***Abstract*—With the disturbing rate of utilization of water assets in these days' universal, water deficiency has develop as more noteworthy recognized than any time in recent memory. Collecting water is a territory frequently track upon yet the idea of shrewd water gathering includes handiest come inside the type of thoughts, no longer executions. This proposed framework also is an idea to modernize water collecting anyway the sketches toward its usage is in progress and execution is a genuinely spotless test. The well known setup albeit adaptable, incorporates an expanded floor whereupon a water sensor controlled with the guide of Arduino is fixed. A servo engine also is snared to the water sensor and is fueled through the Arduino. Upon the commonness of water, the water sensor turns on and signals are sent to the Arduino. The code on Arduino is handled following inside the initiation of servo engine with the end goal that a gulf for accumulating water opens up. At the same time, an electronic mail is sent to the individual's cell to tell him/her on each event the gulf endless supply of precipitation and accordingly closes once it's finished. Along these lines, our proposed framework moves in the direction of the advancement of water the board in towns, making it another assignment closer to gathering water the shrewd way.**

Keywords—Arduino, servo motor, water sensor, water management

I. INTRODUCTION

As per the United Nations World Water Development Report, propelled 19 March 2018 all through the eighth World Water Forum, and related to the World Water Day, the overall interest of water has been expanding at a cost of 1% predictable with yr amid the last numerous years as a result of people increment, financial improvement and another in admission design among various components and could keep on developing widely in the predictable fate. It's fundamental to address the world's water requesting circumstances in the meantime as simultaneously giving over additional preferences vital to all components of economical improvement. Supportable improvement has been characterized as "progress that meets the desires of the current without bargaining the limit of things to come ages to satisfy their own needs". In expounding the idea of feasible improvement, the writing has ceaselessly determined that individuals – which incorporate town occupants are people in biological systems, and that they might be at last chargeable for versatility and sustainability of surroundings assets and contributions. Networks in this way need to search for techniques to both remain adaptively inside the stacking capacity offered to them or begin ensuring assets including water. A standout amongst the most not irregular methodologies to moderate water for across the board capacities or for groundwater energize is downpour water gathering [1].

Downpour Water Harvesting is a demonstration of getting and putting away water for later use. As we perceive water is the most perfect state of water, this water can be used for various purposes after significant refinement technique as required. Water lack isn't bizarre in nowadays' enormous urban areas and the regular machine of water reaping is less more then likely for use in the present currently developed houses. Thus despite the fact that water gathering can be incredible in those districts it's presently not renowned adequate because of its technique for usage which has now not prevalent with time [2].

(A) History

The shooting and putting away of water is a way that goes again bunches of years while individuals started to cultivate the terrains and required ways to deal with inundate plants. In warm atmospheres, getting precipitation consistently chosen ways of life or death toll for a couple of networks. While the requirement for keeping water fell away because of urbanization inside a definitive a huge number of years, we by and by need to return to this well established and quintessential piece of greener dwelling.

Human advancements inside the Indus Valley had been far additional unrivaled than we may might suspect lately. In some of the authentic urban areas that still remain, we will in any case find colossal tanks that were sliced into the stone to amass water

while there has been heavy precipitation. These have been utilized to safeguard the masses and neighborhood plants going into more sizzling, dryer times and had been nourished by severa stone ravines that weaved their way through the city. A portion of those stone tanks are as yet utilized these days in segments of India.

Another methodology that has been utilized for many years in India is to develop water reaping frameworks on apex of the tops of homes. It's a basic age that has unfurl the world over, for the most part to nations comprehensive of Brazil and China [3].

The period of water gathering is profoundly established inside the social material of India with an assortment of notable strategies in any case found today. These include:

Talibs: Medium to monstrous measured stores that give water system to plants notwithstanding expending.

Johads: Dams which are utilized to catch and hold water.

Baoris: Wells delved into the ground that are as often as possible regardless utilized for devouring.

Jhalaras: Specially developed tanks which can be utilized for the neighborhood individuals and otherworldly capacities.

Aside from India, for the term of the season of the Roman Empire, water arrangement have moved toward becoming something of a craftsmanship and innovation, with numerous new urban areas fusing kingdom of the fine art time for the time. The Romans had been aces at these new patterns and impressive advancement was made right up till the 6th Century AD and the standard of Emperor Caesar [4]. One of the greatest surprising water gathering structures might be found in Istanbul in the Sunken Palace which ended up used to gather water from the boulevards above. It's large to the point that you can cruise round it in a ship.

(B) Present Day

In China and Brazil, rooftop water reaping is polished for giving water to local use, devouring water, water for animals, water system purposes and reviving ground water. Gansu region in China and semi-dry North East Brazil run considered one of the biggest tasks for water reaping.

In Beijing some lodging gatherings right now are including water in its transcendent water sources after right cure.

In the US, until 2009 in Colorado, water reaping ended up controlled however at this point proprietor of the inhabitant is permitted to put in a housetop downpour accumulation framework as long in light of the fact that it meets the predefined criteria.

In Ireland, Professor Micheal Mcginley of Dublin University College established a dare to structure a downpour water reaping model inside the normal gadget configuration adventure module [5].

(C) Types of Rainwater Harvesting

Water Harvesting is widely isolated into two techniques:

- Surface Runoff Harvesting
- Rooftop Rainwater Harvesting

In this paper, we can be for the most part speakme around housetop water gathering as it's far less exceptionally estimated and more prominent powerful whenever did appropriately can help with enlarging the ground water level of the region.The gadget uniquely comprises of catchments, conveyance and channel out [6].
Catchments: The surface or bay that straightforwardly gets the precipitation is named the catchment of a water reaping framework. It might be the porch, patio, or cleared or unpaved open floor. The porch can be level RCC/stone rooftop or inclining rooftop. The inconveniences that outstanding here are:

i) The tidiness of the rooftop and subsequently the water. A delta that might be evacuated and cleaned off frequently could suggest less cost required for filtration.

ii) Houses in urban areas nowadays aren't worked with open and level housetops. The build of a housetop ordinarily depends upon elements alongside climate, esteem, look and usefulness. Contributed rooftops are regularly utilized atmospheres with heavier downpour and snow fall as they offer quicker and less entangled water dropping and seepage of the rooftop. For example, progressively contributed rooftops might be discovered the northern region of the USA where more snow and downpour gather and a wonderful arrangement all the more level rooftops in the southern region of the USA where considerably less snow and water aggregates.

II. LITERATURE SURVEY

Recent researches have contributed to the improvement in the region of IoT through this paper we can have a short idea of a mission that is to grow a shrewd water gathering process making utilizing IoT. In our writing overview we've alluded and considered uncommon examinations papers in regards to the major idea of IoT. Utilizing IoT in different fields to associate things, administrations

and individuals for reasonable tasks is a pattern now a days in vogue innovation.

The Internet of Things might be utilized for getting the correct amount of water on the correct goal for the best possible time frame and most straightforward when needed. This can be the errand of extraordinary soil sensors and climate sensors as an approach to talk their readings to a particular server. Web of Things age furthermore permits in booking the upkeep just as the shutdown of siphons on a customary establishment. There are streamlining methodologies which could progress of time convey to the inhabitants of a city with respect to the inaccessibility of water for the term of any exact factor in time. This empowers the water guideline government not most straightforward in gathering the alright water needs in a city; rather it additionally helps inside the preservation of benefits and quality [8].

The forces of IoT were utilized significantly by method for a couple of organizations who've taken a stab at keen water control. The accompanying posting obliges of a portion of their endeavors toward the worldwide endeavors of keeping water the utilization of IoT:

- Smart Monitoring-To dissect water cure framework and control it from wherever each time
- Smart Watering Techniques to vegetation-Water the vegetation as steady with their prerequisite
- Smart Water Meters Status-Calculates the use of water and as reliable with the ordinary programming just that tons amount of water is outfitted.
- Potable Water Monitoring-Monitors the top notch of faucet water
- Chemical Leakage Detection in streams Detects the measure of spillages or wastage tossed in waterway
- Swimming pool far away estimation Controls the pool conditions and necessity of water
- Pollution levels in the ocean Controls the seawater to get defiled
- Water Leakages-Detect the spillage and help to find the deficiencies
- River Floods-Monitors water level varieties in water bodies

III. PROPOSED MODEL

The proposed system that we have developed draws inspiration from a combination of various existing smart water management systems that already exist. It is therefore not a direct emulation of said systems but rather a hybrid of the most efficient kind. Firstly, it takes inspiration from the IWCM that has come up with an elaborate water harvesting scheme suitable for both rural and urban areas. The system that it has proposed works in a similar fashion, except that the is collected in different containers that are spread over the entire locality. It also consists of water level indicators fixed to the inside of the containers in addition to vents that open up to catch rainwater. Second inspiration is drawn from Project ph 5.6 that deals with the act of rainwater harvesting but in a smart way [16].

To obtain the most sustainable, economical & efficient water management system, certain architectural requirements are to be fulfilled. Only upon the fulfilment of these requirements can the system produce successful results in the long run, thus enforcing more of its production in the market & enabling various companies & communities to study from it and go on to improvise upon already existing features so as to procure an even better model for smart water management. The body of Integrated Water Resources Management (IWRM) has laid down the following requirements that the architecture of a water management system using IoT devices will need to comprise of:

Requirement no. 1: The following water management functions should be covered by the system:

1) Remote management of physical elements and operation of basic units

2) Identification of resources in the water network

3) Definition of operations and conditions over the network.

Requirement no. 2: It should support interoperability with other applications such as geographic information systems and also databases containing information regarding soils, weather forecast, environment, farming, etc.

Requirement no. 3: It should provide a flexible and extensible architecture for the integration of various systems. To do that, it must define open interfaces among communication and process control layers, and also integrate IoT systems for a direct access to individual water management devices.

Requirement no. 4: It should support integration with legacy systems, controlling current equipment. Water management infrastructures currently deployed in the countryside consist of many interconnected and simple devices that must be managed using legacy systems. They integrate communication functions, data models, and protocols dependent on an specific technology of the

manufacturer. Overriding these systems with new ones is not always a feasible solution [10]. Figure 1 gives the block diagram of the proposed model.

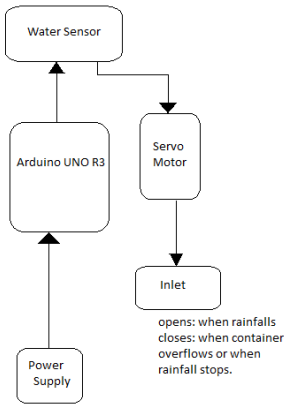

Fig. 1:Block Diagram

The set-up, despite the fact that worked to solid little scale attempts can likewise deal with colossal scale provided the fundamental substance of the gadget is consolidated.Right off the bat, the downpour water falls upon the outside of the water sensor that is fixed onto the surface with the end goal that it faces the skies. After detecting the downpour beads, the water sensor turns on and begins to send alarms to the joined servo engine. A servomotor is a revolving actuator or direct actuator that lets in for explicit oversee of rakish or straight capacity, speed and increasing speed. It comprises of a proper engine coupled to a sensor for capacity remarks. This sensor is in developed to turned out to be associated with the sliding entryway on the floor of the floor that slides open to uncover a social affair compartment for reason of finding approaching precipitation. As the water gathers into this field, alarms are effectively sent to the harnesser to signify water levels. On the exercises of flood of water into the container, the entryway naturally closes in the wake of alarming specialists that the crate has been full to the overflow. This water accumulated is eventually utilized for different human and mechanical games. It can similarly additionally be sent for filtration if in any regard it gets dirtied upon end starting from the earliest stage [14]. Figure 2 depicts the working flow of the proposed model and Figure 3 and 4 shows the result of the model.

Proposed Algorithm

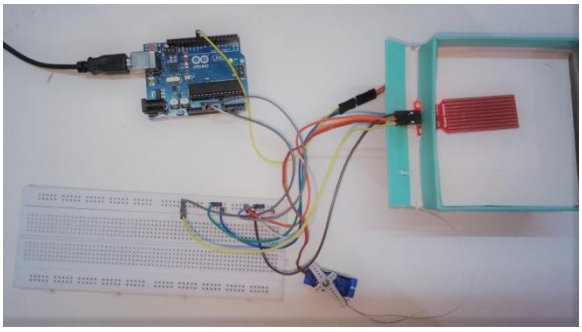

Fig 3: Closed Inlet

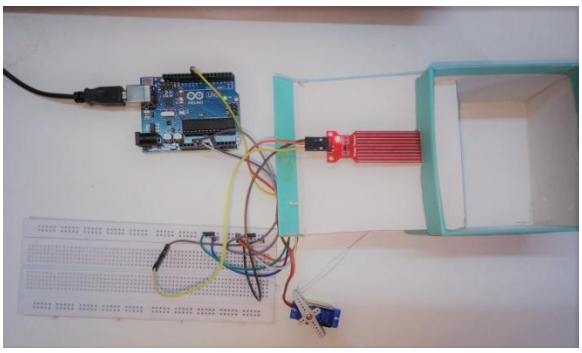

Fig. 4: Opened Inlet

IV. CONCLUSION

The Smart Rainwater Harvesting has to be used in an powerful and possible thing such that it is able to mitigate the effects of depleting groundwater degrees and fluctuating climate conditions. This is extraordinarily a present day research field and it's miles anticipated to grow in future. There is lot of

labor to be achieved in this rising area. Here we get primary expertise on how the water harvesting may be advanced based on the outcomes achieved from this device.

***Abstract*— The demand of highly functioning storage systems has led to the evolution of the filesystems which are capable of successfully and effectively carrying out the data management, configure new storage hardware, have proper backup and recovery it as well. The research paper aims to find out which filesystem can serve better in backup storage (e.g. NAS storage) and compute-intensive systems (e.g. database consolidation in cloud computing). We compare such two most potential opensource filesystem ZFS and BTRFS based on their file I/O performance on a storage pool of flash drives made available over iSCSI (internet) for different record sizes. This paper found that ZFS performed better than BTRFS in this arrangement.**

Keywords—bandwidth, block device, BTRFS, file I/O performance, filesystem, iSCSI, storage pool, subvolume, ZFS

I. INTRODUCTION

Back in 1920s, even storing a byte required expensive magnetic tapes and today just a simple image file shared over internet is in MBs. From magnetic disks to optical ones and from hard disks to flash drives, the hardware evolution for storage has immensely decreased in its physical size and enormously increased in storage capacity, access speed, portability and ease of use. The hard disks have moving mechanical parts to perform operations and the SSDs have none, which makes them less prone to failure due to the physical damage occurring within. Thus, the use of SSDs is a better choice in storage environments. The new NVMe technology is even faster than SSDs but it puts a lot of load on PCI, hence the limited use-cases-- advanced analytical apps, DevOps, etc.

Today storage demand has become so massive that it is a challenge to maintain the data, expensive hardware, its backup & recovery and other infrastructure involved. To address the issues, the industry has evolved to adopt the use of storage controller, storage hypervisors, etc. When the need of more storage strikes, it requires businesses and organizations to expand their storage, mostly to scale it up. To achieve higher, proficient performance and lesser downtimes, the storage has to execute many other CPU intensive tasks such as compression, data deduplication, checksum calculations, snapshots, cloning data, etc. Addition of new hardware and configuring it into the system stresses out the central controlling and processing system. To avoid this, there is a scaling-out storage approach, which adds compute resource along with the storage.

As filesystem are the basis of storage, they need to handle such extreme degree tasks and meet the need. Two such promising and flexible opensource filesystems are ZFS and BTRFS. They are not just filesystems, but include volume managers too, which makes them a faster and complete stack above storage (on the other hand, Ext4, XFS and other filesystems do not have such mechanism built-in). Both ZFS and BTRFS have distinguished features structured into them in their own different ways.

This paper aims to study these two filesystems as per their File I/O performance, when the storage is provided over internet in RAID 6 configuration with default pool settings. We analyzed that ZFS has intelligent ARC cache mechanism which boosts its performance in read operations. We used asynchronous writes that is why its ZIL (ZFS Intent Log) feature was not used (else for synchronous writes this feature makes the writes very reliable) but the approach used to write the data from buffer to disk in form of transaction groups helped. BTRFS on the other was limited by the record size and the absence of cache. Hence, this thesis recommends ZFS as the designated filesystem in the backup storage system (or in NAS storage).

Next section briefs about different work already done to compare these two filesystems. Section III presents the experiment of this paper in detail. Then, performance results are discussed in Section IV. The results are more analyzed in Section V and finally Section VI concludes the outcomes of the experiments conducted.

II. RELATED WORK AND BACKGROUND STUDY

Our previous work [1] presents a detailed literature survey for this experiment. This section includes its brief summary, describes important terminologies necessary to understand the experiments and reasons why the experiments are setup in a certain way.

A. Brief literature survey summary

Most of the experiments previously done were on native computer system, that is, there was no communication between two systems for storage over internet. Several authors have examined the performance of these filesystems over different storage configurations, like for single disk, multiple disk, other RAIDs based on the use of different types of disk accessing protocol, record sizes, file sizes, mount options, hypervisor, microbenchmark and macrobenchmark tests. [2] illustrates the data structure of BTRFS and how checksums are calculated in case of disk failure for data recovery. The paper [3] presented the performance of ZFS and EXT4 on SATA disks over iSCSI and found that ZFS worked better with increasing number of disks. The paper [4] which asserted the effectiveness of the in-built defragmentation tool of BTRFS is a special mention.

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

Apart from the performance comparisons, [5] study of end-to-end data integrity about ZFS bought attention to the big security issues of memory corruption for ZFS. Thus, filesystems bring security challenges of access control, encryption & data integrity along with them.

B. Background Study

Filesystem is the data structure that governs how data is written to and fetched from storage media. So, when working for storage, first the disks are to be formatted with a suitable filesystem. Next comes mounting it to the system and one can choose to configure the disks as a storage pool using different RAID combinations instead of using single disks. It is actually faster in performance, proper data management and most important, backup and recovery in case for failure or disaster. Volume managers are required to achieve such configurations. ZFS and BTRFS both have their own volume managers, so they directly communicate with the block devices, which makes them faster than that of using the volume manger provided by the host OS, in our case, by Linux. ZFS has an advantage that when a storage pool is created, it is by default mounted with proper settings as well. Whereas, for BTRFS one has to mount the disks via the native *mount* command provided by Linux. Both of these filesystems provide great features like compression, data deduplication, checksum, creating snapshot, subvolume and clone of data, etc. Checksums prevent the silent data corruption and help in data recovery. When mounted in default mode, the compression and data deduplication are set off for both filesystems and checksum calculations are kept on.

There are different ways to test the working and efficiency of the filesystems. Either to test their functionality one at time or test them under real life working scenarios. The former tests are microbenchmark tests and latter ones termed to be the macrobenchmark tests. This experiment tests the File I/O performance (which majorly focuses on how the filesystem executes its read and write file operations) of the filesystems for various record sizes. The *record size* is the unit of data that will be handled at a time while performing the read and write operations. The operations are to be performed asynchronously, it means, that they are first written to journal of the filesystem and then performed to the actual storage media.

For the experiment setup, Linux OS was the best choice as it is easier for debugging and has compatible options for storage subsystems [5]. iSCSI that is an IP storage protocol for mapping the block-oriented storage data over internet [6], is emerging strong because it can be implemented over larger distances & provides security with IPsec [7]. For iSCSI to work, some target technology is required to configure the LUNS at the target system. The paper [8] studied various Linux iSCSI targets like STGT, LIO, SCST, IET and deduced that SCST has many advantages over others such as it has better support for back-storage handlers in both kernel & user space, has easy session management & target configuration, etc. Flash drives are chosen as the storage which work alike SSDs. The next section covers the detailed approach of the experiment.

III. Approach And Methodology

The approach to this experiment is to create a scenario where an initiator system could use the storage provided by the target system over iSCSI as block device. The target system already would have the storage pool configured with the respective filesystems. The initiator should be able to write and read files to that available storage with the help of open-iSCSI. The tests examined the storage for I/O having variable record sizes of 32 KB to 32 MB and 512 B and results were recorded.

A. Environment Setup

The configuration for this experiment involved three computer systems. Out of which two behave as target, each for ZFS & BTRFS and the third as an initiator. The hardware specification of all these three computer systems are same, the details can be found in Table I and software information in Table II. Table III shows system specific software information.

TABLE I. SYSTEM HARDWARE

System Hardware	Specifications
Processor	Intel(R) Core(TM) i7-3770 CPU @3.40GHz
Memory	3GB
Motherboard	Hewlett-Packard 339A

Each of the target systems creates the RAID 6 storage pool (with default mount and pool settings) out of four 8GB SanDisk Cruzer Blade USB Flash Drives and subvolumes were created to be given as storage block device to hand over the storage over iSCSI to initiator. At a time only one target communicates with the initiator.

TABLE II. SYSTEM SOFTWARE

Software	Specifications
OS	Ubuntu 18.04.1 LTS
Kernel	Ubuntu 4.15.0-44-generic

TABLE III. SYSTEM SPECIFIC SOFTWARE

System	Specifications
ZFS Target	ZFS version 0.7.5-1 ubuntu15
BTRFS Target	btrfs-progs version v4.15.1
Initiator	FIO version 3.1

B. Testing Tool

The Flexible I/O Tester Benchmark is used for the experiments in this thesis (refer Appendix E for installation). Microbenchmark operations such as sequential write, sequential read, random write, and random read help to analyze filesystems better. Each test ran for 600 seconds with a varying record size of 512 B and from 32 KB to 32 MB. After completion of each test, both target and initiator were rebooted. After the completion of all the tests for a particular record size once, the RAID 6 was reconfigured at target system. For more accurate results a set of tests was repeated for a total of five times. The output file has all the metadata of the execution. Here, the output file is of JSON format, hence easy to read and navigate.

C. Capturing IO Statistics

ZFS was benefitted by its built-in *iostat* tool to acquire the I/O. As BTRFS has no such tool of its own, I/O was acquired using the functional Linux utility *sysstat iostat*.

