared to renewable energy source. Generation of energy through renewable sources is recommended pollution free energy. [1-2].

Main sources of renewable energy are hydro, bio-fuel, wind and photovoltaic [3]. Most beneficial and popular sources are PV and wind. Power generation using sunlight has growing rapidly in last few decades in India because power generation using sunlight provide various benefits such as less cost, pollution free, less maintenance charges and uninterrupted accessibility during day.

PV panel supplied regular DC power for get better efficiency of PV system, MPPT methods is extremely important [4]. Various methods of MPPT are Perturbation and Observation (P&O), Fractional Short-Circuit Current, fuzzy logic control, Incremental conductance, Ripple Correlation Control and Fractional Open-Circuit Voltage technique. Extraction of maximum power from PV is varied with solar irradiance and cell temperature. As a result to extract the maximum power from PV system on- line tracking of MPP is necessary [5, 6].

For MPPT perturb and observe (P&O) is usually used because its implementation is simple. P&O algorithm provides maximum power output by increasing or decreasing output voltage of PV panel.

PWM technique is usually used in DC to AC converter [7-9]. The PWM technique is extremely useful, in this method width of gate pulses are composed by different phenomena. In PWM based inverter output voltage is kept equal to rated voltage regardless of load. Output voltage in traditional inverters fluctuates according to variation in load.

The Z-source converter can convert and enhance voltage quality in single stage, but when it is supplied from conventional sources boosting factor is low. In a Z-source inverter an impedance circuit is used it provides connection between power source and inverter circuit [10]. The only difference between Z-source inverter and PWM based conventional inverter is use of impedance circuit in ZSI.

II. SYSTEM DESCRIPTION

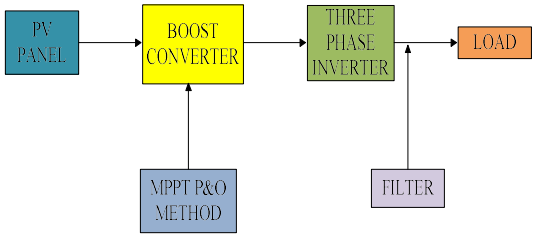

Fig.1. Basic arrangement of proposed scheme.

Fig.1 displays the basic arrangement of PV system. It has a PV panel connected with DC to DC boost converter.The Sun light in the form of photons incidence on PV array which generates electricity.PV panel output is controlled by MPPT technique (P&O) through boost converter. Three phase inverter is directly supplied by DC output of boost converter and provides AC voltage to load through a LC filter.

A. PV Modeling

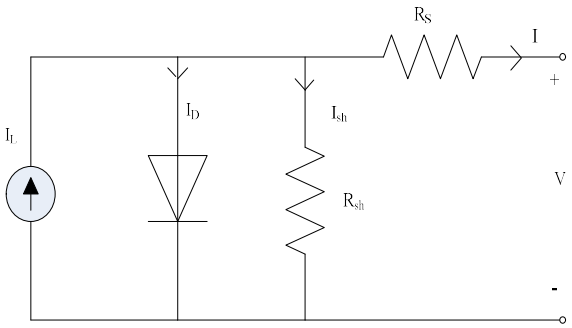

Fig.2. One diode model of PV cell.

Fig.2 represents one diode model of PV cell.

Here,
I_L = Cell current produce by light
I_D =Diode current
I_{sh}= Current lost in shunt resistance

$$I_D = I_O[\exp\left(\frac{V + IR_S}{\eta V_T}\right) - 1] \quad (1)$$

η = Diode ideality factor
I_0 = Saturation current
V_T = Thermal voltage
Thermal voltage given by:

$$V_T = \frac{kT_C}{q} \quad (2)$$

k = $1.381*10^{-23}$J/K
q = $1.602*10^{-19}$C
Complete governing equation for single diode model:

$$I = I_L - I_O[\exp\left(\frac{V + IR_S}{\eta V_T}\right) - 1] - \frac{V + IR_S}{R_{sh}} \quad (3)$$

Fig.3 and Fig.4 represent current-voltage and power-voltage curve of PV panel and different waveform obtained from PV panel.

Different parameters value of PV panel is illustrated in Table 1.

IV. CONCLUSION

In proposed model, conventional and Z-source based PV connected have been investigated and compared. The proposed z-source inverter has shown better performance than conventional SVPWM based inverter. From the result it is clear that z-source inverter provides 7.56% THDwhereasSVPWM based conventional VSIinvertergives 39.29% voltage harmonics. It has been shown that high quality waveform at output of Z-so-urce based inverter can be reached by using suggested method.

***Abstract*—there are many features proposed in the literature for voice activity detection (VAD). Shen et al. [20] first used a spectral entropy-based feature to detect regions of speech spurts under noisy conditions. However, VAD employing this feature was unreliable when the noise level greatly exceeds the speech level. To improve the performance of spectral entropy based VAD under low signal-to-noise ratios (SNRs), spectrum of a signal over a frame is divided into sub bands and spectral entropy is computed over these bands. Later, these spectral entropies are weighted and summed to obtain the entropy. Based on the amount of noise in each band, weights were found empirically. This approach was named as banded spectral entropy (BSE) [21]. In [24], deviation threshold computed from approximate ramp line and the sorted spectral coefficients of the band are adopted to decide useful/useless bands. In this paper, we propose a novel Teager Energy Band Spectral Entropy (TE_BSE) feature for VAD. Here, we carryout enhancement of spectral peaks employing Teager energy of each frequency transformed speech frame. This is followed with dividing of spectrum into sub bands and entropy computation over each band. The summing of entropy from each useful band is done to get TE_BSE feature. We identify useful/useless bands following [24]. Later, we present the performance of our proposed VAD in terms of probability of detection (P_D), probability of false alarm (P_{FA}) and probability of error under different noises and SNRs. Finally, from the VAD results on real-world sample, proposed VAD outperforms statistical based VAD by Sohn et. al. [8] with improved P_D not at the cost of increase in P_{FA}.**

Keywords—Voice Activity Detection; Spectral Entropy; Band Spectral Entropy; Teager Energy Operator;

I. INTRODUCTION

A process of marking the boundaries or classifying between speech and non-speech (silence, background noise etc.) segments of a digital speech signal is popularly known as voice activity detection (VAD)**.** Speech/non-speech detection as a preprocessing step, enhances the performance of applications including robust speech recognition [1,2], discontinuous transmission [3,4], real-time speech transmission on the Internet [5] or combined noise reduction and echo cancellation schemes in telephony [6,7]. Speech/non-speech classification task is not as trivial as it appears; indeed, most VAD algorithms fail when the background noise increases. Numerous researchers have proposed different schemes for detecting speech regions in a noisy speech signal [8-11].

The different VAD methods include those based on energy thresholds [13], pitch detection [16], spectrum analysis [15], zero-crossing rate [3], periodicity measure [17], higher order statistics in the Linear Predictive Coding (LPC) residual domain [18] or combinations of different features [3,4,19]. Shen et al. [20] first used a spectral entropy-based parameter to detect regions of speech spurts under noisy conditions. However, their method is unreliable when the noise level greatly exceeds the speech level. Additionally, the spectral entropy relies on the variance of spectral magnitude to distinguish speech from noise, but the variance of spectral magnitude in turn strongly depends on the nature of noise.

One can improve the robustness of spectral entropy by exploiting banded structure of speech spectrogram and discarding bands dominated by noise, thereby enhancing the banded nature of speech spectrogram. Spectral entropy thus computed is called the banded spectral entropy (BSE) [21]. However, BSE does not sufficiently specify the organization of the banded nature on the spectrogram. Therefore, in [21], Wu and Wang have proposed a set of weights to compensate for this drawback. These weights have been found empirically by the authors [21] to sufficiently characterize the speech signals rather than by simply computing spectral entropy of each sub-band [20]. Although the weighted BSE remains a good feature parameter, the detection sometimes fails at very low SNRs. The question that needs to be addressed is the following: *How is one to discard the noisy bands and hence, effectively retain only the useful bands*?

In [22], it was shown that the number of noisy bands (or useful bands) is related to the background noise level. A Minimum Mel-scale frequency Band (MiMSB) parameter proposed in [23] has been used in [21] to estimate the varying noise levels by adaptively choosing one band with minimum energy. A Normalized Minimum Band Energy (NMinBE) parameter has been proposed to accurately decide the number of useful bands. The authors in [21] have used the number of useful bands empirically derived from the knowledge of NMinBE. Further, it has been assumed in [21] that a short window of non-speech interval exists prior to the commencement of the input signal and the mean and variance of the logarithmic Adaptive BSE (ABSE) has been initialized on the estimates computed from this window. Successively, the relative mean and variance of the logarithmic ABSE values are updated during non-speech periods.

In contrast, our proposed band selection scheme is easy to setup and has too less empirical parameters as part of the initialization. This scheme exploits the banded structure available in noisy speech spectrum and selects those sub-bands where speech dominates over noise. We examine the banded structure on speech spectrogram to detect speech/non-speech regions as used in [21], but differ from it in terms of selection of useful/useless bands. Our band selection scheme depends not exclusively on the statistical behaviour of speech, but also on speech contaminated by noise in sub-bands. Specifically, we exploit the well-known fact that the formants play a major role in modelling speech signals in a compact way, and that the first three formants are sufficient to synthesize intelligible speech. Therefore, the detection of speech/non-speech is equivalent to identifying the presence or absence of formants.

In this paper, we adopt band spectral entropy (BSE) in [21] to compute the entropy. However, our approach is different on two counts (i) Selection of useful/useless bands in a spectrum employing deviation between coefficients that approximate ramp line (ARL) and sorted spectral coefficients (ii) Enhancement of spectral peaks employing Teager energy operator (TEO) on the signal spectrum such that the spectral peaks are enhanced. This is followed with the smoothening of present spectral estimates with past spectral estimates. Further, our work deviates from [24] on second count. In section, II we discuss spectral peak enhancement and smoothening employing TEO and later computation of BSE. We name this new feature as Teager energy band spectral entropy (TE_BSE). Section, III presents theory behind the selection of useful/useless bands proposed in [24]. In section, IV we present experimental setup in extracting TE_BSE feature followed with performance analysis this feature under (i) Stationary noise (ii) Non-stationary noise and (iii) Non-stationary heavy noise environments. Finally, we present the VAD output employing proposed feature and compare with statistical based VAD by Sohn et. al. [8]. This followed with concluding remark and some vistas for future.

II. BAND SPECTRAL ENTROPY

We now review the procedures in [20, 21] in some more detail. The entropy measures the randomness of the signal $x(.)$ with the defined probability density function $f(x)$as

$$H(x) = -\int f(x)\log\big(f(x)\big)\,dx. \tag{1}$$

Shen et al. [20] employed it to discriminate speech from non-speech signals as part of ED. The speech signal is observed over a frame of length, N. The Short-Time Fourier Transform (STFT) of lth frame, $s(n,l)$, is given by

$$S(k,l) = \sum_{n=0}^{N-1} w(n)\, s(n,l)\exp\left(-\frac{j2\pi kn}{N}\right), \quad k = 0,\dots,N-1, \tag{2}$$

where$|S(k,l)|$ represents the spectral magnitude of the kth frequency bin of the lth frame, N being the total number of frequency bins and $w(n)$, a Hamming window. Excluding the symmetry and squaring each of$|S(k,l)|$, let

$$S_{msq}(k,l) = |S(k,l)|^2, k = 0,\dots,\frac{N}{2}-1. \tag{3}$$

Then, the probability associated with each $S_{msq}(k,l)$ component $P(j,l)$ can be estimated by normalizing

$$P(j,l) = \frac{S_{msq}(k,l)}{\sum_{k=0}^{\frac{N}{2}-1} S_{msq}(k,l)}, 0 \le j \le \frac{N}{2}-1. \tag{4}$$

The corresponding spectral entropy over a frame is

$$H(l) = \sum_{j=0}^{\frac{N}{2}-1} P(j,l)\log\big(1/P(j,l)\big). \tag{5}$$

Spectral entropy depends on the variation of the spectral energy but not on the amount of spectral energy. Consequently, spectral entropy, and hence the performance of VAD, are robust to the changing noise levels [20]. However, the magnitude associated with each point in the spectrum is affected by noise and, therefore, VAD performance would degrade severely at low SNRs. Further, the observation in [21] about 'effect of noise in the spectrum' was primarily restricted to a few sub-bands instead of a full band. This naturally suggests multiband analysis and necessitates the entropy computation for each of the sub-bands [21]. The sub-band energy of a given frame is computed as follows:

$$E_{SBE}(m,l) = \sum_{k=(m-1)*(N/2N_b)}^{\left(\frac{N}{2N_b}\right)-1+(m-1)*(N/2N_b)} S_{msq}(k,l), \quad 1 \le m \le N_b, \tag{6}$$

where N_b is the total number of sub-bands for each frame ($\mathrm{N_b} = 32$) and represents the energy of the sub-band. Again, we define the probability associated with each sub-band as

$$P_{SBE}(m,l) = \frac{E_{SBE}(m,l)}{\sum_{k=1}^{N_b} E_{SBE}(k,l)}, 1 \le m \le N_b. \tag{7}$$

The BSE parameter, $H_{SBE}(l)$, is now computed as

$$H_{SBE}(l) = \sum_{m=1}^{N_b} P_{SBE}(m,l)\log\big(1/P_{SBE}(m,l)\big). \tag{8}$$

Further, in [21], a set of weights is proposed to compensate for this drawback. These weighting factors are found empirically to characterize speech signals more effectively than by simply computing spectral entropy of each sub-band. Although the weighted BSE remains a good feature, the detection sometimes fails at very low SNRs. Therefore, it is required to discard the noisy bands and retain others.

A. BSE using Teager Energy Operator

Formant tracking using the Teager energy operator (TEO) has been proposed by many researchers [25-28]. In [28], multiband approach along with TEO is employed in formant tracking. We are motivated by the efficacy of TEO in formant estimation and have adopted it in our approach. A discrete version of TEO on a time domain signal, $x(n)$is given by

$$E_{Teager}\big(x(n)\big) = x^2(n) - x(n-1)x(n+1), \forall n. \tag{9}$$

To enhance peaks in the spectrum, and thereby to track the formants, we employ TEO on $S_{msq}(k,l),\ k=0,\dots,-1,$ in (3). This results in $S_{Tmsq}(k,l)$. However, this enhancement comes at the cost of enhancing spurious peaks in $S_{msq}(k,l)$ due to the difference operation in TEO (refer (9)). To derive the benefits of TEO and minimize spurious peaks, we use convex combination of S_{msq} and S_{Tmsq} as follows.

$$E(k,l) = \alpha S_{msq}(k,l) + (1-\alpha) S_{Tmsq}(k,l), \quad k = 0,\dots,(N/2)-1. \tag{10}$$

Here, $0 \le \alpha \le 1$. To find the probability associated with lth frame, we use (4) and replace $S_{msq}(k,l)$ by $E(k,l)$ as

$$P_T(j,l) = \frac{E(k,l)}{\sum_{k=0}^{\frac{N}{2}-1} E(k,l)}, 0 \le j \le \frac{N}{2}-1. \tag{11}$$

The corresponding spectral entropy is computed as follows:

$$H_T(l) = \sum_{j=0}^{\frac{N}{2}-1} P_T(j,l) \log\left(\frac{1}{P_T(j,l)}\right), 0 \le j \le \frac{N}{2}-1. \tag{12}$$

We observe that the dominance of formants in sub-bands introduces sparseness (presence of structure) and the absence of formants or noise contamination introduces denseness (absence of structure). We attempt to detect formants by utilizing banded structure of speech signals [21]. From $E(k,l)$, we compute the sub-band energy, sub-band probability and associated entropy using (6), (7) and (8). Thus,

$$E_{SBE}^{T}(m,l) = \sum_{k=(m-1)*(N/2N_b)}^{\left(\frac{N}{2N_b}\right)-1+(m-1)*\left(\frac{N}{2N_b}\right)} E(k,l), 1 \le m \le N_b, \tag{13}$$

$$P_{SBE}^{T}(m,l) = \frac{E_{SBE}^{T}(m,l)}{\sum_{k=1}^{N_b} E_{SBE}^{T}(k,l)}, 1 \le m \le N_b \tag{14}$$

and

$$H_{SBE}^{T}(l) = \sum_{m=1}^{N_b} P_{SBE}^{T}(m,l) \log\left(1/P_{SBE}^{T}(m,l)\right). \tag{15}$$

III. Selection of Useful/Useless Spectral Bands

In [20], weighted BSE is supported with useful/useless band selection using NMinBE parameter under low SNRs. We differ from [20, 21] in the selection of useful/useless sub-bands. Here, we examine each frame by equally partitioning $P_T(j,l), 0 \le j \le \left(\frac{N}{2}\right)-1$, into N_b sub-bands as $P_T^b(m,l)$, where $b = 1,\dots,N_b,$ and $m = \left(\frac{(b-1)N}{2N_b}\right),\dots,\left(\frac{bN}{2N_b}\right)-1$. The presence/absence of structure in sub-bands is equivalent to the presence/absence of formants in the sub-bands. We argue that the presence of formant amounts to sparseness and that their absence, due to the presence of noise, yields denseness. This provides a basis to measure sparseness or denseness via the deviation of an approximate ramp line (ARL) [24] from the sorted $P_T^b(m,l)$ coefficients. The sorted $P_T^b(m,l)$ coefficients are henceforth denoted as $\tilde{P}_T^b(m,l)$. We connect the first coefficient of $\tilde{P}_T^b(m,l)$ to the last coefficient to generate ARL. Subsequently, we sample ARL with uniform intervals between samples. Here, ARL is computed for each sub-band in the frame of a given speech signal.

We observe that for the sub-band, the $\tilde{P}_T^b(m,l)$ coefficients are closer to ARL when non-speech/noise dominates over speech and that they are relatively removed from it otherwise. Closeness to ARL is computed by taking sum of square difference between samples of ARL and $\tilde{P}_T^b(m,l)$ coefficients as

$$CL^b(l) = \sum_{m=\frac{(b-1)N}{2N_b}}^{\frac{bN}{2N_b}} \left(ARL^b(m,l) - \tilde{P}_T^b(m,l)\right)^2. \tag{16}$$

We present some features of the proposed scheme.

- When speech formants dominate over noise in a sub-band, the deviation of $\tilde{P}_T^b(m,l)$ coefficients from ARL is higher than otherwise. This accounts for correct performance.
- When noise dominates over speech formants in all the sub-bands, speech sub-bands may be identified as non-speech, thus resulting in Missed Detection (MD). This occurs when speech is completely masked by the noise under very poor SNR conditions.
- Noise induced spectral peak in the sub-bands results in false alarm (FA) in the event of sub-bands having no speech signal. This occurs when a non-stationary narrow band noise in non-speech region presents itself a peak within sub-band. Then, any appreciable deviation generated by this noisy spectral peak away from ARL will result in a non-speech packet being detected as a speech packet.

The nature of ARL and $\tilde{P}_T^b(m,l)$ coefficients under additive babble noise during speech/non-speech frames for the SNRs, $0, 5$ and 15dB is presented through Fig. 1 – Fig. 3. Here, the sub-band b is fixed and $\tilde{P}_T^b(m,l)$ coefficients from (i) Speech plus babble noise frame; and (ii) Babble noise only frame are used to obtain ARL and plot of sorted coefficients of $\tilde{P}_T^b(m,l)$, respectively. Conclusions drawn from these plots are summarized as follows:

- When SNR is at 0 dB, the difference in the range of $\tilde{P}_T^b(m,l)$ for speech and non-speech frames is not so pronounced. However, large deviation of $\tilde{P}_T^b(m,l)$ from ARL can be noticed for the speech frame than for non-speech frame. This helps in deciding *speech/non-speech* sub-bands in a frame and to the computation of SBE when a sub-band is declared as *speech*. As SNR increases, $\tilde{P}_T^b(m,l)$ range increases/decreases for speech/non-speech frames as also the deviation from ARL.

A Deviation Threshold (DT) is selected empirically to achieve minimum MD and restrict FA to an allowable range. Each sub-band is checked for the presence or absence of formants based on the deviation achieved and compared with the DT. This refined adaptive band selection scheme will adapt quickly to change in signal and noise conditions. Thus,

the proposed approach has less parameters to setup arbitrarily than in [21]. Threshold for BSE is initialized assuming first 200ms as non-speech region. We differentiate speech regions from non-speech regions using the BSE feature computed from useful sub-bands. A simple hangover scheme is employed to minimize fast switching between speech and non-speech and vice versa.

IV. Experimental Setup and Result Analysis

We evaluated our VAD scheme by considering clean and noisy speech signals that are sampled and digitized. Sampling frequencies of 8 and 16 kHz are considered in our evaluation. Then, sampled and digitized speech signals are framed such that the successive frames do not overlap. Here the frame length is chosen to accommodate 320 speech samples. The number of sub-bands, N_b is fixed to 32. In computing $E(k,l)$ using (10), we set α to be 0.3. To simulate the noisy speech with SNRs from $0-40$ dB, speech signal is added with 13 different noises: Babble, F16, Tank, Factory, Car, Subway, Fan, Pink, HFchannel, Machine Gun, Destroyer Engine, Military Vehicle, Jet Cockpit and White.

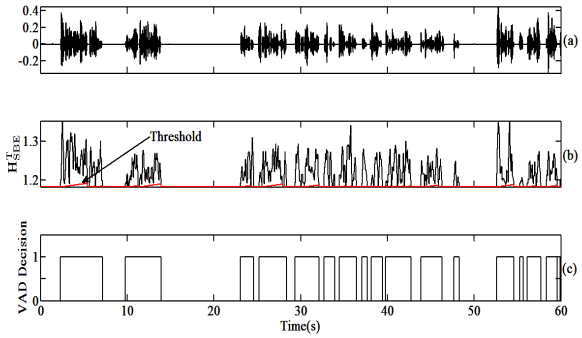

Fig. 4. Result of VAD under clean signal (a) Speech signal (b) Band Spectral Entropy and Threshold (c) VAD Decisions (Speech = 1;Non-speech = 0).

The SNR is varied in steps of 5dB. The results of VAD using proposed scheme under clean and noisy conditions are presented (refer Fig. 4). Here, Fig. 4(a) is speech sample under clean conditions. Figure 4(b) shows H_{SBE}^T and the threshold computed for the speech signal in Fig. 4(a). The corresponding

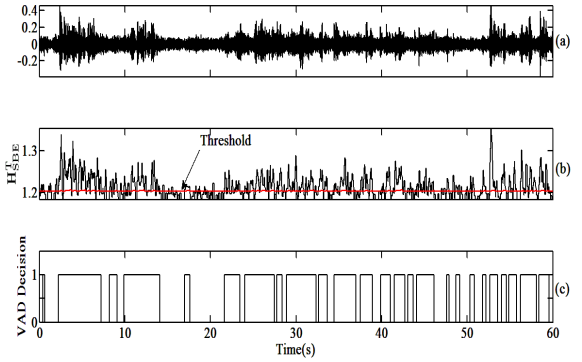

Fig. 5.Result of VAD under Babble noise with SNR = 0dB (a) Speech signal (b) Band Spectral Entropy and Threshold (c) VAD Decisions (Speech = 1; Non-speech = 0).

VAD decisions are in Fig. 4(c). In Fig. 5 – Fig. 7, we added Babble, Jet Cockpit and Subway noises to the speech in Fig. 6(a) to simulate respective noisy speech signals where the SNR is maintained at 0 dB. Parts (c) of Fig. 5 – Fig. 7 show VAD decisions with the proposed approach. We observe from Fig. 5(c) that in the presence of speech-like noise, such as Babble, FA errors are more pronounced than MD errors under low SNR conditions. However, the VAD decisions presented in Fig. 6(c) and Fig. 7(c) are for non-speech like noises such as Jet Cockpit and Subway noises where it can be observed

that FA and MD errors are minimal for the same SNR setup. This is attributed to the robustness of the proposed speech /non-speech band selection scheme under additive non-speech like noises as against Babble noise.

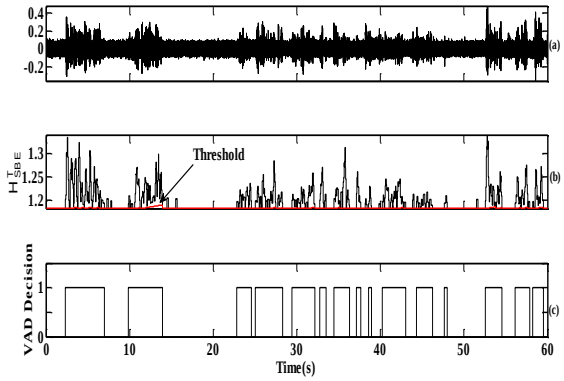

Fig. 6. Result of VAD under Jet Cockpit noise with SNR = 0dB (a) Speech signal (b) Band spectral entropy and threshold (c) VAD Decisions (Speech = 1; Non-speech = 0).

We evaluate the proposed scheme considering more than 46 speech samples from the *Switchboard Corpus*, a corpus of spontaneous conversations by multiple speakers over telephone [29]. In the performance evaluation that follows, we compare VAD results from our scheme with the manually segmented speech/non-speech information provided with the database. The results are presented for the SNRs from -10 to 40dB. Here, speech with additive noises is broadly classified under three categories: (i) Non-stationary Noisy Speech (NsNS) (ii) Non-stationary Heavy Noisy Speech (NsHNS); and (iii) Stationary noisy speech (SNS).

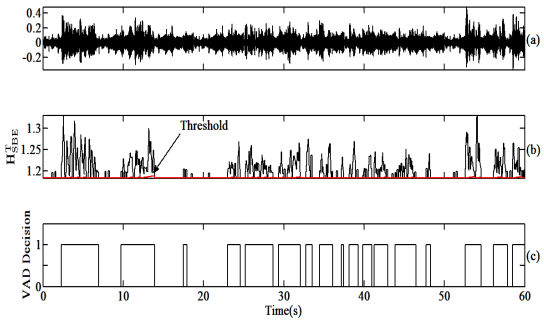

Fig. 7.Result of VAD under Subway noise with SNR = 0dB (a) Speech signal (b) Band spectral entropy and threshold (c) VAD Decisions (Speech = 1; Non-speech = 0).

Analysis of the performance of our scheme under these three noisy conditions averaged over the number of speech samples is presented as follows:

- P_D^S represents the ratio of the number of speech packets correctly recognised to the total number of speech packets. In Fig. 8(a) P_D^S is more than 0.8 for the SNRs greater than or equal to 0 dB. Under NsHNS conditions (see Fig. 8(b)), we achieve similar performance as in the Fig. 8(a) except for the case of Destroyer Engine noisy conditions. However for SNS conditions as presented in Fig. 8(c), similar performance of Fig. 8(a) is achieved except for the case of additive Car and Fan noisy conditions. This is due to the effect of these noises on the banded structure of speech; consequently, DT fails to detect the speech bursts.
- However, the corresponding Probability of False-alarm (P_{FA}) presented in Fig. 9(c) is lower than the achieved P_{FA} for NsNS and NsHNS conditions (see Fig. 9(a) and Fig. 9(c)). The trade-off is significant.
- Probability of Error, (P_E), combines both the errors P_{FA} and P_{MD}--upon multiplying with the prior probabilities,i.e. probability of speech packets and probability of non-speech packets for a given test speech sample. Thus, P_E represents the total error vis-à-vis speech - non-speech detection and the goal is to achieve lower P_E under different noisy conditions. Fig. 10 presents P_E for the three noisy conditions. Under SNS conditions,P_E is lower than 0.1 for SNRs greater than 0 dB, except the Car and Fan noises. This is due to higher P_{MD} even though P_{FA} is less than 0.2. For NsNS & NsHNS conditions, P_E is less than 0.2 for SNRs greater than 0 dB except Babble, Destroyer Engine and Military Vehicle noises, as shown in Fig. 10(a) and Fig. 10(b). We know that the Babble noise is speech like and as expected, P_{FA} is higher, and hence,higherP_E.

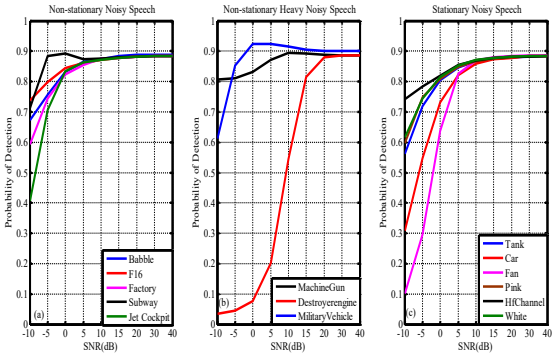

Fig. 8.Probability of speech detection (P_D^S) vs. SNRs in dB (a) Non-stationary noisy speech (b) Non-stationary heavy noisy speech (c) Stationary noisy speech.

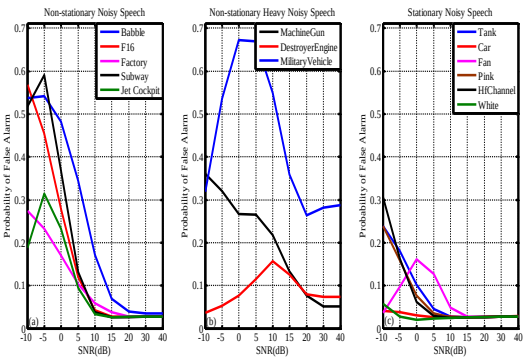

Fig. 9.Probability of False-alarm (P_{FA}) vs. SNRs in dB (a) Non-stationary noisy speech (b) Non-stationary heavy noisy speech (c) Stationary noisy speech.

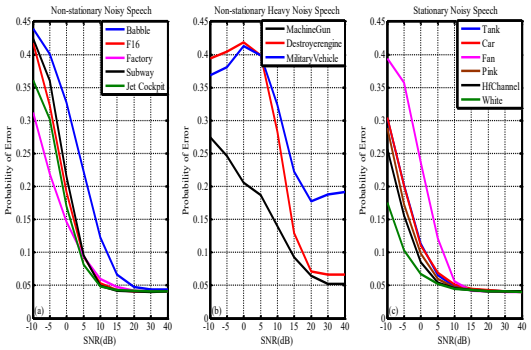

Fig. 10. Probability of Error (P_E) vs. SNRs in dB (a) Non-stationary noisy speech (b) Non-stationary heavy noisy speech (c) Stationary noisy speech.

We present VAD of our scheme in Fig. 11 for a real world speech sample having background noise and low fidelity. Result thus obtained is compared with the popular scheme proposed by Sohn et. al. [8]. For the P_D^S under both schemes are similar with minimal P_{MD} in favour of our scheme. It is important to note that this performance also comes with minimal P_{FA}. However, it is not true for VAD in [8]. Further, perceptual and statistical tests on VAD results corroborate good performance of our scheme over [8].

CONLUSION

In this paper, we proposed a novel Voice Activity Detection (VAD) using Teager Energy based Band Spectral Entropy (TE_BSE). We segmented the input speech signal into non-overlapping frames. For each frame,we compute the entropy via normalized frame signal energy obtained for each sub-band. However, this parameter was seen to be sensitive to noise. We recognized that the signature of speech signal is embedded in a formant structure. We employed the Teager Energy Operator (TEO) to enhance formant peaks of the sub-band spectrum. This comes at the cost of enhancing high frequency regions of the spectrum under low SNRs. To exploit the benefits of normalized signal energy and TEO, we employed them under convex combination. Using the approach in [24], to obtain deviation threshold to declare each sub-band as useful or useless. Useful sub-bands are used to compute spectral band entropy. We differentiated *speech regions* from *non-speech regions* using the SBE feature computed from useful sub-bands. Finally, we evaluated the proposed scheme under simulated noisy (NsNS, NsHNS and SNS) and real world conditions to assess the robustness in providing accurate VAD decisions. The enhanced performance of the proposed schemes under varying noise conditions as claimed through the simulation studies is actually borne out in the implementation on real world speech signals.

The schemes proposed and analyzed in this work may readily be gainfully employed for cleaning up several speech signals when contaminated by various types of noise from the environment. One of the very promising applications of the VAD studied here can be in speech compression for transmission in the context of audio conferencing over the VoIP such as in Skype.

***Abstract*—India is an agricultural country with the staple food being rice and wheat. The farmers serve as a backbone to our nation. But, the livelihoods of the agriculturists are at stake. They incur heavy losses due to crop failure and natural calamities. The emerging technology has provided many solutions to upgrade their lifestyle, but still there are challenges. Our main motive is to design a farmer friendly application- Agri Succor to sell their commodities directly to the customers at a reasonable market value without any mediator with the help of volunteers. For the efficient utilization of our mobile application by the farmers, we have incorporated features like information in regional language, crop-disease identification and sell their products directly. This application will emerge out as an essential productivity tool for the farmers if implemented in future**

Keywords—Farmers, Agri Succor, crop disease identification, mobile application

I. INTRODUCTION (*HEADING 1*)

We all are much aware of the fact that India is an agricultural country and tea, cotton and spices are the main exports. Rice and wheat are the most important crops in India because they are the staple food. However, our country, especially Tamil Nadu does not have an accessible agricultural information system for the farmers to gain knowledge on any of the agriculture related problems and solutions. So, there is not much scope in promoting agricultural activities to farmers who serve as a backbone to our nation. But for the past decade or so the lives of the farmers are at stake due to losses incurred during the land cultivation, harvest and natural calamities. The field of information technology has a huge impact on people nowadays and hence, there are many solutions commercially made available for the upliftment of the farmers. Yet, none of them proved to be such helpful in improving their livelihoods. There are also many mobile applications that are specially designed for farmers. Most of these apps mainly focus on only one particular feature like crop management, usage of pesticides, etc. Still, such applications lacked in some aspects as the farmers are unaware about the existence of such applications. Even if they are aware about those applications, the farmer does not know how to access it even though it is in his native language as he might be illiterate.

Our proposed project provides an ultimate solution to all the problems above mentioned. With the assistance of the Tamil Nadu Agritech portal[1], we will handle this situation by establishing a buy-sell platform exclusively for the farmers welfare with almost all kind of facilities.

The main objective of our application is to design a farmer friendly mobile application. So, we have named our app as 'Agri Succor'- Agriculture Helper. The proposed app is interlinked to the TNAU Agritech portal [1] for getting authentic information. Through this application, the farmers can sell their products produced on their farmlands directly to buyers at a reasonable market price. This application bridges the gap between the farmers and consumers through the most crucial role players- the volunteers. There is no intermediate involved in this process. The most astonishing feature of our application is that it is available in the regional language. We also provide another important characteristic – voice to text conversion. As a result, the farmer can enter the details either in text or in speech format. The farmers can get agriculture related information from other fellow farmers or volunteers connected through this application. The solutions for the farm related problems are extracted from the Tamil Nadu Agricultural Agritech application. An additional aspect is employability is created for the volunteers.

First of all, we discuss about the related works about the existing mobile applications on agriculture. Then, we explain about our proposed system which includes the architecture, methodology, as well as the implementation of the Agri Succor application. It is followed by the advantages of the application.

II. RELATED WORKS

A. CCMobile App: CC stands for Connected Crops[2]. User can read the environment metrics like temperature, humidity, etc. Sensor readings are available through SMS or email alerts, graphing and the climate factor historical data. It optimized crop management but it covered only the climate factor

B. Spray Guide: Spray Guide[3] calculates the amount of solute, the amount of solvent, the mixing time and the spraying areas ,etc. Users can share their experience together with data and results to others over their social accounts.by using the this app ,produce quality product but this is not supported crop diseases detection.

C. IFFCO Kisan: It is offered by Indian Farmers Fertiliser Cooperative Limited (IFFCO). IFFCO Kisan[4] seeks advice from the agricultural experts and scientists about crops, agriculture cycle, etc. It is used to provide good Water management but not in the regional language

D. Mandi Trades: Mandi Trades[5] is a buying or selling platform by marketing of farm products. It Uses location intelligence to get a map-based view of both buyer and seller info, along with the geographical proximity. This app eliminates middlemen but it is not ensure the quality check.

E. myRML Farmer: Farm and crop specific precision solutions built with the help of India's top most agriculturists. myRML[6] Works by using specific tools it was designed to analyze or provide information on different aspects of farming habits. It provides high level guidance but there is no provision for weather forecast.

F. AgriSync: AgriSync[7] enables farmers and advisors to connect and resolve support issues using a mobile video customer service platform. It allows the advisor's organization to see open cases, resolution status and farmer feedback in real-time.

G. RainbowAgri Market: RainbowAgri[8] helps in digitizing and branding agriculture. It is a simple mobile and web based tool to profile the farmers, organize and manage farming communities.

III. PROPOSED WORK

The proposed system is designed to provide a friendly interface especially to the farmers. The three main roles of our application are farmers (sellers), volunteers and buyers. The personal details of all the users are highly confidential and secure. In this mobile app, the farmers can provide details about their farmlands and groceries that are being cultivated in their land. The information can be entered either in text or voice format that too in his/her own language. Once the crop has been harvested, the farmer can upload the image of the plant. The plant is checked for the pesticides level and the disease is identified in the app. The recovery solution for the same is provided either in video, audio or text format which are obtained from the Tamil Nadu Agritech application. Once the plant is quality checked, it can be viewed by the buyers who can purchase them at an affordable market price and delivered with the help of the volunteers. Hence all the facilities are available under one roof.

The architecture of the proposed system is shown in Fig.1. The architecture depicted below shows the overall structure of our project. The database plays a major role in gathering and retrieval of data.

a. Collection of Data: The input can be given as text, voice or else as image when the crop is diagnosed for any disease with the help of TNAU application. The interested buyers and sellers can register in this app using the buy- sell platform. The interested volunteers can enroll themselves for uploading the agriculture related news, new government schemes for the betterment of the farmers.

b. Retrieval of Data: The farmers can get the authentic information on crop disorders, recommended pesticides, buyer & seller information, product details and recovery solutions in text, voice and video formats in the corresponding native language. The data which is gathered need to be organized as a report. Using crucial strategies, the data is converted to report before sending them to the farmers, volunteers and consumers. This result can be either in the form of text or voice as per the wish of the user. Data retrieval is the defined as the process of identifying and extracting data from a database, based on a query provided by the user or application. It is achieved through the usage of SQL Processing.

All the features in the architecture are realized through the implementation process

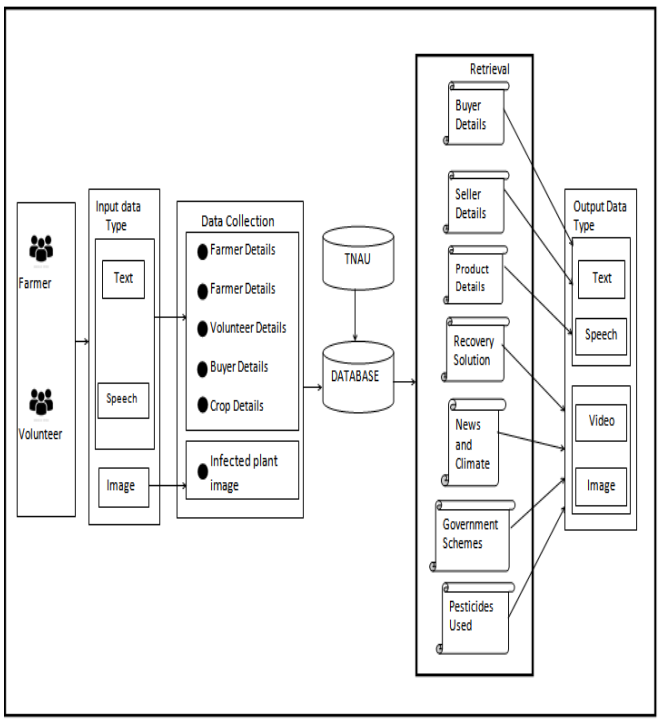

Fig.1. Architecture of the proposed system

A. IMPLEMENTATION

The implementation of the Agri Succor app is divided into three sections:

1. **Interface design:** It consists of three form designs for the use of farmers, volunteers and buyers.

Designing the interface of the application involves three main modules:

a. ***Farmers login***: The farmer login is shown in Fig.2.It consists of the entire details of the farmer including his location, type of crops cultivated in his farmland, price of his farm products, etc. given as text or voice with the option for regional language if required. This information is stored in the database. The farmer can even upload images of his commodities to check the level of pesticides used as well as check for any crop related disorders. He can have access to remedial measures for the crop diseases. In addition to this, he can keep a tab on the agriculture related news and schemes. He can even provide suggestions for the crop diseases to assist other fellow farmers. He can sell his produces to the consumers directly with no intermediary between them.

b. ***Volunteers login:*** The Volunteers login is shown in the Fig.3.The regular updates regarding agricultural schemes, climate and suggestions on crop cultivation are provided by the volunteers. Their main duty is to create awareness among the farmers regarding all kind of agricultural information. The much needed employability is given to these volunteers for their dedicated work. The delivery of farm products to the customers are done with the help of these volunteers

Fig.2. Farmers login

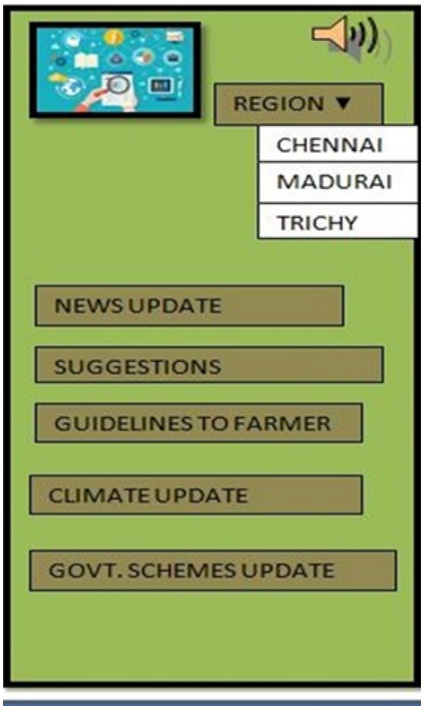

Fig. 3. Volunteers login

c. ***Buyers login***: The Buyers login is shown in Fig.4. The consumers who are willing to buy the farm products directly from the farmers need to enter their information. Once they select the items of a specific farmer, notifications are sent to the respective farmer. The ordered items are safely delivered to the customer.

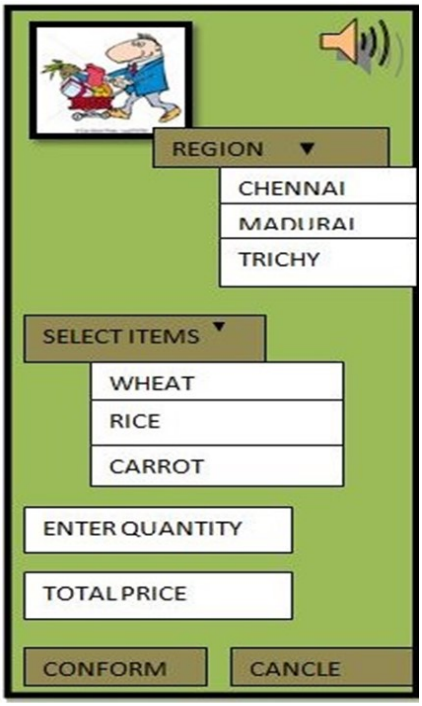

Fig. 4. Buyers login

2. **Voice to text conversion:** For extraction of voice signal, we use Mel-Frequency Cepstral Coefficient algorithm [9] and Minimum Distance Classifier. Support Vector Machine methods are used for speech classification. These techniques are highly efficient in converting the speech to text and vice versa.

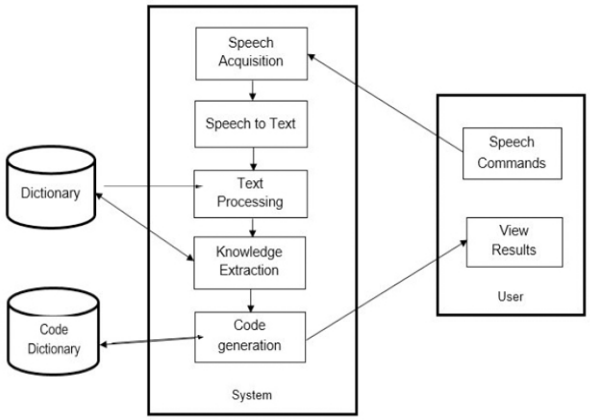

Fig.5.Voice to text conversion

3. **Disease identification:** Crop disease identification is done with the help of suitable image processing techniques. The procedure involves classification, feature extraction, multi-scale signal analysis, pattern recognition and projection

IV. BENEFITS

The Agri Succor will indeed be beneficial in almost all aspects. Some of the most important advantages of the proposed system are listed below:

a. Through the use of the application, both the standards of agriculture and farmers can be raised up.
b. The details can be given as voice or text input.
c. It also increases the job opportunities for the unemployed youth.
d. The commodities are freshly handpicked and delivered to the customers at a reasonable market value.
e. The application can be accessed in the regional language.
f. Instant updates on agricultural schemes, climate, crop diseases and their solutions are provided by the farmers and volunteers.
g. Quality check of the farm products before marketing them ensures that only disinfected items are sold.
h. The remedial measures for the crop diseases are provided in terms of text, voice and video. Considering the above pros of our application, we hope that this project will truly enhance the lifestyle of the farmers.

V. CONCLUSION

Through this mobile application, most of the problems faced by the farmers are provided immediate solutions and guidelines. If this initiative will be implemented in future, unemployability will be reduced to a considerable extent. Moreover, the betterment of the farmers could surely be realized. This application will emerge out as an essential productivity tool for the farmers.

***Abstract*— Wireless Sensor Network (WSN) is widely used in Internet of Things (IoT) based Precision Agriculture (PA) to increase the crop productivity and yield. Parameters like pH, temperature, soil moisture, air humidity are measured in PA for monitoring the field remotely. The nodes used for WSN's are low-cost tiny sensor node that monitors the environmental parameters and collects the data and transfers these data to sink. These nodes are energy constraint as they are placed remotely and are equipped with batteries which have limited power. Minimizing the energy usage and maximizing the lifetime of the network are the major challenge faced by the sensor nodes. In this paper, we address some of the existing energy efficient routing protocols for precision agriculture.**

Keywords — Energy efficiency; Routing Protocol; Sensor Networks; Precision Agriculture; IoT

I. INTRODUCTION

A Wireless sensor network (WSN) is a network of low-cost tiny sensor nodes deployed over a certain area. The nodes sense, process and transmit data using wireless medium. WSN with IoT is widely applied in diverse areas such as agriculture [8] [9], medical care [10] [11], disaster management, industrial control, national defence, etc. In precision agriculture WSN is used to increase the productivity and yield of the crop by continuously monitoring the field for environmental data.

In precision agriculture, parameters like air temperature, soil moisture, pH, air humidity, etc. are measured to continuously monitor the field without human interaction [8]. The sensor node senses the environmental condition and transfers these sensed data to the sink or the base station or cluster head. The sensor node comprises of units for sensing, processing, transmitting and supplying energy. The sensing unit senses the environmental parameters, the processing unit process the data. The radio unit is utilized for transmitting and receiving the data and power unit provides power to the node.

Sensor nodes interact with each other and the sink using the routing protocol. Classification of the routing protocol is based on the network structure.

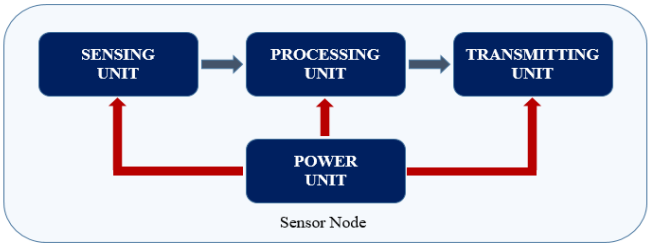

Fig. 1. Components in a sensor node

Transmission of data over a long distance consumes more energy compared to sensing and processing [1]. Minimizing energy usage is needed as power is a restricted entity for these sensor nodes as replacing or recharging the battery after deployment is not simple. Minimizing consumption of energy improves the life of the network. The key problems are energy consumption and network's lifespan. In this paper, multiple routing protocols are addressed using wireless sensor network to minimize power consumption for IoT-based Precision Agriculture (PA).

Agriculture is usually done in hectors of land, so monitoring the land manually increases the labour cost, the texture of soil varies in each region of the agricultural field. The precision agriculture concept has overcome the traditional agricultural methodology. In precision agriculture, monitoring of the agricultural land is supported using drones, tractors, sensors, etc. Maximum agricultural land coverage, sensor node energy, and routing protocol scalability are the few elements that influence the WSN implementation in precision agriculture. It is also necessary to update the farmer on environmental conditions on a continuous basis.

The paper is structured as follows: the associated study is given in Section II. Section III introduces the challenges faced during a routing protocol design. In Section IV, classification of routing protocols in WSN is presented. Section V addresses various energy-efficient routing protocols for precision agriculture. Section VI outlines discussion and open subjects for future studies. Finally, the paper is concluded in Section VII.

TABLE I. CHALLENGES RESOLVED BY EXISTING ROUTING PROTOCOL

Protocol	Limited power	Limited memory and storage	Deployment	Scalability
EETF	Transmit only useful information	Once data has been transmitted, it is discarded	Deterministic	No
SOUL	Using energy computer software components	The sensed data is stored for 4 hours and then discarded.	Deterministic	No
PTSR	Using heterogeneous nodes and region based deployment	Only stores information about the elected cluster head	Deterministic	Yes
IMR	Hierarchical routing based on tiers	Only store information regarding its level	Deterministic	No
EEZRP	Nodes energy level is considered	Store route data in the routing table and discards after completion of the round	Random	Yes
IEE AODV	Each nodes energy level is considered while selecting the path	Store route data in the routing table and discards after completion of the round	Random	Yes
EEHC	Using heterogeneous nodes and efficiently selecting the cluster head	Only stores information about the elected cluster head	Random	Yes

II. RELATED WORKS

In our related routing protocol research, WSN routing protocols may differ depending on application (based on protocol operation) and network architecture (based on network structure). Many researchers have carried out their research on routing protocols.

Design of routing protocols can be classified as proactive, reactive and hybrid protocols. All nodes maintain the knowledge about its next hop node in the proactive protocol. All nodes relay on its neighbouring nodes to send data. The data are only sent after mutual agreement between the two nodes. Reactive protocol, or demand routing protocol is based on query reply. The route is only established when a data needs to be sent. Hybrid protocol is a protocol based on distance vectors that contains the features and benefits of the link state protocol.

The operation of the routing protocol can be categorized based on multipath, query, negotiation, and Qos. Multipath-based protocol utilizes various routes rather than a single route to improve network performance. By keeping various routes between source and destination, fault tolerance can be improved, but it increases the energy usage and data traffic. The recipient nodes propagate a request for information from a node through the network in the query-based protocol. When a request is received, the node sends the data. Negotiation-based protocol utilizes negotiation to eliminate the transfer of redundant data. The decision on data transmission and reception is made based on the availability of the resource. Qos-based protocol balances energy consumption and information quality by providing data with relevant QoS metrics such as delay, power or bandwidth.

III. CHALLENGES FACED DURING A ROUTING PROTOCOL DESIGN

The wireless sensor nodes face many challenges as they are deployed remotely in the field. So when designing a sensor node these challenges needs to be considered as this can cause failure of the node [13]. The challenges faced by the wireless sensor nodes are discussed in this section. Table I discusses the challenges resolved by some of the routing protocol.

A. Limited power

The nodes are placed remotely in the field and they are subjected to failure due to depletion of the battery and due to the environmental changes. Minimizing the nodes' power usage as they are deployed remotely is the biggest constraint for wireless sensor nodes. For a prolonged period of time, these nodes need to operate remotely in a field and the battery cannot be replaced or recharged once deployed. Once the node's energy level reaches its minimum, the node becomes faulty and this effectively impacts system efficiency. A WSN routing protocol should minimize power usage and maximize the lifetime of the network.

B. Limited memory and storage

The sensor nodes have limited processing and memory capabilities. The sensor node has an internal memory of 2 KB to 256 KB and internal storage of 48KB to 2GB. An efficient algorithm needs to be designed in order maintain a trade-off between storage, bandwidth and computational complexity.

C. Deterministic or random deployment

Based on the application requirement, the sensor nodes can be implemented deterministically or randomly in WSN. Large-scale applications such as forest fire detection, etc. random deployment is used and sensor node determinist deployment is done for applications such as water leak detection, etc. deterministic deployment of sensor nodes is

done. The sensor nodes deployed in large area have no prior knowledge regarding their position and this makes the network more complicated as location-based protocol needs to be introduced.

D. Scalability

Sensor nodes in WSN can be deployed in large area randomly, and the designed routing protocols should be capable of scaling within the network. The communication connections between sensor nodes and sensor nodes and sink established for data transmission may not be direct. The routing protocol should, therefore, be able to identify the most effective communication path between the nodes.

IV. CLASSIFICATION OF ROUTING PROTOCOLS IN WSN

WSN routing protocols are categorized based on their network structure. It is classified as data-centred, hierarchical, and location-based [12].

A. Data-Centred protocols

Data-Centred also knows as the flat algorithms are based on query mechanisms. Here, the sink node sends a request for obtaining the data, this mechanism prevents continuous data transmissions and also saves the energy consumed. Directed Diffusion and SPIN (Sensor Protocols for Information via Negotiation), are some of the flat algorithm paradigms.

B. Hierarchical protocols

Hierarchical protocols use a cluster-based system in which nodes are split into tiny clusters and the role or function of nodes in a cluster varies. The energy of the nodes can be conserved by aggregating data with cluster heads (CHs). TEEN (Threshold-Sensitive Energy-Efficient Sensor Network Protocol) and LEACH (Low-Energy Adaptive Clustering Hierarchy) are some of the hierarchical algorithm paradigms.

C. Localization - Based protocols

Localization-based or geographic protocols are used when the position of the nodes is unknown. The position information is used to route the data to the required areas of interest. In this case, data flooding is restricted to save the network's energy. GAF, GEAR are some of the geographic algorithm paradigms.

V. ENERGY EFFICIENT ROUTING PROTOCOLS IN WSN FOR PRECISION AGRICULTURE

A routing protocol is used for transferring data between two sensor nodes or sensor node and sink. Routing protocols designed for WSN are desired to meet few parameters such as efficiency in energy consumption, scalability in a field, robustness and convergence. Reliable communication and choosing an energy-efficient routing, route and reducing the consumption of energy of the network as a whole is the main criteria that the designed routing protocol must satisfy. The major factor affecting the energy consumption is a continuous retransmission of data. The transmission of the data consumes

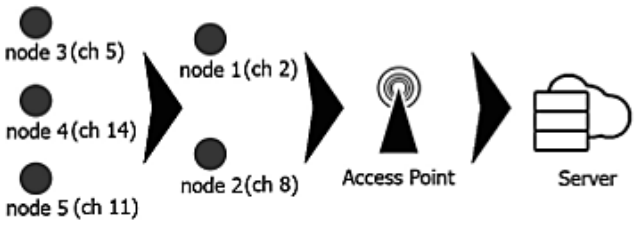

Fig. 2. Sensor topology of EETF [1]

Some of the energy efficient routing protocols which can be applied to precision agriculture are discussed in later section.

A. An Energy-Efficient Transmission Framework

Energy-Efficient Transmission Framework (EETF) is a data-driven algorithm based on greedy method which minimizes the energy consumption with lower complexity [1]. The algorithm focuses on energy efficient data transmission, which minimizes the energy consumption and guarantees data transmission rate. The algorithm is intended to discover the ideal route for transmission of the collected data with less transmission energy between the sensor nodes and the sink. The sensor node captures the data from the field and when useful data are available on sensor node, the sensor node finds the neighbouring node and transmits the data (Fig. 2).

The energy efficient transmission framework is divided into five modes: listen, collection of data, transmission of data, sleep and idle mode. The nodes are located sparsely in the field so that they can rely on the nearby node for the transmission of data to the sink. The sensors sense the data and stores in the buffer during the collecting data mode. After collecting the useful data, the sensor transmits the data in transmitting mode. It is said that the energy-efficient transmission algorithm effectively minimizes the energy consumption of the sensor nodes and also ensures secure transmission. The algorithm is compared with SPIN and ESPIN protocols.

B. SOUL

Sensor nodes' system for data acquisition of Long range (SOUL) is a theoretical framework in which designed sensor node hardware and software focuses on managing energy consumption and message grouping to enhance the lifetime of sensor nodes. SOUL is designed with five hardware components: microcontroller, Real Time Clock (RTC), power unit, acquisition unit and communication unit. The hardware has an energy control unit which switches ON/OFF the transducers.

The Sensor node software deals with minimizing the energy consumption while sensing, processing, transmission and reception of data. The algorithm monitors the sensor's energy level and a data system is used for packet transmission. The energy management model deals with computer software components (CSC). Energy monitoring CSC, which is used to estimate the nodes energy level after each round (a round has data acquisition, processing, transmission, and sleep mode). Sensor node management CSC deals with acquiring the data, grouping and transmission of data and also deals with confirming the transmission of data using acknowledgement

packet. Quality monitoring CSC ensures that the nodes are in line-of-sight with the coordinator. Transmission window is created in order to avoid collision during packet transmission.

C. Periodic Threshold Sensitive Routing Protocol

In PTSR [4] authors considered a square field which is further divided into nine sectors as shown in Fig. 3. Type-1, type-2 and type-3 heterogeneous sensor nodes are considered for the acquisition and transmission of environmental parameters. These sensors vary in their initial energy level. The energy level of Type 3 sensor is more than type 2, and type 2's energy level is more than type1. Type 1 sensor nodes are placed in the innermost region followed by type 3 then type2. Type 3 is placed in the middle region to eliminating coverage hole in the field. The base station selects the cluster heads for the middle and outermost area. The Type 1 sensor node transmits the information straight to the base station, while the Type 2 and Type 3 node relays on their cluster heads to transmit the information. Type 2 cluster head transmits the information to a cluster head of type 3 that reaches the base station further. The sensor node transmits data only when the set threshold is reached.

D. IMR

Integrated MAC and Routing protocol (IMR) [3] has a hierarchical architecture in which the network is divided into three tiers. The node who has the data broadcasts RTR packet, and the node whose level is less than senders tier responds with CTR packet. After receiving data, the node sends back ACK packet, and now receiver becomes the sender and the process continues. IMR is compared with protocols such as DSR, AODV and AOMDV and it is found that IMR is proven to perform better compared to DSR, AODV and AOMDV in terms of average network lifetime. The results are simulated using NS2.

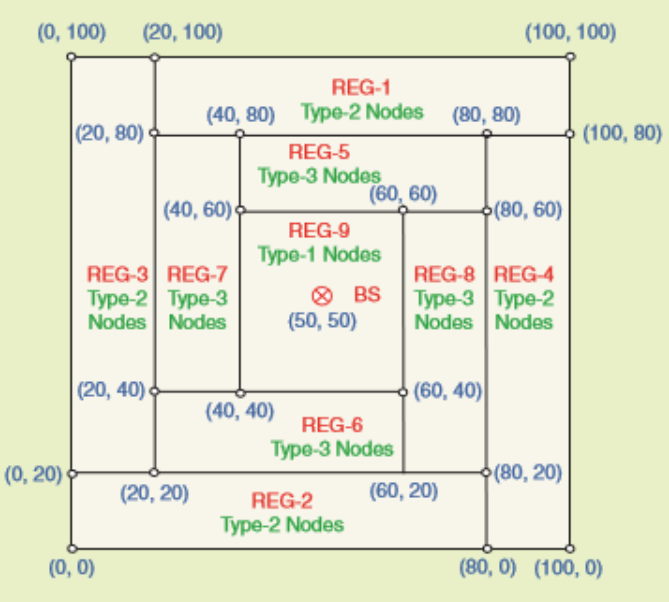

Fig. 3. PTSR network architecture [4]

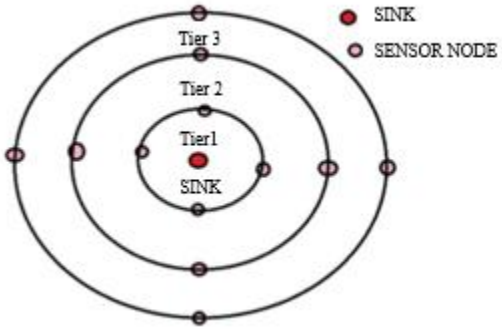

Fig. 4. IMR architecture [3]

E. EEZRP

In the Energy Efficient Zone-based Routing Protocol (EEZRP) [5] the nodes are localized using RELMA localization approach. The nodes are allocated areas depending on their number of base station hops. Based on the sensing range, the region is split into squares and is presumed to be twice the square's side length. Each cell is assumed to be either covered by one node or by the active node in the neighbouring square. This eliminates the sensing hole issue. The parameters used for selecting the active nodes are residual energy, distance, buffer size and sleep rounds. For determining the path distance and available energy of the nodes are considered. Subscribe or publish paradigm is used to achieve fault tolerance. The EEZRP protocol works better in terms of network life than the current LEACH and DSC protocols.

F. IEE AODV

IEE AODV [6] is an energy efficient AODV in which the energy efficiency is considered along with choosing the optimal path. Reactive protocols such as AODV, nodes select the best path to transfer the data. In traditional AODV energy was not considered as a major factor. IEE AODV integrate drain count into the traditional AODV, i.e. measuring the energy level of each node in the path and incrementing the drain count value by 1 if the energy has reached its threshold. The path which has the least value of drain count and with shortest distance is selected. If the drain count for more than one path is same, then min hop count is considered. If more than one path has same min hop count, then, the path where node's transmission power is least is considered. IEE AODV obtains a better network lifetime as compared to the traditional AODV. Link failure is managed by choosing an alternate path, the path related information's are stored in the destination during the route discovery period.

G. EEHC

The Energy Efficient heterogeneous clustered protocol [7] deals with heterogeneous nodes, which vary in their initial energy level. The benefits of using heterogeneous nodes over homogeneous nodes are that they help extend the network's lifetime, enhance the effectiveness of data transmission and

TABLE II. ENERGY EFFICIENCY ACHIEVED BY THE ROUTING PROTOCOL

Protocol	Energy efficiency achieved by the routing protocol
EETF	81.53% more efficient than SPIN and 36.84% more efficient than ESPIN
SOUL	56.9% more efficient in best case and 40% more efficient in worst case compared to normal sensor node.
PTSR	62% more efficient than EEHC protocol.
IMR	15% more energy efficient than AODV.
EEZRP	2.5% more efficient than LEACH protocol
IEE AODV	6.5% more efficient than AODV
EEHC	10% more efficient than LEACH with same power module.

decrease data transmission latency. The EEHC utilizes three kinds of heterogeneous nodes that differ in their initial level of energy. Nodes with β and α times energy compared to normal nodes are categorized as super-nodes and advanced nodes respectively, and few are normal nodes. These nodes are deployed uniformly over the field. EEHC protocol is an enhanced LEACH protocol. The selection of cluster head in EEHC protocols is defined so that each set of nodes has different probabilities and the node with maximum power level is selected as the head of the cluster. EEHC protocol performs better compared to the existing LEACH protocol with homogeneous node and LEACH with heterogeneous nodes. As the energy consumption of this protocol is less it can be used in the agricultural domain.

VI. CONCLUSION AND FUTURE RESEARCH

The sensor nodes sense the environmental condition in wireless sensor networks and transmit the information to the head of the cluster or the sink. Continuous data transmission consumes more energy than processing and sensing. The major issues and challenges faced by the routing protocols are energy efficiency, reliability, scalability, etc. these issues still exist and needed to be solved in the sensor networks. In this paper we have discussed some of the routing protocol which can be applied to IoT based precision agriculture. The protocol should minimize the use of energy and maximize the lifetime of the network. The energy efficiency achieved in each protocol is shown in Table II. None of the protocols discussed are best suited for IoT-based precision agriculture. PTSR protocol relatively performs better than others as it satisfies full coverage of the agricultural land and also continuously updates the user regarding the same. A Routing protocol needs to be designed which satisfies all the requirements in IoT based precision agricultural domain.

VII. ACKNOWLEDGEMENT

We would like to express our immense gratitude to our beloved Chancellor Sri. Mata Amritanandamayi Devi (AMMA) for providing the motivation and inspiration for doing this research work. The authors would like to thank everyone who was instrumental in doing this research work.

***Abstract*—The beamforming based underwater wireless optical communication (UWOC) systems with phase shift keying (PSK) modulation is elucidated in this work. UWOC is a powerful technology which is used for large speed underwater communications. Turbulence is the main mortifying factor of underwater, when light waves are propagating through underwater. For mitigating the turbulence spatial diversity technique is used. The belongings of absorption and scattering are measured here. For calculate the system BER, the sum of log-normal random variables are used. Transmit beamforming is a method to minimize the channel interference. By using transmit beamforming technique the spatial separation between symbols are increased. Study the enactment of UWOC PSK with beamforming and without beamforming. Also compared the enactment of each configuration with existing one. Here, we can analyse that the numerical result of UWOC PSK with beamforming shows a better result than the conventional method, i.e, the BER of UWOC PSK with beamforming is less than that of UWOC OOK.**

***Index Terms*—MIMO, Underwater wireless optical communication, Log-normal fading channel,Optimal combining, Transmit beamforming.**

I. INTRODUCTION

The data transmissions through water environment without guides are known as Underwater wireless communication (UWC) in [1]. The operation is based on wireless carriers, the carriers may be acoustic waves,radio-frequency (RF) waves, or optical waves. Underwater wireless optical communication (UWOC) has smart and upcoming alternative. In current years light can be used for wireless communication. The visible light is subjected to attenuation in seawater and also the information of aquatic optics is limited, because of these reasons the initial progress of UWOC is not much better than the earlier terrestrial free-space optical communications. The initial applications of UWOC are limited one and they are generally used for military purpose. Comparing to the previous works the optical transmission shows that it has larger bandwidth, high security, and the time latency is very less. The UWOC is a promising technology and it have been used in several applications, due to its properties like reliability, scalability and flexibility. Because of this advantage UWOC used as a prevailing technology as in imaging, high-throughput sensor networks, etc. Because of the degrading factors of channel i.e., absorption, scattering, and turbulence the UWOC channel, is currently used for short-range communications [2]. If we can overcome these three impairments, we may use the UWOC in more applications. In previous years there has been number of experiments are done for characterizing the impairing effects for different water types.

In this paper, UWOC PSK with beamforming is elucidated. For combining the optimal combiner (OC) technique is used. To obtain the absorption, scattering and their belongings into account, the Double Gamma function model is used. Which is based on channel impulse response are taken in to account. Fading coefficients are modeled by log-normal random variable. Then multiply the fading coefficient with the above impulse response. By using beamforming the spatial separation between the symbols are increased.

II. UWOC CHANNEL

UWOC is one promising technologies. Along with its advantages it has lots of limitations since its medium having main three impairing effect. They are absorption,scattering and turbulence.

A. Absorption and Scattering

The optical beam's propagation through the underwater makes collaborations of photons and seawater particles. The photons are loss their energy if it is passing through the water, because there are enormous particles are there at the medium. which is termed as absorption and which is an lasting process. In scattering the photon's are transmitted to different [3]. It produces loss to the system, only few lights are reached at the receiver. The distortion due to these two are modeled by using $u(\lambda)$ and $v(\lambda)$ where $u(\lambda)$ is the absorption coefficient and $v(\lambda)$ is the scattering coefficient, and λ denotes the wavelength of that propagating light. Moreover, $w(\lambda)$ is total effects and can be measured as $w(\lambda) = u(\lambda) + v(\lambda)$. The value of these coefficients can be alter with λ and types of water. [4] shows that at the wavelength interval $400nm < \lambda < 530nm$ the presence of absorption and scattering is less. So to understand the data communication UWOC systems mainly used the blue/green region in the spectrum. The channel impulse response has been simulated, by using the above two degrading effects [5]. $h_{0,ij}(t)$ is the impulse response between transmitter and receiver. Here it is fading free and the data is

transmitted between i^{th} transmitter at the transmitter side and j^{th} receiver. The link distance and angle of divergence are important parameter. When increases the channel introduces more loss. This behaviour is unobserved in clear water, the water turbidity and multiple scattering can also affect the system performance,they are ostensible. As increasing this two the performance become decreases. The above difficulties can be avoided by increasing the angle of pick up and the receiving cross section.

B. Turbulence

Absorption and scattering effects and how they are characterized are explained in the above section. [6] here the effect of turbulence is taken into account, multiply the fading-free impulse response with multiplicative fading coefficient i.e., multiply $h_{0,ij}(t)$ with α_{ij}^2 with log-normal distribution. [7] which include the weak oceanic turbulence cases. Turbulence is another fading reason which can be introduced by log normal distribution of UWOC. Due to the intelligibility of background noise of underwater UWOC system typically employ large receiving aperture, thus reduces the turbulence effects [8]. Although the links is modeled by a RV, and due to the highly-scattering nature of UWOC channels and for simplicity, the perfect arrangement are there in this system. [9], for modeling the turbulence-prompted dwindling let $\alpha = \exp(X)$ which is the fading amplitude of the channel with log-normal probability density function (PDF)

$$f_\alpha(\alpha) = \frac{1}{\alpha\sqrt{2\pi\sigma_X^2}}\exp\left(-\frac{(\ln(\alpha) - \mu_X)^2}{2\sigma_X^2}\right). \quad (1)$$

Where the fading log-amplitude X which is having a Gaussian distribution with mean(μ_X) and variance (σ_X^2) this can normalize by fading amplitude in such a way that E[α^2]=1 which implies μ_X=σ_X^2.

III. IMPULSE RESPONSE MODELING

The modeling of impulse response are important aspects. The impulse response modeling is based on Monte Carlo (MC) [10]. The below described the Double gamma function model how they related to MC.

A. Double Gamma Function model of impulse response

The viable form of the UWOC link's impulse response is presented here. The optical thickness can be written as τ = zr where z is the extinction coefficient and r is the link range. In Beer's law the path loss versus τ is considered. [3], the absorbance of light depend upon many parameters, and the multiple scattering of light induces path loss. In this work, there main aim is the modeling of UWOC channel. In [11] includes the initial usage. Which is based on clouds. The seawater and clouds have different channel properties, it is inspired by the dispersing nature . For modeling the UWOC links this modeling can be apply with relatively large value of τ where multiple scattering light may dictated [12]. The expression of the double Gamma functions is,

$$h(t) = A_1\Delta t e^{-A_2\Delta t} + A_3\Delta t e^{-A_4\Delta t}, (t \geq t_0) \quad (2)$$

where A_1, A_2, A_3 and A_4 and $\triangle t = t - t_0$. The four parameters are to be solved, t is called as the time scale and $t_0 = L/v$ is called as the propagation time. The parameter set (A_1, A_2, A_3, A_4) in (2) can be calculated from the simulation results of Monte Carlo (MC) method using nonlinear least square criterion as,

$$(A_1, A_2, A_3, A_4) = \arg\min\left(\int [h(t) - h_{mc}(t)]^2 dt\right) \quad (3)$$

In (3) the $h(t)$ and $h_{mc}(t)$ are the simulation results of impulse response. The $h(t)$ is the double Gamma functions model and $h_{mc}(t)$ is the MC model. To return the argument of the minimum the $argmin(\cdot)$ is used. By using curve fitting approach the (3) can be solved.This can be done by software such as MAT LAB. The multiple scattering effect is studied by using SPF. The energy distribution is also described by this scattering phase function (SPF). The SPF can be in the form $\beta(\theta, \lambda)$

$$1 = 2\pi\int_0^\pi \beta(\theta, \lambda)\sin\theta d\theta \quad (4)$$

The scattering phase function is similar to that of Rayleigh scattering. The system mainly focused blue/green region of visible light.

IV. UWOC PSK SYSTEM MODEL

An UWOC PSK with beamforming system is considered here. In the earlier case UWOC with OOK modulation is taken in account. Both equal gain combining and optimal combining are taken in [2]. The possibilities of underwater wireless communication is carried out their along with its limitations. Here beamforming properties and PSK modulation are taken along with UWOC, thus it outperform the conventional system performance. Here the beamforming based UWOC with PSK modulation is taken instead of UWOC OOK. The input signal is transmitted through the channel and combined using optimal combining at the receiver side. As it mentioned in Fig. 1, signal are propagated from transmitter to receiver through the channel,channel containing the impairing effects. $h_{0,ij}(t)$ is for absorption and scattering of i^{th} transmitter to j^{th} receiver and the turbulence is modeled as a multiplicative fading coefficient α_{ij}^2, which is a log-normal distribution. The distribution is based on weak oceanic turbulence. The aggregated impulse response both at the transmitter and receiver is $h_{i,j}(t) = \alpha_{ij}^2 h_{0,ij}(t)$. The transmitted signal s(t)

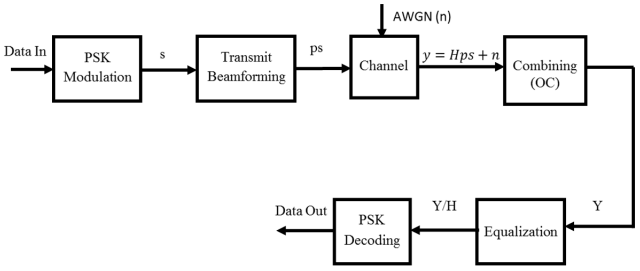

Fig. 1. UWOC with PSK and Transmit Beamforming

$$S(t) = \sum_{k=-\infty}^{\infty} b_k P(t - kT_b), \quad (5)$$

In this the $b_k \epsilon(-1, 1)$, and $\Gamma(t) = h_0(t) * P(t)$, the * is the operator named as convolution. In the earlier case the $b_k \epsilon(0, 1)$. $y(t)$ is the received optical signal. This can be expressed as,

$$y(t) = S(t) * \alpha^2 h_0(t) = \sum_{k=-\infty}^{\infty} b_k \alpha^2 \Gamma(t - kT_b) \ , \quad (6)$$

Equal power are allocated to all the transmitters. The transmitters and receivers are located in an random manner. The general impulse response expression is $h_{i,j}(t) = \alpha_{ij}^2 h_{0,ij}(t)$. The Fig.1 shows the simple UWOC PSK with beamforming block diagram where the data to be transmitted is passing to PSK modulation. The modulated data x is multiplied with beamformer matrix to avoid interference. In the earlier case containing an OOK modulation after it passes through the channel. Here by using the beamformer matrix interference can be minimized. The output of transmit beamformer ps is transmitted through the channel. They subjected to the underwater impairing effects and noise. The output of the channel is $y = Hps + n$. The optimal combining technique is used in the receiver side. Then the out is Y/H. By using PSK demodulation the data is demodulated. UWOC channel with all the three impairing effects are shown in Fig.2. Where $h_{0,ij}(t)$ is the combined effect of absorption and scattering. Then multiply this with turbulence. Convolution in time domain is similar to multiplication in frequency domain, FFT (Fast Fourier Transform) is used for that purpose. In the proposed work there we consider different configurations like SISO, SIMO, MISO and MIMO.

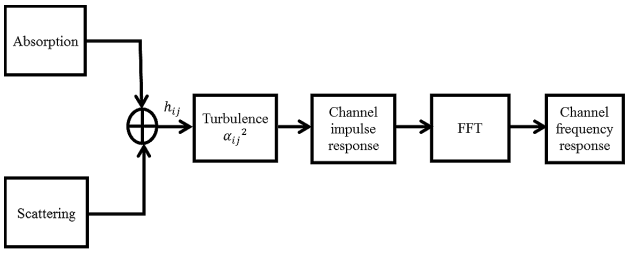

Fig. 2. UWOC Channel

V. Simulation Results

The simulation results for the BER enactment of UWOC PSK with Beamforming system in various scenarios are presented here. For channel fading statics consider log-normal distribution, equal power are distributed between the transmitters and the fading statistics are similar for all links. Aperture area at the receiver side are similar for all the receivers. The impulse response is based on MC method. The result is compared with an threshold to measure the received signal for to ensuring the transmitted data. Before reaching signal on the receiver side the input are added by the noise. At last, the received data is compared with the transmitted data for determining the BER value. This is based on a particular transmitted power. The different MIMO configurations are carried out here. Their performance comparison also considered, of them MISO gives a better performance than that of others.The performance of UWOC OOK is compared with UWOC PSK with beamforming and without beamforming. Firstly taken SISO transmission which is considered in a

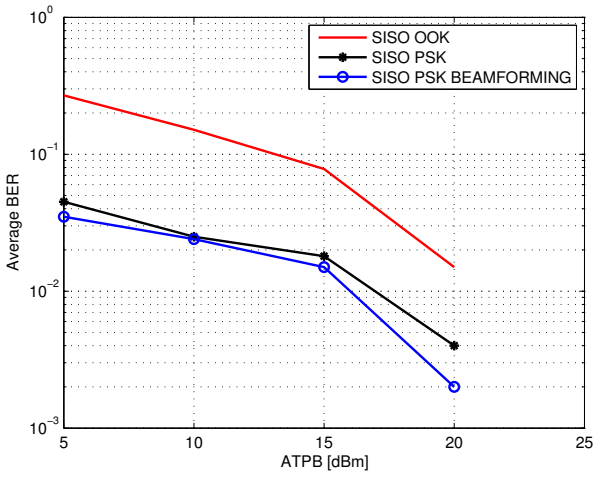

Fig. 3. SISO Configuration

coastal water link with 25m distance ie, UWOC PSK with beamforming and without beamforming is compared in Fig.3. Also compared this results with UWOC OOK modulation. The UWOC PSK with beamforming outperforms than other two. The beamforming technology is introduced to minimize the interference, thus to improve the enactment of the system. In the graph x-axis indicates the ATPB (Average Transmitted Power per Bit) and y-axis indicates the average BER (Bit Error Rate).

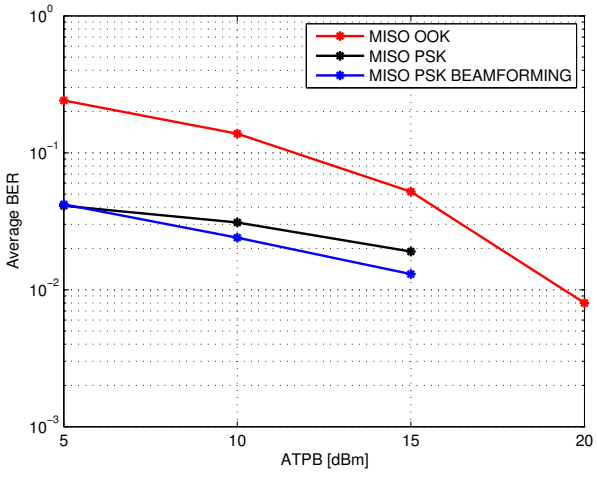

Fig. 4. MISO Configuration

Fig. 4 depicts the BER of coastal water with 25m distance.The performance of MISO with OOK is much better

than that of other configuration. The proposed work shows that the PSK UWOC with beamforming gives better result than that of PSK UWOC and OOK UWOC. The spatial separation between the symbols are increased by beamforming. The

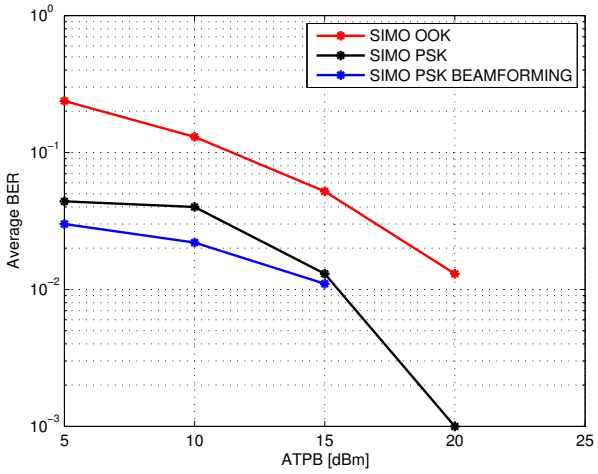

Fig. 5. SIMO Configuration

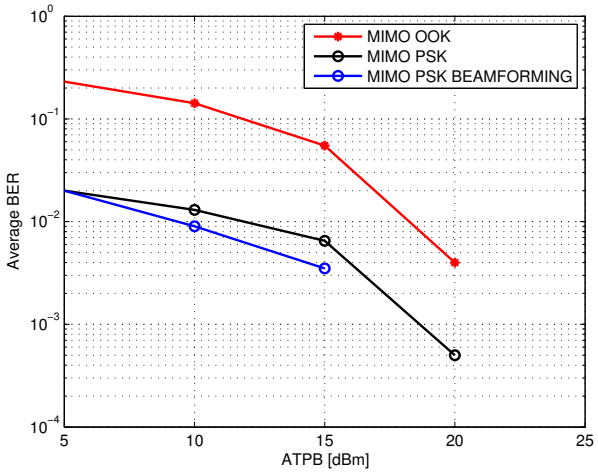

Fig. 6. MIMO Configuration

Fig. 5 and Fig. 6 shows different configuration's performances i.e, SIMO and MIMO. In all these cases UWOC PSK with beamforming shows less BER than that of other two cases. For transmit beamforming the channel phase is estimated and angle is estimated. This angle effect is eliminated by beamforming technique. The above all cases the comparison of conventional method and proposed work are considered, that shows the importance of proposed work. The Fig. 7 shows the comparison of UWOC OOK and Beamforming based UWOC PSK in its absorption and scattering effects. The UWOC with PSK and Beamforming gives a better BER performance than that of conventional UWOC OOK.The Fig. 8 shows the turbulence comparison of proposed and conventional method. Their

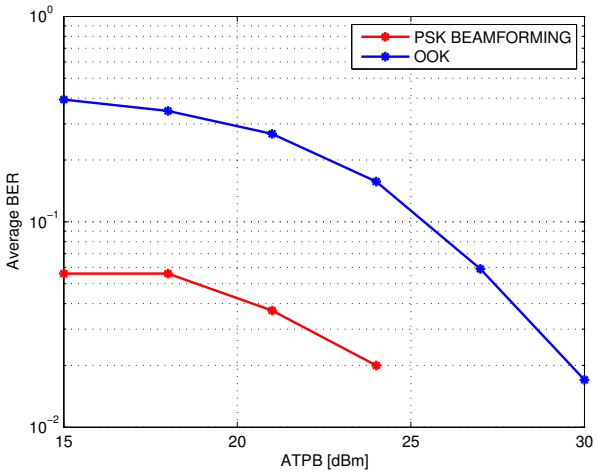

Fig. 7. Absorption and Scattering Effects

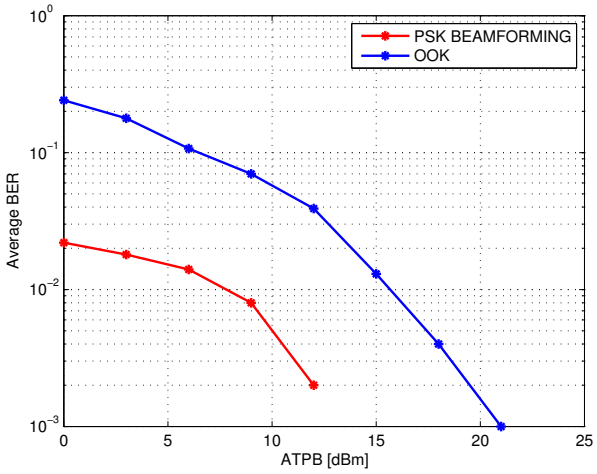

Fig. 8. Turbulence Effect

also proposed work shows less BER than that of conventional one.