IV. Performance Results

This section presents the final performance results of the experiments organized by the type of experiment. The captured IO results of the five repeated tests were averaged for all of the record sizes.

A. Sequential Write

Fig 1 shows the write performance of ZFS and BTRFS over RAID 6 for sequential write operation. ZFS performs consistently better for increasing record sizes with write bandwidth of 3.3MBps to 4.3 MBps, whereas BTRFS fluctuates more. For record size 512 B and 8 MB there is approximately equal performance difference.

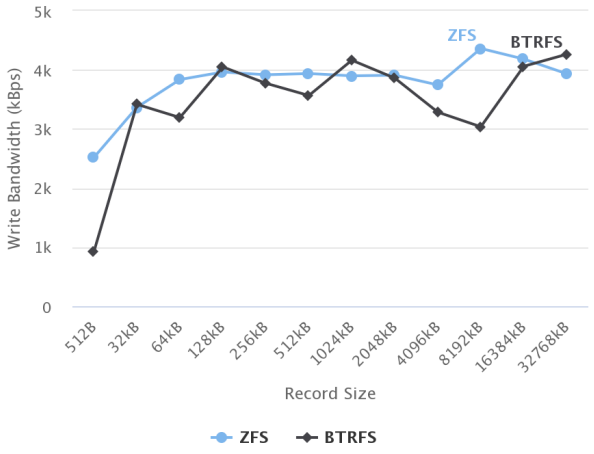

Fig. 1. Write Bandwidth for Sequential Write test.

B. Sequential Read

Fig 2 indicates the read performance of ZFS and BTRFS over RAID 6 for sequential read operation. Clearly, ZFS outperformed BTRFS with read bandwidth of 9.5 MBps to 10.5 MBps. Very vast performance difference can be noticed between these two filesystems.

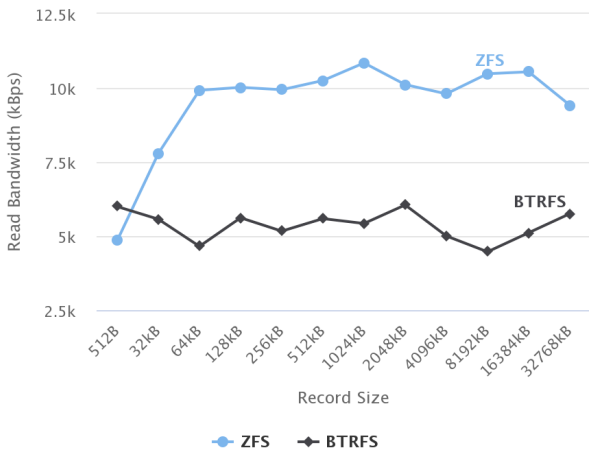

Fig. 2. Read Bandwidth for Sequential Read test.

C. Random Write

Fig 3 depicts the write performance of ZFS and BTRFS over RAID 6 for random write operation. BTRFS performed better than ZFS with write bandwidth of 3MBps to 4.5 MBps. ZFS here again had a consistent run. A big performance difference was seen for 1 MB record size.

D. Random Read

Fig 4 shows the read performance of ZFS and BTRFS over RAID 6 for random read operation. ZFS read better than BTRFS and as record size increased from 256 KB, its read bandwidth hiked. Massive performance difference was observed between these two filesystems.

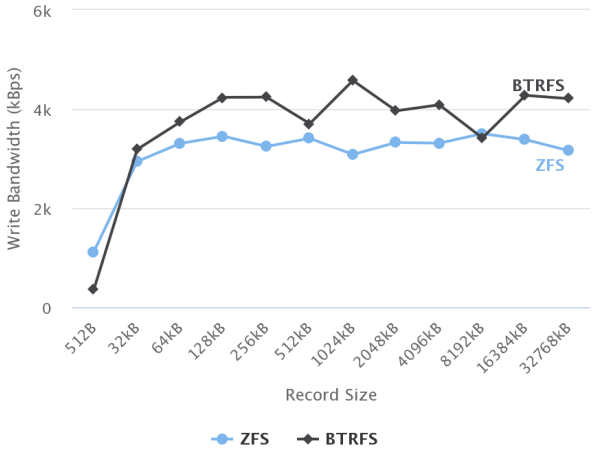

Fig. 3. Write Bandwidth for Random Write test.

V. Analysis

The outstanding difference in ZFS' performance for both sequential and random read operations is the use of primary cache. ZFS by default has the primary cache enabled. This cache is part of RAM and is resizable from 64 MB to 75% of the system's RAM. This cache is governed by the ARC (advanced replacement cache) mechanism which is a combination of MRU (most recently used) and MFU (most frequently used) replacement policies. ZFS keeps data as records and such records are composed of blocks.

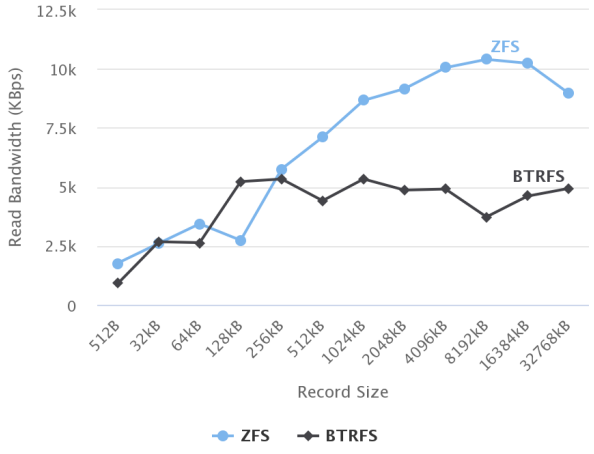

Fig. 4. Read Bandwidth for Random Read test.

For sequential read, as block size increases, the data being transferred increases too. After a certain block size (e.g. 64 KB in) the bandwidth becomes steady due to following reasons: first, as the ARC cache is intelligent to predict the next demand in data, it is pre-fetched, which improves performance. This is helpful in the situation where the block sizes are increasing and there is frequent transfer of data from storage pool to cache. Second, ZFS has to validate data before bringing it into cache which consumes time.

These both factors sort of balance each other and give near to steady performance for varying block sizes.

For random read, similar reasoning is valid. Although, as the data here is accessed randomly, the data pre-fetching does not work as such. But ZFS succeeds in dealing with this by maintaining the ghost MRU and ghost MFU lists in the ARC cache. The data, which is replaced from the cache, gets its metadata linked to these ghost lists, making them faster to access on next demand (also there is no need to validate the data again, thus saving time in checksum validation). Another factor that influenced the performance here is that the random write operation experienced some frequent pool damages (e.g. for block size 128 KB) which led to performance degrade for the next random read operation. Similar dip in performance occurred for block size of 32 MB. There are other block sizes for which the damage occurred, but they were not as frequent as the above-mentioned block sizes. These damages might have taken place due to iSCSI or network connection errors.

Coming to ZFS ability to carry out asynchronous sequential and random write, the ZIL (ZFS Intent Log) feature is not functional by default. ZIL is a logging feature for synchronous writes only. In our case with sync property of pool set as standard, writes are buffered in the cache and after an interval are written to storage disks as transaction groups. So ZIL is not at all functional. But the intelligent mechanism of how blocks are picked up for writing comes into play. The devices in storage pool are divided into metaslabs which contain the blocks. These might blocks vary in size to a maximum of record size. Data blocks are written in localized metaslabs (termed as active metaslab) of the devices and adjacent to same sized blocks. Metaslab has a data structure which keeps track of free space in that particular metaslab. This speed up the process of finding location to save the data. With ZIL enabled, the synchronous write.

Whereas, with ZIL enabled, the synchronous write addresses the data integrity but creates overhead of 2 writes (one to RAM and other to ZIL itself) and another 4 write penalties for the RAIDZ configuration of pool. In such case using a fast device as a SLOG will be beneficial.

BTRFS struggled as its default block size is the page size of the underlying OS, in our case 4 KB. Other limitation was that BTRFS does not use cache which degraded the performance. Also, we know in the case of ZFS that it suffered from some pool damage, but in case of BTRFS we are not sure that no such damage occurred or BTRFS was not able to detect it.

There are several scenarios where ZFS can be included in the storage system solutions. But to avoid monocultures, this paper emphasizes that sequential reads and writes should be considered and that too for backup and data warehouses.

VI. Conclusion

Storage as we know, serves various types of businesses ex. different kinds of servers, computational technologies, data driven support systems, database consolidations, supporting virtualization, backup, etc. The analysis conducted using the filesystem and disk I/O benchmark standard, Flexible I/O Tester on Linux highlighted the behavior of ZFS and BTRFS filesystems for write, read, random write, and random read operations over a storage pool of flash drives in RAID 6 configuration. We recommend ZFS as the designated filesystem in the backup storage system (or in NAS storage). This recommendation is supported by the features of ZFS that amplified its working with variable record sizes. ZFS has intelligent and scalable ARC cache which boosts its performance in read operations. We used asynchronous writes in which the data from buffer to disk was written in form of transaction groups and blocks are picked in a smart manner, which is very functional in random write operation.

Database consolidation and VM snapshot management workload can be designed to test these filesystems further. The setup for such workloads will be heavily intensive on memory, storage and CPU. Although this type of workload should be asynchronous, but if chosen otherwise, use SSDs as storage in RAID 10 configuration and NVMe disk as a SLOG device with ZIL enabled.

Abstract: **The data-sharing in cloud computing will enable many users to share the data. This helps in accessing the information easily and to share the data efficiently. The healthcare data will have to be shared amongst different healthcare centers and the medical practitioners. This involves security issues while sharing the healthcare data within a group. We provide the group model for sharing of data that is based on block based design where the group members will perform the key agreement to get the common group key that helps to shares the data securely. The fault tolerant property is provided by this design which can detect the malicious attackers during the group data sharing. The proposed group data-sharing is compared with the existing data sharing models w.r.t. the time cost of computation for group key generation and sharing of data.**

Keywords— Cloud computing, group data sharing, block based design, key agreement.

I. INTRODUCTION

The Personal health has been brought the great concern in modern residents. The population development and aging, the influence of health-care dictate and demands require for novel and the advanced solutions. At greater integration scale and lower cost, the availability of the computing re-sources has profited healthcare practices. With the help of development and success of the internet that plays an eminent role in maximizing the quality and access so the process is interrelated to the healthcare, which is determine the ICTs (Information of Communication Technologies) [1]. The E-health is defined as the ICTs application to the healthcare, which has come in normal use. While, these ICTs models can be considering many significance in the domain of healthcare, on top of the specific number of ICTs which is based on the emerged paradigm of health-care. There is a widespread use of electronic health record (EHR) [2]. Cloud computing is one of the popular health-IT infrastructures for facilitating EHR sharing. Healthcare providers and all the insurance companies store the electronic medical records in centralized databases .This includes maintaining health records, monitoring of patients etc.

The E-health can be widely defined as the ICTs application to the healthcare that has come in normal use. The co-operation between specialists in terms of the health experts, who can be working together efficiently, and generated their management in sharing and activities their information about the victim easier and in normal manner, and thus they can give cure to the patients. The systems of health are enable for citizen to have control their own health. However, there are security and privacy issues related to the health-care data. The security and privacy protection of cross-institutional electronic patient records is of major importance. The major concern is security in EHR networked systems and for communicating patient data. Here the physical security, network security, application security, internal systems security, secure data-backup strategy, secure internal policies and procedures, third-party certification are considered.

In this paper, our aim is to confirm the security of information sharing within a group in health care cloud security network. Here multiple data owners can freely share the outsourced data with high security. The entity authentication services are provided. The fault detection and fault tolerance is performed to identify the malicious user. We present the block design based key agreement protocol by extending the structure of the symmetric block design to support multiple participants. It enables multiple data owners to freely share the outsourced data. Here the adaptive symmetric block design is constructed as the group data-sharing model to support group data sharing in cloud computing. Here each group member performs the key agreement to derive a common group key to ensure the security of the outsourced group data. The help of group members can produce the normal group key. The semi-trusted and attackers of cloud server has no access to create the key. Cloud Security Service Third Party Verifier takes responsibility for the cloud storage auditing and key updates.

This paper is organized in such a way in section-II Literature survey, section- III described our proposed method, in section- IV, evaluation and medical outcome that is represented and in section- V conclusion.

II. Literature Survey

The research on various security and privacy issues related to health-care data is being addressed and many solutions have been proposed. In [3], the security and privacy issues of HER is given. The paper [4] provides the risk-management methods proposed for health-care environment. It focusses on managing the healthcare by using the fuzzy-logic. In paper [5] [6], it discusses the need in increase of standardized protection levels in the health-care network. In the paper [7], the security of personal-health record is proposed. It addresses the reduction of complexity in key management for the multiple record owners, which is used in the encryption of data being shared by patients to doctors.

In paper [8], it focusses on protected sharing of data in cloud by maintaining the information confidentiality and also the information integrity. The Protected secure data sharing methodology is used which will encrypt the files using only one encryption key. Two key shares technique is used wherein one key is given to user and other key is maintained by the verified third party. This helps in identifying the insider-threat and thereby the stealing of medical files being shared. The response for varying key size is demonstrated in it.

In paper [9], the secure method of resource sharing between more than one people whom from the group, is the main goal. The security and confidentiality is provided which helps in sharing the documents among multiple users of cloud. This paper provides advanced encryption scheme to encrypt the documents to be shared. The documents that are shared can be accessed once the verification of the accessing user is done and is valid. The aim of this paper [10] is provide the dynamic group-data sharing which will is useful for the health-care organizations to share their data that would involve other health organizations. In this paper they use the ternary-based tree approach which can have more health-care organizations and the computation of key used in sharing of messages would increase with the increase in number of member in group.

In [11], introduced the system of E-Healthcare, which is main role in civilization. This type of system aims at storing and collecting the details of patients and also sharing the information, which is related to the health. It has also higher concerns about the privacy of patient's and the security of information. It maximizes the systems of healthcare to isolated and remote locations, that has limited access to the remote healthcare and medical technologies, which can be provided via the telecommunications. They also gather the issues of health and personal information of real-time from the patients and send them to the provider of healthcare for authorized experts to decide on the corresponding cure. They transmit PHI in terms of image and text to Cloud and also personal problem which is interrelated to the medical history. A method for removing the authorized experts to decide on the corresponding cure, and has been broadly utilized in the storage f cloud to minimize the upload bandwidth and storage space.

In [12], MeDshare is addressed which provides a way to share the medical data which can avoid the privacy issues. This system can monitor which entities can access the data for any malicious activities. This can track the data that is being accessed. All activities are recorded and performed in proof way. The model of data sharing is utilized between the cloud-service providers, which is designing by block-chain. This design uses the smart-contracts and certain other mechanisms for accessing the data and to track the nature and behavior of information and have an access to the violated access done by malicious attacks etc. Auditing of data is achieved by this design. In paper [13], proposes the protocol of key exchange protocol that can be based on cipher text –encryption and policy that is attribute based. This establishes secure communication amongst all the participants who exchange messages among them. The attribute based encryption will make to achieve the user level privacy and data access control. Overall it achieves the secure way of communication among the fog-nodes.

III. Proposed Model

A) *System Model*

Fig1 shows the system model of sharing of data among different group according to our Proposed-SM (System Model). The model of system contains 3 entities such as Cloud, CSSTPV (Cloud security service Third party Verifier) and group members.

1) ***Cloud*** **:** the cloud gives the user with unlimited storage services. It gives convenient and efficient storage services for the users. The cloud here semi-trusted party providing data storage and data download services. The users who requires similar information and its related documents or files, will form a group and upload their respective data to cloud. These files can now be shared to other members of group.

2)CCSTPV *:* The client encrypts the information and upload it to cloud using key which is downloaded from the Cloud Security Service Third Party Verifier (CCSTPV) and is responsible for the storage of cloud auditing and give updates to key.

3) Group members: The group participants who wish to share the data to intended user first by identifying the group key, which helps in data sharing. With the fault tolerance capability, the member can identify the changes in the group key if any.

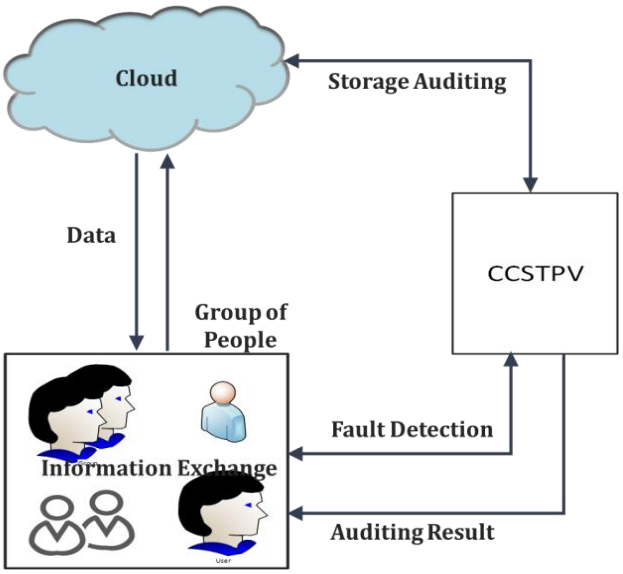

Fig 1: System model of information sharing according to the PSM

B) Construction of the model of Group data-sharing:

The group of information-sharing method applying the symmetric incomplete block based design i.e. (n, i+1, 1) design. It is a decentralized model. By this model, each user can identify the intended sender or receiver of message based on this model. Here n is the total users/participants as well as the number of blocks where blocks decide which user must belong to which block. This is decided by $n= i^2+i+1$. Each block will have i+1participants. Every single 2 participants appears simultaneously in the blocks of n. This in turn will decide to which block and in turn which participant the message must be delivered to. The generation of the (n, i+1, 1) design is explained in flowchart [Fig2].

The flow chart will give step by step details about the block based design. The user pos is the user position which specifies the column number and the block, the user will be belonging to. A sector is said to be group of blocks. For the generation of group key, each $block_i$ must have $user_i$. Therefore similar to above flowchart the steps are followed to generate another structure S which satisfies the block based design technique having property of each block S_i having $user_i$.

The Block diagram [Fig3] shows the block-based technique of group key agreement protocol and it is explained as follows:

There are 3 phases in the method of key agreement.

1. **Initial phase**: In this phase, the CCSPTV generates the parameters of system and distributes the private key to respective user and the public key to all the users. Mapping of private and public keys are done.
2. **Key generation phase:** Involves 2 rounds to generate the common group key. Users will receive the secret messages and then the common group key is generated. This helps in sending the messages to the intended user.
3. **Authentication phase**: This involves identifying the malicious users in the group, verification of authenticity is done.

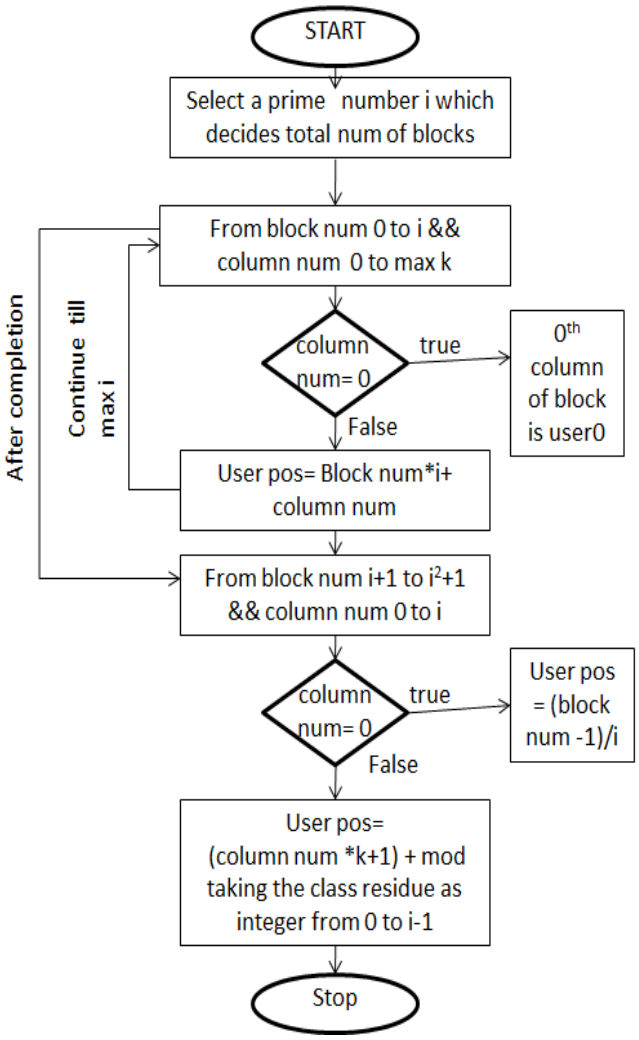

Fig 2: Flow chart of Block based design

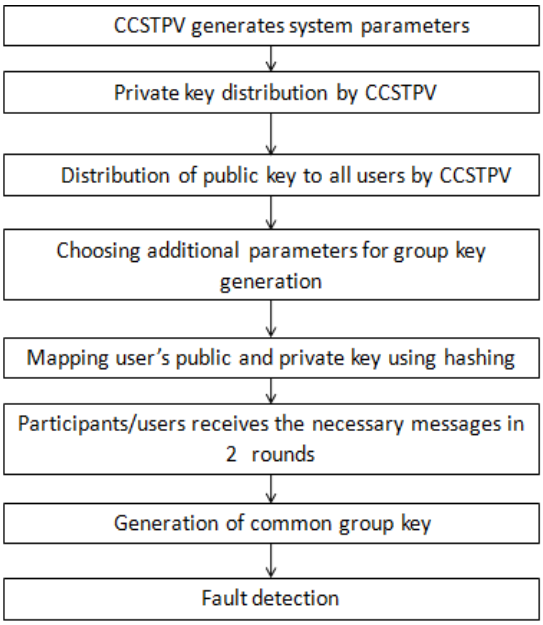

Fig 3: Steps of the key agreement protocol

IV. Simulation Result And Analysis

The experimental evaluation PSM is done using the C programming language. The PSM evaluation uses are the GNU and PBC (Pairing based Cryptography) more than one Precision of Arithmetic Library in VM-ware workstation (12) machine on the Cent-OS (6.7).

Our proposed system PSM is the proposed system model is compared with the IBFTA protocol. IBFTA protocol [14] is an identity based fault tolerant approach which is a key agreement of protocol which is used in exchanging messages among different users. The time cost comparison is done in order to identify which scheme is faster according to the design for exchange of messages, with the increase in the number of participants, both the protocols will have increase in cost for computation. The computation cost for multiple participants and for different phases is found and our protocol efficiency has been compared.

Considering the time cost, the comparison is done first according to the phases of key agreement protocol. Consider initial phase [Fig4], when the number of participants n=7, the time cost for computation in our protocol is 15.7% more efficient than IBFTA protocol [14]. When n=31, our protocol is 65% more efficient. The efficiency of our protocol is more when the number of users increase. When n=993, our protocol is said to be 99% efficient when compared to the IBFTA protocol.

In key agreement phase [Fig5], even when there are less number of users or more the efficiency when compared to IBFTA protocol [14] is high. When there are 7 users, total computation cost is less which is 90% efficient than IBFTA scheme [14]. When n=133 and n=993, the common group key generation is faster and this is 98% efficient to that of IBFTA protocol [14].

In authentication phase [Fig6], time cost when there are less users involved, n=7 our protocol is 8% efficient than IBFTA. In other cases, Yi protocol's time cost is more efficient than our protocol only in this phase. With increasing number of consumers, the time cost of our protocol in this phase increases. IBFTA protocol is 93% efficient than our protocol when n=993.The main reason is that in our case the modular exponentiation is done during this phase which takes more time and this is not the case in IBFTA protocol[14].

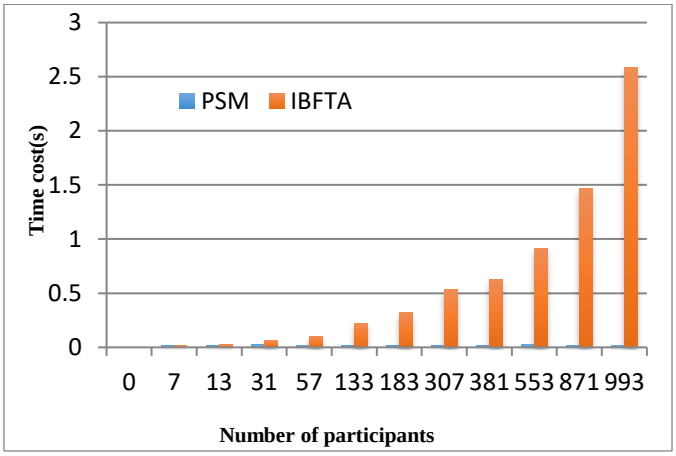

Fig4: Initial Phase

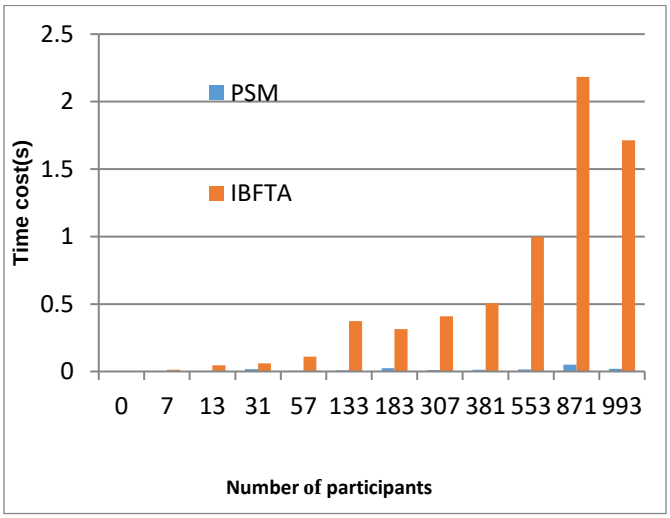

Fig5: Key Agreement Phase

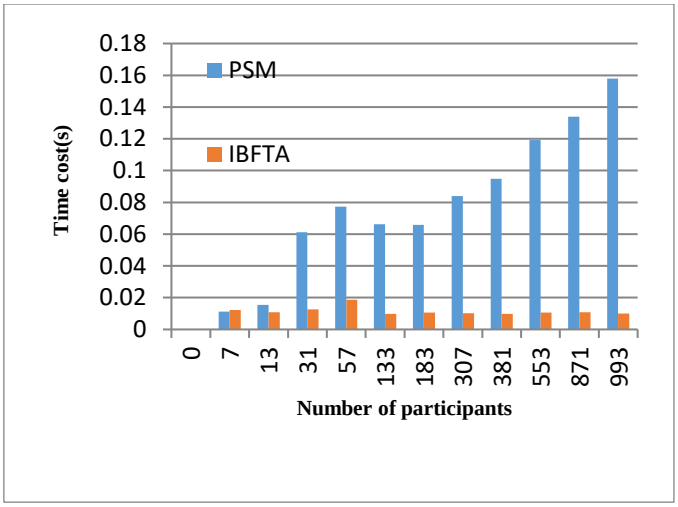

Fig6: Authentication phase

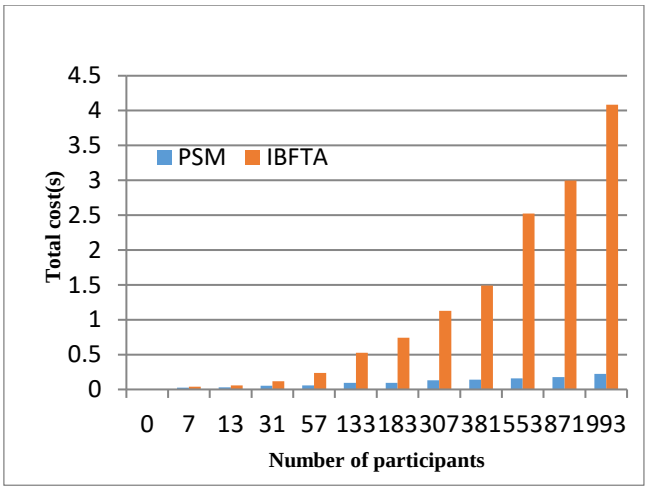

Fig7: Efficiency comparison for multiple participants

Comparing the efficiencies for multiple participants [Fig7], the total computational cost for the participants is considered. The computation cost for IBFTA protocol [14] continuously increases with increase in number of users (n). In our protocol this computation increases based on prime number i, which decides n. For 7 users, our protocol is 34% efficient. For 133 users our protocol is 82% efficient, for 871 and 993 users ours is 94% efficient all in comparison to the IBFTA scheme. Overall, our protocol is supreme compared to IBFTA scheme [14].

V. Conclusion

In this paper, the healthcare of data sharing is achieved by a block based design data-sharing model where, the data can be shared between different groups by generating the common group key. This proposed method involves different phases in group key generation and thereby the data-sharing is obtained. This method is much more efficient when compared with IDFTA w.r.t the computational costs. About 94% efficiency is obtained for the multiple participants for computation cost when compared to the IDFTA protocol. Therefore, our protocol is much more efficient in sharing the data in a faster way.

***Abstract*— now day's many industries are using autonomous robot due to their high performance and reliability and which is a great help for human beings. Autonomous cars, one of the most trending topics all over the web a car with no steering wheels, pedal, and with the most advanced technology autopilot. An autonomous vehicle is able to recognize there surrounding and finding the path there itself. Autonomous robot senses their surrounding with the help of different sensors such as Lidar, radar, ultrasonic sensor, infrared sensor; GPS etc. the control system used in autonomous vehicle read the information from the surrounding and find the appropriate path as well as the various obstacles are present on the path. Most of the autonomous vehicles are used for the obstacle detection purpose. In this project, the obstacle detection system is developed and the IR sensor usually used for the distance measurement. The sensor-based four-wheeled autonomous electric robot used to move the vehicle in the predefined path and avoid the obstacle during motion using the data logged from the IR sensor. Suppose during motion the robot doesn't have enough space to pass through the obstacle it must be stopped there itself or otherwise it moves by avoiding the obstacle. The system can be designed in Simulink environment.**

Keywords*— *Autonomous vehicle, Obstacle detection, Arduino mega 2560, Sharp distance IR sensors (Long and Short range IR sensor), Dual shaft DC geared motor, l298n dual h bridge steeper motor controller.

I. INTRODUCTION

The autonomous electric vehicle has received a lot of attention during the past decade and prototype versions of the autonomous vehicle have been developed by different vendors. Now, the research is going on autonomous vehicles all over the world, based on theories of innovation and leading design. According to this research produces various new technologies used in the autonomous vehicle and electric vehicle. Because of this autonomous vehicle there are lots of technology are used for the transportation purpose. Such as where we live, how created a new industry which build our cities and infrastructure. there are various names of Autonomous such as self- driving vehicle , robot or the car without driver etc. Is a vehicle that is able to sense it's surrounding and moves were safe and desirable. There is no human supervision is required for an autonomous electric vehicle, everyone in an autonomous vehicle is a passenger or it can travel with no occupant at all. The primary components of the autonomous electric vehicles are sensors, actuators, and controller unit Autonomous cars consist of multiple combinations of sensors. The real-time data that can be generated from the actuator such as servo motor that must be processed and analyzed to perceive their surroundings. The Autonomous electric vehicles emit less pollutant in the atmosphere rather than the conventional fuel engine-based vehicles.

There are various technologies are required for developing an autonomous vehicle such as radar sensor is used for detection of obstacle and after detecting object it measure the distance and angle of object. Lidar sensor is used for measurement of distance in the form of variable ranges. Ultrasonic sensor is also used for measurement of distance during the object is detected. Video is used for reading the road signals, direction sign, and nearby vehicles. A central computer collects and analyses all this data to help it steer, accelerate, and brake, as needed. The Potential benefits of an autonomous electric vehicle include increased safety, increased mobility, reduced costs, reduced crime, and increased customer satisfaction. And some other advantages are reduces the cost and fuel consumption capacity is also reduces and the size of autonomous vehicle is also reduces because of reducing the size of vehicle the space required for the vehicle of parking purpose is also reduces. The Autonomous electric vehicle has some disadvantages like liability for damage, software reliability, loss of driving-related jobs, loss of privacy; it is very difficult for autonomous vehicle to operate in heavy rain fall and snow and also in heavy disaster. The autonomous electric vehicles must also have the functionality of vehicle collision avoidance systems. In the present vehicles, the vehicle collision occurs due to the distraction of the drivers while driving. In the case of driverless vehicles, the collision of the vehicle will not occur, since the controller unit that controls the vehicle by continuously observing the road conditions.

Most of the Companies are uses autonomous car for developing and testing purpose such as Google, Volkswagen, BMW, etc. In 1920 the experiment of the autonomous vehicle started. In 1980 the first autonomous car is developed. Google has done remarkable work in this field for the past few years. The combination of an autonomous and battery-powered the vehicle has proven to be a breakthrough in the automobile industry. The

autonomous electric vehicle consists of both hardware and software developers such as those involved in sensors, artificial intelligence, mapping, & network connected services for transportation, advanced driver assistance system. The electric car uses battery for storing electric energy and by using this electric energy the car produces the motion in different direction. The electric vehicle does not produce any form of pollution during motion. Because of this the electric vehicle provide pollution free environment as compared to other types of vehicle. The electric vehicle does not uses any form of fuel for driving purpose it uses electric energy instead of fuel. Sometime the battery inside the electric vehicle is discharge so upon charging the vehicle can be moved.

For design automated driving functionality Automotive companies use MATLAB and Simulink software which include computer vision algorithm development, control development, and sensor fusion, etc. Most of the companies' select MATLAB and Simulink software for development purpose because the design of model in Simulink environment is easy as compared to other software and the cost required during design process is very less and size of design is also very compact. Simulink uses block for design the system instead of code used in MATLAB. The Simulink is easy as compared to MATLAB because it provide a simple environment for development of system.

II. LITRATURE REVIEW

Geetinder, Sourabh, Jaspreet and Samreet (2014) give information about the Google driverless car. The car won't have steering wheels the steering can be done while looking out the obstacles, Accelerators or brake pedal can be used for correction of the speed limit and in any traffic condition it can go or stop there itself. All the work of the Google driverless car can be carried out by sensors and software. The Google driverless car consists of three parts such as Google maps that are generally used for navigation. Google maps provide information about the road, traffic signs, etc. the second part is the different types of hardware sensors such as Lidar, video camera, position estimator, distance sensor, aerial and computer these sensors are used for obstacle detection and the third the part is artificial intelligence the data coming from Google maps and hardware sensors are given to artificial intelligence for determining the acceleration. The main part of artificial intelligence to drive the passenger safely and legally to his destination.

Mustapha, Zayegh and Begg (2013) explain about the different sensor used for obstacle detection and distance measurement. There are various sensor used for obstacle detection and distance measurement few of them are IR sensor and ultrasonic sensor. The system uses different type of material for obstacle detection such as paper, plastic, books, plastic etc. The characteristics defined by both the sensors are different the linear characteristics are given by ultrasonic sensor and nonlinear are given by IR sensor. The IR sensor resolution is high as compared to ultrasonic sensor.

Mohammad (2009) gives the information about two distance measurement sensor. The amplitude response of the IR sensor depends on the reflectance properties of the target. The ultrasonic sensor has slightly higher resolution than the IR sensor. The care should be taken while placing the object from the sensor because a slight change in the angle produces a slight difference in the actual distance. The amplitude from the US sensor is dependent on the orientation of the obstacle relative to the sensor and distance, The amplitude of the IR sensor does not have much effect where the small orientation of the reflecting surface. There is no effect of Surface color and smoothness on the output signal of the ultrasonic sensor. The reflectivity of an obstacle is depending on the amplitude of the IR sensor.

Varghese and Boone (2015) explain about the various technologies used to enable autonomous vehicles and advantages, disadvantages associated with each autonomous vehicle sensor. This paper also explained about the internal vehicle systems, external world sensing, sensors, systems, and various factors that play into autonomous vehicle design. Although the single sensor does not provide full information about the autonomous vehicle so that the fusion of sensor is used to drive the autonomous vehicle fully.

Vairavan, Ajith, Shabin and Godwin (2018) they develop one vehicle which is nothing but the robot. This robot is used of obstacle detection and avoidance. The obstacle that are generally detected with help of ultrasonic sensor and avoidance that can be done using arduino microcontroller. In order to detect the obstacle the ultrasonic sensor is placed at the front side of robot. With the help of ultrasonic sensor place on front side of robot the data can be sensed. After data sensing the ultrasonic sensor sense whether the obstacle is present or not if the obstacle is present it detect the obstacle and change the path in which there is no any obstacle are present. After that the data sensed by ultrasonic sensor is given to the controller for the motion of the vehicle and direction of vehicle.

David (2012) explains about the simulation tool used to drive electric vehicle. A simulation is the important tool that provide large amount of benefit for design the model because while designing the cost of the development is reduces. By embedding the entire simulation model during design process can decrease the design time and cost of the design so that most of the companies can complete and test the design with in time. The path changing for an autonomous vehicle is important for the system and to generate a new way to pass the front vehicle without having any collision.

III. METHODOLOGY

The process of measuring the distance to an obstacle can be performed by managing the input and output signals which are coming from the Sharp distance IR sensors. In that input and output signal management there consist of signal processing, conditioning, parameterization, and integration, etc.

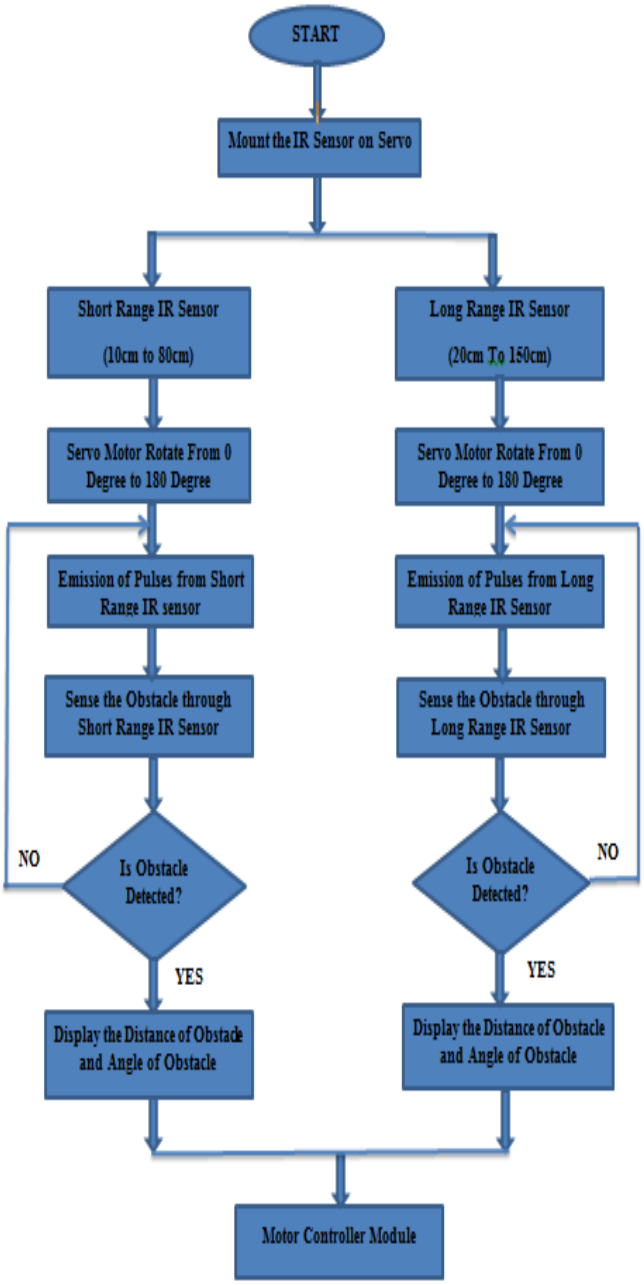

Fig.1. Flow Diagram of Obstacle Detection Using Sharp Distance IR Sensors

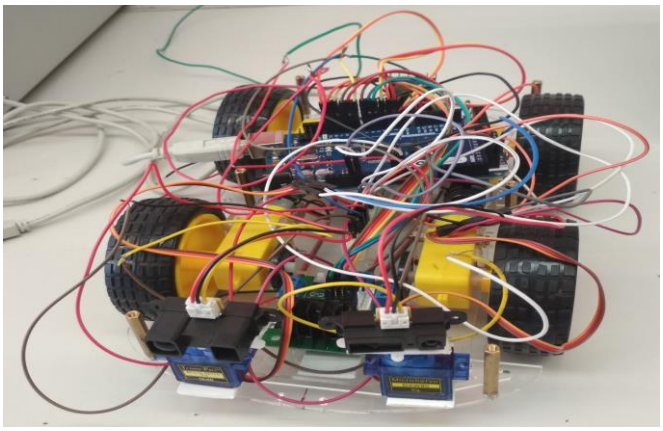

Fig.2. Photograph of Experiment Setup

A. *Signal Processing*

Signal processing is a subfield of information, mathematics, and electrical engineering that is generally used for analysis, synthesis, and modification of the signals. This signal processing that can be done by logging the data coming from both Long range and Short range infrared sensor this logging data are taken from Analog input pin of Arduino i.e. pin A1 for short range IR sensor and A2 for Long Range IR sensor this pin gives the value of ADC count. After using the specific the formula which is based on ADC count i.e. Short-range IR sensor distance can be calculated by using a formula such as

$$\text{Distance (cm)} = 4800/ (\text{Sensor Value} - 20) \quad (1)$$

And another formula used for calculating distance using Long range IR sensor which is nothing but

$$\text{Distance(cm)} = 9462/(\text{sensor Value} - 16.92) \quad (2)$$

B. *Conditioning*

When data is logged from the IR sensor according to logging values the condition is applied in the State flow. There are two State flow are included in single State flow one for servo motor rotation from 0 degrees to 180 degrees. According to condition given in State flow servo motor rotated from 0 degrees to 180 degrees after rotation angle of the servo motor is calculated. And another State flow is used to calculate the obstacle angle from start to end point of the obstacle when the obstacle is detected for both the sensor. This two State flow can be run parallelly because both IR sensors are mounted on the servo motor. According to servo rotate, the IR sensor detects the obstacle.

C. *Parameterization*

Parameterization that is generally used for measurement of a different parameter from the different sensor both the IR sensor detects the obstacle within the specified limit. After detecting the obstacle IR sensor measure the distance of obstacle and this distance can be represented on display. It will also measure voltage, velocity, etc.

D. Integration

Integration of all the components is the final part of my project which is nothing but the process of bringing all the components together with the components such as sub-system into a single system and ensuring that the subsystem works the same as the system and integrating part can be done by embedding all the modules together and tested and assuring their condition to work towards the goal. The integration can be done by combining both the system such as calculate the distance of obstacle using both the IR sensor and the output of IR sensor i.e. distance is given to motor controller model in the form of input according to the distance and speed condition the time can be calculated from that time the condition is given in State flow so that the motor rotates in forward, right, forward and right direction. The benefit of integration is lower development cost, increase reliability and security. Integration is necessary to enable the flow of data through the system as well as provide the necessary data for system functions. If the system that is not integrated results in a significant increase in cost and resource consumption.

IV. RESULTS AND DISCUSSION

The results were discussed by comparing the output of both the IR sensor with respect to distance. Chart 1 shows the distance measurement of both the IR sensor. When the obstacle detected both the IR sensor shows the variations in the distance while when an obstacle is not present it will show the constant distance measurement. By comparing the distance of both long range and short range IR sensor the long range IR sensor gives the accurate result as compared to the short range IR sensor because the range of long-range IR sensor is more as compared to short range IR sensor. The operating voltage for both the IR sensor is kept constant i.e. of (5v).