VI. CONCLUSION

The beamforming based UWOC PSK are studied in this work. Channel modeling takes all the impairments into account. The impulse response are obtained by using MC simulations. The numerical results indicates that the performance beamforming with PSK gives better result than that of conventional method. By beamforming the channel separation between the symbols are increased. Transmit beamforming is used here to improve the performance. The turbulence have important roll in UWOC systems, the performance of UWOC increases with decreasing the turbulence value. The individual turbulence effects and absorption and scattering effects are also shown there, in order to specify the importance of proposed work. The proposed work shows that beamforming based UWOC PSK outperform that of UWOC OOK.

***Abstract*— Shortage of workforce is one of the most critical issues facing agriculture today. Automation of farm machinery can mitigate this to an extent, however, in a middle-income country like India, the cost of automation has to be minimized in order to encourage wider adoption. An attempt has been made in this study to design a machine learning based system to to improve the distance measurement accuracy of a low-cost GPS receiver deployed for vehicle localization and tracking in an autonomous harvester designed for harvesting onion. Nine different machine learning based models are evaluated for their effectiveness in improving the distance measurement accuracies for step sizes ranging from 2-10 meters. Results indicate that machine learning based system proposed is capable of improving the measurement accuracy of GPS system under test.**

Keywords— Global Positioning System (GPS), Accuracy, Machine Learning.

I. INTRODUCTION

Agriculture has traditionally been one of the major sources of employment and a major contributor to the GDP of most of the developing countries over the past half century. However, this share has been declining over the years as more and more people give up agriculture for other occupations. Considering India as example, the percentage of males employed in agriculture has decreased from 57.72 in 1991 to 37.2% in 2018[1] . Similarly, female employment in agriculture as a part of the total workforce has dropped from 76% in 1991 to 55.38% in 2018[1]. The only solution under such circumstances is to introduce automation in agriculture. This has been attempted widely in developed countries[2], however, in developing countries like India, the cost of employing such machinery is prohibitively expensive. Development of low-cost alternatives for automation of agricultural machinery is essential under such circumstances. An attempt in this regard has been made in [3]. A prototype autonomous onion harvester has been developed [3] with autonomous navigation within the field to be harvester, as one of its major features. Global Positioning System (GPS) has been employed to identify the location of the harvester and for the measurement of distance the vehicle has covered. However, high precision GPS module were observed to be too costly and hence, an alternative approach of choosing a low-cost, lower accuracy GPS and then augmenting its distance measurement accuracy using machine learning was taken. The autonomous onion harvester prototype and the GPS module under test (uBlox Neo 6M) are presented in Fig. 1.

Section 2 presents the literature in the area, the methodology is presented in section 3, results are presented in section 4 and the conclusion in section 5.

II. LITERATURE SURVEY

There have been several studies on augmenting the accuracy of GPS systems. In[4], a navigation system has been designed using GPS for an autonomous car in which GPS provides the data for the current location of the car and the target location details are taken from a map. A compass is used for getting the heading of the car, which helps in getting the required correction in heading for its navigation. In[5], design of a school bus tracking system, in which GPS position data is used for its tracking and Kalman filter has been used for efficiently predicting the arrival time of bus by taking its speed, distance to travel(from GPS coordinates) as input for the system is presented. In[6], the precision of two different GPS(SPI-Pro, GPS-5 Hz and MinimaxX, GPS-10 Hz module for distance calculation in high-speed mode has been compared. It is observed that GPS-10 Hz has better accuracy to calculate the distance in high-speed mode. In[7], accuracy of distance measurement for three different GPS modules has been computed. Overall error in the distance accuracy varies from 3.3 to 18.53% depending upon the device selection. A tracking system has been designed in[8], using dead reckoning and a GPS module for tracking animals which also calculates distance travelled and improve the life of tracking collar which are used to collect data. [9]presents the design of a system to improve the accuracy of vehicle attitude estimation for low-cost INS/GPS integration by using the GPS measured course angle. In[10], a system design for positioning of tractors by improving the precision of low-cost GPS is presented. A model for localization of the vehicle in an urban city by using SVM to overcome the limitations of extended Kalman filter is presented in[11].

It is observed from the surveyed literature that machine learning can be an effective means to address the error in measurement produced by GPS systems. In the subsequent

section, the methodology employed to realize such a system is presented.

Fig. 1 Autonomous onion harvester prototype (GPS module under test inset)

III. METHODOLOGY

A. Data Collection and analysis

The first step in the process is to collect the data. In the present study, the GPS receiver employed is uBlox NEO-6M[12]. This receiver has 50 channels. It has time to first fix during cold start of 27 seconds and during hot start is 1 second. It has a maximum navigation update rate of 5Hz and its horizontal position accuracy is 2.5 meter. For data collection, the GPS setup was installed at a fixed location. uBlox GPS was interfaced with an Arduino Mega microcontroller board and the received latitude and longitude data was logged.

To collect data from the GPS receiver, the data collection setup was moved in the pattern shown in Fig 2. In the figure, each arrowhead represents one completed movement step. Hence, it can be seen that there are total of fourteen steps (or locations) in the movement path. Approximately 100 latitude-longitude values were collected for the GPS receiver at each location before the movement to next location was made. In Fig 2, data collection started from the rightmost point at the eastern side and ended at the leftmost point at the western side. Data has been collected following the same pattern for movement step sizes of 2-10 meters, i.e. total of nine sets of readings, each comprising of fourteen locations, were taken.

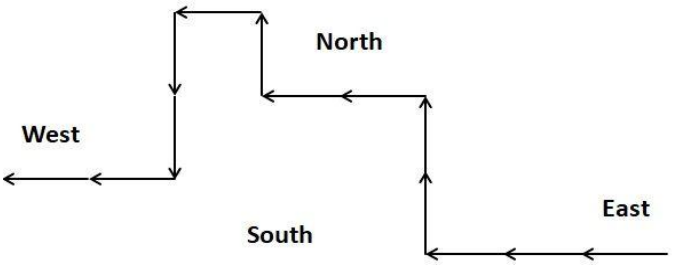

Fig. 2 Movement pattern for Data collection

The latitude-longitude value detected by the GPS at a fixed location is found to be continuously fluctuating. An example is presented in Fig. 3, where the location readings produced by the GPS module when stationary after the 4th step with step size of 2 meters, is shown. A total of 100 location readings were logged, and it is observed that the position readings were non-stationary in nature.

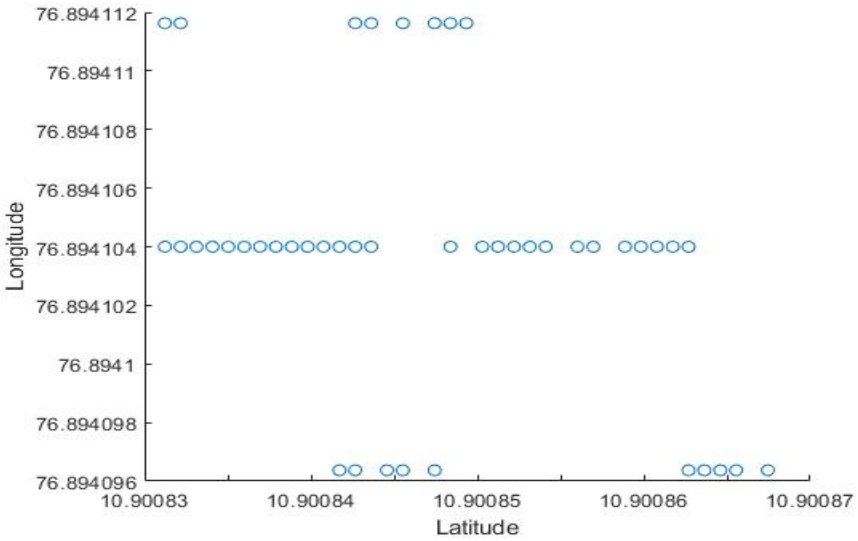

Fig. 3 Scatter plot of position detection readings from GPS for a fixed location

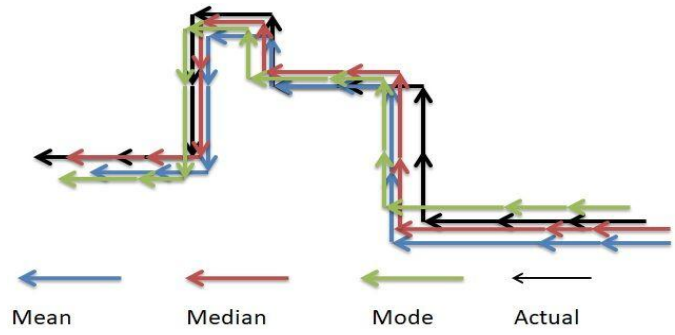
Consider the *i*-th reading logged by the GPS module to be denoted by:

$X_{ij} = \{\varphi_{ij}, \lambda_{ij}\}$ where φ_{ij} and λ_{ij} are the latitude and longitude respectively for the *j*-th location reading at the *i*-th location. To analyze the variation in the collected data, mean, median, mode, standard deviation, maximum value and minimum value was calculated for all the sets of data. Then the distance between all the consecutive fixed locations was calculated by considering the mean, median, mode, mean + standard deviation, mean - standard deviation, minimum value, maximum value and the average of maximum & minimum value using the Haversine formula in (1).

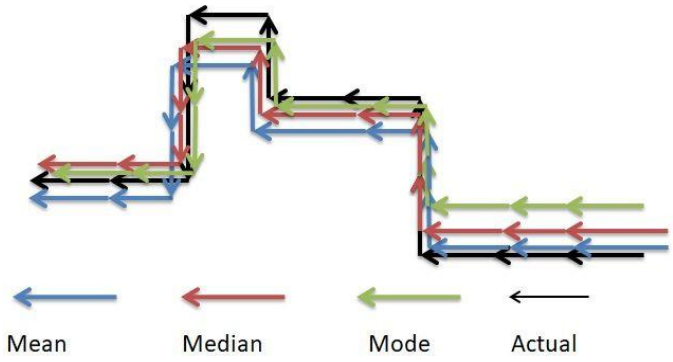
$$d = 2r\mathrm{Sin}^{-1}\left(\sqrt{\mathrm{Sin}^2\left(\frac{\Phi_2-\Phi_1}{2}\right)+\mathrm{Cos}(\Phi_1)\,\mathrm{Cos}(\Phi_2)\,\mathrm{Sin}^2\left(\frac{\lambda_2-\lambda_1}{2}\right)}\right) \quad (1)$$

d = distance between two points
r = radius of earth
Φ_1, Φ_2 =latitude of the two points
λ_1, λ_2 =longitude of the two points

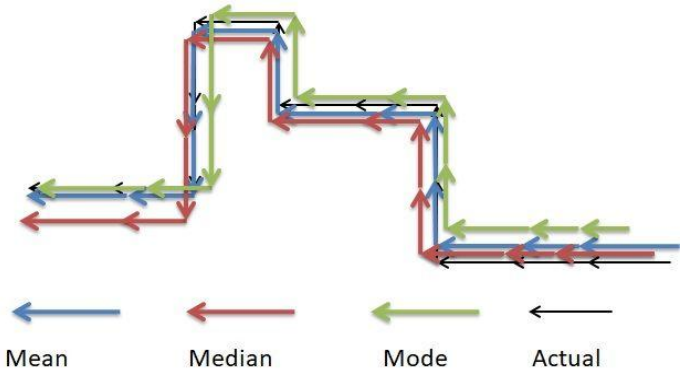
Then the error in the calculated distance has been calculated by comparing it with the actual distance taken between consecutive fixed locations. The results are graphically represented in Fig. 4.



(a)



(b)



(c)

Fig. 4. Actual vs calculated distance using mean, median and mode of the location coordinates for step sizes of (a) eight meters, (b) nine meters and (c) ten meters

The algorithm to find the distance between fixed locations and error in the calculated distance is given below:

```
Input: Location //(Lat,Lon) array for
all locations

Begin

1. min_step ← 2  // minimum step size is
2 meters

2. max_step ← 10  // maximum step size
is 10 meters

3. step_count ← 14 // total 14 steps for
each step size

4. FOR j = min_step : max_step

    FOR k = 1 : step_count

summ_stats{j,k,1}←mean(Location{j,k})

summ_stats{j,k,2}←median(Location{j,k})

summ_stats{j,k,3}←mode(Location{j,k})

summ_stats{j,k,4}←std.deviation(Location
{j,k})

summ_stats{j,k,5}←summ_stats{j,k,4}+
summ_stats{j,k,1}

summ_stats{j,k,6}← summ_stats{j,k,4}-
summ_stats{j,k,1}

      summ_stats{j,k,7}←max(Location
{j,k})
```

```
      summ_stats{j,k,8}←min(Location
{j,k})]
          IF k > 1
            Distance{j,k-1}←
Fn_distance(summ_stats{j,k},summ_stats{j
,k-1})
          // Fn_distance gives distance
between all the consecutive locations
using Haversine formula.
          Error{j,k-1} ← j-Distance{j,k-
1} //Subtracts all the distances from
the step size.
          END IF
     END FOR
END FOR
END Algorithm
```

Function to calculate distance between two GPS coordinates:

Input: latlon1 = Latitude and longitude of 1st location, latlon2 = Latitude and longitude of 2nd location.

Begin

```
1. radius ← 6371;
2. lat1 ← latlon1(1)*pi/180;
3. lat2 ← latlon2(1)*pi/180;
4. lon1 ← latlon1(2)*pi/180;
5. lon2 ← latlon2(2)*pi/180;
6. deltaLat ← lat2-lat1;
7. deltaLon ← lon2-lon1;
8. a=sin((deltaLat)/2)^2 +
cos(lat1)*cos(lat2) *
sin(deltaLon/2)^2;
9. c=2*atan2(sqrt(a),sqrt(1-a));
10. d_km=radius*c;
```

end Function

B. Machine learning models considered

To minimize the error in measured distances, machine learning models were employed. Nine models based on three different machine learning techniques were evaluated for their effectiveness, namely, multiple linear regression, regression tree and Support Vector Regression (SVR).

1) Multiple linear regression: It is a type of Linear Regression which works with more than one number of predictor variables. The objective of this algorithm is to design the linear relationship among the independent(all features of the system) variables and dependend(output of the system) variable. Multiple linear regression based models are the simplest of models used for regression analysis. The general expression for the output of a multiple regression model is presented in (2).

$$\hat{y} = a_0 + a_1 x_1 + a_2 x_2 + \cdots + a_n x_n \quad (2)$$

Here, $x_1, x_2, \cdots, x_n$ are the features (or explanatory variables) and $\hat{y}$ is the estimated output. Linear regression based models are relatively simple and easy to train, and highly suitable for modeling linear relationships. Hence, multiple linear regression is considered as the benchmark model in this study

2) Regression tree: Regression trees behave in a fashion similar to the classification trees in which the algorithm attempts to successively partition the dataset into subsets that results in the minimum sum squared error(SSE)[13]. For a regression tree T, the SSE is defined as per (3)[13]

$$S = \sum_{c \in leaves(T)} \sum_{i \in c} (y_i - m_c)^2 \quad (3)$$

Where: $m_c = \frac{1}{n_c} \sum_{i \in c} y_i$ is the prediction for leaf *c*

The attribute or feature, splitting using which results in the maximum reduction in *S* is taken as the splitting attribute. The splitting process continues till the termination conditions of $S < \delta$ (usually the threshold δ is a small number, here, its 10^{-6}) or $n_c < minsamples$ ($minsamples$ is the minimum number of samples in the node) is reached.

3) Support Vector Regression (SVR): SVR has been widely used for solutions to nonlinear regression problems. SVR is used to fix the error within a limit whereas simple regression technique is used to reudce the rate of error. A detailed treatment of SVR has been provided in[14]. Three kernel functions are considered in this study, linear, quadratic and Gaussian. The functions are presented in (4),(5) and (6).

$$k(x, y) = x^T y + c \quad (4)$$

$$k(x, y) = (x^T y + c)^2 \quad (5)$$

$$k(x, y) = \exp\left(-\frac{\|x-y\|^2}{2\sigma^2}\right) \quad (6)$$

Here, *x* and *y* are the feature vectors and σ is the standard deviation.

C. Tracking System of Harvester

An android application has been developed for remotely tracking of the Onion Harvester which takes location information from an open source cloud platform namely, ThingSpeak. For the tracking system uBlox NEO-6M GPS module, NodeMCU board which is having inbuilt Wi-fi module and ThingSpeak open source cloud platform has been used. Block Diagram of the Tracking System of Harvester is presented in Fig. 5.

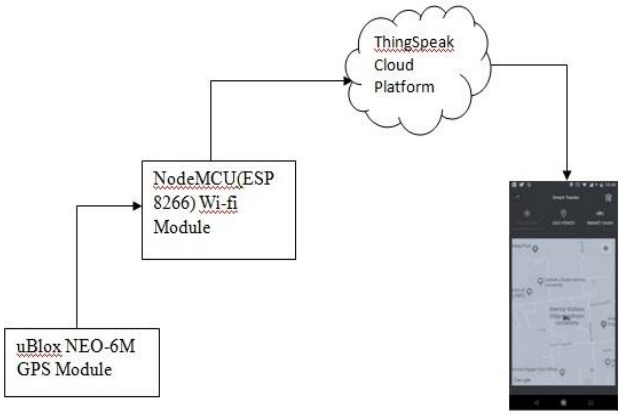


Fig. 5 Block Diagram of the tracking System

GPS module has been interfaced with the NodeMCU board. After receiving the location information(latitude and longitude value) GPS module transmit it to the NodeMCU board using serial communication and then NodeMCU uploads the GPS coordinates to the ThingSpeak cloud platform by using the mobile data connecting to the hotspot facility of the mobile. After getting uploaded to the cloud platform android application will fetch the GPS coordinates from the cloud. Then it will show the GPS coordinates on the android application as an overlay of google map to display the navigation of the vehicle.

IV. Results and Discussion

A ten-folds cross validation approach was taken to evaluate model effectiveness. The performance of the proposed system was evaluated on three parameters, namely the Root Mean Squared Error (RMSE), Mean Squared Error(MSE) and Mean Absolute Error (MAE). The results are presented in Table 1. The parameters were selected using trial and error.

TABLE 1 DISTANCE MEASUREMENT ACCURACY

ML algorithm	Parameters	RMSE (m)	MSE (m)	MAE (m)
Linear Regression		1.57	2.47	1.26
Regression Tree	min. leaves: 4	1.74	3.02	1.34
	min leaves: 12	1.62	2.63	1.29
	min leaves: 36	1.88	3.55	1.59
SVR	Linear	1.62	2.68	1.27
	Quadratic	1.66	2.77	1.23
	Gaussian ($\sigma = 0.66$)	1.68	2.83	1.33
	Gaussian ($\sigma = 2.65$)	**1.42**	**2.03**	**1.10**
	Gaussian ($\sigma = 10.58$)	1.46	2.12	1.19

It is seen from Table 1 that SVR based systems are better capable of reducing the error in measurements. The performance of the best performing system (SVR with $\sigma = 2.65$**)** is presented in Fig. 6.

In Fig. 6, the x-axis represents the step size and the y-axis represents the residuals. It can be seen form the figure that for smaller step sizes, the performance of the proposed system is poorer when compared to larger step sizes. However, it is also clearly visible from the boxplots that the mean of the estimations are accurate to a large extent and accuracy of measurements becomes better and the deviations in the estimation also reduce for larger step sizes.

V. CONCLUSION

A novel, machine learning based technique to improve the accuracy of a commercial low-cost GPS module has been presented in this work. Nine models based on three different

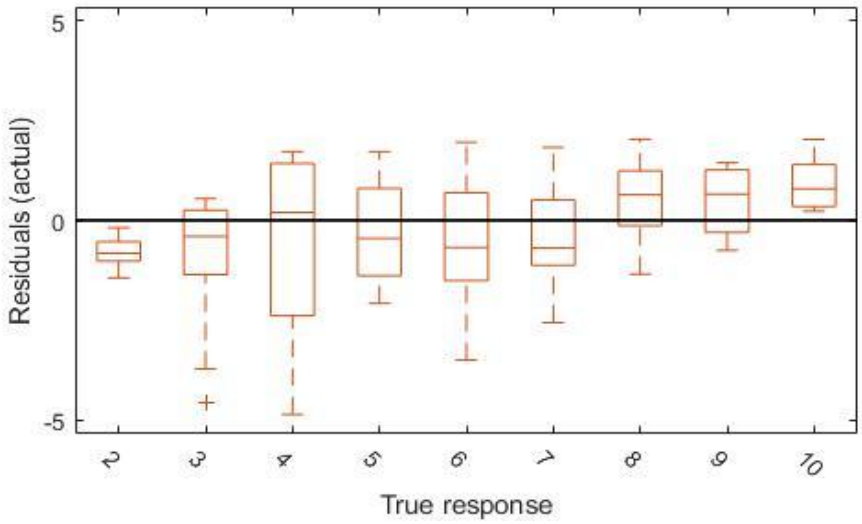

Fig. 6 Residual boxplot for SVR ($\sigma = 2.65$)

machine learning techniques were evaluated for their ability for compensating the variations in the readings produced by the GPS module. It can be seen from the results that the proposed system is well capable of reducing the distance measurement errors. It is also observed that SVM based system is ideally suited for the purpose, resulting in RMSE measurement error of 1.42 meters. Effectiveness of the proposed system can be further improved by taking more number of readings at each location and by employing deep learning based models, both of which could be considered as future extensions of this work

***Abstract*— In day to day life use of vehicle is continuously increasing among all the countries, and as a most important part of vehicle, usage of fuel is increasing and not it is becoming critical problem. So, for accurate measurement of fuel level becomes extremely important. The design and development of Capacitive sensor is some contribution towards the accurate fuel level measurement in automotive sector. Wide variety of existing fuel level sensors are available such as mechanical float type, load cell, ultrasonic trans-receiver based and Capacitive plate sensors. Nowadays all the vehicle has digital display (Dashboard) units, so fuel bunks occurring chances are more compare to other because of the digit roundoff. When we refill the fuel, we don't know the exact amount of fuel added is same as that to the amount paid by us. So here the fuel level measurement sensor plays vital role for customers, at the same time it improves performance and safety aspects related to the vehicle. Currently the capacitive fuel level measurement sensors are used in Aircrafts, where fuel level is considered as most critical parameter. That implies the capacitive level sensor construction is costly for small vehicle. So, the main objective of this paper to working towards the development of low-cost capacitive fuel measurement sensor for 2W/3W vehicles.**

Keywords— 2W/3W, ASIC, Automotive, Fuel level sensor, Capacitive sensor.

I. INTRODUCTION

First digital fuel level indicator was introduced in India by Varun digital indicator, there intentions were better understanding to the driver about amount of fuel available in the tank. They were providing this sensor with up to three-digit resolution. Initially this development was done for commercial and passenger vehicle application, because of long distance travelling with heavy duty load carrying. This measurement system was developed with sensor and digital signal processing to display it on dashboard [11]. At the same time measured amount of fuel level is used in mileage and performance estimation of the vehicle.

Most of Fuel bunk incident happens in India during fuel filling at the petrol pump, because of the accuracy of the fuel level measuring sensor and unawareness of the customer. Practically if you see when we fill the petrol, we don't know how much petrol he filled in the tank independent of amount of fuel said by us. So, for authentication the fuel level sensor becomes extremely important. This day the fuel cost is continuously increasing, so OEM started working on improving efficiency and hence everyone comes up with different efficiency improving techniques. And EFI is one of them which continuously monitor the fuel injected by fuel pump in the engine and corresponding power generated by the engine [12].

In old fuel level measuring technique such as float type resistive potentiometric, pressure sensor based. There intention of the sensor was only to display amount of fuel present in the tank.

Usual methodology of measuring fuel level uses the different principle of operation, where its contribution in using, completely depends on the accuracy and the cost of the sensor. Because of the cost volume of utilization in actual vehicle makes impact [2].

II. RELATED WORK

At the point of time, the fuel level in the tank varies. It results, the change in dielectric constant of the sensor measuring plate so which results in effective change in capacitance of the sensor. At the point when we got capacitance value, a straightforward numerical preparing can without much of a stretch illuminate the height of the fuel. If we consider coaxial link type structure [7], so the internal electrode radius is r and R gives the range of the outside terminal. In construction of the sensor, its height is 'L' and fuel level is 'h'. In the condition when there is no fuel in the tank, Ɛ0 speaks to the dielectric consistent in the vacuum 8.8542x10-12 F/m; then the capacitance C_0 *is* expressed as:

$$C_0 = \frac{2\pi\varepsilon_0}{\ln(R/r)}L \qquad (1)$$

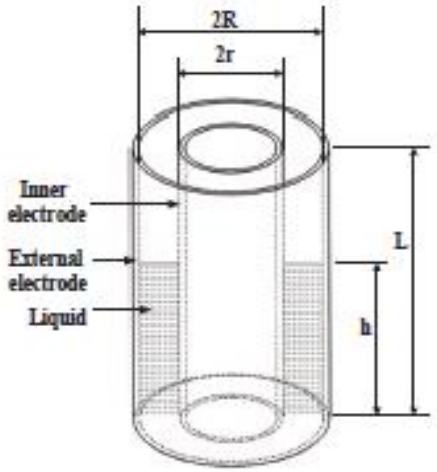

Figure. 1. Fuel level sensor structrure

In the above figure capacitive sensor structure is shown, where fuel level is expressed as 'h', to estimate the fuel level in terms of capacitance. It underneath the level influenced by the relative dielectric Steady, of the air (1.0058). alludes to the dielectric steady of the fuel level 'm'. In the sensor output estimation procedure comprises main ingredient which is separated by two different medium such as air and fuel [1]. The capacitance estimated by both the medium are different, below expression.

$$C_o = \frac{2\pi\varepsilon_1\varepsilon_0(L-h)}{\ln(R/r)} + \frac{2\pi\varepsilon_r\varepsilon_0 h}{\ln(R/r)} \qquad (2)$$

The deliberate capacitance measures by the senor is 'C_0', it is directly proportional to the level indicated by fluid, which changes in real time while continuously level varies. however, the general permittivity of the fuel and the air are unique. In view of the direct connection of capacitance, which is result of change in capacitance and fuel level 'h'.

which in turns to the actual level of the fuel.

Initially when the tank contains no fuel, the medium between both the plates is air. So, it defines the capacitance between the both plates represented as C_0.

$$C_0 = \frac{2\pi\varepsilon_1\varepsilon_0 L}{\left[\ln\left(\frac{R}{r}\right)\right]} \qquad (3)$$

Keeping equation (3) in equation (2),

$$C = C_0 + C_0(\varepsilon_r - \varepsilon_1)\frac{h}{\varepsilon_1 L} \qquad (4)$$

Equation (4), shows that capacitance is comparing to the dielectric steady, and fluid dimension changing in the fuel tank will incite substance relative change between the both the plates. For alteration of the sensor. Notwithstanding the steady and, and moreover fixed characteristics. The capacitance will augment as a component of the liquid stature h. By evaluating the capacitance of the two plates, the fuel level in the tank can be resolved. Equation (4) shows C reaches a maximum at C_{max} when h equals to L.

$$C_{max} = C_o + C_o\left(\frac{\varepsilon_r}{\varepsilon_1} - 1\right) \qquad (5)$$

Other than the construction and operating behavior of the sensor, it is also mandatory to consider the other operating conditions. Because this sensor is being installed inside or on the tank. So, sensor will directly come in the contact with all type of fuel, even the owner is not sure about the adulteration of the fuel and many other things [1].

Even the environmental conditions like Sunlight, rain will contribute to the change in performance of the sensor, which might be in turns the degradation of the sensor life and in the outcome accuracy of sensor will be changed. So, all OEM's will do the analysis on the sensor before installing on actual vehicle, even as organization who will develop as actual sensor will also do deep analysis for performance to insure all the major aspects before going to the customers [1-4].

III. PROPOSED SYSTEM

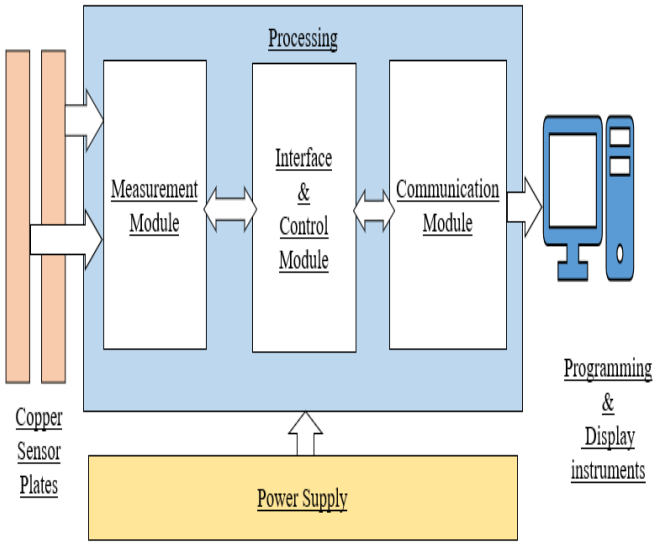

Figure. 2. Fuel level sensor block diagram

Block diagram has all the blocks, which are used for measurement of capacitance. Measurement system contains four major section, i.e. Sensor plates, Processing Power supply and display section. Sensor's measured raw data is sent to the measurement module, this data has been converted from capacitance to level corresponding to the tank using capacitance to digital converter IC. Some additional calculations and for calibration and level matching are done under the same block. Communication blocks providing the data to displaying. Power supply module is universal to all the modules and providing constant supply of 5V to all modules. Programming and display module used for data calculation and calibration using the programming. To display result Serial communication window is used [8].

The two sensor plates are placed o the tank, from outsied so it will not have direct contact with fluid,these plates measures the change in capacitance, and prosesed

capacitance by obove system is corrosponds to the level in the tank [6].

IV. Results analysis

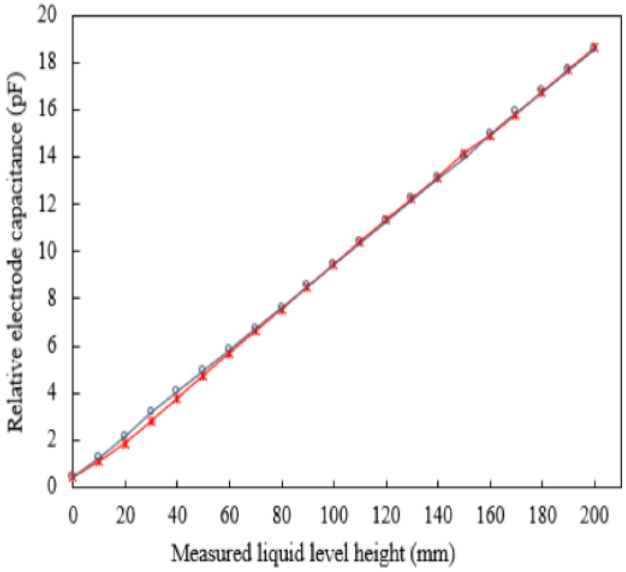

Figure 3. Relationship between fluid level and output capacitance.

When the measured fuel level is stable, the relationship between the sensor output capacitance and measured fuel level is linear. The input and output curves of the sensor were measured during the experiment and then fitted and linearized.

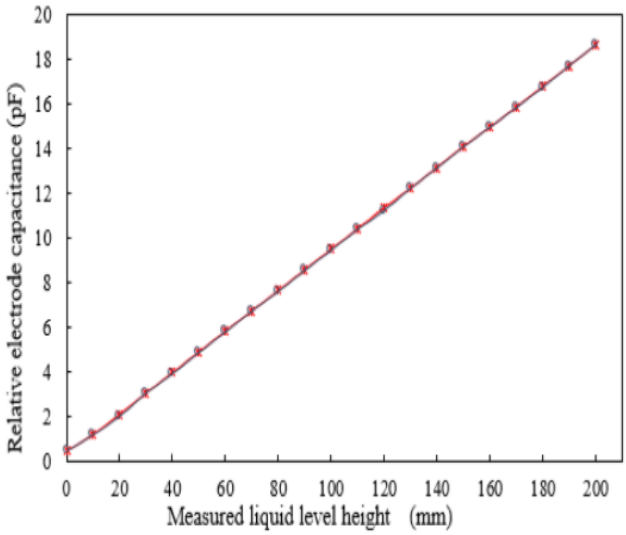

Figure11 4. Relationship between fluid level and average output capacitance

The relationship between the fluid level and output capacitance is shown in above figure, the experimental results show that the capacitances measured from reference electrode and measuring electrode with respect to each other. Level electrode measures actual level of amount of liquid present in the tank, capacitance proportional to the fluid height and reference electrode measures for fluid type and temperature variations.

V. Conclusion

This paper expounds efficiently the general plan of implanted fuel sensor and shows the practicality from the structure to the naturally sheltered circuit structure. The proposed thought which comprises of capacitive sensor fuel estimation framework that obtains the deliberate fluid level and this information is given to the vehicle parameter indication display to indicate actual level. The processor handled the information by computing height in the liters that data is conveyed to the controller section to give other functionality like SMS, connectivity such as uploading data on clouds. Also, during meantime controller conveys the information to the owner using connectivity. In this way, this stays away from the fuel burglary events while fuel filling and in parking also. At the same time system can also useful in leakage detection.

VI. Future scope

As the fuel monitoring system is real time application, and level is monitored continuously we can implement fuel theft detection, whenever there is large decrease in fuel level in tank the system is activated giving the owner the precise indication of fuel content. So, this can be extended to tracking system where the vehicles fuel data can be directed to a database were each vehicle can be tracked easily by the owner. There is a scope for developing low cost sensors and implementing data acquisition system for storing the data of fuel fillings per month or per week as it is monitored continuously.

***Abstract* – IoT (Internet of Things) enables the devices to be smartly connected with each other to share the data and collect it for future analysis. With the expansion of time, the applications of IoT are increasing in every sector of society like homes, devices, vehicles, health sector, and many more. The wireless communication in IoT makes use of different wireless communication protocol, one such protocol is NFC. The card emulation technique in NFC is widely used in payment sector and research is in progress to enhance its application area. Smart cards in IoT are used to store the keys and user identification information to provide an easy way to authenticate users and provide them the service. In this paper, we will represent a communication protocol between an IoT device and the user smart phone using card emulation technique that can be used in many sectors of IoT. The protocol will eliminate the use of smart cards in IoT by providing users with virtual cards that can be stored and accessed with smart phone. The protocol provides an authorization facility of user, and controls the access of illegitimate user.**

Index Terms – Internet of Things, NFC, card emulation, authorization, smart phone.

I. INTRODUCTION

With the increased use of internet in the past few years, several new ways technologies discovered that uses the internet and provide ease to users in their daily life. One such technology is Internet of Things (IoT), which is used for transferring the information among the devices connected and humans. IoT is a network of intelligent objects which have the capability to share the collected data with the other connected device, store it for future analysis and allow them to take any action on behalf of the owner in the environment [1], [2]. With the large number of devices present in IoT environment, it allows the companies to keep the record of the items produced, and secure them from theft, produce the items according to its consumption in the market, and can incorporate the changes in the items accordingly. The consumers can control the IoT devices with their smart phone through application, which provides ease to them in their daily life.

For communication in IoT protocols used are- short range network and low power wide area network [3]. The short range communication network will include the Bluetooth, Near Field Communication (NFC), RFID, ZigBee, and Z-Wave. The low power wide area network will include SigFox, which is a wireless communication technology for objects with low energy consumption like sensors and machine to machine applications. In addition, the other category is cellular technology that makes use of GSM, 3G/4G for communication and are used by applications which require large distance for operation.

NFC which is a short range communication protocol has gained a lot of attention in the past few years, after its effective use in smart phones for transferring the data and making payments. NFC is used in IoT as it provides easy data sharing and network access and provides multi-level data security. NFC works in three modes – reader/writer mode, card emulation mode and peer to peer mode [4]. The IoT applications are mainly based on the peer to peer mode of NFC.

The applications of IoT are increasing with the time to provide ease to users in the daily life by controlling the objects with smart phones. These applications are based on peer to peer mode of NFC. Some of the examples are described further. A smart library system which was based on IoT, make use of NFC for tracking the books [5]. A smart parking system which is based on the protocols used in IoT and make use of NFC for peer to peer mode for information transfer and e-wallet for payment [6]. Other examples include authorization facility for public health devices [7], an IoT based vehicle location detection system which makes use of NFC tags and readers for gathering the information [8]. Other than NFC, IoT systems are also proposed which works on Raspberry pie and are used for home automation and surveillance system [9].

For the ease in user authentication, security or authentication tokens are used which is a physical device. To verify a user identity- keys, passwords and biometric data are stored on the pocket sized smartcards which are a type of authentication token [10]. To authenticate the user smart cards are also used in IoT with multi–server environment [11] and distributed cloud computing service [12]. The protocol allows a user to login to the authentication server using a smart card which verifies the user and the authentication server by generating the same session key. Other than this, IoT is also combined with the smart card- HSM, to protect the cryptographic keys and the enrolling certificates on an IoT device [13]. Smart card-HSM is a lightweight hardware security module, in a smart cards, USB or MicroSD form, to secure the ECC and RSA keys in a key store which is remotely managed. The security to the keys is provided by

the secure element which offer tamper resistant runtime environment to store cryptographic keys and the codes.

For accessing the different applications, the user needs to carry different smart cards with them. The cards can be used for different purpose like authentication of user, providing access to certain applications, storing the keys and code, identification purpose, etc. To eliminate the carrying of number of cards and to provide ease in usage to the customer, card emulation technique was proposed. Host card emulation technique enables a NFC enabled smart phone to emulate a contactless smart card [14]. It is much popular in payment application which allows a user to pay through their smart phone by emulating them as a payment card.

In this paper we will present a protocol for authenticating the user to the IoT applications and devices by using the card emulation technique. The user instead of using the smart cards for accessing the IoT device and application will use the smart phone which will emulate as the smart card and provide access. This will eliminate physical carrying of cards and provide an ease to the user to access the applications using their smart phones by making use of NFC.

Further, the paper is organized as follows. Section II describes the background details. Section III describes the related work. In addition, Section IV describes the proposed system and section V shows the results of simulation which is then followed by section VI as conclusion and then acknowledgment and references.

II. BACKGROUND

The Secure Element (SE) is a union of hardware component, software, medium, and the use of protocols which are used in a smart phone to provide secure storage [15]. SE enables a user to securely execute the application and store the keys, data, and codes related to the application in a secure area. SE is also used for authentication process in the application which needs secure system for execution. SE is available in three forms – removable SE, inbuilt SE and cloud based SE [15], [16].

A. Removable SE

Removable secure elements are the one that can be removed from the mobile device when necessary. MicroSD cards [17] and Universal integrated circuit cards (UICCs) [18] are the types of removable SE. UICC are the new generation SIM cards which are present in the mobiles, laptops that are used for the high speed network. It is a type of smart card which has its microprocessor, softwares and storage units. It is advancement to the SIM cards. UICC can support multiple applications over it and it communicates through Internet Protocol (IP). It is also capable of supporting multiple PIN codes to prevent misuse of personal data.

MicroSD card secure element is advancement to the technology where the mobile device turns into the NFC enabled device by inserting a micro SD card. It offers low risk, and issuer centric storage type for a fast implementation and high control.

B. Inbuilt SE

Inbuilt SE is secure element which is built in the mobile system and works in the same manner as the removable SE. SE is used to store secret keys and provide a secure storage to the mobile device. It is non detachable and supports multiple application to execute. It needs high level of security as compare to removable SE and works with all smart card standards. The working of the chip and the NFC controller is based on the pre-defined protocols.

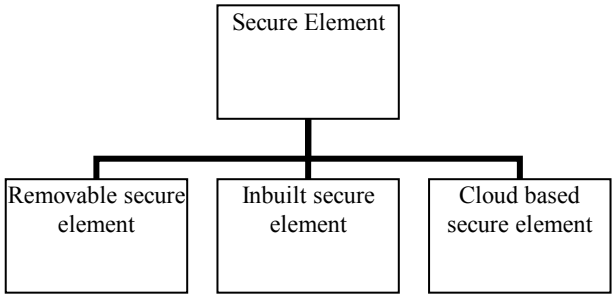

Fig. 1 Types of secure elements

C. Cloud based SE

With the physical SE, it was difficult to integrate them with the mobile devices because of the interdependencies which were needed to create relationship between the two components. To overcome such difficulties, industries moved towards the cloud based or remote SE. Cloud based SE reduced the complexity and cost of maintaining the physical SE. The cloud based SE requires a proper level of security to the stored data.

III. RELATED WORK

There are some IoT based systems that were earlier proposed to increase the IoT application area. These systems are based on communication protocol NFC which is used in IoT.

Brian et al. [5] proposed a smart library system which is based on IoT and provides book tracking by the use of NFC. The system provides facility to the user to get a book from its place through NFC tags and Local Positioning systems (LPS) based on Wi-Fi. The physical entry of the user to library needs biometric finger prints and user device authentication is performed to authenticate the device before accessing the services. LPS allows a user to track the book to a rack or to a user and the books are embedded with NFC tags and the racks are embedded with NFC reader.

Mainetti et al [6] proposed an IoT based parking system, using heterogeneous sensor network including RFID and light sensors. The system made us of the cloud platform and IoT gateway along with user interface provided by DriverApp and TrafficApp. To exchange the information between different entities, RESTful communication was used. The proposed system is time consuming as the involved procedures takes lot of time.

Lee [7] proposed NFC peer to peer based authorization protocol that is used between public health devices and mobile including NFC P2P facility. The protocol uses NFC data exchange format and Record Type definition for sharing data over NFC standards. It performs IoT device and user registration to the server.

Sukumar [8] proposed a vehicle location system helpline system based on IoT. The system uses NFC tags and readers to achieve the objective. NFC tags are used on the bus and the NFC readers are installed on every bus stop to update the IoT about the last stoppage location of the bus. The system is only proposed for bus facility.

IV. PROPOSED SYSTEM

This section will present the proposed protocol for authenticating the user to the IoT applications through the smart phone by using card emulation technique. This section will cover the system entities, phases of protocol and working. The protocol will be proved with the help of the sequence diagram. The proposed model is shown in Fig. 2.

A. System Entities

1) *User/User device:* The user who is willing to use the IoT application and will be able to access it through the smart phone which is the user device.

2) *NFC terminal/reader:* The NFC based terminal where the user will share his credentials by using the NFC based smart phones. The terminal will be used to read the data from the user device and provide the service to the user if authenticate them successfully by servers.

3) *Card Service Provider (CSP):* This is a cloud based secure element which will be needed to store the authentication keys and its original id that will be required while accessing the application. The server will be verified by the IoT service provider.

4) *Authentication Server (AS):* The server will be used to authenticate the user by its id and pin. The id stored on AS will be the virtual id, which will be mapped to original id in CSP. The server will be verified by the IoT service provider.

5) *IoT service provider:* The service provider who will provide the access to the IoT application by smart phones. The application running on user mobile to access the IoT device by card emulation will be hosted by the IoT service provider.

B. System Phases

The system is divided into six phases – Registration phase, enrolling phase, Card & Key generation phase, Encryption phase, Verification Phase and Access phase.

1) Registration Phase: This phase will deal with the registration of the user to the application running in the mobile device to access the IoT device. The user will enter the required details to the registration page and a user account will be created through which the user can access the IoT devices. The user will get a user id and a password for accessing the account.

2) Enrolling Phase: This phase will deal with enrolling the user to the required IoT application, for example- IoT based car parking system, library management etc. The user will enter his details to get a virtual smart card which can be used by user to access the particular application. The original user id will be stored at CSP and a virtual id will be stored at AS for verifying the user.

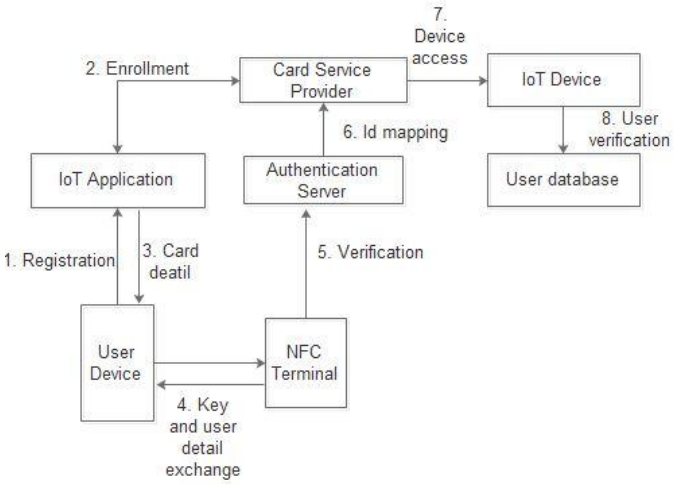

Fig. 2 Proposed Model

3) Card & Key generation phase: This phase deals with generating the card details for the user like the user virtual id and its pin which will be used to access the IoT application. It will also include the generation of keys which will be used for securing the data transmission. The keys will securely get stored in the cloud secure element for maintaining the privacy of the keys, and will not be stored on user device.

4) Encryption Phase: After card generation when the user will access the IoT based application, the data transmitted between the user device and the terminal will be encrypted by a symmetric key to bind the generated data to a particular terminal. This will avoid the sniffing attack which is common in NFC. The symmetric key will be generated by Diffie-Hellman algorithm.

5) Verification Phase: In this phase the data received by the terminal will be decrypted by the symmetric key and will be send to the AS for authenticating the card details send by the user. The AS on successful authentication will send the user virtual id to the CSP.

6) Access Phase: The CSP on receiving the virtual user id from AS, will map it to the original user id to get the selected user keys. The keys and virtual id will then be shared with the IoT device for communication and storing the user data that accessed the IoT based application.

C. *Working*

Fig. 3 represents the flowchart of the proposed system and describes how the system will work from initial stage to the final stage. To secure the user access, the application will take user fingerprint as the initial authentication at device level. The user id and pin will be used for authentication at application access level.

Fig. 4 and Fig. 5 describe the working of the proposed system. Fig. 4 shows the registration phase, enrolling phase and card & key generation phase. After the completion of these three phases, the user will be provided with a virtual card that will be securely stored on the user device. Fig. 5 shows the working of the system after the generation of the card, which includes the encryption phase, verification phase and access phase. The completion of these phases will provide authenticate user to access the IoT devices.

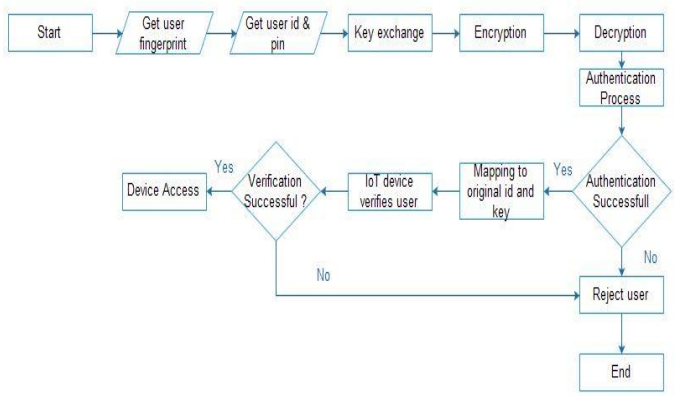

Fig. 3 Flowchart of the system

The protocol provides an authorization facility of user, and controls the access of illegitimate user. To access the application, the user needs to verify its biometric credentials which will be stored in smart phone memory. Once the user access the application, using the virtual cads provided to the user can access the IoT application.

D. *Mathematical Representation*

To access the service, the user device and the NFC terminal will perform initial communication to exchange the symmetric key K_i generated by Diffie – Hellman algorithm. The IoT application will encrypt the user credentials virtual user id V_i and pin with K_i.

$$v = g^x \bmod p$$

$$u = g^y \bmod p$$

Where p is a prime number and g is co-prime to p. x and y are the random numbers chosen by the user and the terminal.

$$K_{i=}(g^x)^y \bmod p \text{ and } (g^y)^x \bmod p$$

The key K_i will encrypt the V_i and pin using the symmetric key algorithm.

$$\text{Encrypt } \{V_i, \text{pin}\}\ K_i$$

The terminal on receiving the encrypted data will decrypt it with K_i and forward V_i and hashed pin *h*(pin) to AS, for authenticate the credentials.

$$\text{Decrypt } \{V_i, \text{pin}\}\ K_i$$

$$Z_i = \{V_i, h(\text{pin})\}$$

AS will receive Z_i and check if the user is registered or not by using V_i. On successful authentication, AS will forward the V_i and S_i to the CSP.

$$S_i = h(V_i)$$

CSP will verify the user by V_i and on successful verification will map V_i to the original id and communication key KEY_i. CSP will forward the encrypted V_i and KEY_i to IoT device for access to the user. The V_i and KEY_i will be encrypted by a shared key K_Z to secure the id and keys from key stolen attack.

$$\text{Encrypt } \{V_i, KEY_i\}\ K_Z$$

The IoT service will be maintaining a database of authorized user, which will be created during user registration. The data received will be decrypted by K_Z and if V_i matches in the database the user will get access to the device by the use of Keys.

$$\text{Decrypt } \{V_i, KEY_i\}\ K_Z$$

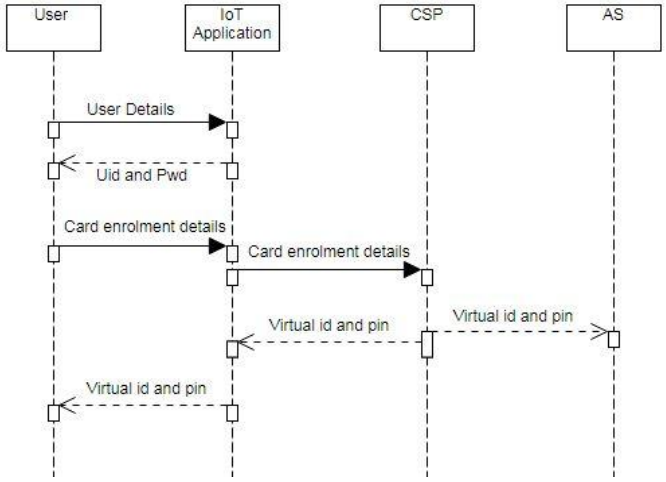

Fig. 4 Registration, Enrolling and Card & key generation phase.

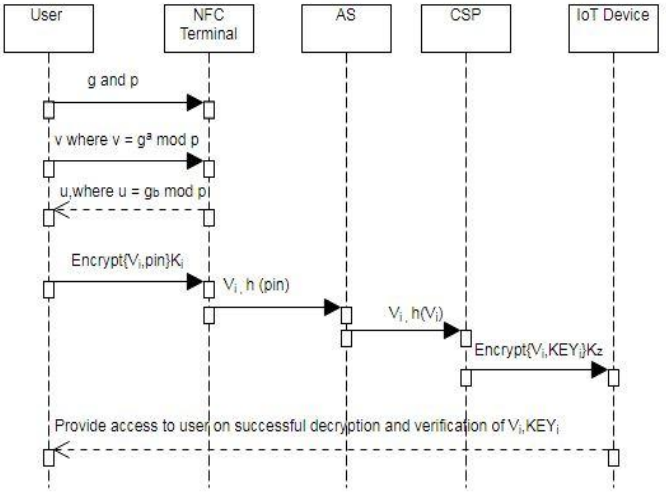

Fig. 5 Encryption, Verification and Access phase

V. RESULTS

The proposed system is implemented on AVISPA tool and is verified on the same platform. AVISPA stands for Automated Validation of Internet Security Protocol and Application [19]. It is a tool which can be used to analyse the large scale sensitive and internet security based applications and protocols. The tool can be used to find the attacks over protocol proposed. Fig. 6 shows the message sequence chart for the proposed system in AVISPA and Fig. 7 shows the security of the protocol under attack searcher (ATSE) in AVISPA tool.

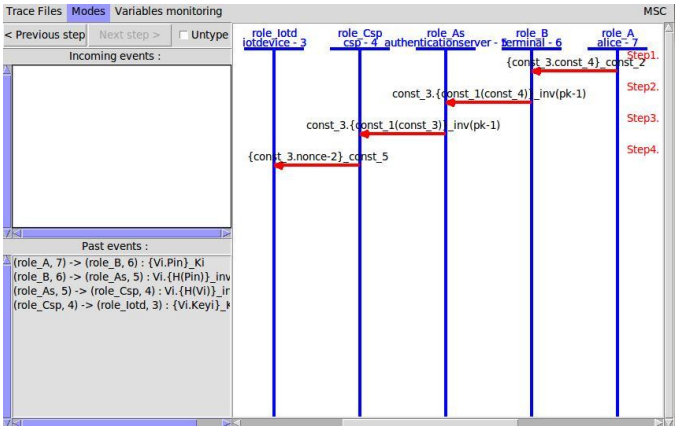

Fig. 6 Message sequence diagram in AVISPA

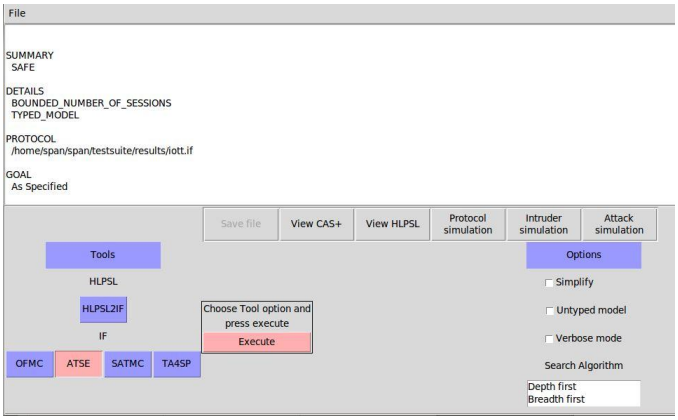

Fig. 7 Simulation result under ATSE model

VI. CONCLUSION

In the last few years, IoT has increased its use and the application area. Every industry in the current time depends on data and IoT improves and enlarge this data by connecting many devices that are capable of decision making. In this paper, we proposed a system that eliminates the use of smart cards in IoT system for authentication, and storing keys. To replace the smart cards we made use of card emulation technique and cloud based secure element to store the keys securely. The model can be used for authentication purpose, accessing any IoT device, and storing the communication keys. The model only allows the registered users to access the services. The paper has discussed few of the previously proposed systems for IoT making use of NFC for their access. In addition, the simulation result of protocol on AVISPA is also included.

ACKNOWLEDGMENT

This publication is an outcome of the R&D works undertaken under the YFRF project under Visvesvaraya Ph.D. Scheme of Ministry of Electronics & Information Technology, Government of India and being implemented by Digital India Corporation.

***Abstract*— Cloud computing is nowadays developed as a scalable and cost-effective technique. It facilitates many features in the computing environment like resource pooling, multi-tenancy, virtualization etc. In order to avoid resource maintenance, computing has been done on the service provider's infrastructure. Data security is the main concern in cloud computing because it is stored in data centers provided by service providers. DDoS attacks are rapidly growing in the cloud environment and have become a serious threat to cloud consumers. SDN is used to identify and prevent DDoS attacks in the cloud and it simplifies network complexity. In this paper, we have proposed a method that detects and mitigates DDoS attacks in cloud computing using the features of SDN with high accuracy and low computational cost. The proposed system is able to block the illegitimate users and allow only legitimate users to access the cloud services. The results are calculated by simulation experiments.**

Keywords*— *Cloud computing, SDN- based cloud, Software-defined networking, DDoS attack, OpenFlow.

I. INTRODUCTION

Cloud computing originates new era of computing and it has grown rapidly, not only in industries but also in academia due to the important characteristics provided by it, like - pay as per usages, on-demand self-service, rapid elasticity, broad network access and resource pooling. The basic services offered by the cloud are - infrastructure as a service (IaaS), platform as a service (PaaS) and software as a service (SaaS), which attracts great interest of users and provide advantages like reducing the operational and overall cost [1].

In the area of computer networking, a new technology is drawing attention is software-defining networking (SDN). It leverages the lack of programmability in existing networking architecture. The conventional networking architecture is simplified through SDN by decoupling network control plane from infrastructure plane and facilitates new features of networking. The logically centralized control plane provides programmability that allows writing new software logics for implementing new control functionalities and these control logics deploy in the data forwarding plane. Many companies like HP, IBM, and CISCO, etc. provides the platform based on SDN technology and many companies including Google, Amazon, and Microsoft uses SDN platforms for their data centers and public clouds platforms which shows the scope of SDN in the IT industry.

Therefore, implementing SDN in the cloud can simplify the operational complexity of cloud and can enhance its performance based on parameters like routing, switching, monitoring, virtualization, network traffic engineering, and most importantly load balancing. . The integration of SDN and cloud leads to the development of SDN based clouds where the SDN controls network infrastructure and extends cloud services with Networking as a Service (NaaS) [2]. SDN provides new opportunities to ensure the security of cloud computing environment through networking [3] by detecting and preventing the threats that target cloud environment. Among all security requirements, availability of data and services is essential for implementing core operations i.e. providing cloud services and implementing on-demand self-service feature. Cloud services and data availability is mainly damaged due to DDoS attack by making them unavailable for its intended users and targets the service providers to degrade their services and breach the trust between the service provider and its customers [4]. The DDoS attack is performed by more than one machine or bots where a bot is a compromised machine developed when a malware code is injected in the machine and follows the instructions given by the attacker and the group of compromised machines is known as a botnet. SDN provides i) centralized control to the network and ii) open programming that provides real time implementation and modification of detection algorithms in network devices.

Apart from these benefits, the SDN-based cloud may also introduce potential security risks like separating the data and control plane may introduce a new attack surface for the attacker. SDN itself is a target of DDoS attack and also an attacker can take advantage of its features to perform the attack. The hardware devices – forwarding switches and controllers are supported by data plane and control plane respectively and possible vulnerabilities in the hardware devices can lead to attack in SDN. Security threats to SDN include unauthorized access (at controller and application plane), data leakage (side channel attack at data plane and forwarding policy discovery), data modification, fraudulent rule insertion at the control plane, and controller-switch communication flooding (Denial of Service). Although all the security threats degrade the performance of SDN- based cloud but DDoS is a major threat which has a disastrous effect on the whole cloud environment.

In this paper, we present a methodology that is able to detect DDoS attack in cloud environment by implementing detection method on the controller of control layer. After detecting an attack packet, the system will block the malicious packet and also remove the malicious entries from the switches flow table.

The organization of this paper is as follows: - Section 2 describes the basic features of cloud computing, SDN and DDoS attack. Section 3 presents an overview of existing methods to prevent DDoS attacks in the SDN based cloud environment. In Section 4 provides an architectural description of the proposed model along with implementation. Experimental analysis and performance assessment of our proposed approach is in Section 5.

Section 6 concludes the paper followed by acknowledgment and references.

II. BACKGROUNG

Cloud computing is defined as "*a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction*"[1], according to NIST (National Institute of Standards and Technology).

Many companies provide cloud services like –

- IaaS - Google Compute Engine (GCE), Digital Ocean, Rackspace, Microsoft Azure, Cisco Metapod, Amazon Web Services (AWS), etc.
- PaaS - Windows Azure, AWS Elastic Beanstalk, Apache Stratos, Google App Engine, OpenShift, Force.com etc.
- SaaS - Salesforce, Google Apps, Concur, Dropbox, Cisco WebEx, GoToMeeting, etc.

In the cloud computing architecture basic delivery models are public, private, hybrid and community cloud. Cloud computing provides flexibility, adaptability, and scalability according to various user demands by using virtualization functionality in its core. The cloud computing architecture is depicted in Fig.1.

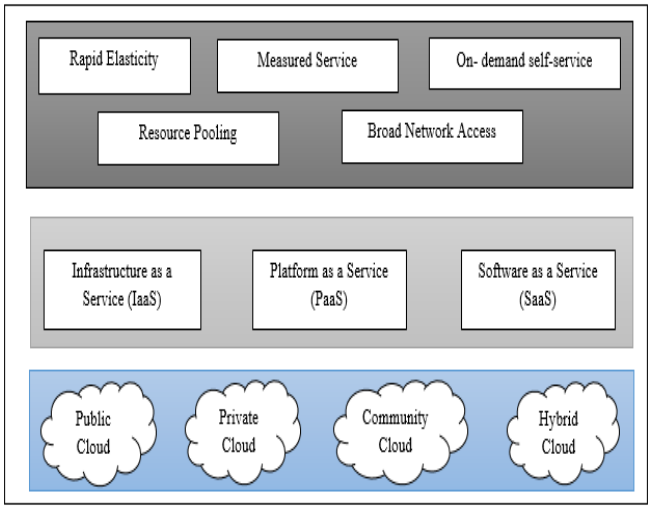

Fig.1 Cloud computing architecture

The framework of SDN is comprised of three layers: - infrastructure layer (data plane), control layer (control plane) and application layer, shown in Fig.2. Forwarding switches which are present in the data layer can be physical or virtual that can be used to forward the packets as per the entries defined in the flow table. The incoming and outgoing services for the packet are provided at the infrastructure layer in SDN environment. The control layer is responsible for formulating the forwarding rules for the packet by analyzing them and it also manages the infrastructure layer. Controllers are the software that communicates with forwarding devices using southbound API interface and networking applications using northbound API interface and are used to provide programmability and network monitoring. Controllers communicate with each other through the eastbound/ westbound API interface. The standard interfaces like southbound APIs such as OpenFlow, ForCES, PCEP, etc. are used to connect the infrastructure and control layer. Control plane provides hardware abstraction for SDN applications. The application layer has various networking applications for network security, network monitoring and analysis, network virtualization, mobility management, and policy implementation. The controllers communicate with applications or software in application plane using northbound APIs [5].

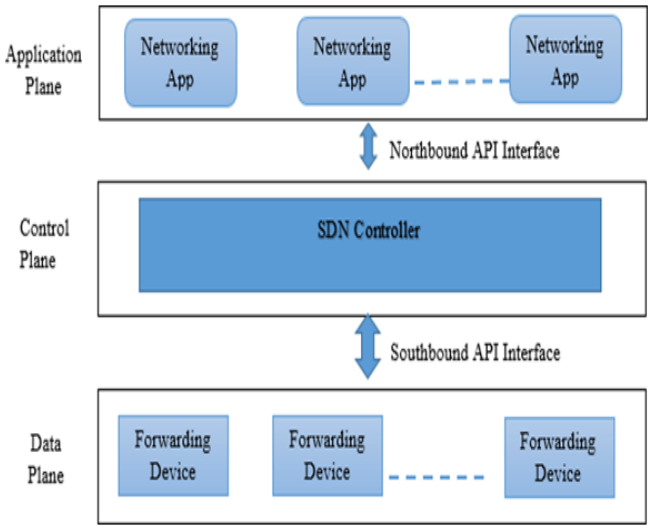

Fig.2 SDN Architecture

The evolution of SDN- based cloud has drawn attention from companies and as well as researchers in recent years. Existing cloud networking architecture follows the single policy method for all cloud users such as single security policy applied on all the cloud services does not provide quality of service (QoS) to the user for some cloud services. SDN has a feature of open programmability that provides the privilege to modify or redesign the existing algorithm or method in real time and due to logically centralized feature of SDN it will be reflected to all devices connected in the network. SDN provides network function virtualization which guarantees stable network performance in SDN-based cloud environment. Advantages provided by SDN based clouds over conventional cloud include quality of service (QoS), server virtualization, storage centralization, network centralization, security, etc.

The security of SDN based cloud increased due to features of SDN. Although SDN based cloud has several advantages, it experiences many challenges such as –

- Performance: the controller cannot handle large amounts of traffic.
- Availability: Controller failure affects network availability
- Scalability
- Security

III. RELATED WORK

In this section, we will review the currently available solutions to detect and prevent DDoS attacks in a cloud computing environment based on the SDN. Braga et al. [6],

presented a lightweight method for DDOS attack detection on the basis of flow analysis and centralized control mechanism and made use of self-organized maps (SOM) for traffic classification. The process occurred in three stages: - flow collection, feature extraction and classification. Giotis et al. [7], used sFlow's packet sampling feature to improve scalability and reduced the communication between the forwarding switch and open flow (OF) controllers. It also used the SDN's dynamic rule update and traffic analysis feature. Passito et al. [8] exploits the abstraction feature of SDN and proposed a framework for the formation of cooperative SDNs is AgNOs and expended its domain beyond the enterprise network. Shin et al. [9], proposed a mechanism named AVANT- GUARD that enhanced the functionality of the OpenFlow enabled switches to prevent malicious flows for the controller. Wang et al. [10], proposed a mechanism for DDoS attack prevention after examining the impact of SDN in DDoS defense and observed that SDN can be useful for DDoS attack detection and mitigation. Therefore, they provide DDoS attack detection and mitigation architecture "DaMask". It is divided in two components: DaMask-D and DaMask- M. DaMask- D is based on anomaly detection system and DaMask- M is a DDoS mitigation system that immediately responds to the attack.

Cui et al. [11], has presented a mechanism, SD Anti-DDOS, which detects DDOS attack with the aim of reducing reaction time to mitigate the attack. It consists of four module architecture in which data stream unusual traffic detection algorithm is used for attack detection and blocking the packets from the source and release the space occupied by the malicious packets in flow table to mitigate the attack. If the response time is large, the SDN controller is forced to process a large number of traffic packets, which increases the possibility of controller failure. Sahay et al. [12], proposed an autonomous DDoS attack mitigation scheme *ArOMA,* which works to coordinate different types of DDoS mitigation systems from the ISPs and its users systematically and exploits SDN programmability and centralized control features. Yan et al. [13], has presented a SDN controller scheduling algorithm which uses multiple queues and utilizes different time slicing approaches according to intensity of DDoS attack.The algorithm provides a gradient for the normal SDN switch by processing the flow request process using other switches during the attack. Xing et al. [14], presented a system, SnortFlow which is an intrusion prevention system (ISP) based on Snort and OpenFlow. It detects intrusion and reconfigures SDN to provide security to the cloud from intrusions. The system uses Snort's intrusion detection functionality and OpenFlow's flexible network reconstruction functionality. Bhushan et al. [15], proposed an algorithm to reduce the DDoS attack while modeling the flow-table space. When a switch cannot handle the incoming flow request because the flow table is not empty, then approach analyze the status of other switch's flow table to recognize the appropriate switch to handle traffic and also discard the less usage and attack traffic flow rules.

IV. PROPOSED ARCHITECTURE AND METHOD

The current cloud architecture is not able to provide clear and effective security policies against DDoS attack and the security policies has been generalized to each user, due to which some of the organizations are in dilemma that adaption of public cloud is beneficial for their organization or not. Thus, in this research work, we propose a solution for the above problem using SDN architecture in the cloud environment. The logically centralized architecture and programmability feature of SDN provides the analysis of network traffic towards the cloud more effectively. Our proposed approach will be able to detect the DDoS attack and mitigate the attack by blocking and extracting malicious flow entries from the flow table. The framework of SDN based cloud is depicted in Fig.3.

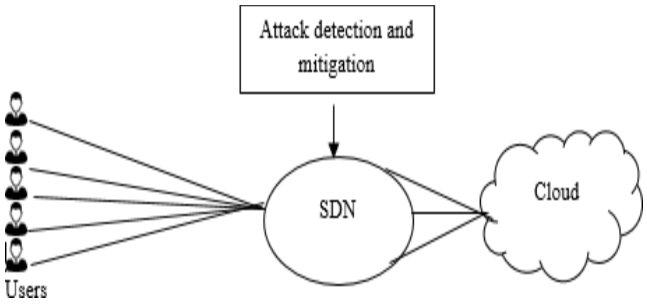

Fig.3 SDN- based cloud

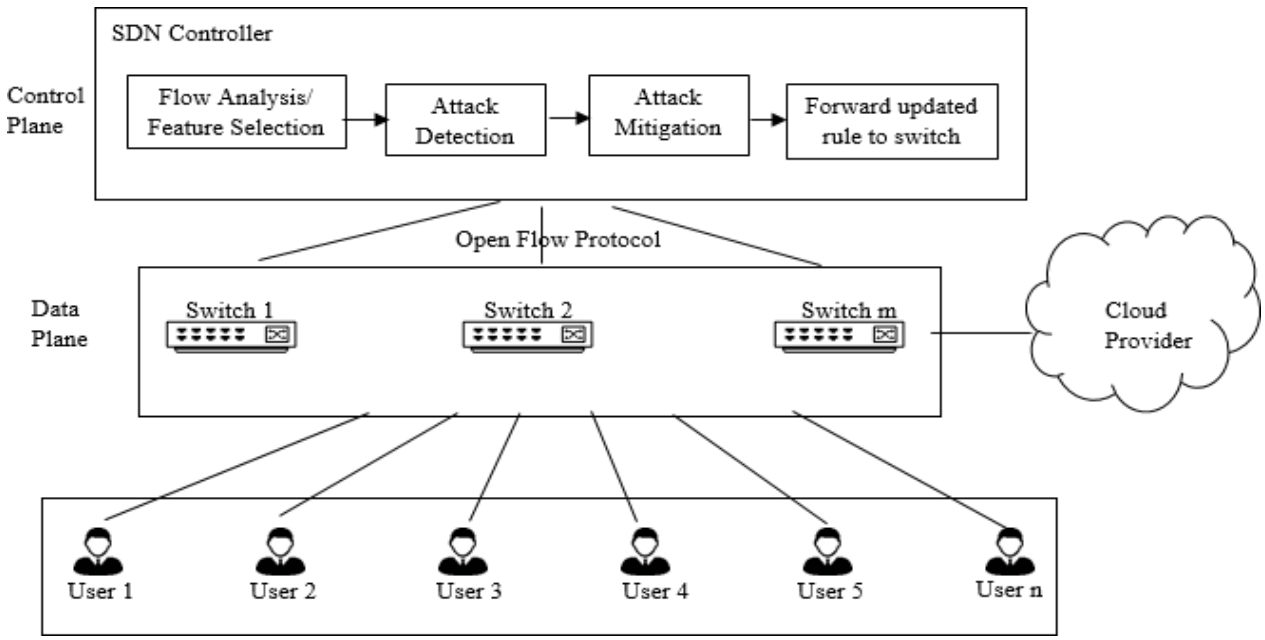

Fig.4 Architecture of proposed approach

A. *Proposed Architecture*

The proposed scheme is described in Fig.4.

- SDN Switches: A switch is a packet forwarding device based on flow table rules. The flow tables are stored at the switch and have limited memory space. The switches are responsible for collecting the client's requests and send it to the controller and update the flow table entry according to the controller's response. The OpenFlow (OF) protocol is used to provide communication between the switch and the controller.
- SDN Controller: A controller is responsible for packet forwarding by the switch and is the backbone of entire network. Attack detection and mitigation algorithm are implemented on the controller. The SDN controller receives flow entries from switches and the controller performs various functioning (data collection, flow analysis, attack detection, and mitigation) to achieve the objective.
- Cloud Users: This entity uses cloud services provided by a cloud service provider.
- Cloud provider: This unit provides many services for cloud users

B. *Attack Detection and Mitigation Approach*

Our attack detection approach is based on artificial neural network. Using neural network algorithm's features, the DDoS attack detection system can identify normal traffic and malicious traffic. In the attack detection system, the controller collects the flow entries from switches and uses principal component analysis (PCA) approach to generate eigenvalues of the flow and is forwarded to trained neural network systems to determine normal traffic packet or a malicious traffic packet. To analyze the data, a dimensionality reduction approach PCA is used. It modifies correlated variables into linearly unrelated variables (principal components) using orthogonal transformation. The n^{th} principal component of transformation is the linear combination of original variable and orthogonal to $(n-1)^{th}$ principal component and has n^{th} highest variance. The resulting vectors contain uncorrected and orthogonal set of values. For a reduction in dimensions of data, consider only a few initial principal components as it has large variance data of the original data set and there is a negligible variance in others, hence the variance loss is minimal. Steps follow to perform transformation:-

- Consider a set of information or data $X_1, X_2, X_3, X_4, X_5, \ldots\ldots, X_n$, where each information has vector length p. The data matrix $X_{n \times p}$, where each n row represents the set of observations and the p columns represents features.

$$\mathbf{X} = \begin{bmatrix} x_{11} & x_{12} & \cdots & \cdots & x_{1p} \\ x_{21} & x_{22} & \cdots & \cdots & x_{2p} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{n1} & x_{n2} & \cdots & \cdots & x_{np} \end{bmatrix}$$

$$X = [X_1 \quad X_2 \quad \ldots \quad \ldots \quad X_p] \tag{1}$$

- Calculate the empirical mean observation:-

$$\mu = \frac{1}{p}\sum_{i=1}^{p} X_i \tag{2}$$

- Find experimental mean with each column j = 1 to *p*.
- Construct an experimental mean vector **u** of dimension p x 1 from calculated mean values

$$u_j = \frac{1}{p}\sum_{i=1}^{p} X_{ij} \tag{3}$$

- Calculate the deviation from mean:

$$A_{n\times p} = X - u \tag{4}$$

- Calculate covariance matrix:

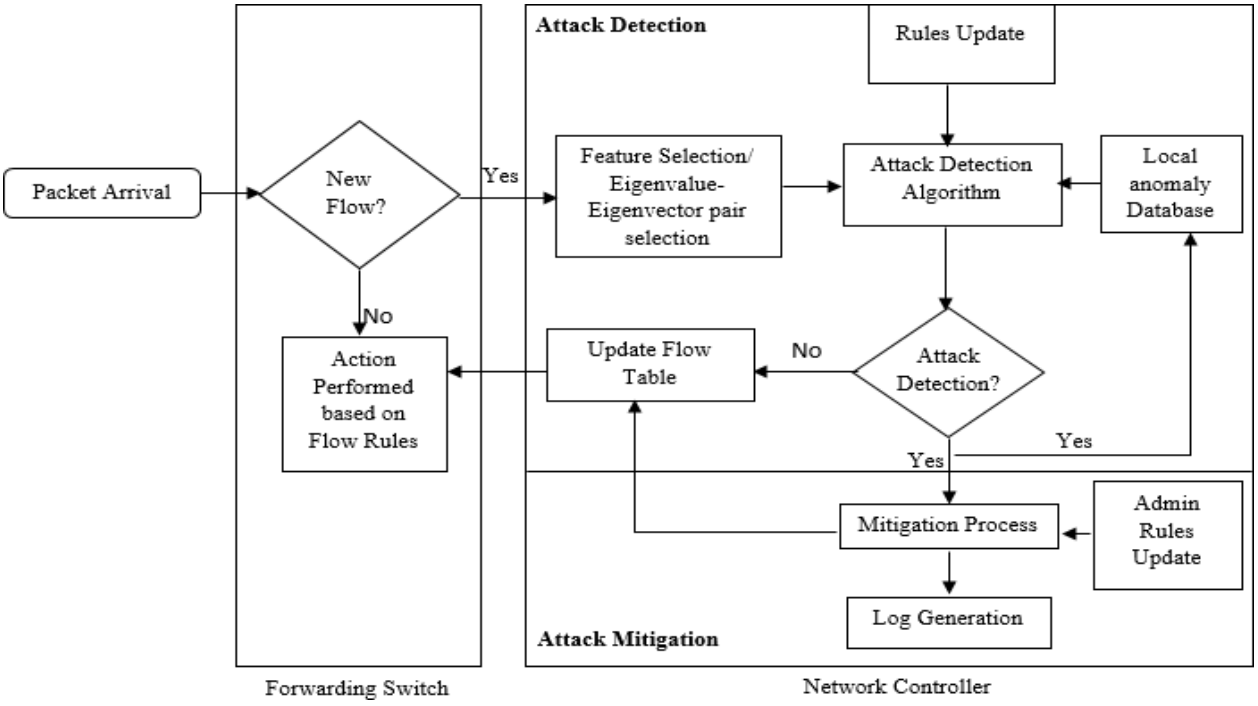

Fig.5 Flowchart of proposed model

$$C_{p\,x\,p} = \frac{1}{n} AA^{T} \quad (5)$$

- Find the Eigen values and eigenvectors of the covariance matrix: - The eigenvalue - eigenvector pairs are calculated by Singular value decomposition (SVD) method and suppose (λ_1, v_1), (λ_2, v_2), $(\lambda_3, v_3)\ldots$ (λ_p, v_p) are eigenvalues - eigenvector pairs of covariance matrix C. Select k inherent dimensionality subspace eigenvectors which has highest eigenvalues. The dimensionality k can be calculated by:-

$$\frac{\sum_{i=1}^{k} \lambda_i}{\sum_{j=1}^{p} \lambda_j} \geq \beta \quad (6)$$

Here β is the ratio of the amount of information contained in the subspace to the total amount of information. We construct a matrix $U_{p\,x\,k}$ from k eigenvector and each eigenvector contains p Eigen values.

The attack detection consists of two stages: training and testing. During the training phase, neural network is formed on a predefined training dataset. In the system, the extracted flow is taken as the input parameter and the target value as the output parameter. Target values for normal traffic and malicious traffic are assigned as 0 and 1, respectively. We used a multilayer perceptron (MLP) algorithm which is a feed-forward neural network that classifies network traffic as normal or malicious traffic. Fig.5 describes the complete flow of our proposed scheme.

To detect the attack, the packet flow is captured and preprocessed to remove the features (eigenvalues) and then transferred as the input of the MLP to detect whether it is a normal flow or malicious flow. If it is found in the form of normal flow then the normal forwarding rules will be implemented in the flow table, but if it is found as a malicious flow, then the mitigation of the attack is necessary. For the attack mitigation, we have identified the switch that sends the request to the controller for malicious flows and adds a blocked rule for that particular source and destination IP address pair. The blocking rules have the highest priority among all flow rules and drop packet operations are used to block the malicious flow. The mitigation architecture is shown in Fig. 6.

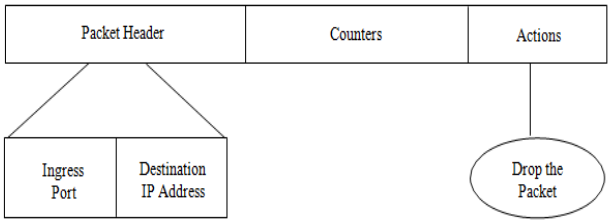

Fig. 6 Mitigation approach

V. EVALUATION

The proposed system uses Mininet, a SDN simulation tool and implemented on a python based open source platform for SDN applications - POX controller. The proposed system contains six hosts (h1, h2, h3, h4, h5, h6) where h1 is a cloud server. The normal traffic is generated using Scapy tool which is a packet manipulation tool and it helps to produce TCP, UDP, ICMP, SCTP traffic. "Low Orbit Ion Canon (LOIC)" tool is used to generate DDoS attack traffic in this paper, which is popular and also able to generate different types of attack: - TCP/SYN, UDP, and HTTP flood attacks. Normal traffic is generated from host h3 and h4 and host h2, h5 and h6 have generated malicious traffic. Normal traffic includes TCP, UDP and ICMP protocol data, and the traffic of the attacks includes TCP floods and UDP floods. The parameters of the MLP model used in this approach are shown in Table 1.

TABLE I. MLP parameters

Parameter	Value
Total layers	3
Hidden layer neurons	5
Rate of learning	0.2
Momentum	0.2
Maximum no. of epochs	500

In order to mitigate the attack, we need to detect the malicious traffic and for attack detection, we have trained the detection system in advance with the predefined dataset. We used OpenFlow controller to mitigate the attack. When new flow arrives, the switch sends a request to controller and controller replies with appropriate actions such as Forward, Drop and Modify-fields. In this paper, we examine the network traffic and classify normal traffic and malicious traffic, if the detection system has identified malicious packet, it sends to the attack mitigation system.

Fig. 7 describes the controller's network load with time and Fig. 8 shows the utilization ratio of the CPU of the controller.

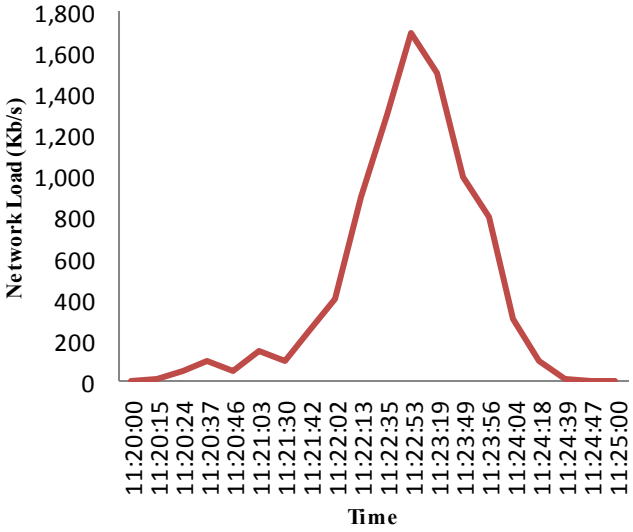

Fig.7 Controller's network load with time

The mitigation system initiates a flow to the switch for mitigating the attack. The new flow contains the source IP address of the malicious packet and attaches a Drop action in the action field with the highest priority. The flow rules are added in the flow table of the switch and if a new packet

comes from the same source IP address it will dropped by the switch. The accuracy (rate of correctly classified instances for every class) of the attack detection is driven by:

$$\text{Accuracy} = \frac{\text{TN} + \text{TP}}{\text{TN} + \text{TP} + \text{FN} + \text{FP}}$$

- Precision is a positive predicate and calculated by:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

- A recall is a positive sensitivity value and determined by:

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

In this paper, we calculate the accuracy, precision and recall values and have achieved overall accuracy is 99.97%, precision is 0.99 and recall is 1.

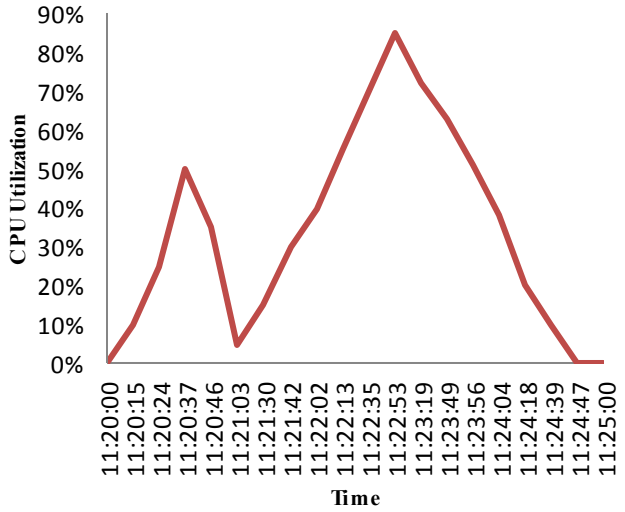

Fig.8 Controller's CPU uses over time

VI. CONCLUSION

Cloud computing and SDN have gained popularity, but DDoS attacks are a major threat to cloud computing environments. However, the collaboration between SDN and cloud computing technology effectively prevents DDoS attacks. The SDN has many features that help in designing an effective DDoS attack mitigation approach. Our proposed approach allows traffic collection and analysis, followed by DDoS attack prevention algorithm in SDN which is implemented on POX controller in Mininet simulator that allows legitimate flow to access the cloud computing environment. The accuracy, precision, and recall have been evaluated in this paper which provides very less false positive. Apart from this, in this paper we also discussed some of the previously proposed schemes for DDoS attack prevention in cloud environment using SDN. Our future work consists of studying new techniques of detecting vulnerabilities and attack in SDN-based clouds and working on on-demand security as a service in SDN-based cloud.