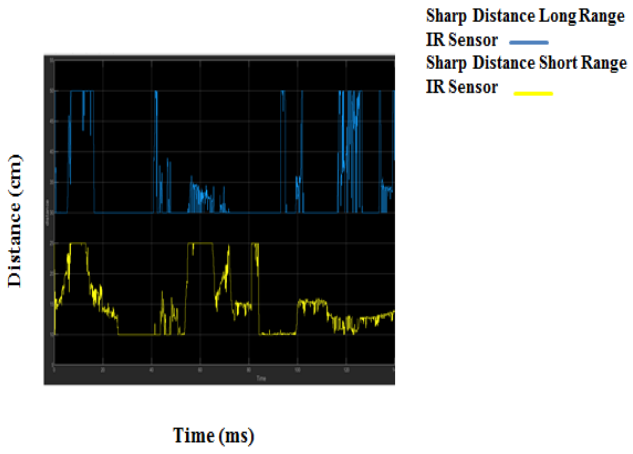

Chart.1. Distance vs time graph

V. CONCLUSION

The goal of my project is to develop a sensor based four-wheeled autonomous robots which detect the obstacle in his path with the help of data logged from the Sharp distance IR sensor and move the robot in the predefined path. During motion if the car doesn't find enough space to pass through the obstacles it must stop there itself otherwise moves in a predefined path by an avoiding obstacle. This project is been designed and implemented with ATmega 2560 Arduino microcontroller in Simulink domain. The work which is performing experimentally has been carried out carefully. Sensor output will be given to the controller. According to signals given to the controller, it will run the wheels in different direction i.e. forward, right, forward, right and speed based on the input signals.

VI. FUTURE SCOPE

The Future scope of my project is to design the same sensor based four-wheeled autonomous electric robot using LIDAR sensor instead of using sharp distance IR sensor because the LIDAR sensor also used for detection of obstacle and measurement of distance but the distance can be easily estimated using LIDAR. The range of LIDAR is very high i.e. 1000feet to 4000 feet. LIDAR provides 360 degrees of resolution. And also develop the GPS system for moving the vehicle from one point to another point.

***Abstract*— The above paper gives the detail design of Solar PV system along with its synchronization with grid connected systems. In this paper detailed design of system along with the design of boost converter, design of inverter system for 180 degree conduction mode along with its SPWM technique and grid synchronization using Phase locked loop technique has been discussed. The PV panel's DC output is amplified by using boost converter up to desired value. which is further converter into A.C. supply by using 3-phase inverter which is working under 180 degree conduction mode which can be controlled by Sinewave pulse width modulation techniques. The reference signal for the system is derived by the grid using phase locked loop so the output of the inverter is in synchronism with grid with respect to phase as well as frequency.**

Keywords—PV panel, Inverter, Boost Converter, SPWM, PLL, Grid Synchronization.

I. INTRODUCTION

In the current scenario of world energy sector, renewable sources are growing their importance every day. This is due to limitation of the conventional resource and adverse environmental impacts of the conventional energy. Among the all Renewable energy sources available, solar energy seems to be a major competitor [1] as it is widely and almost everywhere available in nature and its conversion to electricity through photovoltaic process does not cause harm to environment. The electrical energy which is generated through solar PV system can be used to operate the different types of applications and loads. Solar energy is generated by means of solar photo-voltaic systems, which use arrays of PV panels that convert solar irradiation into electricity. It is reliable and cheap as compared with others.[3]

The Solar generation PV system consist of two types first one is Isolated or standalone system where batteries are used for storing electrical energy and then it is directly fed to load. This system is mostly popular in remote areas, where there is complete absence of grid transmission system or it is impractical to provide power system for light loads. Standalone system is also popular among charging low power appliances. Similar to grid tied system, standalone system also requires similar components for power generation like boost converter, inverter etc. but the addition to that it also requires battery i.e. energy storage system. The size of battery system is directly proportional to the energy requirement of load so it makes system much more costly and bulky for higher power applications. That's why this standalone system is mostly used for low power applications. [12]

The grid tied PV systems also known as ON grid photovoltaic system or grid connected solar photovoltaic system is solar PV system which, instead of storing the energy in the batteries, prefers to transmit the generated energy into the grid, which decreases the cost of battery system but increases the complexity as it need it needs grid synchronization in order to archives stability in the system.[6]

II. LITERATURE SURVEY

A. Photovoltaic System

Photovoltaics is the type of technology and research which directly convert sunlight into electrical energy. The solar cell is the elementary building block of the photovoltaic technology. Solar cells are made of semiconductor materials, such as silicon. [2]

The photovoltaic cells are made up of two or more thin layers of silicon which is common semi-conducting material. When the semiconductor is exposed to light, electrical charges are generated and this can be conducted away by metal contacts as direct current (DC). As the power output from a cell is small inadequate , so more than one cells are combined which forms a 'string'. This increases the output voltage os the system considerably. Classification of Solar pv panels is shown in fig 1.1

Monocrystalline silicon PV panels

Such Monocrystalline panels can be made using cells made up of only one cylindrical crystal of silicon. This system is very effective and has high efficiency as it can transform around 15% of the sun's energy into electrical energy. But the process of production of monocrystalline silicon is very difficult and complicated which increases the cost of them.

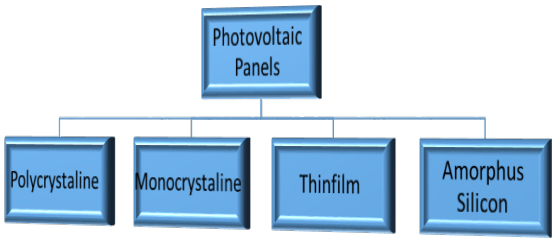

Figure 1: Classification of PV panels

Polycrystalline silicon PV panels

Polycrystalline photovoltaic is also called as multi-crystalline cells. This multi silicon cells are made-up of cells

which are cut from an Ingot of a melted and re-crystallized silicon. They are cut to form thin wafers and again molded into complete cells. This type of panels requires low cost to produce than monocrystalline cells, Though it is low cost and less complicated to manufacture as compare to monocrystalline it has less efficiency i.e. up to 12%.

Thin-film silicon PV panels

Thin film type of panel is a type of multi-crystalline, In this silicon is finely grained .Thin film PV panels are normally enclosed in a transparent and insulating polymer with a tempered glass cover and then fitted into a metal framed module.

Amorphous silicon PV panels

Instead of making rigid crystalline structure, amorphous silicon panels are produced by composing silicon in a thin homogenous layer. These panels can absorbs good amount of solar energy than crystalline type of panels. These panels are very thin that's why it is also called as thin film panels. This type of panels has less efficiency than crystal panels, it can convert only 6% of energy into electrical energy.

B. Off Grid Vs Grid Configuration

As shown in fig. 2 Solar configuration can be of two types i.e. On-Grid & OFF-Grid, depending upon various geographical factor, type of application and availability of resources. On grid system is connected to grid while off grid isolated system.[9]

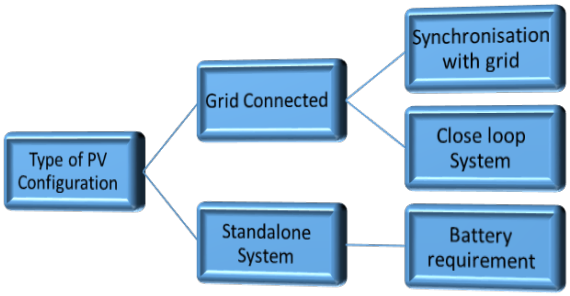

Figure 2:Types of PV panels Configuration

Standalone system requires battery to store the energy, which again increases the cost of the whole system. The drawback of battery requirement will be overcome by grid connected system where instead of storing generated energy it is injected in the grid which omits the energy storage system. Again grid connected system has its own challenges like Synchronization of voltage with the grid, which increases the complexity of the system.[4]

C. Structure of Grid Connected System

The figure no 3 shows the structure of grid tied photovoltaic system. Any energy storage system like battery is absent in grid connected system but feedback control is used from grid to inverter for synchronization. The PV panel generated the D.C. electrical energy in from solar radiation. The generated D.C. Voltage is amplified to desired voltage level by the boost converter. This system is either open loop or close loop system where controller can be used to maintain the output of boost converter. The output power of boost converter is of DC type, which is then fed to inverter to convert it to desired AC voltage which is then either supplied to load or supplied to grid. As discussed earlier there are certain challenges associated which supplying power to grid i.e. synchronization of voltage which is then obtain with help of PLL i.e. Phase Locked Loop system. PLL generated the reference signal which is then fed to the SPWM system of inverter, which generates respective switching signals for inverter and phase & frequency synchronization can be obtain.

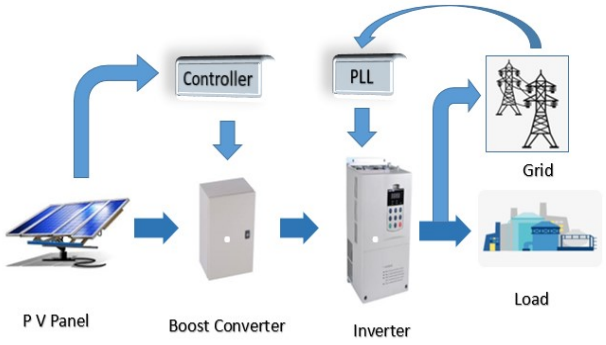

Figure 3: Grid Connected structure of PV System

III. DESIGN & SIMULATION OF SYSTEM

The figure 4 shows the block diagram of MATLAB simulation of the grid connected photo voltaic system. It consists of PV panel block which is the simulation of PV panel, next to it is a boost converter which can be implement to amplify the DC Voltage to desired value. Three phase Inverter circuit is used to convert the DC voltage to three phase AC, SPWM i.e. sine wave pulse width modulation is used to generate switching signal for the three-phase photovoltaic inverter whose output is given to load and Grid. For synchronization of the output voltage PLL i.e. Phase lock loop system is used which measures the frequency along with its phase angle of the grid and according reference is provided to SPWM system.

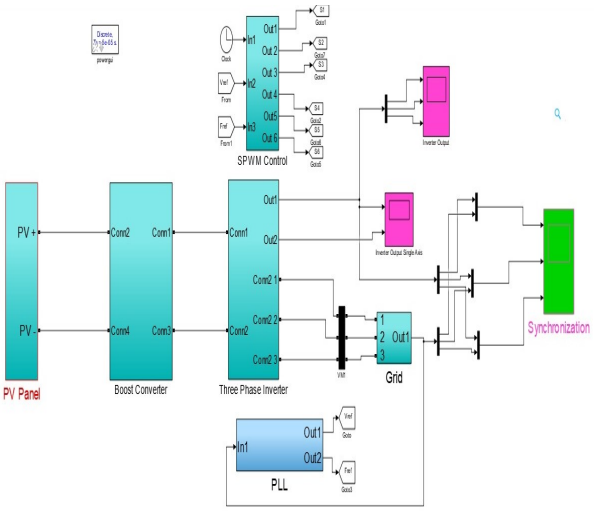

Figure 4: Simulation of Grid Connected PV system

A. PV Panel

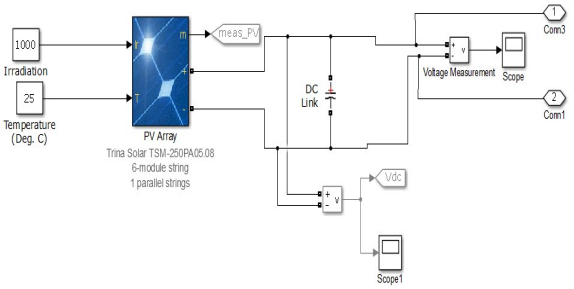

Figure 5: PV panel simulation

The MATLAB simulation of P.V. panel is shown in Fig. 5, input for the panel are temperature & irradiance. DC link capacitor is used to keep the output voltage constant. The VI & PV characteristics of the solar panel is shown in figure 6.

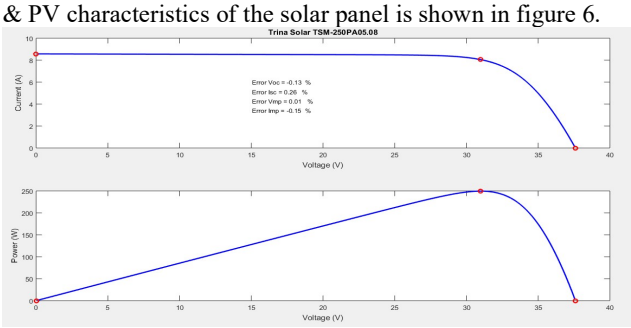

Figure 6: V-I & P-V Characteristics

B. Boost Converter

The function of boost converter is to "step-up" an input voltage to some desired higher voltage level, which is essential for a load. This unique capability is achieved by storing energy in an inductor and releasing it to the load at a higher voltage. This brief note highlights some of the more common pitfalls when using boost regulators. These include maximum achievable output current and voltage, short circuit behaviour and basic layout issues. Figure 7 shows the simulation of Boost converter. Design of boost converter includes design of deciding modulation index along with calculation of switching frequency, inductor & capacitor of the circuit.

i. Selection of Duty Cycle : Duty ratio is the parameter which decides output voltage magnitude. The relation between output voltage is proportional to duty cycle. [8]

$$D = 1 - \frac{V_{in} \times \eta}{V_o} \quad \text{.....(1)}$$

Where η is estimated efficiency of the boost converter.

.

ii. Selection of Inductor : As increases in the inductor value, output current also increases because of the reduction in ripple current. As the inductor value decreases, current limit also decreases. But it is need to take care of the inductor must always have a higher current rating than that of the current.

$$L = \frac{V_{in}(V_o - V_{in})}{\Delta I_L \times f_s \times V_o} \quad \text{.....(2)}$$

V_{in} = input voltage
V_o = required output voltage
f_s = switching frequency (minimum)
ΔI_L = desired ripple current of inductor,
Where ΔI_Lshould be 20% to 40% of output current.

iii. Selection of Capacitor : It is always recommended to implement low ESR capacitors to decrease the voltage ripple. It is recommended to use data sheet while doing the calculation of capacitor and inductor. The following equation is implemented to find the capacitor values of boost converter to attain desired voltage level.

$$C = \frac{I_o \times D}{f_s \times \Delta V_o} \quad \text{.....(3)}$$

Where ΔV_O is the desired o/p voltage ripple.[8]

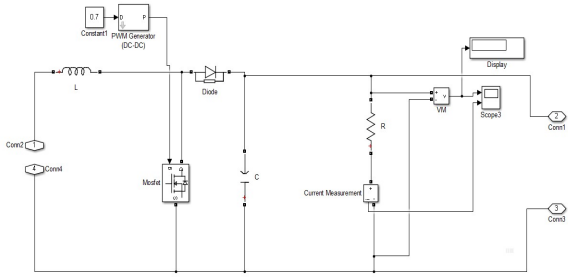

Figure 7: Simulation of Boost Converter

C. Three Phase Inverter

Three single-phase bridge inverters can be connected as shown in Figure 8 to form a configuration of 3-Ø inverter.[10] The individual phase voltages of the 3-Ø bridge circuit are identical to the square voltages output by 1-Ø bridge circuits. The voltages of the 3-Ø inverter are displaced in time by 120^0.

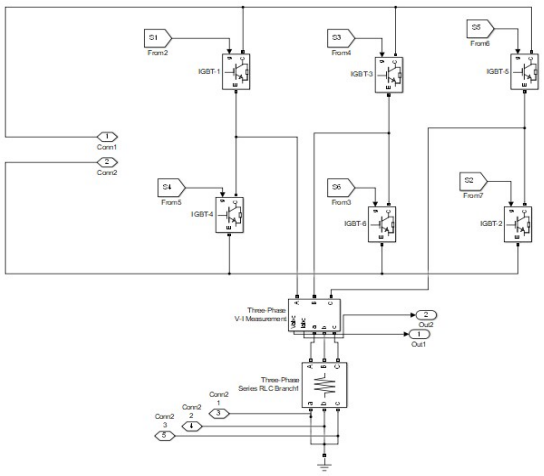

Figure 8: Simulation of Three phase Inverter

D. Sinewave Pulse Width Modullation (SPWM)

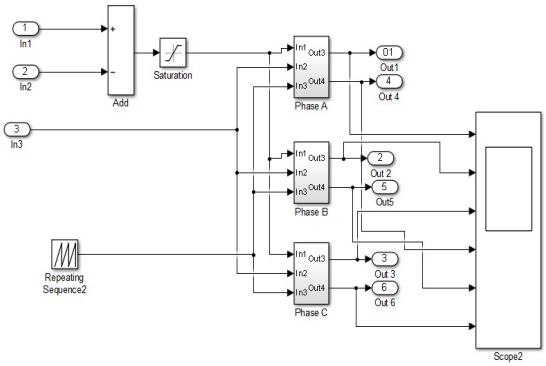

Figure 9: SPWM Simulation

The most common and popular technique for generating sinusoidal wave is SPWM i.e. known as Pulse Width Modulation. Simulation of SPWM is shown in figure 9. This PWM technique includes generating a digital waveform, for which the duty cycle can be modulated in such a way so that the average voltage waveform corresponds to a pure sine wave. The method of producing SPWM signal is comparing sine wave with triangular wave or saw-tooth wave. This Sinewave PWM signal is implemented for controlling power semiconductor switches like IGBT, MOSFET etc. The output produced by inverter is such that it resembles with sine wave. Filter consists of inductor and capacitor which is known as LC-Filter can be implemented to make a smooth sinusoidal waveform out of square wave ac output. With the help of this SPWM method production of much more similar AC waveform than that of others is possible.

E. Phase Locked Loop System (PLL)

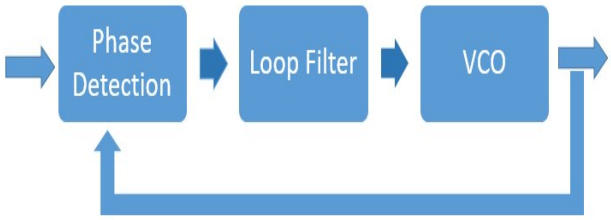

Figure 10: Block Diagram of PLL system

The most important factor of the phase locked loop (PLL), is the phase difference between two given signals. Phase locked loop system also has the ability to detect the phase difference between the two different signals. The difference between reference signals phase and actual signals phase is called as “error signal”. This error signal is used to control phase angle as well as the frequency of two signals. [5]

The basic block diagram of phase locked loop is shown in figure 10 where there are three main elements of the PLL have shown. These elements are respectively phase detector, voltage controlled oscillator i.e. VCO and the filter [13]. At phase detection, the reference signal and the feedback signal which can be generated from VCO are being compared and error signal is generated. This error is then passed to filter for which can be further transmitted to VCO. The Voltage Controlled Oscillator produces an oscillatory signal. This oscillatory signal is again fed to phase detector to get compared with the input reference signal. This identify the phase difference between the two signals, i.e. the error signal. The error signal is then again passing through loop filter. This is the low pass filter which attenuate the high frequency signals and only allows the low frequency signal. Then this error signal is supplied to the control terminal of the VCO.[9] The error of any change in this voltage is considered that it tries to reduce the phase difference and difference in frequency between the given signals. As initial stage the loop is out of lock but as the error reduces the system gets locked and phase angle and frequency gets synchronized with each other .

IV. SIMULATION RESULTS AND ANALYSIS

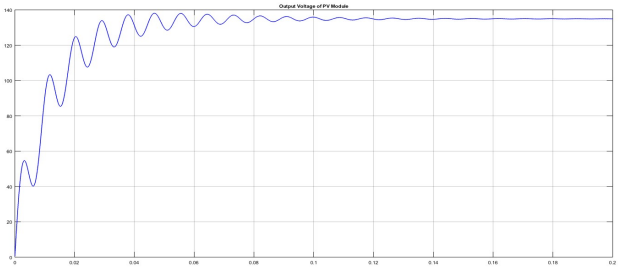

Figure 11: Output of PV panel

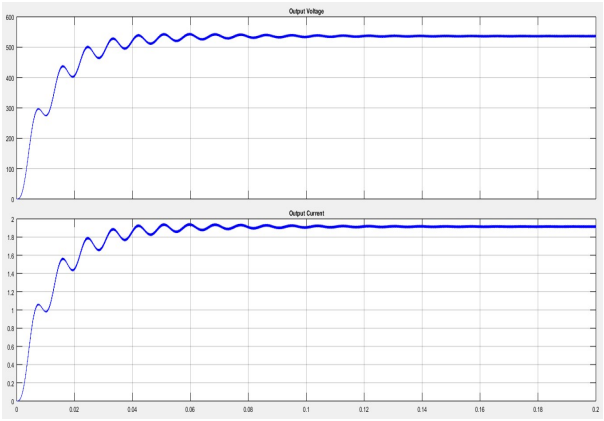

Figure 12 : Voltage & Current of Boost Converter

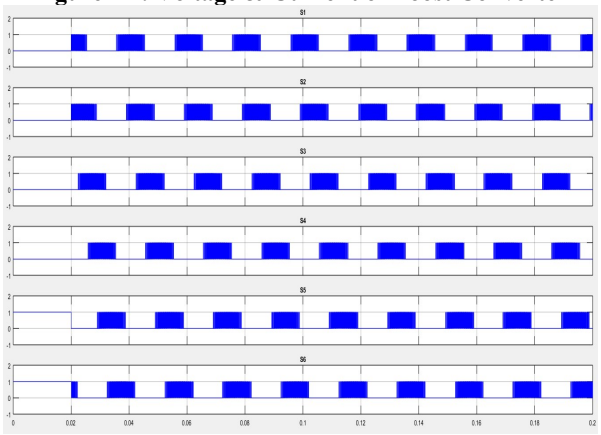

Figure 13: SPWM signal for 3 phase inverter

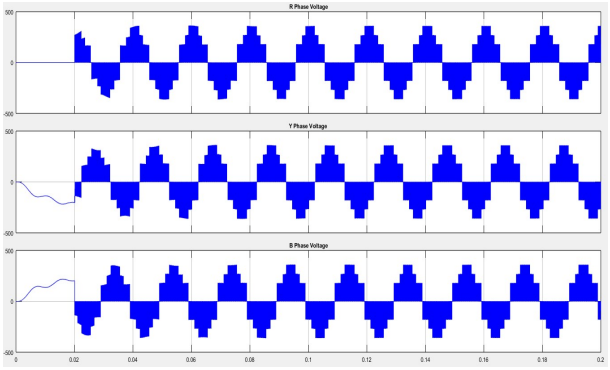

Figure 14: Three Phase Inverter output voltage of three phases

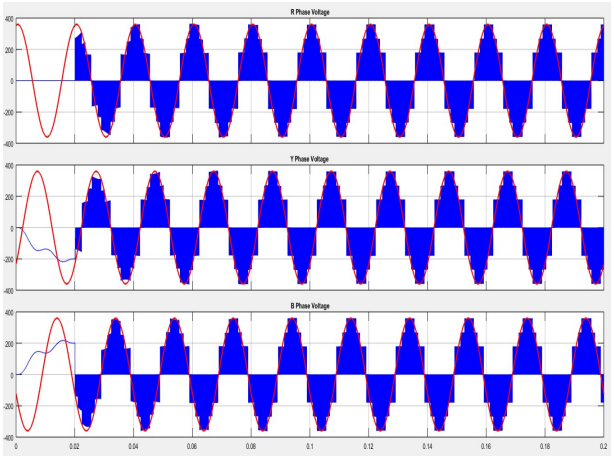

Figure 15: Grid Synchronization

The figure 11 shows the output of the PV panel generated due to solar radiation which is around 132V. This voltage is then fed to Boost converter to amplify the voltage up to 500 V which is shown in figure 12. This DC voltage is applied to 3-Ø inverter which working at 180-degree conduction mode, whose SPWM control signals are shown in figure 13. This inverter converts the DC voltage into 3 phase a.c. voltage which is shown on Figure 14. Inverter gives 440V phase to phase voltage which is same as of grid. This voltage is synchronized with grid voltage which is shown on figure 14. The output of inverter fig no 14 & 15 shows delay of one cycle i.e. delay of 20mlsec, this delay is required PLL loop to measure phase angle of the grid and respectively adjusting & synchronizing output voltage of three phase inverter.