ACKNOWLEDGMENT

This publication is an outcome of the R&D works undertaken under the YFRF project under Visvesvaraya Ph.D. Scheme of Ministry of Electronics & Information Technology, Government of India and being implemented by Digital India Corporation

Abstract **- Due to hike in price of conventional source of energy we attentive toward non -conventional source of energy. This paper with present of a hybrid solar-wind energy system with gird connected. Hybrid solar-wind system consist wind , solar source and ac loads. In solar dc output system is raised by boost converter. MPPT technique is used to maximize the output of solar system. The wind subsystem is made of a permanent magnet synchronous generator and rectifier, boost converter for maximum output. Voltage regulator is used for controlling the hybrid solar & wind system. Modeling of hybrid PV and wind turbine which is controlled by voltage regulator is explained. To increase reliability & reduce reliance on one single source we connected these two systems.**

Keywords-MPPT, Hybrid System, Voltage Regulator

I. INTRODUCTION

Over the last few years because of growing the evaluate of fossil fuel to making the electricity, high depletion of non - renewable energy and environment anxiety so we turn to focus toward on non-conventional source of energy.[1] Right now the renewable energy source are come essential throughout the world. Modernity utilization of dissimilar renewable sources alike sun ,wind & hydro is made use to produce the power & it is fateful for human life.it can be detract of requirement of electricity & abate the pollution impact[1]

Conjunction of two and more renewable source energy is hybrid power system. PV –fuel cell, PV-Biomass, wind – PV etc. are hybrid energy source[16]. Due to ecological abate the cost and fit for rural usage. A hybrid system of PV-wind power are cost effective energy solution with elevate reliability and power characteristics [3,4].Aim of this paper is modeling of hybrid solar PV/Wind power system. All the essential main parameter of this model can be improved and impact the working on hybrid power system. The introduce model made of PV array , wind conversion system ,DC/DC converter, battery, voltage regulator[16,17]. Here Voltage regulator is used for control hybrid system. .Matlab/Simulink is used for PV/Wind simulation model.

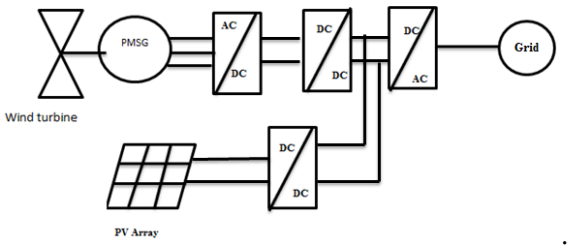

Fig.1 block daigram of hybrid system

Fig. 1 shows a hybrid power system which is comprise PV array and wind energy system which is associated to grid through different converters [5].

II. MODELING OF PV CELL

PV cell is fundamental element of PV system. To attain needed voltage and current no. of PV cell connected in series and parallel. PV cell is a semiconductor diode consist with p-n junction which is spark the light. Simulation of mathematical model of PV cell is helpful to show voltage, current& power conduct at different operating condition [6]. In a PV cell series resistance (Rs) is linked in series along with parallel conjunction with photocurrent source (Iph), grandstand diode (D) and shunt resistance (Rsh). Fig.2 shows corresponding circuit of PV cell.

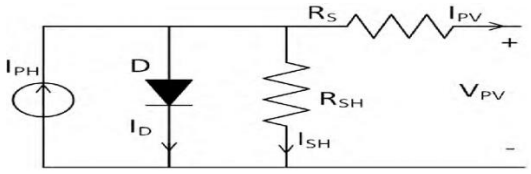

Fig.2 Solar cell basic circuit

Current source of solar cell, current of diode ,current shunted diode display by *Iphs* ,*Ids* ,*Ishd*

$$Ipvs = Iph - Ids\left(e^{q(Vphs+Ipvs*Rs)/nKT)} - 1\right) - \frac{Vphs + Ipvs * Rs}{Rs} \quad (1)$$

Where

Iph = induced solar current

Ids= diode saturation current

qs=electron charge

ks =Boltzmann's constant

ns=ideality factor

Ts=temp ^{o} k

By changing the value of solar irradiation level& working temp. we can change the value of induced solar current

$Iphs = Ishc + Kj(Tct - Trt) * Irs/1000$

Ishc= cell short circuit current

Kj= temp coefficient

Tct, *Trt*=reference and working temp.

III MPPT TECHNIQUE

Results of output power of PV modules are fluctuating according to their environmental condition.so we need to use control technique which help to get high power regardless environmental condition alike temp. & irradiance.

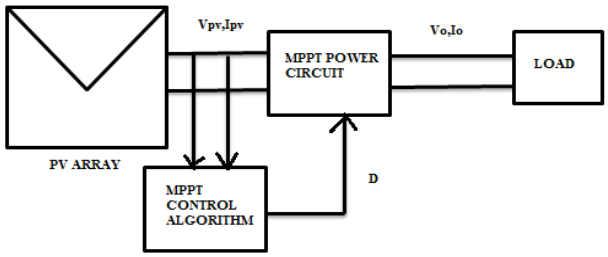

Fig.3 Block diagram of MPPT control

Fig. 3 shows block diagram of MPPT control .There is have to existence a maximum power point because PV cell has nonlinear relationship that is hold on growing with atmosphere condition ,temp.& irradiance level. In this paper perturb and observe (P&O) technique is applied for tracking maximum power at varying temp.& irradiance. It conducts by continually evaluate the terminal voltage and current of PV array, then continually perturbing the voltage by addition small interrupt ,then observing the modification of power to find control signal. Variation developed by variable switching duty cycle. Duty cycle is control by perturb & observation (P&O) MPPT algorithm [6]. DC-DC boost converter is used to convert dc to high level DC output voltage.

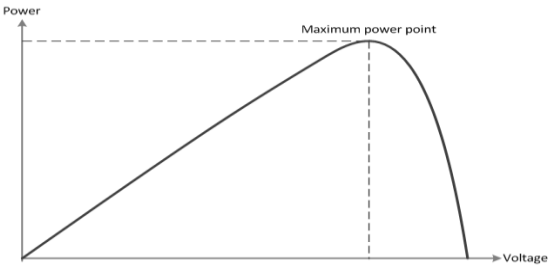

Fig.4 MPPT graph

Fig. 4 shows MPPT graph with respect to power and voltage.

By varying duty cycle converter output voltage is preserve constant .the solar PV array output show

$$Vpv = (1 - D)Vout \quad (2)$$

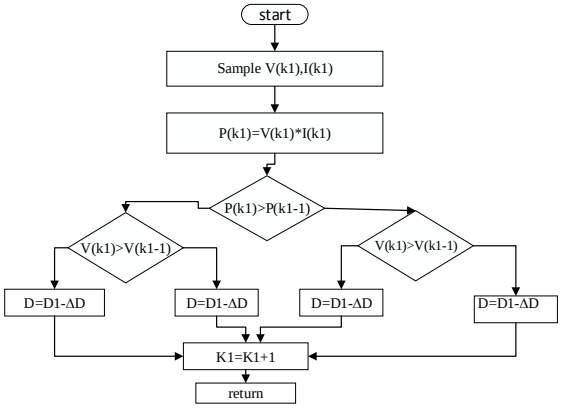

Fig. 5 MPPT flow chart

Expressed variation in output voltage of PV array with different level of solar irradiation and temperature [7,8].

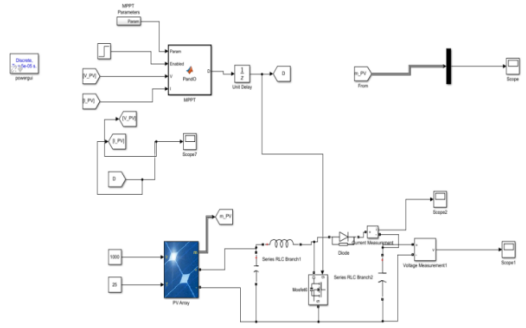

Fig.6 PV panel with MPPT (P&O) technique.

Fig. 5, 6 show MPPT flow chart and simulation of PV array with MPPT technique.

IV WIND MODEL

The arrangement which convert wind energy to mechanical energy called wind turbine. The power occupy by wind system is represent by this equation [9]

$$Pmechp = \frac{Cpc(\alpha,\gamma)\rho A}{2} \qquad (3)$$

Fig 7 shows a wind turbine system model which gives 3 phase AC power then rectifier is used for convert AC power to DC power. For coupling both systems we need convert AC power to DC power with same magnitude. Here we used PMSG synchronous machine because PMSG work is raised reliability of wind turbine. It is an electrical rotating machine in which field excitation is composed by permanent magnets .There is no need reactive magnetizing current. Synchronous generator has many merits corresponding low burden, compact design, & advance capability [10].

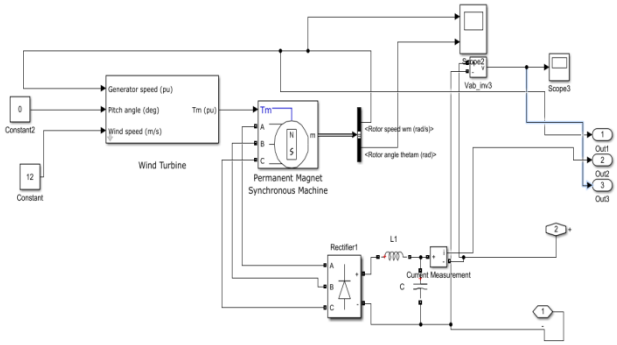

Fig.7 modeling of wind turbine

V BATTERY SUBSYSTEM

Fig. 8 display battery MATLAB model, in which by using three phase inverter battery connected with main supply. Battery system is charged when system run without any problem and used battery power when system is run abnormal condition [2,15].

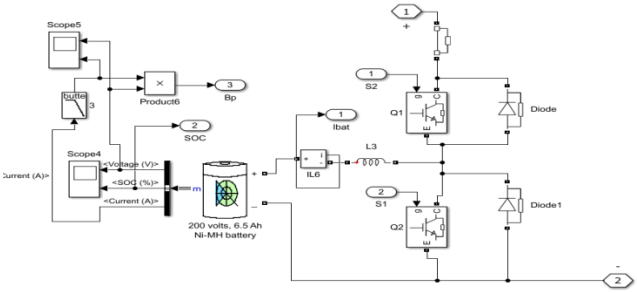

Fig.8 modeling of storage system

VI VOLTAGE REGULATOR

Fig.9 shows an inverter transforms DC to AC power at desired frequency which is controlled by voltage regulator. In voltage regulator generated DC transform into three phases AC by PWM signals. The PWM signals comprise three sinusoidal signals with 120^0 phase shift, compared vector control signals with high frequency carrier signal and produce needful pulse for operation [15]. Due to 120^0 Phase to neutral voltage Vph at the fundamental frequency shows as

$$Vphs = \frac{(2\sqrt{2})}{\pi}\cos\left(\frac{\pi}{6}\right)Vdcs \qquad (4)$$

Where Vph is the generated phase voltage at the terminals, and Vdc is the input voltage of the inverter. The PID control PWM technique is applied to produce desired pulses for the inverter [13].

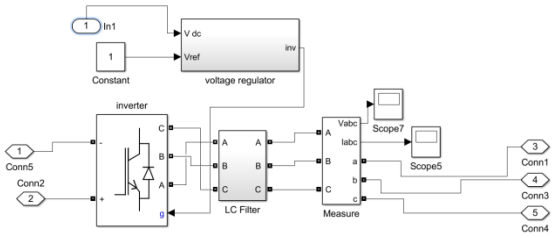

Fig.9 modeling of inverter with voltage regulator

VII RESULTS AND SIMULATION

Fig.10 is represent simulation of hybrid system which is comprise solar and wind sources and energy user block and control by voltage regulator. Solar irradiance and wind speed is taken for simulation. Fig.10 shows output of solar and wind generation system. Hybrid system is run for 0.3 sec in Matlab/Simulink software. Fig.11,12show DC voltage after using boost converter which is boost PV array voltage to a high level dc voltage with MPPT technique & wind turbine output in which PMSG wind turbine produce AC voltage and then rectifier transform AC to DC voltage , Fig.13 show dc boost voltage after coupling both PV/Wind subsystem. Fig.14, 15 show three phase AC voltage after using inverter which is not in pure sinusoidal form & three phase AC voltage without any fluctuation when we connected system to grid respectively.

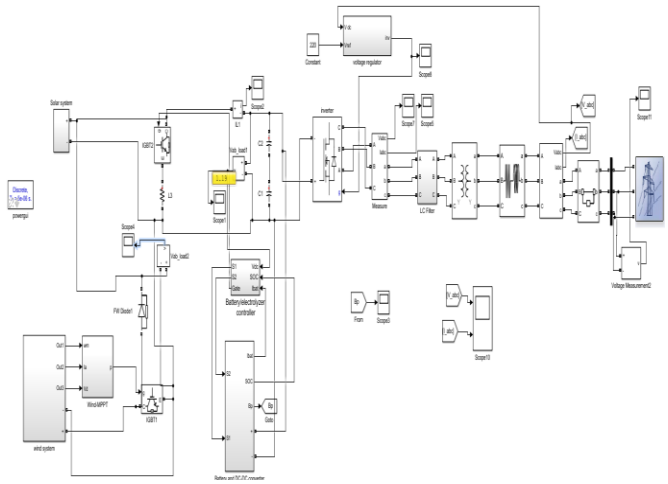

Fig.10 modeling of hybrid PV/wind/battery system controlled by voltage regulator

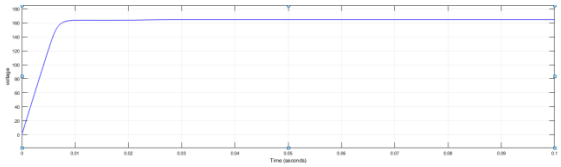

Fig 11 solar output voltage

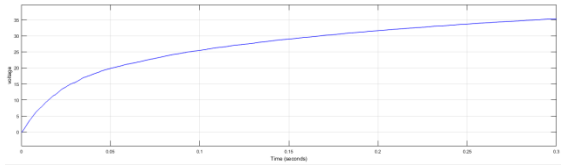

Fig 12 wind output voltage

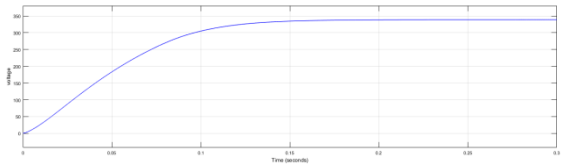

Fig 13 hybrid solar and wind voltage

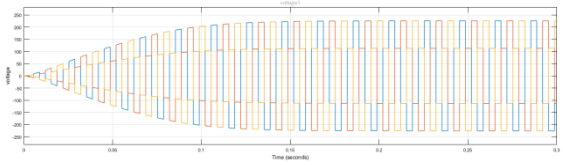

Fig 14 output voltage after inverter

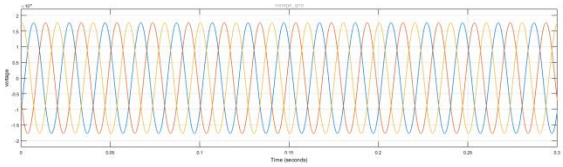

Fig 15 output voltage when hybrid system connected to grid

VII CONCLUSION & FUTURE SCOPE

This paper represents a hybrid system which is comprised solar and wind generation system and controlled by voltage regulator. By using MATLAB software simulation was controlled .The operation of system is evaluate at various wind speed and irradiance stages. The introduce hybrid system is examine wind speed at 12m/s and solar PV panel at irradiance 1000w/m^2 and temp 25^0 form t= 0 to t=0.3sec. is applied then coupled both DC voltage to DC link is controlled by voltage regulator and performance is evaluate & improved. To fulfill the requirement of electricity in a remote area hybrid system is used. The developed system working is performed in Matlab/Simulink software and results are displayed .Other renewable energy sources is used for hybrid system instead PV/Wind energy sources and to get more reliable and satisfied results several control technique is used for inverter in place of voltage regulator.

***Abstract* - Solar power unit is needed to increase the lesser voltage of solar panels to the voltage of the power grid; thus, converter should have an immense voltage gain with few switches otherwise it leads to system complexity. A three-port converter with enhanced topology for renewable power utilizations based on Z-Source network is suggested to fix these issues well. This Z-Source network symbolize the suggested converter's distinctive characteristics. One port of energy storage system for energy storage and supplying, and the last one is for loads. It is followed with new topology design and output analyses by MATLAB.**

Keywords— Five-terminal, impedance network, renewable energy systems, three-port converter, MATLAB Simulink.

I INTRODUCTION

In the interest of clean, immense suitability, and sustainable benefits of renewable energy schemes such as photovoltaic panels and wind turbine generators Use a big percentage of electricity production to replace traditional expensive, lesser-efficiency and polluted production of electricity [1][2]. However, there is a significant disadvantage of renewable energy systems, i.e. wind or solar are linked to climate and this difficult or intermittent feature extended the intricacy of grid implementation. [3], [4]. One solution issue of energy storage system for stabilizing output of energy storage systems[5]. An instance of a solar energy conversion system with energy storage scheme is displayed in Fig.1, where solar power units are needed to increase the lesser voltage of solar panels, so it takes a high voltage boost converter [6], In addition, the bidirectional energy storage unit combines renewable energy systems to balance output. In order to link the PV and output of load, it required minimum two converters [7]. The diagram shows that power converters are used to bridge various renewable energy systems and energy storage systems into a sub-scheme and to track power transformation and storage to match outputs [8].

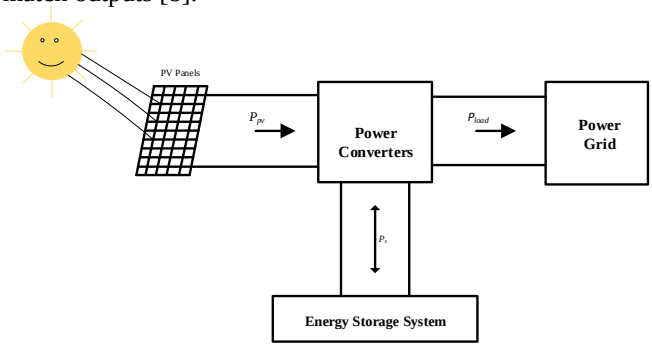

Fig. 1 Solar energy conversion system with energy storage unit.

For this purpose, Multi-stage converter with multiple ports are better to operate conversion of power and grid assimilation for variety of sources. For example, for matching renewable resources, energy storage and utility grids, various phases of power converters are incorporated as shown in Fig. 2

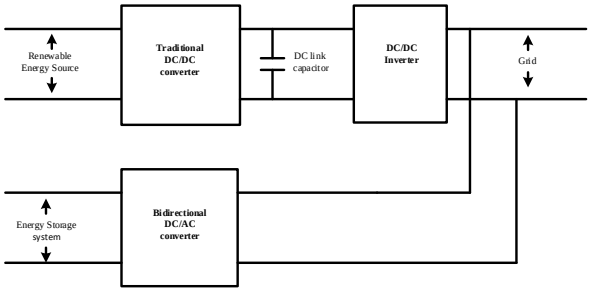

Fig. 2 Multi-port conversion system

Therein, three converters This results in low system effectiveness and high system costs [9]. Existing switches

also enhance the complexity of the system [10], and Such converters ' control policies, reduce stability [11], To resolve issues of renewable energy and energy storage applications a multi-port single stage converter is introduced. A three-port DC to DC converter is designed in [12][13]. Not only did the converter provide higher voltage yield but also provide multiple modes of operation. However, therein Many switches and complicated control strategies are still available, due to this, it increases the system instability[14]-[17]. A single-stage converter with multiple ports is therefore necessary which is based on impedance networks with these characteristics.

- Component ports for renewable resources connecting
- Assimilation of the scheme for storage of energy.
- Huge increase in voltage output.
- Issues related to shoot-through is nullified.
- Immense performance and flexibility, small size, less price.

Impedance networks are known to have the benefits of immense voltage yield, resistance to shoot through problem [18]-[20]. by using impedance networks technique, an impedance network with two quasi z-source is designed[21], A converter with three ports is suggested here.

This paper coordinated as follows: Section II presents Multi-terminal Z-Source Impedance Network. Section III and IV represents system design and analysis and modes of operation respectively. In Section V, simulation model and verification are displayed. Parameter designs are displayed in section VI and conclusion in Section VII.

II MULTI-TERMINAL Z-SOURCE IMPEDANCE NETWORK

Second fundamental network is continues current qZS network. The difference between basic Z-Source network and continues-current qZS network is only a diode in forward direction is placed in continues-current quasi Z-Source network between the inductor in cascade format, and capacitors are placed in different parallel portion via inductor [15]. The resultant output of current by continues - current qZS network has zero fluctuations or constant current is to be shown so this network is called continues-current qZS network, which is displayed in Fig.3(a). Third fundamental network is discontinues-current qZS network, which is displayed in Fig.3(b). In this network (discontinues current qZS network) has two sets of inductors and capacitors are parallelly connected and a diode is placed between them.

Discontinues-current qZS network's output has Intermittent current and fluctuations present in current, so it is called discontinues-current qZSource network.

As displayed in Fig.4, a distinctive converter with three ports is designed., therein, two qZS impedance networks as represented in Fig. 3(c).

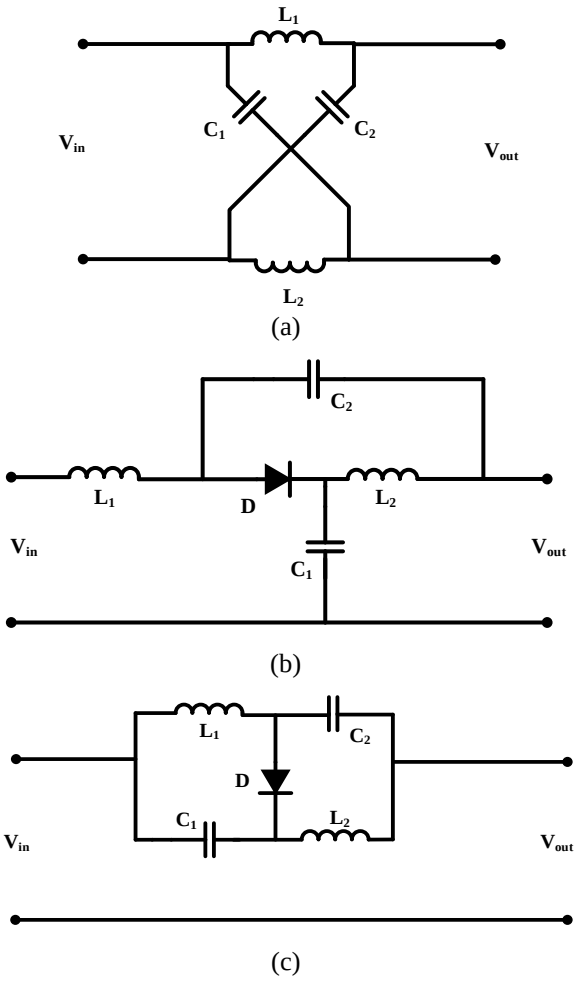

Fig.3 (a) Basic Z-Source network, (b) Continuous-current qZS Circuit, (c) Discontinuous-current qZS network

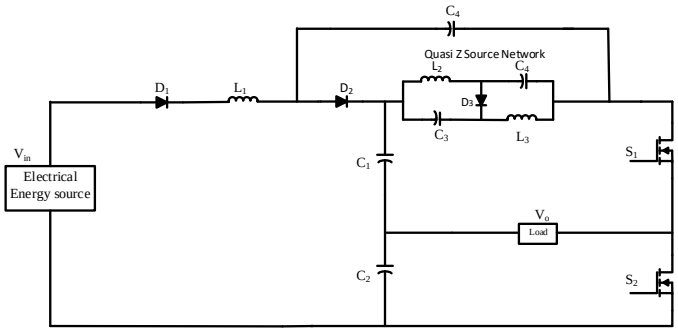
III SYSTEM DESIGN AND ANALYSIS



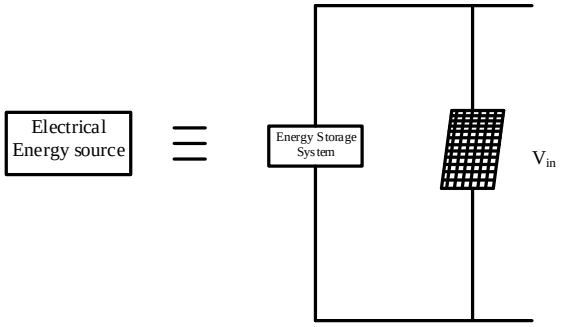


Fig.4 Schematic of the proposed converter

The proposed converter consists of diodes D_1, D_2 and D_3 two switches, S_1, S_2, and a two quasi z-source impedance network composed by three capacitors C_1, capacitors C_2, capacitors C_3, and three inductors, L_1, inductors L_2. The distinctive characteristics of the design are as follows, such as just two three-port switches, few elements, High performance, small size, low price, and high flexibility.

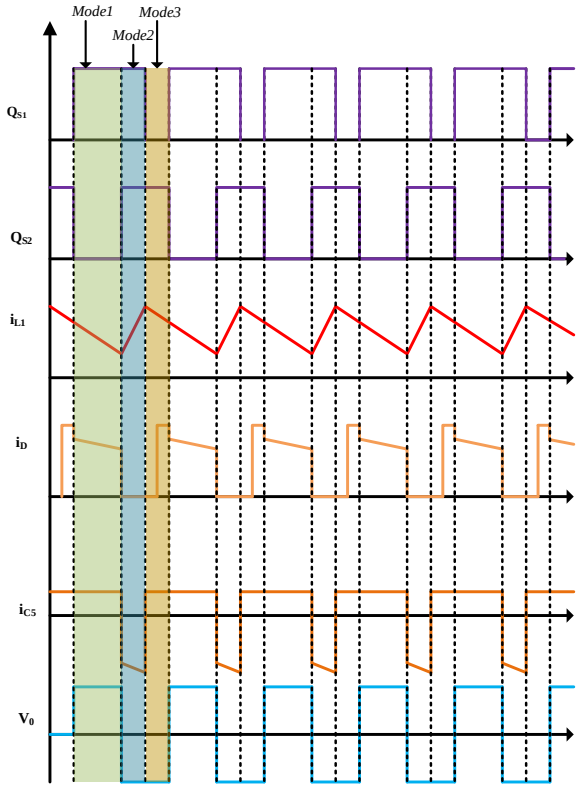

Fig.5 Key waveforms of $d_1 = 0.8$, $d_2 = 0.5$

In all renewable energy instances, the suggested converter can work. The energy from sun that is solar energy can be used as an example for all cases.

- In shiny day when solar energy is generous, it is used to charge the unit.
- When clouds are there and solar energy is limited, the energy from the storage unit is transferred to the load.
- During night time or in rainy days that is in absence of solar energy, the energy from the storage unit is transferred to the load.

Consider that in every case the input is constant by the PV penal or by the energy storage systems.

There are three modes shown in Figs. 6(a), 6(b), and 6(c). Denote d_1, d_2 as the duties of the switches S1 and S2. Assume d1 ≥0.5 and d2 =0.5. Fig.4. Key waveforms of are shown in Fig.5.

IV Modes of Operations

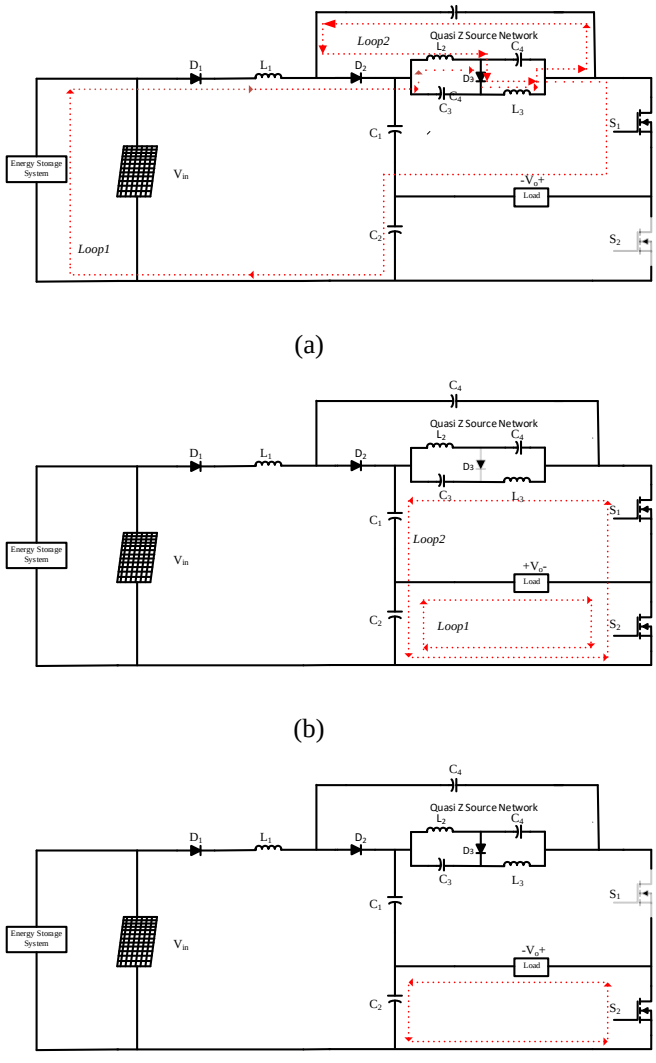

Fig. 6 Equivalent circuits (a) Mode I: S_1 on, S_2 off; (b) Mode II: S_1 on, S_2 on; and (c) Mode III: S_1 off, S_2 on.

- Mode 1: (Fig. 6(a)): S_1 "ON" and S_2 "off" current flow through C_1, load, S_2. In loop2 current is reversed and flow through D_2, L_2, D_3, and L_3 in this mode inductor L_2 and L_3 are charged and discharged simultaneously.
- Mode 2: (Fig. 6(b)): S_1 and S_2 are "ON" C_2 is discharged in loop1 and current flow through D_1, D_2, L_2, D_3, L_3, S_1 and load in loop1. In loop2 C_1 is discharged and current is flow through C_1, C_3, L_3, S_1, S_2 and C_2.
- Mode 3: (Fig. 6(c)): S_1 and S_2 are "ON" C_2 is discharged in loop1 and current flow through D_1, D_2, L_2, D_3, L_3, S_1 and load in loop1. In loop2 C_1 is discharged and current is flow through C_1, C_3, L_3, S_1, S_2 and C_2.

V SIMULATION MODAL AND VERIFICATIONS

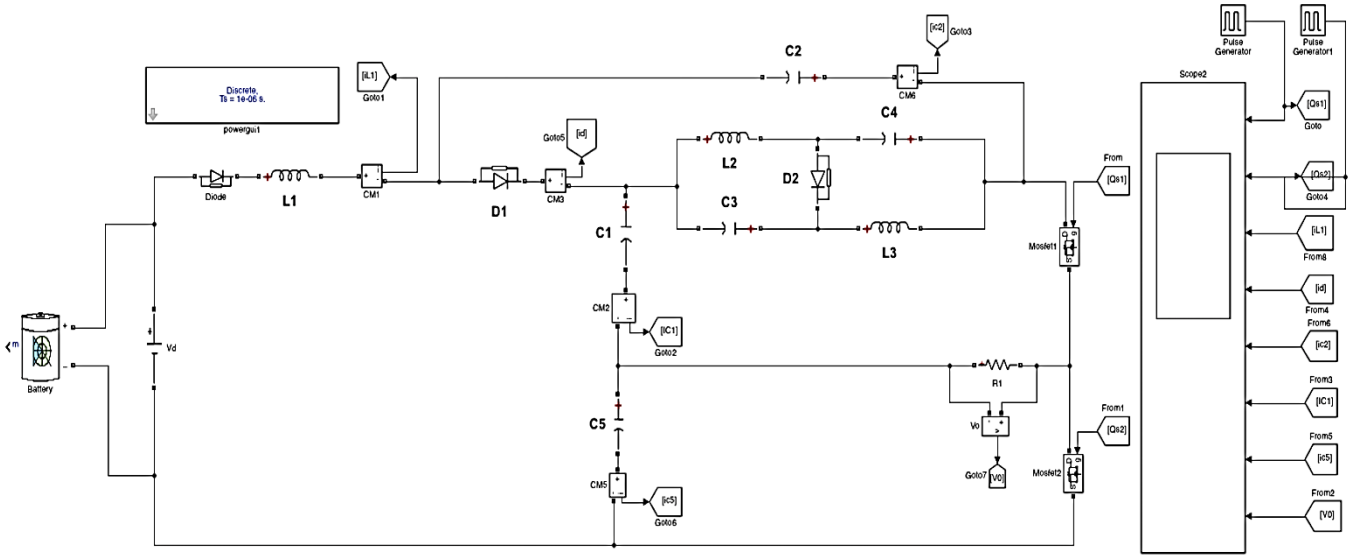

Fig. 7 Simulation model of proposed converter

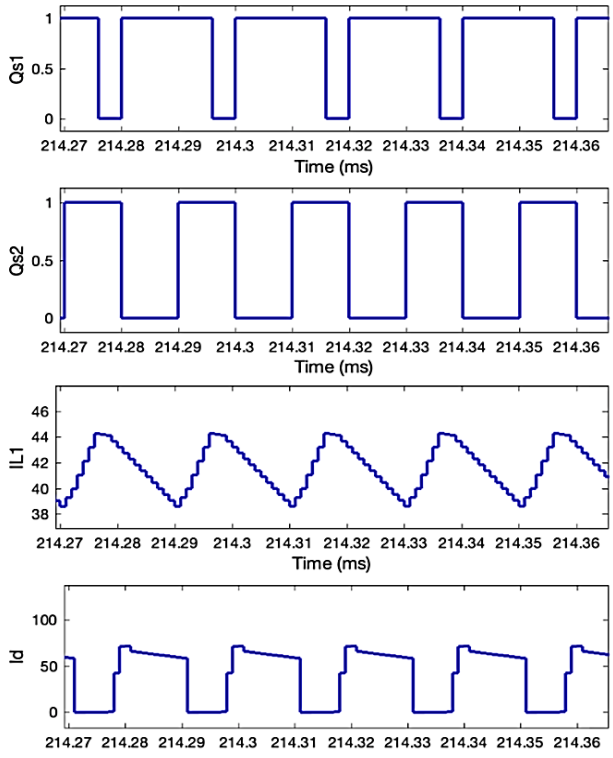
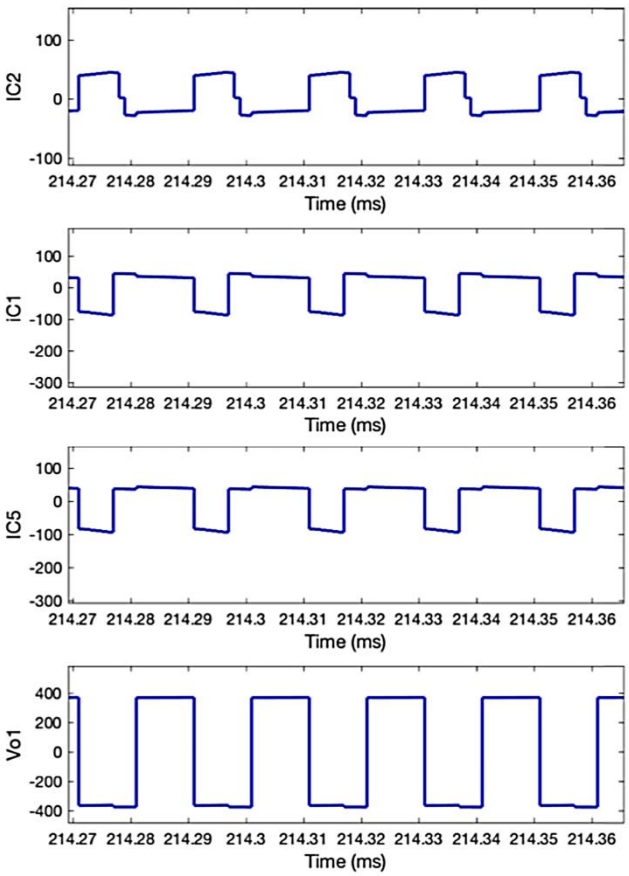
MATLAB software is used for verification to check the validity and feasibility of the suggested converter and the parameters of simulation are displayed in TABLE 1. Simulation results are represented in Fig.8(a) and Fig. 8(b), Which are compatible with the Figs 4 theoretical evaluation. The duty ratio of given switches Q_{s1} and Q_{s2} is d_1=0.8 and d_2=0.5. Output voltage v_0 is symmetric with about ±400V as displayed in fig. 8(a),(b).



(a)



(b)

Fig. 8 Simulation results.

These eight figures depicted in Fig. 8show the driven signals of S1 and S2, currents of D, $L_1(L_2)$, C_1, and C_3, output voltages of V_{o1}

VI Simulation Parameters

Input voltage V_d Switching frequency fs	100V 50khz
Inductors L_1, L_2, & L_3	470µH
Capacitor C_1, C_2& C_3	330µF
Load	50Ω
Active Switch	Power MOSFET
Diodes	PN Junction

VII Conclusion

This paper developed a new topology framework of renewable power applications and power storage units bridging three-port converters. The distinctive topology is defined by a few numbers of elements and a distinctive impedance network structure. It can not only achieve distinct circumstances for the harvesting of renewable energy, but also boost the gain in output voltage with high power storage unit's stability. In order to understand This new topology and its benefits are provided with a thorough assessment. Then, small-signal model is Carried out for converters stable operation. Finally, comprehensive simulation checks are performed. The future scope of proposed model can be extended using voltage stabilizer which gives constant input to the system when the weather conditions changes. It can explore to hardware implementation for boost mode also and can be analyzed for various topologies as unidirectional converter.

***Abstract*—The massive multiple input multiple output (MIMO) system is a prodigious method that could improvise a communication system's capacity with the aid of an increased number of antennas. The fundamental challenges of massive MIMO system are complicated channel modeling, high dimensional channel state information (CSI), and narrow radio frequency chains (RF chains), etc. For solving this problem we introduce deep neural network (DNN) framework for direction of arrival estimation (DOA estimation). Using the information obtained about DOA and gain that is complex, the channel is estimated and mean square error (MSE) performance is evaluated for both DOA and channel estimation.**

***Index Terms*—MIMO, CSI, RF, DNN, DOA, MSE**

I. Introduction

The increase of visualization network infrastructure and the necessity of efficient and sustainable utilization of energy are the key requirements of next generation communication systems. The highly increasing data traffic growth will be the greatest challenge for designing 5G communication networks. [1]. Massive MIMO (m-MIMO) systems can improve a communication system's capacity with the aid of an increased number of antennas [8]. The complex channel modeling, the high dimensional CSI and large number of accessing users, etc [7] are some of the practical challenges faced by m-MIMO. Without introducing efficient schemes, the performance of the system will degrade.

In recent years, various techniques were developed to enhance the capacity of m-mimo. In [4] a full space spatial spectrum sharing strategy is introduced by using two cognitive radio base station (CBS) at adjacent sides of a single cell. A 2-D spatial basis expansion model (2D-SBEM) is used to represent channel vectors, which helps in mitigating pilot contamination and training overhead problem. Then [10] provides several beam selection techniques for beam-space MIMO (B-MIMO) that helps in reducing radio-frequency (RF) complexity of millimeter wave transmitters. In previous researches, deep learning has been proved to be effective for Channel State Information (CSI) localization, channel equalization, and channel decoding. Network traffic control is an essential component for delivering a variety of services and experiences to users in a mobile-centric heterogeneous networks. [5] shows an effective method of deep learning neural networks to significantly improve heterogeneous network traffic control. [16] shows how a Bayesian framework is used in orthogonal frequency division multiplexing (OFDM) systems for joint channel estimation and sampling frequency offset.

This paper organization methodology is described below. Section II outlines the review of literature regarding the earlier researches on the topic. The massive MIMO and deep learning model used is described on section III. Simulation results are presented on section IV and the paper is concluded in section V.

II. Literature Review

The basic MIMO system, its design, architecture, advantages, disadvantages, future scope etc., are explained in [7]. The main advantage of MIMO system is increased data rate by many folds, without any extra bandwidth.

[14] describes how the channel estimation of a m-MIMO system can be done using 1-Bit Quantization. In this system, the Expectation-Maximization(EM) algorithm combined with a sparse recovery method yields better results. In a m-MIMO system a low rank channel estimation is done where the sparse properties of channel environment are exploited is reviewed in [9]. Based on the signal model in [6], for sparse channel estimation, a region of received signal free from interference is used. It yields an estimator which has low complexity and the received signals used on a small scale for estimation.

[8] analyses the performance of Up-Link (UL) and Down-Link (DL) in cellular networks using m-MIMO system. The total number of antennas required to attain maximum efficiency with minimum Mean Square Error (MSE) and Regularized Zero Forcing (RZF) are also derived. The performance analysis using factor analysis is given in [2].

A novel mm-wave frequency transmission scheme exploiting both the concepts of Beam-space MIMO communications and beam selection are discussed in [10]. It resulted in higher power efficiencies than a full system with significant reduction in RF complexity. [11] shows joint estimation of channels and carrier frequency offset in OFDM systems using a statistical framework. Main defect of a MIMO-OFDM system is time ambiguity with channel fading and phase noise. [3] introduces how joint Bayesian estimator and bounds estimated can be used to reduce these defects.

[15] describes the effect of missing sensors in estimating the DOA of the signal using Multiple signal classification (MUSIC) method. It was found that the missing sensors significantly degraded the accuracy of MUSIC. [12] performs a 2-D estimation of DOA using a less complex Unitary Estimation of Signal Parameters via Rotational In-variance Techniques algorithm. It was concluded that estimated accuracy depended on the array configuration and incident directions of the signal.

The channel characteristics of m-MIMO systems are very complicated, so the traditional methods are not capable of recording the real-time changes of channel condition. Because of sharp variations in channel characteristics, the DOA and channel performances are degrading.The CSI of a m-MIMO system can be auto-detected using a machine learning (ML) technique. In 2006 a new technique called deep learning, which can take care of big data and solve complex nonlinear problems effectively was proposed [1], [13].

III. System Description

The three stages of DOA and channel estimation using machine learning for MIMO system - massive MIMO system model, deep learning based estimation for DOA, and deep learning based channel estimation. Fig. 1 shows an up-link model for a massive mimo system, where the base station consists of M number of receiver antennas and a K number of user equipment(UE) where each has a single antenna is used and H is the channel matrix.

A. Model of the System

Here we consider a system model with M number of antennas arranged in a uniform linear array fashion in one base station and K number of UE. The assumption made here is that BS has zero information based on each path of the user. Now the up-link model of user K is shown below [17]

$$\mathbf{h}_K = \sum_{i=1}^{J} g_{K,i}\mathbf{a}_t(\theta_{K,i}) = \mathbf{A}_{t,K}\mathbf{g}_K, \tag{1}$$

where J is denoted as the number of resolvable path and $g_{K,i}$ is the complex gain. Physical DOA of i-th path can be represented as $\theta_{K,i}$ and $a_t(\theta_{K,i})$ is defined as the steering vector. The up-link channel matrix can be denoted as $H = [h_1, h_2, ..., h_k]$.

A precoding based on zero forcing is used here to reduce user to user interface [1], [17].

$$\mathbf{x} = Ps \tag{2}$$

where s is the source code and P is precoding.Then, the received signal is

$$\mathbf{Y} = H\mathbf{x} + N \tag{3}$$

where N is Additive White Gaussian Noise (AWGN).The channel gain and the information about DOA are key characteristics of channel modeling.

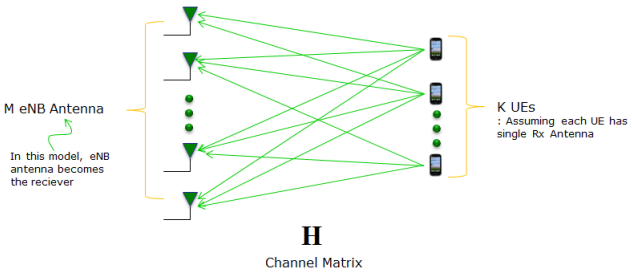

Fig. 1. Massive MIMO up-link model

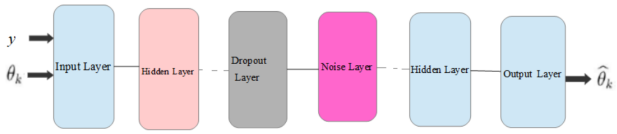

Fig. 2. Framework for DOA estimation based on deep learning

B. DOA Estimation Using Deep Learning

This section illustrates a framework of the massive MIMO system for DOA estimation based on deep learning. Deep learning neural network (DNN) through nonlinear operations and propagation aids for the high computational complexity of massive MIMO system [1].

DNN is the profound form of artificial neural network (ANN). Multiple hidden layers are present in DNN, and each hidden layer consists of a large number of neurons. In the output layer, the nonlinear function uses the weighted sum of all neurons. The sigmoid function and the another function known as ReLU function are the most commonly used nonlinear functions.

$$f_{\text{Sigmoid}}(q) = \frac{1}{1+e^{-q}} \tag{4}$$

$$f_{\text{ReLU}}(q) = \max(0, q) \tag{5}$$

where q is the argument of function.

A framework for DOA estimation based on deep learning is being shown in Fig. 2. There are two stages for the DNN one is for training the DNN i. e., offline learning scheme and the other is online deployment for testing. The so obtained received signal vector Y is obtained depending on a fixed channel matrix H is used as training samples. The received signal Y from all directions is collected based on different channels. The θ_k is generated randomly, which is used as a training set along with Y (i.e., training samples used in DNN). The next stage is online deployment where DOA is estimated and a specific channel model is obtained.

The mean square error for the estimation of DOA parameters can be calculated as

$$MSE = \frac{1}{n}\sum_{j=1}^{n}\left\|\theta_k - \widehat{\theta}_k\right\|^2 \tag{6}$$

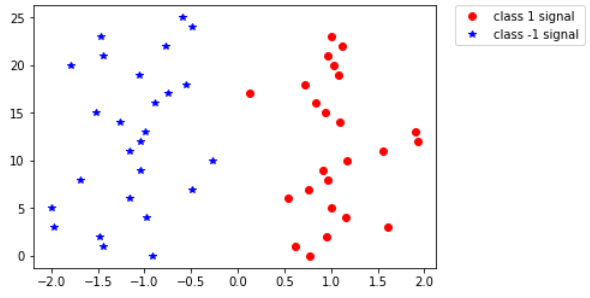

Fig. 3. BPSk in AWGN channel using simple perceptron

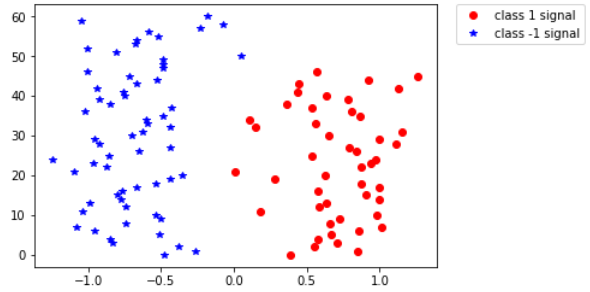

Fig. 4. QPSk in AWGN channel using simple perceptron

where n is the number of samples, and $\widehat{\theta}_k$ is the prediction. For obtaining estimated θ_k, a loss function which is calculated using MSE is as follows

$$L = \frac{1}{K}\sum_{k=1}^{K} MSE \tag{7}$$

The loss function that follows as a part of the DNN framework is calculated using the gradient decent algorithm.

C. Channel Estimation Based on Deep Learning

For obtaining the channel matrix characteristics, a deep learning method is introduced in this section while considering a massive MIMO system. Here, the co-variance of channel matrix having low rank is considered [9]. The channel matrix can be obtained by using DOA information from the previous section and the complex gain. Let us assume that, $\widehat{Y}$ is the output signal vector that is estimated. Loss function, l_1 can be expressed using the following equation:

$$l_1 = \frac{1}{n}\sum_{j=1}^{n}\left\|x_j - \widehat{Y}_j\right\|^2 \tag{8}$$

where x_j is the j-th transmitted signal. Our main aim is to minimize the gap or variation between output of the DNN and the signal that has been transmitted. The performance analysis of channel estimation based on deep learning can be evaluated by using MSE concept.

$$MSE = \frac{1}{Kn}\sum_{j=1}^{n}\sum_{k=1}^{K}\frac{\left\|h_{k,j} - \widehat{h}_{k,j}\right\|^2}{|h_{k,j}|^2} \tag{9}$$

IV. EXPERIMENTAL RESULTS

The performance of DOA and channel estimation is being analyzed in this section. The simulations have been done in Python 3. 6. Tensorflow is used to design and process DNN. A massive MIMO system was taken into consideration, where the base station consists of $M = 128$ antennas and $K = 128$ is the number of single antenna users. They are connected by $P = 5$ resolvable paths. DOA $\theta_{k,i}$ is randomly distributed in space $[-\frac{\pi}{2}, \frac{\pi}{2}]$, and the distance between antennas $d = \frac{\lambda}{2}$. The collected signals from all direction were used as training samples and the sampling interval is $0.01°$.

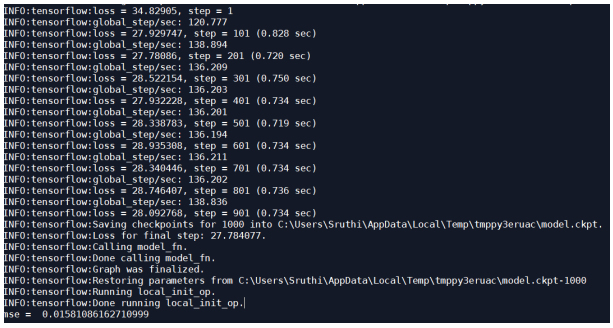

Fig. 5. MSE calculated for DOA estimation when $M = 1$ and $K = 10$ is used

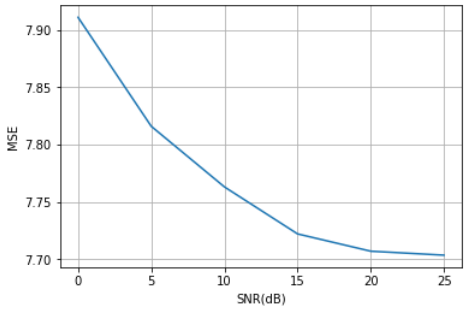

Fig. 6. Mean square error for estimation of DOA parameters when $M = 128$ and $K = 128$

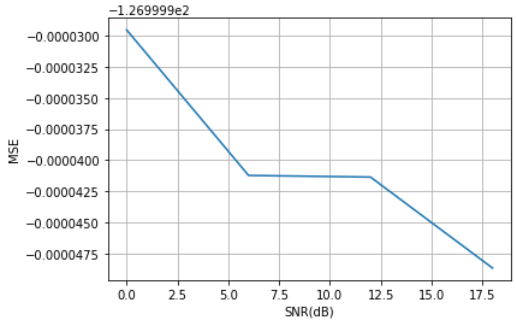

Fig. 7. Mean square error for estimation of channel parameters

In Fig. 3 and Fig. 4 a binary phase shift keying(BPSK) and a Quadrature Phase Shift Keying (QPSK) modulated signals passed through a AWGN channel is classified using a simple perceptron. The number of epochs taken is 1 for BPSK and 10 for QPSK when SNR is 4 and the BER obtained is 0. It is observed that as the SNR value is increased the signal is classified correctly and for small SNR values the classification is not perfect. Fig. 5 shows the mse calculated for DOA estimation. Here a single transmitter antenna is used, and the number of single antenna users $K = 10$. Number of iterations used is 1000 and it is observed that the MSE calculated is 0.0158.

The performance is illustrated in Fig. 6 by plotting the MSE for the estimation of DOA parameters against SNR using the DL technique where $M = 128$, $K = 128$ and here we consider length as $L = 10$ for the training sequence. It could be noticed that MSE value for the estimation of DOA parameters is decreasing gradually when SNR value is increased.

Again, Fig. 7 illustrates the MSE for estimation of channel parameters against SNR using DL method. The number of iterations carried out is 20, the learning rate is set as 0.01 and the batch size taken is 5. It is observed that the MSE first reduces steadily and then it remains constant upto 12dB and then it reduces steadily as the SNR value increases. That means Fig. 7 yields a poor BER rate. The performance could be improved by increasing the count of iterations, batch size and increasing number of training and testing samples. In this simulation the training set comprises 100 examples and for testing we use 20 samples.

V. CONCLUSION

The massive MIMO system is implemented using a deep learning scheme in this paper, where additional antennas are used at the base station and DNN is integrated into single antenna users. At first a massive MIMO system model is constructed and then a DNN is developed, in which many hidden layers are included to increase the ability of representation. This novel DNN is used for DOA estimation and the information thus obtained along with the complex gain information is used for channel estimation. The MSE performance against SNR is obtained for DOA and channel estimation.

In the future, the deep learning model can be further developed to reduce the number of required pilot DOA. Hence, the computational complexity in massive MIMO channel estimation will decrease.

FPGA Implementation of 8-bit SSA Multiplier for designing OFDM Transceiver

Mallapareddi Sagar and Ganapathi Hegde
Department Electronics and Communication Engineering
Amrita School of Engineering, Bengaluru
Amrita Vishwa Vidyapeetham
India

***Abstract* —— In recent technology of digital signal processing applications, we have number of modulation and demodulation techniques. In this domain multiplexing technique is having greatest importance as it has a transmission and reception part with secure systems for communication. Thus orthogonal frequency division multiplexing (OFDM) is superior to other multiplexing techniques, which has multiple carriers with very much robust frequency selective distorted channels. OFDM will have a number of modules such as serial to parallel converter, modulator, IFFT, FFT, demodulator and so on. The Proposed work will concentrate on arithmetic operations in OFDM with re-modified technique using large integer values such as addition, and multiplications. This large integer based arithmetic operation technique were designed using Schönhage–Strassen algorithm (SSA). Thus the proposed method will focus on this SSA algorithm based arithmetic operations with Number Theoretic Transform (NTT) and Inverse Number Theoretic transform (INTT) method. Proposed method of OFDM will replace FFT-IFFT to NTT-INTT method and this application is developed in Verilog HDL and synthesized in Xilinx vivado 15.4. It proved better results in terms of area and delay when compared with conventional design.**

Keywords—SSA,NTT,INTT,FFT,IFFT,Orthogonal frequency division multiplexing(OFDM).

I. INTRODUCTION

In the digital communication technique multi-carrier transceivers is increasing in recent digital world. In this type of communication high speed and secure communication is required to transfer and receive the message [1]. The telecommunication system have multiple signals to disturb a communication bandwidth in series of over-lapping and non-over-lapping bands, thus multiplexing based communication is required to reduce this disturbance which ensures data privacy on un-trusted communications [2]. Thus a statistical multiplexing of variable bandwidth communications is introduced, in this area orthogonal frequency division multiplexing (OFDM) is a high priority one, to transfer and receive the data in high secure communication with multi carrier bandwidth, and it has a capability to divide higher data rate stream into number of lower data rate stream over multiplexed orthogonal subcarriers [3]. OFDM contains QAM or QPSK modulator/demodulator (depending on spectral frequency), FFT/IFFT module, serial to parallel/parallel to serial converter.

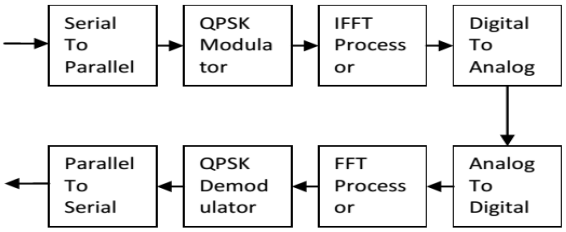

Fig. 1. Basic design of OFDM Blocks.

In the implementation of OFDM technique, it has a lot of arithmetic operations such as additions, subtractions, multiplications and divisions. For more secure communications system will requires a arithmetic operations for data privacy on un-trusted servers. Thus proposed area of arithmetic operations will have efficient schemes to handle large integer multiplications on Schönhage–Strassen algorithm (SSA) [4], [5]. This algorithm proved better results in asymptotic complexity of million bit multiplications in number theoretic transforms (NTT) [6], compared to existing multiplications method of Karatsuba algorithm [7]. This Number theoretic transform (NTT) method is compared to Fast Fourier Transform (FFT) to recognize as viable solution for occupying less area in larger size of multiplications with traditional and different set of twiddle factors. Thus, a NTT/INTT method will have a capability to replace FFT/IFFT in OFDM technique with same modulation and demodulation technique [8]. Following manner the remaining portion of the paper is configured. Section II reviews the SSA algorithm with using NTT and INTT method. Section III describes the proposed method OFDM with INTT/NTT Integration with QPSK Modulation and Demodulation. Section IV gives the detailed results and experimental implementations. Finally Section V gives the conclusion of this paper.

II. RELATED WORK

The SSA Algorithm is best one for multiplying operands which has maximum word length close to few million bits [9]. Traditional multiplication methods, Karatsuba-Ofman method, Toom [10] -cook [11] method is not going to work as the word length increases. Thus, this SSA algorithm of large integer multiplications [12] achieved through NTT/INTT method, which is described in Algorithm 1.

Algorithm 1 : Schönhage – Strassen algorithm

// Inputs :P (multiplicand, u bits), Q(multiplier, u bits), B(base=2^b)
// Output : Z=P x Q
{

1. Initialization: Decompose P and Q, respectively, into a sequence of digit p_n and q_n, $0 \le n < M$, using base B. Then assign $p_n=0$ and $q_n=0$ by zero padding for $M \le n < 2M$.
2. $P_k = NTT(p_n)$, $Y_k = NTT(q_n)$;
3. $Z_k = P_k \otimes Q_k$; // point-wise multiplication
4. $Z_k = INTT(Z_k)$;
5. carry = 0;
6. for i =0 to 2M-1 { // resolving carries computation
7. sum = z_i + carry;
8. sb_i= sum mod B; carry = |sum/B|;
9. }
10. return $Z= \sum^{2M-1} sb_i \times 2^{ib}$;
11. }

Algorithm 1 describes complexity of two integer multiplication of X and Y and output Z with respect to 2^b. Once initialization of decomposed input bits X and Y into the sequence of digit X_n and Y_n with respect to modulo M. This inputs will convert it to X_k and Y_k as per NTT and INTT method of Frequency to time conversion and time to frequency conversion, the output data will come from point wise multiplications, and finally resolving this carries computations by using modulo 2M-1, and return the output value in Z .

III. PROPOSED METHOD OF OFDM WITH NTT/INTT

In this Proposed method of orthogonal frequency division multiplexing (OFDM) [13] technique which carries a number of frequency bands, in a single band of subcarrier, which carries a user information in differentiating form of various spread spectrum technique such as FDM, OFDM, COFDM, VOFDM, WOFDM, and so on. This OFDM technique will has a multiple access and multiplexing method of user data streams onto downlink and uplink in sub-channels.

A. OFDM Transmitter

In this OFDM Modulation Technique started from Serial to parallel converter, this converter will convert the user data of multi-bit into single bit, then the second step needs some modulation and demodulation technique, here this design will have QAM-QPSK 4 Quadrant Modulation and Demodulation will integrated, The output of QPSK data will give to NTT-INTT module as per real and imaginary conversion through fading block to added error signal, then output of INTT module which gives a modulated data is given to DAC module to transmit the modulation signal. In this Fig.2 block diagram will describe this flow of OFDM modulation.

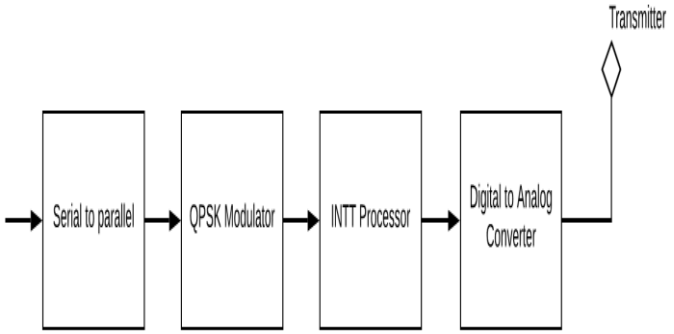

Fig. 2. Block diagram of basic baseband OFDM transmitter with using INTT.

In this QPSK modulation is a variation method of BPSK modulation, it will have a Double side band suppressed carrier modulation scheme, here it will describe in 4 Quadrant with using quadrant phase angle method. Output of serial to parallel conversion block will alienated into two signal such as SIN and COS wave, it will multiplied with encode TX module with respect to carrier Oscillator, and finally added with this two output of SIN and COS, these modulation signal will be taken from here, Fig.3 will show this flow of QPSK modulation.

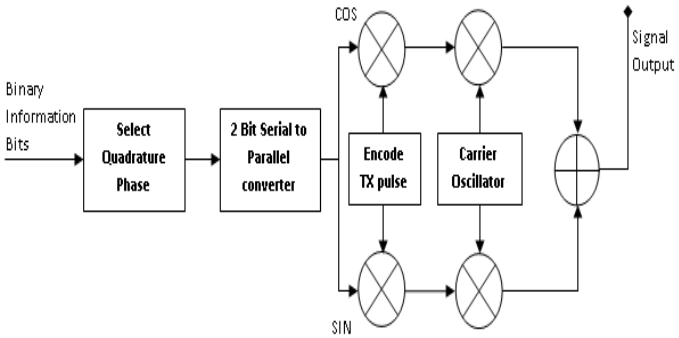

Fig. 3. QPSK Modulation.

B. OFDM Receiver

In this OFDM Demodulation[14] Technique ,it receives the input from transmitter and it is given to analog to digital converter, this digital data will process in NTT block with same in the method of IFFT its regarding frequency to time, this output data will give to QPSK demodulation to split and identified the quadrant to take a digital values, these digital n-bit value will give to parallel to serial converter, and these final data will checked in Bit Error Rate (BER), Fig.4 will describe a OFDM Demodulation.

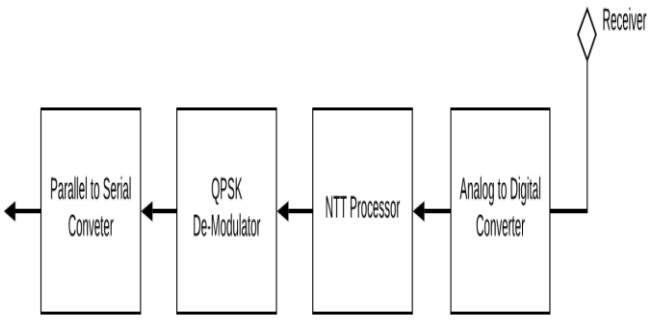

Fig. 4. Block diagram of basic baseband OFDM receiver with using NTT.

In this block of Fig.4 will have a QPSK demodulation after the NTT Processor with frequency to time conversions, in this QPSK demodulator will determine the phase changes from the modulation of SIN and COS, and it will identified four possible states such as 0, π, +π/2, -π/2. Fig.5 will describe this quadrant phase shifting method in π/4.

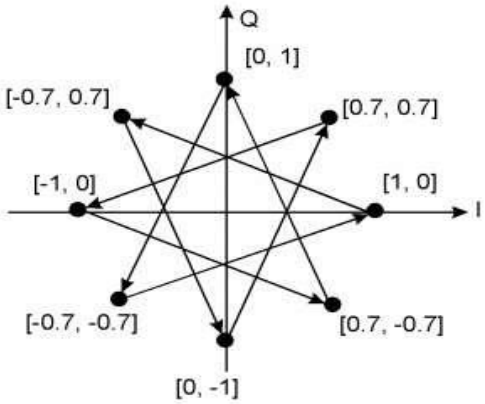

Fig. 5. π/4 shifter QPSK Constellation.

As per this Quadrant phase shifting QPSK demodulation will consider and recover the original input information's with help of Carrier recovery module, low pass filter, symbol timing recovery, decision circuits, multiplexer, Fig.6 will describe this in details, how this demodulation will happen in QPSK. As shown in Fig.6, the input signal of modulation will received to BPF (Band Pass Filter), it will reduce the noise in upper and lower range of input signal, and the signal will pass through carrier recover circuit, such as the numerical control oscillator will take to correct the error signal and generate the high frequency noise using COS and SIN multiplier, after multiplier the output signal will give to low pass filter (LPF), and we get the noise reduction output, it will give as a input of decision circuit, the decision circuit will find the range of frequency changes as per the modulation and generate the differential signal, those differential output will multiplexed and taken as a output in recovered signal.

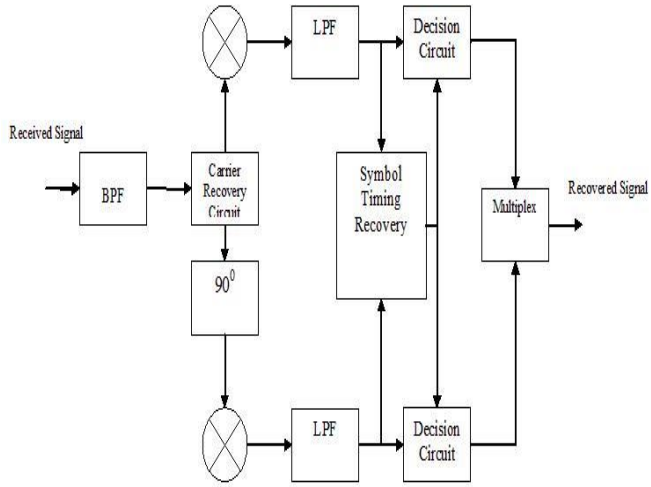

Fig. 6. Block diagram of QPSK Demodulator.

IV. RESULTS AND EXPERIMENTAL IMPLEMENTATION

Implementation of this OFDM transmitter and receiver using NTT-INTT module and QPSK 4-Qudrant modulation is done separately and tested on FPGA, and then both the system were integrated to form single system. Here we have given a input data in a .hex file, its having some hexadecimal data, it will readout from file reading code and given into QPSK8_NTT_MOD at 8-bit with including carrier signal generation from voltage control oscillator, this file reading method and carrier signal generation given in test bench of this code.

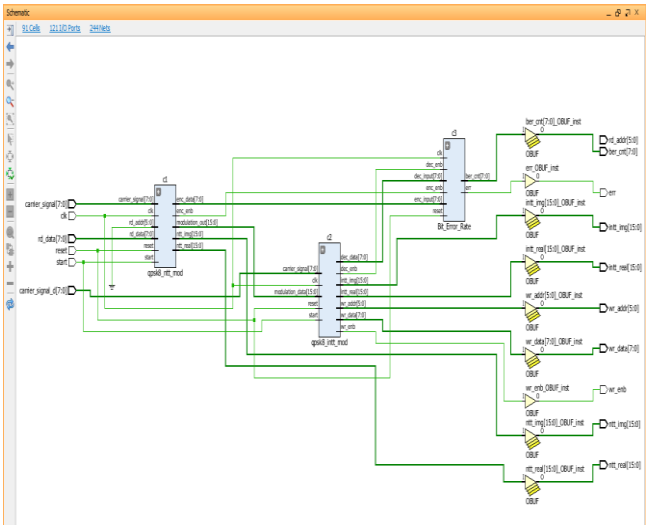

Fig. 7. OFDM Transmitter and Receiver Top module.

The top module of OFDM transmitter and Receiver as shown in the Fig.7 it contains QPSK8_NTT_MOD, QPSK8_INTT_MOD and BER Testing.

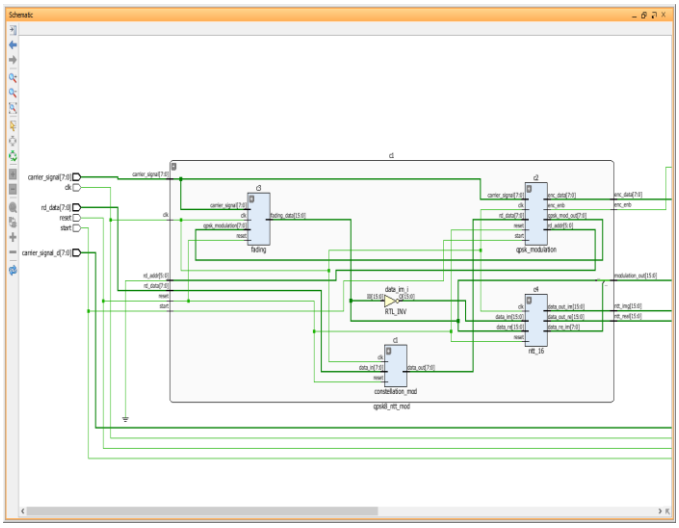

Fig. 8. OFDM Modulation.

As shown in Fig.8 the QPSK8_INTT_MOD block will contain constellation modulation, QPSK modulation, NTT_16 point and Fading code for adding the errors. Fig.9 shows QPSK8_NTT_MOD block will contain INTT_16 point, QPSK Demodulation, Constellation Demodulation, this modulation and demodulation code will give a data to Bit Error Rate code, this bit error rate will receive this data, and sampled as per the demodulation time, then it will compare both modulation and demodulation data and given the error output for testing.

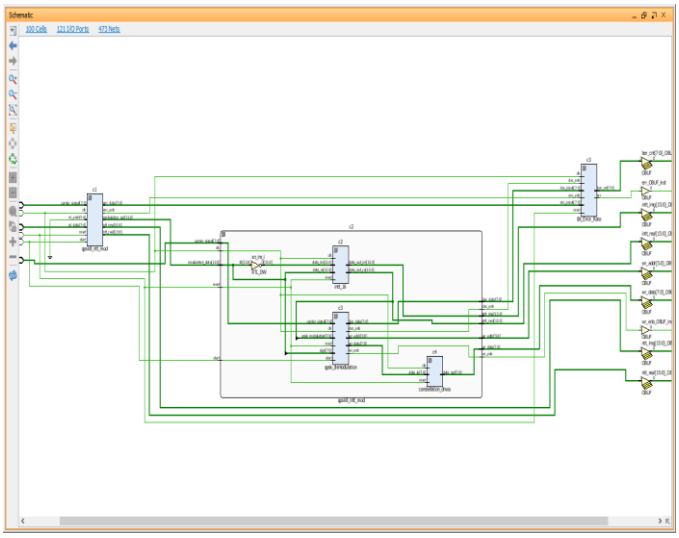

Fig.9. OFDM Demodulation.

This system is designed completely on Verilog HDL and Synthesized on Xilinx vivado 15.4.An extended work of SSA multiplication is done separately and the simulation result including the synthesized diagram of SSA multiplier is shown in Fig.10 and Fig.11 respectively. In SSA multiplier output as shown in the Fig.10 we have taken two numbers a=98 and b=2 and the multiplied output is 73mod123.

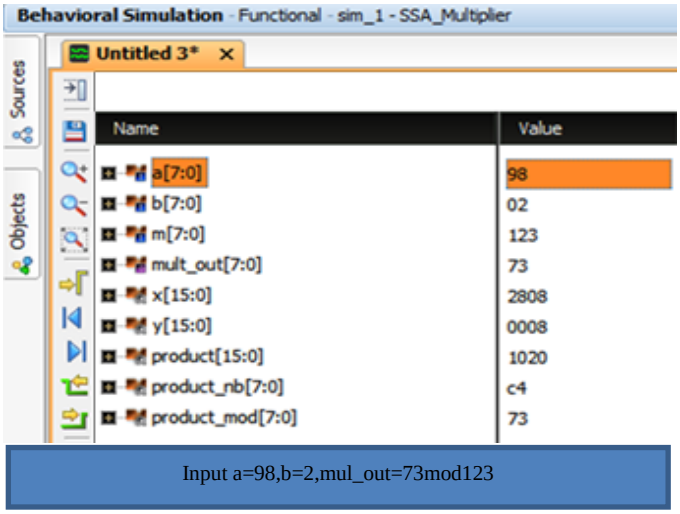

Fig. 10. SSA MULTIPLIER simulation results.

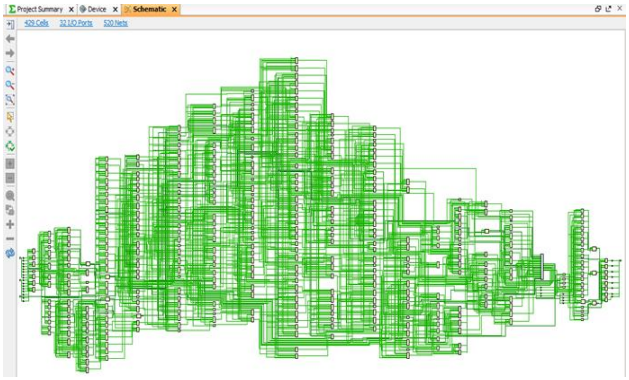

Fig. 11. SSA MULTIPLIER synthesized design.

Table I. Area and Delay Comparison

Parameters	Number of slices	Number of LUTs	Delay(ns)
16 Point NTT	969	1636	25.847
16 Point INTT	907	937	24.503
SSA MULTIPLIER	2107	1301	63.9211
Proposed OFDM system	2557	4717	77.268

Table II. Area and Delay Comparison

Parameters	Number of slices	Number of LUTs	Delay(ns)
16 Point FFT	1168	2304	30.687
16 Point NTT	969	1636	25.847

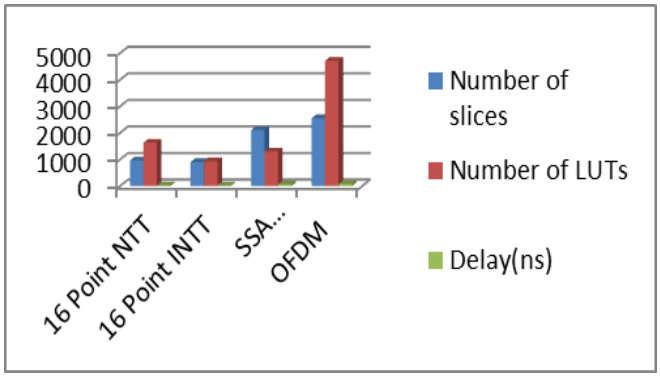

Fig. 12(a). Area and Delay Comparision.

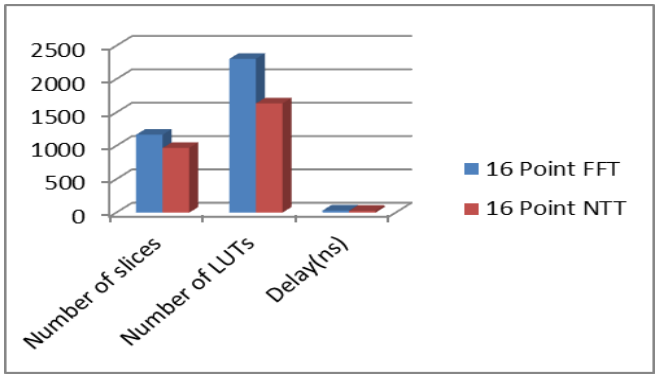

Fig. 12(b). Area and Delay Comparision.

In the Table I the delay and area comparison of entire proposed OFDM system is given. Table II clearly shows that NTT consumes 29% less LUTs and 15.77% less path delay as compared to FFT [15]. The bar graph shown in the Fig.12 (a) and Fig.12 (b) for the Table I and Table II respectively. This certainly shows that the overall OFDM area and delay can be reduced using the proposed method and also provides more computational features.

V. CONCLUSION AND FUTURE SCOPE

In this research work, we explored feasible solution of OFDM modulation and demodulation technique with low complexity SSA based multiplication of large integer focusing on FPGA implementation . We have designed and proved the performance of QPSK 4 Quadrant modulation and demodulation technique with NTT-INTT modulation and demodulation in OFDM using SSA algorithm. Finally proposed method shows that NTT consumes 29% less LUT's and 15.77% less path delay as compared to conventional method of FFT.

Future research may include more optimization of design using advanced algorithms to reduce overall power and delay. Thus this OFDM methodology is suitable for all digital signal processing applications for transmission and reception of large data with less bit loss in high speed communications.

***Abstract*—In the last few years, information and communication technology market has been witnessing rapid growth. In future, 5G Service Based Architecture (SBA) with a multitude of key enabling technologies are expected to provide a wide range of services such as rapid emergency response, virtual hospital kiosks, wearable devices, autonomous vehicles, etc. With the proliferation of tiny IoT devices and drones, it is envisioned that the network densification will take place in future 5G networks. This paper provides an overview of location module co-located at the 5G gNodeB (gNB-Base Station) to deliver location information in the dense 5G network. The location module provides opportunities to deliver effective location information from the network side together with popular navigation tools and applications like Google maps. The paper also addresses the design of an example use case and developed proof of concept of Platform as a Service (PaaS) for drone operations in 5G.**

***Index Terms*—5G, 5G SBA, DoA estimation, API, Platform, Drone Services.**

I. Introduction

Nowadays location-based services and technologies are rapidly increasing but applications such as autonomous cars, telemedicine and emergency services need precise location services [1]. Currently, these location data are obtained from the Global Positioning System (GPS) and then provided to the Over-The-Top (OTT) Applications. This information is used to provide several location-based services including navigation and route suggestions etc. Service Providers (SPs) or Network Operators use the information from the GPS through the network signaling procedures to cater to the needs of emergency calls [1].

In future, the 5th generation communication technology (5G) will transformation in to a new set of technology and service capabilities for a wide variety of vertical industries such as automotive, healthcare etc. 5G will become unified network to provide new applications and services across different vertical sectors. In recent years, there has been significant attention gained in developing a vertical for smart cities. In urban scenario, sources are denser, tightly coupled and always connected to the internet. Ubiquitous coverage in an ultra-dense environment is provided with the help of the densely deployed small cells and macro cells [2]. Fig. 1 explains the current location techniques and the requirements for delivering location information in 5G networks.

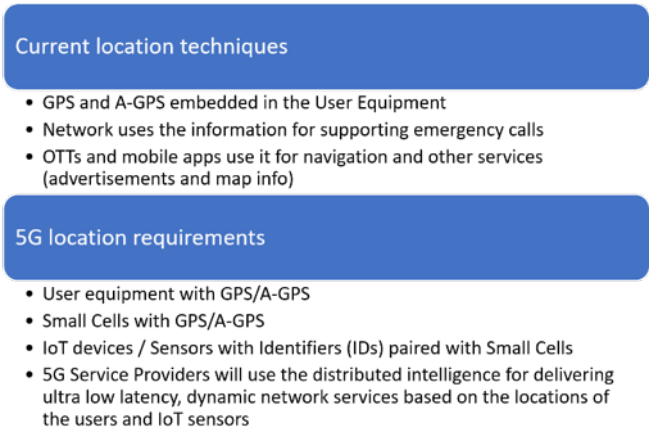

Fig. 1. Existing Location Techniques and 5G Location Requirements

From the service point of view, the 5G Core Network (CN) is more important because it provides functions such as mobility, authentication, security and session management. Now that the 3rd Generation Partnership Project (3GPP) standardized the core network to SBA [3]. The SBA enables globally connected services and platforms to meet the demands of different vertical industries.

The paper is organized as follows: Section II of the paper explains 5G key enablers and background on the location module. Section III explains about the utilization of API in 5G SBA. Section IV explains the architecture of the location module in the network. Finally, 5G SBA Platform as a Service (PaaS) use case has been outlined followed by summary and section V cover the paper conclusions.

II. 5G Enablers and Background on the Location Module

The key enablers in 5G are Network Function Virtualization (NFV), Mobile Edge Computing (MEC), Software Defined Networking (SDN) and Application Programming Interface (APIs) [4]. Fig. 2 shows the illustrations of key enablers in 5G.

- **NFV** mainly transform the functional modules of a network into network function software and instantiates at the right time when needed.

- **MEC** is introduced in the 5G core network to improve the service environment and the user experience by virtualized server platforms for reducing the network traffic and signal load in the core network [4].
- **SDN** is a foundation layer that enables SPs to move workloads in a virtualized network. SDN provides agility, flexibility and availability thereby offering the ability to spin-up new services dynamically.
- **APIs** plays a vital role in the delivery of services to the 3rd party with the help of Network Exposure Function (NEF).

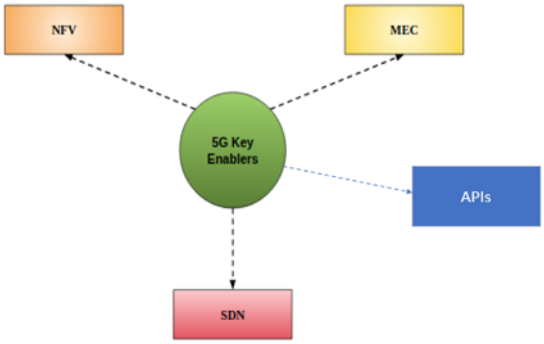

Fig. 2. Key enablers in 5G

A. Background to the Location Technologies

OTT provides applications to offer services such as navigation, messaging, teleconferencing, video and music streaming, etc. OTTs are the stakeholders in SP network. OTTs need user location to offer better services like video recommendation, route suggestions, automated call and video quality improvement. These OTT use GPS modules available on the devices for location information. GPS based locations are accurate only up to 8m [5].

Fig. 3 explains how the OTT collects the location data from devices using the GPS module. Let M1 and M2 be two mobile handsets with GPS module. Consider that the user of M1 device is searching for a video in the OTT application. The OTT application will request the built in GPS module for the location and time data. The module receives the beacon signal from at least four satellites and these beacon signals are used to extract the location coordinates and current time [6]. The location coordinate and time data will be given to the OTT server. The OTT server has algorithm to sort the video as per the user request, location, date of upload and the users interest from his recently watched videos. The user gets to see video that is more relevant to him [7].

OTT can provide the service through the network but they cannot assure any quality in the services. The quality in the services is handled by the SP. It depends on the signal quality, bandwidth availability, etc. 5G technology will utilize Internet of Things (IoT) devices deployed for different applications such as Smart City air quality monitoring, Smart Healthcare wearables, Telemedicine Kiosks, Emergency Response services, Surveillance Cameras, Traffic Signals, Point

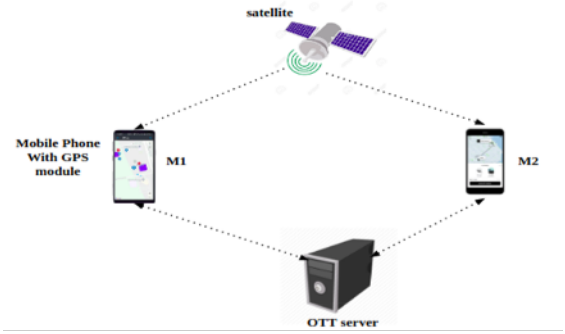

Fig. 3. GPS based location services used by OTTs

of Sale machines. Locating these devices using GPS is near impossible activity. The tiny IoT sensors may not have the hardware capability to host GPS receiver. To overcome these challenges, distributed location management is required from the 5G network side. The paper proposes a location module to improve the location services delivered by the OTT. The Location module is co-located on the 5G Base Station servers (gNB) and Sensor Gateways.

III. Utilization of APIs in 5G SBA

Currently, 3rd Party applications communicate with the network server using the APIs. As shown in Fig. 4, in the 5G network, APIs are expected to be used widely at the remote cloud and edge of the network. The APIs are central in the overall service delivery and bridge the developers to the network capability and provide secure access to the SP database [8].

Representational State Transfer (REST) and Simple Object

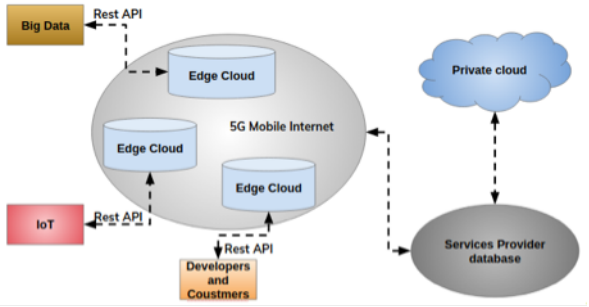

Fig. 4. Role of APIs in 5G SBA

Access Protocol (SOAP) are the most commonly used API services. REST API will provide functionality to handle and deliver the data. The client application can create, obtain, list, or modify the server data by using the HTML protocols such as GET, PUT, POST and DELETE. XML and JSON are the most commonly used data format in APIs. XML is a markup language that is capable to display text data. JSON is more human-readable format which deliver the data more in the form of data structure in the modern programming language [8]. In 5G, the APIs will play a vital role in the service delivery.