V. CONCLUSION

This paper gives an overview of the grid tied photovoltaic system which includes the selection of PV panels, designing of boost converter depending upon the input and required output, design of three phase voltage source inverter along with Sinewave pulse width modulation system with Phase locked loop system. To synchronize the output of voltage source inverter the reference voltage of grid is fed to phase locked loop system where frequency along with the phase angle of the grid is measured and accordingly reference signal is generated and feed back to SPWM system so that the synchronization can be obtain between inverter output and grid. DGPVs are expected to play important part in future electrical power sector, with consideration of unbalanced grid conditions, islanding and better solutions to power quality issues under high penetration level of DGPV.

ACKNOWLEDGMENT

It is my honor to express acknowledgment to my guide and teachers, who guided me during the preparation of this paper and my project. I would like to present my thanks to my Guide Prof. SV Murkute who motivated me every single time of need, gave his support and valuable time. Last but not least, I am thankful to the almighty. It was his blessing that saw us till the end.

***Abstract*—Induction motors (IM) are utilized in many industries because of their advantages such as high efficiency, high starting torque, low maintenance and economical. Traditional PI controller is sensitive to parametric variations of motor. Additionally, use of PI controller introduces high flux and torque ripples in field oriented control (FOC), this affects performance of motor. This paper discusses use of offline fuzzy tuned PID controller for a space vector pulse width modulation (SVPWM) fed indirect field oriented control (IFOC) of IM drive. The system uses fuzzy Mamdani type I controller to improve transient response. The paper proposes sensorless speed estimation of IM using Luenberger observer. Effectiveness of sensorless speed control of IM is demonstrated in MATLAB/Simulink.**

***Index Terms*—Induction motor, Space vector PWM (SVPWM), IFOC, Fuzzy logic controller (FLC), fuzzy tuned PID, Luenberger observer, Simulink.**

I. Introduction

Nowadays, requirement of controlling of electrical drives is increased. New electronics devices like microprocessors and DSP processors can provide good speed control accuracy. Motors used in an electric vehicle are induction motors, BLDC motors & DC motors. IM is commonly used in the industries because of their special features like, variable speed, rugged operation, self-starting. BLDC motors are utilized in many industrial applications. Induction motors are advantageous over brushed dc motor drives and BLDC. The advantages of IM included ease of operation, high starting torque, high dynamic response [1],[2].

These motors are available for 1 ϕ & 3 ϕ variants. Therefore it is necessary to improve the performance of motor to obtain desired result. Scalar control and vector control are two main types of AC machine control. Due to ease of execution, scalar control is widely used. In scalar control method, direct torque control is utilized to enhance performance of motor. The vector control method is widely used for speed control. Scalar control method has further divided into V/F technique. In V/F technique, the constant Voltage to frequency ratio gives constant motor torque throughout the speed range. The vector control method further divided into two types: direct torque control (DTC) and field oriented control (FOC). DTC is used to control torque of three phase ac motors. DTC further classified as: direct self-control (DSC) & space vector modulation (SVM).

FLC improves the speed response of the system which cannot be improved by the conventional PID controller. Complicated nonlinear systems with uncertainty can be handle by the FLC [4]. The FLC will give a poor response for speed variations and load variation. To reduce this drawback an offline tuning method is introduced with FLC. In this method the PID controller parameters are tuned offline for obtaining better response to load changes. Fuzzy tuned PID controller has all benefits of a FLC and conventional PID controller like simplicity in control [7],[10].

Luenberger observer (LO) gives the best performance under steady state and low speed operation, but dynamic performance is not good. Extended Luenberger observer (ELO) is complicated to design and implement in DSP. Under load condition performance of ELO at low speed is poor [3].

Organization of paper is: Section-II gives introduction about indirect field oriented control system for IM. Section-III describes space vector PWM technique. In Section-IV, Fuzzy tune PID controller is designed. Luenberger observer is designed in section V. Obtained results are shown in section VI. Finally, in section VII conclusion is given.

II. Indirect Field Oriented Control (IFOC) of IM

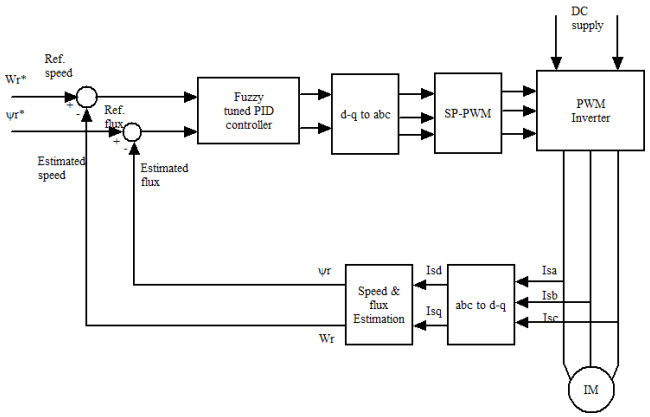

Fig. 1. Schematic of sensorless speed control using FT-PID controller

In FOC, control of IM is complex, because control of decoupled torque & flux generating components of stator currents is complex. To overcome these drawbacks, high performance indirect FOC is used. Proposed work shows high performance of fuzzy tuned PID controller to control speed of AC machine. In this proposed work, performance of PID controller is enhanced by fuzzy logic control and speed estimated by speed estimator. Speed estimators are used instead of speed sensors to reduce the control circuit complexity.

Schematic of proposed work is shown in figure 1, which consist of IM, inverter, FLC with PID tuning, FOC and speed estimator. Here speed is estimated by Luenberger observer and calculated speed is compared with reference speed, error is given to FLC. FLC reduces error and gives signal to space vector PWM and generated SVPWM signals are given to inverter. Feedback signals are taken by sensing the voltage and current.In proposed system speed of IM is controlled through fuzzy tuned PID controller using luenberger observer. For sensor less speed control technique, current senses from motor and converted into d-q format. From that speed is calculated using luenberger observer. An error signal is generated from difference between reference speed & calculated speed. This error given to fuzzy tuned PID controller, from which it gives correct output to achieve reference speed [5],[6].

III. SPACE VECTOR PWM (SVPWM)

PWM technique is employed to inverter to get variable voltage and frequency for variable speed drives. Inverter output in the form of space vectors represents principle of the SVPWM. For execution of SVPWM, reference voltage is calculated using nearest two active vectors & zero vectors. In this control method, simulink model is designed for IFOC. Space vector transformation is as shown in figure 2.

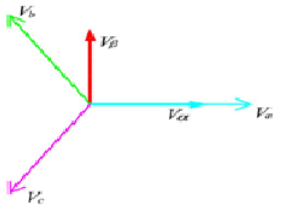

Fig. 2. Space vector transformation

3-phase system $V_a(t), V_b(t) \& V_c(t)$ can be written as;
$V = \frac{2}{3}(V_a(t) + V_b(t)e^{j\frac{2\pi}{3}} + V_c(t)e^{-j\frac{2\pi}{3}})$
The possible space vectors are shown in figure 3,

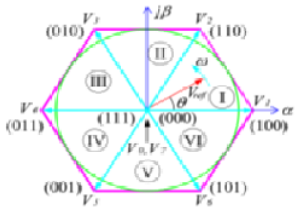

Fig. 3. Eight possible space vectors

TABLE I
SWITCHING STATES AND MAGNITUDE

Space vector	Switching state	Magnitude
V_0	000	0
V_1	100	$\frac{2}{3}V_{dc}e^{j0}$
V_2	110	$\frac{2}{3}V_{dc}e^{j\frac{\pi}{3}}$
V_3	010	$\frac{2}{3}V_{dc}e^{j\frac{2\pi}{3}}$
V_4	011	$\frac{2}{3}V_{dc}e^{j\frac{3\pi}{3}}$
V_5	001	$\frac{2}{3}V_{dc}e^{j\frac{4\pi}{3}}$
V_6	101	$\frac{2}{3}V_{dc}e^{j\frac{5\pi}{3}}$
V_7	111	0

The magnitude of six active vectors is equal to (2/3) V_{dc}. The vectors V_1-V_6 are known as active state vectors and V_7 & V_8 are known as zero state vectors. SVPWM waveforms are shown in fig. 4. SVPWM is a technique utilized in final step of FOC to find PWM signals for inverter switches to generate desired three phase voltages to IM.

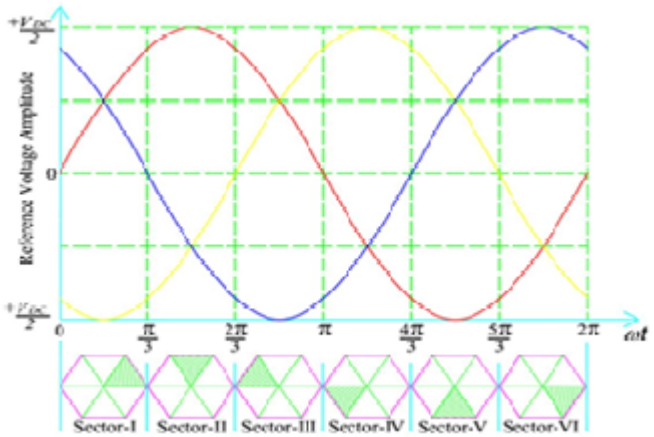

Fig. 4. SVPPWM waveforms

IV. FUZZY TUNED PID CONTROLLER DESIGNING

Fuzzy Logic allows values in between one/zero, high/low true/false, etc. FLC is simple to execute. It consists of fuzzification, fuzzy rules & defuzzification. Fuzzy rules describe relationship between input, output. They are written using IF-THEN statements. Input is taken as error between reference speed & estimated speed [11].

In offline fuzzy tuned PID controller, rules are designed using properties of PID controller & characteristics of IM. Parameters of K_p, K_i, K_d are tuned as load changes. FLC has two inputs: error (e) & change in error (de) and three outputs: K_p, K_i, K_d as shown in figure 6. Equations for offline tuning is acknowledged as below [9],[12].

$$U(t) = K_{pnew}e(t) + K_{inew}(t) + K_{dnew}de(t)/dt \quad (1)$$

$$K_{pnew} = K_{pf}\alpha$$
$$K_{inew} = K_{if}\alpha$$

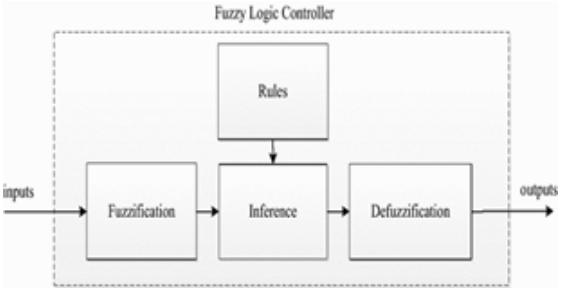

Fig. 5. Schematic of FLC

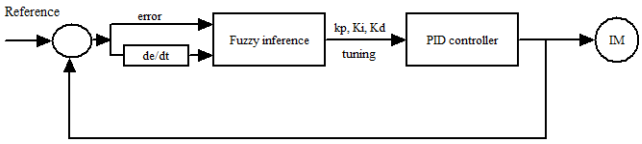

Fig. 6. Block diagram Fuzzy tuned PID controller

$$K_{dnew} = K_{df}\alpha$$

Where,
α = scaling factor, K_p, K_i, K_d are obtained from FLC.

TABLE II
FUZZY RULES FOR KP

PM	NS	Z	PS	PM	PL	PL	PL
PL	Z	PS	PM	PL	PL	PL	PL

Fuzzy rules are designed according to error as well as change in error. If value of error is negative large, transient response is high. To reduce high transient response derivative gain of controller is high. Rise time is large. To minimize rise time, proportional gain of controller is increased. To achieve zero steady-state error, value of integral gain is increased. The transient response output from model is improved compared with FLC controller & steady state error is eliminated.

Schematic of FLC is shown in above figure 5. Input variable of fuzzy system is speed error E. Speed error can be represented as:

$$E = \omega_{ref} - \omega_{act}$$

The torque reference is controller output variable of IFOC. Controller observes speed error signal and accordingly changes its output. Therefore actual speed w_{act} reaches the reference speed (w_{ref}). Here, for designing FLC, Mamdani method is used. It has fuzzy input and fuzzy output. Choice of fuzzy sets & membership functions are necessary for designing FLC.

Fuzzy sets (linguistic definition) proposed here are defined as follow:
PM = Positive Medium,
PL = Positive Large,
PS = Positive Small,
PLM = Positive Large Medium,
ZE= Zero,
NS = Negative Small,
NM = Negative Medium,
NL = Negative Large,
NLM = Negative Large Medium,
VSE= Very Small Error,
VBE= Very Big Error.

V. DESIGNING LUENBERGER OBSERVER

To determine the Synchronous speed and electrical angle following equations are used to implement flux observer [8]. The simulation diagram is as shown in fig 14
From, indirect vector control,

$$\Theta_e = \int \omega_e = \int (\omega_r + \omega_{sl})dt \tag{2}$$

The rotor circuit equation is given by,

$$R_r i^e_{dr} - (\omega_e - \omega_r)\Psi^e_{dr} + \frac{d\Psi^e_{dr}}{dt} = 0 \tag{3}$$

$$R_r i^e_{qr} + (\omega_e - \omega_r)\Psi^e_{dr} + \frac{d\Psi^e_{qr}}{dt} = 0 \tag{4}$$

Rotor flux linkage is given by,

$$\Psi^e_{dr} = L_r i^e_{dr} + L_m i^e_{ds} \tag{5}$$

$$\Psi^e_{qr} = L_r i^e_{qr} + L_m i^e_{ds} i^e_{qs} \tag{6}$$

From above equations we can write,

$$i^e_{dr} = \frac{1}{L_r}\Psi^e_{dr} - \frac{L_m}{L_r} i^e_{ds} \tag{7}$$

$$i^e_{qr} = \frac{1}{L_r}\Psi^e_{qr} - \frac{L_m}{L_r} i^e_{qs} \tag{8}$$

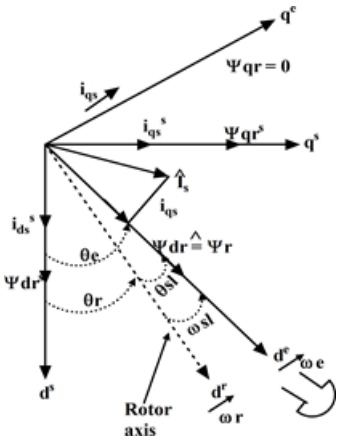

Fig. 7. stator current, Stator flux & Rotor flux vectors on ds-qs plane

If we substitute above values in equations 3 and 4, we obtained,

$$\frac{d\Psi^e_{qr}}{dt} + \frac{R_r}{L_r}\Psi^e_{qr} - \frac{L_m}{L_r} R_r i_{ds} + \omega_{sl}\Psi^e_{dr} = 0 \tag{9}$$

$$\frac{d\Psi^e_{dr}}{dt} + \frac{R_r}{L_r}\Psi^e_{dr} - \frac{L_m}{L_r} R_r i_{ds} - \omega_{sl}\Psi^e_{qr} = 0 \tag{10}$$

For decoupled control,

$$\Psi^e_{qr} = 0 \tag{11}$$

$$\frac{d\Psi^e_{qr}}{dt} = 0 \tag{12}$$

Now, substituting the above values in equation 9 and 10, we obtain,

$$\frac{L_r}{R_r}\frac{d\hat{\Psi}_r}{dt} + \hat{\Psi}_r = L_m i^e_{ds} \tag{13}$$

$$\omega_{sl} = \frac{L_m}{\hat{\Psi}_r}\frac{R_r}{L_r} i^e_{qs} \tag{14}$$

If we consider $\hat{\Psi}_r$ as constant ,then from equation 13 we obtain,

$$\hat{\Psi}_r = L_m i^e_{ds} \tag{15}$$

Therefore, by using equation number (1), (12) and (13) flux observer is designed.

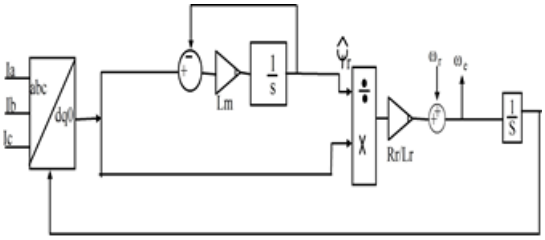

Fig. 8. Block diagram of Luenberger Observer

Where,
ω_e = Estimated speed,
ω_r = Rotor speed,
ω_{sl} = Slip speed,
R_r = Rotor resistance,
L_r = Rotor inductance,
L_m = Magnetizing inductance,
i^e_{qs} = q^e axis stator current,
i^e_{ds} = d^e axis stator current,
i^e_{qr} = q^e axis rotor current,
i^e_{dr} = d^e axis rotor current,
Ψ^e_{qr} = q^e axis rotor flux linkage,
Ψ^e_{dr} = d^e axis rotor flux linkage,

VI. SIMULATION MODEL & RESULTS

The structure of FOC is given in figure 9. Input to speed controller is reference speed & actual speed of motor. Output of speed controller is given to FOC. Actual speed of motor & stator current of motor are also given to FOC. According to the switching pulses, controlled AC voltage produced by the inverter is applied to IM. 3-phase diode rectifier is utilized to convert ac into dc . For sensorless speed control, speed estimator namely Luenberger observer is used. Three stator currents I_a, I_b, I_c, are given to the observer to estimate speed.

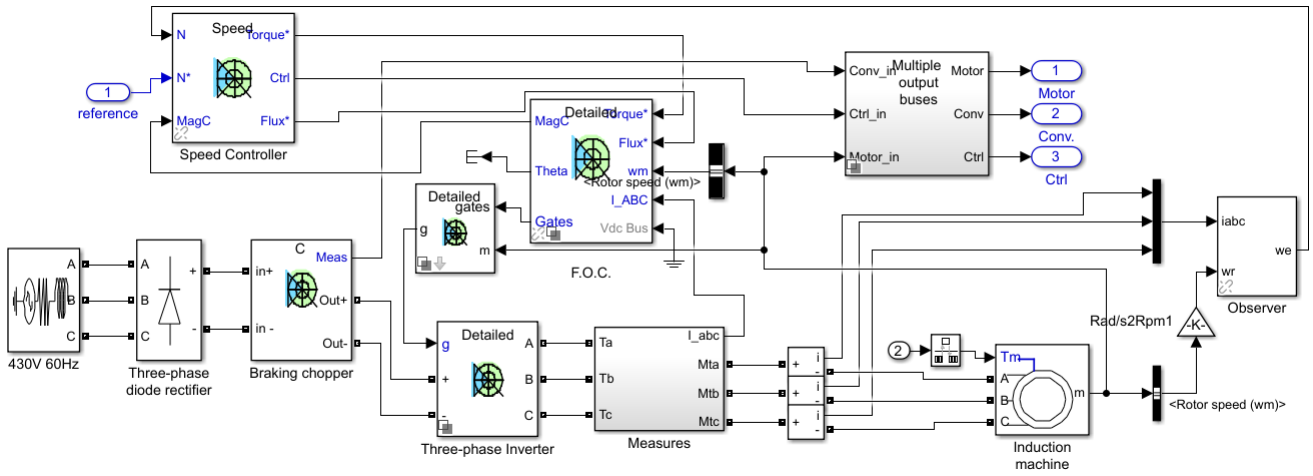

Fig. 9. Simulink diagram of IFOC for speed control of IM

Estimated speed is given to speed controller. In speed controller, 49 rules based on IF-THEN statements as shown in table II, III & IV FLC is implemented to reduce error. For various speed & torque values results are obtained as shown in fig. 10, 11 & 12. Fig. 13 shows output stator current and DC bus voltage for the speed 500 rpm & torque 2 n-m.

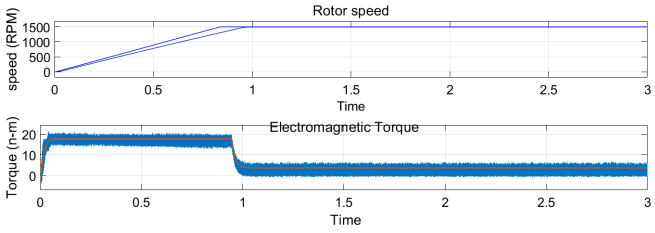

Fig. 10. Output speed at 1500 rpm & torque 2 n-m

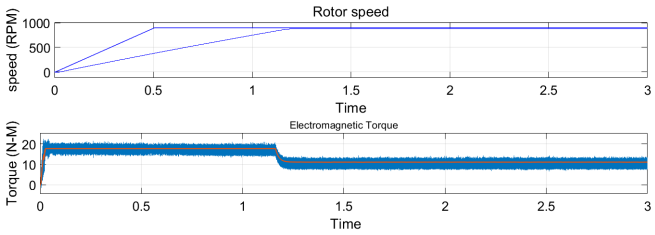

Fig. 11. Output speed at 900 rpm & torque 10 n-m

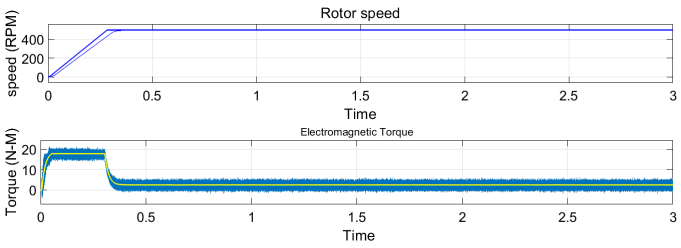

Fig. 12. Output speed at 500 rpm & torque 2 n-m

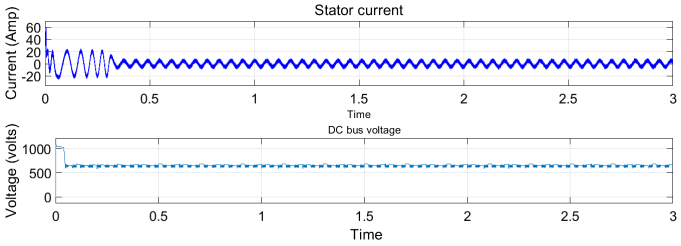

Fig. 13. Output stator current & Dc bus voltage speed at 500 rpm & torque 2 n-m

TABLE V
PARAMETERS OF 3HP IM

Sr. no.	Parameters	3 HP IM
1	Power	2238 W
2	Supply Voltage	430 V
3	Frequency	50 Hz
4	Stator Resistance	0.435 Ω
5	Stator Inductance	0.002 H
6	Rotor Resistance	0.816 Ω
7	Rotor Inductance	0.002 H
8	Mutual Inductance	0.06931 H

VII. Conclusion

The Luenberger Observer based FT-PID (Fuzzy tuned PID) is designed in this paper to estimate rotor speed. FT-PID reduces torque ripples and gives better response. From results, it is seen that FT-PID controller is suitable for all speed ranges with vector control technique. FT-PID has better response as compare to FLC. The actual speed is exactly tracking the reference speed for different speeds as seen in the results. The sensorless speed control using FLC is suitable for applications like electric vehicles, industrial purpose, robotics, etc. Speed controller works accurately with least error between actual speed & reference speed. Moreover, the speed controller improves overall transient response of system.

***Abstract*—The curing section of rubber manufacturing plant requires a lot of manual intervention for checking pump status. The energy of each pump is viewed on the energy meter manually. In case of power failures, pumps in the entire curing section are manually switched on using star-delta configuration. This brings time loss and quality defects. Thus the company incurs huge loss. In order to minimize the manual intervention that is required to check the pump status, the proposed system aims at monitoring the energy consumption of the pump in the curing section of the rubber processing plant. This paper presents a real-time energy monitoring system which has the capability to acquire data from a three-phase supply network connected to the pumps, store the acquired data and display the data on the screen. This data is then used to check the real time status of the pumps and indicate the presence of faults, thus automating the process of monitoring the pumps using PLC and SCADA.**

Keywords— Energy Monitoring; PLC; SCADA; HMI

I. Introduction

Over the past two decades, the electric power industry's involvement in power distribution automation has been principally focused on remote monitoring and control of the distribution systems and their equipments. Advancement in metering and communications have meant that electric power utilities worldwide are increasingly adopting the technology of energy monitoring system to provide better and more efficient services to electric consumers. Development of an online energy monitoring system via PLCs in the industries are accomplished by the use of

- Data Acquisition
- Communication Protocol
- Processing within Energy Meter and host central station [1]

In the Rubber Processing Plant, each of the pumps are controlled by a VFD (Variable Frequency Drive) by comparing the voltage from the header line, transmitted by pressure transmitter, to the set value in the drive [2]. The comparison leads to a change in the frequency of the motor,

thus making an effect on it's pumping. The energy values are tapped from the VFD into an energy meter.

The curing process includes 11 critical stages. Each stage is an important part of the overall curing of tyres. Every stage is a process in itself that must run for a specific time interval to maintain standardised results.

Parameters of concern throughout the curing process are curing time, heating temperature and energy consumed by the pumps. The effect of process parameters on tire vulcanization have been studied [3]. If these parameters are not maintained in all the 11 curing stages, the tyres produced will be scrapped off due to various quality defects. Most importantly, every stage in the curing process is irreversible. This means, if any error occurs due to manual intervention or machine faults, then the output tyre will be scrapped off.

Energy monitoring techniques provides the company with feedback on operating practices, it also provides early warning of unpredicted excess consumption caused by equipment malfunctions, operator error and lack of effective maintenance. Energy monitoring systems helps to envision energy consumption trends (daily, weekly, seasonal, operational) and identify specific areas of wasted energy, observe how it changes to relevant driving factors impact energy efficiency, develop performance targets for EM programs and manage energy consumption, rather than accept it as a permanent cost. The aim is to reduce energy costs through improved energy efficiency and energy management control. Other benefits generally include increased resource efficiency and improved production budgeting [4].

A real-time energy monitoring system is discussed in this paper correctly fetches data from the energy meter of individual pumps through Modbus TCP communication. SCADA systems have been developed which allows the operator to view the logged data in a graphical form. Necessary measures can be undertaken by analysing the data in order to save power and minimize its wastage [5].

The paper is organised as follows: Section II explains the methodology which includes the proposed system. Section III demonstrates the results obtained by using HMI and SCADA which consists of the display of power values of each pump and the set point for the header line pressure. Section IV consists of the conclusion based on the observed results.

II. METHODOLOGY

The proposed system aims at minimizing the efforts of manually checking power consumption of the pump.

The first stage of the project involved using a Human Machine Interface (HMI) panel [6], wherein two pump parameters (power and energy) of a few pumps were displayed in real time. The objective was to temporarily monitor both of these parameters. In order to do so, the following steps were taken:

1. Data of one pump were acquired from its energy meter[7] by using a PLC unit through an Ethernet gateway [8].

2. This data was processed to obtain power and energy values of the pump which were then displayed on the HMI panel.

The second stage of the project involves the following steps:

1. To transfer data from the energy meter into a PLC (Programmable Logic Controller) unit, an Ethernet gateway is used. The gateway device helps in segregating bulk data into single streams.

2. The PLC unit (Micrologix 1400) [9] is used to acquire the power and energy consumed by the pump from the energy meter (EMS network). PLC unit (ControlLogix 5572) [10] is used to fetch the pressure of the header line, which is part of the curing network. Both these networks are then combined into a single network using a network translation device (1783-NATR).

3. The 1783-NATR [11] helps in configuring multiple machines on a single line to have identical network settings. The output of the NATR is connected to the SCADA system. This data comprises of parameters like run-time, power, energy consumed and also displays the mode in which the pump is working.

4. The data on the SCADA screen [12] is analysed depending on the needs of the company.

5. Therefore by using PLC and SCADA we achieve real time energy monitoring of the curing pumps.

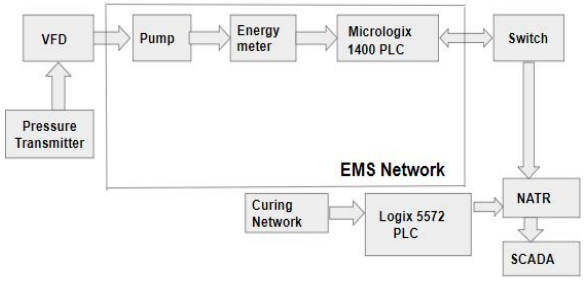

Figure 1. Proposed system block diagram

The inputs to the NATR is given from the EMS network and curing network. The EMS network gives the power consumption of the pumps while curing network gives the pressure from the header line. Fig. 1. shows the block diagram of the proposed system to be implemented. EMS network consists of an Ethernet gateway and PLC. The Ethernet gateway acts as a gateway for data transfer between energy meter and PLC by using Modbus TCP protocol. The energy meter acts as a server and the PLC acts as a client. The input values at the PLC are processed using Micrologix 1400 and then given to the NATR which converts the private port to public port. The second input to NATR is given from the curing network. The Supervisory Control and Data Acquisition (SCADA) system is a communication and control system used for monitoring, operation and maintenance of energy and power.

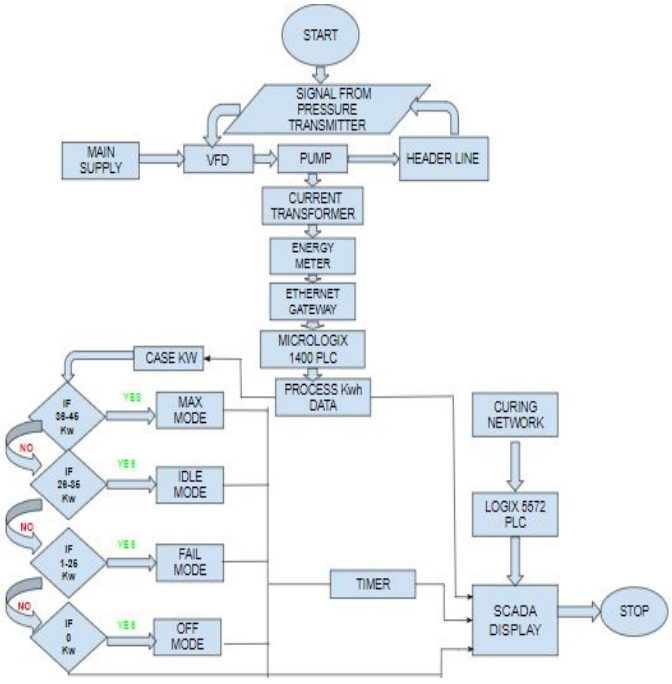

Figure 2. Flowchart

Fig. 2. is the flowchart of the automation process. The flowchart designed can be categorized into three major segments.The first segment shows how the speed of the pump is controlled. A pressure transmitter installed on the header line transmits a signal to the VFD (Variable Frequency Drive). The main supply is also given at the drive. The two voltage levels are processed and accordingly the VFD changes the frequency of the pump thereby varying the speed of the pump. The change in the speed of the pumps results in the change in the pressure in the header line. The next segment identifies the mode in which the pump is working. An energy meter is used to tap values from the current transformer which is present in the VFD panel. The energy meter displays the instantaneous energy, power and operating frequency of the pumps. An ethernet gateway is used to ensure communication between the energy meter and the PLC unit (MicroLogix 1400 PLC). Once the data is received on the PLC unit, with the help of PLC programming the data is processed and thus we determine the mode in which each pump is working. There are four modes in which the pump works depending upon the power consumed by the pump, namely, Max mode, Idle mode, Fail mode and Off mode. The last segment allows a general view of the data monitoring panel on a SCADA software which is displayed on a computer screen. A timer is used to record the time for which the pump is working in a particular mode. A curing network exist which consist of the pressure values of all the pumps in the curing section. These pressure values are processed using a Logix 5572 PLC. The data from this PLC, the timer data, the energy values of the pumps and the data which specifies the mode are all sent onto a SCADA software which is displayed on a computer screen.

III. Results and Discussion

A HMI panel was used to view the pump performance parameters for a certain period. Fig. 3. shows the main screen on the HMI panel. Selecting any one of the first three buttons, we get the screen which displays the pump parameters (ie. power and energy) as shown in Fig. 4.

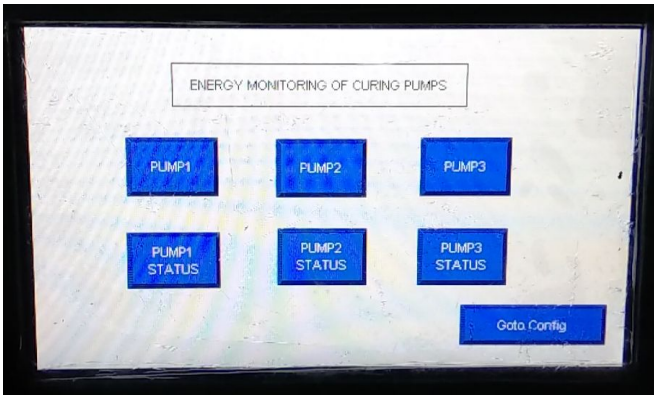

Figure 3. Main Screen of HMI Panel

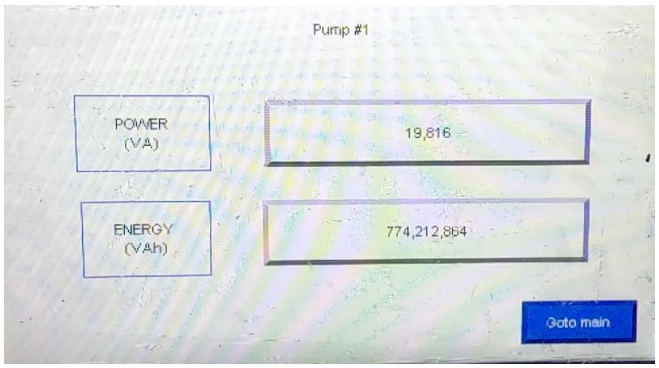

Figure 4. Power and Energy readings of Pump 1 on HMI screen

Figure 5. Pump power status of Pump 1 viewed on HMI Screen

Various pump power status values viewed on the HMI screen (Fig. 5.) include:

- MAX state is used to indicate that the pump is under load and the power is varying between 36-45 kW.
- IDLE state indicates that the pump is in healthy working condition when power drawn is above 20 kW.
- FAIL state is used to indicate that the pump is poorly functioning when the power drawn by the pumps is less than 20 kW.
- OFF state is to indicate that the pump is off.

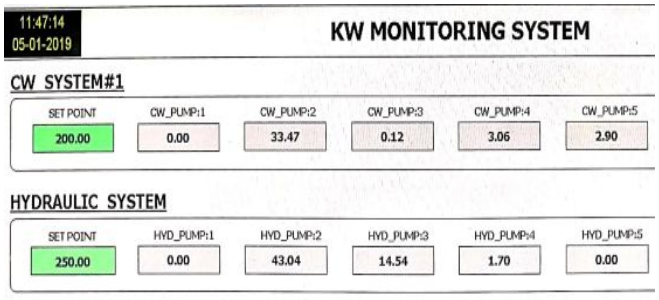

Figure 6. SCADA Screen showing power values of CW SYSTEM#1 and hydraulic pumps

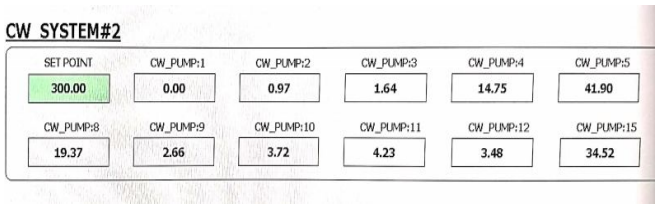

Figure 7. SCADA Screen showing power values of CW SYSTEM#2 pumps

Further on, the monitoring system was implemented on SCADA software to be displayed at the operator's workstation.The general view of the data-monitoring panel is shown in Fig. 6. and Fig. 7. which displays the power values (in kW) for each of the cold water (CW) and hydraulic pumps. The pumps are categorised as CW SYSTEM#1 pumps, hydraulic pumps, and CW SYSTEM#2 pumps. The CW SYSTEM#1 pumps are part of Trenches 1 & 2, whereas the CW SYSTEM#2 pumps are part of Trench 3 up to Trench 9.
The set point value indicates the pressure at the respective header line. This value can be changed by the user as and when required. The kW values are updated each time the pressure at the header line goes below the pressure set point value.

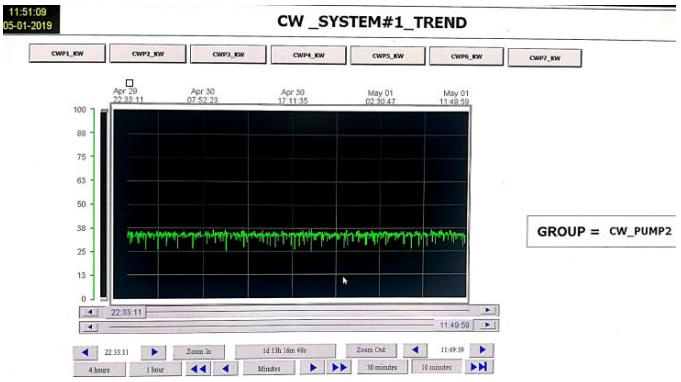

Figure 8. Trend showing power consumed v/s time of CW pump.

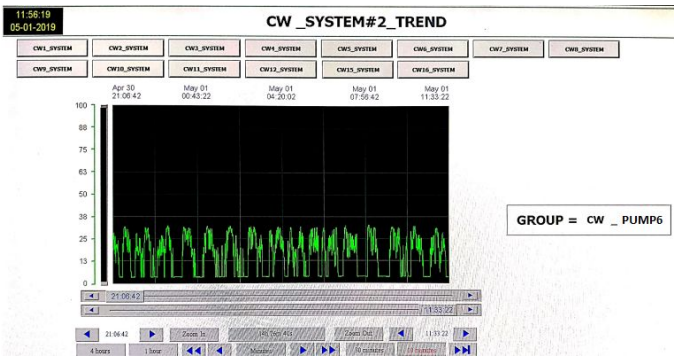

Figure 9. Trend showing power consumed v/s time of CW SYSTEM#2 pump.

Trend determines the gradual change in a process over a certain period of time. Fig. 8., Fig. 9., and Fig. 10. depict the plot of the real time power values. The plotted power values

are continuously updated and displayed depending upon the set time.

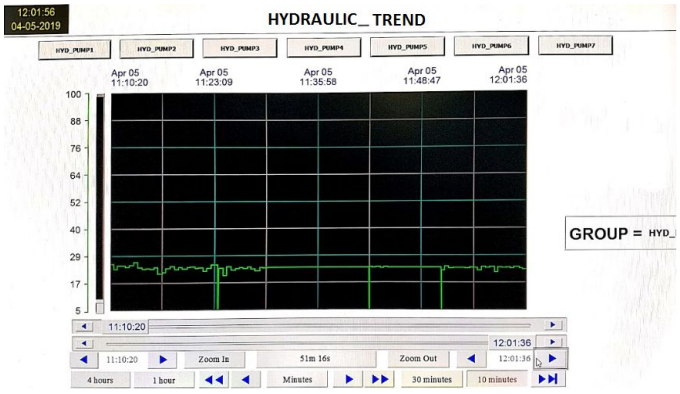

Figure 10. Trend showing power consumed v/s time of hydraulic pump.

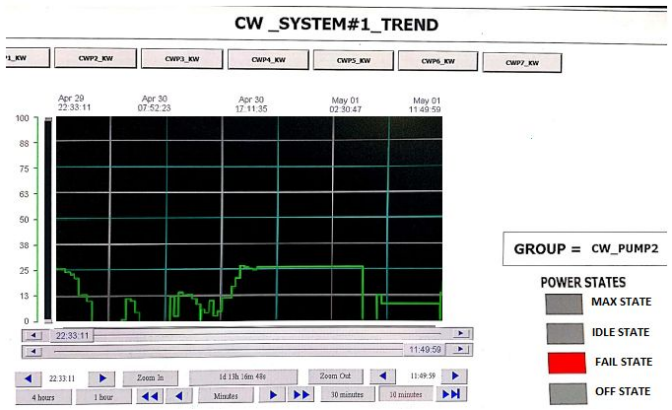

Figure 11. Trend showing power consumed v/s time of CW SYSTEM#1 pump when FAIL state is detected.

In Fig. 11 the onset of failure of the pump inefficiency is detected by the red indication that can be viewed in the power states section. This pump should be frequently monitored. If it remains in the FAIL state for a period of 48 hours, proper troubleshooting procedures should be employed by the operator.

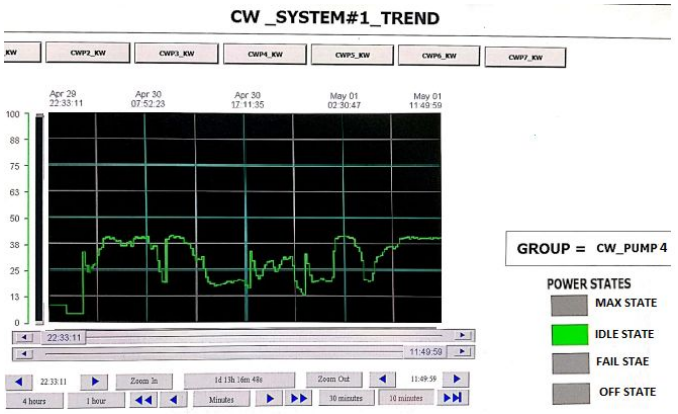

Figure 12. Trend showing power consumed v/s time of CW SYSTEM#1 pump when IDLE state is detected.

Fig. 12. depicts the healthy working condition of a pump (IDLE state). This state indicates that power consumed by the pump is above 20 kW.