IV. Architecture for Location Module in 5G SBA

Location module supports the functionality of localization engine which can deliver more accurate location compared to the other localization techniques that uses GPS. The location module co-operates with a direction finding and beamforming module within the 5G gNB. The super-resolution techniques provide the directions of the users as well as the small base stations. It is also anticipated that the small cells within the network provide their own locations using embedded GPS module. The IoT devices within the proximity of small cells will be coupled with the sensor identifiers (IDs). The overall locations are collected by the network and converted into detailed location map which will include IoT devices and sensors deployed in the network. All information are stored in SP database to generate intelligent maps. Fig. 5 gives an overview of location engine architecture in 5G SBA. Location engine is enabled by the following:

- **GPS Info:** Collect location information with GPS and provide to the OTTs.
- **Radio Resource Management (RRM):** RRM coupled with network intelligence will map sensor IDs to small cell locations.
- **API and NEF:** APIs interacts through NEF to securely provide location information to 3rd party applications.
- **Beamforming / Direction Finding:** Helps to estimate angles of arrival of different sources in the network.

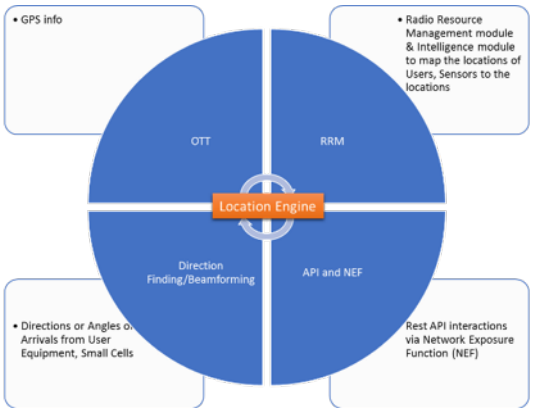

Fig. 5. Location Module Architecture in 5G SBA

The software architecture of the location module for 5G SBA in described in Fig. 6. The software design is done using the Python programming language. It consists of 3 major parts such as Location data storage , Location generator, REST API, Visualization Dashboard.

- **Location Generator:** In the location generator the angels and distances of user equipment estimated from the small cell will be converted to the latitude and longitude of the of the user equipment .
- **Location Data Storage:** The coordinates of the devices as obtained from the location generator, device id, base station to which the device is connected is stored to the database at MEC.

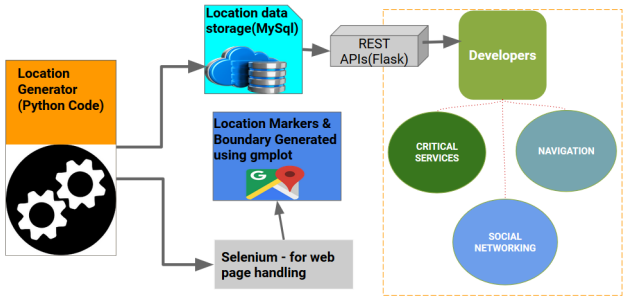

Fig. 6. Software architecture of the location module

- **Visualization Dashboard:** Visualization dashboard at the SP side will help the operator to track the users or devices in real time.
- **REST API Services:** The REST API provides the location data from the database to the 3rd party applications. 3rd party application developers use the APIs to improve the location accuracy in their Applications.

The following section explain the proof of concept and use case developed to showcase the functionality of the 5G SBA and Location module in drone rental application

V. 5G SBA Platform: Use Case and Proof of Concept for Drone Rental Services

Platforms are one of the key enablers in 5G to support applications and provide different services on the cloud. Platforms are scalable, flexible and dynamically programmable where many network functions are built, configured and deployed based on the network, traffic and use case dependencies to enable service [9]. Platforms offer APIs to provide Platform as a Service (PaaS) to deliver real-time location information, which is reasonably challenging. This paper designed an example use case and developed proof of concept for 5G SBA Platform which can be utilized by drone operators.
Drone or quad copter is a lightweight and flying object that can be used in various applications such as on air seed sowing for the large cultivation field, remote monitoring the cultivation field, cargo delivery in e-commerce, emergency response etc. With the current generation of communication, drone services are not widely established mainly due to the poor coverage and connectivity [10]. The drone services will become a reality with 5G enabling deeper coverage and connectivity [11]. Fig. 7 shows the proof of concept architecture developed for the drone rental service in 5G.

A. Drone Rental SP Infrastructure

The service provider infrastructure consists of an application server and a dashboard. The server handles the user information and location data of each drone given to the users. The dashboard, displays the live location of the drones for tracking and health status of individual drones.

B. 5G SBA providing NEF capabilities to APIs

5G SBA consist of NFV which enables different services such as enhanced Mobile Broadband (eMBB), massive Machine Type Communication (mMTC) and ultra-Reliable Low

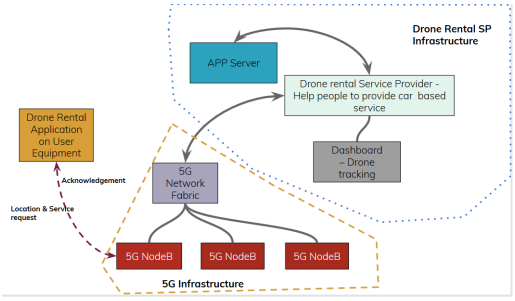

Fig. 7. Architecture developed for Drone Rental Service

Latency Communication (uRLLC) to the 3rd parties [12]. Each drone will be connected to the network using 5G small cells. By using the location engine, the location of each drone is estimated and the data is stored to the database. As shown in the Fig. 8 by using the SPs APIs, the drone can be tracked more precisely with data stored in the SP database. REST API provides location data from the database to 3rd party applications securely via NEF.

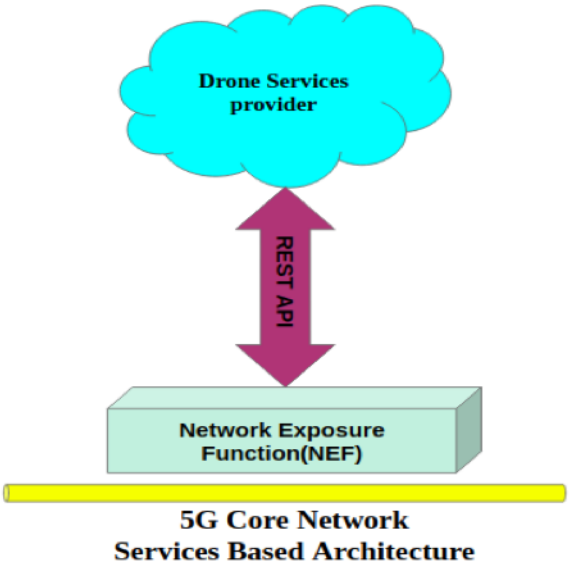

Fig. 8. Service Provider Infrastructure

C. User Interface for real time tracking

It is expected that all the drones are tracked by the SP using the location engine explained previously in this paper. The client application in the User Equipment (UE) will receive the location of the drone through the REST APIs from the drone SP database. This will help the owner of the drone to locate it, get the state of charge, remaining flight time, etc. The client application also offers drone service request, payment and reservation. Apart from the mobile application, the website offers drone services for the drone users to check the availability and reserve drones online. The web page also supports payment option. The web page was designed using the HTML and PHP. Snapshot of the web page is shown in Fig. 9. The page to locate the drone was generated using the location module that co-located with the 5G Base station. Fig. 10 shows the mobile application developed as a proof

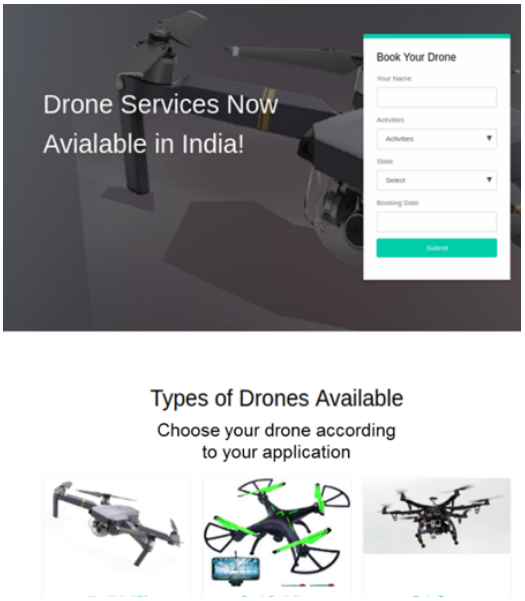

Fig. 9. Webpage provided by the drone rental company

of concept to demonstrate location tracking of drone. The blue markers represent the drones, the red marker represents the base station to which the drones are connected and the blue layers represents the coverage of the base station. Drone owners can use this application to track the drones by using the APIs provided by the SP. Third party applications can use the APIs to offer additional services to the customers along with the services offered by the drone provider.

The location services play a vital role in tracking the drones

Fig. 10. Mobile Application for real time tracking of Drones

and monitoring its health. Platforms allow users to remotely control the drone operation using the client application. Advanced Machine Learning algorithms can be applied to automate various services such as autonomous address discovery, navigation and product delivery. Fig. 11 shows the example

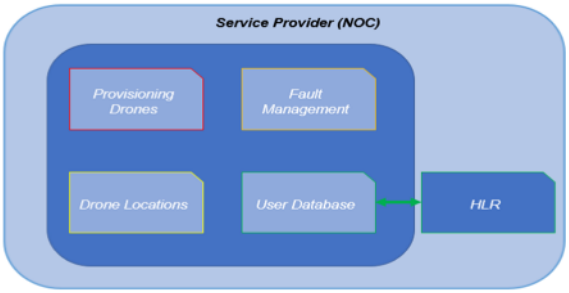

Fig. 11. Example SP dashboard operational aspects

SP dashboard at the Network Operation Center (NOC). The SP dashboard has the following modules:

- **Home Location Register** (HLR) is the primary database that holds the information of the subscribers. HLR is maintained by the 5G SP and it contains user information such as name, address, account details, data balance and settings.
- **User Database** is managed by the drone service provider to store details of the users. Details such as name, address, type of service requested, history of service opted, payment details and
- **Drone Locations** is provided by the location module in real time.
- **Fault Management** module frequently checks for the health of the drones and reports it to the NOC.
- **Provisioning Drones** module initiates the licensing and monitors the consensus of the user agreement. If any violation is observed, it initiated auto return function where the drone is returned back autonomously to the service provider.

VI. Conclusion

This paper proposes a location module for 5G communication technology. The proposed module supports the 3rd party mobile applications and OTT Services by providing enhanced location data of the user or IoT devices. By using the location modules APIs, the OTTs or applications can get the accurate location data for devices from the SPs. By using this method, it is ensured that the personal details of the devices or consumers are protected by the SPs. The paper concludes by showing example APIs and Platform framework that can be utilizing the 5G SP. It is anticipated that the proposed SP based location framework will help the OTTs to provide more secure location based services without exposing the user identity.

***Abstract*—VLC is need of high-speed data rate transmission for next-generation networks. LOS communication is a must for a high-speed VLC communication system. In the VLC system, we have formed a high-speed Visible light communication system utilizing WDM, and PI scheme for broadcast information in the visible form of eight channels, each one bear 10 Gbps data accomplished by the VLC link of 160 m. We have compared performance improvement using AMI coding and duo binary coding. The bit rate of 10 Gbps up to 160m has been investigated using Q factor in eye diagrams and bit-error-rate (BER) which is targeted to achieve the value greater than 7 and less than 10-9 respectively. VLC system simulation is done on Optisystem 15.**

Keywords—Alternate mark inversion; Duobinary, Wavelength-division multiplexing; Polarization interleaving; VLC communication

I. INTRODUCTION

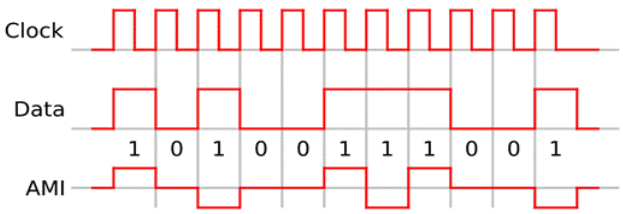
Visible light communications (VLC) systems is a data communication which uses visible light between 400-800THz (780-375nm) ranges in the electromagnetic spectrum[1]. In this paper, the laser diode is used as a source in the WDM (Wavelength division multiplexing) PI (polarization interleaving) Visible light communication system[2]. VLC (Visible light Communication) using WDM (Wavelength Division Multiplexing)–PI (Polarization interleaving) Transmission System for long distance transmission and high-speed data LASER is used[1]. A LASER pointer, with alternate mark inversion and Duo binary Coding, has better accomplishment in VLC systems due to the high distance along with luminous beam concurrence. High-speed and Long-reach Hybrid AMI-WDM–PI is used in VLC communication system [3]. In this paper, we compare AMI Coding and Duobiny coding with the help of WDM-PI VLC system [4-6]. In this paper, we compare between AMI (alternate mark inversion techniques) and Duobinary techniques using WDM (Wavelength Division Multiplexing)–PI (Polarization interleaving) Visible light communication System.

1) Coding

In this paper, we compare two coding techniques, Alternate Mark Inversion (AMI) and Duo binary coding with the help of WDM-PI VLC system. These two techniques are

A. AMI Coding

AMI is Line coding techniques. AMI is a bipolar encoding in which if 0 is generated then it touches reference line means neutral (zero) voltage represents binary 0 and if 1 is generated then alternating positive and negative voltages show binary 1 [7].



B. Duobinary Coding

In communication, Duobinary is also a return-to-zero (RZ) line coding and duobinary coding is also bipolar encoding techniques, in which three values are used which are +,- and zero in which two are nonzero values. this type of signal is the duo binary signal [7-8].

2) Wavelength Division Multiplexing:

- WDM is an analog multiplexing technique to combine the optical[8] signal.
- Light has a property that keeps it from mixing and allows it to be separated into its wavelength.
- To utilize the high data rate capability of FSO, WDM has been devised.

• Wavelength division multiplexing method used to increase the capacity of the system[9].

II. SYSTEM DESCRIPTION

The integrated VLC WDM–PI technique designed is displayed in Fig 1 and architecture is simulated using OptiSystem™15 software.

1) AMI System:

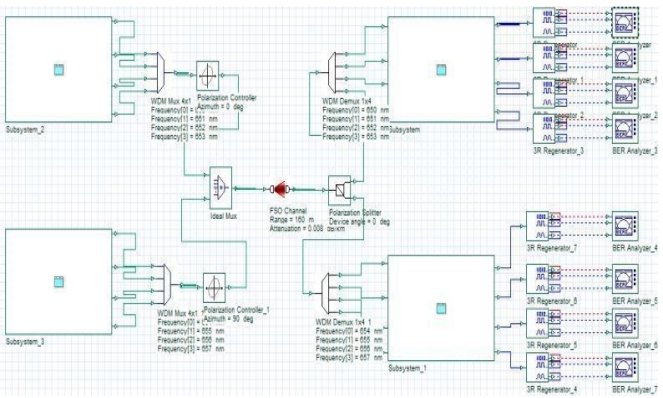


Fig. 1. Proposed 10 Gbps AMI–WDM–PI VLC communication system.

B. Transmitter

Implementation of Tx stage of AMI FSO Visible Light Communication System using AMI-WDM-PI is shown below in figure 2[3,9]. In the transmitter side firstly bit sequence generator is present which transmit the bit sequence after that dual port Mach-Zehnder modulator is present which modulated the binary sequence. In the block diagram, signal modulates over illuminated sources of 0 dBm and wavelength of 650 nm along with 1 nm separation. Delay-and-add and subtract procedures are used to produce AMI line codes [2]. Data are transmitted through NRZ pulse generator, as in on–off keying [10-11].

In the below block diagram even and odd channels are present in the form of data channels and this even and odd channels are individually multiplexed[2]. Polarization controller maintained the two multiplexers output. This two polarization output give to ideal MUX input and this MUX output combined with the channel in the form to switch the azimuth specification of the even and odd channel to orthogonal signals[2].

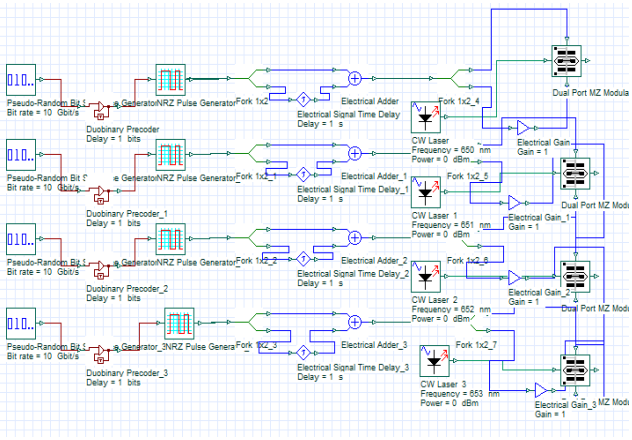

Fig. 2. Implementation of Tx stage of AMI FSO VLC.

C. FSO channel

• The FSO channel[3] includes a Tx and an Rx antenna.

• In the free space wireless channel (FSO) even and odd channels are present in the form of data channels and this even and odd channels are [2] individually multiplexed with the help of WDM multiplexer. the polarization controller maintained the multiplexer output. [11].

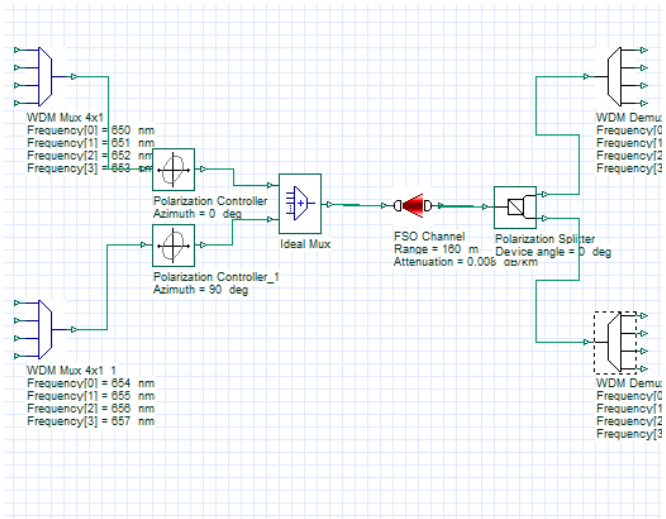

Fig. 3. Channel operation in VLC System

D. Receiver

In VLC system at the receiver [5], side contains polarization splitter (PS) which split the FSO Channel signal output, give approval polarization stage, this signal split into even and odd signals. The polarization splitter output is later recognized by a photodiode PIN for demultiplexing, signal filter by the Bessel low pass filter[2].

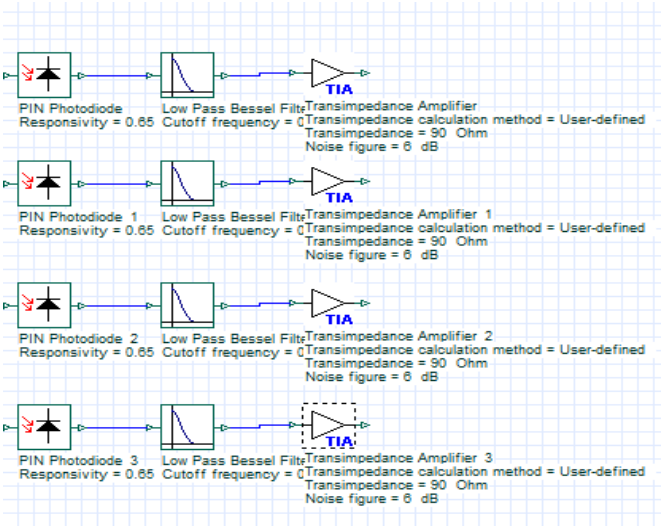

Fig. 4. Receiver operation in FSO VLC System

D. Duobinary

- The Duo binary was produced by first generating an NRZ duo binary signal utilizing a precoder and a duo binary pulse generator[12].
- Figure1 shows a system transmitting a Duo binary signal at 10 Gb/s.
- The duo binary precoder used in this place was composed of a Binary not gate along a delayed feedback path.
- AMI and Duobinary transmitter side are same except Duobinary transmitter side have binary NOT before Duobinary precoder.

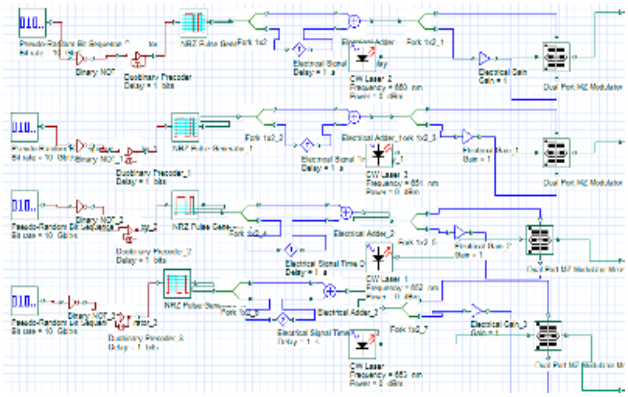

Fig. 5. Implementation of Transmitter stage of Duobinary VLC System.

III. RESULTS AND DISCUSSION

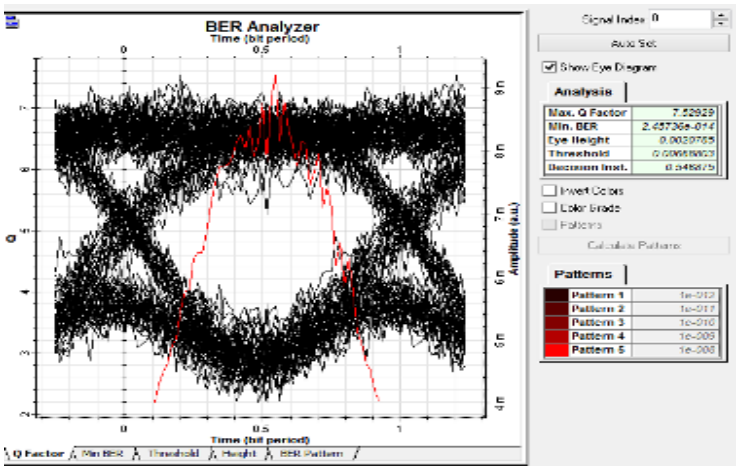
A. Figures and Tables

1) Positioning Figures and Tables: The specification value details of this system are specified in Table 1.

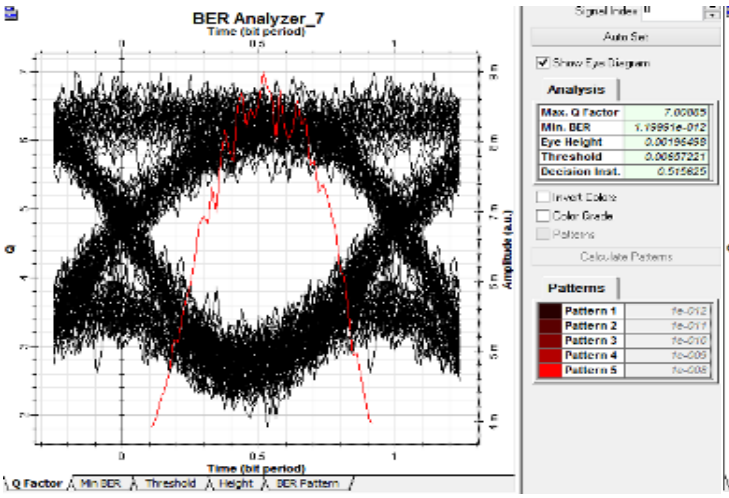
Table Head			
	Parameters	***Value***	***Subhead***
1	Bitrate	10	Gbps
2	Distance	160	m
3	Operating wavelength	650-657	nm
4	Time window	12.8-009	s
5	Sample rate	640e+009	Hz
6	Sequence length	1024	bits
7	Sample per bit	32	
8	Number of samples	32768	
9	Symbol rate	10e+009	Symbol/s
10	Transimpedance amplifier	90	Ohm
11	Noise Figure	6	dB

A. *AMI–WDM–PI*

Figure 6 performs the efficient estimation of the planned AMI–WDM–VLC communication system in the form of Q factor and BER[14]. In this system, we used channel distance 160 m with 10 Gbps bit rate sequence. Channel 1 and Channel 8figure 6 shows accomplishment evaluation of the planned transmitter, channel and receiver respectively. The Q-factor for channel 1 is 7.52929 dB for link length 160 m whereas for channel 8 it is noted as 7.00885dB at FSO.likewise, channel 1 BER value is recognized as 2.45736e-014whereas channel 8, it is noted as 1.19991e-012 at FSO transmission of 160m, respectively.

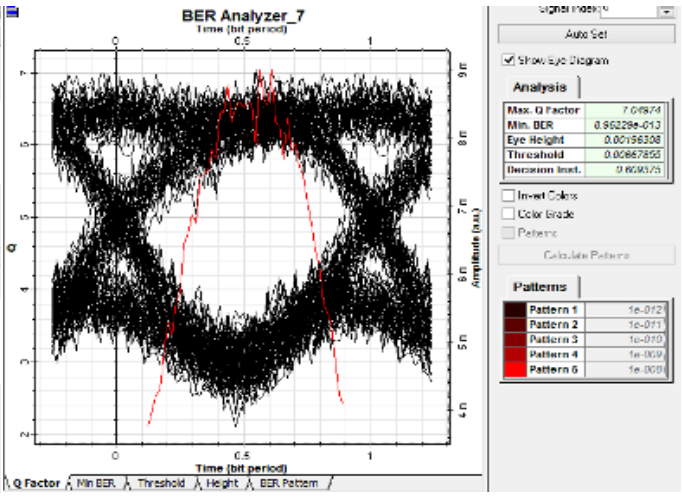


(1) Channel 1eye diagram for AMI system



(2) Channel 8 eye diagram for AMI System

Fig. 6. Eye diagram analysis for channel 1 and channel 8 at the receiving end of 160m

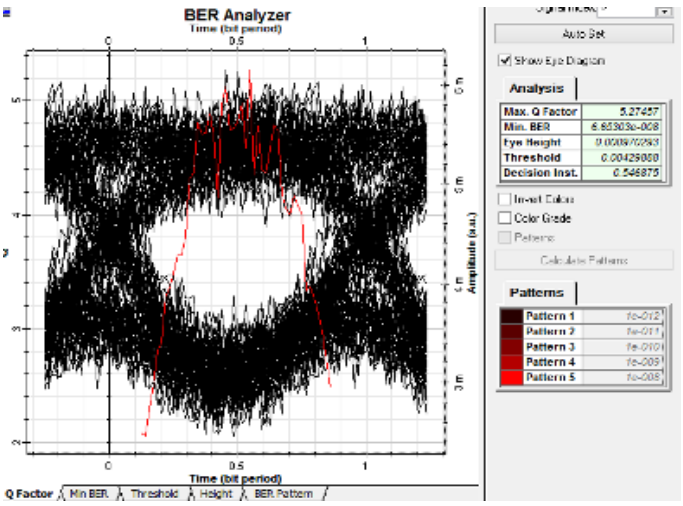


(b)Channel 8 eye diagram for Duobinary system

Fig. 7. Eye diagram analysis for channel 1 to 8 at the receiving end of 160m

B. Duobinary–WDM–PI

Figure 5 performs the efficient estimation of the planned Duo binary–WDM–VLC communication system in the form[13] of Q factor and BER[14]. In this system, we used channel distance 160 m with 10 Gbps bit rate sequence. Figure 5 shows the accomplishment evaluation of the planned Duo binary system respectively. We get channel 1 Q-factor is 5.27457 dB for link length 160 m whereas for channel 8 it is noted as 7.04974dB at FSO. likewise, channel 1 BER value is recognized as 6.65303e-008 whereas channel 8, it is noted as 8.96229e-013 at FSO transmission of 160m, respectively.



(a) Channel 1 eye diagram for Duobinary System

IV. CONCLUSION

We compared between AMI scheme and Duo binary using WDM–Polarization interleaving Visible light communication system. The whole designing structure is based on FSO optical link of 160 m with the 10 Gbps data. The results are stated in forms of eye diagrams that demonstrate that entire eight channels, each one accomplish10 Gbps AMI-encoded data and Duo binary data, are transmitted and retrieved well with adequate BER, and Q Factor. It has been observed that the AMI is better than Duo binary encoding scheme in the form of Q factor as well as BER which is targeted to achieve the value greater than 7 and less than 10-9 respectively[14].

Abstract: **The automotive industry is increasingly focused on specialization and customization. The goal is to optimize product features with regard to transport effectiveness, safety, quality and environmental impact leading to a minimized lifetime cost for the vehicle. But one piece in the puzzle is to have better understanding of how the vehicles actually are used, through the sensor data available in the vehicles. Here we develop a data logging system for off highway mining equipment's. The GSM, GPRS and Ds3231 RTC modules are used for this data logging system. The different parameters readings from the sensors are stored and uploaded to server if some errors are diagnosed. This error data is saved in SD card and the error diagnosed data is logged to cloud through network. from the server the data can be easily opened in monitoring desktop or phone. For further fault analysis and research, can be done in manufacturing service center.**

Keywords: GPRS/GSM; SIM900a; DS2331 RTC Module; Data logger and Arduino Mega

I. Introduction

As society is making lighting up the transportation needs of the world is a tremendous issue with wide effects on nature and on human lives. One way of making the transportation solutions more effective is to use a specially tailored vehicle for the intended usage. The automotive industry is increasingly focused on specialization and customization. The goal is to optimize product features with regard to transport effectiveness, safety, quality, and environmental impact leading to a minimized lifetime cost for the vehicle.

Present day trucks are perplexing electro-mechanical frameworks with many arranged Electronic Control Units (ECUs). Sensors are placed throughout the system. This connectivity makes it possible to access sensor signals, which give a view of the state of the vehicle and its components and subsystems. The available information is of interest to a number of different stakeholders, as for example development, fleet owners, and traffic accident researchers [2]. The stakeholders want to optimize the vehicle and its functionality, which leads to a need for various types of information, as for example driver behavior and vehicle usage Developers want to know how the vehicle is performing, to get errors, faults, and abnormal behavior [8], in order to improve the vehicle and understand when and why components fail [3]. Fleet owners are able to plan for maintenance to minimize the risk of vehicles breaking down and missing scheduled runs. Drivers, fleet owners, automotive companies, and insurance companies are all concerned in on-board information from the vehicles.

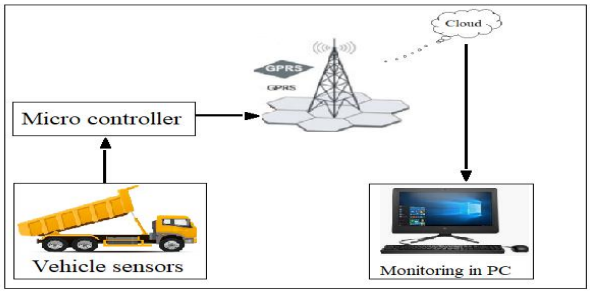

Fig 1. The structure of data logging system.

As we are using the internet the structure pushes toward getting to be confirmed and constant data watching and real time data monitoring is also possible using GSM/GPRS system [9]. In this paper we have designed a real time data logging system for off highway mining equipment. Here the data is recorded through sensors whenever any error takes place in the equipment, this data is logged and saved in SD card and from server it can be easily monitored in PC or phone. For further analysis the structure of this system is shown in the above Fig 1. To build this we are using Arduino Mega microcontroller here the data can be logged at any interval of time to maintain the date and time [7] we are using RTC module DS3231 and get the temperature, speed and current readings [6].

The rest of this paper is composed this way. In area II we have examined the past work accomplished for this undertaking. In segment III proposed work, we

have made an analysis of technologies used and the overall system architecture of the system is discussed. In section IV, we have analyzed the raw sensors data. In section V, we have represented the flow chart of the work. In section VI we have wind up the paper by showing outcomes. Lastly in section VII we concluded the paper and the future work.

II. Previous work

In the field of vehicle data acquisition and logging study there exists both fully ready products, research ideas and prototypes [4].

There are many telematics products created on vehicle data [10]. Volvo Trucks has a fleet and vehicle supervision system called Dynafleet, where available info is, for example, vehicle position, driver rest times, fuel consumption and service intervals. General Motors has a system called OnStar, which has almost the same services. Part of this system is vehicle diagnostics, which uses the diagnosing errors for the different systems. Some other companies also have similar products. The work in this project concentrates on the on-board analysis. The aim in this project is also to extend the available information from the vehicle and describes different research solutions to vehicle data logging and analysis.

III. Proposed work

A. Internet of things (IoT)

Earlier, the internet comes to be used for in truth getting to locations to speak with each special. anyhow, with the development of improvement, the internet is used for interfacing machines with higher limits and occasional strength usage to the cloud. further, in recent times huge affiliation of sensors that would benefit and way records may be made with those devices. Additionally, a tiny bit at a time went with this came the likelihood of "Internet of things" with the help of which PC can accumulate information about any substance.[1]

B. Vehicle logging

The modern trucks are complex mechatronic system containing several distributed and networked ECUs. The different ECUs are specialized to handle specific subsystems and their functionality, for example an Engine Control Module or Gearbox Control Module. Each ECU receives and transmits messages on the different networks using CAN protocol. The ECU controls the specific subsystem, by getting the input from the sensors and sends the output signal to the actuators. In the event of faults Diagnosing the Trouble Codes are set and The On-board Diagnostics [14] connection is the legally defined standard for the connection through which diagnosed errors can be studied at manufacturing service-centers [11].

C. The system architecture and specifications

Here the gateway is made of GPRS,GSM sim900a module, DS3231 RTC module, SD card and Arduino Mega microcontroller.

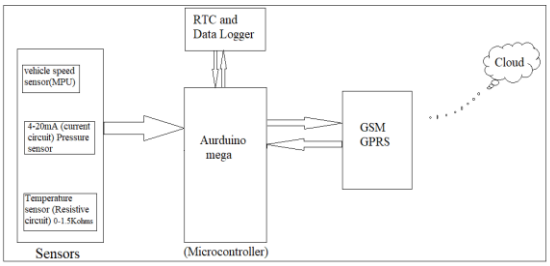

Figure 2: system architecture of logging system

The sensors of the dumper truck measures such as eingne oil temperature, eingine oil pressure and speed of the vehicle are programmed by microcontroller and the data is logged. The system architecture of logging system is as shown in Figure 2.

D. Arduino Mega

The Arduino Mega-2560 is a microcontroller board (ATmega2560). It has 54 digitals enter and output pins (in which 15 can be used as PWM outputs), 16 analog inputs, four UARTs (hardware serial ports), a 16 MHz crystal oscillator, a USB connection, an electricity jack, an ICSP header, and a reset button. The information and yield pins are utilized for developing the placing for composing packages for the board. This device makes a level to structure our framework. With the assistance of this current gadget's exhibition which can be utilized to connect to IoT.

E. Pressure transducer:

- Make: ADZ (made in Germany)
- Pressure rating: (0-400PSI) (0-27.5bar)
- Electrical rating: (10-32V) (4-20mA)
- Minimum 10V is required to drive the current through channel.
- Requires two port pins for communication.
- This is current type sensor.

F. Temperature sensor:

- Make: ADZ (made in Germany)
- Temperature rating: (0-400PSI) (0-1500Ω)
- Electrical rating: (10-32V) (4-20mA)

- Minimum 10V is required to drive the current through channel.
- This is resistive type sensor.

G. Speed sensor:

- The inductive impact in the sensor's curl is creating the wavering voltage, for example, one sort of sinusoidal waveform signal (~ AC voltage).
- The voltage sign created by the sensor relies upon the speed of the flywheel and the number of turns in the curl. The yield voltage could be likely somewhere in the range of 1V and 5V
- When the fly(gear) wheel with the teeth goes in enough close separation to the shaft stick of the sensor, the attractive field encompassing the loop is changed. Because of the adjustments in the attractive field, and the voltage is prompted in the loop, which is relative to the quality and rate of progress of the attractive field. One completely complete swaying is created for every tooth that goes adjacent to the sensor post stick.

H. GPRS/GSM sim900a

- Single supply voltage: 3.4V – 4.5V
- Supports UART interface
- Supports a solitary SIM card
- Firmware redesign by investigating port
- Communication by utilizing AT directions
- Power sparing mode: Typical power utilization in SLEEP mode is 1.5mA
- Frequency Group: SIM900A Dual-band: EGSM900, DCS1800. The SIM900A can look through 2 frequency band groups consequently.
- Dual-Band GSM/GPRS 900/1800 MHz.
- RS232 interface for direct correspondence with PC or MCU unit.
- Configurable baud rate.

H. DS3231 RTC module

The DS3231 is ease, amazingly particular real Time Clock that can maintain hours, minutes and seconds, simply as, day, month and three hundred and sixty-five days. Likewise, it has programmed recompence for bounce years and for a substantial duration of time with underneath 31 days.

- Accuracy ±2ppm from 0°C to +40°C
- Accuracy ±3.5ppm from -40°C to +85°C
- Digital Temp Sensor Output: ±3°C Accuracy
- Register for Aging Trim
- RST Output/Pushbutton Reset Debounce Input
- Two Time-of-Day Alarms
- Programmable Square-Wave Output Signal
- Simple Serial Interface Connects to Most Microcontrollers
- Fast (400kHz) I2C Interface
- Battery-Backup Input for Continuous Timekeeping
- 3.3V Operation

IV. Analyzing the raw data of sensors

A. Pressure sensor (Engine oil pressure)

Precision of analog channel A1 = 5/1023=0.0048875V or 4.88mV

The resulted curve of pressure sensor obtained is a straight line, not passing through origin and cutting the Y-axis. It is shown in the fig below in result section

Considering Y= mx+c, standard equation of a straight line.

Where,

Y= Current(mA) output of transducer

m= Slope i.e. (mA/bar) = (current/pressure)

x= pressure applied to the transducer

c= offset current output of transducer when no pressure is applied

Therefore, the slope value obtained by calculating is m = 0.56mA/bar

Y=current in mA	M=slope	x=pressure in bar	C=offset current
4	M0=0	0	4
5.1	M1=0.56	2	4
6.8	M2=0.56	5	4
7.4	M3=0.56	6	4
9.7	M4=0.57	10	4
	Mavg=0.56		

Table 1: Average Slope calculation

B. Temperature sensor (Engine oil temperature)

Raw data of sensor resistance R_s raw = Analog read A_0

Voltage V_{in} = 5V

R_c buffer = R_s raw * V_{in}

Voltage across resistance R_c, $V_{RC} = R_c$ buffer / 1023°C

R_S buffer = $((V_{in} / -V_{RC}) -1)$

C. Speed sensor (Engine crankshaft speed)

Fly wheel is a geared wheel which has 118 teeth's, and the Coil winding is concentrated at the tip in which magnet is cylindrical in shape

When the tip of sensor faces the teeth of a flywheel flux converges closely increasing flux density as shown in Figure 3.

When the tip of sensor faces the gap between teeth's (during normal time) the flux is distributed as shown in Figure 4

Therefore, as flux converges and redistributes the coil in that region feels the changing flux and generates the EMF

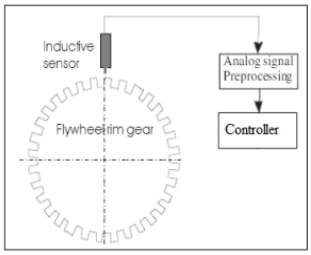

Figure 3: Schematic representation of speed sensor

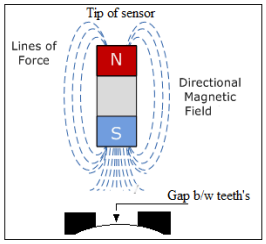

Figure 4: when sensor tip coincides the gap

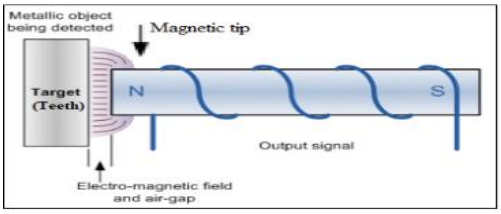

Figure 5: when teeth coincides with sensor pin

If number of teeth counts is 118, one rotation is completed

If in a minute number of counts=N

Then, N/118 give number of rotations in a minute i.e.=(N/118) RPM

V. Flow chart of the project work

The figure 6. below shows flow of the proposed project. With the help of Arduino Mega-2560, DS3231 RTC module, GSM/GPRS module as shown in figure 2 above. After accumulating information of temperature, pressure, and speed from sensors. The data is uploaded to the server. And monitored in PC or phone.

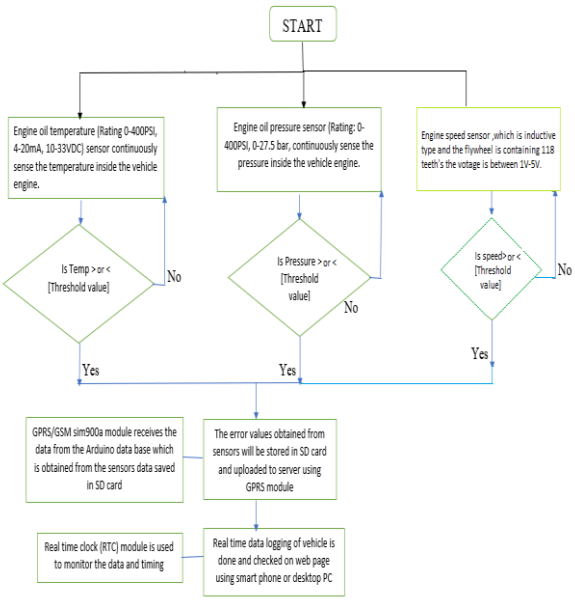

Figure 6: flow diagram of our project

VI. Result and discussion

With the assist of Arduino Mega-2560, DS3231 RTC module, GSM/GPRS module as verified in figure 2. After accumulating information of temperature, pressure, and speed from sensors [6]. The data is uploaded to the server. And monitored in PC or phone. Figures 7,8,9,10 and 11 and Table 2 and 3 depict the results.

We have taken the Engine transmission oil temperature and air pressure raw data were temperature sensor is resistive type, as a result current and temperature linearly increases as shown in the Figure 9. Resistive curve which is nonlinear in nature [5], were the pressure sensor is current type of sensor, as the result there is a change in pressure which is shown in the Figure 8, Current v/s Pressure curve which is linear in nature is as shown in Figure 11.

Current in (4-20mA)	Pressure in bar	Pressure in KPa
4	0	0
5.1	2	200
6.8	5	500
7.4	6	600
9.7	10	1000

Table 2: Data obtained from pressure sensor

1bar = 100KPa

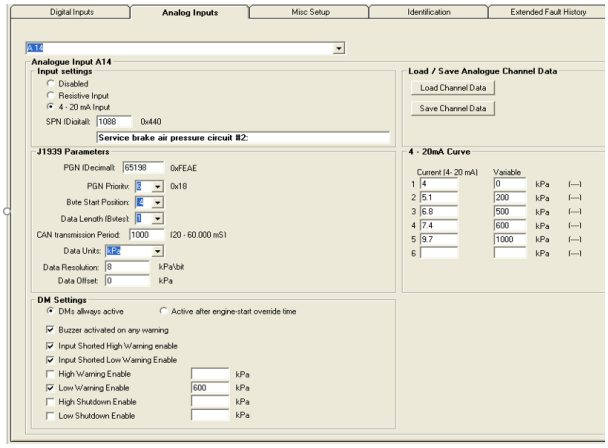

Fig. 7: The data logged by pressure sensor is monitored in PC

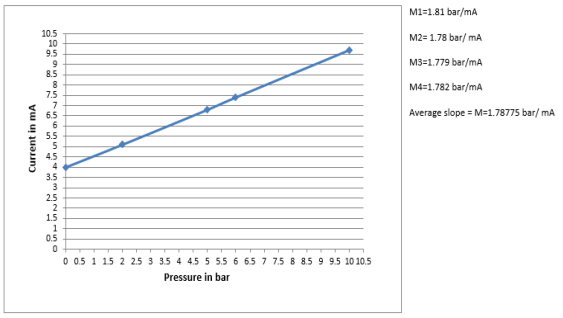

Fig. 8: Resultant curve of current v/s pressure

Resistance in K	Temperature in ℃
1029	40
460	60
164	90
74	120
40	140

Table 3: Data obtained from temperature sensor

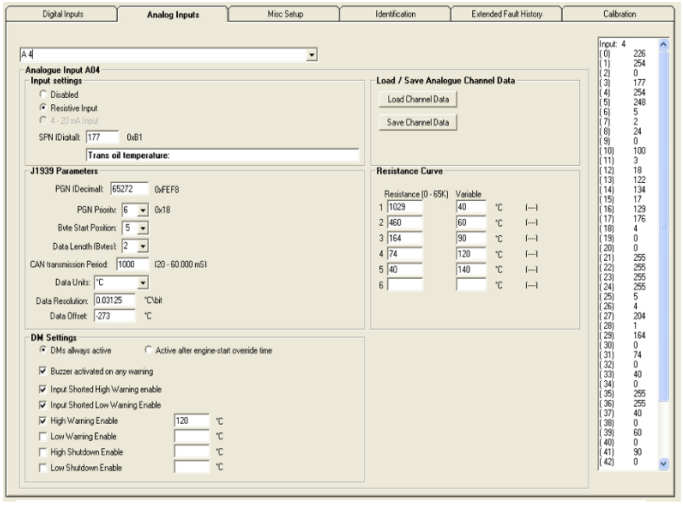

Figure 9: data logged by temperature sensor is monitoring in PC

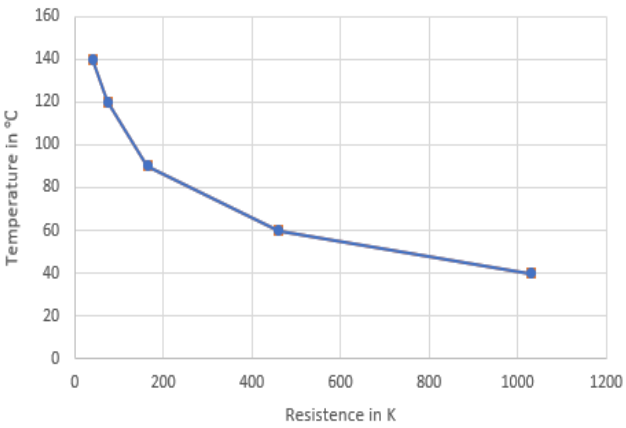

Figure 10: resultant curve of temperature V/s resistance

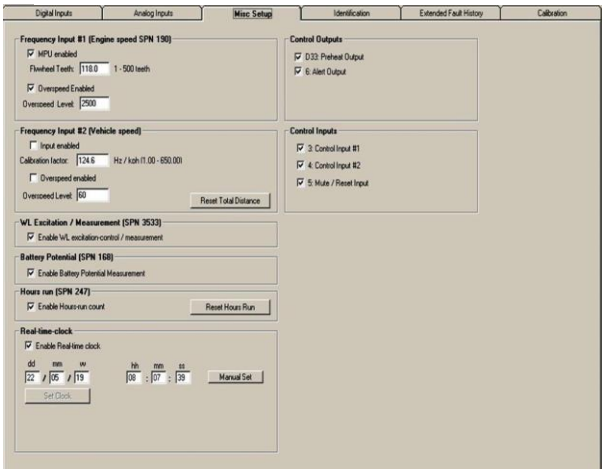

Figure 11: data logged by engine speed sensor is monitoring in PC

VII. Conclusion and Future work:

This project work provides the error information to the driver as well as the manufacturer which would help in a well-operational configurable on-board vehicle data system. Present day trucks are unpredictable electro-mechanical frameworks with many arranged Electronic Control Units and Sensors are put all through the framework. This connectivity makes it possible to access sensor signals, which give a view of the state of the vehicle and its components and subsystems. The results of remote vehicle data logging system for off highway mining equipment's is shown in the result and discussion section.

The next step would be to run the created hardware unit on actual vehicle. This would give the opportunity to determine the resource usage in detail. In this project, tests were conducted where the analysis gave useful results for monitoring engine pressure, engine crankshaft speed performance, and vehicle engine temperature, but there are many more other settings in the vehicle where the study is likely

to be applicable. Appropriate areas could be opted to monitor and detect between different driver behavior or to monitor definite subsystems as the engine, transmission, or air suspension.

***Abstract* — Advancement in communication systems has resulted in the increase of services of different wireless technologies such as WiFi (Wireless Fidelity), LoRa (Long Range WiFi), LTE (Long Term Evolution), WiMAX (World Wide Interoperability for Microwave Access), etc. 4G wireless technology gives all enhanced features such as cost-effectiveness, high data transfer rate and provides direct communication. LoRa also provides mobility feature and portability feature. Installation and implementation of these networks are easy. LoRa and LTE wireless networks give high data transfer rates and better service when compared to other networks like 1G, 2G, 3G etc. and these networks are heavily used by the users for communication. LoRa caters to long-range communication. The other technologies such as WiMAX is not widespread across India. Bluetooth technology has disadvantages like short-range, slow data speed, poor data security when compared to LoRa and LTE. This paper provides related work on LTE and LoRa performance-based simulations. In our Simulation, we have shown how LTE and LoRa work with different node densities such as 25, 50, 100, 150 and 200. PLR (Packet Loss Ratio) is calculated as nodes increase with increased traffic. PLR is compared between LTE and LoRa. The experiment is done using OMNET++ tool. Performance of LTE and LoRa is tested separately. Simulation results have shown that performance of the LoRa is better when compared to LTE because PLR is high on LTE network with increased node density and increased traffic compared to LoRa.**

Keywords— LTE, LoRa, PLR, PGW, D2D (Device to Device)

I. INTRODUCTION

Transfer of data between two or more points that are not physically connected is termed as wireless communication. The distance is short, like a few meters for remote television control, or thousands or even millions of kilometers. It includes multiple types of fixed, mobile and portable two-way radios, cell phones and radio access networks. Usage of these wireless networks is increasing day by day. As traffic demand grows exponentially, users are facing problems with loss of data and increasing latency. Different technologies are used in the 21st century to support efficient data transfer such as WiFi, Bluetooth, Infrared and D2D (Device to Device) in cellular networks. [1]. The users of any wireless technology expect always the best connection at any time with high-speed data transfer. In order to meet the user requirement, technology is growing day by day and the capacity of the cellular networks has been increasing with advanced technology such as 3G and 4G. Still, there exists a demand for higher network capacity and faster traffic. LTE (Long Term Evolution) and LoRa (Long Range WiFi) networks are widely used by the users.

LoRa is used for low cost and unregulated point to point network connectivity. Features of Long Range WiFi (LoRa) are:

- Maximum output power 2000mW
- Data transfer rate: 300 Mbps
- Frequency: 2.4 GHz IEEE 802.11 b/g/n
- It works with indoors and outdoors

Long Term Evolution introduces an omnipresent network concept. LTE also offers higher data rates for many previously unavailable services and applications. This facilitates global roaming among different types of mobile access networks. LTE supports various scalable bandwidths from 1.4 MHz to 20 MHz [2]. Few LTE features are listed here:

- Increased data rate, DL 3Gbps, UL 1.5Gbps
- Improved performance at cell edges
- Range up to 20 Km.
- Bandwidth from 1.4 MHz to 20 MHz
- Supports equally TDD (Time Division Duplexing) FDD (Frequency Division Duplexing)

In order to find the most suitable and the best network to send data as the traffic flow increases, simulation is done with different node densities and traffic flows. The proposed work is done with the OMNeT ++ simulation tool. Performance of the network is evaluated by PLR (Packet Loss Ratio). PLR is evaluated by adding interference that modifies the signal in an abnormal way. The interference of data is evaluated by using LoRa and LTE network.

This paper presents an analysis of PLR (Packet Loss Ratio) with LoRa WiFi and LTE technologies. This paper contains following sections: Section II summarizes the Related Works, Section III has the Comparison of Technologies, Section IV has Experimental Design and Section V has Results and Analysis.

II. RELATED WORKS

Shihab Jimaa et al [3] present a futuristic approach about LTE in Cloud Radio Access Network, Multihop Wireless Networks and MPLS (Multi-protocol label switching). Here, LTE uses uplink and downlink transmission based on multiple access technologies. This paper focuses on the LTE requirements and multiple access technologies used in LTE. According to the results observed, uplink and downlink used for peak bit rate with

the help of High-Speed Packet download Access (HSDPA) and High-Speed Packet uplink Access (HSUPA).

Zeeshan Hameed Mir et al [4] appraise two Communication standards namely 802.11p by IEEE (Institute of Electrical and Electronics Engineers) and LTE (Long term evolution) by 3GPP for vehicular networking. This has a variety of parameters such as vehicle density and average speed. The standards of communication are compared in different scenarios with delay, scalability and mobility. As per the results, LTE has higher network capacity and supports mobility. It was also observed that delay increases as the network load decreases. Results show that IEEE802.11p provides end-to-end delay of less than 100ms and a 10-kbps throughput.

Abhijeet Bhorkar et al [5] presented analytical expressions of LTE-U throughput in the presence of WiFi. Paper shows the results with the help of threshold and transmission power during the usage of LTE-U and WiFi. It also compares the performance of WiFi and LTE-U. In some scenarios, transmission power of LTE-U and WiFi is reduced to 30dbm when transmission power is 20dbm, it improved the WiFi throughput. So, LTE-U is better with WiFi in terms of throughput.

Tauseef Ahmad et al [6] proposed the wireless network performance where LTE is used in Medium Access Control (MAC) layer. Traffic in User Datagram Protocol (UDP) is considered for evaluation. Throughput, end-to-end delay and jitter parameters have been evaluated. For downlink scenarios, parameters such as bandwidth and packet size were considered. As per the results, bandwidth and throughput were increased, but delay and jitter were decreased. This is implemented with NS2.

Dong Hyun Kim et al [7] proposed the communication of WiFi and LoRa technologies with the help of Long-Range, low-power and a large amount of data transmission. To provide efficient data transmission, WiFi and LoRa technologies are used. It also finds the distance between WiFi and LoRa. It is implemented with WiFi, LoRa gateway and an end device which is to test the performance of developed device. RSSI (Received Signal Strength Indicator) has valuated according to the distance and data rate. Based on the results obtained, LAN can communicate with high transmission rate and LoRa can communicate with low power and long-distances.

Martin Bor et al [8] describe the impact of the selection of parameters that define LoRa transmission based on performance of communication. This work developed a link probing regime that helps to find transmission parameters, which satisfy functional requirements. So, the method for LoRa transmission deploys the LoRa wireless network. Here, every transmission parameter is tested based on the performance impact. Based on the results obtained, a good transmission parameter suitable for a stronger network operation and balanced energy utilization is identified.

R.Bosisio et al [9] proposed a multi-antenna E-UTRA which conforms to 3GPP recommendation. The downlink is used in the system performance. Here, the users' scheduling and interference mitigation (like interference coordination and interference randomization) is proposed in terms of E-UTRA and compares the performance between the interference. According to the results, method is efficient for the traffic load because of the randomization of coordination and interference.

Mahmudur Rahman et al [10] proposed the interference avoidance method for LTE downlink. The proposed method is evaluated with simulation and it is compared with number of references mechanisms. It also attains the higher performance. Cell edge and throughput are compared to the previous methods. Here the mechanism is used in various scenarios. In terms of results, it shows that static mechanisms achieved improved cell-edge throughput.

Si WEN et al [11] proposed several interferences in coordination mechanism that includes centralized power control, resource allocation, mode selection strategy and distributed self-optimization schemes. These schemes provide, routine of D2D communication enabled network and evaluate the effect of local service ratio and user density. It also analyzes the efficiency of single cell assessment and multi-cell simulation. Based on these analyses, the results are observed that Device to Device communication increases the capacity of the cellular network.

Muhammad Usman Memon et al [12] provides a comprehensive assessment of the WIFI and ZigBee technology interference. Paper shows that how results are analyzed which gives the deployment information used in radio access technologies to avoid common interference. Here, the results show the ZigBee communication with various frequency offsets and distance respectively in the two scenarios. The ZigBee and WiFi investigated with the help of experiments and tests and the results were used in distance and frequency offsets between both the technologies.

Rongqing Zhang et al [13] proposed a scheme which make a network corresponding to the ideal resource sharing. They also introduced an interference-aware graph-based resource sharing mechanism which is more effective in allocating the resource at the base station with the less difficulty in computation. With the respective results, it analyzes two resource sharing schemes. Performance is more about network data rate that confirms the effectiveness of communication and the D2D communication underlays traditional cellular networks.

Thiemo Voigt et al [14] examine the use of directional antennae and more number of base stations with internetwork interference. Here, directional antennae signal strength at receiver side is evaluated without increasing transmission energy cost. According to this paper, both the methods improves the LoRa network performance in the interference settings. Based on the results, the directional antennae and several base stations have improved the performance.

Charalampos Orfanidis et al [15] examine the interference interactions between LoRa and IEEE 802.15 4g networks. It shows LoRa receives high packet rate with IEEE 802.15 4g interference. Paper shows the evaluation of protocols for both radio access networks. According to the results, LoRa is much better under interference than IEEE 802.15 4g and radio configuration of LoRa is important for degree of tolerance. Here the main significance of results comes in both the radio platforms where there are collision avoidance mechanisms, reliability and robustness in the higher layers.

Salah Eddine Elayoubi et al [16] proposed a model of inter-cell interference for the distribution of collisions which takes an effect of power control. Proposed model calculates the power in terms of Markovian Analysis. Paper compares different interference mitigation schemes. Based on the results, the two frequency planning schemes (reuse1 and reuse3) are compared, although reuse3 decreases interference and overall throughput because of the loss of resources.

Klaus Doppler et al [17] presented the for D2D communication method and events in LTE network. Here the D2D communication analysis provides feasibility in system simulations and in terms of traffic, the buffered traffic holds cellular and D2D connections. In terms of throughput, it reduces the D2D peers where it is not located in the same room. According to the results, D2D communication works under the cellular network. So, the throughput will increase to 65% compared to D2D traffic which is relayed on a cellular network.

Cenk M. Yetis et al [18] classified the problems of signal space interference as proper and improper based on various equations. With the help of Bernshtein's theorem, it finds the feasibility analysis by using MIMO interference channels. It has observed that when the system is improper, then it is infeasible in other systems.

Pengcheng Bao et al [19] described the problem in the D2D communication which underlays cellular networks. Some of the concepts such as accessible region and reusable region are used. It calculates boundary of both accessible and reusable region. With the help of this scheme, it effectively increases the interference between both regions.

Jaeyoung So et al [20] describe the LoRa network server(LNS) implementation on OpenStack. Experiment is done using open sources for LoRa terminal, LoRa gateway and OpenStack. According to the results, the operations on LNS has classified as four blocks: the gateway agent, application server agent, LoRa data and LoRa Agent. It also improves the scalability and maintainability and conform to system design.

Giriaja CV et al [21] provided a SNR based Master-Slave Dynamic D2D Communication Algorithm (SMSDCA). Algorithm increases the resource utilization and also provides better QoS. D2D channel is assigned by the base station. The proposed method considers the SNR, energy, and movement of the device. This is implemented in a MATLAB simulation. Result shows the throughput and count of users served in D2D communications. According to the results, the interference in the D2D communication is decreased by assigning the transmission power.

III. COMPARISON OF TECHNOLOGIES

TABLE I Comparison of LoRa and LTE

Features	LoRa	LTE
Modulation	SS Chirp	OFDMA
Bandwidth	500-125kHz	200MHz
Data Rate	300 Mbps	DL 3Gbps UL 1.5 Gbps
Output power	20 dBm	23-46 dBm
Range	15 Km	Up to 20 Km
Cost	Low	High
Power consumption	Low	High

IV. EXPERIMENTAL SETUP

A. Experimental setup for LTE

The performance of LTE is evaluated by sending 500B of data using OMNET++. LTE is a network for high-speed data communication. ENodeB and UE nodes represent the LTE network. The experiment is done with different node densities. eNodeBs are base stations in the LTE network. UE is a device used by the end-user for communication. UE uses the PGW (Packet Gateway) for communication. PGW that acts as an interface between various technologies. Fig.1 shows the experiment was done in 3000 * 3000 simulation area where various node densities such as 25, 50, 100, 150, and 200 and with different traffic flows such as one flow, two flow, three flow, four flow and five flow for each node densities. The packet interval is sent in 100ms with the linear mobility model. These simulation parameters and values are shown in the table II. One flow represents the main flow and two flow is adding interference to the main flow and it goes on up to four interference.

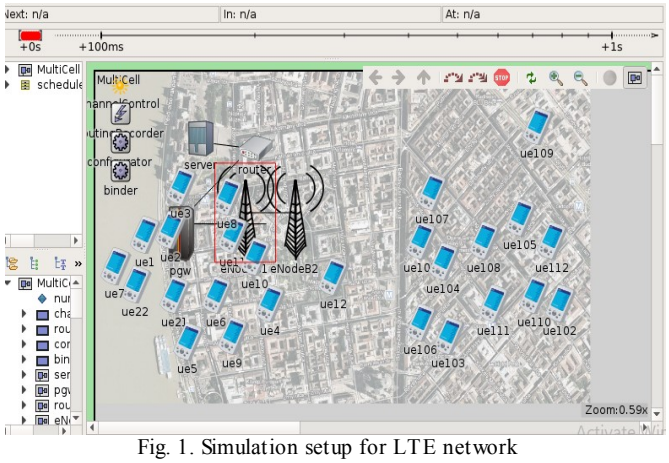

Fig. 1. Simulation setup for LTE network

TABLE II Simulation parameters and values

Parameters	Values
Simulator	OMNeT++
Node Density	25, 50,100, 150, 200
Flows	1,2, 3,4 5 flows
Packet Interval	100ms
Mobility Model	Linear Mobility Model
Simulation Area	3000*3000

B. *Experimental setup for LoRa*

The performance of LoRa is evaluated by sending 500B of data using OMNET++ and compared with LTE. Fig.2 shows the simulation was done in 3000 * 3000 simulation area where different node densities as 25, 50, 100, 150, and 200 and with different traffic flows as one flow, two flow, three flow, four flow and five flow for each node densities. The packet interval is sent in 100ms with the linear mobility model. These simulation parameters and values are shown in the table III. One flow represents the main flow and two flow is the main flow with adding interference to the main flow and it goes on up to four interferences.

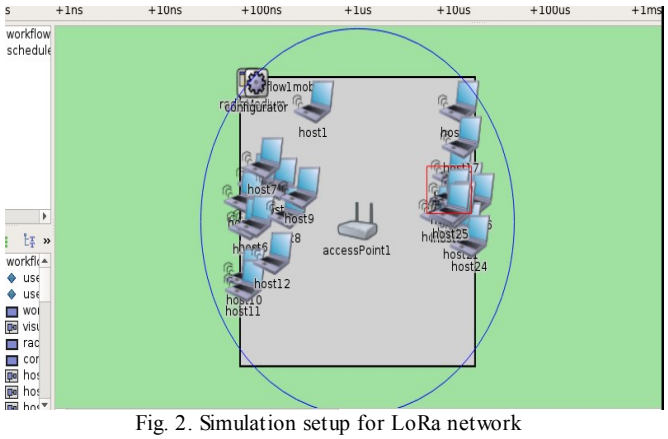

Fig. 2. Simulation setup for LoRa network

TABLE III Simulation parameters and values

Parameters	Values
Simulator	OMNeT++
Node Density	25, 50,100, 150, 200
Flows	1,2, 3,4 5 flows
Packet Interval	100ms
Mobility Model	Linear Mobility Model
Simulation Area	3000*3000

V. RESULTS AND ANALYSIS

A. *LTE Network*

Table IV shows the PLR (Packet Loss Ratio) for LTE network as traffic increases by one flow up to five flows.

TABLE IV. PLR for LTE network.

Flows	PLR				
	Node Count				
	25	50	100	150	200
1	0.2	0.2	17.6	19.6	19.6
2	11.6	19.6	30.2	37.4	39
3	15.6	26.4	36	40.2	57.2
4	17.8	36	48	48	59.4
5	19.6	48	77.6	77.6	81

Fig.3 shows the PLR ratio for LTE network with different node densities 25, 50, 100,150 and 200 with different interference - one flow, two flow, three flow, four flow and five flow.

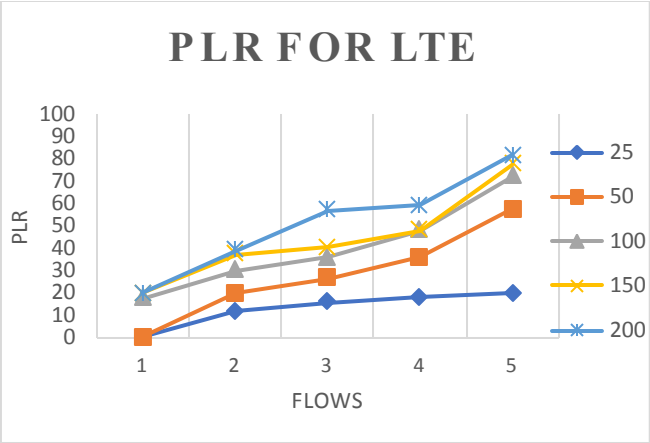

Fig. 3. PLR for LTE with various node densities and interference

In the above experiment, PLR is calculated by using the formula as follows:

$$PLR = (No\ of\ lost\ packet / No\ of\ sent\ packet) * 100 \quad (1)$$

The simulation results show that as traffic flow increases for increased node densities, packet loss ratio also increases. PLR is high with 200 node density for all the traffic flow when we compared to other node densities 25, 50, 100, and 150. PLR is less with 25 node densities when compared to other node densities 50,100 and 200.

B. LoRa Network

Table V shows the PLR (Packet Loss Ratio) for LoRa network as traffic increases by one flow up to five flows.

TABLE V. PLR for LoRa Network

Flows	PLR				
	Node Count				
	25	50	100	150	200
1	0	0	0	0	0
2	0.6	1.6	1.6	1.8	3/39
3	1.6	5	7.4	8.8	10.4
4	7.2	7.6	8	9	13.8
5	8.6	9.4	15.8	16.2	17.8

Fig.4 shows the PLR ratio for LoRa network with different node densities 25, 50, 100,150 and 200 with different interference one flow, two flow, three flow, four flow and five flow.

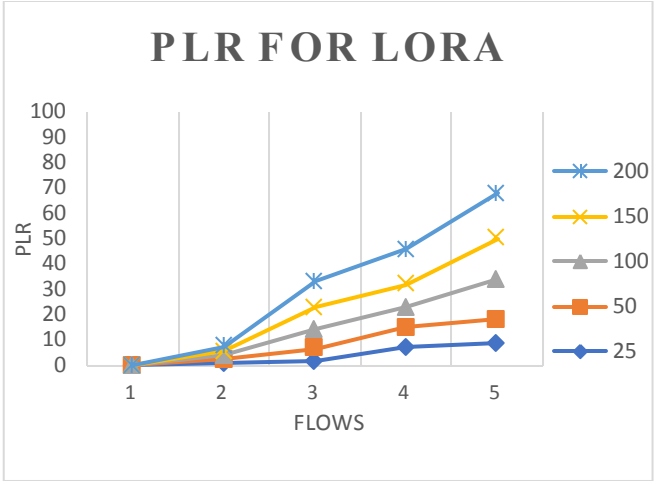

Fig.4. PLR for LoRa WiFi with various node densities and interference

Simulation results proved that the performance of LoRa is better, i.e. PLR is less when compared to LoRa WiFi. Results have shown that as traffic increases, PLR also increases and it is decreased with less traffic flow. PLR is high in LTE when there is the same traffic in both LTE and LoRa. So, the performance of LoRa is better than LTE with different node densities and traffic flows.

VI. Conclusion

The overview of this paper explains on LoRa WiFi and LTE wireless networks provide high data rates and better service when compared to other networks like 1G, 2G, and 3G etc. These networks are heavily used by the users for communication. In our Simulation, we have shown how LTE and LoRa work with different node densities 25, 50, 100, 150 and 200. PLR is calculated as nodes increases with increased traffic. PLR is compared between LTE and LoRa. The results of the simulation showed that the performance of LoRa is better when we compared to LTE because PLR is high in LTE network with increased node density and increased traffic compared to LoRa.

Abstract— The superior semi Z-source arrangement resounding DC to DC converter as a hopeful topology for the PV module level power gadgets applications. The converter includes a wide information voltage and burden guideline go on account of the multi-mode task, for example at the point when the shoot-through heartbeat width balance and stage move tweak are joined in a solitary changing stage to understand the lift and buck working modes, separately.

Keywords: solar photovoltaic; resonant converter; DC to DC converter; quasi Z-source converter; renewable energy; MIC

I. INTRODUCTION

A two-organize topology is proposed, which comprises of a lift converter and a SRC. The lift converter steps the changing PV voltage VPV to a halfway steady voltage transport VDC, mid. The SRC converter is worked at fres,1 fifty-fifty cycle broken conduction mode (HC-DCM). This empowers an exceptionally effective voltage change by using the transformer spillage inductance as reverberation inductance and the charging current in mix with the parasitic yield capacitances of the full-connect MOSFETs for ZVS switching. A DC-to-DC converter is an electronic circuit which changes over a wellspring of direct current (DC) starting with one voltage level then onto the next. It is a class of intensity 8 converter. The DC yield voltage is constrained by fluctuating obligation cycle. There are three essential kinds of DC – DC converters considered for DC control transformation. These circuits are structured by utilizing a semi directing switch, for example, a thyristor, IGBT, GTO. The switch is turned on by an entryway beat (obligation proportion). The switch is associated in arrangement with the heap to a DC supply, or a positive voltage is connected between the terminals. At the point when the turn is killed, the present stream diminishes which is considered as underneath holding current, or an invert (negative) voltage is connected among anode and cathode terminals. Along these lines, legitimate entryway beats are required for acquiring the ideal converter yield. The impedance arrange gives a proficient outcome the power change Different topologies and control strategies utilizing distinctive impedance-source systems have been displayed in the writing, e.g., for flexible speed drives, uninterruptible power supply (UPS) disseminated age, (energy component, photovoltaic (PV), the breeze, and so on.) battery or super capacitor vitality stockpiling electric vehicles. The general square graph for impedance arrange is appeared in figure1. With the exchanging design, it is feasible for electrical power change application.

By and large, the Z-source converters are ordered into two fundamental sorts: one is voltage-encouraged another is a current-sustained inverter. Notwithstanding, ZSI gives the support between the source and inverter extension and it effectively makes the short and an open-circuit whenever relying upon the method of activity. Accordingly, the customary VSI/CSI based impedance arrange experiences following issues like broken info current in the lift mode for the voltage-encouraged ZSI. The improved exhibition creates the answer for this issue which has equipped for bidirectional power stream and buck– help activity, despite the fact that the changes must be turn around blocking gadgets. This topology is for the most part conceivable in sustainable power source age and basic engine drives applications.

II. LITERATURE SURVEY

Zambra, D. A. B., et al., (2010) proposed "Examination of NeutralPoint-Clamped, Symmetrical, and Hybrid Asymmetrical Multilevel Inverters." This paper presents execution files, for example, complete symphonious bending, first-request mutilation factor, second-request twisting variable, normal mode voltage, semiconductor control misfortune circulation, and warmth sink volume. Staggered inverters are intended to exhibit 99% productivity at the ostensible working point [1]. Fundamentally, these kinds of structures require countless. Qian, W., et al., (2011) proposed "Trans-Z-source inverters." The proposed inverter is developed by utilizing two inductors and capacitors 64 interfaced with DC source and the inverter connect [2]. This is workable for both buck and lift activity expanded voltage gain and the voltage worry in the yield waveform. It is another bidirectional power stream based diode - impedance organize for building up the switch blocking IGBT. In this way wide scope of voltage is acquired from different applications, for example, half and half/electrical vehicles to other engine applications.

Trinh, Q. N., et al., (2012) proposed "another Z-source Inverter Topology with High Voltage Boost Ability." This paper proposes the voltage gain proportion of SL inverter is high and little shoot - through obligation proportion. The volume and cost of the framework are practically same as those of the regular one. Symphonious current is delivered over the inductor with inverter side. Huge channels are required.[3]

Nguyen, M. K., et al., (2013) proposed "TZ-Source Inverters." This paper proposes a solitary stage high-advance up lift voltage inverter dependent on transformers, called TZ-source inverters. This inverter creates an exceptionally high lift voltage gain when the turn proportion of the transformer is bigger than one. This decreases the transformer's size and weight while delivering a similar yield voltage gain yet the transformer windings produce voltage stresses.[4]

Tang, Y., et al., (2013) proposed "Z-source AC-AC converters taking care of compensation issue." In this paper, a Z-source AC-AC converter is displayed to improve the buck-support capacity, which incorporates four switches in single stage and six switches in three stages. For wellbeing reason, another correspondence technique is utilized without utilizing any snubber circuits. The outcomes are confirmed both by recreation and trial bad habit. These converters have more points of interest and accomplish low exchanging misfortunes and less number of switches, thusly high effectiveness and extraordinary unwavering quality were accomplished.[5]

Reddy ,T. S., et al., (2013) proposed "Novel DC-DC Converter for PV framework with High Voltage Gain." This paper exhibits another group of dc– dc converters real points of interest of this topology are the info current is ceaseless with low swell; the information inductor is intended for double the exchanging recurrence, with resulting weight and volume decrease; the voltage worry over the switches is lower than half of the yield voltage, and normally cinched by one yield channel capacitor. As a weakness, a little snubber is vital for each switch and one extra winding for every cell is required for the autotransformer.

Zengin, S.J, et al., (2013) proposed "Decoupling Capacitor Selection in DCM Flyback PV Micro inverters Considering Harmonic Distortion" [6]. This paper centers around the choice of least decoupling capacitor esteem for the best possible task of irregular conduction mode by thinking about the all out symphonious twisting (THD) and PV control usage proportion [11]. A decoupling capacitor choice strategy for single-stage and two-organize flyback inverters is proposed. For single-arrange inverters, the decoupling capacitor is set over the PV yield terminals, and ought to be estimated by the ideal THD limit. For two-organize inverters, the control strategy for the dc– dc converter decides the phase where the decoupling capacity happens. 66 Thus, the PV side decoupling capacitor ought to be dimensioned by the PV control usage proportion, and the inverter side decoupling capacitor ought to be chosen by the ideal THD confinement. It is noted from the proposed framework yield reaction of the information voltage module, channel to source voltage and exchanging beat, transformer essential voltage and auxiliary voltages, input current, transformer optional side current, yield voltage, yield current, and yield voltage are decreased [12].

Beriber,D., et al., (2013) proposed "MPPT Techniques for PV Systems." This paper proposes another plan to expand the yield control from dc interface sun oriented board [7]. Consequently the converter requires MPPT circuit. The lift converter is utilized to venture up the vitality level just as to coordinate the 50 load voltage. There are three MPPT procedures for reviewing power creating application, for example, Perturb and Observe, Incremental Conductance, fluffy rationale based following method. The P&O and Incremental Conductance are extremely old model calculations and it has more downsides. The unfaltering state working point wavers greatest area, it might be the wastage of intensity from the PV board. However, the fluffy rationale controller gives quick and stable following most extreme power as contrasted and other control procedures. The significant bit of leeway of this plan is that it quantifies the PV

current flawlessly. Das, M., et al., (2014) proposed "A Novel Control Strategy for Standalone Solar PV Systems with Enhanced Battery Life." another control plot ABC (three stage) to DC is proposed for an independent PV application [8]. There are two power changing over stages utilized for high increase DC– DC activity, which is trailed by three stage converter. The responsive power load is considered for PV based independent application and the dynamic power request is constrained by controlling the dc connect voltage. Besides, the responsive power is constrained by shifting the inverter yield voltage size. The greatest power tracker is consolidated with the controller. The MPPT give control at the season of sun powered power request and improve the battery lifetime. However a dump load isn't required for overabundance vitality charging and load generation. The bidirectional converter is utilized to understand the DC interface based battery association.

III. PROPOSED SYSTEM

The galvanically bound semi Z-source game plan full DC-DC converter is assessed as a cheerful methodology for Photovoltaic applications [9]. This control system contains the qZS sort out (LqZS1, LqZS2, CqZS1, CqZS2, SqZS), a full-interface inverter (S1… S4), the voltage doubler rectifier (D1, D2, C1, C2) and a phase up isolation transformer TX.

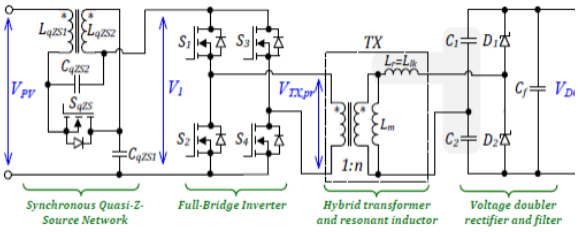

Fig 1. Block diagram of proposed system

The voltage range information is accessible. no matter what voltage, current knowledge incorporate. From above estimated structure the input is from pv panel which is 11.33 V (from fig 4). After Using full bridge inverter this 11.33V DC is converted to ac which is as input to to the transformer which having ratio 1: 230. Using VDR we get the increased voltage in dc form whicg is near to 30V (From fig 5)

Table I Specifications of Components used in the Hardware

Component	Specifications
S_1, S_2, S_3, S_4	MOSFET IRF 540
S	MOSFET CZ01B508
D_1, D_2	UF 5408, 4Amp, 250V
C_f	0.1uF ac 400Vac
L_f	1.2mH 4Amp

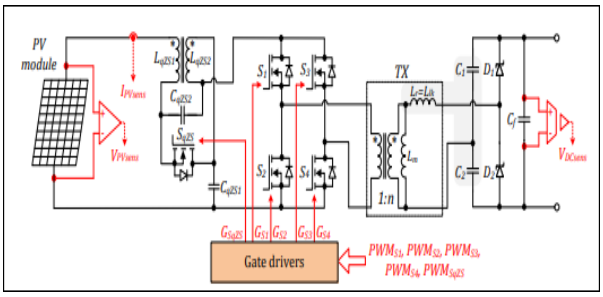

Fig 2 Block diagram of the control system

The proposed control framework is very basic since it doesn't control the DC-connect voltage. In many appropriated age applications, the DC-interface voltage is adjusted by the power utilization of the heap, for example inverter, vitality stockpiling, and so forth. On the off chance that the DC link voltage surpasses the cut off points characterized for the typical task, the insurance calculation will cripple the converter activity.

IV. RESULT

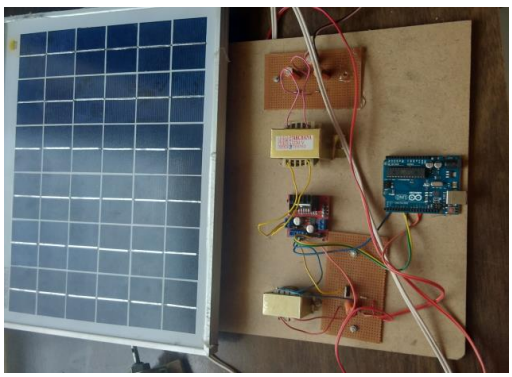

Fig 3. Hardware model of proposed system

Fig . 4. Input voltage from PV panel.

Fig 5. Output voltage from voltage doubler rectifier side

V. CONCLUSION

An unusual single-sort out galvanic in nature withdrawn huge development in DC-DC converter. Because of the different mode operation the results from the output are with increased in voltage range and this is our main aim for this methodology. Course of action reverberating tank consolidated to the helper bit of converter incorporates a extensive voltage data and weight rule expand. Let the above defined system gives the results which having high inclination with above methodology, believing upon the working condition we get desire results.

For future work we will develop it for the aircraft technology as well as for distributed power generation which will generate from renewable as well as non-renewable sources.

ABSTRACT **- The paper presents a Buck-Boost converter with reduced ripple current based delta star network. The main objectives are to reduced current ripples and improve Efficiency of the Conventional Buck Boost Converter. A delta to star impedance network using converter input side .The proposed system consists of the Buck Boost Converter's inductor, a Coupled based inductor, Resonant inductor & capacitor. The buck boost converter efficiency is poor for high gain and Current ripple high.so, proposed Buck Boost Converter ripple current can be Reduced and efficiency can be improved. Hence the Buck Boost Converter with delta to star network is used to improve the above mentioned-parameters.**

The existing and modified system is verified using MATLAB simulink software and results proves the above mentioned parameters.

Keywords – Impedance network, Buck Boost Converter, Ripples Reduction

I INTRODUCTION

Current scenario Different delta to star techniques have been developed & studied in the literature survey to be adopted in the circuit to increase converter's o/p performance, that is the Conversion ratio, to different benefits like the Distributed systems powered by renewable sources. Examples, WIND power system, & SOLAR system .then commonly used as LED driver, used for power factor corrections ,used in HVDC system ,and used in hybrid electric vehicles[1] – [5] .But , some papers have been put into improve converter's input side performance, that is the current ripple of the input side, using delta star networks.

Very unique from way to deal with the ripples problem of the buck boost by converter using proposed network in input side of the boost converter disadvantages are Lower Dynamic Response of the circuit & make the boost circuit un necessarily big and decreasing the efficiency , using the coupled based delta star technique is one of the final solution.[6] but, most technologies are implemented by replacing the converter's input side inductor with coupled based delta star Network.[7] which may not be an convenient applications in industrial benefits as it required to improve the real circuit of the conventional converter.[9]-[12] currently, one another coupled based delta star network has been proposed in to reduce the i/p side ripples without the value to replace the Converter's Inductor. but, two capacitor pair are needed in this type of

method & the Resonant Inductor is required to be comparatively high.

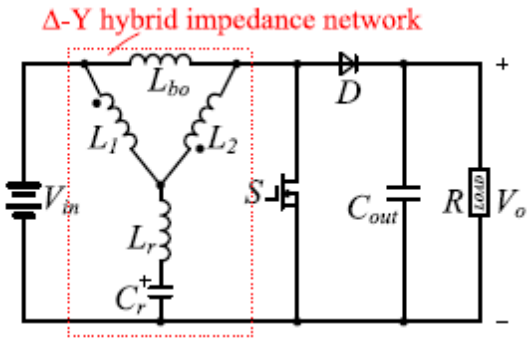

Figure 1.Conventional boost converter with impedance network

Figure 1 Shows the structure of conventional boost converter. This work propose a delta star technique based conventional converter to work with the ripple problem for the bst converter . delta star network consists of a main inductor, a L1,L2 (coupled) inductor, and a Lr inductor & two capacitor. The existing system remains the conventional converter's original circuit and voltage conversion advantage reduce the ripples & the improve efficiency of the conventional converter.

The paper presents a structure for effectively reduced ripple current with high efficiency ,but no help for minimized the Average Current of the buck-boost circuit's inductor.in this case we are using delta to star network based modified Buck Boost Converter with reduced input ripples. Active solution can adopted to reduce the input side ripples for conventional boost converter. The most attractive and typical solutions is to merge other power converters using an Interleaved Converter. the i/p current distributed to Inductor in other power converter and i/p side ripples can simultaniously reduced by normally controlling other power converters. and, the stress of current on each other normal power converter's inductors can be distributed at same time. But, this technique may high to the cost increases and very complex of the existing system as more passive & active component are needed.