IV. Conclusion

The proposed system helps to monitor real-time energy consumption and power values of the cold water pumps and hydraulic pumps used in the curing section of the rubber processing plant. The power values are used to determine the status of each pump. The system logs the measured and calculated electrical data in a database, creating a record of the data for analysis. The data logged can be viewed and analyzed to take measures to save power and minimize its wastage. The implemented trends depicts the power consumed by the respective pump over a period of time. The energy monitoring system therefore minimizes the manual intervention of the operator. Thus human error is minimized resulting in improved reliability.

Acknowledgement

We would like to acknowledge MRF Limited, Goa for providing us the opportunity to implement the energy monitoring system in real time in their factory. We would also like to express our special gratitude and thanks to people from MRF Limited, Goa, for giving us their attention and time.

Abstract*— Cloud computing is one of the emerging area in the business world that help to access resources at low expense with high privacy. Security is a standout amongst the most imperative difficulties in cloud network for cloud providers and their customers. In order to ensure security in cloud, we proposed a framework using different encryption algorithm namely Extended hill cipher and homomorphic encryption. Firstly user data/information is isolated into two parts which is static and dynamic data (critical data). Extended hill cipher encryption is applied over more important dynamic part where we are encrypting the string using matrix multiplication. While homomorphic encryption is applied over static data in which it accepts n number of strings as information, encode each string independently and lastly combine all the strings. The test results clearly manifests that the proposed model provides better information security.

Keywords*— Cloud Computing, Extended Hill Cipher, Homomorphic Encryption, Data Storage, Security.

I. INTRODUCTION

Cloud computing is utilized to get to the assets effectively from the outsider specialist so as to grow the business with low capitalization cost. Due to vast unstructured data over the cloud, information security is the prime concern. Thus, in order to ensure security of the distributed storage, we proposed a framework based on two distinctive encryption algorithms. In this model, user data/information are isolated into two parts such that the secured information is considered as dynamic data while the rest data as static part followed by applying two diverse encryption techniques namely extended hill cipher over the powerful information i.e. dynamic part and homomorphic encryption over static part of the data. The resultant encrypted data is stored in the cloud, thereby making the both common and critical data more secured compared to the previous security techniques that too at the low cost.

Given plaintext x, extended hill cipher converts x into cipher text $y=A\cdot x \pmod n$ where A is the matrix key where $|A| ! =0$ and n represent by 256 [1]. If cryptanalyst knows m pairs (x,y) of successive plaintext and cipher text, he/she can calculate the key matrix A by computing $A=Y\cdot X^{-1} \bmod n$, where X and Y are $m\times m$ matrices of plaintext and cipher text.

In extended hill cipher, strings are divided into group of three and every group is associated with its ASCII values [2]. Extended hill cipher gives better security in comparison to simple hill cipher because hill cipher encrypt only homogenous data and apply modulo 25, while extended hill cipher encrypt heterogeneous data type and apply modulo256.

Further, homomorphic encryption permits executing computations on the scrambled information [3]. It is one of the progressed cryptographic procedures that support arbitrary number of both operations addition as well as multiplication on cipher text. To retrieve user data $x=A^{-1}\cdot y \pmod n$ where A is original inverse matrix, y is encrypted matrix and n represent modulo 256.

The structure of this paper is as follows: Section II describes the related research work. Section III explains the proposed technique in detail. Evaluation of the scheme by different experiments is done in Section IV and finally Section V concludes the paper.

II. RELATED WORK

The significance of security in cloud has pulled the great attention nowadays. Safe cloud storage architectures are of prime concern. Cong Wang et al. [4], have suggested the protection issues related in distributed storage. Whenever a data vulnerability is scrutinize during the storage process, the accuracy identification across the distributed servers are ensured by simultaneous identification of misbehaved nodes through analysis in term of privacy functioning. It is proved that their technique is dominant to handle certain failures, malevolent data modification attack and even server attacks.
J. Shen et al. [5], considered cloud as semi-trusted and proposed a model for urban information sharing by using attribute based cryptography. The procedure they presented is sheltered and can challenge potential assaults. G. Feng et al. [6], point out that when the server load increases the chances of information leakage are there at the time of transmission in cloud servers. They proposed an adequate system encoding in closed cloud environment. Wang et al. [7], proposed a plan that allows clients to review the distributed storage for correctness of the data inside the server. Their plan likewise underpins protected and powerful unique information altering activities. They have accomplished the information uprightness just as information accessibility in distributed storage. J. Hou et al. [8], considered that at peak load, client's

information is put away through CSP (cloud server supplier), regardless of whether CSP is trusty, programmer still gather client information from server in the event that they deal with the distributed storage.

Above mentioned authors attempt to improve the security in cloud service in various terms. Lightly of them used various encryption approaches at different positions, while others attempt to tackle the protection issue with the help of inspecting or building their own security frameworks. Moreover, there is a typical issue in these research works. When the CSP itself is untrusted then these approaches are not effective ones and cannot avoid internal attacks or prevent the CSP from selling user's data to earn illegal profit. Therefore, we introduced a new secure cloud storage technique in this paper. We are dividing file into two parts and applying two cryptographic techniques. We can achieve high degree privacy protection of data. In our scheme encryption helps to protect fine-grained security of the data.

III. PROPOSED FRAMEWORK

The proposed secure cloud storage framework is shown in Fig.1 which consists of seven components namely user, static files, dynamic files over which homomorphic encryption and extended hill cipher encryption algorithms are applied, merged file and cloud server provider. This structure is utilized to store and recover information in a safe way from the cloud server. At server there are numerous customers utilizing the distributed storage services. The cloud server administrator knows the proprietor of the information and deals with the solicitation of the customer. The cloud server director chooses what information ought to be sent by customer's solicitation. Now suppose if CSP itself is untrusted there is a chance of data leakage, thus to avoid this problem, we proposed user level encryption techniques.

In fig.1 initially user data is divided into two separate parts which are static and dynamic. After splitting the data, apply the different encryption techniques on both the data. Static files fall under homomorphic encryption technique while dynamic files representing crucial data fall under more efficient extended hill cipher encryption technique. To retrieve the user data from CSP, user sends the request to the cloud server and CSP grant the user request and sent the user data which is encrypted file. After receiving the file from CSP, both the files fall under reverse decryption technique. Finally merge both files to get original data safely.

A. Extended Hill Cipher Algorithm

Extended hill cipher is a technique based on linear algebra. In extended hill cipher encryption algorithm, each string is grouped into multiple of three and initialized with its ASCII values in matrix form and then multiplied by 3 × 3 matrix whose determinant is not zero. Resultant matrix undergoes modulo 256 and stores the value in another matrix. Then convert resultant valued matrix back to its character form representing the encrypted cipher text. To encrypt the message, each section is multi played by the inverse of the original matrix. In hill cipher we can only encrypt homogeneous data and apply modulo 25. While in extended hill cipher encryption is applied to heterogeneous strings with modulo 256. Thus, the extended hill cipher provides better security to the customer's information.

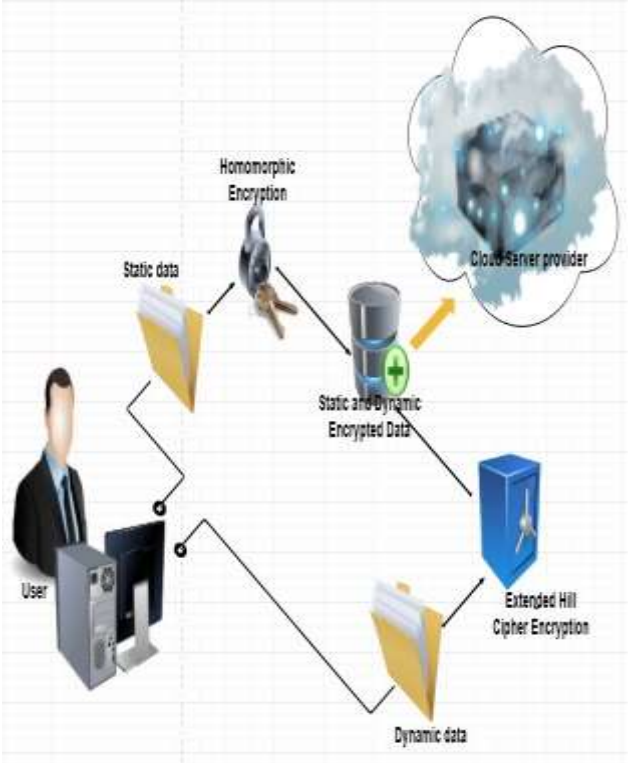

Fig.1 Secure Cloud Storage Framework

- Select invertible matrix A
- Calculate $y=A \cdot x \pmod n$.

  Alice sends (y, A) to Bob.

Where A is key matrix, y represent cipher text and x represent resultant plain text.

a. Encryption Process

- Select a plaintext message to encrypt containing all characters as well as special symbol and digits.

  Let's take an example, Nit_kkr9@gmail.com is our plaintext message and we will convert plaintext to cipher text.

- Initialize a 3x3 square matrix with nonnegative integer each less than 256.

$$A = \begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}$$

- Check its determinant does NOT equal to zero, $|A| \neq 0$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}$$ =6(16*15 – 17*10) – 13(24*15 – 17*1) + 20(24*10 – 16*1) = 441

- Group the string into group of three as follows Nit_kkr9@gmail.com

  Example:-[Nit][_kk][r9@][gma][il.][com]

  If the string length does not have mod 3 == 0, repeat the last letter.

- Convert the character into its ASCII value

$N-78$	$_-95$	$r-114$
$i-105$	$k-107$	$9-57$
$t-116$	$k-107$	$@-64$
$g-103$	$i-105$	$c-99$
$m-109$	$l-108$	$o-111$
$a-97$	$.-46$	$m-109$

- Multiply the converted matrix into given matrix

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 78 \\ 105 \\ 116 \end{bmatrix} = \begin{bmatrix} 3104 \\ 3854 \\ 5085 \end{bmatrix}(\text{mod})256 = \begin{bmatrix} 32 \\ 14 \\ 221 \end{bmatrix}$$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 95 \\ 107 \\ 107 \end{bmatrix} = \begin{bmatrix} 3245 \\ 4017 \\ 5324 \end{bmatrix}(mod)256 = \begin{bmatrix} 173 \\ 177 \\ 204 \end{bmatrix}$$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 114 \\ 57 \\ 64 \end{bmatrix} = \begin{bmatrix} 2116 \\ 3034 \\ 4209 \end{bmatrix}(mod)256 = \begin{bmatrix} 68 \\ 218 \\ 113 \end{bmatrix}$$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 103 \\ 109 \\ 97 \end{bmatrix} = \begin{bmatrix} 3331 \\ 4053 \\ 5368 \end{bmatrix}(mod)256 = \begin{bmatrix} 3 \\ 213 \\ 248 \end{bmatrix}$$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 105 \\ 108 \\ 46 \end{bmatrix} = \begin{bmatrix} 3268 \\ 3553 \\ 4626 \end{bmatrix}(mod)256 = \begin{bmatrix} 196 \\ 225 \\ 18 \end{bmatrix}$$

$$\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}\begin{bmatrix} 99 \\ 111 \\ 109 \end{bmatrix} = \begin{bmatrix} 3367 \\ 4153 \\ 5502 \end{bmatrix}(mod)256 = \begin{bmatrix} 39 \\ 57 \\ 126 \end{bmatrix}$$

- Convert each entry in the matrix back to its ASCII string representing the cipher text.

```
Original string is: Nit_kkr9@gmail.com
Encrypted string is: ▯▯¡▒╣D┌q♥F°—β↕'9~
```

Fig.2 Encrypted String (Cipher Text)

b. Decrypting a String

In order to decrypt the cipher test into plain text, you must know the encrypted matrix. Get a cipher message to decode it in plain text or Standard English string.

- Calculate A^{-1}.
- Calculate $x=A^{-1} \cdot y \pmod{n}$.

  Where A^{-1} is invers matrix, y represent cipher text and x represent resultant plain text.

- In the given example decrypt the message

```
Encrypted string is: ▯▯¡▒╣D┌q♥F°—β↕'9~
```

Fig.3 Decoded String

Given extended hill cipher with original matrix

$$A=\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}$$

- Group all encrypted string into multiple of three and replace each of them into its ASCII values

$$\begin{bmatrix} 32 \\ 14 \\ 221 \end{bmatrix}\begin{bmatrix} 173 \\ 177 \\ 204 \end{bmatrix}\begin{bmatrix} 68 \\ 218 \\ 113 \end{bmatrix}\begin{bmatrix} 3 \\ 213 \\ 248 \end{bmatrix}\begin{bmatrix} 196 \\ 225 \\ 18 \end{bmatrix}$$

- Get the inverse of the original matrix. i.e. Inverse of matrix A^{-1} = Adj (A) / |A|,

$$(Adj)A=\begin{bmatrix} 6 & 24 & 1 \\ 13 & 16 & 10 \\ 20 & 17 & 15 \end{bmatrix}= \begin{bmatrix} \begin{bmatrix} 16 & 10 \\ 17 & 15 \end{bmatrix} & \begin{bmatrix} 13 & 10 \\ 20 & 15 \end{bmatrix} & \begin{bmatrix} 13 & 16 \\ 20 & 17 \end{bmatrix} \\ \begin{bmatrix} 24 & 1 \\ 17 & 15 \end{bmatrix} & \begin{bmatrix} 6 & 1 \\ 20 & 15 \end{bmatrix} & \begin{bmatrix} 6 & 24 \\ 20 & 17 \end{bmatrix} \\ \begin{bmatrix} 24 & 1 \\ 16 & 10 \end{bmatrix} & \begin{bmatrix} 6 & 1 \\ 13 & 10 \end{bmatrix} & \begin{bmatrix} 6 & 24 \\ 13 & 16 \end{bmatrix} \end{bmatrix} =$$

$$\begin{bmatrix} 70 & -343 & 224 \\ 5 & 70 & -47 \\ -99 & 378 & -216 \end{bmatrix}$$

$$A^{-1} = 441 \begin{bmatrix} 70 & -343 & 224 \\ 5 & 70 & -47 \\ -99 & 378 & -216 \end{bmatrix} =$$

$$\begin{bmatrix} 0.158730 & -0.777778 & 0.507937 \\ 0.0113379 & 0.158731 & -0.106575 \\ -0.224491 & 0.857143 & -0.489796 \end{bmatrix}$$

- Multiply the enciphering matrix with inverse matrix and modulo 256.

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011337 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 3104 \\ 3854 \\ 5085 \end{bmatrix} =$$

$$(mod)\ 256 = \begin{bmatrix} 78 \\ 105 \\ 116 \end{bmatrix}$$

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011339 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 3245 \\ 4017 \\ 5324 \end{bmatrix}$$

$$(mod)\ 256 = \begin{bmatrix} 95 \\ 107 \\ 107 \end{bmatrix}$$

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011337 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 2116 \\ 3034 \\ 4209 \end{bmatrix} =$$

$$(mod)\ 256 = \begin{bmatrix} 114 \\ 57 \\ 64 \end{bmatrix}$$

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011337 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 3331 \\ 4053 \\ 5368 \end{bmatrix} =$$

$$(mod)\ 256 = \begin{bmatrix} 103 \\ 109 \\ 97 \end{bmatrix}$$

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011337 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 3268 \\ 3553 \\ 4626 \end{bmatrix} =$$

$$(mod)256 = \begin{bmatrix} 105 \\ 108 \\ 46 \end{bmatrix}$$

$$\begin{bmatrix} +0.158730 & -0.777778 & +0.507937 \\ +0.011337 & +0.158731 & -0.106575 \\ -0.224491 & +0.857143 & -0.489796 \end{bmatrix} \begin{bmatrix} 3367 \\ 4153 \\ 5502 \end{bmatrix}$$

$$(mod)\ 256 = \begin{bmatrix} 99 \\ 111 \\ 109 \end{bmatrix}$$

- Convert each integer in the plaintext into its corresponding ASCII values.

$$\begin{array}{llll} N-78 & _-95 & r-114 & g-103 \\ i-105 & k-107 & 9-57 & m-109 \\ t-116 & k-107 & @-64 & a-97 \\ i-105 & c-99 & & \\ l-108 & o-111 & & \\ .-46 & m-109 & & \end{array}$$

- The decrypted string is now as original plain text: Nit_kkr9@gmail.com

B. *Homomorphic Algorithm*

A homomorphic encryption technique allows user to operate on encrypted text directly. Thus, making use of homomorphic encryption assures customer's data secure in all states: storage, transmission and processing. Shi Zhongpan et al. [9], presents a homomorphic calculations focusing on database and fulfill homomorphic expansion and augmentation. Boneh D et al.[10] clarify the homomorphic encryption ideas; this system is connected to the cloud condition to secure the information. The homomorphic encryption procedure permits executing calculations on the encoded information.

Basic concept of homomorphic encryption is shown in figure-2. Suppose a user want to add two numbers 5 and 10, which are stored on cloud data server in encrypted form (assume 5 instead of 10 and 10 instead of 20 respectively). Each digit are multiply by 2 and to reverse divide by 2.

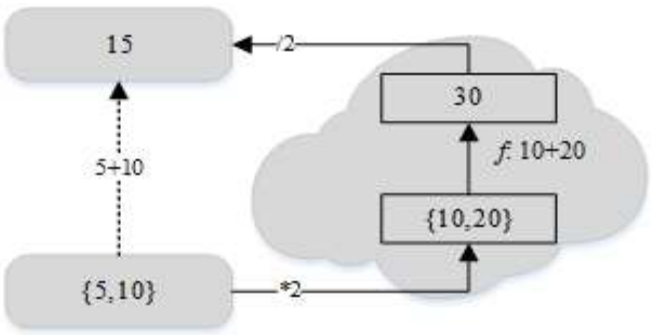

Fig.4 Homomorphic encryption

Homomorphic encryption can be either partial homomorphic or fully homomorphic encryption. Partial homomorphic encryption scheme supports either addition operation (known as additive homomorphic encryption scheme) or multiplication operation (known as multiplicative homomorphic encryption scheme). Such a scheme can perform limited number of operations. On other hand, fully homomorphic encryption (FHE) underpins random number of the two operations.

1. *Encryption Process*

At first we group the message and group length is to be decided as per the user's interest for protection. Now, each group is encoded by the homomorphic calculation.

- Select two random numbers and select two big prime numbers X and Y (more the number of digits are, safer the data is).

- Calculate N=X× Y, and get a random Z;
- Divide the plain text W into sections of length (I) whose count of digits is less than X, W = $w_1,w_2,w_3,\ldots wt$.
- Use the encryption algorithm $C_i = (W_i + I*X) \bmod N$, and compute the cipher text C = $c_1,c_2,c_3\ldots$etc.
- Send the decoded text C to the receiver.

2. *Decryption Process*

- The receiver gets the cipher text C, and groups $C=c_1,c_2,c_3\ldots ct$;
- Use the key X and the decryption algorithm $W_i = C_i \bmod X$ to compute w_i.
- At the last, we can get the plaintext W.

IV. Experimental and Result Analysis

The motivation behind this paper is apply encryption over the cloud data in order to provide information safety and to increment consumer satisfaction by not allowing the third party attack. For evaluating the proposed technique, security attack and time complexity are tested with the other important algorithms.

TABLE I. AVERAGE TIME COMPLEXITY ANALYSIS IN (SEC)

Data size (mb)	001 - 010	011 - 020	021 - 030	031 - 040	041 - 050
Caser cipher	1.0596	2.8152	5.4287	7.5783	8.9846
XOR - Cipher	0.447	1.3581	2.1476	3.0006	3.9989
Vigenere cipher	2.3306	5.7173	8.5286	12.4501	23.5996
Homomorphic	0.4458	2.2071	3.1156	4.5183	6.3086
Hill cipher	860.4412	1806.2217	2440.7313	3086.0851	3832.3503
Extended Hill cipher	1444.3303	2781.1141	4136.5001	5314.4113	6564.2563

A. Security Attacks

Security is the safety of the information that is put away on the distributed storage unit. There are numerous cryptographic techniques for limiting third party attacks. There are many types of attacks on any cryptosystem such as Cipher text Only Attack (COA), Known Plaintext Attack (KPA), Chosen Plaintext Attack (CPA), Dictionary Attack, Brute Force Attack (BFA), and Fault Analysis Attacks (FAA) out of which the extended hill cipher technique is more suitable for data security due to matrix multiplications in comparison to simple hill cipher encryption, caser cipher, xor-cipher, vigenere cipher and homomorphic algorithm [11].

However, mentioned algorithms consume less time but also provide low security. When we transmit 01-10 MB of data, extended hill cipher provides high security at the expense of more time complexity than any other algorithm.

B. Time Complexity

Time complexity of the framework is determined considering the execution time. So when are transmitting (01-10)...(40-50) MB of information, the extended hill cipher encryption takes more time to all others encryption calculations O ($m^{2.373}$) (Table-1). But when we compare security level, extended hill cipher gives more security than all others. Extended hill cipher basically focuses on the high level security.

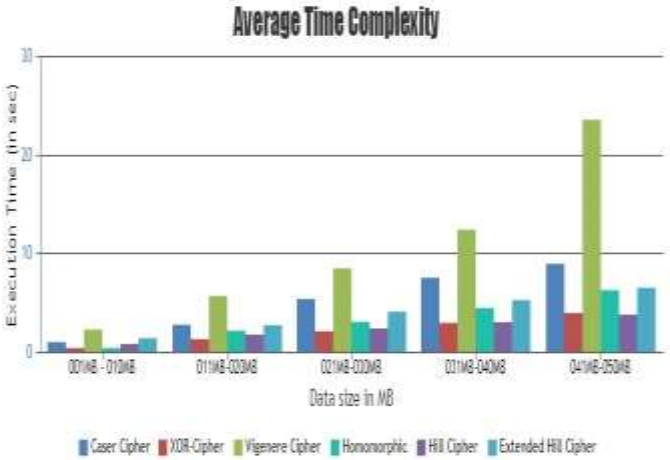

Fig.5 Execution time comparison

When data (in term of megabytes 01MB – 10MB) are encrypted, all the encryption algorithms take approximately same time. However, when we increase the data size, time complexity of all the algorithms increase drastically. In order to represent it in a graph in effective manner, we divided original time (sec) by 1000.