II PROPOSED SYSTEM

A Buck Boost circuit

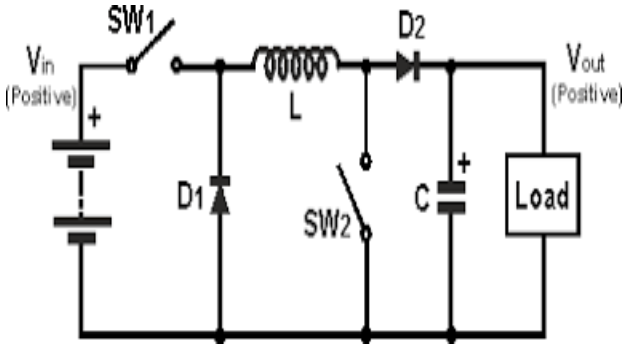

Figure 2.Buck boost structure

Figure 2.shows the circuit of the Conventional Buck Boost converter is greater than or less than the I/P voltage. A circuit having the two main switches, two different diodes, inductor, and output capacitor. The voltage of the magnitudes depends upon the main duty cycle. these converter also known as the Step down & Step up transformers. The i/P voltage is step down/up to some level of less than or more than the input voltages, by using the lower conversion level, the output power is equal to the input.

B.Modified system

This paper proposes delta star network based Buck-Boost converter with current ripple reduced The fig 3. Shows the proposed circuit.

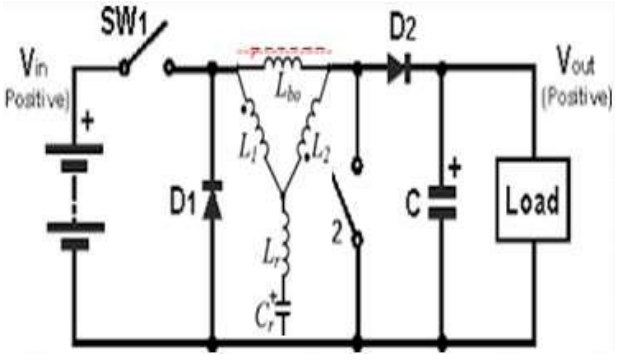

Figure.3.Proposed Converter

The Buck-Boost structure consists of two main MOSFETs S1 & S2,and two converter diodes D1 & D2 & the delta star network consists of a Lbo main inductor , L1 and L2 Coupled Inductor (*L*2 is the secondary and *L*1 is the primary sides),and a additional inductor Lr and two capacitor Cr. The modified converter remaining the Buck Boost Converter's original circuit and Δge conversion advantage reduce the ripple current input side and the current of the inductor.

To modify the equations of the working principle, two assumption are as follows:

i) All components are ideal
ii) Two capacitor size is large that the switching Δge across each capacitor is considered.

C.Modes of operations

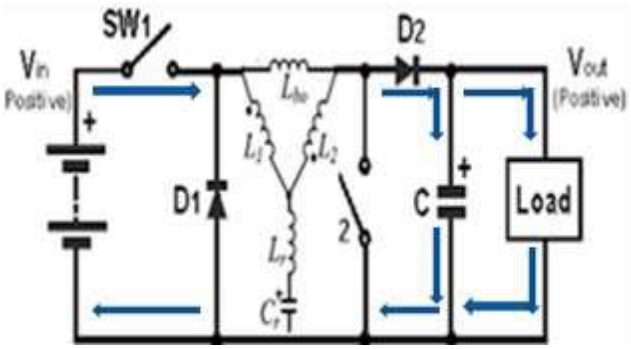
The circuit has 4 modes of operation in both discontinuous & continuous modes of the inductor.

Mode1 : In this mode S1 is ON condition, and converter diode D2 turned ON, Diode D1 reverse bias condition, switch S2 is OFF, current is flowing through the load via the main inductor and current in the load and the charge on output capacitor builds up gradually during the ON period.

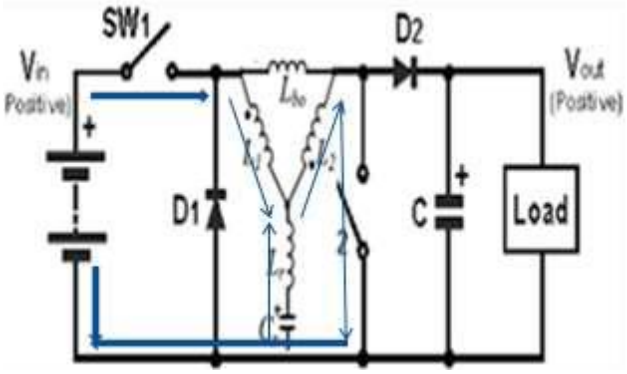
Mode 2 : Switch S2 is ON and S1 still ON & the D2 diode is reversed current by the voltage of the output, The Inductor is charged by the Δge of the i/p V & I increases. and The current through the La inductor & the current through the *Lb*(*iLb*) inductor is Increasing from *iLa* is bigger than *inductor 2 current*, The current through the Lc inductor (*iLc*) is +ve. the is store the energy. As to the increase the value in *iLbo*, The maximum of the ripple eliminated in this case.

Mode 3 :The switch is OFF & the D1 and D2 is same time conducting. the initial source of current now the inductor. The Lbo inductor is and energy releasing & current decreasing. current inductor via (*iLa*) is increasing & current flow in the next *Lb*(*iLb*) is decreasing. *iLb* is bigger than *iLa*, current flowing the *Lc*(*iLc*) is not +ve & the *Cr* is energy releasing. In this mode4, the value is increased in *iLa* can balance the amount is decreased in *iLbo*, the inductor input side current ripple reduced.

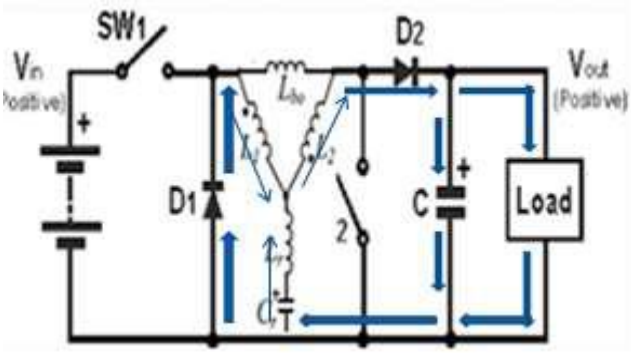
Mode 4 : in this mode switch S1 conducting and diode D2 still conducting, diode D1 reversed biased, switch S2 is turned OFF, current is flowing through the load from the converter inductor and the output Co charged,D2 is now forward bias.



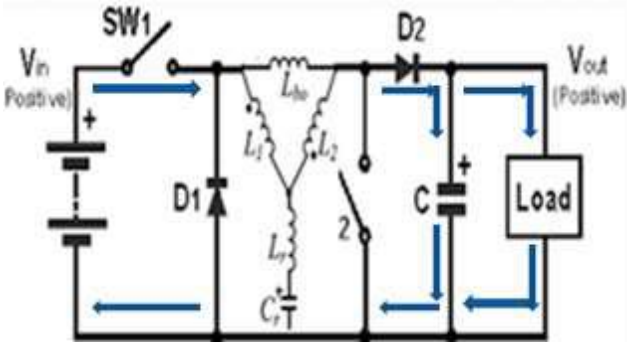
(a)



(b)



(c)



(d)

Figure .4 Modes of operation (a) Mode I (b) Mode II (C) Mode III (d) Mode IV

D.Design equations

converter having the Lbo inductor, two switches S1,S2,Cout capacitor & load. Modified circuit having L1,L2 inductor, Cr inductor, resonant capacitor . By using Kirchof law,

La = inductor 1 + M
Lb= inductor 2 +*M*
Lc= Resonant inductor (1)

where inductor 1 & inductor *2* of the Coupled Inductor and Equivalent inductor is the inductor 3, *M mutual inductor*

Dutyratio

D =Ton/T (2)

Output voltage

Average voltage across the main inductor is zero,

Vo = Dvin / (1 – D) (3)

To design capacitor & inductor of the Buck Boost Converter

Lo = (1-D)Vo/(ΔILO)fs (4)

Output capacitor

Co=D/ (Rfs) (ΔVco/ vo) (5)

The avg current of the conventional converter inductor Lbo, equation given below

IAvg-D=Iin (1- D) (6)

IAvg-s=IinD (7)

Using kirchoff's circuit law for input current

Iin=ILbo + ILa (8)

The i/p side ripples current of the modified converter can be derived as

ΔIin=ΔILbo + ΔILa (9)

III SIMULATION RESULTS

The MATLAB simulation results of the existing & .proposed converter results are obtained and verified. Fig.5 shows the voltage current across the switch and fig 6 output diode voltage and current .

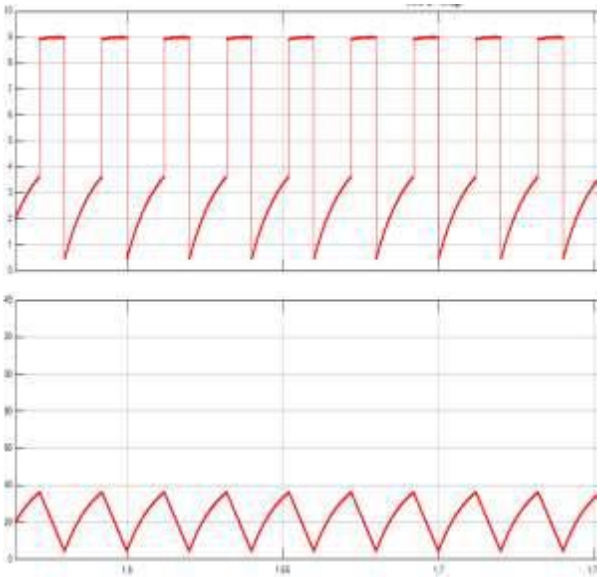


Figure .5 Input current & voltage of the conventional boost converter

Figure 5.shows the inductor current ripple . To reduce the inductor ripple current using the delta to star network & figure 6.diode voltage and current.

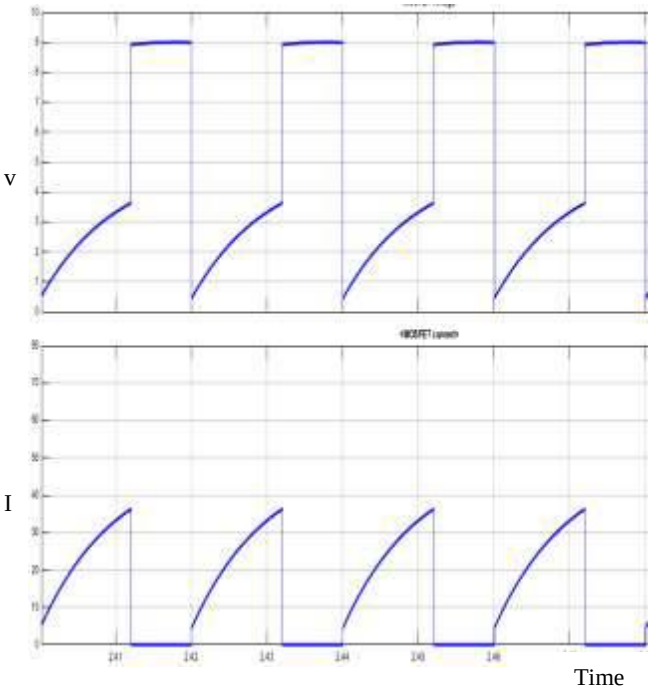

Figure .6 Diode V and I of the boost Converter

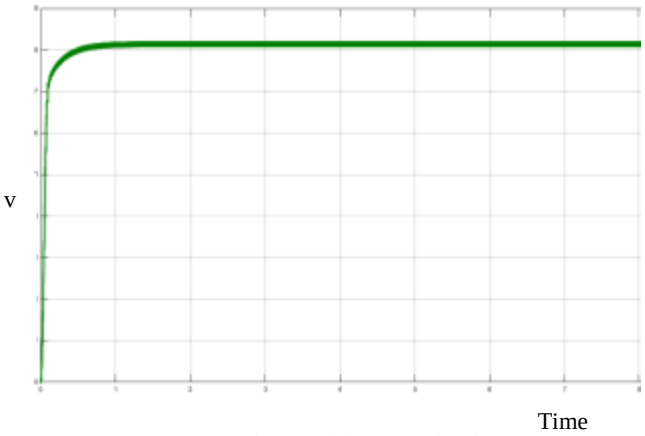

Figure .7 O/P Δge of the conventional boost converter

Figure 5 shows switching across the voltage and current(I) of the boost converter and the ripple (I)current is identified in the traditional converter. Fig7 shows output voltage of the traditional converter.

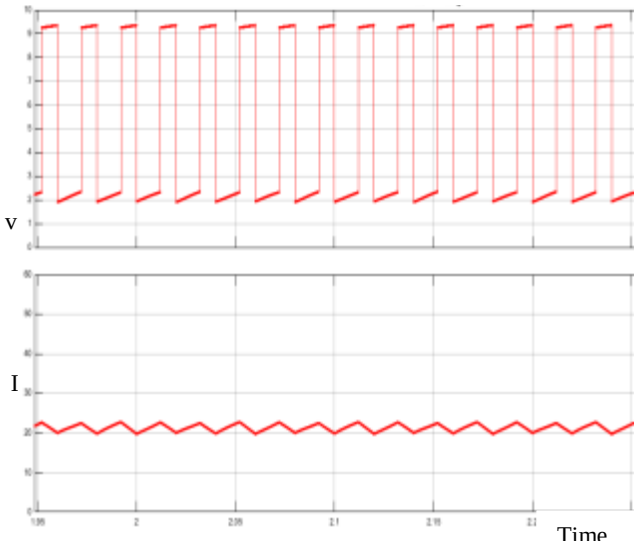

Figure .8 Inductor current and switching voltage of the existing System

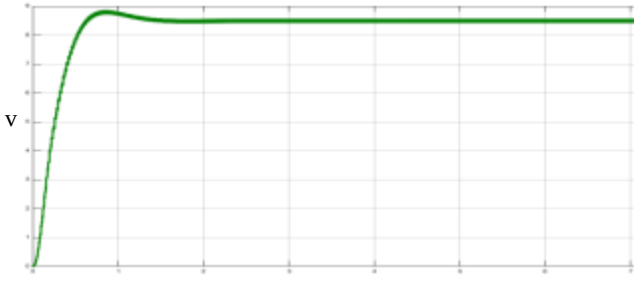

Fig .9 Output voltage of the existing system

Fig 8 shows switching across the voltage and current of the existing circuit, the ripple current can be reduced compared to the traditional converter. Fig 9 shows output voltage of the existing circuit.

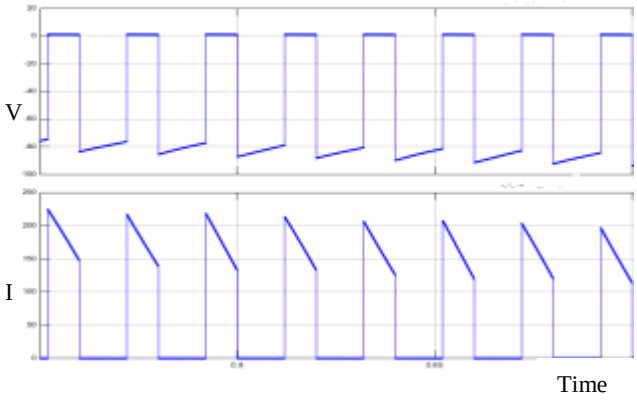

Figure .10 Diode V and I of the modified system

figure 10 diode voltage and current of the modified system. figure 11 shows the inductor current and switching voltage of the modified system.

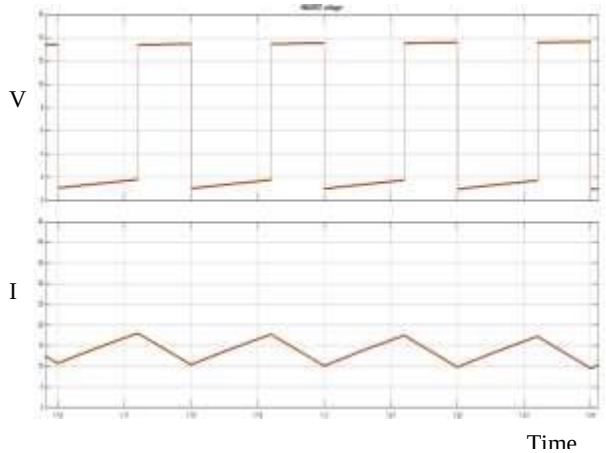

Fig .11 Inductor current and the MOSFET voltage of the modified system

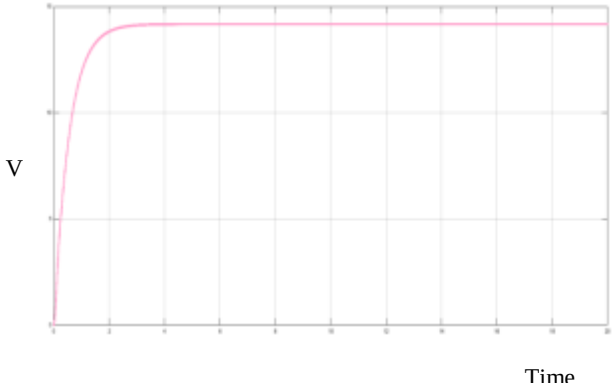

Fig .12 Output voltage of the modified system

Fig 11 shows switching across the voltage and current of the modified circuit, the ripple current can be reduced compared to the traditional converter. Fig12 shows output voltage of the existing circuit.

IV CONCLUSION

The Buck Boost Converter having a star to delta impedance network with reduce input current ripple and improves efficiency. The converter with coupled inductor reduces the ripple current and average current. The delta star network based Buck Boost converter in the main inductor to reduce the ripple current. which apply the delta star network to replace the Inductor in the Buck Boost Converter. The ripple is reduced comparing to the conventional converter .and also improved the efficiency comparing to the conventional converter. The proposed system is used in telecom and computer applications and also used in electric vehicles photovoltaic cells & satellites

Abstrac-- With the continued demands of software organizations, the rate of defect offered in the software cannot be ignored. In the essential process of bug-tracking, software maintenance has been found in the previous findings to improve the security and bug-fixing process by forecast the 'bug quality' of the software project. For this reason, many classifications / forecasting approaches have been created in the year to provide an automated argument on the severity classes.Bug interpretation of bug reports certainly decreases concert of bug prediction models. Manual testing can help lower the sound but brings substantial loads for the development. Bug fixes enable software developers to resolve software problems.

Index Terms: Bug Triaging, Bug Severity, Bug Forecasting, Classification,

I. INTRODUCTION

As recently as promotion in software technology, software organizations are coming up with the latest software development at the latest rates. These are large pieces of software size that contain many lines of code, which results in defects and drawbacks. Today, we are in a situation where the likelihood of flaws in the software is being highlighted, which leads to a lot of speed, which leads to effective failure. This is due to an ever increasing size of new developed software to meet the demands of the people. The beginning of a fault in software is an inevitable event that we can not survive. So, there is only one solution that has been left for us, to find out the fault and after this, as soon as possible, to prepare some methods and tools to remove these defects from the software [1]. Bug fixing system (BTS) reports these defects. These bug tracking systems normally maintain databases for collecting and maintaining bug reports. BTS tracks bugs in a large number of bugs. Therefore, to fix the bugs at slowness time and assets and to find out which should be sort out soon, it becomes a challenging task for the triaging [2]. Preferring bug reports helps developers better manage bugs triggered process. The main bug is instruction book and takes time. The bug report should allow users to compare the information given in new bug reports to the current education, and determine the level of priority [10].

Different Levels for Bug Priority and Severity

1. High severity & High Priority: The decline in all important business cases automatically gets promoted to the current category.

2. High Priority & Low Severity: Any small serious bugs that directly affect the user's expertise are automatically promoted in the current class.

3. High Severity & Low Priority: The defects need to be mounted, though not directly. This will be especially during the ad hoc testing. This implies that practicality is affected to an extent, although it suggests that only some unusual input parameters are used

4. Low Severity & Low Priority: No Writing System Mistakes / Font Cover / Not Applicable within the paragraphs of the third or fourth page of the arrangement and within the main or front page / title. Usually the dimensions of the cell in cosmetic errors or in a table on the UI are classified here.

In order to assist in bug fixing, it have a tendency to introduce a new automatic approach to suggesting the level of priority of the bug report. To do this, we have a tendency to leverage the data within the bug report. A simultaneous and lengthy interpretation of bug reports, in which users can encounter the default. These are the people who are complex, the grate counting bugs and many more. We want to take advantage of this data to foretell the priority level of the bug report [11].

Bug Report Format: Today the use of jira and bugzilla bug trackers for different types of bug tracking system is used to compare bugs. The severity of the bug is an main element in deciding the priority of the bug because the number of bugs is usually high. A bug is basically a description in which software engineers mention the position of a fault in the software system[11].

Table1: Bug report Content[11]

Field	Description
Summ	Summary: This field contains a short description and contains only a few words.
Desc	Description: This field contains a detailed explanation of the bug and information like how a bug has reproduced an error in the output when the bug will occur.
Prod	Product: It is the product affected by a bug.
Comp	Component: It is the component affected by a bug.
Sev	Severity: It is basically the level which is assigned to the bug according to its impact on the software. The severity level for the bugs are the following: • Critical • Major • Moderate • Trivial

*BUG SEVERITY***:** It is the degree to which the error can influence the software. As such, it characterizes the effect that a given error has on the frame. For example: if an application or page fails when a remote connection is clicked, for this situation touching the remote connection of a client is uncommon, however, the effect of the destruction of the use is serious. Then, the severity is high but the need is low [1]. For the most part, the bug reporter does not know how to handle severity, so the standard is assigned in the severity value and discussed below.

(i) Critical: The bug that outcomes at the end of the entire framework or at least one part of the framework and causes broad defilement of the information. The fizzled work is unusable and there is no worthy option strategy to accomplish the required outcomes then the severity will be expressed as critical.

(ii) Major: The bug affects the main function or the main data. This is the solution, but it is not clear and it is difficult. Example: A feature is not a functioning function of a module but it is possible if 10 complex indirect steps are applied in more modules.

(iii) Moderate: The bug that does not bring about the end, but rather makes the framework deliver mistaken, fragmented or conflicting outcomes then the severity will be expressed as moderate.

(iv) Minor: The bug that does not cause the end and does not harm the convenience of the frame and the coveted results can be acquired without effort when solving the bugs and then the severity is expressed as minor.

(v) Cosmetic: The bug that is identified with the improvement of the framework where the progressions are identified with the look and feel of the application then the severity is expressed as cosmetic.

Manual Bug Testing: Bug life is a special set of bicycle states that goes from detection to faultless stability. The number of states that differs from project to defective project. Below Figure 1 are the manual steps taken to diagnose bugs.

- *New:* When a latest fault is logged and posted for the first time, it has been decided as a new status.
- *Assigned:* Once tester post the bug, the forefront of the tester agreed to the bug and allot the bug to the developer team.

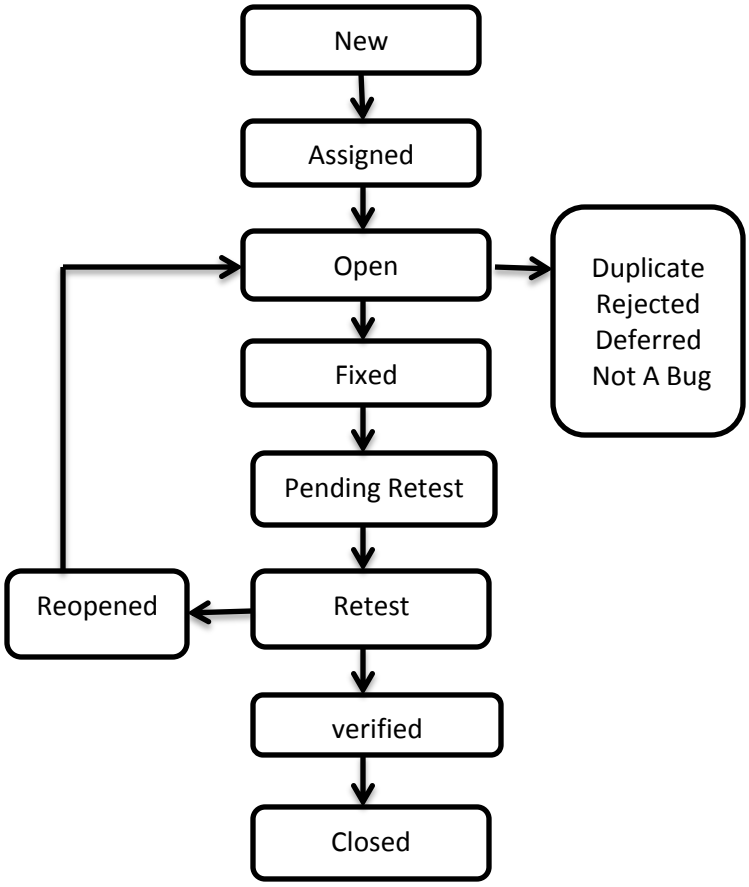

Figure1. Manual Bug Testing

- *Open:* The developer inception analysing and works on fault resolve.
- *Fixed:* When a developer changes the preferred code changes and substantiates the change, he may "fix" the bug situation.
- *Pending retest:* Once the fault has been fixed, the developer gave the code a special code to reassign the code to the tester. Because the software test is left over from the end of the tester, the status represented is "pending request".
- *Retest:* To check whether the developer has made a fix or not and the "re-investigation" to investigate the situation, the investigator reviews the code at this stage.
- *Verified:* Backups the tester bug after the developer define if a bug is originated in the software, the bug has been corrected and the set to status is "verified".*Reopen:* If the bug is still pending, the developer has firm the bug, then the lawmaker has changed the situation to "reopening" again the bug proceed through the lifecycle.
- *Closed:* If the bug is not present then the tester directs the position "closed".
- *Duplicate:* If the defect is frequents twice or the fault matches the same fundamental of the bug, then the situation is "duplicated"
- *Rejected:* If the developer perceives the defect is not authentic defect then it changes the defect to "rejected."
- Deferred: If the current bug is not a prime concern and if it is expected to come in the next freeing, such bugs are evaluated "deferred".
- Not a bug: If this does not affect the functionality of the employment then the given situation in the bug is "no bug".

II. LITERATURE SURVEY

Jindal, Rajni et al. [1] presented a defect severity prediction model by mining the software reports. This model has the ability to predict the severity level of the bug in the bug reports. The defects reports used in this are from the PITS dataset. This data set is popular because it is used by the NASA. Data mining approach is involved to extract the data from the reports and then used by the prediction model. The concept of logistic regression, multi-layer perceptron, and the decision tree is used in this model. The outcomes of the decision tree are best among all when it is compared in the analysis process.

Heena Singla et al. [2] proposed the bug tracking system which identifies the bugs. Physical method is different from software which inputs are accepted and outputs are generated. Any change in the software is usually requested while developing any software system. Mainly, the request is related to software maintenance. The cost of the software is usually spent on software maintenance. The BTS is manually assigned to a respected developer for fixation.

Kwanghue Jin et al. [3] proposed a new programming framework, developed and used as a part of the quality of the fields. Along these lines, bugs ought to be settled accurately to their seriousness levels since they have to isolate seriousness levels. Subsequently, rectify expectation of bug seriousness is required for effective programming improvement and support that designers can know which bug requires to be settled promptly. Prior investigations utilized just content data of the bug report for their forecast systems. In this manner, so as to build up the bug settling, initialize a solid procedure of bug seriousness expectation that additional the Description and Reporter fields since bug columnists record content qualities of the report.

Zhou et al. [4] proposed method of multilingualism by unloading material for computerizing the process of prophecy and adding information mining strategies. The main stage uses the content generation tools to cut down the body parts of the bug reports and perform at the potential three levels. Information connecting strategies are used to connect to two phases. Trials related to previous reviews of similar information - three projects - Reliable get a better upgrade; they have achieved their best results according to overall performance. Seven other well-known open source framework's past reviews have confirmed the searches.

Hans Hansson et al. [5] presented compassionate the dissimilarity between severability bugs and other bugs, in addition to the different severity bugs of their intensity and fixing time period, is a pragmatic study. The introduction of multicore and other parallel designs, there is an expanded necessity for adequate and viable treatment of programming executing on such structures. A huge angle in this setting is to comprehend the bugs that happen because of parallel and simultaneous execution of programming.

Fairuz Amakina Narudin et al. [6] proposed An optional answer to a bug-searching survey by using random training access to machine learning classifiers. Among the diverse system, activity

includes, the four arrangements picked are fundamental data, time-based, content-based, and association based. The approach uses two datasets: open that is MalGenome and private that is self-accumulated. In light of the evaluation comes to fruition, both the Bayes system and irregular woodland classifiers conveyed more precise readings, with a 99.97% genuine positive rate (TPR) instead of the multi-layer perceptron with only 93.03% on the MalGenome dataset.

Fabio Palomba et al. [7] presented the process of estimating bugs about a particular bug. In particular, it evaluate the commitment of a measure of the severity of the odors of the code (i.e, the intensity of the code warning) by looking at the new model's results in conjunction with the current bug reports model and the pattern shown. Results show that the accuracy of error forecasting increases by including the code warning magnitude as an indicator. It also evaluates the actual pick-up given by the intensity list in terms of alternative measures in the model, counting those used to record the intensity of the code warning. They see that the intensity list is much more vital when compared to the different measurements used to anticipate the bugginess of the doubtful classes.

John Anvik et al. [8] proposed automated bug assignments using time-metadata in tf-idf . In this technology, the interest of the developer to use the word is considered to determine the value of the developer skill. It raises the accuracy of bug assignment approach. This term improves the metadata of the word in the automatic bug assignment as an effective parameter in the form of commodity technology.

Yuan Tian et al. [9] presented the concept of multi-factor analysis for bug report prediction. This work is based on machine learning and factors like temporal, textual, author, and bug reports. These factors are considered as a feature and used for the training of the discriminative model using the classification algorithm. This classification algorithm handles the imbalanced data and ordinal class. The proposed model improves the f-measure in the outcomes.

Xiaohu Yang et al. [10] presented software bugs are regular in all phases of the product advancement and upkeep lifecycle. To deal with the report of programming bugs, every one of the engineers utilized following framework in programming bugs. In light of the most vital of programming bugs, countless systems have been intended to oversee and decrease the effect of programming bugs. These systems incorporate bug triaging and designer suggestion bugs need. In regular bug settling strategy, an analyzer or a client distinguishes a bug and presents a bug answer to clarify the bug in bug following frameworks.

Shruti Gujral et al. [11] proposed a calculation of bug severity arrangement which can further enhance the execution of the programmed procedure of bug severity arrangement. The calculation incorporates making a lexicon of condemnatory terms that assistance in choosing severity level naturally. These condemnatory terms are accumulated in the wake of pre-processing of bug reports.

Adhiselvam et al. [12] proposed the concept of the MRTBA in which edge weight is used to take the information and procces calls the program. Here every hub speaks to strategy and each edge speaks to a technique called. The calculation goes into recognition of flawed hubs. The approach mines all hubs at the same level, as well as the hubs, exhibit at various levels. In this approach MRTBA, bug restriction approach has been introduced for dynamic control stream. This work can be enhanced by stretched out with the proposition of steps includes in associating same hubs at various levels. It likewise additionally upgrades to discover aberrant recursions for both the non-trivial and trivial map lessening in programming bug limitation.

Cheng-Zen Yang et al. [13] proposed a method to improve severity prediction of software bug reports suing four quality indicators. Classification of the bug report is based on the Multinomial Naive Bayes (MNB) classifier; where first of all, the preprocessing of bugs is performed then structural information extraction for quality indicator then this data goes to the prediction model and severity is predicted with incoming defect reports also. The outcomes of this approach improved from the existing approaches.

Ali Feizollah et al. [14] presented the 5 machine learning algorithm on the malware data samples collected from the android based genome project. The work is based on the network characteristics by using parameters that are duration of a connection, TCP size, and GET/POST parameters. The performance evaluation is done on the basis of outcome comparison and found that the KNN (K-nearest neighbor) provides the optimal and effective results among 5 classifiers.

Yang et al. [15] proposed a method of severity prediction and bug triage of bug. In this firstly bug reports are take out from the bug repository it gives

the complete information related to the bug. In this method firstly fix the bug and then predicts its severity. The result of the proposed paper shows that this is very effective to fix and predict the bug.

Nivir Kanti Singha Roy et al. [16] proposed the concept of text mining with bi-grams and highlights the determination to make better the order of the bugs in the serious / non-extreme classes. They adopt the NB classifier taking into account the Mozilla and Eclipse datasets commonly used in related work. The outcome is independently subordinate because sometimes the expansion of the bi-grams can aggravate the execution.

N. K. Nagwani et al. [17] focused on the prediction at the granularity of files. This work investigates the respond of the developers on the bug prediction algorithm by using the research question. The purpose of the research objective is to inform informal discussions and third party solutions to informal user studies, data gathered from Google tools and other questions. The outcomes show that there is no notable change in the developer's conduct after using bud prediction algorithm.

Table2: Summary of Literature Survey

S.No	Author	Year	Data Set	Parameter Used	Basic Methodology/Algorithm	Future Scope
[1]	Jindal et al.	2017	PITS dataset	• Sensitivity • Cutoff Point • Area under Curve	-Logistic Regression -Multi-Layer Perceptron -Decision Tree	These 3 models have shown a truly sensible achievement for estimating the high level of flaws. However, because the medium, low and indeed low-level fault level estimation, only the DT model is appropriate.
[3]	Jin, Kwanghue, et al.	2016	Eclipse and Mozilla Dataset	• Precision • Recall • F-measure	-Multinomial Naïve Bayes	Bugs submitted by reporters it do thus for initial time, the accuracy might decline as a result of solely the component applied is employed for prediction, Since no past report former time exists.
[4]	Zhou, Yu, et al.	2016	Bug Report Corpus	• Precision • Recall • F-measure	-Multinomial Naïve Bayes	How many training e.g. are needed in every stage to provide stable prediction result? A mix of independent models will increase performance.
[6]	Narudin, FairuzAmalina, et al.	2016	MalGenome Dataset	• Precision • Recall • F-measure	-Naïve Bayes -Random Forest	The larger the scale of the dataset, the higher is that the time interval to make the detection model and increase the precision, recall and f-measure value.
[11]	Tian, Yuan, et al.	2015	Bug Repository of Eclipse	• Precision • Recall • F-measure	-Gray classification Engine - Linear Regression	Plan to combine there tool with bugzilla or other bug tracking system.
[12]	Xia, Xin, et al.	2015	An open dataset of 6 bug blocker	• Precision • Recall • F-score	-Bagging -Random Forest	The performance of ElBlocker is not perfect. To Enhance the performance ELBlocker need to apply some information retrieval and text mining technique.
[15]	Gujral, et al.	2015	Bug-Zilla repository	• Precision • Accuracy	-Dictionary Based Approach -Multinomial Naïve Bayes	To improve bug classification have to be compelled to add wordbook of terms.
[16]	Adhiselvam et. al.	2016	Input Programs	• Dynamic Control Flows	-Map Reduce Apriori Algorithm	Interlacing ditto node at totally disparate level, self-recursions method to urge the utmost variety of minimum map scale back nodes.

Shadi Banitaan et al. [18] proposed TRiaging Approach utilizing bug reports Metadata.. They perform test assessment on open-source extends to be a specific Free desktop, NetBeans, Eclipse, and Firefox. The comes about to demonstrate that TRAM beats existing machine learning based approaches as far as characterization exactness.

Kim Herzig et al. [19] proposed comprehensive issues with the division of bugs and non-bugs in programming chronicles, which can greatly affect the

accuracy of the equipment and focus that use such information. Methodologies depending on bug *datasets ought to be gone before by a watchful manual approval of information quality; in any event of a noteworthy specimen. Information quality ought to be talked about as a danger to legitimacy. Bug prediction models prepared and assessed on one-sided informational indexes are debilitated to anticipate changes rather than bugs. Sifting through non-bugs while evaluating code quality may even enhance comes about. The arrangement of bug reports is reliant on the point of view of the spectator. Methodologies utilizing bug informational collections ought to approve whether the point of view of the prediction display coordinates the point of view of the bug maker

Xin Xia et al. [20] studied the impact of the misclassification in the bug prediction. It is a bug report of 5 open source projects in which misclassified bug reports have also occurred in which bugs are considered as a feature. The misclassification introduces the bias in the prediction model makes confusion between bugs and features.

Fischer et al. [21] presented the Discharge History is a way to create a database that collects bug information and contains hidden information that is not protected by the wireless control framework, for example, the combination Focus. At that time, fundamental questions can be integrated with organized information to achieve the important perspectives that highlight the development of a product enterprise. Such perspectives enable more accurate thinking about the angle of development and encourage the development of programming. They showed access to Mozilla's vast open source project which offers unique possibilities to look for and approves access.

Malhi et al. [22] Enforcement of Elementary Integrity Check (PCA) strategy in the light of an element of planning. The eligibility of the plan was confirmed on one direction test bed, which uses both direction and unsafe perfection order in both ways. The goal of the examination was to recognize the seriousness of producing imperfection, where there was no access from the beginning of the disorder conditions. The proposed plot has already appeared to present an order of more correct behavior, with lesser fact contribution than using the most importantly watched points. As a result, the machine certifies its usefulness as a powerful tool to evaluate fitness.

III. CONCLUSION

In this paper, bug severity classification has been utilized i.e. a problem related to software engineering for forecasting the most suitable level of a subject that could be helpful in activities like bug schedules. Software bug fixing is a crucial step for open source and business software, so bugs have their severity level [16]. Many attempts have been made to classify defect severity. The text information used for the preview is also the purpose. More searches in this way determine the purpose of predicting the severity of the bug.

***Abstract*—The study in this paper uses the concept of Internet-of-Things (IoT) to represent a station containing a thing of interest termed as Station-of-Things (SoT). Research in communication, computation and sensors innovation has enabled to build intelligent SoT environment. This SoT environment is applicable to numerous situations to identify the inhabitance of chairs in a study hall, seats in a theatre or auditorium, cars in parking-lot, books in a bookshelf, and so forth. In this paper, the proposed communication model, network model and test results show the value of the work which establishes a framework to gauge and assess the inhabitance of the thing in a station. Further, the sensor network enables the capturing of dimensional-data. This data is utilized by a machine learning model to infer the type of a thing. Hence, the study demonstrates a preliminary data model to predict the type of thing in SoT environment.**

Keywords—Station-of-Things (SoT); Smart Parking System; Intelligent Parking System; Wireless Sensor Networks (WSN); Internet-of-Things (IoT); Ultrasonic Sensor; Infrared Sensor; Radio Frequency Identification (RFID) Sensor; Machine Learning (ML); Artificial Intelligence (AI)

I. INTRODUCTION

With the development of innovation and the accuracy of the Moore's law [1], there has been a pattern to advance an intricate microchip to satisfy the necessity of smaller yet powerful cost-effective miniaturized devices. Numerous gadgets these days are outfitted with exceptional registering power, conceivably including additional usefulness and in this manner, it appears to be normal to interconnect gadgets in the period of web innovation. Such availability, upheld by the consolidation of asset compelled gadgets including sensors and actuators, empowers savvy frameworks that acquire data from the physical world, procedure such data, and may perform activities on the physical world appropriately has stressed to build smart environments around us.

Advantages of web innovation include efficient resource management, upgraded profitability and expanded personal satisfaction for human populaces [2]. The joint inspiration fundamental in all exploration fields is to explore how "shrewd innovation" may improve our private and expert life, and how that innovation can be figured it out. To land at our ideal objective, a few disciplines need to contribute, going from specialized disciplines required with sensors and systems to artificial intelligence and human-PC cooperation, and beyond. A system has always been classified as smart [3] system whenever sensors have been used to perceive, interpret the perception and yield wise decisions beyond perceive-act rules. However, intelligent systems are combined with perception and action to derive methods that emphasize refined handling strategies that are driven by technological innovations. Artificial intelligence is a composite of both smart and intelligent systems and relates how the perception can be co-related to the human like actions.

Human portability is a need and without it, individuals will battle to get to the administrations and merchandise and meet social and financial prerequisites expected to satisfy a solid life. A quickly developing worldwide populace, expanding prosperity, urban spread and declining transport costs are pushing this interest for versatility upwards further and further. For example, the number of vehicles sold in the recent years worldwide has consistently risen. Transport is a human asset and a vitality escalated, for instance, which is likewise in charge of a sizable offer in worldwide ozone harming substance outflows. Car is the mostly used land transport. Stopping and traffic blockages keeps down monetary efficiency. Car parking techniques differ and has advanced in the course of recent years with respect to the varying organization needs. They are the consequence of incorporation of different techniques and proliferations in communication, computing and sensing technologies. These techniques have evolved with generation of voluminous data sets challenging to manage.

II. RELATED WORK

The most recent two decades have been caution of the dynamite examination to determine the parking mess. Authors have introduced and proposed different methodologies to implement smart parking. Smart parking is the combination of technology and human innovation to reduce human effort for the parking of vehicles. The smart parking methodologies differ from each other in the detection mechanism used to detect the presence or absence of a car in a parking space, how the occupancy status of parking space is reported to the next base station or server, the communication protocol and architecture in use, the flow of data architecture, hardware and

software that work hand in hand as a standalone system, and so forth.

The researchers have proposed parking models where each parking space is monitored with the deployment of a parking node at each parking space. In [4], the author proposed a GSM (Global System for Mobile) network-based parking reservation system, which allows the driver to pre-book the available parking spaces through SMS (Short Messaging Service). A similar system has been proposed in [5] however, it requires Internet connectivity to pre-book the parking space. The system utilizes light and vibration sensors, that are installed in each parking space to collect occupancy information. In [6], RFID (Radio Frequency Identification) tags are placed at each parking space. The battery that controls the RFID is supplanted by a sunlight-based cell. As the vehicle consumes a parking spot, its shadow will block the sunlight-based light, and subsequently the RFID label won't be fueled, making it stop transmission of information to the reader put at some separation. In any case, this system is faulty, on the off chance that the shadow does not falls on the RFID tag or the sunlight-based cell in the RFID tag is impeded by the motor oil, that may spill from a vehicle may trigger false detection of a car. In [7], the author proposed a WSN (Wireless Sensor Network) based parking system, where the wireless nodes are installed at each parking space, and they report parking availability information to the next base station.

The study has evolved further where the authors have proposed smart parking spaces that can be collectively monitor multiple parking spaces without the requirement of installation of parking node at each parking space. In [8], a camera sensor captures a series of images to analyse time variant parking status, however the system does not have a mechanism to report the occupancy status to the user. The proposed work in [9] is inspired by [8] where in circles are drawn on each parking space. If a car has occupied a parking space, the circle will not be visible by the camera, and system will understand that the parking space is occupied; if the circle is visible, system will consider the parking space to be unoccupied. In [10], the author proposed a parking lot surveillance system that incorporates microphone sensor nodes to detect an acoustic event to improve the performance of camera-based system proposed above.

The efforts of researchers have progressed and they have proposed parking systems that use the combination of two or more technologies for reliable performance. In [11], computer vision is used to extract vehicle information from the license plate, at the entry of the parking lot itself. In [12], the author proposed an IoT (Internet-of-Things) based system inspired by [11], where each parking space is also monitored by a Pi camera and an ultrasonic module. As the driver parks the car in the parking space, the camera at the parking space will match the information collected at the gate. In [13], the author proposed a smart parking framework that uses the integration of both WSN and RFID. RFID readers are placed at the entry and exit of the parking lot. The WSN monitor the status of the parking spaces and the RFID monitors the entry and exit of vehicles from the parking lot. In [14], the author proposed a RFID and GSM based solution to prevent theft of vehicles from an organization. In [15], the author proposed a smart parking system based on the integration of WSN, RFID, ad-hoc network and IoT. It mainly addresses the cyber security issues that may possess a threat to the smart parking network and presents a basic model of cryptographically tackle them.

The work in this paper aims to digitally detect the occupancy of a *station* along with the ability to predict the *thing* type that occupies the *station*. The paper is organized into seven sections. Section III introduces the notion and case-study of *SoT (Station-of-Things)* contemplated in this paper. It also presents the logical, physical and data exchange interpretation of the *SoT* model. Section IV describes the firmware required for the implementation of *SoT* model. Section V presents the *SoT* model for implementation. Section VI depicts the results and the challenges associated. Section VII concludes the work and proposes the future work.

III. STATION-OF-THINGS MODEL

The work in this paper presents a notion to represent the state of a *station* containing an object or a *thing* of interest together constitute *SoT* [16]. Occupancy of benches in a classroom, books on a book-shelf, seats in an auditorium, cars in a parking lot, they all exemplify *SoT*. The use of occupancy of a *thing* and its *size* in a *station* leads to the generation of information useful to derive intelligence in the *SoT* environment.

A. Assumptions

In this paper, a car parking space represents a scenario of *SoT*. The parking space is the effective area required to *station* a car. Ref Fig. 1. the parking space for the implementation of *SoT* model is a semi-closed type, with a tin shed at the top, that serves as the roof and provides shelter to the car with the following dimensions: 450 cm (L) x 350 cm (B) x 300 cm (H). The height of the car is denoted by 'h'. The parking space is within a Wi-Fi (Wireless Fidelity) enabled ecosystem and has provision to provide 220 V power supply. Alternatively, direct solar can be an option, however, it lies outside the scope of the paper.

S1 and S2 are the output of the Sensor_1 (Ultrasonic Sensor) and Sensor_2 (Infrared Sensor) respectively. A and B are the lower and upper thresholds set for the prediction of a car. C and D are the lower and upper thresholds set for the prediction of a Hatchback/Sedan type car. E and F are the lower and upper thresholds set for the prediction of a Crossover type car. G and I are the lower and upper thresholds set for the prediction of a SUV type car.

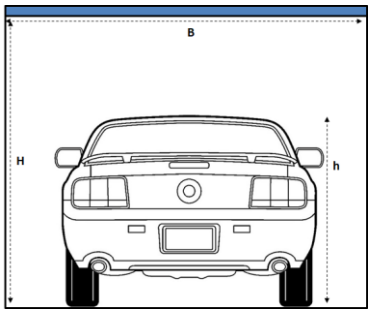

Fig. 1. Data Parameters for Station-of-Things Model: Parking Space

B. *Network Model*

The details of the network models to enumerate network architecture type I and II, Ref Fig. 2. of the *SoT m*odel is as follows: -

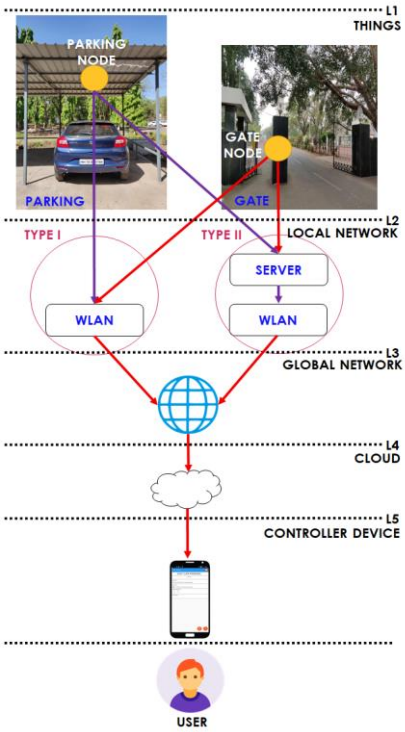

Fig. 2. Station-of-Things: Proposed Network Model

The type I architecture where in layer L1 takes in the deployed nodes (parking node at each parking space and gate node at the common entry cum exit gate of the parking lot) comprising of the microcontroller board and sensor modules, layer L2 is the interconnection of these nodes within a local network such as an organization network, represented as 'WLAN' that enables the flow of data, subsequently layer L3, to allow flow of data from a local network to another local network that is connected to a common global network. Layer L4 is an online service platform to decipher the sensor gathered data, on which layer L5, a controller gadget sits and is overseen by a user.

Layer execution remains the same for type II architecture as in type I. The type II architecture provides a mechanism where most of the data generated within the organization is retained and is not pushed to the cloud. The choice of retaining data will differ from one organization to another. This architectural design is future proof in discrepancies that may occur in Internet dependent networks. The study in this paper progresses with the type II network architecture.

C. *Communication Model*

Ref Fig. 3. is the interpretation how the miniaturized devices with constraint computation is required to communicate with heterogeneous devices connected to the web. There is a prerequisite of a convention that aides and supports such correspondence between heterogeneous gadgets that contrast on preparing, memory and capacity abilities. MQTT (Message Query Telemetry Transport) is a messaging based publish-subscribe protocol [17] that supports such heterogeneity. This protocol has been intended to work in restricted transmission capacity systems to interface with constrained CPU's and with a next to no overhead. The MQTT framework comprises of the clients (nodes) that speak with a server, regularly called a broker. The client can be classified based on the work it performs – a publisher or a subscriber.

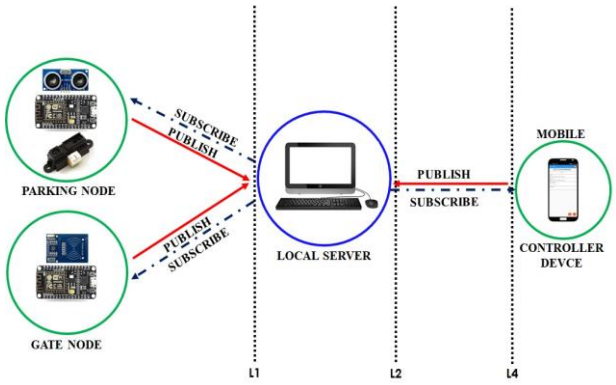

Fig. 3. Station-of-Things: Proposed Communication Model

IV. Data Modelling For Thing Prediction: Firmware

To enable the *thing* prediction using data models i.e. the data generated using the sub-systems, the hardware and software termed as firmware is described below.

A. *Hardware*

The framework equipment is sorted into four principle segments to be specific: parking node, gate node, local server and a mobile.

The parking node comprises of the Node MCU (Microcontroller Unit) [18] which is a solitary board microcontroller dependent on minimal effort ESP8266 Wi-Fi chipset, HC-SR04 US (Ultrasonic) sensor module and the SHARP GP2Y0A02YK IR (Infrared) sensor module. The HC-SR04 sensor module incorporates the transmitter and collector and has the accompanying particulars: 400 cm maximum radius for detection, 3 cm dead zone and 0.3 cm resolution with a beam angle of 30°. The US sensor works on the rules of SONAR (Sound Navigation and Ranging) and RADAR (Radio Detection and Ranging). The GP2Y0A02YK IR [19] sensor module is an active sensor based on the hypothesis of optical triangulation. It is equipped with an IR transmitter and a position sensitive device.

The gate node comprises of the Node MCU that houses RC 522 sensor module which is a passive RFID sensor that works at 13.56 MHz and can detect RFID tags in the similar recurrence from a most extreme separation of 3 cm.

An android OS (Operating System) based mobile application is used to obtain parking information which also supports booking of a parking space. The development of parking application is outside the scope of this paper.

The local server is deployed with storage and computational power.

The 5V/1.5A power adapter is an AC to DC converter, and is used to energize the parking nodes and gate nodes.

B. Software

The Arduino IDE (Integrated Development Environment) is a C language-based programming environment to write and upload the programs to the Node MCU.

C. Power Rating Ajustments

The GPIO (General Purpose Input Output) pins of the Node MCU can supply most extreme +3.3V, however the HC-SR04 US sensor and the SHARP IR sensor is rated at +5V. Supplying +5V to the US and IR sensor was an option, however it could damage the microcontroller board. To avoid this, a potential divider circuit was used to lower the sensor output voltage to a range that can be handled by the Node MCU.

V. DATA MODELLING FOR THING PREDICTION: IMPLEMENTATION

A. Parking Node : Sensor Mounting

Ref Fig. 4. and 5. the sensors can be mounted either on the top (below the shelter) or at the bottom (ground level). Sensors mounted underneath the car are prone to fluids such as oil and water, which may influence their discovery execution. To avoid that, we favored to mount the sensors on the top. This will certainly expand the life of the sensor and decrease its climate affectability.

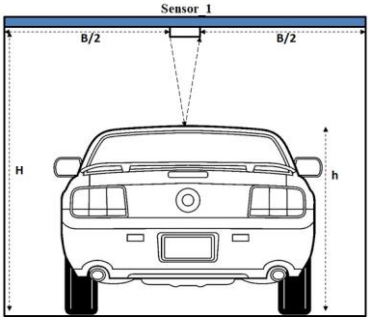

Fig. 4. Station-of-Things: Parking Node Sensor Mounting Type I

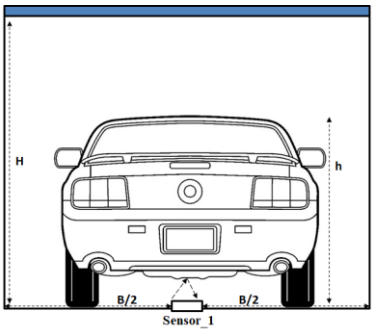

Fig. 5. Station-of-Things: Parking Node Sensor Mounting Type II

Ref Fig. 6. each car parking space is equipped with a two-sensor combination which can detect the inhabitance of a car as well as the data component (height of car) to bring intelligence by deriving information about the type of car parked in the parking space. A parking node collects periodically this information using Wi-Fi. When the status of a car parking space is changed, information about it will be pushed by the node to the further base-station/local server as designed in the communication model; either to the server/cloud/mobile.

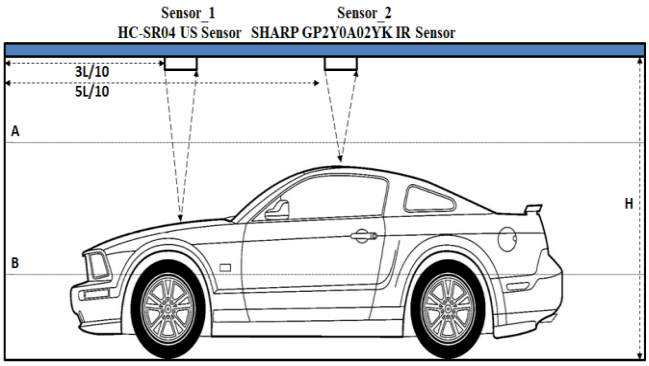

Fig. 6. Station-of-Things: Parking Node Sensors Mounting

B. Parking Node : Sensing Scheme

Table 1. lists the *height* (data component) features of the various car types and models that are pre-fed into the system.

TABLE I. REFERENCE TABLE CONTAINING PRE-FED HEIGHT OF CARS

Car Type	Model	Height 'h' (in cm)	Parameters (Ref Fig. 9.)
Hatchback	Maruti Suzuki Alto 800	147.5	C,D
	Renault Kwid	147.8	
Sedan	Maruti Suzuki Ciaz	148.5	
	Hyundai Elantra	146.5	
SUV	Honda CR-V	168.9	E,F
	Renault Duster	169.5	
Crossover	Hyundai i20 Active	155.5	G,I
	Maruti Suzuki S-Cross	159.5	

C. Parking Space Occupancy Scheme

Ref Fig. 6. and Fig. 7., the values read by sensors S1 and S2 form the input to the algorithmic steps employed to assess the inhabitance of a car in a parking space is as follows:

```
1. Read S1
2. If ((S1≥B)and(S1≤A))
3.      {
4.      Read S2
5.      If ((S2≥B)and(S2≤A))
6.              Output "Car Detected"
7.      Else
8.              Output "Can't Say, Car Detected!"
9.      }
10. Else
11.     Output "Car Not Detected"
```

Fig. 7. *Station-of-Things*: Car Occupancy Heuristics

D. Neighbourhood Hightlights Extraction Scheme

Ref Fig. 8. and Fig. 9., the values read by sensors S1 and S2 form the input to the algorithmic steps employed to assess the prediction of a car type in a parking space is as follows:

```
1. Read S2
2. If ((S2≥B)and(S2≤A))
3.      {
4.      If ((S2≥D)and(S2<=C))
5.              Output "Hatchback_Sedan_Type Car"
6.      Else If ((S2≥F)and(S2≤E))
7.              Output "Crossover_Type Car"
8.      Else If ((S2≥I)and(S2≤G))
9.              Output "SUV_Type Car"
10.     Else
11.             Output "Unknown_Type Car"
12.     }
13. Else
14.     Output "Can't Say, Car Detected!"
```

Fig. 8. *Station-of-Things*: Car Type Prediction Heuristics

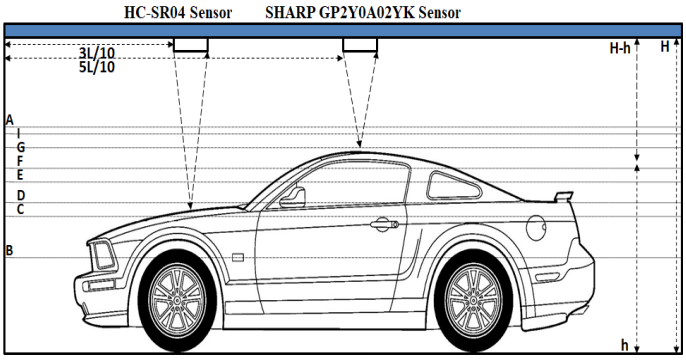

Fig. 9. Station-of-Things: Car Type Prediction Scheme

E. Parking Lot Occupancy Scheme

The gate node is mounted at the common entry way/exit way of the parking lot to monitor the number of cars entering and exiting the parking lot. Ref Fig. 10. describes the RFID sensing scheme employed. At any point of time, the occupancy status of a parking lot is computed as: Available Parking Slots (A) = Total Parking Slots (T) - Checked In Cars (C.I) + Checked Out Cars (C.O).

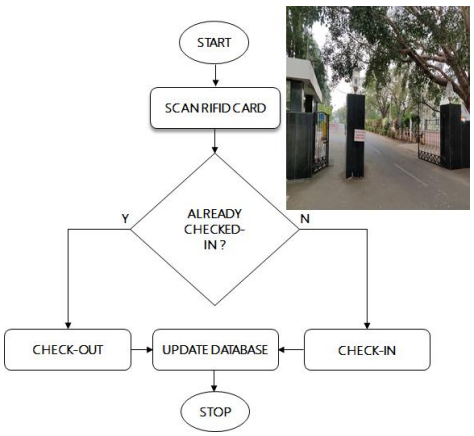

Fig. 10. Station-of-Things: RFID Sensing Scheme

F. Mobile Application Development

Ref Fig. 11. is the android based mobile application interface that is developed and installed in the security staff's device to provide real time parking information, reservation and manage check-in and check-out of cars.

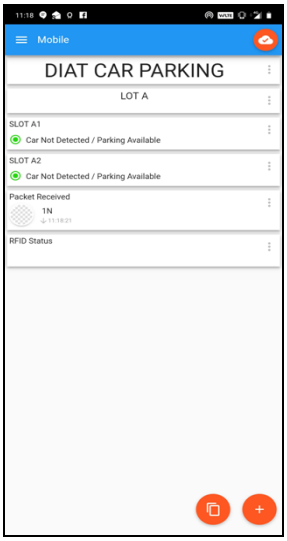

Fig. 11. Station-of-Things: Mobile Application Screenshot

VI. Results & Challenges

The proposed deployment model for *SoT*, Ref. Fig. 9. along with the occupancy detection of the *station*, also enables the prediction, Ref. Table II. The ability to estimate the dimension parameter demonstrates the merit of the work which lays a foundation to estimate the size-parameters of a *thing* in a *station*, Ref. Table II.

Here, the remote estimation of the neighborhood highlights in a parking space (*station*) such as the stature (height) for the extraction of the global features, for example, to anticipate the car type. In the long run, such information parameters inferred utilizing sensor hubs at right position in the *station* show the possibility to forecast the car type and car model. These sensor-hub created information nourishes to give the essential information types to improve machine learning models to enable artificial intelligence.

The difficulties associated here is the placement of sensors to quantify the useful parameters, sensitivity factor of a sensor-hub and ecological factors that affect the rightness in the readings. Deployment of such systems are prone to generation of lot of data leading to big data and hence employing suitable data analytics tools plays a major role to bring intelligence and correct predictions.

TABLE II. RESULTS CONTAINING HEIGHT BASED PREDICTION CAR TYPE

Model	Predicted Car Type
Maruti Suzuki Alto 800	Hatchback/Sedan
Renault Kwid	
Maruti Suzuki Ciaz	
Hyundai Elantra	
Honda CR-V	SUV
Renault Duster	
Hyundai i20 Active	Crossover
Maruti Suzuki S-Cross	
Jeep Wrangler	Unknown
Tata Nano	

VII. CONCLUSION & FUTURE WORK

With the approach of IoT and WSN, the research on building the smart parking systems has advanced rapidly. Variety of smart parking systems exist. A smart parking solution contributes to bring effectiveness in human-endeavors. In areas and regions where installation of cameras to detect a *thing* is prohibited such techniques form a base, to enable identification of a *thing* which occupies a *station*.

The study in this paper proposes a concept of *SoT*, here a parking lot represents a s*tation* and a car represents a t*hing*. The study proposes a technique which utilizes ultrasonic and infrared sensors to detect the desired parameters. A deployment model, network and communication model for *SoT* to the requirement is proposed, Ref. Fig. 9. which predicts the occupancy of the s*tation*, along with the capturing of the dimensional-data parameters for the prediction of the type of *thing*, Ref. Table II, establishing a framework to assess the *size*-parameters of a *things* in a s*tation*. Such systems are prone to push and generate lot of data leading to big data where the rule base data models to map and predict a *thing* becomes the need of an hour which can form a base to advance machine learning models to derive intelligence artificially.

The future work is to study big data modelling and analysis techniques which can accommodate voluminous data.

Abstract— A large time delay during emergency data transfer in WBAN is a challenging task since it involves transmission of time sensitive crucial information to the receiver for immediate treatment of the patient. This paper aims in providing an efficient transmission of Immense Preference Data (IPD) to the respective end user with minimal delay and energy consumption. IEEE 802.15.4 MAC superframe was altered within permitted standards and IPDF Routing Scheme was designed and implemented in which, time slots were efficiently allocated according to data type. Guaranteed Time Slots (GTS) in Contention Free Period (CFP) was allocated to IPD of the slot's possessor and the non-possessor node at t0 and t1 respectively. This provides an immediate and guaranteed transfer of data without any further delay and unnecessary waiting time for channel contention at Contention Access Period (CAP) was also reduced, so as to add to the minimization of power consumption and latency. CAP was further divided into two phases for transmitting Minor Preference Data (MPD) of possessor and non-possessor which minimizes collision of data packets that further decreases delay and power consumption of MPD. Simulations and performance analysis of IPDF scheme were carried out in NS2. Delay and power consumption minimization and PDR and throughput maximization for IPD in comparison to IEEE 802.15.4 MAC standard and PA-MAC was achieved.

Keywords— IEEE 802.15.4 MAC Superframe, MAC Routing Scheme in WBAN, Emergency data handling, time slot assignment, and energy - delay trade – off.

I. INTRODUCTION

IEEE 802.15.4 was chosen as a better standard for WBAN because of its low power consumption and data rate for wireless connection that involves mobile, stationary and portable devices. Also, it consumes less battery power and covers a distance within the range of 10 m which is ideally suited for WBAN. The standard supports 16 channels in 2.45 GHz band, 30 channels with 915 MHz band and 3 channels in 868 MHz band. It has an optional CFP. Also, CAP operation is based on CSMA/CA. It operates with a star or peer – peer topology. MAC management integrating the MAC Layer Management Entity (MLME) Service Access Point (SAP) and data service supporting forwarding and receiving the MAC Protocol Data Units (MPDUs) are carried out by the MAC layer.

The CSMA/CA mechanism at the CAP in IEEE 802.15.4, makes the node to wait for a random back off period until the channel becomes free. Also, there is a response wait time when the node requests for a time slot. Before accessing the channel, the device waits for a random period called back off delay represented by Back off Exponent (BE). A device should wait for a time between 0 to 2^{BE}-1. This expends listening mode energy alone. Contention Window (CW) is the number of back off time periods where the medium has to be sensed to be idle before transmitting the data [10] and [11].

The Beacon Interval,

$$BI = \text{a base superframe duration} * 2^{BO} \text{ symbols} \quad \text{for } 0 \leq BO \leq 14. \tag{1}$$

The active period which is Superframe Duration,

$$SD = \text{a base superframe duration} * 2^{SO} \text{ symbol} \quad \text{for } 0 \leq SO \leq BO \leq 14. \tag{2}$$

Beacon Order (BO) implies the period at which the coordinator has to transmit the beacon. Superframe Order (SO) implies the active period of the superframe.

$$\text{The Duty Cycle, } DC = SD / BI = 2 (SO – BO) \tag{3}$$

When the duty cycle is low, it implies that there is a high sleep time. So altering the SO or BO will have affect the DC. To reduce the DC, BO has to be increased by keeping SO as a constant or decreasing SO by keeping the BO as a constant. So it reduces the energy consumption. But, a shorter CAP length would lead to transmission of pending data at the initiation of the successive superframe resulting in high collision and retransmission. This again leads to increase in power consumption. Retransmission enhances the reliability but, contributes to the packet delay. Decreasing the delay by

sending and receiving the packets in the same superframe contributes in faster medium access and avoids additional delay caused by sleep time. At the same time, the energy – delay trade – off has to be taken into account while designing the routing scheme. The macMinBE and macMaxBE values as fixed by the standard are 3 and 5 respectively. When these values are decreased, the waiting time of a node decreases, thereby increasing the throughput. But at the same time, when the traffic increases, the node tries to access the channel with more probability within a shorter time period. This may lead to several collisions that again results in delay and throughput reduction and vice versa. Therefore, the BO, SO, Number of Back offs (NB), macMinBE, macMaxBE and CW size are the major parameters under concern to improve the network performance.

The primitive traits of MAC layer are to provide and perpetuate the beacon maintenance, GTS operation, medium access mechanism, frame verification and affirmation and association and disassociation of frames [10] and [11]. It has been a challenging task to balance out the energy – delay trade – off during data transmission. When an IPD occurs, the data has to be transmitted immediately due to high time sensitivity of the emergency datum. The contention taking place in CAP for time slot allocation and data forwarding, efficient routing of data according to its priority level and effective bandwidth usage are the primary factors considered in the design of MAC superframe structure of IEEE 802.15.4. Fig. 1 shows the general IEEE802.15.4 superframe structure. The three important parameters namely, delay, throughput and energy consumption, while dealing with IPD were under research and various analyses to bring down the energy consumption and latency, at the same time, increasing the throughput were laid out. The superframe structure was modified according to the aforementioned requirements and further researches were done and a routing scheme was proposed to improvise the above mentioned QOS parameters. An efficient routing scheme on the MAC layer extends in improving the data delivery and reducing the latency.

The paper is organized as follows: Section 2 discusses literature on MAC protocol along with their routing schemes. Section 3 explains the proposed routing scheme in the superframe structure and its operation. Section 4 presents the simulation parameters and discusses the results and finally Section 5 concludes the paper.

II. RELATED WORK

As proposed in [1]: A Modified IEEE 802.15.4 Superframe Structure for Guaranteed Emergency Handling in Wireless Body Area Network, the superframe structure was modified by utilizing the inactive period for emergency data transmission. The inactive period was divided into Emergency Reporting Period (ERP), Emergency Beacon (EB) for notification of an emergency datum and Emergency Transmission Period (ETP) for transmission of the emergency data. The channel was accessed by two mechanisms namely, CDMA based access based on codes and random back off access that uses a time based back off window. CDMA based access mechanism provides higher throughput and lesser delay since; length of the ERP is shorter comparatively. An Improved IEEE 802.15.4 Superframe Structure with Minimum Delay and Maximum CFP Link Utilization [2] supports the maximum GTS utilization by the request nodes. The CFP is divided into 14 slots which is equal to one half of the CAP slot without violating the minimum length of the slot requirement. Also, the CFP is placed next to the beacon when there are GTS requests. Else, CAP follows the beacon frame. This helps in reducing the packet delay since, the node requests are accessed immediately and the data are transmitted immediately without waiting for a long time during contention. Also, many node requests can be processed due to further extension in number of GTS slots, thereby, accommodating in efficient bandwidth utilization in all the three frequency band ranges as laid in the IEEE 802.15.4 standard. The interrupt MAC was proposed in [3]: A MAC Routing scheme for Medical Monitoring Applications of Wireless Body Area Networks, where, frequent interrupts are introduced in between when emergency data arises instead of beacons. This reduces the unnecessary beacon transmission. The interrupt slots are inserted in between the GTS when emergency data arises. But, IMAC superframe structure requires a long beacon length than that is present in the current superframe. So the system is more complex than the conventional superframe of IEEE 802.15.4. When there is less frequent urgent data, this proposal provides better time utilization and energy efficiency. But, when the urgent data frequency is high, IMAC is not a wiser option. The DRT (Delay, Reliability and Throughput) profile was dealt in [4]: Delay, Reliability, and Throughput Based QoS Profile: A MAC Layer Performance Optimization Mechanism for Biomedical Applications in Wireless Body Area Sensor Networks. The optimization of certain QOS parameters with respect to time were carried out and the results show that, reduced delay was obtained during high data rates and frequencies and high delay was achieved at lower data rates and frequencies. A more reliable system at a permissible delay and data rates was achieved using the DRT parameters. The DRT parameters are based on CSMA / CA mechanism while taking IEEE 802.15.4 and IEEE 802.15.6 into concern. The proposed MAC algorithm in [5]: D-MAC: A Dynamic MAC Algorithm for the Body Area Sensor Networks Based on IEEE 802.15.4 deals with dynamically changing BO and SO values in the MAC superframe structure. The BO and SO values in the conventional standard are fixed. But, in the proposed algorithm, the BO ad SO values keeps changing dynamically according to the traffic load so that, Duty Cycle (DC) can be adjusted to the desired values, so as to increase the throughput and decrease the latency and energy consumption. The various traffic adaptive schemes were studied in [6]: Traffic Adaptive MAC Routing Scheme in Wireless Body Area Networks. During high traffic, the number of nodes increase which leads to higher collision due to more channel contention. This leads to packet loss or retransmissions. This affects the delay, throughput, energy consumption and PDR. Therefore, relatively better traffic adaptive routing scheme are necessary to enhance and achieve a balance between energy and delay

factors, maximizing the throughput and PDR. This provides a better system in timely data processing and packet reception with a balance over energy – delay trade – off. In [7]: IEEE 802.15.4 Frame Aggregation Enhancement to Provide High Performance in Life-Critical Patient Monitoring Systems, the frame aggregation technique was proposed. The signals transmitted by the WBAN nodes are a number of small packets within a short time span. This does not utilize the maximum channel capacity as, only the packets that contend and get the channel for transmission are forwarded whereas, the nodes that are not allocated with the slots have to wait for certain time period and again contend the medium for slot allocation and then transmit once it is allocated with the time slot. Therefore, a maximum packet size of about 17 bytes is only getting transmitted in the medium. But the actual capacity of packet size that can be transmitted is 127 bytes. Therefore, it does not utilize the channel to its maximum. So, frame aggregation which uses many MAC frames under a single Physical header are sent within a successful medium access. The performance analysis of frame aggregation technique has shown a tremendous improvement on delay performance and throughput. As proposed in [8]: Priority-based Service Differentiation Scheme for IEEE 802.15.4 Sensor Networks, the CW size and BE are important parameters in designing a MAC routing scheme because, when the CW size is affects the throughput factor and BE affects the delay factor during packet transmission. This leads to adjusting the CW size for enhancing the throughput of the device and BE for decreasing the delay. In [9]: An Emergency Handling Scheme for Superframe-Structured MAC Protocols in WBANs, the authors proposed a scheme for handling urgent data where a Mixed Period (MP) and an Extended Period (EP) were inserted in the MAC superframe of IEEE 802.15.4. The CAP slots were placed in the MP prior to the CFP for transmitting the urgent data at once without any supporting for any further delay. The EP is allotted with a Extended Request Period (ERP), a CFP and an additional CAP for supporting the transmission of those slots that have not been successful during the MP. This EP provides guaranteed transmission of the data. The results show that, the delay provided by the proposed scheme was reduced while handling the urgent data to a great extent. The three algorithms following the three approaches namely, offline computation, model-based adaptation and measurement-based adaptation respectively were compared in [12]: Strategies for Optimal MAC Parameter Setting in IEEE 802.15.4 Wireless Sensor Networks: a Performance Comparison, in order to come up with optimization of IEEE 802.15.4 in terms of maximum reliability and minimum energy consumption. The results validate that the performance of adaptive algorithms are better than the model-based algorithms. This is because the model-based approach does not work well while operating during varying time period in real time scenarios. But, the measurement – based approach works well without the aforesaid limitations. So, the performance analysis of the third approach was laid out and proved. The algorithm proposed in [13]; Modeling and Optimization of the IEEE 802.15.4 Protocol for Reliable and Timely Communications, provides minimum energy consumption during mobile and immobile situations. When the load increases, the algorithms proposed by the authors give better medium access solutions. Under dynamic scenarios, the algorithms supports in quickly making out the errors.

The above literature clearly indicates that, the handling of immense data or urgent data is of vital importance and a proper channel allocation schema is required for efficient data transmission. The data handling, routing of emergency datum with minimal time and delay and maximum throughput and PDR is of primitive concern. Therefore, this paper contribute to modification of the IEEE 802.15.4 superframe structure and proposing a MAC routing scheme to efficiently handle the immense data and allocating the time slots in such a way that, the channel is utilized better with increased PDR and throughput and at the same time, minimizing the delay and energy consumption.

III. PROPOSED SCHEME

Fig.1 shows the MAC superframe structure of IEEE 802.15.4 in beacon mode. Since we operate in 2.4 GHz band with 250 Kbps rate of 16 slots, where, it commences with the beacon period for network synchronization and association at slot 0 and has a Beacon Extension Period (BEP) followed by Contention Access Period (CAP) from slot 1 to 8 where CSMA/CA contention for the channel access takes place. Contention Free Period (CFP) provides Guaranteed Time Slots (GTS) for the IPD requiring immediate data transfer, followed by the inactive so called, sleep period. We can extend or compress the inactive period according to the requirement as per the standard. So according to the customary standard, the IPD would suffer packet loss when it is sent in CFP which is placed after the CAP. When the packet size is more or when CFP in the current superframe is unable to transmit the data completely, it would be stored as pending data and it has to wait until the CFP of the next superframe which would increase the packet delay and sometimes, packet loss when the next superframe is also busy. Since, the medical arena permits a maximum delay of 125ms and 250 ms for IPD and MPD respectively, the average end to end delay becomes an important criteria during data transmission.

Therefore, the proposed routing scheme (IPDF) modifies the IEEE 802.15.4 MAC superframe structure to reduce the delay and power utilization resulting in increased throughput. Superframe ranges intervening both the beacons along with the active and inactive periods and is called as Beacon Interval (BI). Superframe Duration (SD) is time span of an active period. SD and BI rely on aBaseSuperFrameDuration (BSFD), Superframe Order (SO) and Beacon Order (BO). Anyhow, BSFD rely on aBaseSlotDuration (BSD) & aNumSuperframeSlot (NSS). BSFD is dependent on transmission capacity or the bandwidth of the network and it's a constant value which is equal to 960 symbols.

Fig.2 shows the modified superframe structure. The frame is initialized with a beacon following an additional Data Preference Notification Beacon (DPNB) to notify the preference of the arriving data. So BEP in the frame's standard is utilized which does not violate the permissible limit. Also, CFP can be extended, provided, the minimum CAP length has to be 440 symbols. The CFP is placed after the DPNB with 7 slots allowed in the standard. They are GTS allocated only for the IPD. The GTS can have more than 1 slot as per the standard. In IPDF SCHEME, the GTS operates in t_0 and t_1 for the IPD of the possessor and non-possessor respectively. Therefore, the CFP is also modified without violating the permissible criteria as per the given standard. Then follows the CAP, which operates in two phases namely Phase (P1) and Phase 2 (P2), used for transmitting MDP of the possessor and non-possessor respectively. Finally, the inactive period follows the CAP where the node enters the sleep mode when there is no data for transmission. Fig.3 depicts detailed flowchart on the Packet Preference Selection, Channel Allocation and data transmission procedure for IPDF Scheme.

A. Operation of IPDF Routing Scheme

When the data arrives, the beacon initializes the data transmission. The DPNB notifies the preference of the arriving data. If the arriving data is the IPD and it is the slot's possessor, t_0 is allocated immediately in CFP and the data is transmitted at once without any delay. If it is the slot's non-possessor, the node has to wait till the duration of t_0 and only then allocated with t_1 slot. This avoids any collision or unwanted delay of prioritized data as per the medical requirement of <125ms. When the DPNB identifies MPD arriving, then, it makes the node to access the CAP without waiting during CFP thereby, reducing the delay of MPD as well, which has to be <250ms. But, CAP- P1 allows only the possessor's MPD to be transmitted and CAP – P2 allows non-possessor's MPD to be transmitted. During CAP access, the MPD have to follow the CSMA/CA mechanism in order to access the medium while contending, when the medium is busy. The IPDF algorithm explains the aforementioned operation during channel access.

The proposed scheme involves the CAP segmentation into dynamic phases that leads to prevention of bandwidth wastage during channel contention, thereby, utilizing the same, efficiently by priority based transmission of medical data. The length of individual dynamic phase in the CAP can be estimated as,

$$L_n = \sum_{i=0}^{n-1} l_i + L * (N_n / N) \quad (4)$$

where, L is the length of individual phase in the CAP with n taken from 1, during initialization of each phase, N_n is the entire nodes with load grouping based on packet preference and N being consummated count of nodes.

IPDF Algorithm for Accessing the Channel

```
If (Immense Preference Data)
        Access CFP
                If (Possessor node)
                        Allocate a slot at t0
                        Transmit Data immediately at t0
                Else
                        Wait till t0
                        At t1, allocate a slot
                        Transmit Data in t1
                End if
Else
        Access CAP
                If (Possessor node)
                        Phase 1 (P1): Allocate a slot and
                        transmit data
                Else

                        Phase 2 (P2): Channel Contention
                        according to CSMA/CA Procedure
                End if
```

The MPD is inclusive of the entire data traffic excluding crucial data traffic. So, the normal and low preference data packets that is to be sent from the human body continuously for regular monitoring that is not very much time sensitive when compared with the emergency packets, would get into channel contention at CAP.

B. Significant Advancements of IPDF Routing Scheme

The proposed routing scheme brings forth the consecutive significant advancements:

1. A routing scheme with Immense Preference Data Forwarding incorporated with Constructive Time Slot Allocation Scheme was contemplated to maximize throughput, minimize overall delay and utilization of energy by a sensor node thereby, increasing its PDR and lifetime.
2. Since there is a faster access to the channel and possessor data, non-possessor IPD and MPD are transmitted efficiently as explained in the operation of the routing scheme, thereby, decreasing the back off time period leading to reduction in the response wait time.
3. Since the redundant contentions cause unwanted wastage of energy and bandwidth, the proposed scheme greatly overcomes it by efficiently transmitting their absolute data of the possessors in the CFP itself. Only the non-possessors contend for the CAP according to the preference of the data.
4. This results in decrease in Duty cycle which decreases the end to end delay as we transmit and receive the absolute data within that superframe itself and at the same time, circumventing the added delay due to data storage in the coordinator amid the sleep time.

IV. PERFORMANCE ANALYSIS

The IPDF scheme was evaluated using Network Simulator 2 (NS-2). A single hop data transmission with star topology was utilized with assumption that, all the biosensors were affixed to the body with random deployment of the nodes surrounding the coordinator with radius of 4m.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Area	500 m x 500 m
Routing Protocol	AODV
Physical / Mac layer	802.15.4
Channel type	Wireless
Radio Propagation mode	Two Ray Ground
Network Interface type	Phy / Wireless Phy
Interface queue type	Drop Tail / PriQueue
Antenna Model	Omni directional Antenna
Link Layer type	LL
Traffic type	CBR
Network Topology	Star
Channel Rate	250 Kbps
Frequency band	2.4 GHz
Pt = Power of radio transmission	36.5 mW
Pr = Power of radio reception	41.4 mW
Pi = Power of idle listening	41.4 mW
aBaseSuperframeDuration	960 symbols (15.36 ms)
macBeaconOrder (BO)	4
macSuperframeOrder (SO)	3
Beacon Interval (BI)	245.76 ms
aNumSuperframeSlots	16
UnitBackoff Period	20 symbols (0.32 ms)
aMaxSIFSFrameSize	18 octets
aTurnaroundTime	12 symbols (0.196 ms)
macAckWaitDuration	54 symbols (0.864 ms)
macMinBE	3
macMaxBE	5
macMaxCSMABackoffs	4
macMaxFrameRetries	3
CCA	8 symbols
SIFS	12 symbols (0.192 ms)
LIFS	40 symbols (0.64 ms)
Notification Beacon	40 bytes (1.28 ms)

The assumptions made during simulation were that, the data traffic was assumed to be 20 % of Immense Preference Data, 40 % Medium Preference Data and 40 % Minimum Preference Data, the entire nodes operated within the coordinator boundary limit without any intricacies from the neighboring networks. The simulation results for the proposed scheme were evaluated and compared against IEEE 802.15.4 and PA-MAC.

From Fig.4, the contention during CAP was greatly reduced in IPDF scheme, thereby reducing delay, compared to the customary IEEE 802.15.4 standard and PA-MAC, due to limited access in the data traffic load in the intervening CAP phases, by providing a rapid access for IPD and LPD in the channel. In PA-MAC, there was an uncontrolled contention of variable traffic in various phases of CAP and there exists no traffic prioritization in IEEE 802.15.4 MAC during the ingress to the medium resulting in huge delay in the entire network.

Fig. 4 Delay Performance with respect to Node Count

It was observed from Fig.5 that, delay for variable packet volume was very small (<125 ms) as necessary for the medical real time traffic utilization, compared to the customary IEEE 802.15.4 and PA-MAC.

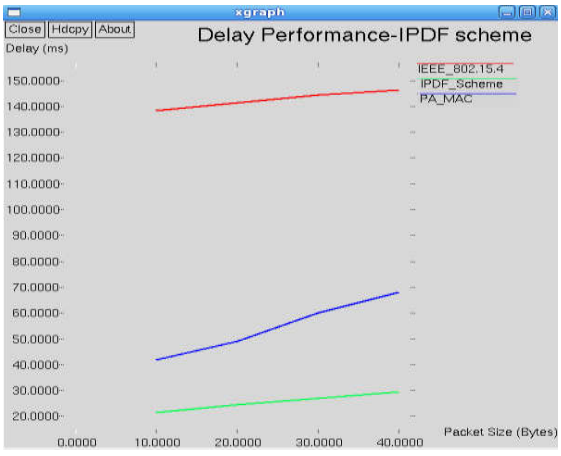

Fig. 5 Delay Performance with respect to Packet Size

When there exists a huge volume of data traffic, only a certain amount of nodes could be accommodated in the system that results in large collision. Whereas, the channel access is confined based on traffic preference in IPDF scheme (IPD in CFP and LPD in CAP, restraining only for LPD traffic). This results in decreased collision, providing a better channel access and thereby, improving the throughput of the network as depicted in Fig.6.

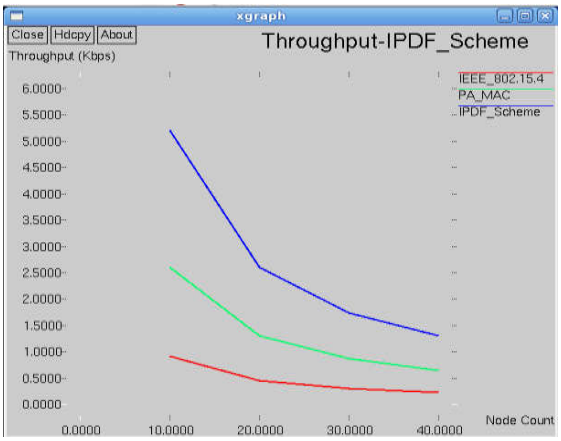

Fig. 6 Throughput Inquiry with respect to Node Count

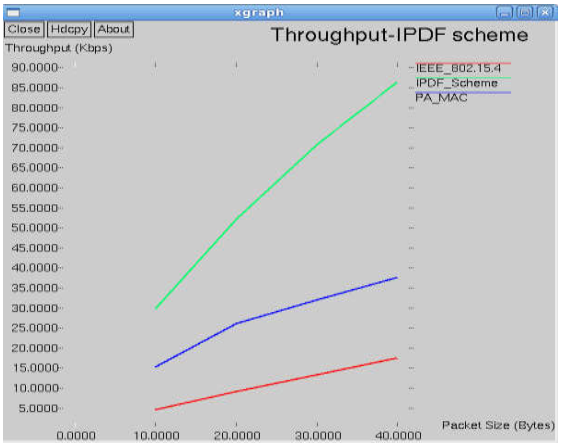

Fig. 7 Throughput Inquiry with respect to Packet Size

Fig. 7 shows that, the throughput of IPDF scheme increases gradually with packet size. When the node count boosts up, the exhausted energy also shoots up due to collision upsurge and therefore, packet retransmits.

From Fig. 8, the PA-MAC and customary IEEE 802.15.4 consumes energy of approximately 10.5 mJ and 10 mJ respectively with 20 nodes, whereas, IPDF scheme uses 9.5 mJ of energy, because, there was a constrained medium access in CAP and CFP was entirely dedicated only for IPD. Due to the CAP phase distinction, the energy consumed was greatly reduced in IPDF scheme due to unnecessary contentions leading to energy exhaustion.

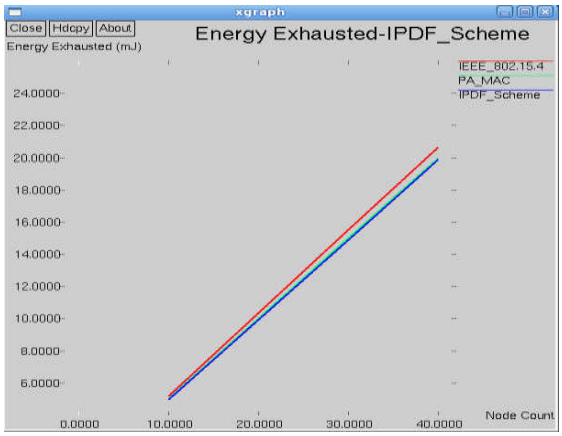

Fig. 8 Energy Exhausted with respect to Node Count

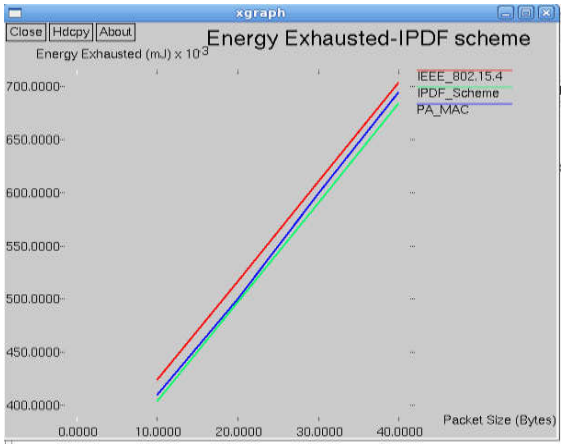

Fig. 9 Energy Exhausted with respect to Packet Size

From Figure 9, IPDF scheme consumes energy equivalent to PA-MAC but, lesser than the customary IEEE 802.15.4, that could transmit IPD and LPD within a short time period compared to the customary protocol and PA-MAC.

V. CONCLUSION AND FUTURE WORK

The Immense Preference Data Forwarding (IPDF) Scheme was designed and implemented with a modified MAC superframe structure in IEEE 802.15.4, by allocating maximum priority IPD of the possessor and non-possessor to t_0 and t_1 in CFP respectively, for immediate data transfer, to minimize the delay associated with IPD traffic. The MPD of the possessor and non-possessor are routed through the P1 and P2 phases in the CAP respectively, to handle the MDP traffic as well. The performance analysis of the proposed Scheme was carried out. The throughput showed a significant increase and delay and energy consumption showed a significant reduction for IPD and MPD of IPDF SCHEME when compared to PA-MAC and customary IEEE 802.15.4 standard. In future, an equitable contention ingress scheme for both medium and low preference data with maximum channel utilization would be considered.

***Abstract* — A library is a collection of information resources and provides invaluable services to its users for reference and borrowing of books and documents. As the library grows in size, the problem associated with the maintenance of the books also grows. Searching a book in the library manually is a tedious process and if there is any misplacement of the book either intentionally or unintentionally then it consumes more time and more effort to search the book. To overcome this problem an attempt is made to introduce automation of library for fast searching of books and to pick or place the book in a particular rack. A robot with an arm is developed which is able to find the book at particular position and then pick or place in a particular rack in the library.**

Keywords —— Library, robot, robotic arm, Arduino, infrared sensor, WIFI module.

I. INTRODUCTION

International Federation of Robotics (IFR) defines a service robot as a robot which operates semi or fully autonomous to perform services useful to the well-being of humans and equipment, excluding manufacturing operations. Robotic arm is a mechanical arm which is manually controlled through wired or wireless systems to perform the desired task in various fields of application such as military tasks, hospital operations, dangerous environment and agriculture.

The main aim here is to build a robotic arm that is capable of picking the particular book and in case of any misplacement of the book the robotic arm should be capable of picking the particular book required by the user. The system that is built has two circuits namely Arduino circuit with Wi-Fi module for control operation and motor driver circuit to drive the DC motor. A robot with an arm is developed which is capable of searching the book at particular slot and then pick or place the book in a particular rack in the library. To create a systematic, faster and efficient operation, Arduino will be used which will process the input received from the WIFI module and perform the programmed action. This system proposes a database that provides a way of searching the required book to pick or place, to find the misplaced book and to get the information about the status of the book. A GUI is developed on visual basic platform. The GUI has icons such as add book, search book and reset. The hardware of the system consists of line follower robot that navigates in the library and detects the exact location of the required book. The visual basic platform is interfaced through WIFI module with the robot to pick or place the book in the designated position as per the instructions of the user.

II. EXISTING SYSTEM

In the library the books will be placed in the designated position of racks and if any user needs a particular book will first check the availability of the book and search the book in that designated position. But the problem is if someone by mistake or purposefully places the books in wrong positions then it is very difficult to locate the book. The user or the library staff has to search all the racks to locate the book which will be either time consuming or sometimes it may not be possible to locate the book at all.

III. PROPOSED SYSTEM

In the proposed system a robot with an arm is developed such that whenever a user wants to borrow a book will first search for the availability of the book. If the book is available then the user will press a button to inform the robot to bring that book. The position of the book will be sent to robot through WIFI module and the robot will move and bring the book. The advantage of this system is even if the book is misplaced the database will be updated to the new position of the book so that robot will search the book and pick it. Further in this proposed system whenever a book is returned back by the user, the robot will be intimated to place the book in designated position and that position details will be updated in the database.

IV. IMPLEMENTATION

A. Block Diagram

The Block diagram of automated library system using robotic arm is shown in Fig. 1. The automated library system consists of IR sensor, Arduino, robotic arm, WIFI module, DC motors and motor drivers and PC. It has two sections: a transmitter section and a receiver section. Transmitter section consists of PC for sending the commands to the robot through WIFI module. Receiver section consists of microcontroller to process the signals received through WIFI module.

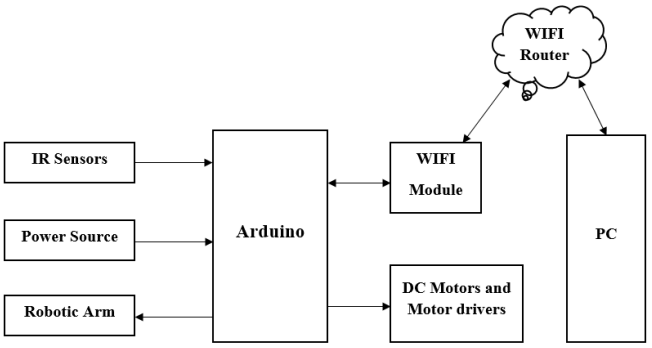

Fig. 1 Block Diagram of Automated Library System using Robotic Arm

The automated library system is concerned with the implementation of pick and place task using Arduino board. Instructions from user are sent from PC via WIFI module to the Arduino and the protocol used for communication between PC and controller is serial UART. The received data is processed and corresponding output is sent to the motor driver which enables the DC motors for the movement of robotic arm and line follower robot.

Arduino

Arduino is a software and user community that design and manufacture computers. It is a open source software and microcontroller based kit for building digital devices and interactive objects that can sense and control physical devices. Here Arduino controller is used to process the commands required for the movement of motors, line follower robot and to control all other peripherals.

DC Motor

The DC Motor is a class of rotary electrical machines that converts electrical energy into mechanical energy. The common type of motor work on the force produced by the magnetic fields. The speed of the DC motor can be controlled using either a variable supply voltage or by changing the strength of the current in its field windings. DC motors are used for the movement of the robot and also for the movement of grippers.

Motor Driver(L293D)

The L293D motor driver is used to provide user with ease and user friendly interfacing for embedded application. The L293D is a dual H-bridge driver that can drive up to 1 Amp per bridge with supply voltage up to 24V. In automated library system using robotic arm two motor drivers is used to drive four DC motors.

Robotic arm with gripper

Robotic arm is an anthropomorphic structure which resembles human arm. In this project DC motors of 30RPM are used for the movement of the robotic arm and also for opening and closing of the gripper. Robotic arm with gripper is used to pick or place the book in to the rack.

IR Sensors

IR sensor uses the light sensor to detect specific light wavelength in the infrared (IR) spectrum by using an IR LED and it works on the principle of obstacle detection. The IR transmitter continuously emits the light, whenever the book is detected by the IR transmitter then the light gets bounces back to the IR receiver which indicates that the book is present in the rack and also used for line tracking of the robot.

Power Source

The battery is used to deliver required amount of power to all the components in the project. In this project line follower robot is energized using a 12V and 7.2A battery and all other components like IR sensors, Arduino, WIFI module and motor driver are energized using 12V and 1.2A battery.

Liquid Crystal Display (LCD)

A 16 X 2 LCD can display 16 characters per line and there are 2 such lines and each character is displayed in 5 X 7 pixel matrix. LCD is used to display the commands sent from the PC.

B. Algorithm and Flowchart

The algorithm used in the automated library system using robotic arm is:

- Configure WIFI module and Arduino.
- Set or define the input and output port.
- Set the baud rate as 9600 and enable the transmission pins for communication.
- Initialise LCD.
- Send the appropriate input from the PC to the Arduino through the WIFI module.
- Commands from PC are processed in the Arduino.
- The processed input from Arduino (i.e. book number) is sent to motor driver which runs the appropriate motors.
- If valid book number is entered, Robot moves towards the defined book position.
- If the book is found the robot pick the book and returns it to the destination.
- If the user wants to return the book, the robot pick the book from the user and moves towards the predefined position and places it.

The flowchart of Automated Library System is using Robotic Arm is shown in Fig. 2.

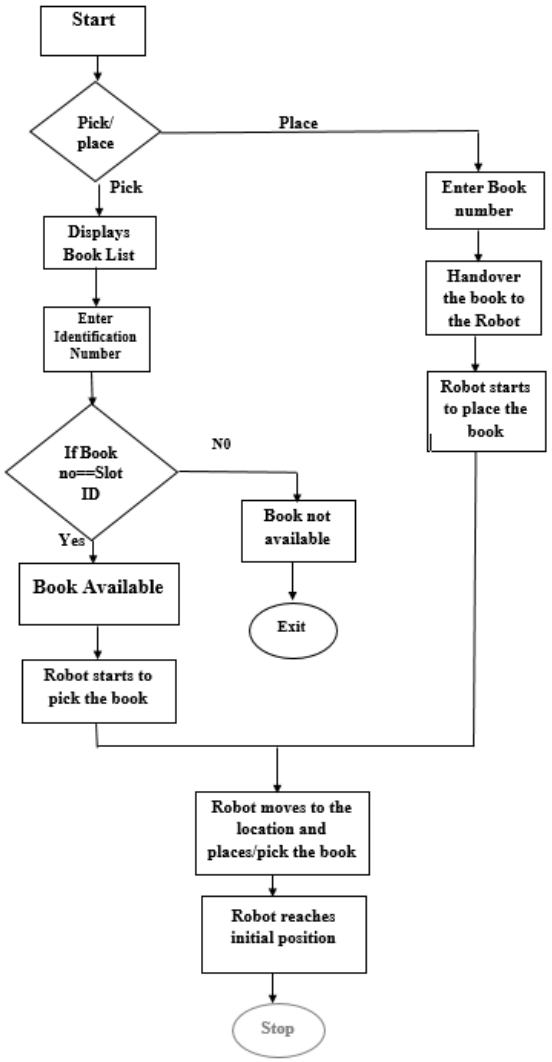

Fig. 2. Flowchart of Automated Library System

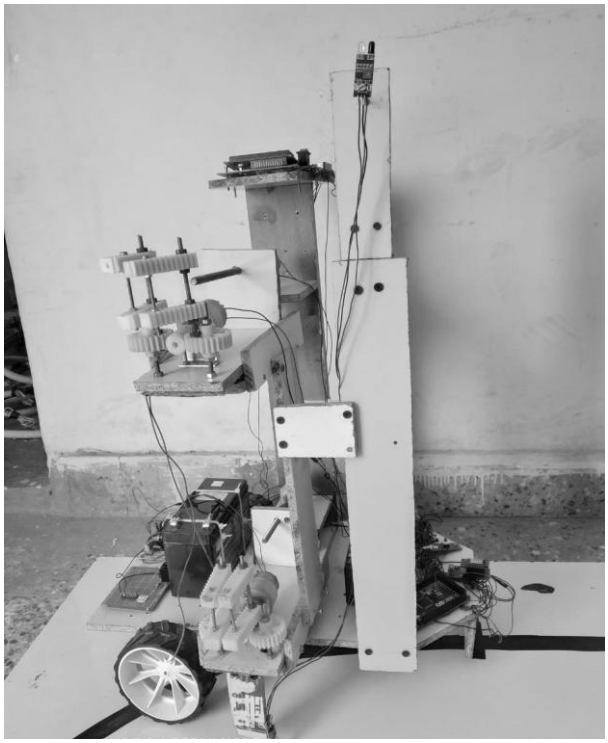

Fig. 3. Working model of smart energy meter

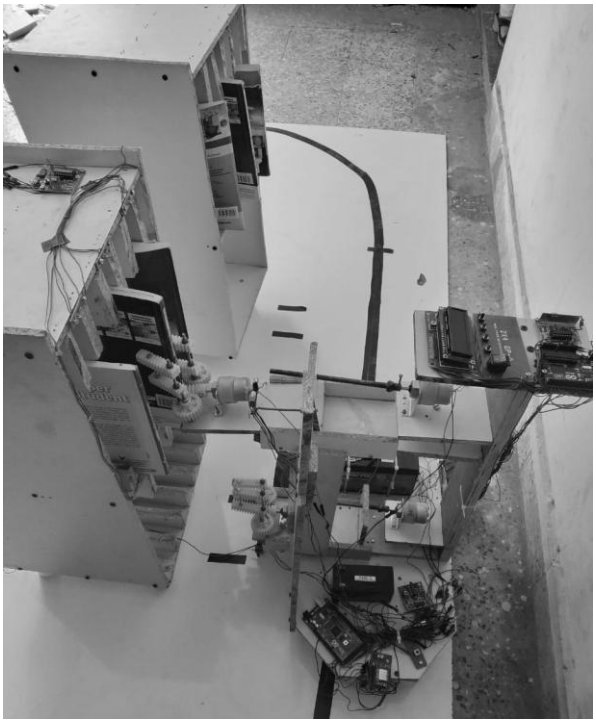

Fig. 4. Robot picking the book at a particular slot

V. RESULTS AND CONCLUSION

A. Results

The working model of the Automated Library System is shown in Fig. 3. The hardware of the automated library system using robotic arm consists of gripper and triangular bars to hold the book firmly. The system uses four DC motors each of 30 RPM and two Johnson motor each of 30 RPM with 6 to 7 kg torque is used. Motor drivers converts lower currents into higher currents that are used to drive the motors. Motor driver can drive two DC motors simultaneously. The system uses RF transmitter and receiver to communicate between Arduino and obstacle detectors. IR sensors are used to detect the book i.e. whether the book is present in the slot or not and they are also used for line follower robotic vehicle and make the robotic vehicle to stop at particular slot to pick as shown in the Fig. 4 or to place the book as shown in the Fig. 5

.

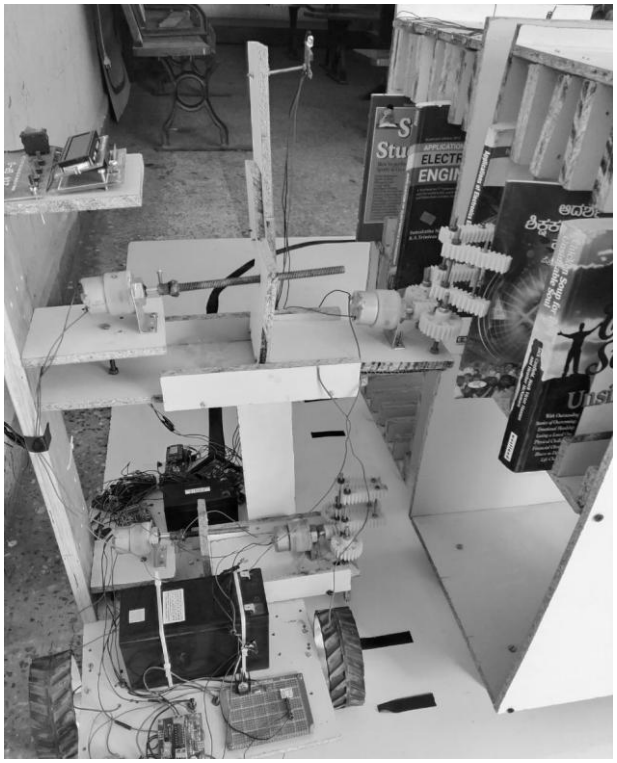

Fig. 5. Robot placing the book at a particular slot

The visual basic window of the automated library system using robotic arm uses VBA (Visual Basic for Application) language. The interface of the visual basic window is provided with different type of icons such as add book, search book, reset and close icons. The visual basic window of the automated library system using robotic arm is shown in Fig. 6.

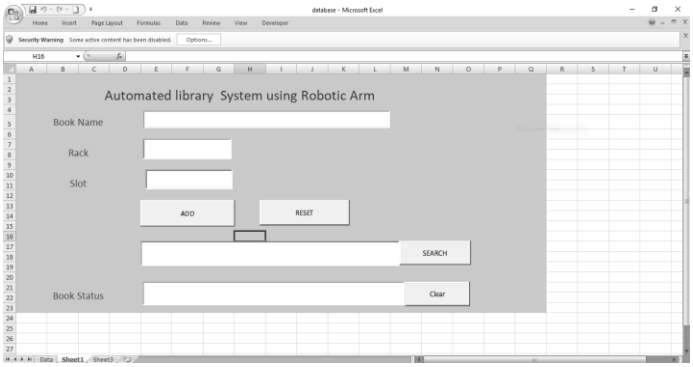

Fig. 6. Visual basic window of the automated library system using robotic arm

The search icon is used to search a particular book in the library. The result of searching the particular book in the library is shown in Figure. In this visual basic platform search option is used to search a book. In this comport the details such as book name is entered. This comport shows whether the book is available or not in the slot of the rack in the library. If the book is available then the robot moves to the predefined position to pick the required book and returns it to the destination as shown in Fig. 7. If the book is not available in the library the PC shows the comment in the comport as Book not available as shown in Fig. 8. The add book icon is used to add new book to the XL Macro database used in automated library system using robotic arm. Whenever we want to add new book to the database as shown in Fig. 9, the name of the book that is adding should be written in the comport and then press the add icon as shown in Figure. The reset icon is used to reset the visual basic window.

Fig. 9. Database to display the book numbers

B. Conclusion

The main objective was to overcome the problem of searching the books in the library and provide automation in a user friendly manner. The robot with an arm is designed which can search the required book, pick the book from the rack and deliver the book to the issue counter. It can also place the book in its designated slot once the book is returned by the

borrower. The hardware and software required for automated library system using robotic arm has been designed and tested successfully.

C. Future Scope

The robot can be made more efficient by incorporating image processing technique to identify the books and book slot to pickup or place the books.

***Abstract*: A lightning protection system (LPS) of an urban 110 kV substation is designed and analysed according to NFPA 780 and IEC 62305-3 standards. The analysis of the LPS is based on the value of risk assessment. The total area of the plant is described by one soil layer with uniform resistivity. This study aims to improve the understanding of unexpected attitude of the grounding grid system under lightning strike currents by explaining the basic notion of the lightning protection level. The program is integrated with the CDEGS software, which provides effective geometrical modeling with object and result visualization. Furthermore, module and automated fast Fourier fransform is implemented in this study to simulate electromagnetic fields in the period and frequency scope. These current values are compared to the desired protection levels within the standards. The study results show that for the improved protection of the system against lightning, the total power grid must be considered as a source of improvement for studying shielding influence and the protection levels provided inside this substation.**

***Keywords- LPS;NFPA780; shielding failure; CDEGS software; step voltage*.**

I. INTRODUCTION

A lightning protection system (LPS) is an extremely controversial subject. It is difficult to obtain realistic information on the capacity of the system even if precautions are accurately calculated. Lightning is a natural phenomenon that cannot be controlled by humans, but LPSs are not. Lightning protection provides a path to direct high energy into the soil, which is achieved by a grounding grid under the area to be protected. Lightning strike causes large potential differences in the electrical systems that are distributed one by one in the substation grounding grid. In this study, a 110 kV substation is designed, and the lightning voltage and current, and the LPS protection of the substation during a thunderstorm are calculated. The designed LPS results in reduced impact of lightning disturbances and improved robustness of the grid substation. The assessment of the LPS is performed using traditional techniques from the literature [1]. Lightning generates considerable voltage anomaly in high transmission and distribution grid systems in direct strikes. These considerable voltage anomalies lead to line power failure. New evolution have made it prospective to expand a solution to lightning problems, and also to decrease the total cost of the substation grid design [2].These studies and analyses are carried out to provide high protection for this substation. This model proposes a new design of electrical stations and is accomplished by modeling simulation using the CDEGS software shown in Fig. 1. In some cases, lightning affects the upper part of the substation, which does damage to most of the equipment inside the substation, leading to a complete cessation of all parts of the substation. Insulation flaw on 110kV transmission line in front of the substation can get short circuit currents with high magnitude [3]. Electrical grid substations can be abnormal to different forms of voltage deflection. Through the design point, the engineer should select the risk scale for which the substation is designed according to the risk standard, is common, attached to the basic insulation level chose. To reduce the occurrence of such specific risks copper was added to the top of one corner of the substation [4]. In the present paper, a new analytical implementation of lightning is presented. The primary circuit arrangement is the same as in [5]. However, the present implementation was extended to include lightning surges on a 110 kV urban substation. To estimate a performance in the first moments of a lightning pulse, the high frequency content of the lightning current stroke is used as an approximation of the first strike. The time domain waveform is transferred to the frequency domain by using rolling sphere method [6]. LPS is designed by the keraunic scale at the material position of grid substation, that is defined accordingly the average number of thunderstorm days per year, and is related to the density and quantity of flashes to the ground [7]. A substation was designed and studied according to the yearly average flash density in the region Ng=10(f/km square/ye) reliance on the global map of the lightning frequency –strike. In this study, three-dimensional 110 kV ground grid substations are applied, and transient responded simulations in the CDEGS software and the assessment of the lightning performance of the substation was performed. All calculations were

conducted and analyzed according to the international standards for the design of 110 kV substations. Moreover, the plan was built on the full frames that provide high protection of the substation. For modeling, the lightning current flowed into the ground.

II. SYSTEM CHARACTERISTICS

This paper describes the Controllability of a grounding grid system for a 110 kV urban substation by MALT model using the CDEGS software. The size of the substation is 58.5 x 36 m2, and the soil resistivity is uniform layers. The depth of the layer is 3 m, and the assessment of the soil resistivity is 2000 Ω.m. The intelligent designing of the substation grounding grid is represented in Fig. 1. When lightning strikes this substation, a part of the lightning strikes current flows to the soil through the down conductor and its grounding system. However, if the lightning strike current is high, the insulator would be flashover, and a side of the lightning current invades this station. Therefore, this model was developed to handle the problems resulting from lightning strikes. We relied on optimal measurements to obtain the protection parameters like the touch and step voltages. We analyzed the basic rules to get high protection for the substation. We also discussed if the substation needs an LPS.

A. Ligthning Protection System(LPS)

An LPS consists of an air_termination system (ATS) for the above upper-most parts of the construction with down-conductors and an earth_termination system. For controllability protection level selection, the IEC standard point out to the assessment of the risk mentioned in [8, 9]. Four lightning protection levels (LPLs) for the models are realized to fulfill the desired LPL performance class. For each LPL, a set of maximum and minimum lightning strikes current parameters is fixed. Each set contains level-dependent and level-independent construction rules. Four classes of LPSs (I, II, III, and IV) are defined as a set of building rules, based on the identicaling LPL. We used the risk assessment to determine the class of the LPS. If Nd ⩽ Nc the system does not need an LPS, and if Nd > Nc, otherwise. Risk assessment depends on the parameters shown in Tables 1 and 2. The main risks of lightning are studied extensively using mathematical modeling and simulations. The structure of the substation is designed by the CDEGS software explained in Fig. 1, and all calculations of risk assessment are explained in the following.

B. Lightning Risk Assessment

The risk assessment is performed to determine if the substation needs an LPS. For this, the lightning strike frequency (Nd) should be compared to the tolerable risk factors (Nc). The comparison is conducted by the ratio between the acceptable risk and the lightning strike frequency. If the calculated rate is 1.0 or higher, then an LPS is required, and if it is lower than 1.0, then there is no need

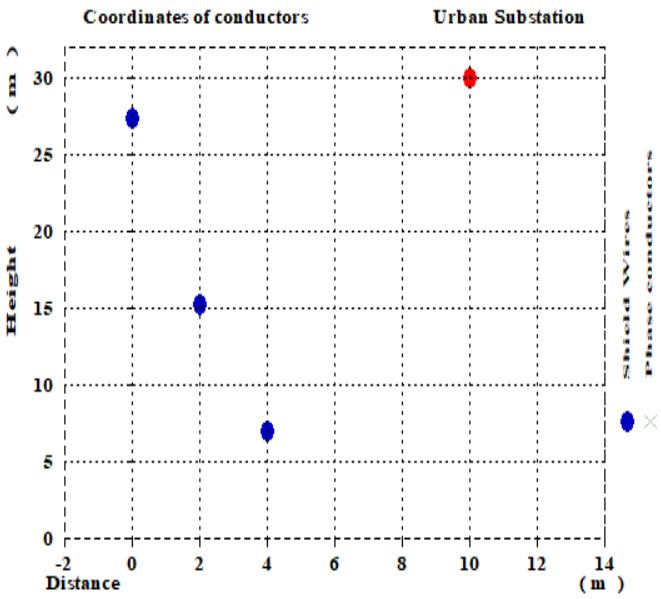

Fig.1 110kV substation grounding grid using CDEGS software.

for an LPS. The application is through NFPA 780 - 2008 edition [10]. The lightning strike frequency to the system can be calculated as Eq. (1):

$$Nd=Ng*C1*Ae*10^{-6} \quad (1)$$

The lightning strike frequency (Nd) consists of the common area of the facility (Ae), its surrounding environment (environmental coefficient C1), and the lightning flash density (Ng) of the city. The common area of the substation structure can be obtained as

$$Ae=L+W+6H(L+W)+9*3.14H^2 \quad (2)$$

Where L, W and H are the length, width and height of the structure, respectively. At this substation, the surrounding environment of the facility has an integral effect, so the designed external structure is critical to avoid the impact of lightning strikes, and all factors indicate that the high protection of the station leads to full stability of all parts of the substation [11]. The tolerable risk of the facility (Nc) is determined by Eq. (3) and is dependent on the structure coefficient (C2), contents within the structure (C3), structure occupancy (C4), and lightning consequence coefficient structure (C5).

$$Nc=C1*(10^{-3})/C2*C3*C4*C5 \quad (3)$$

Equation (1) and (3) are used to locate the distribution of lightning strike current capacity that below the shield wire. The structure is metal, and the coefficients are shown in Table 1, according to NFPA-780. Furthermore, after applying Eqs. (1) and (3) and Table 1, the result of the lightning risk assessment will determine whether an LPS should be installed. From the results in Table 2, we find that an LPS should be fixed because Nd>Nc or the ratio of Nd/Nc is greater than 1. Three LPLs used in this study are based on the standards. Commonalty lightning parameters are primary input variables for determining the effectiveness of voltage-

TABLE 1. C COEFFICIENT SPECIFICATION

protection. More recent lightning strike measurements were obtained by SES-shielded -CDEGS software.

III. LPS

There are four part of LPSs (I to IV), as shown in Table 3. The qualities of an LPS are determined by the characteristics of the model to be protected and by the considered LPL. The standard corresponding to LPLs defined in IEC 62305-1. After that, to determine the protection level class, the efficiency protection (E) is calculated to be 99% according to Eq. (4). A lightning strike is uncontrollable However, it can be discovered and lightning be tracked [12, 13].

$$E \geq 1\text{-}Nc/Nd \quad (4)$$

A. ATSs

An ATS is designed to prevent lightning damage to the substation. It should be designed to avert uncontrolled lightning strikes to the protected structure ATSs can consist of rods, spanned wire cables, meshes, conductors in the substation grounding grid.

We used air-termination rods according to [14] when the surface requires some rod air terminal units, we determine the air termination dependence as Eq. (5).

$$d = 2 \text{ sq. } (2*r*h\text{-}h\text{^}2) \quad (5)$$

Where d is the distance between two rods (m), r is the radius of the rolling sphere (m), and h is the height of the rods (m). At all events, earth-termination system designs with a considerable area between conductors and the soil buried deeply in the ground lead to lower step-voltages on the surface than those that are less deeply buried or have shorter conductors.

TABLE 3. CLASS OF LIGHTNING LEVEL AND EFFICIENCY IN IEC 62305-1[3]

Class of Protection level	LPS efficiency
I	98%
II	95%
III	90%
IV	80%

For determining the placement of the air termination system for changeable surfaces: the first one is the covering angle method for the height variation between two plan surfaces and the second is the rolling sphere method for the height between more surfaces in the situation of frame with complex spheral size. According to the standard DEHN shield, the determined height of the air-termination rods h (m) is presented in Fig. 2(a). The intelligence depth of the rolling sphere is controlled by the generality significant distance of the air termination rods from each other [15]. Air-termination rods are used to protect the surface of the substation on the roof against a direct lightning strike. The maximum lightning current depending on the value of the rod is shown in Table 4.

B. Down-conductor systems

We hope to minimize the damage caused by lightning to this substation. It is necessary to use a down-conductor system for the LPS. Exemplary estimation of the distance between down conductors and LPS are shown in Table 5. All values are given by IEC 62305-3 [16]. In this system the down-conductors are placed in one of the corners of the 110kV substation; they are distributed around the perimeter. The down-conductors are connected directly to the substation. They are installed directly onto the structure because of the temperature increase phenomenon during a lightning strike to the LPS. If the wall is made of an ordinarily inflammable material, the all value down conductors may be installed directly on or in the wall, as shown Fig. 1

C. Earth-termination systems

Earth-termination systems are an essential bit of LPSs. They must be designed to ensure safe lightning current transition into the ground grid wanting make step voltages on the surface of the soil, which would be serious to human beings. The attitude of an earth-termination system under high lightning currents was studied to minimize hazardous overvoltages.

TABLE 4. VALUE OF THE RODS AND MAXIMUM CURRENT DEPENDENCE FOR LEVEL I

Symbol	Computation result of the Parameters

Maximum lightning Current(KA)	200

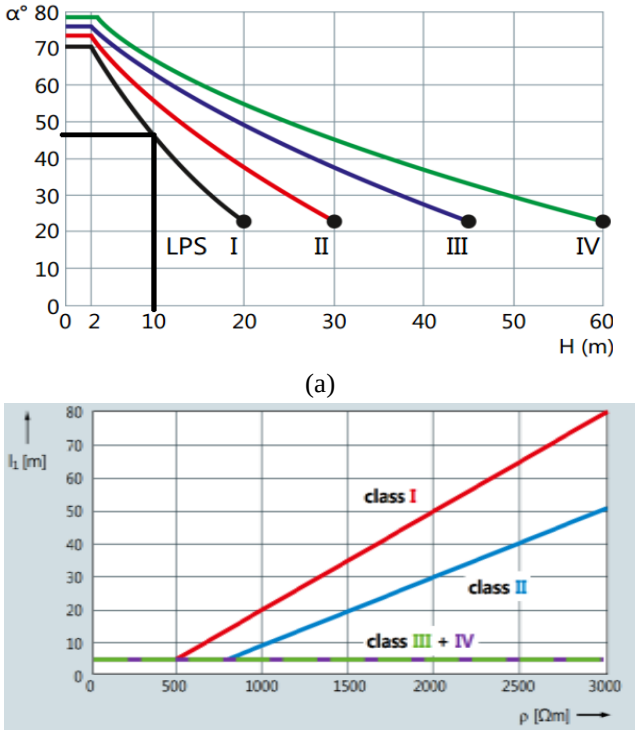

Fig. 2. Model of the LPL [15]. (a) Description of the resulting value of the LPS between angle α and H (m), (b) Minimum length of each earth electrode according to the resistivity and the LPS class.

This was performed by many authors theoretically both in the frequency and time domains [10]. In an earth-termination system, the length of earth electrode should be calculated according to the class of the LPS to determine the soil resistivity layer. For class I, the ρ = 2000 Ω.m and the length of the electrode is 50m, as shown Fig. 2(b).

IV. PEAK LIGHTNING CURRENT

Lightning currents that can pass during a direct lightning stroke can be simulated with the surge current of a waveform of 10/350 μs in IEC 62305-1. For class I, the peak value current is 200kA, conformable to the first short strike LPS. The lightning surge current can be jointly outlined by the attached double exponential-type function in Eq. (6) and Fig. 3.

$$i(t) = I/\eta * \exp^{\wedge}(-\alpha t) - \exp^{\wedge}(-\beta t) \quad (6)$$

Where I is the peak current, η is the correction factor, t is the time variable, and α and β are time constants. In this system, to calculate the lightning surge, we also used the Heidler representation of the lightning surge

TABLE 5. CLASS OF LIGHTNING LEVEL AND EFFICIENCY IN IEC 62305-1[3]

IV	20

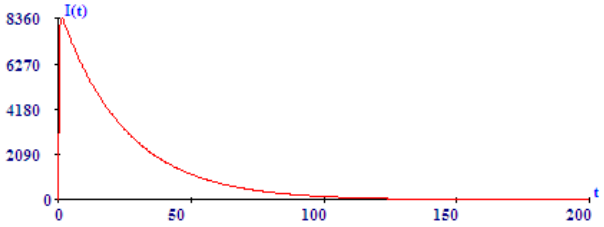

Fig. 3. Double exponential-type function of the lightning surge using FFTSES

and subsequent current pulse wave as one of the most widely used surge models for the lightning surge propagation in the transmission line and grounding system. The Heidler surge function value is described in Table 6. The field methods are mostly more accurate than circuit or substation approximation, but they take into account all electromagnetic phenomena. The calculation is carried out for conductive structures with single earth electrodes in the earth with 2000 Ω.m. The surge current distribution in the vertical and horizontal elements of the LPS is calculated during a lightning strike to the corner of the substation. In this study, the effectiveness of high current density that progresses the grounding realization is not taken into account that is a path adopted by many researchers [9-12]. In high lightning currents, the electric field at the ground electrodes may be larger than the electric force of the soil, resulting in collapse. This generally get better the grounding performance especially in lower resistivity soil. There is no unanimity on the simple formularization that takes into account the influence of this complex and patchy process as they are forced by the necessary underlying simplifications and proposition.

V. COMPUTATION RESULTS

The computation step is mostly based on the use of the well-known SES shield to design the substation according to the lightning specification, striking distance, and ground flash density. The probability for a stroke current smaller than 12.52 kA is 15.571%. Additionally, the likelihood that there will be one failure per year is 1 per 0.0033%. All substation characteristics, critical and intermediate values, are computed by the CDEGS software, as shown in Tables 7, 8 and Fig. 4. From the result of the risk assessment

using the CDEGS software, the collection area of direct strikes to the structure (58.5 x 36 m2) is 2.229 m and the overhead lines from direct strikes are 34.05 m. The CDEGS software firstly utilized the fast Fourier transform to draw the time domain lightning surge zone. The 110 kV substation need to perform to reform the faults and the past studies indicate the possibility of variable current depending on the grounding potential rise. In this study, we attempted to find reasonable solutions to solve the problems resulting from the chosen values of the soil resistivity and the quality of the conductors. All the resulted in this paper indicated positively solutions to help their implementation. By far, the maximum cost-effective control of the assessment of high-transmission lines under a lightning is the optimization of the shielding angle and the decrease of the grounding resistance. Furthermore, for the 110 kV substation, the standard was updated using the CDEGS software to improve the spacing rods.

Lightning surge per year	1 per -30594 y

Based on the results represented in this paper and according to all international standards for the protection of high- voltage substations, it was concluded that the effects of lightning can be reduced using LPSs. In addition, Fig. 5(b) shows the summary of the study in terms of the optimal representation of the calculation of top step and touch voltages in the protection of the human elements and equipment and all various types of 110 kV substations. This study indicates out that the process of the analysis and follow-up effects of lightning can be made with four levels of protection algorithms, but level 1 is preferred for the use as it is good for efficient treatment of the effects. Furthermore, in this paper, we explained the analysis by the CDEGS software that can process the problems and in turn should be implemented by subsidiary stations depending on LPS mechanism. According to the IEC standard of LPLs, the attachment between the substation top and the grounded structure takes place for lightning strikes at a critical distance from the structure. This distance is fixed as the radius of the level used in the rolling sphere model of locating lightning down conductors on the structures. The analysis was applied according to [8].

VI. CONCLUSION

In this study, a new design for a 110 kV urban substation is proposed. According to the optimization process, the LPS is calculated to be placed in one corner of the substation. The stepwise procedure for designing the earth grid was presented. The design parameters were obtained from the risk assessment using the SES shield in the CDEGS Software. The results of this study show that the representation of the substation includes the calculation of all parameters things that lead to the occurrence of any risks, which considered correctly according to the international standards. The grounding grid was also computed against any hazards considered in this study. A substantial analysis whether an LPS should be applied is performed by the designer when a new substation is designed or an existing structure is updated. Lightning risk assessment is a tool that can be used to determine whether an LPS is required. Touch and step voltages were estimated and considering the human body presence on the soil surface. The results show that the approximate mode in this study is suitable for determining lightning-caused voltage peaks considering the horizontally stratified ground with acceptable accuracy.

***Abstract*— This article describes a new topology of single-phase pulse width modulation (PWM) AC to AC converter, the designed converter does not need to follow the duality of the input voltage for secure switching and requires one of two techniques which is a smooth switching or lossy RC snubber strategy. In this recommend work the usual phase support of PWM AC to AC converter is supplanted with the switching cell framing and coupled inductor hence, the Step-Up type pulse width modulation (PWM) AC to AC converter is formed. The simulation presented in the setting of MATLAB-2016 b.**

Keywords—AC-AC Converter, Boost inductor, Pulse width modulation (PWM), Switching cell (SC), Commutation problem.

I. INTRODUCTION

For AC-AC energy power conversion requiring varying output voltage and variable frequency, the most common configuration is the dc-linked voltage source inverter, like pulse width modulation (PWM) inverter. This approach shows a multiple mode of operation for single-phase grid converter (SPMC) topology [1]. New zero-voltage transition, energy factor, three phase ac-ac converter with high frequency single-phase connection in many applications where the voltage regulation is needed, it is used [2],[3],[4]. topology of a single-phase ac -ac converter capable of producing voltage output to buck or increasing topology design mode uses a minimum of two segment overlapping controlled switches in each input cycle. this topology is easy, low cost and minimum numbers of devices [5]-[6]. A dynamic voltage restorer (DVR) type technique is also used switching cell structure so DVR has no switching issue and therefore does not need to sense the input voltage duality [7]-[8]. In conventional approach commutation problems arise, damaging switching elements so eliminating these problems using switching cell structure and coupled inductor with boost inductor which increasing high efficiency and low cost [9]. In this paper, the solid AC-AC converters link with PWM of z phase connection is implemented without the issue of commutation. For practical applications and highly attractive by means of magnetic integration of the discrete coupled inductor with boost inductor in single phase ac converter [10]. Fig. (1) shows implementation of stage-legs this structure can produce a wide frequency range without taking into account the input frequency. Which proposes a single-phase ac-ac converter with a diode-clamped neutral point system [11]. Noise from EMI is one of the main problems during grid tied power converter construction [12]. In this topology, the number of switches is reduced to just four, resulting in reduced losses and higher efficiency compared to earlier topologies.

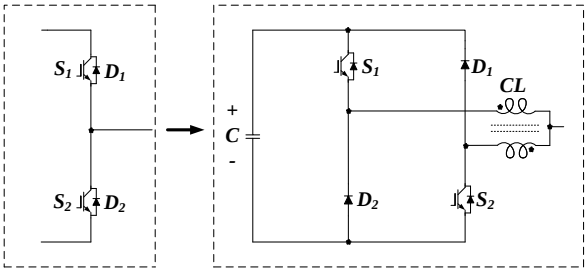

Fig. (1) implementation of stage legs

II. CONSTRUCTION OF DESIGNED CONVERTER

In this construction of proposed converter switching cells, a filtering inductor, two capacitors and load are employed. This Converter approach is introduced with two switching cells, P-type and N-type, having their intimations and demands in electronic circuits. Basic cell structure is introduced in this paper having a switching segment (IGBT) and a diode.

The P-type is a reflector circuit of N-type and vice-versa. The topology of Proposed PWM AC-AC converter has been depicted in Fig. 2. that mainly consists four bidirectional IGBT switches, Sw_1-Sw_4, and coupled inductor with boost inductor [13]. There are many problems arise in conventional approach so reduce all them using switching cell structure with boost inductor. The step-up type converter is displayed in Fig 1[14]. With this configuration, the proposed converter can bear both dead and overlap time without harming equipment for switching. This design can prevent the shoot through issue created problem such as door miss triggering signals. Thus, it is possible to design an externally secure and durable scheme. So, Fig.2. conventual shown as below-

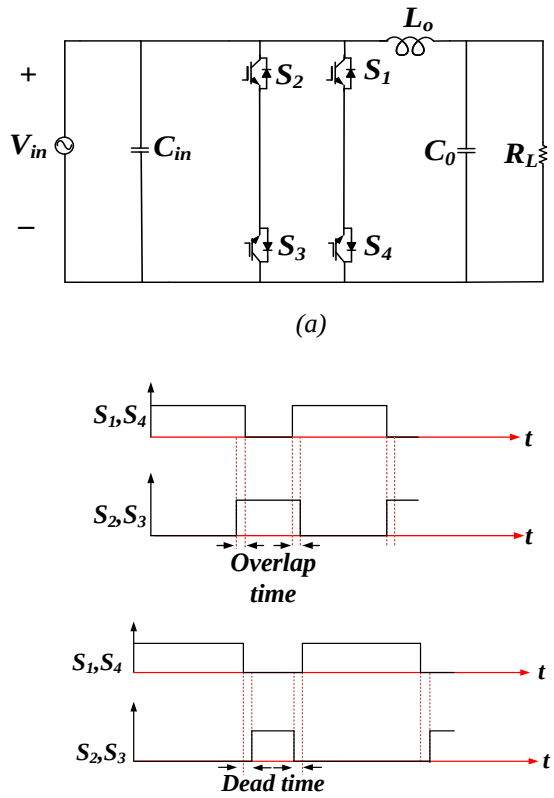

Fig.2. problems of switching in conventional ac-ac PWM converters.[15].

III. Performance Of The Proposed Converter

Fig.3 indicates the operation of proposed converter. In this figure current is flowing between the switching legs, boost inductor and the couple inductor. Only the positive half cycle of voltage input is considered Similarly, negative can be analyzing because the structure is symmetric between the upper side and lower side leg. The center recognized as ground potential between these legs and known as and inductor connection terminals is marked as 'A' and 'B'. Figure indicates the proposed converter's operational waveforms when D<0.5. Since there are four continuous modes for conduction and 3 level unipolar voltage for top and bottom leg depending on the duty cycle.

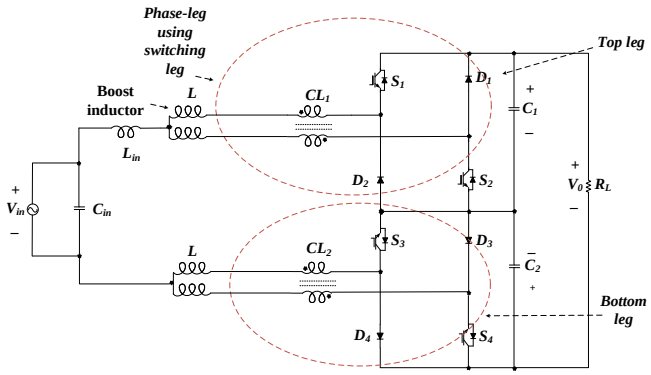

Fig.3.Proposed Step-Up converter with SC, coupled inductor and boost inductor

In the document, it is presumed that the two binding inductors are identical with each other and it is presumed that the coupling coefficient is near to infinity. then fig.4 shows modes operation boost ac-ac converter and modes are following as:

1. Mode A

The switches S_1, S_4 are all switched on in this operating mode and the diodes D_1, D_4 are all switched off. The input inductor which is a coupled inductor is denoted as L_{in} that stores the energy of the input and L_s is the self-inductance and voltage are as follows:

$$v_A = \frac{v_{C_1}}{2} \quad ; \quad v_B = \frac{v_{C_2}}{2} \tag{1}$$

$$v_{AB} = v_A - v_B = \left(\frac{vC_1}{2} - \frac{vC_2}{2}\right) = \frac{v_o}{2} \tag{2}$$

$$vL_{in} = v_{in} - v_{AB} = v_{in} - \frac{v_o}{2} \tag{3}$$

$$\frac{di_{L_{in}}}{dt} = \frac{vL_{in}}{L_{in}} = \frac{v_{in} - {}^{v_o}/_2}{L_{in}} \tag{4}$$

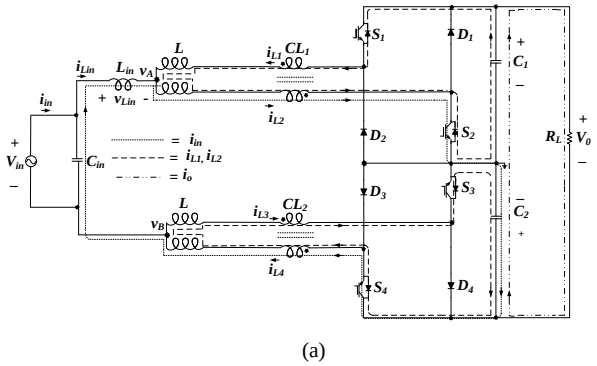
$$\frac{di_{cm1}}{dt} = \frac{vc_1}{4L_s} \tag{5}$$

$$\frac{di_{cm_2}}{dt} = \frac{v_{C_2}}{4Ls} \tag{6}$$

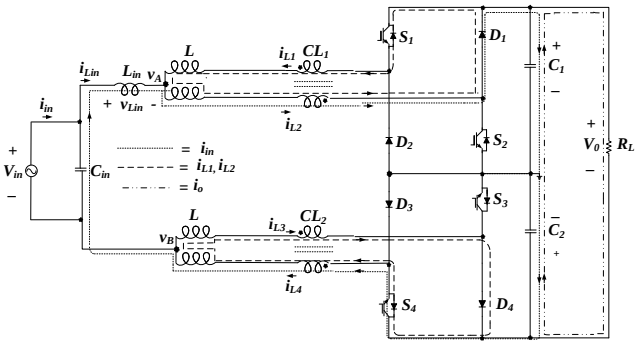
2. Mode B

The switches *S*2 and *S*3 turn OFF in this mode of operation while *S*1 and *S*4 remain ON. The diodes *D*1 and *D*4 turn ON cause of freewheeling action and *D*2 and *D*3 remain OFF. The energy stored in the L_{in} is transmitted through S_4, D_1 to the output. The relationships between current and voltage are as follows:

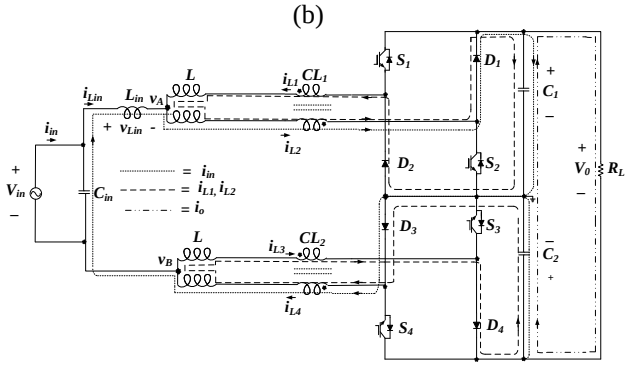
$$v_A = v_{C_1}, v_B = v_{C_2} \tag{7}$$



(a)



(b)



(c)

Fig.4 proposed converter's operating modes when (D<0.5). 1. Mode A *(0 ~ DTs)* 2. Mode B *(DTs ~ 0.5Ts)* 3. Mode C *(0.5Ts ~ (0.5 + D) Ts)* 4. Mode D *((0.5 + D) Ts ~ Ts)*

$$v_{AB} = v_A - v_B = v_{C_1} - v_{C_2} = v_0 \quad (8)$$

$$v_{L_{in}} = v_{in} - v_{AB} = v_{in} - v_0 \quad (9)$$

$$\frac{di_{L_{in}}}{dt} = \frac{v_{L_{in}}}{L_{in}} = \frac{v_{in} - v_0}{L_{in}} \quad (10)$$

$$\frac{di_{cm_1}}{dt} = \frac{di_{cm_2}}{dt} = 0. \quad (11)$$

Voltage across capacitor C1 is denoted by Vc1 as similar C2 capacitor is shown by Vc2.

3. Mode C

Mode 1 is repeated in this mode again, but all are switched off with a differencethat switches S1 to S4 and D1 to D4 are all s witched ON. Input power is again stored in L_{in}.

$$\frac{di_{cm_1}}{dt} = -\frac{v_{C_1}}{4L_S} \quad (12)$$

$$\frac{di_{cm_2}}{dt} = -\frac{v_{C_2}}{4L_S} \quad (13)$$

4. Mode D

The difference in this mode is that V_A and V_B will be z ero instead of V_{C1} and V_{C2} during periods B and D.Equation 14 shows the voltage gain of proposed step-up converter with boost inductor.

$$\frac{v_0}{v_{in}} = \frac{1}{1 - D} \quad (14)$$

Fig.5 shows the Step-Up ac-ac converter main operational waveforms when D (Duty ratio) value is less than 0.5

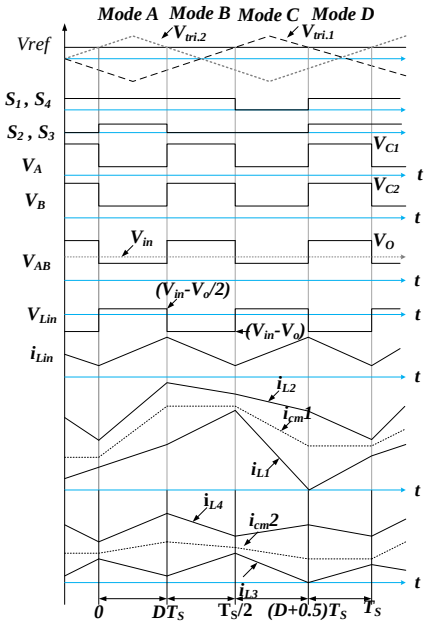


Fig.5. Single -phase PWM boost AC-AC converter key operational waveforms

IV. Simulation Of The Proposed Boost Converter Based On Switching Cell Structure

The simulation model by MATLAB 2016b of the single-phase PWM (pulse width modulation) proposed Step-Up converter is shown below in Fig.6. based on switching cell structure, coupled inductor with boost inductor. Parameters are input voltage (v_{in}=110v_{rms}) and capacitor (C_{in},C_1,C_2=2.2μf) and switching frequency (f=50 kHz) as follow:

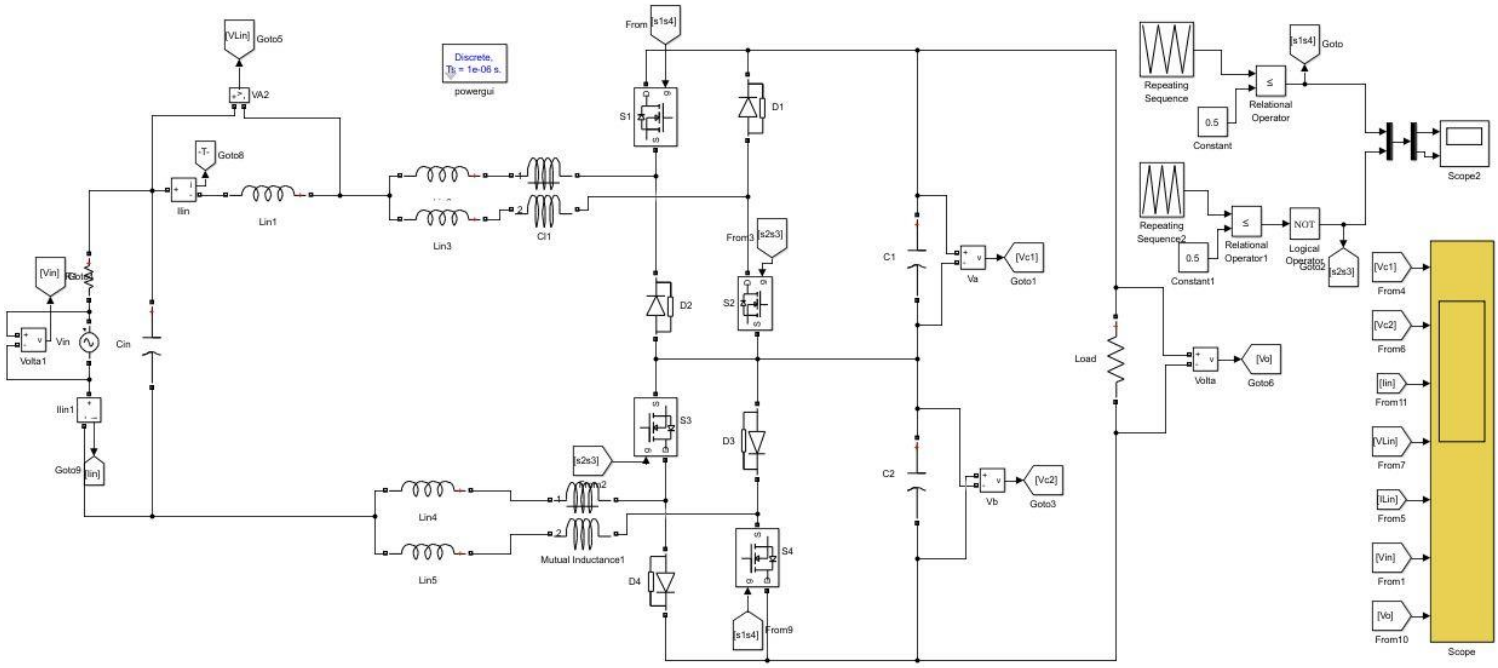

Fig.6.Matlab Simulation Model of Proposed Boost Converter based on switching cell structure

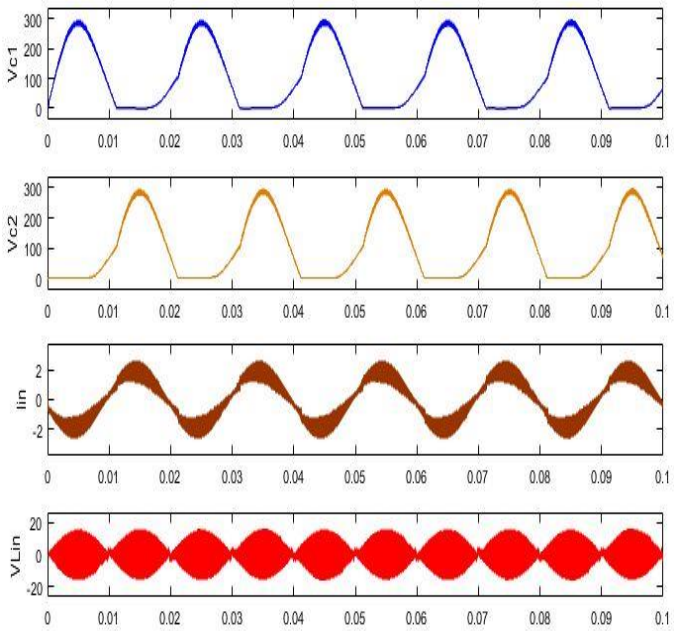
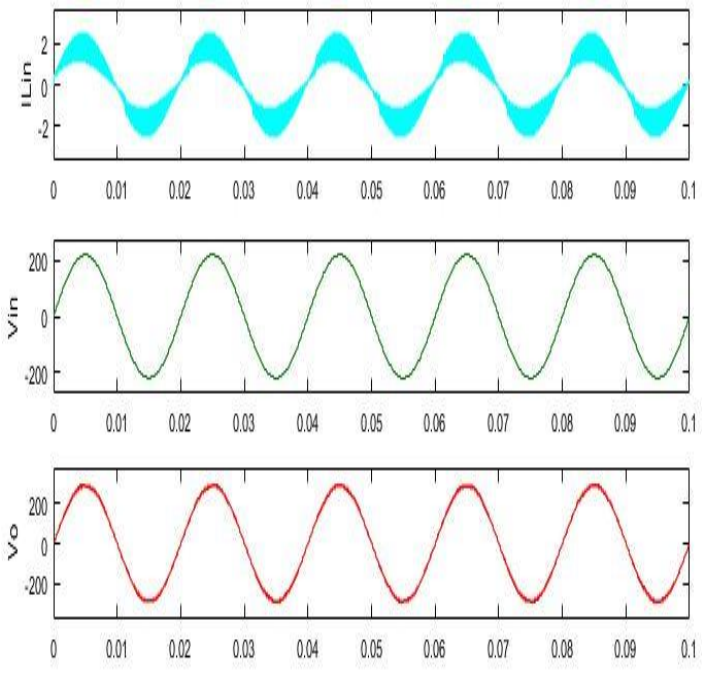
V. SIMULATION RESULTS



(a)

Fig.(a) shows voltage waveform of C1, C2,. Input inductor voltage and input current also.



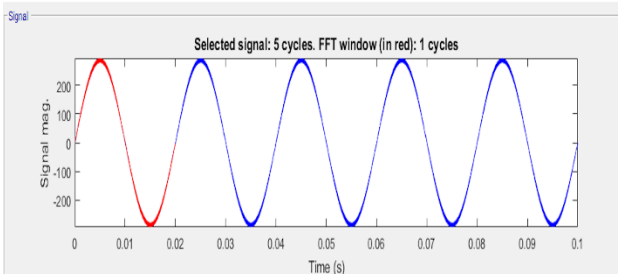
(b)

Fig.(b) shows input inductor current, input voltage, output voltage

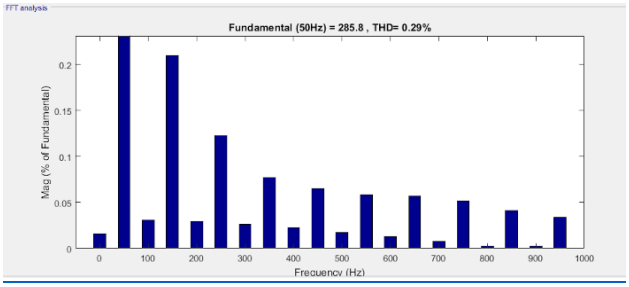
Fig.7. MATLAB simulation result

Fig.7 represents the simulation of the proposed converter. According to the parameter design simulation parameters are selected input voltage (v_{in}=110 v_{rms}), output voltage (v_o=220v_{rms}), output power (p_o=200 w) and D =0.4.

The ac to ac converter step-up operation is obtained from the MATLAB setting. Fig.8. indicates the 50 Hz variable output frequency output voltage and % THD (Total harmonic distortion).



(a)



(b)

fig.8. shows (a)output voltage and its (b) THD (total harmonic distortion)

VI. Conclusion

In this paper, step-up ac to ac converter has been created for single-phase pulse width modulation (PWM), which detects the switching issue in a single-phase direct PWM ac-ac converter without detecting the duality of input voltage. This step-up ac-ac converter uses the basic structure of the SC and the coupled inductor to allow it to be opened and shortened without damaging the switching devices. It is possible to replace IGBT with MOSFET for the primary power device for better outcomes. The suggested converters are used in industrial applications and also can be implemented for future research work. With the use of coupled inductor and switching cell higher efficiency can be achieved.

Deep learning based Customized Model for Features Extraction

[1]Akshya Reghunath, [2]Shalini Vanaja Nair, [1]Jalpa Shah
[1]Dept. of Electronics and Communication Engineering, Amrita School of Engineering, Bengaluru, Amrita Vishwa Vidyapeetham, India
[2]Ennoventure Inc, Washington DC, USA

***Abstract*—In the last few years, deep learning is one of the powerful technique, used for image recognition. Among the various kinds of deep neural networks, Convolutional Neural Network (CNN) nowadays has been widely used for the purpose of image recognition. In this work, we present the customized model developed for feature extraction of medical packages. Now a days, it is difficult to distinguish an original medicine from counterfeit. The proposed model based on CNN can be useful in identifying the original medicine which forms the first step in the process to identify counterfeits. The medicine images are used as dataset for feature extraction and image classification. Medicine package shape, edges and colour are used for feature extraction of customized model. Classification is done to distinguish medicines which is of same colour and differs in their name, printed text, barcode and the company logo. One of the popular pre-trained CNN architecture model VGG-19 is used for comparing the results of developed customized model. Customized model consists of only five layers convolution layer, maxpooling layer, dropout layer, flatten layer and dense layer. In comparison to pre-trained VGG-19 model customized model reduces number of layers from 19 to 5. Number of layers are reduced to 5 because increasing the number of layers were not showing much improvement in the testing results for given dataset. Training accuracy of 93.17% , validation accuracy of 88.68% and testing accuracy of 76.67% is obtained for the customized model. The results can be made more precise and accurate by optimizing the number of layers in the model. In the proposed model we have used 5 layers. The optimization of number of layers is done based on the prediction accuracy. The accuracy of less than 50% was achieved using 3 layers and it is increased up to 76% with 5 layers. No further improvement in the prediction accuracy was observed by increasing number of layers to 6 or 7, so for the proposed model 5 layers are selected.**

I. Introduction

Nowadays, deep learning has become one of the most popular technique which has now found its adoption in various fields [1]. After a great development deep learning became a growing area especially in the region of Artificial Intelligence (AI) and Machine Learning (ML). Various frameworks and libraries [2, 4] which are existing for research and development in deep learning such as Tensorflow, Theano, Caffe and Keras. Out of the many deep learning architecture techniques few of them are Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM), Deep Belief Networks (DBNs), Deep Stacking Networks (DSNs) and Generative Adversarial Networks (GANs). Since, object Recognition has become a critical area of research in the field of Machine Learning as it forms a crucial part of the intelligence system related to Computer Vision, Robotics and Autonomous Vehicles. Extracting the variant features found in the input images is always the most challenging area in object recognition. Convolutional object recognition uses neural networks to predict decisions about the object recognition based on features which is being extracted from the images. The best known deep learning architecture is CNN [4]-[5] for the purpose of image and object recognition. CNN includes a service of layers which includes convolutional layers, pooling layers, the rectified linear unit layers, softmax layers and fully connected layers. CNN is defined as a category of deep neural networks widely used for analyzing visual imagery. CNN have been inspired from the biological processes in which the connectivity pattern between the neuron looks like the organization of animal visual cortex. Each cortical neuron stimulates only in a predefined region of the visual field. This field is known as the receptive field. The receptive field consists of various neurons that are not fully overlapped. CNNs use less pre-processing technique compared to any other image classification algorithms. The learning of CNN from the given features without human intervention, considered as one of the advantage.

The basic architecture of CNN has been shown in Fig. 1. The CNN consists of input layers, output layers and hidden layers. The hidden layers comprises of convolutional layer, pooling layer and fully connected layer. Convolutional layer will apply a convolution technique to the inputs. The CNN may consists of global or local pooling layers, that joins the outputs of each neuron clusters into a single neuron at the next layer. There are two types of pooling layers: one is maxpooling layer which uses the maximum value from every cluster of neurons from the previous layer and second is average pooling layer which uses average value from each of cluster of neurons obtained from previous layer. The output of pooling layer act as a input for fully connected layers. The classification of inputs is done by fully connected layers. Each of neuron in CNN has activation function which process the input and provides appropriate output. The activation function consists of vector of weights and a biases. Improvement in the learning of a neural network depends on incremental adjustments to the biases and weights. The combination of weights and bias is known as filter. The important fact of CNN is that many of

the neurons share the same kind of filter.

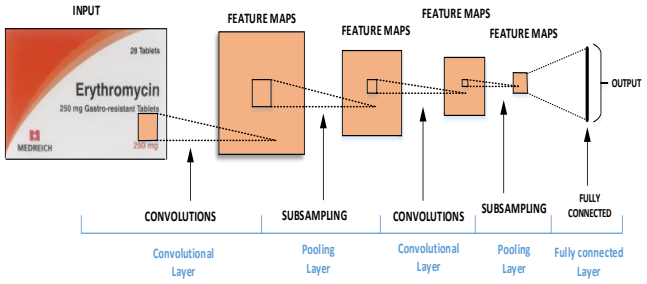

Fig. 1. Basic CNN Architecture

The main objective behind training the CNN is to identify the correct weights with the help of multiple iterations. When CNN is trained using dataset, the network obtains knowledge from this dataset refereed as weights of the network. Thus the weights obtained can be given to any other CNN, rather than training it from the beginning. The pre-trained model can be used for the same purpose after training through large dataset. The pre-trained model may not be able to give 100% accuracy, but it helps to save huge efforts required for training from scratch. We can transfer the weights of pre-trained model for any untrained CNN model, which is known as transfer learning. By doing this we are actually transferring the learning part of the pre-trained model to another model.

In the proposed work, the dataset is created by capturing front and sideview images of various medical packages which contains the information about the features. Cropped images of around 688 medical packages are used. With the help of image augmentation, horizontal, vertical flips and rotation are also used in the dataset. We have used pre-trained CNN model VGG-19, which is found most appropriate to extract features from our dataset. With the help of the pre-trained CNN model for feature extraction, we are exploiting the learning capabilities of the pre-trained model acquired through lengthy training time on very huge datasets.

This paper is organized as follows. Section II presents the review related to features extraction and image classification. Our proposed model is discussed in Section III. Comparison results related to pre-trained model and proposed model are presented in Section IV. Section V concludes this paper and provides some prospective on possible future work.

II. Literature Survey

Image recognition technique is the ability of the software to identify objects and places in images. Human brains can recognize objects without any difficulty and can easily classify them but for a software to recognize, deep machine learning is a necessity. This feature of image recognition for a software was found best with CNN. Image recognition algorithms works by the use of comparative 3D models. The following are the networks which are the most popular ones.

A. AlexNet

AlexNet was the first deep neural network to provide a better accuracy for ImageNet classification with a significant improvement compared to any traditional network. It consists of a total of 5 convolutional layers which is being further followed by 3 fully connected layers. This network uses ReLU activation function which helps in faster training [9]. The ReLU actiation function is placed after after each and every convolutional and fully connected layers. Convolution layer is built using kernel filters. AlexNet also overcomes the problem of overfitting with the use of dropout function.

B. VGG-16

The VGG-16 network uses more smaller sized kernel filters compared to AlexNet. Multiple smaller stacked filters are better than the one with the larger size because it helps in learning more complex features. In the VGG-16 architecture concept of blocks is introduced, where blocks with same filter size applied multiple times in every layer and helps in extracting more complex features.

C. VGG-19

VGG-19 architecture is different from VGG-16 only in depth of layers. The VGG-19 contains three layers more compared to VGG-16. These layers understand detailed patterns of images for effective training. In earlier research work it has been found that by using multi-scale testing VGG-16 reduced the error rate from 8.8% to 8.7% similarly VGG-19 reduced the error rate from 8.7% to 8.6%.

D. GoogleNet/Inception

By comparing VGG network with GoogleNet it has been found that GoogleNet using 7-nets has an error rate of 6.7%, while VGGNet using 2-nets has an error rate of 6.8% which is really competitive. GoogleNet has developed a inception module which approximates CNN with a normal dense construction so that only few members of neurons are used and the width or the number of convolutional filters are always kept small. It has bottleneck layer which helps in reducing the computation requirement.

In the earlier research work [7]-[8] performance of two classifiers methods is evaluated. The two classifiers Linear SVM and Quadratic SVM were used. Results shows pre-trained model AlexNet provides better accuracy on both the classifiers compared to traditional method of features extraction. According to the result it has been found that the pre trained model AlexNet had better accuracy on both the classifiers. Even though both the classifiers have performed similarly but Quadratic SVM gave better results than linear SVM [9]. In [10] to check the quality of leather material using leather images AlexNet CNN model is used. Tanning leathers are having different textures in the same category which is caused due to process of tanning or the skin were being taken from various part of the animal body. Better results are obtained using pre-trained CNN model compared to hand crafted features extraction method. Machine learning

is also used to classify the food categories [11]. Classification was done using Linear SVM and AlexNet. In [12] for original fingerprint identification VGG-19 and AlexNet is used. comparison results show VGG-19 has better accuracy than AlexNet. As VGG-19 produce better accuracy results compared to other networks, in the proposed work we have used VGG-19 for comparison [12].

III. Proposed Model

From the earlier research work it was found that VGG-19 is one of best pre-trained model for object recognition. So, before developing customized model, pre study on our medicine related database is performed using VGG-19. Fig. 2 describes the standard steps followed during training and validation of VGG-19 for features extraction. The dataset is created using front and sideview images of various 688 medical packages which contains the information about the features. Using image augmentation, horizontal, vertical flips and rotation of images are also used. The data set is divided into two parts in which 80% of data set is used as training dataset and 20% of dataset is used as validation dataset. The training and validation of the model is executed for 30 epochs. Each epoch allows one pass through the dataset, within each epoch the corresponding features and labels are extracted. Using extracted features model makes prediction about medical package. The same process repeats for every epoch. Similar process will be repeated in validation using validation dataset. After validation process, cross-entropy loss is calculated to in terms of percentage to determine how accurately the prediction of the medical packages is done. The input images are resized so that it can fit into CNN input layer. Features are extracted after the training and validation of VGG-19. At the end of training and validation different classes of images will be predicted. We have used VGG-19 of 3×3 convolutional layers to classify images into 32 objects. The size of output images from convolution layer are resized with the help of max-pooling layer. There are two fully connected layers having 4096 nodes each are followed with a softmax classifier that helps in the extraction of various features which are being used for classifying the products. The accuracy of classification can be improved by increasing the depth of VGG-19. As an input dataset, medicine package images are used of the size 224×224. The input dataset of 688 different medicine images is used out of which 510 images have been used as the training dataset and 178 images have been used for the purpose of validation dataset. The testing is performed using unseen dataset of 150 different medicine images.

To train the model, we have used an open source software library called Keras-Tensorflow, developed for faster experimentation of CNNs and recurrent networks. We have included few predefined packages such as numpy, pandas, keras etc. Then loading of VGG-19 is done. The last layer of VGG-19 is replaced with 32 classes of our dataset. For learning of complex functions present in the images, ReLu activation function is added to the dense layers and the softmax function is added to the last layer. Next step is loading the ImageGenerator which is inbuilt in keras to train our model.

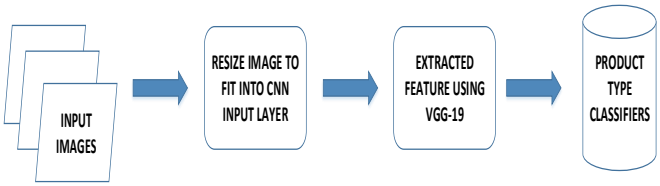

Fig. 2. Training and Validation steps for features extraction

During the training, validation and testing, the performance of the pre-trained VGG-19 model is evaluated based on accuracy. Accuracy is defined as from the given dataset of images how many images are classified correctly by model. Accuracy is represented in terms of percentage. The training accuracy gives an idea about what percentage of images in the current training dataset are correctly classified. Similarly the testing accuracy provides us the percentage of how well model is able to classify new images that does not belong in training dataset. The validation accuracy is used to understand whether the model is under-fitting or over-fitting. The results showed an accuracy of 98% during testing with epochs of 30.

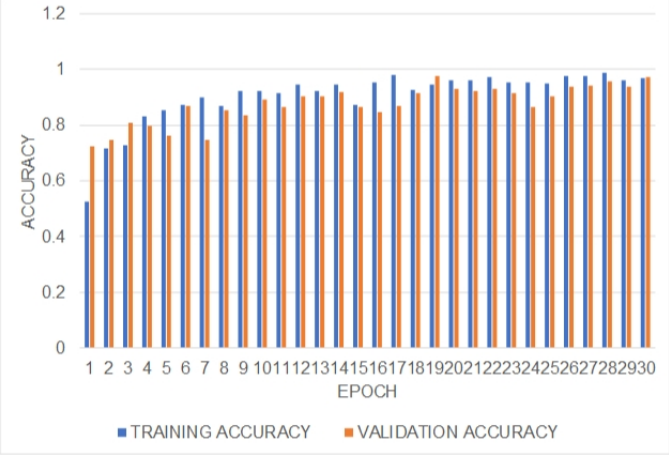

Fig. 3. Training accuracy vs Validation accuracy

TABLE I
Performance Results of VGG-19

	Number of Images	Accuracy
Training	510	97.08%
Validation	178	97.42%
Testing	150	93.33%

The Fig. 3 shows the comparison between the training and the validation accuracy. It has been plotted for 30 epochs. At the beginning huge difference in the values of training accuracy (52.5%) and the validation accuracy (72.5%) is observed. But at the end of 30 epochs training accuracy and validation accuracy are close to each other. The training

accuracy of 97.08% ,validation accuracy of 97.42% and testing accuracy of 93.33% is obtained as shown in Table I.

A. Custom Model

In the VGG-19 number of layers used are 19 which are reduced to 5 in the customized model which helps in reducing computational time and complexity. The custom model is created without the use of any pre-trained network weights. Fig. 4 represents the layers of the customised model. In each convolutional layer, a filter of size 5×5 has been taken and then the filter is being moved across the image to perform convolutional operations. Convolution operations are nothing but summation of element-wise matrix multiplication of the filter values and the pixels in the image. The output of the convlutional layers is given to the pooling layers. Pooling layers are used to downsample the images. The image would contain a lot of pixel values and it is easy for the network to learn the features if the image size is progressively reduced. Pooling layers helps to reduce the number of parameters required and hence, this reduces the computation required. For the proposed model max-pooling layers are used. The output obtained from the pooling layers is then sent to the dropout layer which uses a regularization technique to prevent overfitting. Thus the result obtained after dropout layer will be pooled feature maps which will be converted in to a long vector of data with the help of flatten layer. Next is the dense layer which is the fully connected layer whose function is to classify input images based on features extracted from the convolution and pooling layers. is The custom model analytics are shown in Table II.

dataset of size 150 is used for testing the performance of the customized model. The Fig. 6 shows the comparison between the training and the validation accuracy. At the end of 30 epochs training accuracy and validation accuracy are close to each other. The training accuracy of 93.17% ,validation accuracy of 88.68% and testing accuracy of 76.67% is obtained as shown in Table III. Further training with epochs of 40 shows training, validation and testing accuracy 96.28%, 91.13% and 79.19% respectively, which is approximately 3% more than epochs of 30. With 50 epochs the results further improved to 97.12%, 92.23% and 81.2% respectively which is 4% more than the epochs of 30. On further increase in epochs to lead to degradation of the accuracies.

IV. Results

Results of the Custom Model

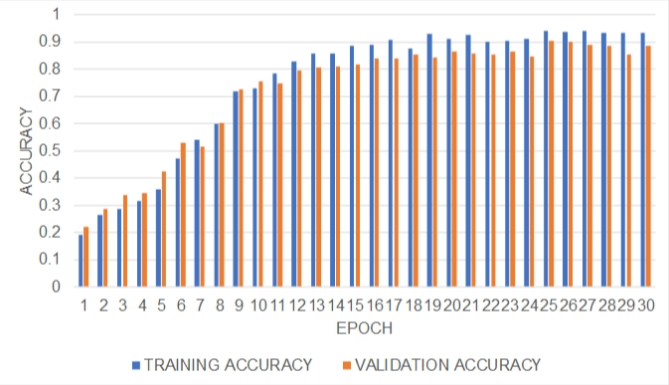

Fig. 6. Training Accuracy vs Validation Accuracy

The comparison results of VGG-19 and Custom Model are presented in Table IV. In the VGG-19 138 Million parameters are used for training the model and 150,000 parameters are used for training the customized model. The training and validation accuracy of both the models are comparable. The difference in testing accuracy of both the models can be minimized further by increasing number of layers, parameters of the customized model.

TABLE IV
Convolutional Neural Network Architecture

Architecture	Parameters	Training Accuracy	Validation Accuracy	Testing Accuracy
VGG-19	138 Million	97.08%	97.42%	93.33%
Customized CNN	150000	93.17%	88.68%	76.67%

V. Conclusion and Future Work

Identification of original medicine packages is difficult through human eye as it looks very similar in view. The proposed work presents customized CNN model which can be used to classify medical packages that looks very similar. The pre-trained model VGG-19 is used for comparing the results of customized model. The number of parameters and layers are reduced in customized model in compression to VGG-19. Customized model results show training accuracy of 93.17% ,validation accuracy of 88.68% and testing accuracy of 76.67%. The model was also tried by adding two more layers to the original layers of Custom Model, still same accuracy result was achieved, but the accuracy can be improved if more number of layers are added, and by changing the value in parameters and it has been left as a future work. The proposed customized model can be used for identifying the original medicine packages.

***Abstract*— We have investigated and proposed a cooperative communicating strategy using non-orthogonal multiple access (NOMA) in which the users are randomly deployed. In this technique there are two randomly deployed sources which share or exchange information with their respective destinations parallely over the same range of frequency through a common shared relay. Further in this strategy, after the symbols are received they are transmitted simultaneously in parallel by both the sources with different powers allocated, the relay sends a coded complex signal super-positioned using NOMA-RS to the respective destinations. The most important benefit of NOMA-RS is that same relay can be shared by two sources. Through the mathematical calculations and simulations, we demonstrate the efficiency of the suggested strategy in terms of outage probability of two source and destination pairs.**

Keywords*— *Outage Probability, successive interference cancellation , relay sharing, non-orthogonal multiple access

I. INTRODUCTION

In order to deliver an overall strong network to a very large number of users and to achieve high signal to noise ratio (SNR), Non - Orthogonal Multiple Access (NOMA) is considered as the most important applicant of 5G because of its highly spectral proficient characteristics [1]. For additional improvement of the effectiveness of NOMA network, cooperative Non Orthogonal Multiple Access with relay sharing (NOMA-RS) using decode-and then forward (DF) technique is presented in the paper [2]–[4], where committed users or relays work together to enhance the system performance by making use of spatial diversity. NOMA-RS, where users who have comparatively better channel level act as a cooperating relay for users that are having low channel level, is presented in [2]. The analysis of capacity of a cooperating relay scheme (CRS) with help of NOMA for spatially multiplexed systems is investigated in [4]. Downlink process of NOMA, employing the amplifying-and-forwarding strategy is explained in [5] and [6]. Furthermore, cooperative NOMA that is introduced in [2]–[6] only considers perfectly implemented successive interference cancellation (SIC).

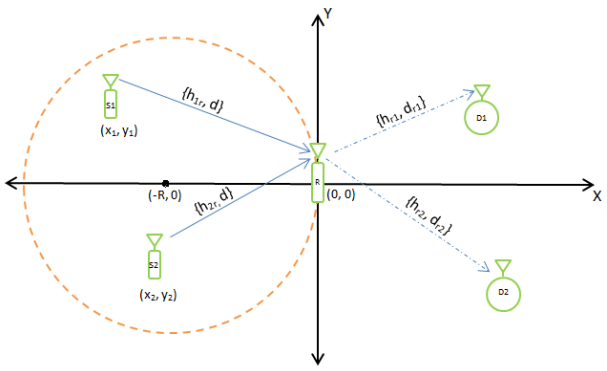

Fig. 1 Model of the System

Based on the already existing theory based on cooperative relay sharing making use of NOMA, there exists a great scope for designing plans that can additionally improve gains in capacity of the proposed system and can deliver great connectivity to very large number of users. In this research paper, we have investigated the effect of the relay sharing (RS) on the characteristics of cooperative NOMA when the users are randomly deployed. Important work of this paper is defined as follows:

1) We have investigated and proposed a cooperative relay sharing technique with the help of NOMA where two or more than two random users are transmitting symbols simultaneously at the same time, and then their symbols are detected and interpreted at relay which are again authorized to be forwarded simultaneously.
2) The analytical outage probability (P_{out}) of NOMA relay has been derived and then analytical results have been

verified by comparing them with simulation results.

II. System Models

We are considering here a dual-hop cooperative relay allocation system as illustrated in Fig.1, where there are two randomly deployed source-destination pairs S_1-D_1 and S_2-D_2 which uses a common relay R which is half duplex engaging DF strategy. Every node is provided with an antenna. It is presumed that there are no straight connections from S_1 to D_1 and S_2 to D_2 due to inadequate channel conditions and physical obstacles. In such situation, both the sources S_1 and S_2 entirely dependent on relay R to exchange information concurrently with their respective recipients D_1 and D_2. This presumption can be explained by taking an example of metropolitan cities where S-D pairs are isolated from each other and there is no line of sight communication available and is also in line with previous works.

As illustrated in Fig. 1, the information is transmitted from sources to destinations over two transmission phases through a common relay R. The two phases, I and II of NOMA-RS are alike to uplink and downlink NOMA respectively. In cellular networks, the bit rate of users over uplink does not rely on the bit rate of downlink and the converse is also true. Besides, it is widely known in research that the rate at which data transfers of the user executing SIC profitably in NOMA system, grows linearly with an increase in transmitted signal-to-noise ratio (SNR) γ_o. On the contrary, the channel capacity of the user that does not execute SIC, almost begins to be persistent when γ_o increases because of the intrusion of other users. If distinctive users execute SIC in uplink as well as in downlink, then users will not be able to get actual advantage from SIC in case of NOMA system. Therefore, the spectral effectiveness of this network will not be enhanced as assumed, as in cooperative systems, the rate at which data is transferred by the user is influenced by the most weak connection.

Consequently, in NOMA-RS, the network is examined accordingly that SIC is executed by the identical user in both uplink as well as downlink, such that the network get benefit from both NOMA as well as shared diversity. The S_1-D_1 as well as S_2-D_2 sets can be thought of as users with high and low bit rate needs, respectively. For our system model we consider d to be random distance which is defined as the distance between the uniformly generated points (sources) inside a circle and the relay which is placed at the circumference of the circle. The coefficients of the channel are defined as $h_{1r} \sim CN(0, \lambda = d^{-v})$, $h_{2r} \sim CN(0, \lambda = d^{-v})$, $h_{r1} \sim CN(0, \lambda_{r1} = d_{r1}{}^{-v})$ and $h_{r2} \sim CN(0, \lambda_{r2} = d_{r2}{}^{-v})$ for links $S_1 \rightarrow R$, $S_2 \rightarrow R$, $R \rightarrow D_1$ and $R \rightarrow D_2$, respectively where v represents path loss.

Considering a circle of radius R centered at (0, 0), the cumulative dustribution function (CDF) of the distance d between two uniformy distributed random points, one located at (R, 0) and other located anywhere on or inside the circle, [11, eq. (21)] is given by,

$$F_d(r) = \frac{1}{\pi R^2}\left[r^2 \cos^{-1}\left(\frac{r}{2R}\right) + R^2 \cos^{-1}\left(\frac{2R^2 - r^2}{2R^2}\right) - \frac{r}{2}\sqrt{4R^2 - r^2}\right]; (0 < r < 2R) \quad (1)$$

Similar results are found for the case when the origin of the circle is shifted to (-R, 0) and the random point at the circumference is located at (0, 0). Therefore, the probability distribution function (PDF) of the distance d is found to be

$$f_d(r) = \frac{2r}{\pi R^2}\cos^{-1}\left(\frac{r}{2R}\right); (0 < r < 2R) \quad (2)$$

The distance between the relay and the destinations namely d_{r1} and d_{r2} are assumed to be constant. The transmission of data in two phases is described as follows.

A. Ordered Statistics

As we have randomly deployed points at the source end of the system we make use of ordered statistics for computing the PDFs of the square of absolute value of channel coefficients namely $|h_{1r}|^2$ and $|h_{2r}|^2$. According to ordered statistics, the channel with worse user *i.e.* the user whose distance to the relay is maximum will always be assigned the channel coefficient as h_{1r}. Given any random variables $X_1, X_2, X_3, \ldots, X_N$, the ordered statistics $X_{(1)}, X_{(2)}, X_{(3)}, \ldots, X_{(N)}$ are also random variables which are described by arranging the values of $X_1, \ldots, X_N$ in ascending sequence. For an unordered cumulative distribution function (CDF), $F_X(x)$, the ordered CDF for that sample has distributions as follows

$$F_{X_{(r)}}(x) = \sum_{j=r}^{N}\binom{N}{j}[F_X(x)]^j[1 - F_X(x)]^{N-j} \quad (3)$$

where r = 1,2,3,…,N. Therefore if we have a channel $h \sim CN(0, \lambda)$, having the CDF of square of absolute of channel coefficient as $F_{|h|^2}(x)$ then for n=1, 2, 3…, N the Power Density Function of ordered variables can be defined as follows

$$f_{|h_{nr}|^2}(x) = \frac{N!}{(n-1)!(N-n)!}\left(F_{|h|^2}(x)\right)^{n-1} \times \left(1 - F_{|h|^2}(x)\right)^{N-n} f_{|h|^2}(x). \quad (4)$$

Therefore for N=2 (after ordering), the PDFs of two channel coefficients can be defined as

$$f_{|h_{1r}|^2}(x) = \frac{2}{\lambda} exp\left(\frac{-2x}{\lambda}\right), \quad (5)$$

and

$$f_{|h_{2r}|^2}(x) = \frac{2}{\lambda}\left(1 - exp\left(\frac{-x}{\lambda}\right)\right) exp\left(\frac{-x}{\lambda}\right). \quad (6)$$

B. Transmission Phase-I

This phase is similar to uplink NOMA. During phase I both the sources S_1 and S_2 concurrently send symbols s_1 and s_2 with powers $\Psi_1 P_T$ *and* $\Psi_2 P_T$, where P_T is the total transmitter power available and $\Psi_1 + \Psi_2 = 1$ is defined as total transmit power constraint $\Psi_1 + \Psi_2$ are representing the power allocating coefficients. We have presumed that S_1 and S_2 have some kind of cooperation depending on which, power is being spread among the sources to fulfill the overall requirement of transmitting power. It is to be noted that the requirement of total transmission power is essential for many real scenarios [7]. Furthermore, we have assumed perfect synchronization of time between the sources S_1 and S_2, so that symbols s_1 and s_2 reach at relay R simultaneously. We have made an assumption that the worse symbol will be denoted by s_2. In this technique R first deciphers the comparatively finer user symbol by assuming the worse user symbol as noise. Then, relay R performs successive interference cancellation to secure symbol of worse user. Therefore, the received signal-to-interference noise ratio for better symbol can be defined as

$$\gamma_{S_1}^I = \frac{\Psi_1 \gamma_o |h_{1r}|^2}{\Psi_1 \gamma_o |h_{2r}|^2 + 1} \quad (7)$$

where $\gamma_o = \frac{P_T}{\sigma^2}$ and σ^2 signifies the variance of noise. Further by considering imperfect SIC, the signal to interference noise ratio (SINR) received for weaker symbol is computed as

$$\gamma_{s_2}^{I} = \frac{\Psi_2 \gamma_o |h_{2r}|^2}{\Psi_1 \gamma_o |g_{1r}|^2 + 1} \quad (8)$$

where, $g_{1r} \sim CN(0, \xi_1 \lambda_{1r})$, and the variable ξ_1 $(0 < \xi_1 < 1)$ is denoting the residual interference level due to the imperfect SIC present at relay.

C. Transmission Phase-II

This phase is similar to downlink NOMA. During phase II, the relay R transmits a superimposed composite symbol $z = \sqrt{\Psi_3 P_r}\, s_1 + \sqrt{\Psi_3 P_r} s_2$, where s_1 and s_2 are the symbols rejuvenate at relay R amid I. P_r is the total power of transmission at R. Ψ_3 and Ψ_4 represent power allocation coefficients and $\Psi_3 + \Psi_4 = 1$. According to the protocol of NOMA, the SINR received at D_1 for symbol s_1 is given by

$$\gamma_{s_1}^{II} = \frac{\Psi_3 \gamma_o |h_{r1}|^2}{\Psi_4 \gamma_o |h_{r1}|^2 + 1} \quad (9)$$

where $\gamma_o = \frac{P_R}{\sigma^2}$. Similarly to phase-I D_2 is performing SIC to interpret its symbol s_2. For performing successive interference cancellation, D_2 interprets high strength symbol s_1 first by considering its own symbol s_2 as noise and then using SIC cancels it to get its own symbol s_2. Therefore, the SINRs received for the symbols s_1 and s_2 are respectively computed as

$$\gamma_{s_1 \to s_2}^{I} = \frac{\Psi_3 \gamma_o |h_{r2}|^2}{\Psi_4 \gamma_o |h_{r2}|^2 + 1} \quad (10)$$

$$\gamma_{s_2}^{II} = \frac{\Psi_4 \gamma_o |h_{r2}|^2}{\Psi_3 \gamma_o |g_{r2}|^2 + 1} \quad (11)$$

where, $\gamma_{s_1 \to s_2}^{I}$ represents SINR that we require at D_2 to interpret s_1, $g_{r2} \sim CN(0, \xi_2 \lambda_{r2})$ and ξ_2 represents the level of remaining noise at D_2.

III. Outage Probability Analysis

This segment explores the outage probability of NOMA – RS over independent Rayleigh faded channels.

A. CDF of S_1-D_1 Pair

Considering (7), (9) and (10), the possible SINR related with symbol s_1 is represented as

$$\text{SINR} = \min(\gamma_{s_1}^{I}, \gamma_{s_1}^{II}, \gamma_{s_1 \to s_2}^{I}). \quad (12)$$

Let $X = \gamma_{s_1}^{I}$ and $Y_1 = \min(\gamma_{s_1}^{I}, \gamma_{s_1}^{II}, \gamma_{s_1 \to s_2}^{I})$.Then using (5), (6) and (7), CDF of X can be represented by

$$F_X(x|d) = 1 - \left(\frac{\Psi_1^2}{(\Psi_1 + \Psi_2 x)(\Psi_1 + 2\Psi_2 x)}\right) \exp\left(\frac{-2x}{\Psi_1 \gamma_o \lambda}\right) \quad (13)$$

Using (12) and the cumulative distribution function of minimal of two exponentially distributed random variables, Cumulative Distribution Function of Y_1 conditional on distance, is computed as

$$F_{Y_1}(y|d) = 1 - \left[\left(\frac{\Psi_1^2}{(\Psi_1 + \Psi_2 y)(\Psi_1 + 2\Psi_2 y)}\right) \times \exp\left(\frac{-2y}{\Psi_1 \gamma_o \lambda} - \frac{-y}{(\Psi_3 - \Psi_4 y)\gamma_o \lambda_{r1}} - \frac{-y}{(\Psi_3 - \Psi_4 y)\gamma_o \lambda_{r2}}\right)\right]. \quad (14)$$

Further the average CDF of Y_1 can be found by integrating (14) with $f_d(r)$ such as

$$F_{Y_1}(y) = \int_0^{2R} F_{Y_1}(y|r) f_d(r) dr\,. \quad (15)$$

Using (1), (14), (15) and utilizing MATHEMATICA, we get

$$F_{Y_1}(y) = 1 - \left[\left(\frac{\Psi_1^2}{(\Psi_1 + \Psi_2 y)(\Psi_1 + 2\Psi_2 y)}\right) \exp\left(\frac{-y}{(\Psi_3 - \Psi_4 y)\gamma_o}\left(\frac{1}{\lambda_{r1}} + \frac{1}{\lambda_{r2}}\right)\right) \times \left(\frac{\Psi_1 \gamma_o}{4R^2 y}\right)\left(1 - \exp\left(\frac{-4R^2 y}{\Psi_1 \gamma_o}\right) I_0\left(\frac{4R^2 y}{\Psi_1 \gamma_o}\right)\right)\right]. \quad (16)$$

where $I_0(x)$ is the improved Bessel function of first order .

B. Outage Probability of S_2-D_2 Pair

Considering (8) as well as (11), the possible SINR related with symbol s_2 is represented as

$$\text{SINR} = \min(\gamma_{s_2}^{I}, \gamma_{s_2}^{II}) \quad (17)$$

Let $U = \gamma_{s_2}^{I}$, $V = \gamma_{s_2}^{II}$ and $Y_2 = \min(\gamma_{s_2}^{I}, \gamma_{s_2}^{II})$. Then CDFs of U and V are given by,

$$F_U(u|d) = 1 - \left[\frac{4\Psi_2}{2\Psi_2 + \Psi_1 \xi_1 u} exp\left(\frac{-u}{\Psi_2 \gamma_o \lambda}\right) - \frac{\Psi_2}{\Psi_2 + \Psi_1 \xi_1 u} \exp\left(\frac{-2u}{\Psi_2 \gamma_o \lambda}\right)\right], \quad (18)$$

and

$$F_V(v) = 1 - \left(\frac{\Psi_4}{\Psi_4 + \Psi_3 \xi_2 v}\right) \exp\left(\frac{-v}{\Psi_4 \gamma_o \lambda_{r2}}\right), \quad (19)$$

Now CDF of Y_2 conditional on distance can be found using

$$F_{Y_2}(y|d) = 1 - (1 - F_U(y|d))(1 - F_V(y)). \quad (20)$$

which represents the Cumulative Density Function of minimal of two random variables. Further the CDF of Y_2 can be computed as

$$F_{Y_2}(y) = 1 - \left[\left(\left(\frac{4\Psi_2 \Psi_4}{(2\Psi_2 + \Psi_1 \xi_1 y)(\Psi_4 + \Psi_3 \xi_2 y)}\right) \Phi(y, R) - \left(\frac{\Psi_2 \Psi_4}{(\Psi_2 + \Psi_1 \xi_1 y)(\Psi_4 + \Psi_3 \xi_2 y)}\right) \Phi(y, R\sqrt{2})\right) exp\left(-{}^{y}/_{\Psi_4 \gamma_o \lambda_{r2}}\right)\right], \quad (21)$$

where,

$$\Phi(y, \alpha) = \left(\frac{\Psi_2 \gamma_o}{2\alpha^2 y}\right)\left(1 - \exp\left(\frac{-2\alpha^2 y}{\Psi_2 \gamma_o}\right) I_0\left(\frac{2\alpha^2 y}{\Psi_2 \gamma_o}\right)\right), \quad (22)$$

C. Outage Probability of S_1-D_1 and S_2-D_2 pair

The outage probability of S_1-D_1 can be found by substituting $y = \gamma_{th}$ in (16), i.e.

$$P_{out}^{S_1 - D_1} = F_{Y_1}(\gamma_{th}) \quad (23)$$

Similarly, the outage probability of S_2-D_2 can be found by substituting $y = \gamma_{th}$ in (21), i.e.

$$P_{out}^{S_2 - D_2} = F_{Y_2}(\gamma_{th}) \quad (24)$$

where, γ_{th} is some threshold SNR.

IV. Results And Discussions

In this section we have discussed the results and compared the analytical and simulation results to validate our work. Fig. 2 represents the outage probabilities of the proposed Non Orthogonal Multiple Access Technique with respect to (w.r.t) SNR, γ_o for S_1-D_1 and S_2-D_2 pairs of source and destinations. For our analysis we have taken the values of $d_{r1} = 1$ and $d_{r2} = 1$ and the path loss exponent $v = 2$. The close consistency between the simulation and analytical results for the outage probability of NOMA-RS validates the precision of our result.

We have taken the value of threshold SNR, γ_{th} to be -5dB. Also we have assumed the power allocation coefficients, Ψ_1 = 0.6, Ψ_2 = 0.4, Ψ_3 = 0.9 and Ψ_4 = 0.1 and the values of residual interferences namely $\xi_1 = \xi_2 = (0.02)^3$. The plot infers that with the increasing value of SNR the outage probability decreases.

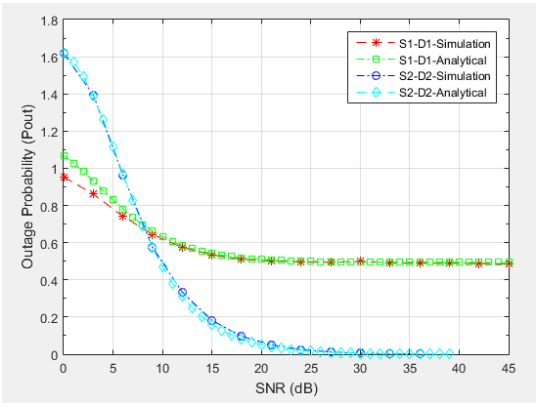

Fig. 2. Outage probability of S_1-D_1 and S_2-D_2 pair w.r.t γ_o, Ψ_1 = 0.6, Ψ_2 = 0.4, Ψ_3 = 0.9 and Ψ_4 = 0.1, $\xi_1 = \xi_2 = (0.02)^3$, γ_{th}= -5dB

Fig.3 represents the outage probabilities of S_1-D_1 and S_2-D_2 pair w.r.t the threshold SNR. The plot confirms the fact that the outage probability increases with the increase in threshold SNR.

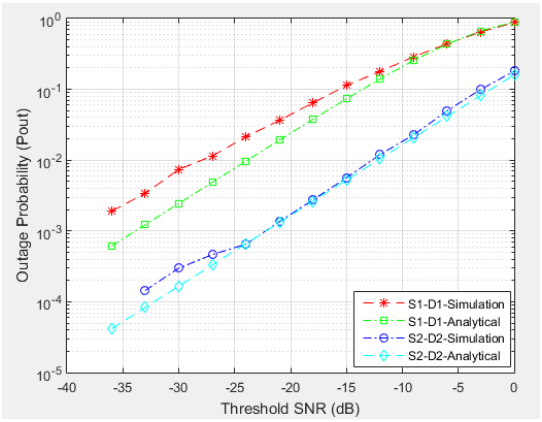

Fig. 3. Outage probability of S_1-D_1 and S_2-D_2 pair w.r.t γ_{th}. Ψ_1 = 0.6, Ψ_2 = 0.4, Ψ_3 = 0.9 and Ψ_4 = 0.1, $\xi_1 = \xi_2 = (0.02)^3$, γ_o=20dB

V. Conclusions

We have investigated and proposed a common relay system for NOMA where the two randomly deployed sources with uniform distribution can exchange information with their respective destinations simultaneously in parallel. We have attained the outage probability of NOMA-RS analytically. We found that the outage probability of NOMA-RS technique significantly depends on the SNR. As the SNR is increased in value, the outage probability decreases. Also the outage probability increases with increase in the value of threshold SNR. It is to be noted that power allocation coefficients have a considerable amount of effect on outage of NOMA-RS. Besides this the benefit of NOMA-RS is that can be serve a large number of devices or users at a given period of time.

***Abstract*—LiDAR (Light Detection and Ranging) is an emerging technology now and has proved to be one of the best techniques for 3D city modeling. Building detection is an important aspect of 3D city modeling as it can help in urban planning, utility services, disaster management, traffic management, environmental monitoring and many other applications. In this paper we propose a method in which building structures can be accurately discriminated from vegetation. Pre-processing of the data is done using a remote sensing tool called Las Tools. The data is structured using kd tree and then further segmented using Euclidean distance clustering. Then we process this data using another open-source remote sensing tool called CloudCompare. This paper will help in imparting a clear idea of how efficiently and accurately building detection can be performed with the help of these open-source tools without deploying much complex algorithms.**

Keywords—LiDAR, kd tree, Euclidean distance clustering, LAStools, CloudCompare

I. INTRODUCTION

LiDAR is an evident technology in the field of remote sensing and has proved to be one of the best methods to efficiently and accurately classify data using it's 3D information. Previously data acquisition was done using hyperspectral and multispectral imaging techniques [1]. Though spectrally rich these datasets demands a huge memory for processing. LiDAR datasets also require quite a bit of memory to process, but they are more accurate and reliable than multipectral and hyperspectral imaging techniques as it contains the 3D information about the data. We know LiDAR stands for Light Detection and Ranging. Like the name suggests it uses pulsated laser pulses which are send to the ground from terrestrial, airborne or spaceborne sensors. This laser pulse travels a huge distance until it hits a target and is reflected back to the source producing highly accurate x,y,z measurements. Thus the range distance R from the source and the destination in LiDAR is found using the formula:

$$R = C\,(t/2) \qquad (1)$$

Where C is defined as the speed of light and t is the time taken for the sending pulse to return back to the destination. This data accounts for LiDAR's z axis which has the height information. The other two axis contains latitude (x-axis) and longitude (y-axis). Thus along with this highly georeferenced coordinates the LiDAR data may also contain GPS time, point classification values, intensity, scan direction, number of returns, return number, RGB (red, green, and blue) values, points that are at the edge of the flight line and scan angle. The LiDAR point cloud is basically a collection of 3D elevation points. A single pulse emitted from the sensor might have one or multiple returns of which first return is the most important one. It contains the top most elevation points of trees or buildings and the last returns are the most insignificant one as it mostly refers to ground data. But the last returns will turn out to be important in cases which only require ground information.

Building detection and extraction plays an important role in 3D city modeling, urban planning, in geographic information systems database and in environmental monitoring. It has become an emerging topic for research in remote sensing and photogrammetry. The data acquired from advanced pre-processing techniques and new sensors is used in this technique. Though technologies are highly developed, it is still a challenge as urban scenes are complex. Building extraction is an important aspect of 3D city modelling as we need to identify and model buildings separately. The height factor of LiDAR data is extracted using Canopy Height Models for urban planning [2]. But while doing so, some misinterpretation takes place where the systems misclassify trees as buildings. Moreover the building boundaries are less regularized and more false positives arise during classification. As the building scenes are becoming more complex new algorithms have to be employed to extract building points from other non-building points.

The main objective of this project is to accurately extract building points and its boundaries from LiDAR point cloud data by employing new feature calculation techniques. This project also aims at eliminating misclassification of trees as buildings which will help us distinguish buildings from trees. Pre-processing of the dataset is performed where we tile the data, remove noise and classify it into ground and non-ground points. Then we have employed mainly two methods for clustering and segmentation of data and then the output obtained is processed using an open source remote sensing tool and the results are checked for accuracy of building points.. Building detection and extraction from LiDAR point cloud data is widely deployed in Urban Planning Visualization, Traffic Management, Utility Services Drainage Calculations, 3D city modeling and several other applications [3].

This paper is organized as follows. The related work and the data description is detailed in section II and III respectively. Proposed work and the result analysis is discussed in section

IV and V respectively. Finally the paper is concluded in section VI.

II.RELATED WORK

The building extraction methods are classified according to the type of data used. Each method has different techniques employed for building extraction. These are broadly categorized as follows:

i. Building Extraction using 2D information

ii. Building Extraction using fusion of 2D and 3D information

iii. Building Extraction Using 3D LiDAR data

A. Building Extraction Using 2D data

The data is obtained using space borne and air borne images. Various techniques like colour invariance specifications, shadow information and corner detection are used to find and distinguish rooftops [4]. And also various energy based algorithms like level-set curve and box-fitting algorithms are employed for accurate building extraction [5]. Though reliable, these techniques have produced shadows and blockage in complex scenes which resulted in erroneous image extraction.

B. Building Extraction using fusion of 2D and 3D information

A 2D-3D fusion based method in which the input data sources can be divided into two, photogrammetry and Light Detection and Ranging (LiDAR). Generally three colour channels are present for photogrammetry, sometimes with an additional infrared channel as well. Mainly height information is contained in LiDAR data. By fusing these two datas the accuracy of automatic building extraction can be improved significantly [6]. But due to the different characteristics of LiDAR and image data the fusion of the two may result in an erroneous output. The concept of image fusion becomes difficult due to the varying characteristics of both the data. The data sets must be arranged at one pixel-level to fully exploit data fusion from multiple sensors. Even a small error in image registration can cause error in the output data. In particular, due to error in image registration in building extraction some trees were misinterpreted as buildings [7]. Secondly the spatial resolution of LiDAR data is low compared to photogrammetry. Both LiDAR and image data may not be available together for certain regions. Optical muti-view imagery was proposed in 2013 [8]. Two main steps are involved one is the segmentation of the roof top and the other is the reconstruction of the 3D roof model. The roof is initially segmented using point-based method using normal estimate and then a shrink and expand technique is used for refinement of the segmented regions. Finally a 3D step line is determined by integrating the optical multi-view image with the points of the segmented rooftop to reconstruct a 3D rooftop model. But this method needs to be further improved to be fully automated.

An automated method to integrate the 3D data with ground view image of facades using projective trajectory is proposed [9]. A feature extraction method in which the input image is segmented. It also combines global feature extraction on a local region segmentation method and an adaptively tessellated Gaussian Sphere with Hough transform [10]. Lines having a common vanishing point are clustered and building facade regions are detected using spatial locality of horizontal and vertical line clusters. The position of the camera is estimated using the roof corners of the facade regions extracted. To automate camera pose several 3D to 2D correspondences are derived using multiple hypothesis. A Hough transform and an M-consensus sample estimator is used to find the correspondence between 3D model and images. The camera parameters obtained earlier are refined by using the 2D corner matches using Lowes algorithm.

C. Building Extraction Using 3D LiDAR data

1) Supervised Model: In supervised model we employ detection algorithm based on features like radiometry, geometry, echo characteristics and topology [11]. Support Vector Machines (SVMs) are used in-order to classify the data. We feed the data into an SVM classifier which will categorize the data into different classes based on the given features and algorithms. SVMs are said to produce promising results if they are trained properly. But in supervised model a lot of training samples must be given to train the SVM classifier to accurately model the data to find the endmost target classes .

2) Unsupervised Model : As supervised models require the adoption of machine learning techniques and are dependent on training samples many experiments have been performed to develop to unsupervised models. It does not require any training data set [12]. Many algorithms such as fitting algorithm, morphological filtering and region growing has been proposed in this method. Fitting algorithm is based on RANSAC (Random Sample Consensus) and Hough Transform [13]. However, due to oversampling in RANSAC unwanted planes in vegetations are extracted. Morphological filtering is based mainly on geometric properties.

A segmentation based building detection approach which gives a performance comparison between the open source point cloud library (PCL) and the commercially available software Terrasolid has been proposed [14]. This novel method adopts a surface based filtering approach along with data structuring using kd tree algorithm. A Euclidian distance based segmentation technique is used to segment the LiDAR point into different clusters. The segmentation is done based on the distance of one point from every other point. In order to reconstruct the buildings the building clusters is separated from non-building clusters by using the histogram of the local normal points of all clusters. The statistical parameters like mean, variance and standard deviation of these histograms does not vary much for a building whereas it varies greatly for trees. This way building points can be reconstructed after segmentation. As the number of clusters are to be defined it will make this process a semi-automatic one.

Building boundary tracing and regularization methods has also been proposed [15]. In this work data gathering is performed as the initial step and the gathered LiDAR point cloud data is separated into ground and non-ground points. These points are then segmented to obtain LiDAR building points. These points are then processed to get a regularized boundary for the pre-processed building points. The main processes involved here are initial boundary detection, boundary tracing and boundary regularization. Initial boundary detection has two parts plane detection and hole detection followed up by boundary tracing. Boundary regularization is done by corner detection and line extraction. Then the footprints of the buildings are generated by using the extracted corners and lines.

Another work proposed in 2014 follows a rule based approach for extraction of roof planes automatically [16]. The LiDAR data is pre-processed to obtain a Digital Elevation Model (DEM). The obtained data is divided into two categories, ground and non-ground. A building mask is generated using ground points where the black areas are used to represent ground which suggest the last returns. Planar roof points are obtained by segmenting non-ground points. The building mask is made into small grids and the cells having the black pixels clustered in away such that each cluster represents an individual tree or a building. Segmentation of the non-ground points within the cluster is done based on neighbourhood relations and co-planarity. Refinement of the planar segments using a rule based approach is done and also another rule based approach is also employed for tree detection and elimination of small random trees in the LiDAR point cloud.

Several other non-analytical approaches based on shape, size, height, structure of the building element and difference between the first and last return were proposed. To differentiate buildings accurately from vegetation many point based and grid based features have been developed [17]. This comprises of point-based features such as normal distribution, flatness and grid based features such as GLCM (Grey-Level Covariance Matrix) homogeneity, roughness and gradient methods. This work aims at using solely LiDAR data by fusing point and grid based features for automatic building extraction. Point-based and grid-based features are employed in order to accurately classify building structures. A point features based on the normal vector variance is proposed. After extracting the features a graph cuts algorithm is employed to accurately distinguish building points. This algorithm combines the features extracted along with the neighbourhood contextual information and thus provides an automatic robust building detection mechanism. A DSM interpolation with feature retention is also performed.

There are several techniques involved in building detection. Though many methods has proved to be efficient there are still some drawbacks that we needs to surpass. Building detection can be performed using 2d data, fusion of 2d-3d data and 3d data alone as well. Building detection using 2d data is more complex and yields less results as compared to the latter two. The fusion of 2d-3d data has shown promising results but are prone to more errors. It can be seen that using 3d data alone is much more efficient and reliable. So here we are solely working on 3d data.

III.DATA DESCRIPTION

The dataset taken for this study is ISPRS Test Project on Urban Classification and 3D Building Reconstruction dataset of Vaihingen city, Germany [18]. Each region in the city is characterized by different styles and the two test areas taken in this project has 35 and 14 buildings respectively with each building larger than 2.5 m^2 in total. Test Area 1 is classified as inner city where there are many complex structured buildings and Test Area 2 consists of High riser buildings of residential area (Fig.1.). The mean point density of the dataset is given as 4 points/m^2 and the median point density is 6.7 points/m^2.

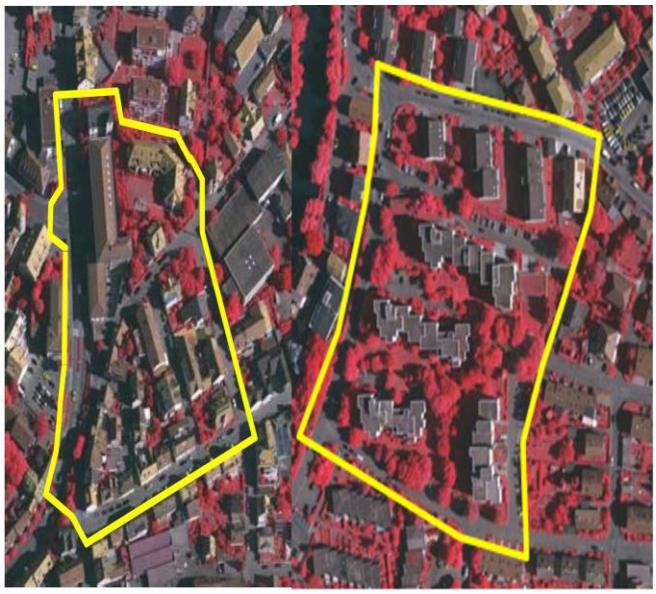

Fig.1. Aerial imagery of Test Area 1 and 2 taken from ISPRS [18]

IV.PROPOSED WORK

The data collected is processed in the following way. Necessary pre-processing techniques are performed using LAStools. The main steps involved in the pre-processing are

A. Pre-processing using LAStools

Firstly tiling of the data is done in order to get specific areas of interest in the dataset. We have to set a buffer while tiling so that that data at the edges is not lost. Here we have used a tile size of 500 and the buffer size of 30. The whole dataset is segmented to obtain a test area and the whole process is applied to this test data.

1) Estimating the ground points: The ground points in the dataset or the bare earth points are estimated (Fig.3). Mostly the last returns will be classified as ground points. This is performed using lasground feature in LASTools.

2) Estimating the Height of non-ground points: This mainly gives the top most elevations of the data or the first returns. The lasheight feature in LASTools helps in obtaining the height model of the building points obtained after

classification. The z-axis of the LiDAR data is replaced with this height.

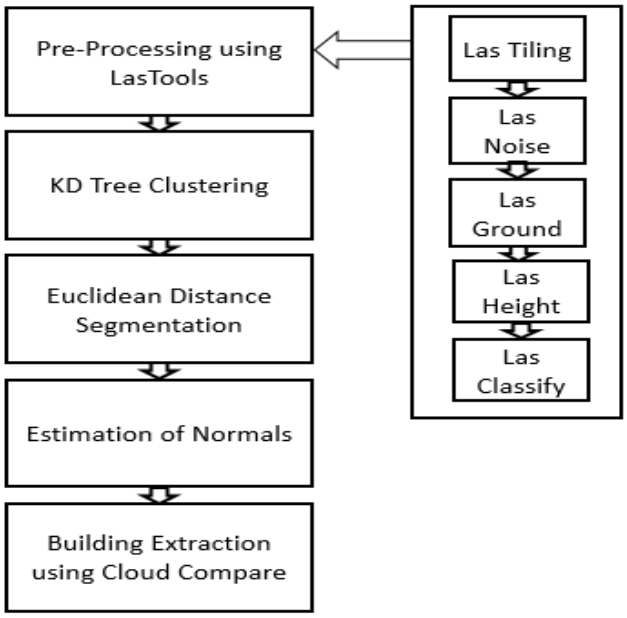

Figure 1. Proposed work block diagram

3) Classification: After classifying the ground and non-ground points we use another classification method called LasClassify by which we eliminate the classified ground points. The non-ground points are then taken and further processed to obtain the desired results. Thus the ground points are completely eliminated

B. Data Structuring

The LiDAR point cloud data is highly unorganized and discrete in nature. This is because the pattern in which the points in LiDAR data is stored is same as the scanning mechanism. So the boundary points of a LiDAR data are random and cannot be fit into a grid which in turn makes LiDAR data difficult to work with. Hence a hierarchical structuring of the data is done using kd tree clustering to make the dataset an organized one.

C. Euclidean distance clustering

Spatially isolated points can be separated using Euclidean Distance clustering [14]. Here the data is classified according to the distance between each point. A certain threshold is determined first and if the point exceeds falls within the threshold it is placed in the cluster and if the point exceeds the threshold it is kept in another cluster. The number of clusters formed can vary for different datasets depending on the minimum and maximum number of points set in the clustering algorithm. This was performed using the open-source library PCL (Point Cloud Library - http://pointclouds.org) in Visual Studio C++.

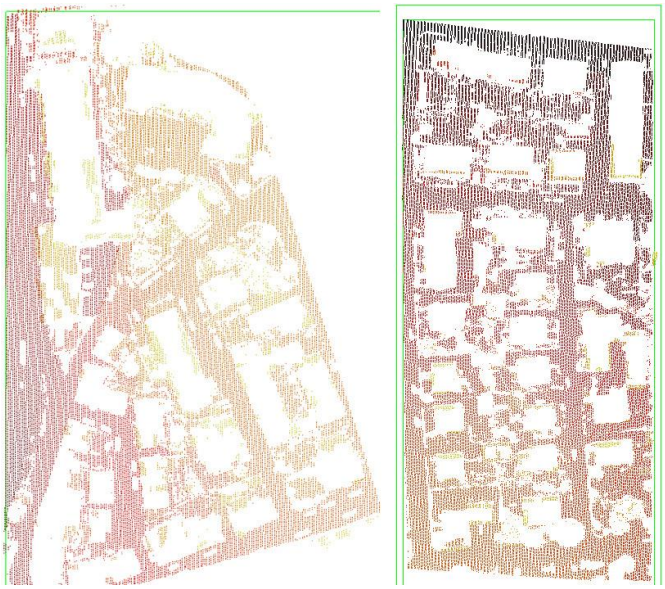

Fig.4. Data points of Test Area 1 and 2 classified as ground

The obtained data (Table. I) is processed to extract building structures. For this we have used another open-source remote sensing tool called CloudCompare. The results thus obtained are checked for accuracy.

TABLE I. RESULTS OF EUCLIDEAN DISTANCE CLUSTERING

Results of Euclidean Distance Segmentation	**Parameters for Test Area 1**	**Parameters for Test Area 2**
Cluster Tolerance (dth)	1 m	0.75m
Min/Max no. of points in the cluster	50-5000	30-3500
Number of Clusters	34	12
No. of buildings in the survey area	37	14
No. of buildings identified	37	14

D. Processing using CloudCompare

1) Estimation of Normals: Building structures are characterized by normals and normal estimation plays an important part in building point detection (CloudCompare 2.6.2, 2019).

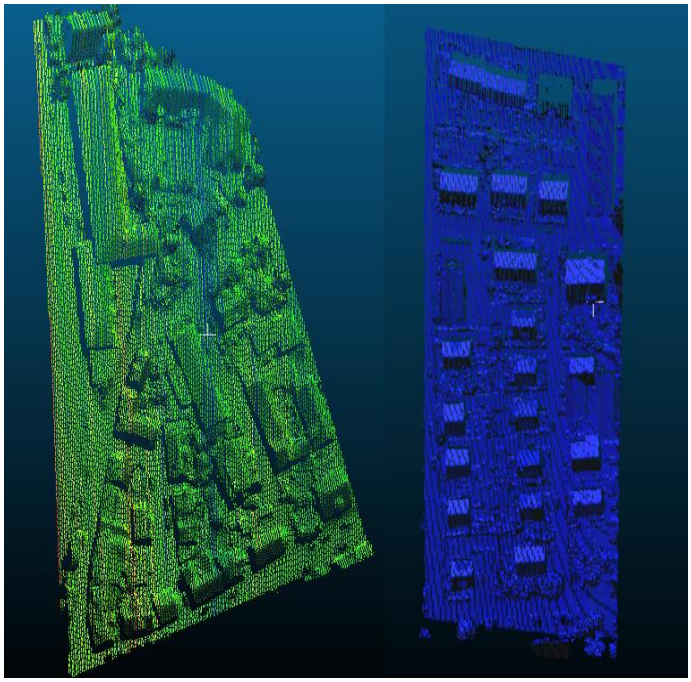

Fig.5. Estimation of building Normals from the data for Test Area 1 and 2

2) Filtering of ground points small shrubs: The filter by value tool is set to efficiently remove the unwanted points below a certain limit.

3) CANUPO Plugin: Further a plugin tool called CANUPO Plugin is used to classify building and tree points [19] .

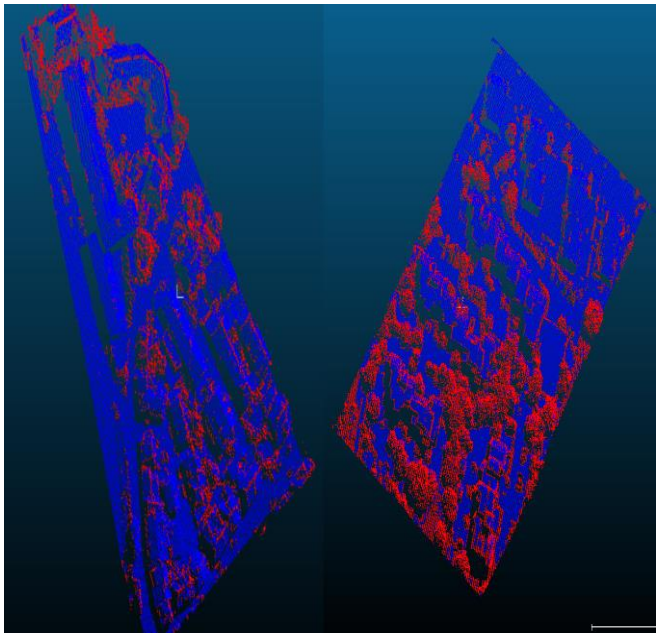

Fig.6. Final classified output for Test Area 1 and 2, where building points are classified as blue and tree points as red. (3D View)

The tool is first trained using building and tree data sets separately and this training data is applied to the test data to obtain well classified tree and building points (Fig.5).

V.RESULT ANALYSIS

The dataset of Vaihingen city, Germany is taken. The whole dataset is divided and two test areas are selected for easy processing and identification of building points. The collected data is filtered and the noise is removed. In LASTools we first classify the ground points and the non-ground points. This output is used to estimate the height of the non-ground points and the z axis which gives the height is replaced by this value thus eliminating the ground points. The non-ground points obtained are classified to buildings, trees etc. by appropriate processing techniques. Data structuring is performed on this filtered output after which Euclidean distance clustering is carried out and the results are shown in Table I. The data is then processed using an open-source software called CloudCompare. First the normals in the dataset are estimated as building are characterized by normals. Small shrubs and trees are filtered out by filtering the points above a particular value. Then we use CANUPO Plugin to discriminate the trees from buildings. For training we feed building data points as well as tree data points separately by segmenting these data points from the dataset. The training data is collected from the dataset by extracting only the target points from the whole data. The training data obtained is applied to the original test data. Now the buildings and the trees are classified into two separate classes. For Test Area 1, a total of 30 buildings are classified separately out of 37 buildings. The number of partially detected buildings and overlapping buildings are 5. And the total number of fully detected building structures are 20 and for the Test Area 2 a total of 11 buildings are classified separately out of 14 buildings. There are no partially detected buildings and the number of overlapping buildings are 2. An overall accuracy of 81% and 78.5% is obtained for test area 1 and 2 respectively depicted in Table II. The overall accuracy is calculated using equation (2).

$$Overall\ Accuracy = \left(\frac{\text{Total no. of buildings detected}}{\text{Total no. of building present}}\right) 100 \qquad (2)$$

The class with the blue colour indicates the buildings and the red ones indicate the trees. A true orthophoto obtained from ISPRS Dataset is superimposed over the DSM (Digital Surface Model) of the output data to identify the number of buildings detected. The total number of buildings detected is calculated for both the test areas and has given promising results. Though some roof top boundary points are misclassified as tree points, this can be avoided by fully exploiting the CANUPO Plugin tool by adjusting the filter values.

TABLE II. BUILDING DETECTION FINAL RESULT

Dataset	Test Area 1	Test Area 2
Total No. of Buildings Present	37	14
Total No. of buildings detected	30	11
No. of Overlapping buildings identified	5	0
Partially Detected Buildings	5	2
Fully Detected Buildings	20	9
Overall accuracy	81%	78.5 %

VI.CONCLUSION

This paper detects building structures from LiDAR point cloud data. The data has been processed with the help of python software, PCL library and two open-source remote sensing tools LASTools and CloudCompare respectively. The data is pre-processed, filtered, structured, clustered and finally classified into two different classes. We can see that structuring along with clustering of data helps to segment the dataset more precisely. This paper has also shown that applying feature based extraction techniques can yield good results. The total number of buildings detected for test area 1 is 30 out of 37 in total and for Test Area 2 is 11 out of 14. An overall accuracy of 81% can be observed for the inner city for test area 1, where there are complex structures and historic buildings. The Test Area 2 shows an overall accuracy of 78.5% for the high riser residential areas. It can also be observed that these open source tools have been instrumental in detecting the building structures without employing complex algorithms. These results can be further improved by exploiting more features of these tools. Here we have given a two-class classification as a final output where we discriminate trees and buildings separately. Several other objects like roads, cars, power lines etc. in urban scenes can be detected easily using these open-source softwares which is the future scope of this project.

***Abstract*—Access to computer technology is of vital importance to people with disabilities. Eyes can be regarded as one of the organs that can help a paralyzed person to communicate suitably. This paper provides a novel idea to control home appliances for disabled people who cannot move anything except their eyes by controlling the computer mouse cursor through their eye movement. The proposed method here uses an eye tracking method for eye movement acquisition, further following a simple circuitry. This system is very helpful for solving the HMI problems of the disabled.**

Keywords - Eye Tracking, Image Processing, Facial Land-mark, Eye Aspect Ratio, Home Automation, MQTT.

I. INTRODUCTION

Nowadays computers have become the most usable devices. They are used for communication, education, entertainment and scientific research. Unfortunately, paralyzed, elderly, and those with restricted upper limb movement find difficulty to use them. This project focuses on hands free computing and an eye controlled home automation for the disabled [1].

This project is a real time eye tracking system that will control the cursor movement by tracking the eye movements of the user and mapping it to the computer screen [2]. Real time execution is obtained by running a web cam (video streaming) and capturing continuous frames of images. Haar cascade algorithm [3] is applied in each frame to detect all the faces in the image. Next, facial landmark detector is applied in each face detected to obtain facial features like eyes, eyebrows, nose, mouth etc. Specific region of interest, eyes in this case, is considered and some image processing techniques are applied for better performance in eye tracking. Eye tracking is done by tracking the position of limbus whenever the users gaze changes. Cursor can be controlled by specific functions in the Python library. A delayed eye blink performs the click action on the device.

As shown in Fig 1. using web cam frame by frame images of the patient is captured continuously (Image capturing). Face and eyes of the patient is detected from the image using Facial Landmark Detection. Using Facial Landmark Detection eye coordinates are obtained and by using those coordinates we are able to track the eye movements. Then by mapping those coordinates with the computer cursor coordinates, cursor control can be achieved. A small delay is established such that if the blink time is equal to the delay time click action is performed.

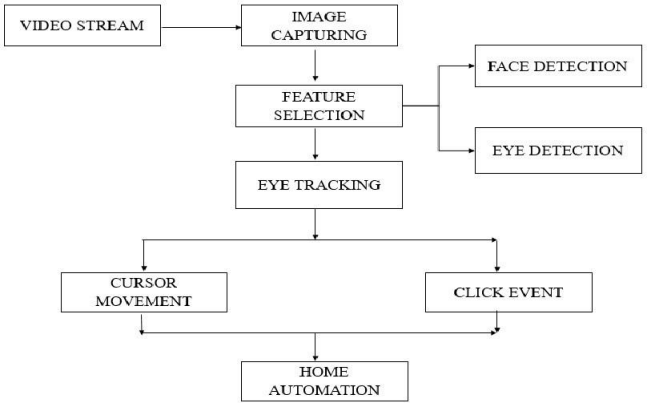

Fig. 1. System Block Diagram

The project not only enables the full control of the device with eyes but also enables home automation using the same concept for the disabled. It includes basic day to day operations like switching on and off an appliance or increasing the speed of fan.

A. ORGANIZATION AND SUMMARY

The remainder of this paper is organized as follows: Literature Survey in Section II, Face and Eye Detection in Section III. Section IV contains the proposed algorithm for Cursor Movement, Blink Detection in Section V, Section VI shows the Home Automation section of the project, Experimental Results obtained in Section VII and Section VIII includes Con-

clusion and at last Future Expansion followed by References respectively.

II. LITERATURE SURVEY

The interaction between humans (the users) and computers plays an important role in today's life. Input devices such as keyboard, mouse etc. are the normally used devices to interact with digital instruments, this devices cannot be operated by disabled peoples. For paralyzed people for whom eye movements and blinks are the only way to communicate with the outside world, an eye movement based cursor control and home automation is proposed in this paper. There are many related works based on this concept:

- Voice Based Method: In this method, voice of the user is analyzed and it is converted to digital form [7]. Based on the user's voice the computer cursor is controlled. But the drawback of this system is that background noise can affect the system.
- Motion Based Method: Normal movement of different organs such as head, foot, hands, etc. is utilized and given as input to the computer. There are many motion based devices such as head tracking system in which cursor control and click event is achieved based on the motor abilities of the head region [8].
- Hand Gesture Based Method: Identifying specific human hand gestures and using them to convey information or for controlling device [9]. The gestures are given as input to the computer system, the system then performs its corresponding task which is already predefined as per the application. Based on color, the hand location is traced and with the help of trained classifiers different gestures are classified.
- SMS Based Home Automation System: A basic home automation system based on SMS (Short Message Service) technology. The system consists of mainly two components: the GSM (Global System for Mobile communications) modem and a micro controller. Here SMS technology is used to exchange data through the GSM module and thereby connecting the user and home automation system. The micro controller acts as the bridge between the user and sensors and actuators of home automation system [10]. This system can supports a wide range of home automation devices such as security, home appliances and telecommunication devices.

III. FACE AND EYE DETECTION

Feature Selection is an important part of this project. The features such as face and eyes detected should be accurate and real time. The chance of obtaining false detection such as detecting chin as eye is very high in case of some detection technique. This can totally affect the output of the system.

In this project Face and Eye features are detected using Facial Landmark detection [4]. Facial landmark detection is a two-step process:

- Localization of face and eyes in the image using Haar Cascades.
- Detection of key facial structures on the face ROI(Region of Interest).

Facial Landmark Detector consist of pre-trained models. To estimate the location of 68 coordinates (x, y) that map the facial points on a person's face, dlib library in Python is used. The dlib library contains pre-trained facial landmark detector. Using Haar cascade face and eyes of the image is detected. The original image and the detected face rectangles is passed as input to the facial landmark detector. The output of the face detector is a vector of rectangles that contain one or more faces in the image. We get 68 landmarks for every face detected and they are stored in a vector of points. The 68-point detector localizes regions along the eyes, nose, mouth, eyebrows and jawline. Using Haar cascade alone may result in less accurate output, landmarks improves face recognition and from the obtained facial landmarks, we can also find the direction of the face using landmark coordinates.

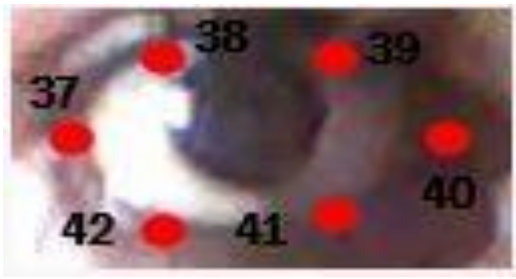

Fig. 2. Eye Coordinates from Facial Landmark

Eye coordinates obtained from Facial Landmark Detection shown in Fig 2 is used for computing cursor control and for estimating EAR which is explained in Section V. By using this coordinate's, eye tracking which is used for cursor control and blink detection is implemented first. There are different methods for Eye Tracking such as Limbus Tracking, Pupil Tracking etc. Here we are using Limbus Tracking. Limbus is the border of the cornea and the sclera (the white of the eye).

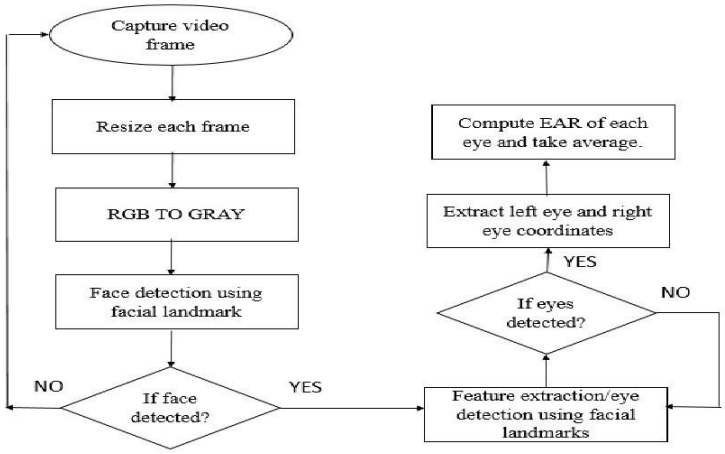

Fig. 3. Algorithm for Eye Tracking

IV. CURSOR CONTROL

Using color tracking method by setting a threshold, Limbus can be differentiated from the white region of eyes. The default position of eyes (pupil at the centre) is stored as initial array. Array obtained by the movement eyes is compared with the initial array and based on this the cursor is mapped. The algorithm for cursor control is shown below:

Algorithm

1) Detection eyes in the image using facial landmark detection and extraction of eye coordinates obtained from facial landmark detection.
2) Convert RGB image of eyes to HSV.
3) Color tracking by setting threshold.
4) Limbus detection using convexhull() in Python.
5) Get eye as array of values.
6) Track the movement of eye by the change in values of array.
7) Compare the newly obtained array with the initial array.
8) Map the array values to the cursor coordinates.

V. BLINK DETECTION

For the application of controlling home appliances, eye blink signals of the user is used which is a natural source of input. After detecting eye coordinates using facial landmark detection, Eye Aspect Ratio (EAR) is computed [5]. EAR is used as an estimate for eye opening state. Here eye is represented by 6 (x, y)-coordinates, starting at the left-corner of the eye and around in a clockwise direction. When the eyes are open EAR is always a constant value and zero when eyes are closed. The ratio falls rapidly to 0 when eyes are closed.

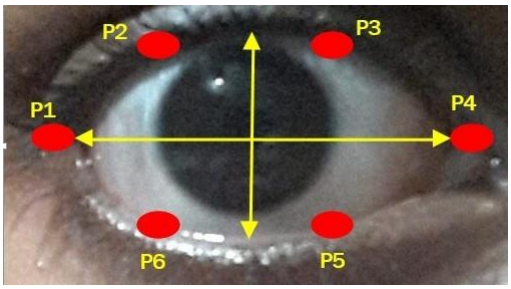

Fig. 4. Calculation of EAR when Eye is in Open state

Steps:

1) Compute the Euclidean distances between the two sets of vertical eye landmarks (x, y)-coordinates (*p2,p6*) and (*p3,p5*)
2) Then compute the Euclidean distance between the horizontal eye landmark (x, y) - coordinates: (*p1, p4*).
3) EAR can be calculated by:

$$EAR = \frac{\|p2 - p6\| + \|p3 - p5\|}{2\ \|p1 - p4\|} \quad (1)$$

VI. HOME AUTOMATION

Automation of household activity such as control of light, fan, other home appliances and security systems in order to provide more convenience, comfort and ease of access for disabled people.

There are mainly three sections in this system:

- Eye blink signal.
- Controller.
- Driver circuit

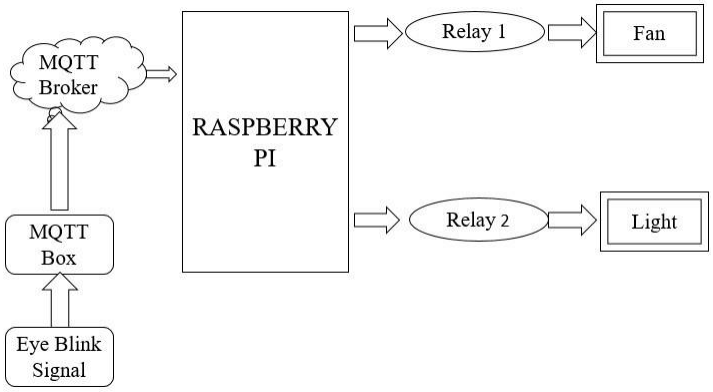

Fig. 5. Block Diagram of Home Automation

The home automation system will control fan, light and other home appliances. The eye blink signal acts as input in real time and send appropriate control signal to the controller. The controller takes appropriate decision based on various sets of inputs and the output of the controller is used to control the appliances. [11]

Program algorithm for initializing the controller- Raspberry Pi

1) Define and declare the output pins connected to Raspberry Pi.
2) Check whether the connection is set and print SUCCESS if set.
3) Create MQTT client with client address, subscription id etc.
4) Subscribe to the topic.
5) Once connection is set receive the payload as inputs.
6) Compare the Payload with a set of predefined strings.
7) Make the two output pin High or Low according to the Payload.
8) If connection is lost print Failed to connect message and display the message and cause.

MQTT (Message Queuing Telemetry Transport) is the communication protocol used [6][12]. MQTT is connectivity proto- col used for IoT applications. It is a publish-subscribe communication protocol. MQTT is used for transmitting short messages at high speed. Here home appliances can be controlled using the MQTT protocol. To connect via MQTT two process should take place Publish and Subscribe.

In this project, the MQTT box acts as the Publisher which publish the message (control signal) to the MQTT broker. The

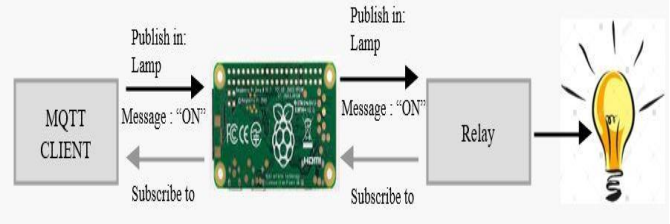

Fig. 6. MQTT Process

received control signal is send to the MQTT client (Relay) and thereby controlling home appliance. Both MQTT Broker and client should be subscribed to the same topic as shown in Fig. 6.

The whole screen divided into two parts (incremented with the no. of application) acting as buttons. When the cursor moves to any one of the buttons and performs the click action by blinking, an event alert pops up for confirmation. Once confirmed, the message lamp on/off or fan on/off is passed accordingly to the server via MQTT.

To publish a message via MQTT:

- Create the client object.
- Create the client connection.
- Publish the message.
- For the publish request, examine the return code.
- Examine the required output in the hardware i.e. Home appliances.

The topic and the payload are the only parameters that are needed to be supplied.

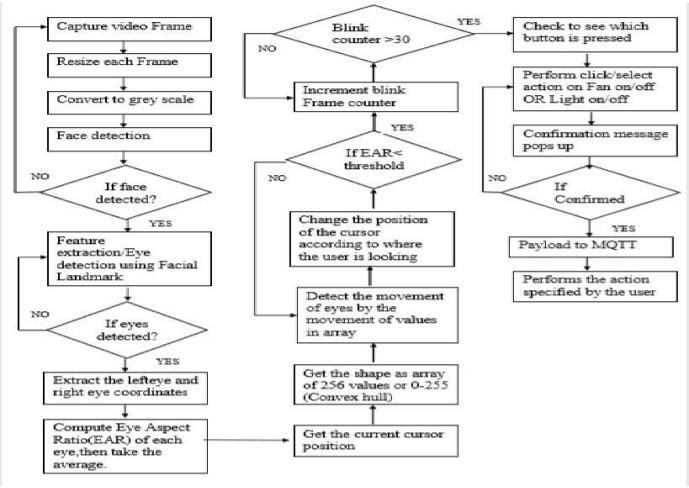

Fig. 7. Algorithm

The overall algorithm of the project is shown in the above figure fig. 7. The project can be divided into mainly three sections:-

- Eye Tracking.
- Cursor Control.
- Interfacing with Home Automation.

According to our application the number of home appliances can be increased and by using MQTT Box it can be controlled from anywhere and at any time.

VII. EXPERIMENTAL RESULT

The system was primarily developed and tested on a Windows 10 PC with an Intel Core i5- 6200U CPU 2.40 GHz processor and an 8 GB RAM. The video was captured with the built-in camera of the laptop. The video was captured at 30 frames per second. The code was written in Python and the code for controller was written in C in Raspbian OS.

Fig.8. shows the face and eye detected image using Facial Landmark Detection. Accurate and real time detection of face and eyes is obtained even if the head is tilted.

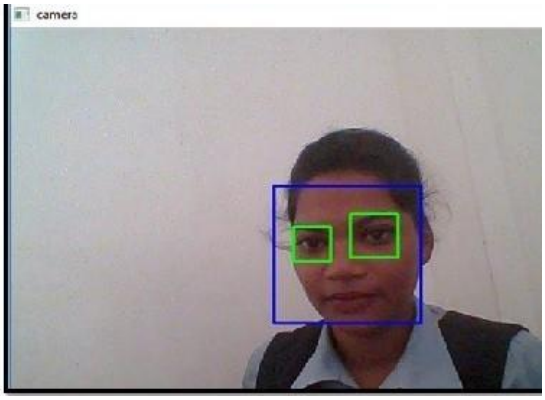

Fig. 8. Face and Eye Detected Image

The Fig.9. shows the result obtained using Facial Landmark. Here by specifying the region of interest i.e. our eyes, contours are drawn using the 6 coordinates obtained in facial landmarks of the eye. By setting a color threshold we can easily track the movement of Limbus and followed by implementing cursor movement.

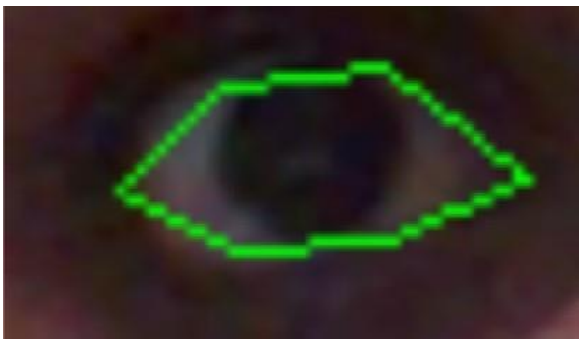

Fig. 9. Eye Contour after Detecting Eyes using Facial Landmark

The following figure is a screen-shot of the MQTTBox. It is a helper program to develop and load test MQTT based clients. The input to the MQTT is the eye blink signal and the advantage of using MQTTBox is that we can enter input manually from anywhere by subscribing the same topic. History of published/subscribed messages for each topic can be

seen through MQTTBox. Thus information's can be accessed from anywhere at any time.

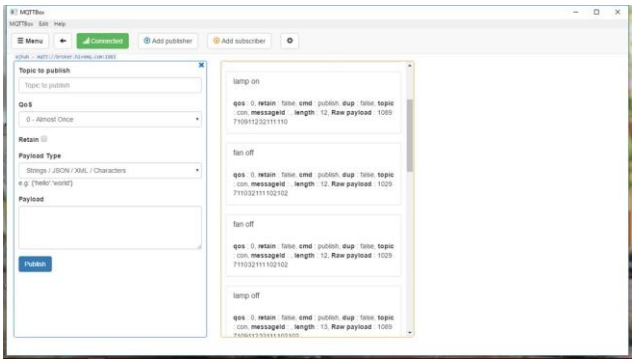

Fig. 10. MQTT Box

The cursor is controlled by tracking the eye movements, blinking performs the click action enabling a pop up message for confirmation. Fig. 11. shows the pop up message for confirmation when a blink is detected.

Fig. 11. Blink detected and select action performed

Finally, when confirmation is given, the payload is published in MQTT and control system responds accordingly.

VIII. CONCLUSION

This paper has presented eye controlled home device for patients where mobility is a point of concern. It is a low cost device for controlling the home appliances using eye movements. The device is based on the acquisition of eye blink signals by the computation of eye aspect ratio. For eye detection, Facial Landmark detection is used which gives more accurate detection than Haar cascade classifiers. This device incorporates the activation and deactivation of Fan and light controlled (can increase the number of home appliances) by eye blink signals.

The main challenge involved in the implementation of the system is the development of a real time eye tracking system. By using the coordinates obtained from Facial Landmark eye tracking was able to implement more accurately and real time processing was also easy.

IX. FUTURE EXPANSION

The project can be extended for detecting emotions and thereby displaying a message or quote to cheer up the user. It can also be used to detect the drowsiness of the user, so that an alarm can be set for safe driving. The project can also be expanded by the implementation of a soft keyboard. By the control action using eye movements, video game can also be played using eye.

***Abstract*— The main objective of this paper was to develop a software application for smart phones to help the visually impaired in assisting their daily activities. The approach focused on helping the visually impaired to navigate from a source to destination without any hassle and to avoid multiple rerouting. The above approach was used to ensure that the users no more faced the issues of re-routing and also provides a voice-based feedback system giving information about their surroundings. Furthermore, the proposed approach was carried out with a single voice assisted application where different features such as calling, messaging, emergency help, landmark and bus stop detection along with the main navigation without rerouting. Hence this helped to provide a single interface voice-based system for the visually impaired to perform basic functionalities on a Smart phone efficiently without depending on another human being for constant assistance.**

Keywords—navigation, voice-based, smart phone, calling, emergency, help, landmark detection, bus stop assistance

I. INTRODUCTION

Blindness obstructs an individual from being able to do general day to day activities. The tasks carried out by human with proper eyesight, even the simplest ones can be considered as a complicated task for them that causes inconvenience in daily and social life.

A number of guidance devices were developed to make their life easier. Initially they walked around along with a dog that helped them to guide their way to the destination. Advances in wearable computing, voice recognition, wireless communication, GIS and GPS (Global Positioning System) have made possible to address the visually impaired and disabled navigation problem. There are many electronic devices that are designed to help the visually impaired to navigate safely and independently. Several devices that provide guidance to a remote location that are available currently are either expensive or too difficult to handle.

In today's world, every single person depends on a smart phone in their day to day life for any simple means. But since there are many applications in a smart phone and the person might need to switch in between applications, this project is concerned with a single voice assisted application where in different features are installed that will help the visually impaired. This project is an approach to help the blind people to make their life easier by providing them an application called STAVI that helps them to call, message, seek help, identify landmarks around, navigate without rerouting etc. just by giving voice input commands. The application provides necessary output for the blind in case of a wrong route thus helping them navigate easily.

II. LITERATURE SURVEY

[1] Proposed an effective algorithm to classify the captured into various classifiers and to implement extraction schemes to detect the same. The final implementation is done through ORB – using FAST as detector and BRIEF as descriptor. However, the use of FAST and BRIEF algorithms is not robust when compared to SIFT and SURF algorithms. Effective only image recognition, no mention of voice-based approach to convey the same to the blind. Future Enhancement of the project included currency note identification but was not effective and did not produce results for torn notes. No mention of the way the input was received. Overall the algorithm is focused onto implement object identification but doesn't integrate various functionalities. [2] proposed an application where various modules have been implemented that includes phone battery information, calling, OCR Recognition, GPS module and indoor guidance activity. The power source for the android application is derived through phone battery and the power source for external modules is obtained through a high capacity solar battery. [3] Proposed a system that can be deployed only for OCR and object identification. The same auditory and video interface can be implemented for various purposes like bus stop detection and assistance to cross roads. The system is highly efficient to implement a single module but can be extended to various domains for future enhancement like navigation etc. [5] proposed an android application that enables to call, send and receive texts with the help of an available phone book. It also makes use of the positioning and battery monitoring. When the app is launched, there are 4 main processes. Two of the processes

are for listening for notifications about new text messages and concerning the battery level as well as the process linked with acquiring geographical coordinates. Speech recognizer helps to access the Google Speech recognition module. The TexttoSpeech class monitors the synthesis of the text to speech. The application has a dedicated phone number contact list besides the already available smart phone book. New additions or deletions can be made with the respective voice command. Similarly, calls can be made with notifications about the new incoming messages. However, it doesn't implement GPS navigation would help the person to travel. [6] proposed an application that is based on object analysis and comparison of the scanned objects stored in the file of mobile application using Image Processing and Artificial Neural Network. ADT-Bundle-windows-x86 software is the software used in order to develop this application.

METHODOLOGY:

Understanding the issues present in the existing approach, there was a need to develop an application embedded over a single system. The modules in our system include Calling, Messaging, Map based Navigation, Volunteer assistance in case of an emergency, Landmark detection and Bus Stop detection. In our application, we help the VI navigate from place to another through voice commands. In case the user takes a wrong turn, instead of rerouting through a new route which might be longer, the application's feature states that it is a wrong turn. Also, for the ease of user, landmarks around the current location such as a departmental store or bus stand are constantly given out as voice commands with certain time interval. The application allows the visually impaired to call someone through voice calling. The next feature is when the user has to send a message to anybody in his/her contact list, the user prompts "SMS" and the contact name, the application reverts back asking what the message is and the user can give his/her voice input. When the application is running, it also reads the incoming messages to the user through voice commands. When the user is in danger, the user can give a voice input of help, the nearest volunteer receives a message giving in the user's current coordinates. This provides an extensive and improved methodology to customize to the needs of the visually impaired and hence achieves the objective of the project.

III. IMPLEMENTATION

The Android application is built with a simple UI to avoid complexities and overlapping of layers within the application. The system architecture shown in Fig 3.1 consists of an Android layer, a server to communicate the data between the front end and backend and a database layer that stores the real time values that is retrieved continuously. The system is built on Android operating system and can be implemented on any latest OS versions. The android front-end layer consists of a button that listens to commands provided by the user. The backend is made of an API that takes the required real time values from the system. The communication between the API and the Outer layer occurs through a Server hosted in a domain. To understand the working of the same, the Server can be hosted locally to test the functionalities and the same can be migrated on a cloud platform in future. To push the real time value from the API and to store the data, a database layer implemented using MySQL is used. The server-side script handling and connections to the database is made using Java which runs on the NetBeans IDE.

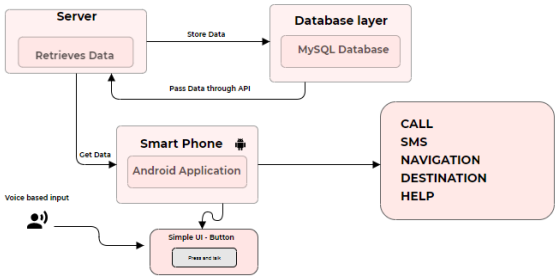

Fig 3.1: System Architecture

MODULE 1: CALLING

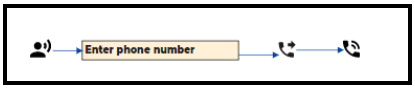

Fig 3.2: Module Architecture – Calling

The UI in Fig 3.2 consists of a Press button that listens to the voice input provided by the user. The user has to configure permissions to the android application that enables the application to access the contacts stored in the phone. Once the user inputs the command "CALL" followed by the number, the Call is automatically redirected to the following person. The voice command is first converted to text and if the text matches the string CALL, the system waits for the user to input the name of the contact and once the command is complete, Call Intent API is used to place a call to the required user. The system checks for the validity of string and only when the string matches the same, Call Intent is invoked. This API places a call from the Android system itself thus providing customization through the STAVI application.

```
(task.startsWith("call")) || (task.startsWith("Call")))

String s[]=task.split(" ");
to=s[1];
for(int i=0;i<StoreContacts.size();i++ )
{

   if(StoreContacts.get(i).toString().startsWith(to))
   {
      String d[]=StoreContacts.get(i).toString().split("\n");
      to=d[1];
      break;

   }

}
call(to);
```

Fig 3.3: Code Snippet – Call

MODULE 2: MESSAGING

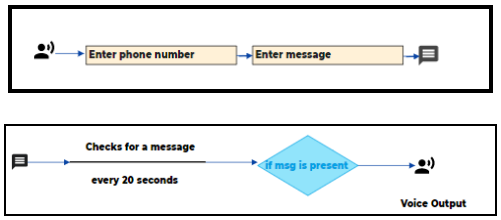

Fig 3.4: Module Architecture – Messaging

The application UI in Fig 3.4 is same as the Calling Feature and it requires a command from the user called "SMS" followed by the number to which the SMS has to be sent. Once the contact details are identified, the system returns with a callback that instructs the user to input the message that needs to be sent. The user then has to prompt the command "MESSAGE" followed by the message. For e.g. to send a message to Alice, the user inputs, SMS ALICE followed by "MESSAGE HOW ARE YOU?"," How are you" is sent to Alice with the same number that is configured to send messages in the android settings. Apart from this, a function call keeps invoking the android system to check if there any messages obtained on the phone at delay of 20s. If a message is obtained during this time interval, the listener detects the change in the event, opens the message and reads the message aloud to the user. To implement the same in android, SEND_SMS permission has to be granted in the application settings. SMS Manager API is used to invoke the Intent that sends the required SMS to the user. The Event Listener that is running in the background checks for the new messages and once the event is invoked, the TTS API is used to convert the message to speech through which the message is read to the user.

```
class check_msg extends AsyncTask<String, Void, String> {
public void onPreExecute() {
}

public String doInBackground(String... args0) {
    try {
        File pictureFileDir =   new File(Environment.getExternalStorageDirectory(), "A");  // getDir();

        String numbers="";
        File f=new File(pictureFileDir + "/msg.txt");
        if(f.exists())
        {
            FileInputStream fis1 = new FileInputStream(pictureFileDir+"/msg.txt");
            byte b1[]=new byte[fis1.available()];
            fis1.read(b1);
            String s1=new String(b1);
            numbers=s1;

        }

        return numbers;
    } catch (Exception e) {
        return new String("");
    }
}
```

Fig 3.5: Code Snippet – Messaging

MODULE 3: VOLUNTEER ASSISTANCE

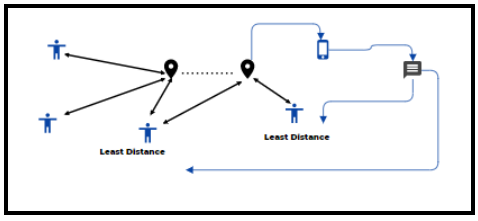

Fig 3.6: Module Architecture -Volunteer Assistance

This feature helps the visually impaired to reach out to a human assistance in case of a medical emergency or travel assistance as shown in Fig 3.6. The database has details of the nearest volunteers or the NGO's present in every geographical area. When the user inputs the command "HELP", the appropriate function call is made, that further queries the database for the nearest volunteer available. Distance formula is used to find the closest distance between the source and volunteer's location. This can be optimized by using Dijkstra's Algorithm. Once the single source shortest path is obtained the distance calculated in the distance formula is pushed on to the tree structure. If a new volunteer is available, the new distance is calculated and compared along with the earlier distance and this new data is pushed to the tree. Once the volunteer details are obtained, an SMS containing the current location is sent along with a default message containing the details of the visually impaired. By this approach the volunteer can access the location of the user and thereby can assist the blind accordingly. To access the location, suitable permissions have to be provided during the configuration settings. A locationManager is set up that invokes Location service. The Location Manager code snippet shown in Fig 3.7 requests the service to get updates of a current location through the service and a Location_Listener is used to update the latitude and longitude accordingly. This updated value is shared across the message to the volunteer.

```
public class  help extends AsyncTask<String, Void, String> {
    public void onPreExecute() {
    }

    public String doInBackground(String... args0) {
        try {

            URL url = new URL(Global.url + "help");
            JSONObject json = new JSONObject();
            json.put("lat",GPSTracker.latitude+"");
            json.put("lon",GPSTracker.longitude+"");
            String response = HttpClientConnection.HttpExecute(url, json);
            String status=response;

            return status;

        } catch (Exception e) {
            return new String("Exception: " + e.getMessage());
        }
    }
```

Fig 3.7: Code Snippet – Help

MODULE 4: BUS STOP DETECTION

Fig 3.8: Module architecture – Bus Stop Detection

The visually impaired often find it difficult to travel in public transport due to lack of information regarding the nearest bus stand and distance between the current location and the nearest bus station. Even after retrieving the bus station information, the visually impaired find it difficult to locate how far the final destination is from the present location. In such cases, the visually impaired usually miss

their destination and find it difficult to reach back to their destination. Therefore, the bus stop feature in our approach helps us to solve this issue as depicted in Fig 3.8. The Bus Stop API takes in values of all the nearest bus stop from the local API, and stores it in the database. A listener in the background provides and audio prompt about the nearest bus stop and how far is the user from the nearest bus stop. Once the user sits inside a bus, he commands the app for "DESTINATION USER_DESTINATION". On checking the destination, the API fetches all the data from maps API regarding all the bus stops on the way to the destination. By doing this the user is aware to when he has to get down.

MODULE 5: NAVIGATION AND LANDMARKS

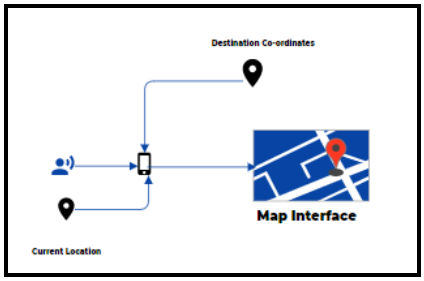

Fig 3.9: Module Architecture: Navigation Assistance

On survey of issues faced by the visually impaired, results of the survey depicted issue regarding navigation with no rerouting. When Google Maps in-built API is used, and the user has to travel from a source to destination, the results are retrieved with multiple routes to the same destination. Once the user starts to travel along a single path and due to circumstances, he moves out of the path, the Google API automatically reroutes itself finding a new path to the same destination. This approach turns out to be disadvantageous for the visually impaired as they are not aware of the routes and if the routes are changed, then they keep rerouting along a new path and often travel longer and tedious routes to reach the destination. In some cases, they end up moving far away from their original destination. Hence a new approach was designed in order to fix a single path between the source and the destination and notify the user when the user takes a wrong route. In order to implement this, the app uses MapMyIndia API that sets a single path from source to destination. The http request shown in Fig 3.10 also has parameters that can specify multiple or single route. If single route is selected, the map sets a single route from source to destination. The source and destination co-ordinates are initially sent to a geocoder function that converts the destination details into map co-ordinates. This is sent along with the Http request made to the API. The API returns with a single route as shown in the Fig 3.11. With this data, the User is prompted continuously providing the details regarding the navigation. In case the user's path does not match the path in the database server, the User is notified with an alert message informing him that it is a wrong route and he has to move back to the old path. The input parameters will be supported in the Route / Driving Directions API request are as below:

1. ***license_key**: the REST API license key allocated to you by signing into our services and registering yourself as a developer (28 Char Alphanumeric).

2. ***Start**: the start (departure) point of the route in WGS-84 coordinates, formatted as (latitude, longitude).

3. ***destination:** the destination of the route in WGS-84 coordinates, formatted as formatted as latitude, longitude.

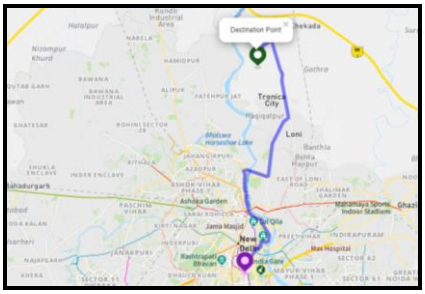

Fig 3.11: Single route selection between source and destination

There is also a continuous feedback provided regarding the nearby landmarks and grocery store to the user. The nearest landmark to the user is retrieved and prompted to the user accordingly.

IV. RESULTS

The application prototype was first developed in Adobe XD to obtain an idea about the working of the project. Using the prototype as the reference, the final application was developed in Android by importing and implementing suitable libraries and packages.

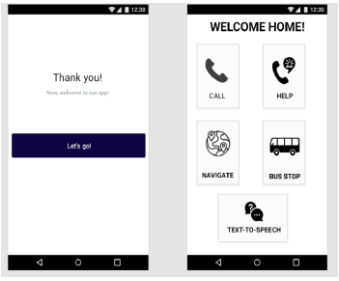

Fig 4.1: Home Page - Prototype

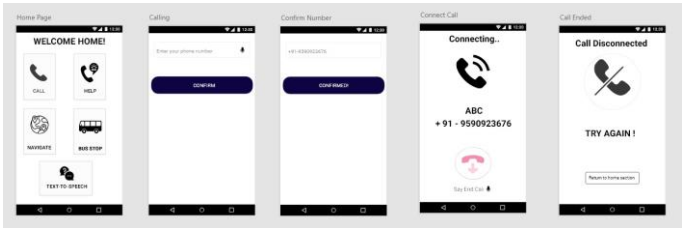

Fig 4.2: Calling - Prototype

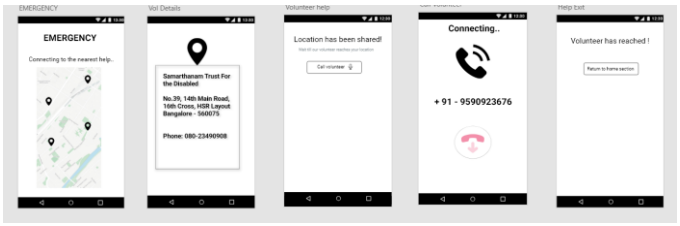

Fig 4.3: Help – Prototype

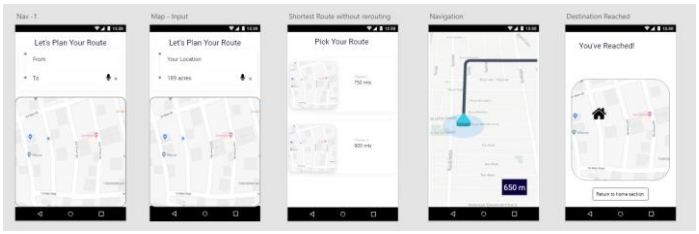

Fig 4.4: Navigation – Prototype

On the basis of the prototype, the final system was developed and the given below are the implementation details of the final system.

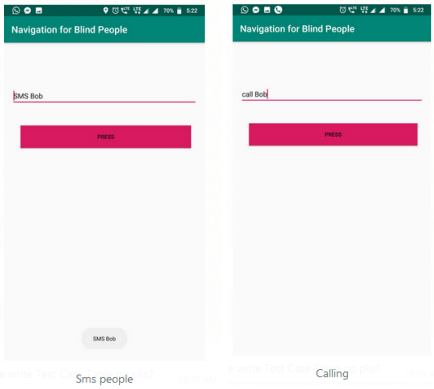

Fig 4.5: SMS and Call features in STAVI

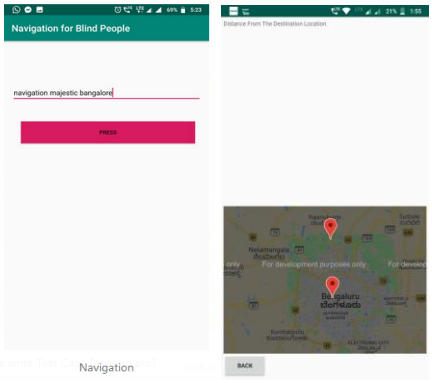

Fig 4.6: Navigation features in STAVI

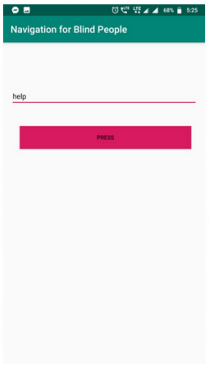

Fig 4.7: Help feature in STAVI

The Fig 4.8 below shows comparative study that STAVI provides variable number of features when compared to other applications.

Lazarillo is an android application that helps the blind to explore the places around and helps to search for category specific locations. This application also helps with navigation of the blind. This application is not efficient and user friendly. The server suddenly stops working.

TapTapSee is an application for the blind which mainly focuses on image identification. It does not provide any help with navigation and travel.

Eye-D provides landmark detection, read text from a document, to live chat with another user. This application is not voice controlled and hence does not help the visually impaired to communicate easily.

Blind Communicator is a communication-based application mainly focusing on SMS, Call, Contact search and Recording facilities. This doesn't not provide any navigation help.

Visually Impaired has 5 basic features: Bluetooth, Call, to run social media applications, Accessibility options and Flashlight none of which help in overall navigation and travel and thus not helpful.

Considering the drawbacks from the above applications, we extract the features that are considered useful for the blind. Thus, STAVI helps to integrate various number of features in a single application and helps to implement the same efficiently.

Applications	Features
Lazarillo	3
TapTapSee	3
Eye-D	5
Blind Communicator	5
Visually Impaired	5
STAVI	6

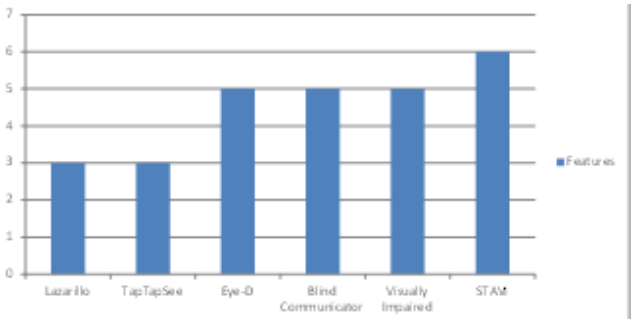

Fig 4.8: Comparison of different applications with STAVI

V. CONCLUSION

Blindness or even partial blindness can cause tremendous difficulties in an individual's life. Even the blind use smartphones to connect to people. With the same idea, the application we have created is focus on helping the visually impaired with the help of smartphones. The application incorporates the use of voice commands to perform different tasks like calling someone or sending an SMS. With the help of this application, the blind can benefit to travel places through voice navigation, gain knowledge about the nearby landmarks and even detect the bus stops when in a bus. The navigation feature also specifies no rerouting function that makes it easier to travel places thus achieving the objective of the project.

Thus, elaborating the comparative study as discussed in the previous sections, STAVI proves to be more efficient with varied number of functionalities when compared to other currently available applications.

***Abstract*-- A state-of - the-art computer network innovation is the Wireless Sensor Network (WSN). Collection of antenna nodes is known as sensor networks. These nodes co-operatively send detected statistics to base station (BS). Thousands of tiny sensor nodes are present in these networks. The WSN networks are controlled with power, memory and computing. In WSNs mainly testing chore is life time of the nodes. The exchange of information from source node to a destination through correspondence channel assumes a noteworthy job in the lifetime of the nodes. So with the help of proper routing protocol, we can boost the survival of the network. Clustering is a type of routing algorithm. By means of clustering, we can prolong the liveliness intensity of the sensor nodes. This increases the lifetime of the sensor nodes. In many clustering algorithms, the selection of the cluster head will play a very vital role and also the location of the cluster head within the cluster plays a foremost role. In this paper, we are proposing a system for choosing a cluster head from a particular location within the cluster that helps other nodes to communicate with the cluster head without consuming much energy. The proposed technique is contrasted and the current strategy with the assistance of simulation.**

Keywords*—*Wireless Sensor Networks, Cluster, Cluster Head, Vice Cluster Head.

I. INTRODUCTION

A Wireless Sensor Network (WSN) is a remote system comprising of spatially dispersed independent contrivances utilizing sensors [1]. These sensors are used to examine physical or ecological conditions. Figure 1 shows simple WSN.

Nodes are conveyed intently in the remote land arrange. Each sensor node is characterized by a set of limited resources.

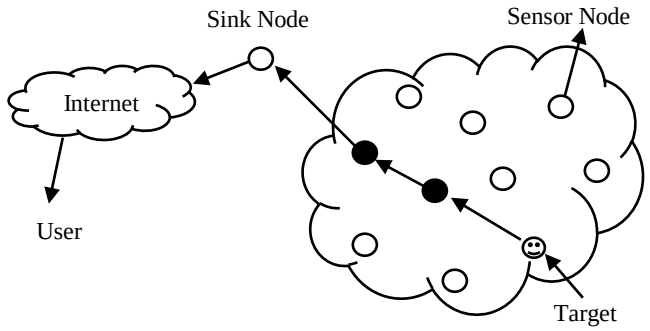

Figure 1 Wireless Sensor Networks

They will sense the surroundings and collect the data from the environment based on the sensing device configuration. Radio sign are utilized to convey with the sensor in the remote sensor arrange. The sensor nodes will process the sensed data and transmit the same thing towards the Sink Node (SN) or Base Station (BS). The main constraints of the WSN are energy, the network bandwidth and routing. These sensor nodes are fueled by batteries. The recharging of the batteries of sensor nodes is not possible, since they are deployed in remote and unattended geographical locations. So energy plays a very imperative part in the existence of the sensor nodes. Energy efficiency is significant to boost the lifetime of WSNs, much more should be focused on energy consumption and the energy utilization must be balanced among sensors. Different techniques have been used in WSN in order to resolve not all constraints together, but one specific constraint at a time. Much research work has been going to decrease the energy consumption in sensor nodes. In such manner, there is a need of better convention which chips away at vitality protection idea and accordingly builds the general lifetime and execution of the system required.

In this paper, we are proposing a cluster head selection technique for a cluster without consuming much energy.

QUALITIES OF WSN

The primary qualities of WSN include:

- Power use imperatives for sensor nodes utilizing batteries.
- Nodes mobility
- Heterogeneity in nodes
- Capacity to endure cruel ecological conditions
- Usability
- Scalability to large scale of consumption
- Capacity to adapt to hub failures
- Production Costs

APPLICATIONS OF WSN

WSN has numerous different applications [3].

- Monitoring the traffic
- Detection of fire
- Nuclear reactor control
- Environment monitoring

- Acoustic recognition
- Military observation
- Monitoring in medical area
- Environmental air, water and soil tracking
- Industrial machine tracking
- Asset tracking
- Building and bridge structural surveillance

The rest of the paper is sorted out as pursues. Division 2 explains the obstacles and design issues in WSNs. The clustering is described in division 3. Literature survey is explained in sector 4. Segment 5 discusses the proposed technique for the cluster head selection. The simulation results are discussed in part 6. The conclusion of the paper clarified in sector 7.

II. Obstacles and Design issues in Wsn

Many margins are in WSNs compared to other networks. The restrictions while designing the WSN are as follows [4]-[6].

- **Wireless in standard**: The wireless medium is in nature fewer secure. The remote medium enables an assailant to just catch any legitimate parcels and effectively embed the malevolent ones.
- **Restricted Resources**: All safety efforts require an exact measure of belongings for the attainment, together with information memory, system space, and vitality to manage the sensor gadgets.
- **Power Limitation**: Energy must be preservedin the sensor nodes after deployment to improve the duration of the individual sensor nodes.
- **Managed Remotely**: detection of the physical tampering in the sensor network is practically impossible due to remote supervision.

There are some problems present during designing the WSN. They are listed below

- **Data Integrity**: Ability to watch that the message has not been adjusted while it was on the framework.
- **Data originality**: Ability to receive the new messages not the old ones.
- **Data Confidentiality**: Secrecy guarantees that a given message can't be comprehended by anybody other than the favored beneficiaries.
- **Self-Organization**: Fixed infra-structureis not available in sensor network to manage effectively.

Energy utilization is the most noteworthy aspect to decide the existence of a sensor organizes on the grounds that generally nodes are driven by battery. The streamlining should be possible by having vitality cognizance in each part of plan and activity.

Various sorts of calculations and conventions are being concentrated to diminish the generally energy use of the sensor networks.

Nodes talk by methods for remote, lossy lines with no establishment. An additional go up against is identified with the confined, as a rule non-reasonable power source supply of the nodes. To construct the lifetime of the framework, the shows ought to be organized from the most punctual beginning stage with the ultimate objective of profitable supervision of the essentialness resources. The wireless protocol we select depends on the purpose necessities.

III. Clustering in WSN

Distribution of nodes to make into teams is thought as clustering [Figure 2]. There are so many clustering algorithms already present [7, 8].The group of sensors is cluster. The cluster is headed by a node is called Cluster Head (CH). The CH is in charge for collecting the cluster members ' information along with transferring the full information to the Base Station (BS). A number of variables influence the efficiency of the cluster, namely energy, network lifetime, delay in electing the cluster head and so on. Network's lifetime relies on the power of the sensors. The power will be utilized for data processing and transfer. If many nodes are sending the same data, there will be lot of redundant data in the network. By using the concept of the Aggregation, redundancy can be eliminated.

Advantages of using Clustering concept

- Redundancy can be decreased using data aggregation.
- Automatic recovery from failure.
- Channel contention and packet collision can be scale down by using clustering.

Disadvantages

- Determination of cluster head in each round.
- Energy consumption for forming a cluster.
- Sensor nodes close to BS lose their power very soon.

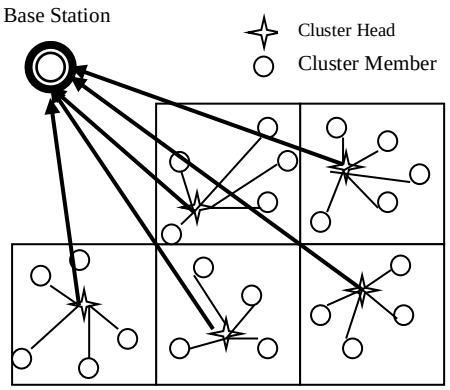

Figure 2: Clustering in WSN

Cluster routing technology has lot of advantages against other routing techniques. Because of this, it is used in most routing techniques in WSN. Clustering can decrease the energy consumption by localizing the statistics traffic.

The CH will accomplish the group information aggregation. CH will take the data from the nodes present in the group. This CH will total the data got from sensors. The aggregated information is sent to the BS. The reliability of the network depends on the CH functionality. In the event that the CH isn't working fine, it influences the entire system execution.

IV. LITERATURE SURVEY

There are many benefits from Clustering of sensor nodes. Clustering promotes network-wide sharing of control. Clustering uses the region of communication to condense the power used in the network. Sensor nodes communicate their information over nearest cluster head. The cluster head will aggregate the information and forwards to the BS.

Sabrine-Khriji et al. [9] have proposed a REDA predicated on the idea of prototype production. The model is precise to the data sensed and utilizes conditional data collected from nodes in consecutive iterations. The REDA wipes out the dissemination of the superfluous information from the sensor hub to group head.

J.K.Deepak Keynes et al. [10] have proposed a cross energy proficient scattered clustering method (CC-LEACH) for crowded WSN. The CC-LEACH demonstrates a lessening in packet fall, power burning up and end-to-end latency for thick WSNs. The simulation findings indicate an increase in the performance, packet shipping ratio with quantity of packets acknowledged at the BS.

Kushal B Y et al. [11] have proposed to enhance the vitality dissemination by altering the group head choice methodology in LEACH calculation and evade the vitality opening issue considering versatility to the sink hub which draws out the lifetime of whole system.

Yasha Istwal et al. [12] proposed the twin CH routing practice with super node having CH with four levels of heterogeneity to pick up the lifetime of a WSN. The goal is to lessen the quantity of choice of CH with the goal that vitality utilization can be limited. The outcome demonstrates the improvement in the lifetime of the system by utilizing the changed LEACH technique.

Lohit B.Dalal [13] proposed an Efficient Dynamic Deputy Cluster Head Selection [EDDCH] that is used to solve the problem of difficult cluster head selection. Efficient vibrant deputy cluster head selection is performed in view of energy level of the node. The node with upper vitality level is picked as cluster head and node with next dimension is delegate group head. Group head gathers the data from part nodes and deputy cluster head moves this data to BS. The simulation examination describes that the projected technique will overcome the imbalance of energy usage, thereby improves the network lifetime.

In [14] Vipin et al, projected a straight forward and well-organized CH selection called SCHS. In SCHS, the territory is isolates into two sections, periphery and internal zone. The hubs present in the internal region will take part in the cluster head determination. SCHS diminishes the intra-group correspondence separation and subsequently improves the vitality adequacy of cluster.

Zhang Ming [15] proposed an associate CH clustering technique based cluster grading (ACHC-CG) in WSNs. The There are three characteristics of ACHC-CG. Initially, divide cluster into grades based on density of the nodes. Secondly, the assistant CH generated based on the created dependent on the rest of the vitality and transmitting separation. This CH is accountable for exchange data between neighbors CH, while main CH is liable for getting sensing data in cluster and processing to diminish energy exploitation of head to drag the lifetime of the network. The simulation result shows prolonging the network lifetime.

K.R.Anu Priyanka et al. [16] proposed a dynamic cluster head election mechanism in which each sensor node compares its residual energy with other nodes. Depending on the left over energy, CH is selected. The simulation shows the increasing the overall lifetime and throughput compared to single level of clustering.

Hai Lin et al. [17] proposed a latest clustering method called DDEC to advance the network efficiency. The DDEC scheme divides the structure into groups with a similar amount of parts to adjust the burden. The group head is chosen in the bunch dependent on residual vitality, separation and thickness. This strategy accomplishes to reduce the intra-group correspondence cost and broadens the system lifetime.

V. PROPOSED APPROACH

Energy efficiency in wireless sensor networks is very important while routing. An opportunistic routing protocol in any network is one of the solutions to increase network lifetime through the use of dynamic routing decision. They will route the network by taking dynamic decisions based on the network conditions.

In Cluster based routing approach, CH selection will play an imperative role for power competence of clustering algorithms. Intra-cluster correspondence relies upon the situation of the cluster head and correspondence vitality relies upon the separation factor. Intra-cluster correspondence includes every one of the nodes and thus much vitality is required for intra-cluster correspondence.

An efficient CH selection technique is required for energy competent communication in cluster. Sensor nodes in nature have small storage circuitry. Computing sensors is highly energy-intensive.

The proposed model protocol has some assumptions. All sensor hubs are homogenous and are stationary. These hubs are area mindful. Just one BS is available exterior the field.

Nodes are unilaterally installed in the field. The complete field is split into two divisions in the suggested system [14]. One is outside, and the other is inside. The division of cluster is revealed in figure 3. Let‘d’ is the distance for partition of pasture. Zone beginning from limit of the field up to the distance'd' is border area and left over zone is called inner area. The number of nodes present in the inner area and border area depend on the value of‘d’. The nodes in the boundary region will not take room in the choice of CH. For CH choice, the nodes in the internal area will be identified. The boundary

zone nodes in each round are always aspect of the participant nodes. The CH is always taken from the nodes' internal region. Ergo, the CH will always be proximate to the core of the cluster. This technique will use less energy for intra-cluster communication.

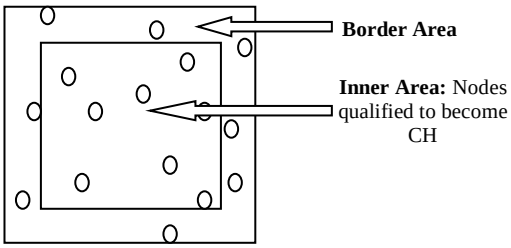

Figure 3: Division of Cluster

In many clustering calculations, the race of the cluster head is done enthusiastically dependent on the remaining vitality. Another CH must be substituted when the CH energy crosses the limit level. Selecting a fresh CH involves lot of power utilization. To lessen the overhead of choosing another cluster head, a reinforcement node must be available in the group which can go about as a cluster head. The backup cluster node is known as ***Vice Cluster Head (VCH).***

In the existing methods, the assistant/vice CH [13, 15] is elected while electing CH. Every cluster will have the CH and assistant / vice CH in this idea. In this concept, any node in the cluster may contest for CH or assistant/vice CH selection process. If the node is present in the border of the cluster, all member nodes have to communicate with the cluster head which leads to more energy consumption due to distance issue.

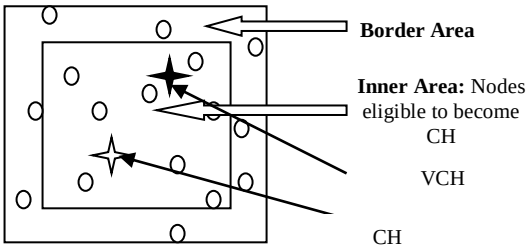

Figure 4: Selection of CH

This can be overcome by limiting the nodes based on node location in the clusteras shown in figure 4. So as to constrain the nodes taking an interest in cluster head choice procedure, we can permit just those nodes inside the internal zone to take part in cluster head choice procedure. Only nodes present in the inner area of the cluster will get chance to become cluster head. Same tactic can be used for the choice of the vice cluster head. If we select the CH / vice CH from the inner area, they will always be nearer to center of the cluster. This decreases the quantity of energy that other nodes need to interact with the cluster head, as all nodes in the cluster are nearly equidistant from the CH.

VI. Simulation Results

A sensor network is used for simulation purposes. The sensor network consists of ***n*** nodes and they are randomly dispersed. All the sensor hubs are considered to have equivalent measure of vitality at first. NS-2[19] is used for the simulation purpose. The location of the sink node is outside the sensing field. Only one sink node is present in the network.

The area used for simulation is 1000X1000 m^2, 1000 sensor nodes are used for simulation. preliminary energy of each node is considered as100J and sensing power is 0.0175J. The power used for transmitting and receiving is 0.9J and 0.8J respectively.

The proposed scheme is compared with the Dynamic Cluster Head Selection Method (DCHSM) [18]. Figure 5 shows the comparison of the planned scheme with DCHSM scheme with respect to packet delivery ratio.

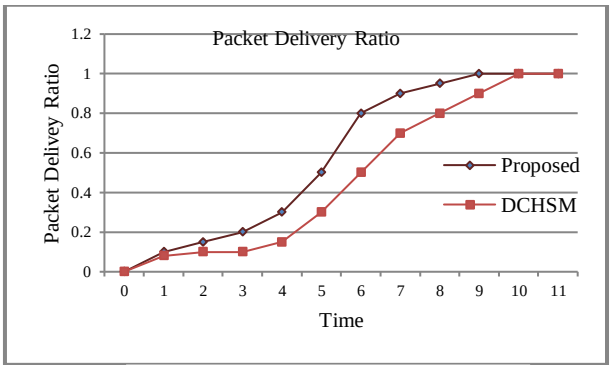

Figure 5: Packet Delivery Ratio

Throughput is defined as successful packet delivery rate in bits per seconds. Figure 6 demonstrates the comparison of the suggested method's performance with DCHSM [18]. Figure 7 demonstrates the comparison between the technique proposed and DCHSM [18] with the amount of active nodes in distinct rounds.

The visualization analysis shows that the packet delivery ratio is enhanced in the suggested proposal as all nodes in the cluster are almost equitable to the CH. Since energy consumed for transmitting and receiving the data is less as compared to the scheme proposed in [18], there will be more nodes active for longer duration than the nodes in the scheme proposed in [18] and also cluster head selection process is not carried out frequently as vice cluster head is available to act as cluster head

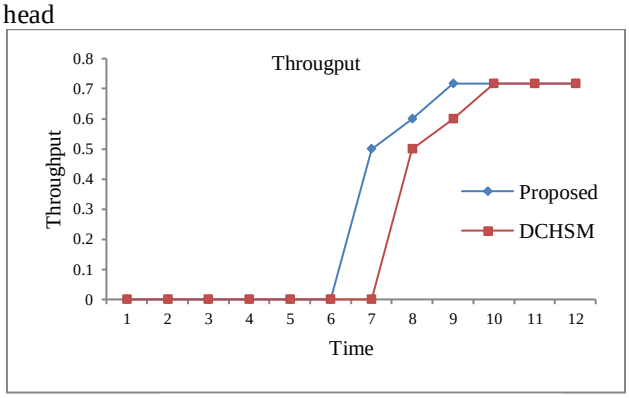

Figure 6: Throughput

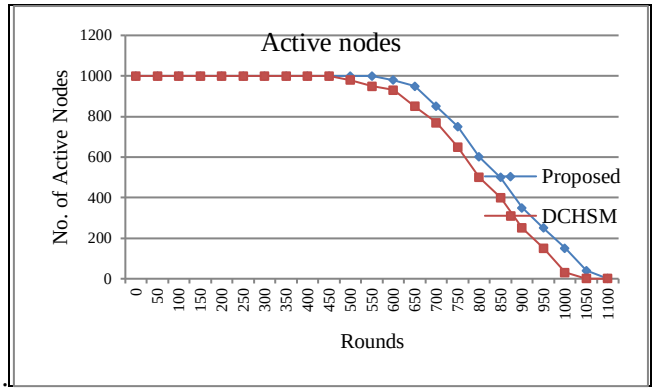

Figure 7: Active nodes

VII. CONCLUSION

Wireless Sensor Network (WSN) is possible future for many applications. This paper discussesthe advantage of selecting a vice cluster head along with a cluster head and the routing concepts in WSN. It is observed that the clustering routing technique can be strengthened. CH choice is a major problem for clustering schemes' power effectiveness. In this paper, the cluster area is alienated into border area and inner area. The CH and VCH choice is held for the nodes present in the internal zone of the cluster. This allows only the nodes current in the cluster middle to become a CH and in turn decreases the energy level needed for other nodes in the cluster to interact with the CH. The results of the simulation display that the packet delivery ratio is strengthened and the energy demand for transmitting the data is lowered relative to the Dynamic Cluster Head Selection Method.

Abstract: **New technologies are expected to lower the investment and reduce cost. Fuel cell generation technologies are now on the verge of being introduced commercially and delivered to market and it might become eminently fuel-efficient and more economical to generate electricity than present utility grid. Unluckily, comprising the systems for power generation from fuel cell have single-phase inverters which draw low-frequency current ripple at twice the output frequency from the fuel cell which may create instability, low efficiency, and lifetime duration of fuel cell stack is shorten. Research in this paper focused on single-stage boost inverter topology with the function of low frequency current ripple (LFCR) reducing to recognition quantity. In addition, present system consists of hybrid switched-inductor step up converter and full bridge inverter which shares a bridge-arm with the converter. The current of boost inductor is designed to work with discontinuous conduction mode (DCM) and analyzed the LFCR in fuel cell output current. The circuit layout, simulation results and performance analysis of 1.26kW/24Vdc, 12kHz are shown to demonstrate theoretical study.**

Index-Terms:-Hybrid-Switched-inductor,Single-stage,Low frequency current ripple(LFCR), Discontinuous conduction mode.

I. INTRODUCTION

Consumption of conventional energy is rising rapidly but sometimes it exhibit uncertainty and discontinuity and also give direct effect on utility grid, if the grid couple inverter used in REGS. Concept of microgrid put forward by researchers which can improve reliability, safety, stability and power supply quality.

Energy storage devices such as fuel cells have various advantages as compared to conventional sources. The direct methanol fuel cell (DMFC) and proton exchange membrane fuel cell (PEMFC) have low-temperature, low heat transmission which makes them ideal for various application [1],[2]. By considering cost issues, the fuel-cell voltage is gradually lesser than 40Vdc and it is boosted up to high voltage of 180-200Vdc for DC to AC inverter [3].

The utmost voltage ratio is broad to 10 times in this state. The orthodox boost converter cannot encounter this requirement owing to the fact that the set off duty ratio in boost converter is close by 1 and urge to high current ripple with less effectiveness.

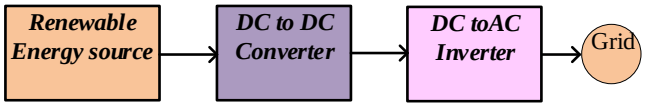

Fig.1 Block diagram of traditional two-stage conversion system

For distribution of power, a grid coupling converter is required for fuel cell system to supply power to grid but having one snag is that the lifetime duration of fuel cell stack is shorten with the ripple current. Thus, in sequence to expand the life duration, the fuel cell ripple current obliged to be diminish in the grid coupling converter [4]. There are various methods to mitigate the current ripples such as by improving control methods like use of active control methods with dual-loop control or with adding hardware circuit [5]. One more method is available to reduce LFCR is through waveform control method [6]. There are several disadvantages of these types of method. Sometime its hard to design the closed control loop which leads to complicate the circuit. Different topologies are mentioned like two-stage power conversion where the front stage is DC to DC converter and the later one is a full bridge inverter [7],[8] which leads to lower the efficiency and controllers are also hard enough to design. The LCL filters are

used in grid couple inverter utilization and is a third order filter which furnished more dense and streamlined designs[9],[10].

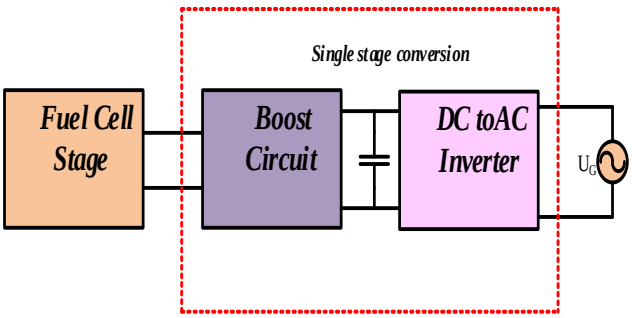

Fig.2 Block diagram of fuel cell based single-stage system connected to grid

Therefore, A new topology where a single-stage boost grid tied full bridge inverter with hybrid switched inductor for fuel cell power generation in discontinuous conduction mode is introduced. The main objective of the proposed inverter is to reduce the current ripple at dc side. It is clearly exemplified in this paper that the projected inverter overall improves the performance of the system.

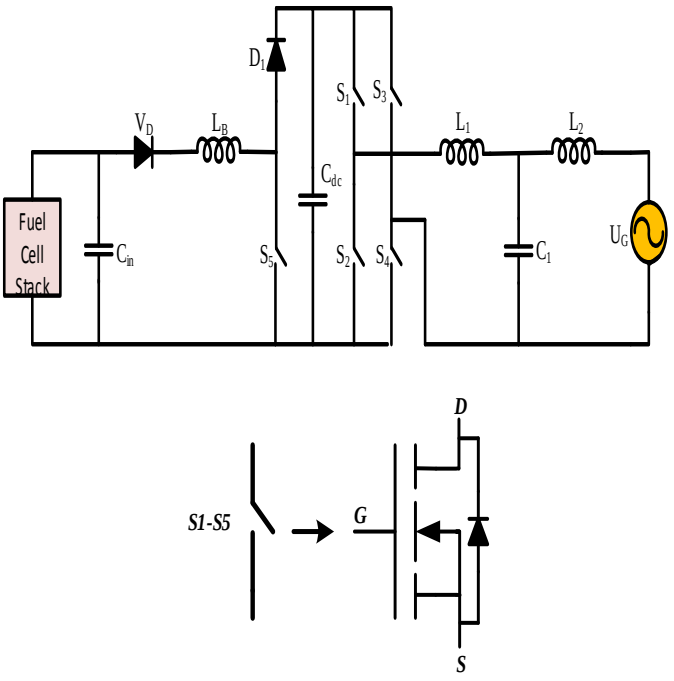

Fig.3 Classical two-stage inverter

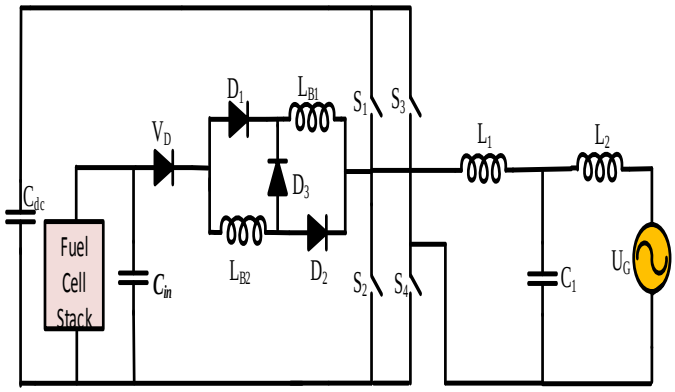
This paper is straightened out as follows: Section II furnish the topology of projected inverter. Section III displays the control strategy of system. Parameters design is presented in section IV. In Section V simulation model and verification is displayed. Finally, conclusion and future scope of projected inverter is subsidized in Section VI.

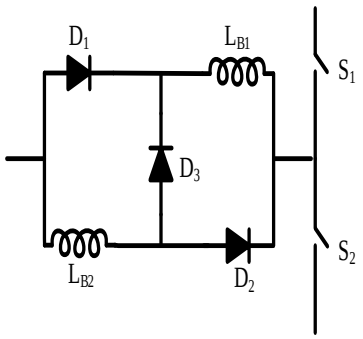
II. SINGLE-STAGE TOPOLOGY

A. *Topology of the projected inverter*

Fig. 1(a) shows a two-stage traditional topography for renewable energy generation system (REGS), such as fuel cell, where the slightest input voltage U_{in} is not so much than the grids peak voltage.



(a)



(b)

Fig.2 Proposed topology: (a) Proposed boost inverter (b) Hybrid switched inductor

The first stage is boost converter & the later stage is inverter with full bridge topology which consist of four MOSFET switches S1-S4. The advantage of conventional two-stage is that it can be controlled easily & separately but has one disadvantage of low efficiency. In proposed topology, the system consists of single stage power conversion where the fuel cell stack used as a DC source, hybrid switched inductor IL_{B1} and IL_{B2} is connected to one leg of full bridge inverter which consist of MOSFET switches. This topology is used as it helps to decrease the cost of the system & also increases efficiency as compared to the traditional two stage conversion system. The current across the fuel cell that is input LFCR is also reduced to minimum limit by the control method.

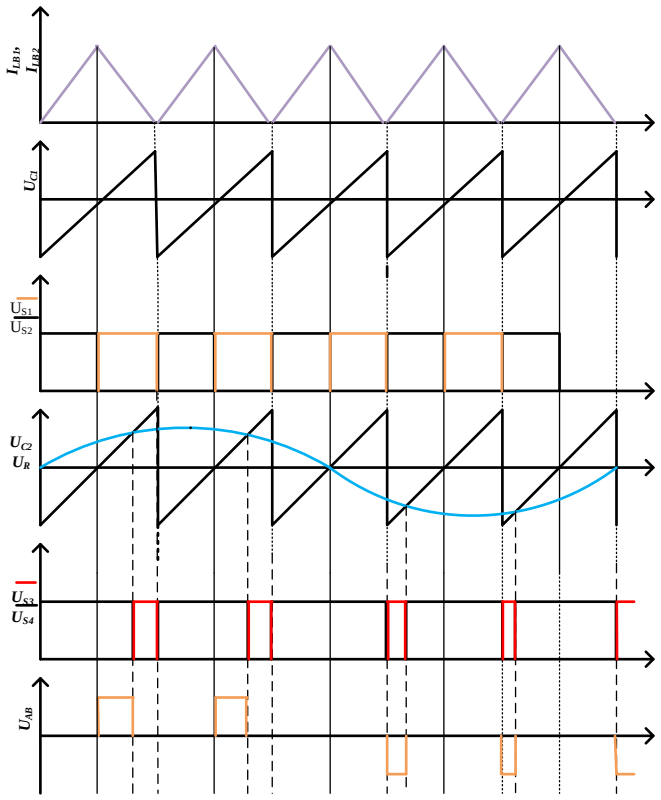


Fig.3 Main waveforms of switches and inverter output

In fig.3, main waveforms of switches are displayed where switching of Switch S_1 and Switch S_2 are retrieved by $U_{cr(carrier\ wave)}$ while switching of another 2 switches are retrieved by comparing U_{cr} with $U_{r(sine\ wave)}$. U_{AB} is the output waveform of inverter.

The boost inductors current IL_{B1} & IL_{B2} should be controlled to reduce current ripple at low frequency. There are several methods to decrease current ripple such as designing resonant controller, waveform method etc. The main disadvantage of these methods is it is so complicated to design. Hence to avoid this, the foresight time of switch S1 and switch S2 is set to half of the switching cycle. The duty ratio of boost circuit is 0.5. The output current of inverter is controlled by SPWM (Sinusoidal Pulse Width Modulation) [12]. The signals for switch S3 &S4 are given by comparing carrier signal U_c & reference sine signal U_r. The output voltage of proposed inverter is also obtained as unipolar SPWM.

The grid current should be in resonant condition with the grid voltage for steadiness purpose. It can be represented for different conditions. Here, $I_{L1}<0$, $U_g<0$ is taken.

For simplification commutation time and dead time of switches are ignored. The key waveforms of operation is shown in fig(4).

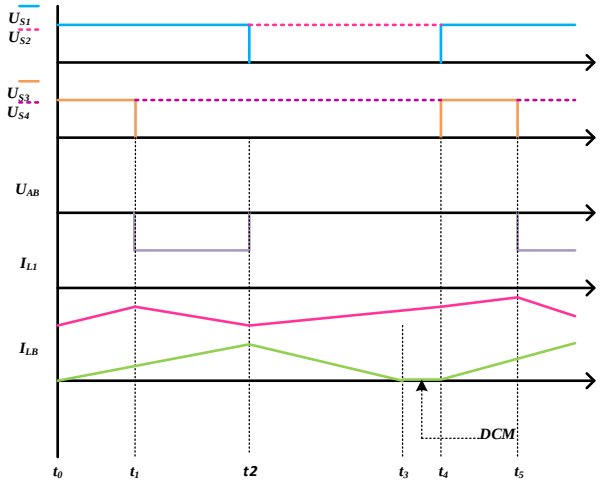

Fig.4 Operation waveforms when $IL_{1<}0, U_{g<}0$

III. CONTROL STRATEGY OF SYSTEM

The control strategy consists of following blocks as shown in fig.5

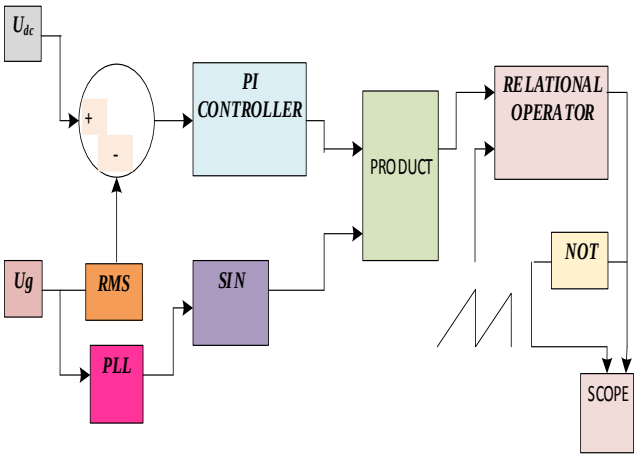

Fig.5 Control strategy of proposed inverter

The two variables, boost voltage at output U_{dc} and grid current I_g need to be controlled. U_{dc} is restrained by PI Controller while U_g is given to PLL block and further compared with output of PI controller that is U_{dc}. Phase locked loop is a kind of feedback loop which is used to lock different waveforms shifted in phase but at same frequency. The reference values of U_{dc} and U_g are taken and further given to gate drive signals of inverter as displayed in fig.5.

IV. PARAMETERS DESIGN

A. *Calculation of boost inductor*

Conforming to paper,boost inductor is designed to work with DCM [12]. The boost inductor can be given by

$$I_{L_{B1,2}} = 0.5 \times \Delta i_{L_{B1,2}} \times (D + \Delta D) = \frac{D^2 T_S U_{in} U_{DC}}{2L_{B1,2}(U_{DC} - U_{in})} \quad (1)$$

$$L_{B1,2} \leq \frac{0.125 \times T_S U_{in}^2 U_{DC}}{P_{FC}(U_{DC} - U_{in})} \quad (2)$$

The fuel cell output pulsation also demands on calculation of final value of boost inductor. The immense P_{fc} requires lesser L_b value.

B. *Power of fuel cell*

The power of fuel cell P_{fc} can be determined by following given equation-

$$P_{FC} = P_{in} = \frac{D^2 T_S U_{in}^2 U_{DC}}{2L_{B1,2}(U_{DC} - U_{in})} \quad (3)$$

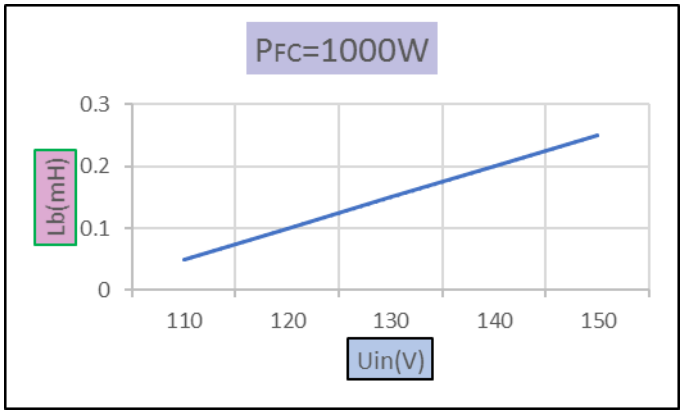

Fig.6 Graph between boost inductor (L_b) v/s input voltage (U_{in})

Formerly, the P_{FC} and switching frequency is monotonous, boost inductor (L_b) can be influenced by U_{in} as displayed in fig.6.

C. *Grid voltage and current*

The grid voltage is given by

$$u_G = \sqrt{2} U_G \sin \omega t \quad (4)$$

Where U_G is the value of grid voltage RMS.
Grid current can be given as

$$i_G = \sqrt{2} \frac{P_{in}}{U_G} \sin \omega t \quad (5)$$

D. *Selection norms for capacitor in input side*

The main advantages of present inverter is that the current ripples can be sensed without any closed loop technique. Cdc acts as a filter capacitor and current across it is consist of two parts that is $I_{DC\text{-}B}$ and $I_{DC\text{-}I}$. C_{DC} is inversely proportional to low- frequency current ripples. The value C_{DC} is taken high with the reference of alpha (percentage of double frequency line). Therefore, three electrolytic capacitors are chosen as boost filter in output side of converter.

S.no	Parameters	Values
1	Input voltage (Uin)	110-180 V
2	Boost capacitor (C_{DC})	400µF
3	Boost output voltage (U_{dc})	360 V
4	VD & D1-3	MUR1540
5	Grid Voltage (u_g)	110/50Hz
6	LCL filters(L1,L2,C1)	L1=4mH, L2=0.5mH, C1=5Mf
7	Switching Frequency (F_{SW})	12kHz
8	Boost Inductors (L_{B1} & L_{B2})	L_{B1}, L_{B2}=1e-4
9	Fuel cell stack	1.26kW

(c)

(d)

Fig.10 Simulation results of the projected inverter

The open loop and closed loop simulation models of projected inverter are displayed in fig.8 and fig.9. The waveforms of projected inverters are displayed in fig.10, where voltage across U_{dc} is presented in Fig.10(a). The voltage U_{ab} is SPWM wave which is used for grid coupled filter design. Fig.10 (c) displayed various waveforms such as output current $IL_{1,}$ boost inductors IL_{b1} IL_{b2} which all shows that the projected inverter is endowed for fuel cell power generation. The retrieved waveform of IL_{b1} IL_{b2} are in DCM as displayed in fig.10(d).

VI. CONCLUSION

This paper presents a single stage boost inverter topology for REGS with reduced current ripples at low frequency as compared to the traditional conversion system. A control technique is also proposed for the better efficiency. A single stage conversion system reduces cost and improves the reliability and the hybrid inductor switch are designed in DCM mode in order to reduce current ripples in input side of the system. In order to understand this topology simulation concludes that the inverter has satisfactory performance as compared to traditional conversion methods. In future, the FC technology is protractible to develop automated fuel cell and can also be explore for CCM instead of DCM. It can be considered for stand-alone application system and backup system. FC stacks integration with various topology of DC to DC converter can be explore and study of a closed loop controller can se analyzed. It can also have applications such as transportation, portable uses as well as for stationary installations.

***Abstract*— This paper present, a enormous gain Ultra wideband (UWB) printed patch antenna by a planar reflector is offered. The reflector is located lower the ground plane with a 15mm distance. By using a reflector, the gain of the antenna have been improved. A determined gain of 6.4 dBi with gain deviation < 2.2 dBi through 3.1 to 10.6 GHz frequency band. A proposed antenna with an overall size 20 × 20 mm^2 fabricated on FR 4 substrate. The simulated results is good contract with the tested results.**

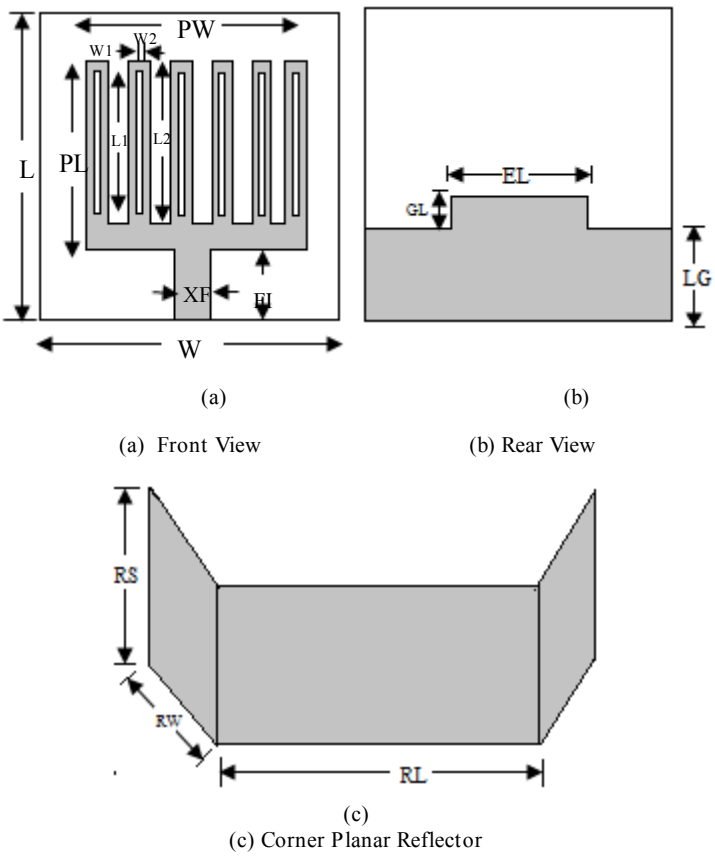
Keywords*— *Compct UWB, Gain Enhancement, Corner Planar Reflector, Radiation pattern.

I. INTRODUCTION

In year 2002, the Federal Communications Commission (FCC) permitted the usage of unrestricted UWB spectrum from 3.1 to 10.6 GHz [1]. UWB antennas are used in many communication applications, viz. imaging, radar, space communication system, etc. [2]. The UWB communication system offers many types of benefits such as wide bandwidth, high-speed data rate capacity for wireless transmission and very low power consumption. Proposal of a small size UWB antenna is a significant challenge owing to some fundamental limitation intended for electrically small antennas [3]. With the comprehensive research on UWB antennas over the past decade, miniaturization of UWB antennas has attracted the researcher's attention. Recently, various compact UWB antennas have been proposed which provide an omnidirectional emission shape through gain of 3-5 dBi [4-8]. However, reducing the dimension of the antenna directly affects the degradation gain and the limitation of the current path [9-10]. In [11-15], improvement of gain has been described using various types of reflectors, including planar, frequency selective surface (FSS), FSS reflector, multilayer FSS, angular, corner and a parabolic reflector. In [11] using FSS layer reflector gain is improved 8- 9.7 dBi over 3.1-6 GHz frequency. Using planar reflector gain is enhanced from 7.5-10.2 dBi over 4.1-10.6 GHz frequency [12]. A gain of curved UWB antenna is improved to 8 dBi in excess of 3.5-10 GHz in [15]. However, antenna structures and reflectors in [11-15], have large dimensions.

Now this article, gain enhancement of a slotted meandering line for compact UWB antenna [10], by a planar reflector is anticipated. The antenna deals omnidirectional radiation shape with less cross polarization < -20dB. The gain differs from 2.2 - 6.4 dBi done 3.1 to 10.6 GHz frequency group. The proposed antenna manufactured and verified, simulated results approve with measured significances.

II. GEOMETRY OF THE ANTENNA AND CORNER PLANAR REFLECTOR



(a) (b)

(a) Front View (b) Rear View

(c)
(c) Corner Planar Reflector

Fig. 1. Structure of offered UWB antenna with Reflector

Elevated consideration of the offered antenna are L= 20mm, W= 20mm, PL= 9.8mm, PW= 12mm, XF= 2.2mm, LG=

5.5mm, RW= 12mm, FI= 5.5mm, L1= 6.6mm, L2= 8.8mm, W1= 0.4mm, W2= 1.2mm, RL= 20mm, RS= 7mm, EL= 8mm, GL= 0.1mm.

The structure of the offered antenna with design parameter is presented in Figure 1. The antenna is intended using FR 4 substrate with an size of 20 × 20 mm^2 having dielectic constant and loss tanget of 4.4 and 0.02 correspondingly. Provide 50Ω microstrip line to the antenna. Impedance matching bandwidth of 7.6 GHz (3.1 to 10.6 GHz) for reflection coefficient <-10 dB is achieved after modification of the finite truncated ground plane using reflector. The distance between reflectors from ground plane is most important for wave reflected from the reflector to be in practical phase with the wave radiated from the radiating patch. Return loss variation of distance between reflector and antenna is shown in Figure 2. A 15mm distance from antenna to reflector is elevated to achieve the extreme gain of an antenna. Dimension of a reflector are optimized for obtaining the high gain as well as the desired radiation patterns. Table I shows the effect of distance between reflector and UWB antenna. The projected antenna is enriched by using the High Frequency Structure Simulator (HFSS) simulation software.

Table I. Comparison table of effect distance of reflector

Sr.No.	Effect of d	Freq range (GHz)	Return loss (db) peak	BW (%)
1.	15 mm distance	3.1-10.6	-40	109.4
2.	25 mm distance	3.2-10.7	-25	107.9
3.	35 mm distance	3.2-10.7	-25	107.9

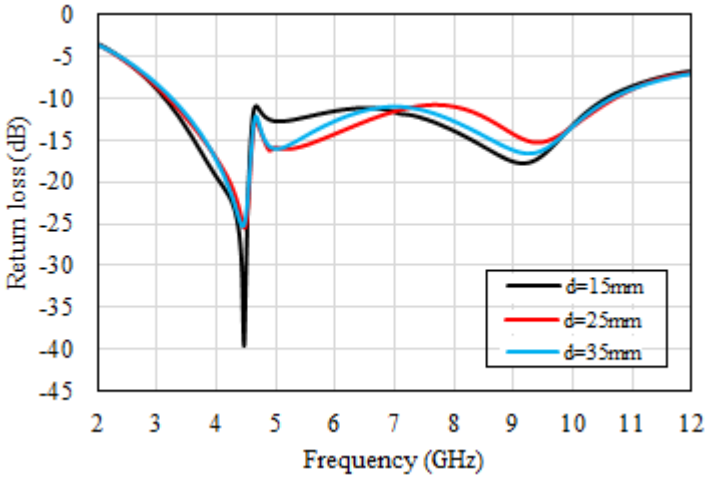


Fig. 2 Retun loss variation of distance between reflector and antenna

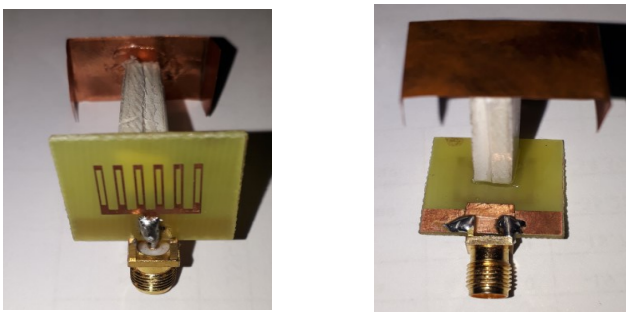
III. RESULTS AND DISCUSSION

The proposed antenna geometry is made-up and verified. The photography of invented antenna with reflector is displayed in Figure 3. The return loss is measured using Agilent VNA (8722ET). The simulated and measured return coefficient of proposed UWB antenna is shown in Figure 4.

The antenna operates in UWB band from 3.1 to 10.6 GHz frequency with its input reflection coefficient below -10 dB. The simulated and tested results are in decent promise with each other.



(a) (b)

Fig. 3. Invented antenna a) Front View with reflector b) Back View with reflector

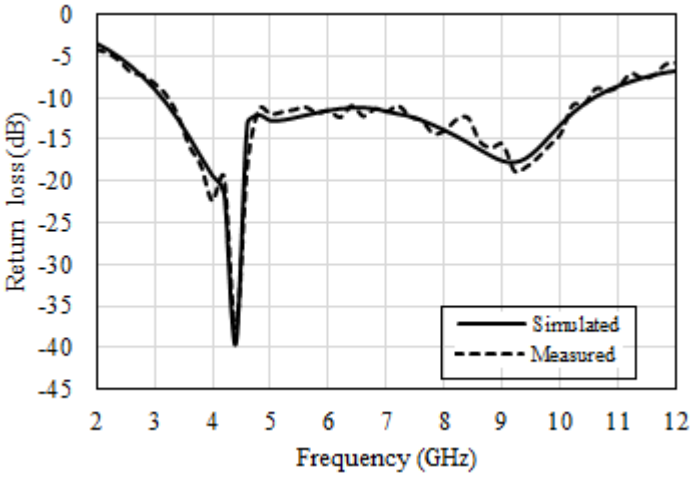


Fig. 4. Simulated and tested return coefficient of anticipated antenna

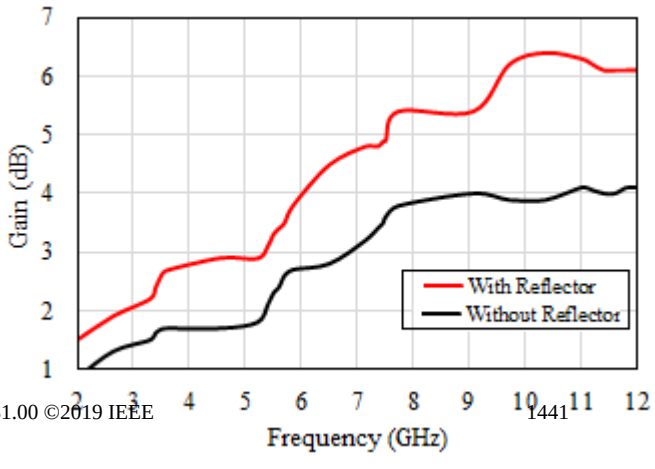
Fig. 5. Frequency vs. Gain plot with and without reflector.

Figure 5 shows a frequency vs. gain plot with and without reflector in the 3.1 to 12 GHz frequency band. The gain is increased by 2.2 to 6.4 dBi over 3.1 to 10.6 GHz with the use of a reflector, the highest gain is 6.4 dBi. The gain of proposed antenna is high compares to without corner reflector antenna with maintaining UWB band.

The simulated 2D radiation configurations for the offered antenna by co-polar and cross-polar at 4 GHz, 6 GHz and 8 GHz is displayed in Figure 6. The co-polar H-plane radiation shape be there purely omnidirectional at the given frequencies. Similarly monopole antenna in E plane



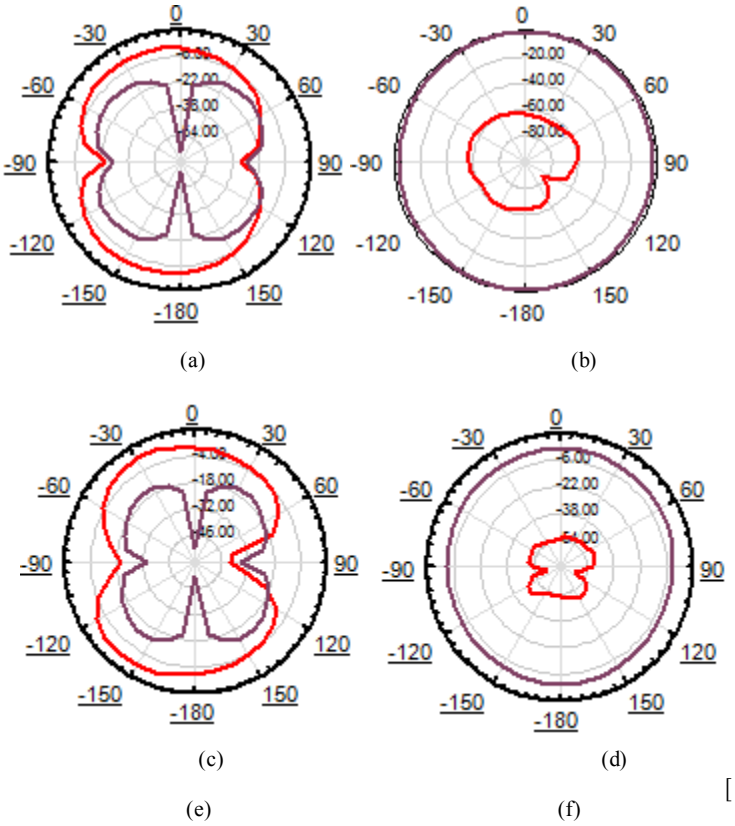


Fig. 6. Radiation configurations for the anticipated antenna with co-polar and cross-polar E-plane and H-plane at resonant frequencies. (a) and (b) at 4 GHz, (c) and (d) at 6 GHz. (e) and (f) 8 GHz.

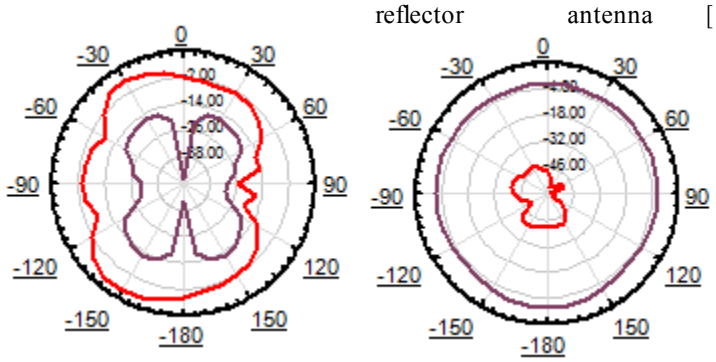
IV. CONCLUSION

Small size of UWB antenna using Corner Reflector is proposed. The antenna is simulated and fabricated on the low-cost material of a FR 4 substrate. The proposed corner reflector antenna



enhanced the gain by 2.2 to 6.4 dBi over the impedance bandwidth of 3.1 to 10.6 GHz. The proposed structure remain wide bandwidth, high gain, low profile and light weight which will be useful in UWB wireless application.

***Abstract*- Power shortage is a very common problem faced by every home and there is no solution to completely eradicate this from its roots. However, with Internet of Things, this problem can be controlled to an extent where people do not have to suffer without electricity for their basic needs such as lights and fans. In our paper, we propose the implementation of a network enabled processing unit in every home (multi-processing unit) that can communicate with a common centralized gateway (Universal Home Gateway) thereby gathering real time data about the demands of the consumer. Also, we propose an installation of two wiring system at each household which is connected only to necessary loads that will have power all the time. Whereas the other connected to heavy (luxury) loads that gets cuts off when demand rises more than supply. Thereby, giving electricity to cater consumer's basic needs all the time. This helps in real time demand side management.**

Keywords- IoT, Smart grid, Customer centric grid and Real time demand management.

I. INTRODUCTION

In Smart Grid, the meters that are installed with the system has a multipurpose role with smart capabilities in order to meet the consumer's demand and needs [1]. The smart meter thus installed can measure real-time electricity usage and communicate data. This enables remote real-time monitoring and control power usage. Thus, consumers are provided with real-time pricing and can analyze the real-time usage information. In this connection Demand Side Management (DSM), Dynamic pricing and Demand Response Management (DRM) programs are applied by utility companies to regulate the energy consumption in homes by connecting the smart meter with many DSM properties and Home energy management system is also applied for the same cause. [2]

The smart meter in each and every household is connected to the internet along with a remote control is made possible [3]. The households are provided with two lines- one connected to heavy loads such as Air conditioners, washing machine, microwave oven etc., and other to only necessary loads such as light, fan, Wi-Fi etc., During the time of power deficit, instead of cutting power to the entire house, the line for the heavy load alone is turned off thereby providing uninterrupted power to the basic necessary loads. [4] This improves load scheduling and service to the customers. With a development in cloud infrastructure and improvement in mobile communications, the forthcoming Smart grids will likely to be more combined with the cyber infrastructure for sensing, control, scheduling, dispatch, and billing. A framework model that can forecast power dissipation profiles for every household as well as increasing per-area-consumption can also be made possible.

II. PRESENT SCENARIO

The existing system is distributed centric and demand response management is very poor, real time data gathering for individual homes is not possible [5]. In case of power deficit, there is a need to cut entire house power supply. Draw backs in the existing system

- Distributer oriented grid design. [6]
- Greater chance of power theft and Poor load scheduling. [7]

III. PROPOSED SYSTEM

We propose the implementation of a network enabled processing unit at every home (multi-processing unit) that can communicate with a common centralized gateway (Universal Home Gateway) thereby gathering real time data about the demands of consumer. [8] Also, the proposal includes an installation of two wiring system at each household one connected only to necessary loads that will have power all time and other connected to heavy(luxury) loads that gets cuts off when demand rises more than supply thereby giving electricity to cater consumer's basic needs all the time. [9]

A. Hardware used

- Ardunio Uno

- ThingSpeak

C. System design

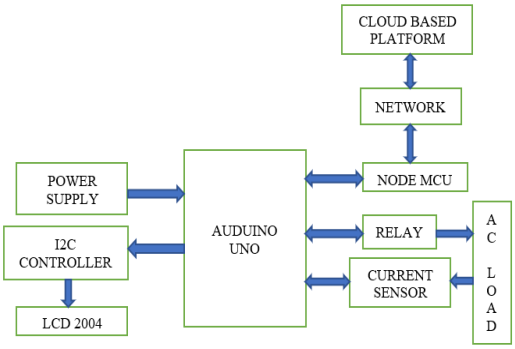

Figure 1.1 Block diagram of the circuit

The fig1.1 explains the block diagram of the proposed system, the 230 voltage AC main electricity supply is converted to 5V DC using a regulated power supply system. LCD 2004 display is interfaced to Arduino Uno using I2C controller. The Hall effect current sensor is used to measure the electricity used from the AC load through the Ardunio Uno. A relay is controlled by Ardunio Uno to switch on/off the AC load based on the signals received from the Ardunio Uno. Node MCU is used to connect system with the network, transfer and receive the data from the cloud through the network.

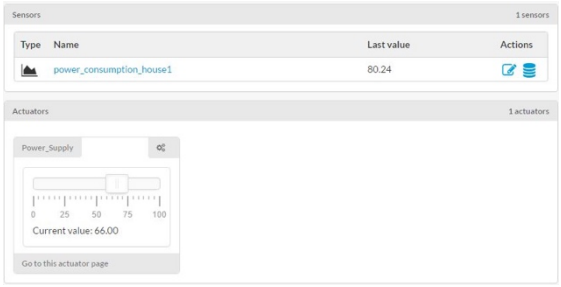

Figure 2.1 The producer side user interface for setting the power limit

Here the Wi-Fi is used as the network for connecting the network with the cloud [12].

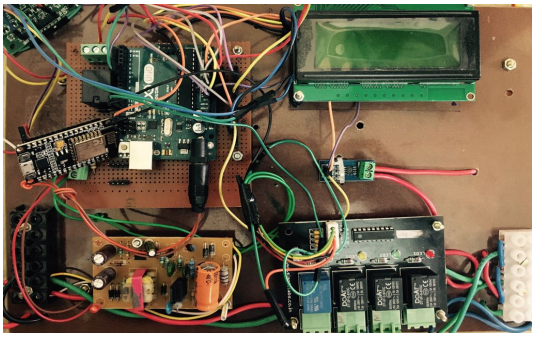

Fig 1.2 shows the hardware components in the IoT based kit

D. Working process

Each household wiring is separated into two wiring systems. (i) Basic needs – it powers the basic lighting, fans and other necessary appliances. (ii) Luxury needs – it powers air conditioning, refrigerator, washing machine and other luxury appliances which does not include under basic needs. When there is a power shortage, there is no need of shutting down the entire system instead only the luxury needs are turned off until the power shortage is rectified. With installing our proposed IoT based kit, we can make this selected power cut possible without majorly interrupting the existing system. The IoT based kit proposed by us is a wireless model which outcomes the disadvantages of the existing power supply models which cuts down the power entirely.

In our model, we have developed a user interface using DeviceHub platform where the producer can check the real time demand and can allocate power limit to every household based on the power produced. Once the usage exceeds the defined limit, it turns off the power to the entire home. But if they manage the use of power by switching off the excess load which falls within the defined limit, it turns on automatically and there is continuous uninterrupted power supply. The consumers can also check the power used by them in their house space in real time through ThingSpeak platform used in this model.

E. Advantages of our model

- Continuous intersection of combined smart grid in same arrangement with smart home applications [10]
- Data collection from multiple sources that constitutes varied communication sensors for customized data access. [11]

Figure 2.1 shows the producer side user interface for setting the power limit for each and every household. shows the real time power consumed based on the usage of power consumed by the customers which was developed using devicehub.net.

F. DeviceHub platform

DeviceHub is a platform used by the young developers to develop an insightful future. Joining hardware and web-based technologies, has always been a challenge. This platform gives a solution with the help of IoT and Cloud integration. DeviceHub platform provides data collection, remote control, cloud services and analytical gateway for new developers. To help the SMEs and other individual developers, PaaS (Platform as a Service) [12], a user-friendly platform, is used to connect the mobile application developers to other electronic devices such as sensors. This PaaS is used in the project to develop the real time data transfer for demand forecast and consumption in real time [13].

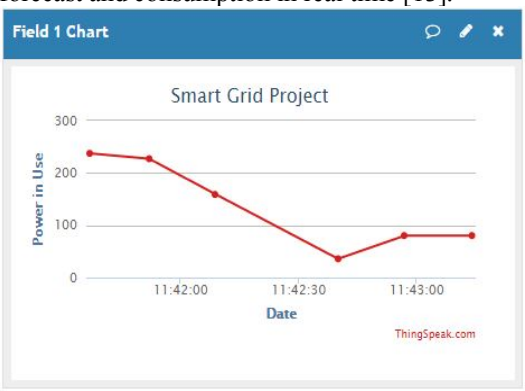

Fig 3.1 Graph showing power in use from Thing Speak

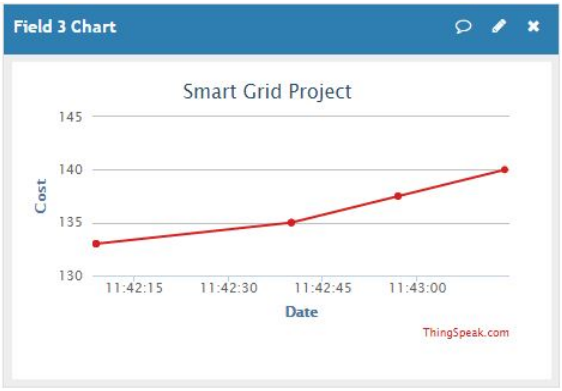

Fig 3.2 Graph showing cost per wh from thing speak

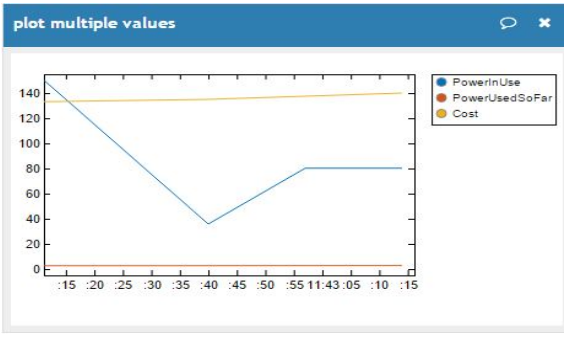

Fig 3.3 Graph showing all values in single graph

G. ThingSpeak platform

Data collection and storage is an important part for any developer. With data usage growing at a faster pace, it is important to have a platform to collect and store the data along with other cloud applications. [14] ThingSpeak is an IoT integrated platform that is used for efficient data storage and collection. This is utilised for analysing and visualizing the data used by the consumers [15]. Sensor data which is widely used can also be redirected to ThingSpeak from Arduino and other hardware appliances that are applicable. [16]

Figure 3.1 shows the consumer side user interface which shows the power in use. Figure 3.2 shows cost per watt hour (Wh). Figure 3.3 shows consolidated graph values of Power in use, Cost and Power used so far in a single graph through Thing Speak platform.

IV. FUTURE SCOPE

Using different types of Information Technology, communication devices and automated checks, power grid is converted to a Smart Grid with combining advanced tools and technologies [17]. With different ideas and developments booming, usage of the smart grid is the key reason for India to be in the front. Despite of facing numerous problems in the smart grid, India is still in the third position for transmitting and distributing network in the world. The few problems currently faced by India are shortage in electricity supply, lack of network access in all the places, demeaning quality and dependability and theft that is widespread[18]. The need to eradicate the above-mentioned problems in a well-organized, reliable and safe environment is vital and this can be achieved by advanced developments in Smart Grid, which in turn will lead to less power fall and power access for all [19].

V. CONCLUSION

The smart grid developed by us reduces the possibility of power shortage and power cuts. The users have the privilege of not suffering even without basic needs during their day to day activities. A smart grid distributes electricity from providers to customers using two-way digital technology to regulate appliances at customers' homes to save energy, decrease costs and increase dependability and transparency. Information and net metering system are used to avoid overlapping of the power distribution and electricity travels from the power plant to home through a remarkable system called the power grid. A modernized electricity network is being promoted by multiple governments, including the Government of India as a way of addressing energy independence, global warming and emergency resilience issues.

ACKNOWLEDGMENT

We thank our friends Praveen Kumar P and Rahaman Basha from Kingston college of engineering and colleagues from Institute of management, Christ (Deemed to be) University who provided us with insights which was a great assistance in shaping our research. We would like to express our gratitude to family, faculties and colleagues of Institute of management, Christ (Deemed to be) University.

***Abstract*—Network security is the process of preventing and protecting against unauthorized access from the Internet. Intrusion detection is a basic part of security tools e.g., intrusion detection systems, adaptive security appliances, firewalls and intrusion prevention systems. There are several types of intrusion Detection System (IDS) exists e.g. Network IDS (NIDS), Host IDS, signature-based IDS, Anomaly based IDS. As huge amount of information in the form of packet flow across network may contains vulnerable information which lead to security threats. Many standard IDS datasets are available for researchers to measure their attack type detection/classification method's performance. In this paper we have done survey on classification methods applied on KDD99 and NSL-KDD. Most of the existing work focused on performance of classifier based on time and overall accuracy. we have shown the results of these papers to do collective study. The detection rate of majority classes (DoS and Probe) are good but not the same case with minority classes (U2R and R2L) when base classifier are used alone. It has been studied that there is as improvement in minority classes detection rate with pre-processing or hybrid classifier. By doing comparative study on results given by existing research papers shows that ABC-AFS [25] perform best among all.**

***Index Terms*—Feature Selection, NSl-KDD, KDD99, Class Imbalanced Data, Detection Rate (DR)**

I. Introduction

From past years, Internet or group of networks is spread around the world connecting large number of users. These networking are used by many organizations to perform information exchange or data transfer. The vast amount of attacks over the Internet makes computer users and many organizations under risk taking and the potential violation of security. The concept of intrusions detected in the system can be expressed as an attempt to invade a system and spread the following aspects which affect the major part of the system such as integrity, availability, confidentiality or the quality of the services in the system. In today's scenario, several information security techniques are available to protect information systems against un-authorization accessibility to the user, duplication of data, alteration, destruction and virus attacks detected. Intrusion is an extreme issue in security, network data can be effected by a single instance of intrusion can which will lead to breach in security in almost no time. The network connections are basically categorized into host-based data also named as an audit data [8] and network-based data (i.e., tcpdump) [9].

A. IDS Dataset

Some publicly available network traffic datasets are as follows:

1) **KDD99**:This data set is an upgraded version of DARPA98 dataset and used in "The Third International Knowledge Discovery and Data Mining Tools Competition". The goal of competition was to develop a network intrusion detector also can say a predictive model should have the capability to differentiate between normal and attack connections in the network.
2) **NSL-KDD**: The "Network Security Lab - Knowledge Discovery and Data Mining" is derived from the KDD99 dataset to overcome its limitation of containing large number of redundant instances. The NSL-KDD contains non-redundant and reasonable number of instances so that accuracy, performance of the classifier can be enhanced [2].
3) **KYOTO 2006+**: This dataset includes network data from Kyoto University's "Honeypots" [14].
4) **ADFA** : This Intrusion Detection Dataset developed to perform experiments by Host IDS. [10].
5) ISCX 2012: The dataset was created by "Information Security Centre of Excellence at University of New-Brunswick". Overall 2450324 network flows for a week is included in this dataset [3].
6) **CICIDS2017**: It also consists of network data as labeled flows consists of the timestamp, protocols, IPs and ports of both source and destination as well as attacks evaluated using CICFlowMeter [16].
7) **UNSW-NB15**: It contains combination of benign and synthetic attack behaviours which is generated by the "IXIA PerfectStorm" tool in the Cyber Range Lab of the "Australian Centre for Cyber Security (ACCS)" [18], [19].

B. KDD99 and NSL-KDD

In this papers, we will discuss about results of different classification techniques on KDD99 and NSL KDD. The dataset contains 39 attack types which are broadly classified into 4 attack type i.e. Probe, Denial of Service (DoS), Root to Local (R2L) and User to Root (U2R) as shown in Table1 [36] . The test set contains additional attack which are shown in bold font.

1) **DOS**- In this, an intruder try to make network resource unreachable by temporarily or indefinitely interrupting service of the host in network. Some examples of DOS attacks are mail bomb, teardrop, back, Ping of Death (pod), smurf, Neptune, land etc.
2) **U2R**: An unauthorized individual/party try to access the system using authorized account and make attempts to misuse vulnerabilities in the system to have root user privileges. Some example of U2R attack are rootkit, xterm, perl etc.
3) **R2L**: An intruder seeks to get the right of sending packets over targeted network by gaining local access as a user of the network. It is also known as Root to user (R2U) attack.
4) **Probe**: In this, the information about targeted host or network is collected so that state of the network can be learned and more formally for renaissance purpose.

TABLE I
ATTACK TYPES [44]

S.no.	Attack Category	Attack Types
1	DoS	**Apache2**, **Processtable**, Neptune, Land, Pod, Teardrop, **Mailbomb**, Smurf, **UDPstorm**, Back
2	Probe	Satan, Portsweep, **Saint**, Nmap, **Mscan**, Ipsweep
3	R2L	**Xterm**, **Httptunnel**, Rootkit, **Ps**, Buffer_Overflow, Perl, LoadModule, **SQLattack**
4	U2R	Imap, Spy, WarezMaster, Guess_Password, Warez-Client, MultiHop, Ftp_Write, **Named**, **Sendmail**, **Xlock**, **SnmpGuess**, **Xsnoop**, **Worm**, **SnmpGetAttack**, Phf

In section 2, discussion on different machine learning techniques are applied to KDD9 and NSL KDD dataset are provided. In section 3 we will discuss the outcome of these techniques and the comparative analysis has been done which is shown in table 2.

II. RELATED SURVEY

A study by Jim Anderson [1] based on one of the earliest works on intrusion detection and recommended number of ways for analyzing audit data of system. His methods utilize gathered an audit data for analysis of performance and were designed for batch mode processing, means collected data of complete day would be examined at the end of the day.

The classification problem in intrusion detection area has been examined for quite a long time using existing machine learning techniques comprising conventional classification techniques e.g., Decision Trees (DTs), k-NN, Bayesian, SVM, Self-Organized Maps (SOMs), Genetic Algorithm (GA), Artificial Neural Networks (ANNs), hybrid classifiers (combination multiple machine learning techniques) and fuzzy logic. A survey on utilization of these methodologies and 55 research articles reports its statistics during the period 2000-2007 was given in [15]. The survey demonstrates that K-NN and SVM were the most widely used methods while there is an increment in utilization of hybrid methods after 2004. Another recent survey [17] provides in-depth review of intrusion detection by using computational intelligence which includes the description of Swarm Intelligence methods and classification algorithms. Recently, incorporation data mining techniques with "On Line Analytical Processing (OLAP)" tools is introduced [20]. It has been shown that this collaboration provide a good solution to handle problem in IDSs, for example low detection rate and high false alarm rate.

As huge amount of network traffic data is generating by organizations, to handle such data Extreme Learning Machine (ELM) is used in [13]. Comparison of ELM has been done with Random Forest(RF), SVM(Linear) and SVM(RBF) based on three parameters (Accuracy, Recall and Precision). Experiments were performed on NSL-KDD training dataset which are randomized then partitioned into three parts (full, half and one-forth). Mostly, researchers evaluate performance of presented IDS in the context of data mining by utilizing the standard KDD Cup 1999. However, the imbalanced distribution of class in the data set causes minority class problem which leads low detection rate of such classes. Two commonly used sampling methods (over-sampling and under-sampling) to alleviate the minority class problem were examined in this research. However, these methods are less effective to resolve the problem is shown in [53].

The RF algorithm is applied in anomaly, misuse and hybrid detection. The hybrid approach is proposed for detection of both misuse and anomaly attacks [7]. The framework consists of two phases, phase1 the misuse detection is applied so that known intrusions are filtered out from the datasets then in phase2 entering the anomaly detection component to enhance the performance of the approach. Feature selection algorithm are applied which select 34 attributes based on its importance. Thorough examination of four important techniques for anomaly detection which comprises statistical, classification, clustering and information theory provided in [11].

A new hybrid feature reduction technique has been proposed for classification by combining the approaches of both PCA and IG with an ensemble classifier based on SVM, multilayer perceptron (MLP) and Instance-based learning algorithms (IBK). The evaluation of IG-PCA's performance done on three standard datasets, namely Kyoto2006+, NSL-KDD and ISCX 2012. The reduction in computational cost of the proposed method significantly among all experiments is shown [5].

Another new hybrid classification technique based on approaches of Artificial Fish Swarm (AFS) and Artificial Bee Colony (ABC) algorithms is proposed. Removal of irrelevant features performed using Correlation-based Feature Selection

(CFS). "Fuzzy C-Means Clustering (FCM)" applied to partition the training dataset. This hybrid method was performed on UNSW-NB15 and NSL-KDD datasets. The size of feature set after reduction is 6 for both these dataset [25]. Intrusion detection using AdaBoost has been presented [12] in which decision stump is selected as a weak classifier. Versatile initial weights and a simple strategy (described in section D) are adopted to enhance the algorithm's performance and avoid over-fitting. The algorithm is performed on KDD99 dataset. The "Feature Selection, Weight, and Parameter Optimization of SVM using GA (FWP-SVM-GA)" based on the features of both SVM and GA algorithm is proposed in [6]. Experiments were performed on standard KDD99 dataset and dimensionality reduction (selection of 19 features) has been done using GA and SVM.

A. Class Imbalanced Data

In-depth review of modeling techniques includes classification algorithms, model evaluation and data preprocessing. Authors have reviewed 527 papers related to imbalanced data from practical as well as technical point of view [38]. Some basic techniques for imbalance learning are as follows:

1) **Pre-processing**
   a) **Resampling**: The number of instances are randomly selected from the original data sample with replacement in such a way that number of instances in each drawn sample are approximately equal to the original data sample. Because of replacement, the selected number of samples consists of redundant cases are used by resampling methods. Mostly used resampling methods (three hybrid, eight undersampling and nine oversampling methods) e.g. SMOTE, SMOTE-ENN, SPIDER, AHC, RUS, OSS etc are discussed in [21].
   b) **Feature Selection and Extraction**: The process of selecting subset of attributes to improve classifier's performance is known as Feature selection. It has three methods (filters, wrappers, and embedded) [37]. Unlike Feature selection, new features space is created from the original feature space by utilizing functional mapping in feature extraction [33], [35].
2) **Cost-Sensitive Learning**: In this kind of learning, misclassification of rare class samples is assumed higher cost related to majority classes. Such learning can be incorporated at data as well as algorithmic level [39].
3) **Ensemble Classifiers** [43]: Following method to create ensemble classifier
   a) **Bagging**: It is the abbreviation of Breiman's bootstrap aggregating method provides flexible and straightforward ways of accomplishing a high accuracy [45]. In this method, various subset of connections are randomly taken from the complete training dataset with replacement. More than one classifiers of the same category are trained using newly created subset. By using majority voting, combination of particular classifiers are achieved.
   b) **Boosting**: In 1997, Freund and Schapire presented a boosting algorithm called as "Adaptive boosting" in short "AdaBoost". The technique develop a set of hypothesis and particular hypothesis determines weighted majority voting of the classes to combine decisions [47].
   c) **Stacking**: The outcomes of classifier's ensemble provided as input to next 2^{nd} level meta classifier possess capability of learning the mapping between ensemble outputs and actual classes [46].
4) **Modification in Algorithmic Classifier**: The learning capability of an existing classification methods should be improved in order to enhance classification accuracy for imbalanced dataset. Some common techniques to improve decision tree, Naive Bayes, K-NN, SVM, ELM and rule-based classifer are discussed in table 5 in [38].
5) **Multi-Class imbalanced learning**: In [40], ad-hoc learning algorithms, "One-Versus-All (OVA)" approach and "One-Versus-One (OVO)" approach decompositions for addressing learning problems in multi-class imbalance data has been studied. OVO outperforms OVA is shown in their experimental results but OVA requires less decomposition (i.e. time efficient) that's why still popular than OVO.

III. Comparative Analysis

In [48], an optimal decision forest known as Kernel Miner which won second place in the competition of "KDD'99 Classifier Learning Contest" held in August 1999 has been used. The tool works with more number of databases e.g. as Oracle, MS Access, dBase, SQL Server etc through or directly OLEDB/ODBC and basically developed for Windows 95/98/NT.

In [29], feature subset merit measure and feature correlation metric has been introduced to quantify the relevancy and correlation among features for the efficient feature reduction. Authors have proposed new learning classifier algorithm.

In [50], an appropriate classifier are selected by performing experiments using different classifiers (Naive bayes, Best-First tree, MLP, Random Forest Tree) on NSL KDD dataset. To perform effecient classification, 26 features are selected using SFFS [51]. The classfication of test set was done using both 20% train set and whole train set. Their result shows that Naive bayes Performance is better compared to remaining classifiers.

In [30], a model for "Fast Learning Network (FLN)" based on "Particle swarm optimization (PSO)" is presented namely, PSO-FLN. For training FLN and ELM classifer, the comparison of developed model has been done with number of meta-heuristic algorithms.

Comparison of various methods for creating a multi-class SVM classifier using a set of binary SVM classifiers and aim to determine best multiclass SVM model [52]. WOAR SVM has been proposed and Differential Evolution (DE) model selection is used to get an optimal set of SVM hyperparameters. The

WOAR SVM is compared with (OAO, OAR, DAG, ADAG, ECOC) SVM.

A new hybrid approach is proposed on the basis of Binary Classifiers (BC) and K-NN for improvement and reduction in performance and bias towards majority classes respectively. In step 1, various BCs are employed and one composite module to efficiently identify the actual class. Further, the connections/instances with uncertain classes are transferred to step 2 to identify their classes using k-NN. Experiments were performed on two test set ($KDDTest^{+}$ and $KDDTest^{-21}$) [49]. we have shown experimental results on $KDDTest^{+}$ in table 2.

The SVM method is combined with Clustering based on "Self-Organized Ant Colony Network (CSOACN)" to take the characteristics of "Combining Support Vectors with Ant Colony (CSVAC)". A consistent as well as uniform train set and two test set namely (t_1 and t_2) are created from 10% KDD99 dataset on which algorithm is implemented and evaluated. Experiments show that CSVAC performed better than SVM and CSOACN alone with respect to DR and execution time efficiency [32]. For simplicity, result on t_2 test set is shown in Table 2.

In [42] a new method which is an association of DGSOT and SVM is presented, starts with an original training set and expanded gradually with the help of clustering structure which is generated by DGSOT. Comparison of their method with the random selection and Rocchio Bundling techniques with respect to accuracy improvement and training time gain has been done on benchmark DARPA 1998.

In [41], a method comprising of filtering, discretization and classification methods to maintain the classifier's performance results with a reduced features set of KDD99 has been presented. The new reduced training set is created using two class binarization techniques [34](One vs Rest and One vs One). The process of creating reduced training data using 3 different manner described in section 7.3 [41]. In all these 3 newly subset, original training set containing 494,021 connections are reduced to 46,093, 494,021 and 46,093 connections.

Classification on KDD99 dataset have been done using functional network and performed comparison with other techniques (Different SVM models, ANOVA ensemble and linear perceptrons) [23]. Basically functional networks are general form of neural networks which consists of input layer, output layer and one or more computing layer as well as contains knowledge about structure of the problem and data [24]. Implementation has been done using polynomial, Fourier and exponential functions.

In [26], a new hybrid learning method is presented on the basis of features such as density, cluster centers, and nearest neighbors (DCNN). The number of features has been selected using Fisher Scores and SVM are 19 which is similar to work in [27]. And performed comparison of DCNN with CANN [31] and k-NN with k=21.

In [4], another model based on CNN-IDS is proposed. The original connection/traffic vector is converted into an image format to reduce computational cost and performance of proposed CNN model is examined on KDD99 dataset. Feature reduction is done using PCA and Auto Encoder (AE). CNN also used in [22] and shows approximately similar result.

A wrapper method uses GA and Logistic Regression (GA-LR) as a search strategy and a learning algorithm respectively for network IDS to perform good feature selection has been presented [28]. Three decision tree (NBTree, RF and C4.5) are used for classification. The experiment was conducted on two standard KDD99 and UNSW-NB15 dataset. Different subset of attributes are created using GA-LR of size 15, 16, 17, 18, 20 and 22 from NSL-KDD among which best subset is selected of size 18. Similarly with UNSW-NB15 (Size of best subset selected is 20). As scope of this paper is within KDD, result of C4.5 with reduced attribute is shown in table 2. The symbol '-' in table 2 indicates value is not provided in the corresponding paper.

IV. Conclusion and Future Work

In this paper, comparative analysis of different classifiers based on the recall of each five class from different research papers with overall accuracy is shown in table 2. Most of these researches mainly focus on overall classifier accuracy, time complexity etc. Classifier accuracy is affected due to majority classes. As R2L and U2R are minority classes so their detection rates are not very good when base classifiers such as kernel Miner in [48], J48 or C4.5 and NB in [50], (J48, RF, KNN, NB) in [49], pure SVM in [42] are used as shown in table 2. Also variation in SVM (OAR, OAO, DAG, ADAG, ECOC, combine with Rocchio Bundling) unable to give good DR of R2L and U2R [42], [52] but its proposed method gives better result . In some research papers Neural Network has been used for classification such as functional Networks in [23], CNN in [4] does not provide good solution for minority. Performance of classifier should be evaluated not only based on overall accuracy but also with respect to DR of each class in dataset. With an appropriate pre-processing or combining some technique to base classifiers such as C4.5, SVM+DGSOT, DCNN, BC+k-NN provides some improvement to U2R and R2L DR [26], [28], [41], [42], [49]. ABC-AFS gives best result compared to all other classifers.

The false detection of minority class will lead to many discrepancies in IDES. There are a lot of techniques exists that enhanced classifier accuracy by improving majority class detection rates. We should explore also techniques to correctly detect rare events or minority classes without effecting detection of majority classes which will cause classifier un-biased and add on its enhancement. Also will evaluate ABC-AFS on other imbalance dataset.

***Abstract*— The field of educational data mining has enabled the researchers, educators to predict the student's pass rate, failure rate, dropout rate etc. The main reason for dropouts of the student is the failure of students. Several researchers have proposed various educational data mining techniques for predicting the student performance and analyzed existing techniques on educational datasets. In this paper, we have analyzed the performance of four machine learning algorithms on educational dataset used for the early prediction of student performance. While there is a rich literature survey in student performance prediction, our work differs from existing works as follows:(i) Our prediction is not limited to binary classification of pass and fail but we have used a multiclass classification in which student are divided into three classes namely poor, average, good performing students;(ii) We have used data preprocessing, feature extraction, fine tuning of parameters of algorithms to build the model which is not focused by many researchers;(iii) We have built a more accurate model with 95% accuracy and lesser execution time;(iv) We have studied the relationship between various attributes through a correlation heatmap. This paper will elaborate on student performance prediction techniques and give a comparative study among them.**

Keywords—data mining; educational data mining; student performance prediction; prediction analysis; dropouts

I. INTRODUCTION

Over the last few years, the field of educational data mining saw a huge increase in number of researchers. Educational Data Mining can be applied in several areas such as user grouping, student performance prediction, user modeling or profiling, trend analysis [1]. New statistical methods, machine learning algorithms are being developed by the researchers to mine the educational data for a better understanding of students, teachers and their different attributes [2]. The inspection of educational data to upgrade performance of students and teachers is not a very new thing [5]. Due to the latest advancements in institutes, expansion in computing facilities and web-based learning has attracted researchers to create new techniques for examining the educational data [3]. The data can be taken from the admission system, registration system, and library management system, syllabus management and course management systems [4]. Data can be used to predict student performance [6].

Educational Data Mining used in this research, predict the students' performance by using four machine learning techniques namely decision tree, random forest classifier, gradient boosting classifier and extreme gradient boosting classifier. There are various classification techniques applied by researchers to predict student performance [7]. Only few of them addressed multi-class classification with good accuracy and lesser execution time. Also, very few existing works studied the relationship between attributes and only few considered selection of relevant attributes as an essential step to predict student performance and fine tuning of algorithm parameters. This research will give a more accurate model by which the teachers or administrator not only predict the failure of the students but also categorizes them according to their levels. Necessary steps can be taken by administrator, teachers and students to prevent failure and to improve performance. This will act as alarming system to students reflecting their drawbacks [8].

The rest of the paper is organized as follows. Section II describes the existing works related to this research. Section III describes the dataset, feature extraction process, and gives the relation between attributes through a correlation heatmap. Section IV describes proposed methodology to build our prediction model. Section V discusses the result achieved by the model. Section VI summaries the paper by giving a conclusion and discuss the future work.

II. RELATED WORK

Number of researchers had proposed various prediction models for the prediction of students. This section elaborates some of the related works.

In [9], the authors proposed a bilayered structure which consists of ensemble predictor and base predictor using which student's performance in degree program was predicted. The dataset was collected from University of California after examining the undergraduate students over 3 years. There was diversity in datasets as major, culture and specialization of students was different. The courses which were relevant for

student performance taken for student performance were chosen by probabilistic matrix factorization. The research work was only confined to courses which were mandatory but did not consider elective courses for prediction.

In [10], a predictive model was proposed by the authors to predict the academic performance of students. Three classifiers namely J48, PART, RIPOR were modeled on the dataset of 932 students of a University in Columbia to analyze and evaluate their performance. It was found in the research that after four iterations, J48 performed the best among three classifiers which were used. Highest accuracy which was achieved by J48 classifier after 4th iteration is 86.4%. Data preprocessing, attributes selection had a significant effect on accuracy of the model.

In [11], the authors proposed a K-means clustering analysis on student data through which students were clustered into different clusters as a good or bad performer. During the placement and admission process, this analysis was found to be helpful. The internships, projects, skill sets, SSC, HSC, and B.E. marks were few parameters included for this analysis. The implementation was very easy. However, there is need to involve socio-economic attributes in student data. In future, other efficient clustering techniques like Fuzzy C-Means should be applied to improve efficiency.