V. Conclusion

Cloud Storage is simply storing data and providing backups of data on virtual cloud server. In cloud storage server, security is a major issue. Encryption is a main technique to solve the data leakage problem. At the point when security level in cloud turns out to be high then integrity and privacy will be high for clients and specialist co-ops. So, we proposed a secure technique to avoid data leakage problem from server side as well as user side. Proposed algorithm which is efficient, secure and unassisted provides security as well as static confidentiality to the data. The technique guarantees the transmission information between the cloud and the customer side safely.

According to [12], the time complexity of matrix multiplication is O ($m^{2.373}$), where m is the degree of the matrix. Also, the time complexity of adding two matrices is O (m^2) , Moreover, the time complexity of XOR two matrices is O(m^2) . Thus, the total time complexity of EHC is O ($m^{2.373}$) + 2 × O (m^2) ~= O ($m^{2.373}$); i.e. the complexity of EHC is O ($m^{2.373}$) which is little bit more then to the complexity of the hill cipher. Time complexity may be improved in future.

***Abstract*—In this paper Inertial delay control(IDC) based sliding mode control(SMC) for 4 wheel steering(4WS) vehicle which focuses on the maneuvering flexibility and steering stability of the vehicle. To achieve above a new method for variable steering ratio(VSR) is introduced. A nonlinear vehicle model is considered along with the uncertainties in cornering stiffness, mass and vehicle speed. To compensate the effect of nonlinearities and uncertainties and also controlling lateral dynamics an IDC based SMC is proposed to achieve required side-slip angle and yaw rate of vehicle based on VSR. Further a simulation is executed to analyze the performance of proposed controller for 4WS by tracking the system dynamics to follow the desired model regardless of the nonlinearities and uncertainties. The proposed controller is also validated with Carsim software.**

***Index Terms*—Variable steering ratio, four wheel steering, sliding mode control, inertial delay control, Carsim**

I. Introduction

As automobile industry is developing very fast and most of the people rely on vehicle, stability of vehicle is a big factor. Earlier for yaw stability of vehicle, reseachers used Active front wheel steering(AFS) but it was limited to stability in low to medium speed region of the vehicle due to saturation of lateral forces. As the advancement to get the stability in the high speed region active front steering was combined with braking(DYC), or with ARS i.e 4WS. [1] During turning vehicle performance can be enhanced by actively steering rear wheels as well as front wheels (4WS). The 4WS system can control both yaw rate and lateral velocity of the vehicle. In [2], LPV controller was implemented for velocity varying 4WS vehicle model having uncertainties in mass, cornering stiffness and external disturbances. A second order dynamics decoupling controller was designed in [3] for 4WS vehicle by decoupling the lateral speed and yaw rate. An optimal control theory based controller was designed for model matching in low and high speed of 4WAS is done [4]. An active 4WS non smooth sliding mode controller with finite time convergence was designed for an electric vehicle in [5] to track the desired model. In [6] sliding mode controller having an intergral sliding surface was proposed to eliminate steady state errors. In [7] DOB control strategy for 4WAS was presented, to deal with ignored nonlinear vehicle model and cross wind disturbance.

The steering ratio (SR) is ratio of handwheel and front wheel angle, which has impact on the maneuvering flexibility and vehcile stability [8]. This SR should be varying with vehicle speed because 1) at low speed to get the maneuvering flexibility the SR should be small so that for small handwheel angle it will produce large front wheel angle and 2) at high speed to prevent steering sensitivity a large SR should be given to satisfy the steering stability [9]. Different methods were designed and derived to get the Variable Steering Ratio (VSR) such as constant yaw rate gain , constant lateral acc. gain,combination of both [10] and Fuzzy neural network approach [9]. In summary most of the present researchers focuses on yaw stability, while focus on maneuvering flexibility and steering stability are focused less and very fewer have done the combination of robust yaw stability of 4WS based on VSR strategy.

In this paper the focus is on maneuver flexibility and steering stability and a robust Inertial delay based SMC is applied to achieve yaw stability i.e to follow the desired model of lateral dynamics. The validation is done in Carsim software.

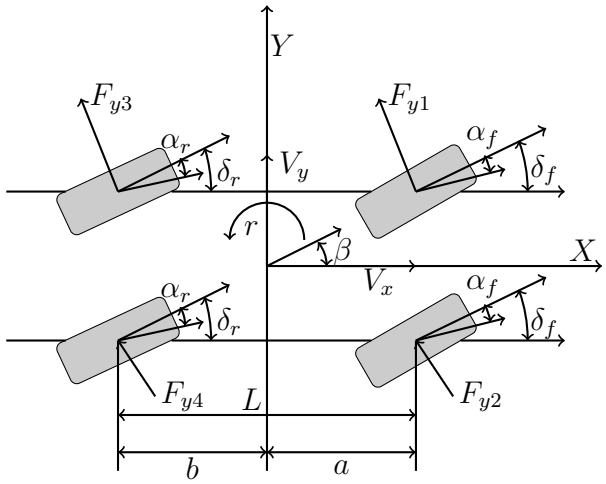

Fig. 1. 4 wheel steering dynamic model

This paper key features are as follow :

- Nonlinear 4WS vehicle model is derived also uncertainties in cornering stiffness, mass, vehicle speed are taken.
- The new function for variable steering ratio is proposed using this strategy the desired model of vehicle lateral dynamics is obtained.
- To track the desired vehicle lateral dynamics regardless of nonlineartities and uncertainties a robust Inertial Delay Control based sliding mode controller is designed.
- Validation of proposed controller in Carsim software.

Organization of this paper is as follow, Section I gives brief introduction of latest work. Section II derives the 4WS nonlinear vehicle model along with desired model of lateral dynamics. An IDC based sliding mode controller is implemented in Section III. Section IV shows the effectiveness of proposed controller and Section V convey robustness through Carsim validation. Section VI is conclusion.

II. Problem Setup

A. Modelling of nonlinear 4WS vehicle

A double track model of 4 wheel steering vehicle is seen in Fig.1 . [11], [12] The 2 DOF vehicle model captures the lateral dynamics obtained as

$$mV_x(\dot{\beta}+r) = F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x1}sin\delta_f + F_{x2}sin\delta_f + F_{x3}sin\delta_r + F_{x4}sin\delta_r \quad (1)$$

$$I_{zz}\dot{r} = a(F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{x1}sin\delta_f + F_{x2}sin\delta_f) - b(F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x3}sin\delta_r + F_{x4}sin\delta_r) + \frac{tw}{2}(F_{y1}sin\delta_f - F_{y2}sin\delta_f + F_{y3}sin\delta_r - F_{y4}sin\delta_r + F_{x2cos\delta f} - F_{x1}cos\delta f + F_{x4}cos\delta r - F_{x3}cos\delta r) \quad (2)$$

where δ_f and δ_r are front and rear wheel angle, $a_y = v_x(\dot{\beta}+r)$ is the lateral acceleration at C.G of vehicle. F_{xi} and F_{yi} are longitudinal and lateral forces simultaneously produced by front and rear tires. i is the sequence of tires .The slip angle of front and rear tires are obtained as

$$\alpha_{1,2} = -\delta_f + \beta + \frac{ar}{v_x}$$
$$\alpha_{3,4} = -\delta_r + \beta - \frac{br}{v_x} \quad (3)$$

we have considered a linear tire model i.e. assuming that slip angles are small thus, the lateral forces are given by

$$F_{y1,2} = -\mu c_{1,2}\alpha_{1,2}$$
$$F_{y3,4} = -\mu c_{3,4}\alpha_{3,4} \quad (4)$$

where μ is co-efficient of friction between road & tyre.$c_{1,2}$ and $c_{3,4}$ are the cornering stiffness of front and rear wheels respectively

The vehicle weight is evenly distributed i.e no logitudinal load transfer occurs.Thus the vertical loads are obtained as

$$F_{z1,2} = \frac{mgb}{2L}$$
$$F_{z3,4} = \frac{mga}{2L} \quad (5)$$

where g is the accceleration due to gravity. Now the longitudinal tire forces are given by

$$F_{xi} = \mu F_{zi} \quad (6)$$

by re-arranging (1–2) equations, vehicle lateral dynamics are derived as

$$\dot{\beta} = \frac{1}{mV_x}(F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x1}sin\delta_f + F_{x2}sin\delta_f + F_{x3}sin\delta_r + F_{x4}sin\delta_r) - r \quad (7)$$

$$\dot{r} = \frac{1}{I_{zz}}[(F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{x1}sin\delta_f + F_{x2}sin\delta_f)a - b(F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x3}sin\delta_r + F_{x4}sin\delta_r)] + \frac{t_w}{2I_{zz}}(F_{y1}sin\delta_f - F_{y2}sin\delta_f + F_{y3}sin\delta_r - F_{y4}sin\delta_r + F_{x2}cos\delta f - F_{x1}cos\delta f + F_{x4}cos\delta r - F_{x3}cos\delta r) \quad (8)$$

As there are uncertainties in cornering stiffness , mass, vehicle speed and lateral and longitudinal forces are multiplied with nonlinear terms all these are lumped together in disturbances and again re-arranging the system equations we get,

$$\dot{\beta} = B_{11}\delta_f + B_{12}\delta_r + d_1 \quad (9)$$

where $B_{11} = \frac{2c_{1,2}}{mV_x}$, $B_{12} = \frac{2c_{3,4}}{mV_x}$ and

$$d_1 = \frac{1}{mV_x}(F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x1}sin\delta_f + F_{x2}sin\delta_f + F_{x3}sin\delta_r + F_{x4}sin\delta_r) - r - B_{11}\delta_f - B_{12}\delta_r$$

$$\dot{r} = B_{21}\delta_f + B_{22}\delta_r + d_2 \tag{10}$$

where $B_{21} = \frac{2ac_{1,2}}{I_{zz}}$, $B_{22} = \frac{-2bc_{3,4}}{I_{zz}}$ and

$$\begin{aligned} d_2 = \frac{1}{I_{zz}}(&F_{y1}cos\delta_f + F_{y2}cos\delta_f + F_{x1}sin\delta_f + F_{x2}sin\delta_f)a \\ &-b(F_{y3}cos\delta_r + F_{y4}cos\delta_r + F_{x3}sin\delta_r + F_{x4}sin\delta_r) \\ &+\frac{tw}{2}(F_{y1}sin\delta_f - F_{y2}sin\delta_f + F_{y3}sin\delta_r - F_{y4}sin\delta_r \\ &+F_{x2}cos\delta f - F_{x1}cos\delta f + F_{x4}cos\delta r - F_{x3}cos\delta r) \\ &-B_{21}\delta_f - B_{22}\delta_r \end{aligned}$$

B. Reference model of lateral dynamics

The desired steering response is obtained from 2 DOF bicycle model of FWS vehicle which requires a desired front wheel angle (δ_{fd}).The VSR strategy is used to get δ_{fd} according to vehicle speed.
By studying conditions for VSR strategy from [8] we have proposed new function of VSR ,

The newly proposed VSR is given by

$$i = i_0 + a(1 - e^{-\alpha V_x^3}) \tag{11}$$

$$\delta_{fd} = \frac{\theta_{hw}}{i} \tag{12}$$

where i is the VSR , θ_{hw} is Handwheel angle, i_0 is initial value ,i_0+a is the final value and α decides rate of exponential term.

The desired lateral dynamics model for 4WS will be same as derived for FWS so that the perception of driver does not change.Thus the desired lateral dynamics are given by

$$\beta_d = \frac{k_\beta}{\tau_\beta s + 1}\delta_{fd} \tag{13}$$

$$r_d = \frac{k_r}{\tau_r s + 1}\delta_{fd} \tag{14}$$

where k_β and k_r are proportional gain : $k_\beta = 0$, $k_r = \frac{V_x}{(L+KV_x^2)}$, K is the understeer gradient $K = \frac{m}{L}(\frac{b}{c_1c_2} - \frac{a}{c_3c_4})$, τ_β and τ_r are time constant for desired side-slip angle and yaw rate respectively,

The state space equation of desired model is obtained as

$$\dot{x}_d = A_d x_d + B_d u_d \tag{15}$$

where , state vector $x_d = \begin{bmatrix}\beta_d \\ r_d\end{bmatrix}$,state matrix $A_d = \begin{bmatrix}-\frac{1}{\tau_\beta} & 0 \\ 0 & -\frac{1}{\tau_r}\end{bmatrix}$, input matrix $B_d = \begin{bmatrix}\frac{k_\beta}{\tau_\beta} \\ \frac{k_r}{\tau_r}\end{bmatrix}$ and desired input $u_d = \delta_{fd}$.

III. Control strategy for yaw stability

Aim of this controller is to enhance maneuvering flexibility and steering stability.
Sliding surfaces used for side-slip angle and yaw rate tracking are stated as follow

$$\sigma_\beta = \beta - \beta_d \tag{16}$$

$$\sigma_r = r - r_d \tag{17}$$

For control strategy the system can be represented in the form of

$$\dot{\beta} = u_\beta + d_\beta \tag{18}$$

where $u_\beta = B_{11}\delta_f + B_{12}\delta_r$

$$\dot{r} = u_r + d_r \tag{19}$$

where $u_r = B_{21}\delta_f + B_{22}\delta_r$
by differentiating both sliding surfaces

$$\dot{\sigma_\beta} = u_\beta + d_\beta - \dot{\beta}_d \tag{20}$$

$$\dot{\sigma_r} = u_r + d_r - \dot{r}_d \tag{21}$$

the required control is obtained as

$$u_\beta = -\hat{d}_\beta + \dot{\beta}_d - K_\beta\sigma_\beta \tag{22}$$

$$u_r = -\hat{d}_r + \dot{r}_d - K_r\sigma_r \tag{23}$$

Estimation of uncertainty using inertial delay control method, the estimation of $d_\beta \& d_r$ are calculated by

$$\hat{d}_{\beta,r} = \frac{1}{\tau_{1,2}}(\int \sigma_{\beta,r}dt + \sigma_{\beta,r}) \tag{24}$$

the dynamics of uncertainties estimator thus becomes [13] [14]

$$\hat{d}_{\beta,r} = \frac{d_{\beta,r}}{\tau_{1,2}s + 1} \tag{25}$$

$$\dot{\hat{d}}_{\beta,r} = \frac{\tilde{d}_{\beta,r}}{\tau_{1,2}} \tag{26}$$

$$\tilde{d}_{\beta,r} = d_{\beta,r} - \hat{d}_{\beta,r} \tag{27}$$

then by differentiating and substituting :

$$\dot{\tilde{d}}_{\beta,r} = \dot{d}_{\beta,r} - \frac{\tilde{d}_{\beta,r}}{\tau_{1,2}} \tag{28}$$

Thus by applying Lyapunov stability, $\tilde{d}_{\beta,r}$ is bounded by $\mid \dot{d}_{\beta,r} \mid \tau_{1,2}$.
Putting u_β and u_r in (20) and (21) we get

$$\dot{\sigma}_{\beta,r} = -K_{\beta,r}\sigma_{\beta,r} + \tilde{d}_{\beta,r} \tag{29}$$

now the sliding condition i.e $\sigma\dot{\sigma}$ becomes

$$\sigma_{\beta,r}\dot{\sigma}_{\beta,r} \leq -\sigma_{\beta,r}(K_{\beta,r} \mid \sigma_{\beta,r} \mid - \mid \tilde{d}_{\beta,r} \mid) \tag{30}$$

This states that $\sigma_{\beta,r}$ will go to zero asymptotically.Thus ensuring side-slip angle and yaw rate will track the desired trajectories.

TABLE I
SPECIFICATIONS OF 4WS VEHICLE

Model specifications	Values
Mass of vehicle (m)	1270 kg
Yaw moment of inertia (I_{zz})	1536 kgm^2
Front axle to C.G distance (a)	1.01 m
Rear axle to C.G distance (b)	1.9 m
Wheel base length (L)	2.91 m
Track width (t_w)	1.55 m
Cornering stiffness of front tires ($c_{1,2}$)	45386 N/rad
Cornering stiffness of rear tires ($c_{3,4}$)	45386 N/rad

IV. SIMULATION RESULTS

To validate, the simulation of the proposed controller is performed on MATLAB/Simulink. In order to verify the robustness of the proposed controller for 4WS we have compared it with passive vehicle and applied same controller to FWS. Observing the limitations of FWS over 4WS by comapring with desired value of yaw rate and sideslip angle.A J-turn maneuver i.e constant handwheel input(θ_{hw}) of 1.74 rad is given by driver and vehicle has been simulated for two logitudinal speed(V_x) i.e for low speed–13.88 m/s (50 $Kmph$) and high speed–33.33 m/s (120 $Kmph$).As all the paramters such cornering stiffness,mass , vehicle speed have uncertainties and are lumped together in disturbances.To compensate this disturbances the IDC is used to make the real time estimate of disturbances.Further controller uses this estimate to attenuate effect of lumped disturbances.Take values of vehicle parameters from Table I and for controller parameters refer Table II for simulation purpose.

The Fig. 2b depicts that yaw rate error for passive is more than AFS and 4WAS.AFS and 4WAS shows almost same response for yaw rate. But the main difference can be seen in Fig. 2a due to the limitation of AFS of controlling only one state the sideslip angle is very poor as compared to 4WAS response.Still it is considerable for low speed region as vehicle stability is mostly depend on yaw rate .Now, for high speed region as sideslip angle increases the vehicle stability not only depends on yaw rate but also sideslip angle.Thus controlling both yaw rate and sideslip angle is important at high speed.The simulation results for high speed from Fig. 3 shows that tracking response of 4WAS for both dynamics are superior than AFS and passive responses.

V. CARSIM VALIDATION

The robustness of the designed controller is observed in simulation section.However ,some assumptions were made at the time of deriving the mathematical model.So,to verify the practicability of IDC based SMC 4WAS Carsim-Matlab co-simulation is performed.Carsim is popular tool used in automobile industry to validate different control strategy.In this Carsim a C-class hatchback car model is considered. In Fig. 4, the CarSim results are obtained for higher speed, from Fig. 4a the side slip angle of passive steering and AFS are not tracking the desired tracjectory but the proposed 4WAS tracks it closely.In Fig. 4b tracking error of yaw rate of passive is not comparable with AFS and 4WAS, the yaw rate tracking error of 4WAS is less than that AFS. For strictly reducing yaw rate error the required steering input by 4WAS is more than that of AFS and passive as shown in Fig. 4c. In Fig. 4d the rear wheel angle is shown which is an additional actuator of 4WAS.

TABLE II
CONTROLLER PARAMETERS

Controller Parameters	Values
K_β, K_r	5
τ_1, τ_2	0.005

VI. CONCLUSION

In this paper an IDC based SMC strategy was implemented on 4WS vehicle.Firstly, a nonlinear vehicle model was derived considering the uncertainties in cornerning stiffness,mass and vehicle speed. Then new VSR strategy was formulated to obatin the desired lateral dynamics.The nonlinearities, uncertainties are estimated by inertial delay control method. To compensate this effect and control the lateral dynamics i.e both yaw rate and sidelip angle to track the desired model of lateral dynamics a robust SMC was designed. The simulation results shows that limitation in FWS was overcome by 4WS. Lastly,the robustness of proposed controller was validated through Carsim for J-turn maneuver. Future scope for this work could be done by reducing the use of additional actuator i.e rear wheel by analysing the $\beta - \dot{\beta}$ phase plane method.

***Abstract*—Due to the scarcity of skilled labourers, areca growers are finding it difficult to harvest their crop. Arecanut tree climbing is a risky job which requires skilled labourers. If a person slips while climbing, it will be irreparable damage to him and as well as to his family. In recent years, getting labourers who climb the arecanut tree is a major challenge. Arecanut trees grow to a height of about 60 to 70 feet. It is required to climb the arecanut tree around four to five times in a year for harvesting. Only skilled labourers can carry out these operations. In this paper, a Smart Arecanut Plucking Robot is designed through which some of the above difficulties are addressed. This robot is designed to climb the arecanut trees of varying diameter. Here, the robot can be operated either in manual mode or in automatic mode. Six pneumatic cylinders are used with an air compressor for robot movement. Arduino UNO is used for controlling the pneumatic cylinders. The robot climbs as human climbs the tree and a camera is mounted on the robot to get the live video streaming. Raspberry Pi is used for interfacing camera to get live video streaming of the plucking operation. By watching the live video, the position of the cutter can be adjusted. The android application RaspiCAM Remote installed in users android phone is used to watch the live video stream sent by the Raspberry Pi present in the robotic unit. A robot is successfully tested on an arecanut tree of varying trunk diameter (up to 7 inches) and heights (up to a maximum of 45 feet). The user is successfully able to guide the robot to cut the ripened arecanut bunch.**

***Index Terms*—Pneumatic Cylinder, Solenoid Valve, Air compressor, Camera, Raspberry Pi.**

I. INTRODUCTION

People from the rural part of India mainly depend on agriculture for their livelihood. Arecanut and Coconut are the main crops cultivated in Karnataka and Kerala. Regardless of mass distribution and spread of arecanut trees around these regions, arecanut reaping is still done without safety measures resulting in major issues [1]. Farmers are finding it hard to climb arecanut trees and there is a scarcity of trained arecanut tree climbers. Skilled workers need to climb the tree manually for collecting the arecanuts which is risky and dangerous. To help the farmers in arecanut harvesting, there are numerous machines in the market. They are not successful since they require a lot of muscular power of the labour for its operation. At present, a completely safe device is not available in the market for harvesting the arecanuts. To address both productivity and security, there is a need to invent the machine for arecanut harvesting. In this paper, a robot is designed to climb the arecanut tree and cut the arecanuts. Various models (semi-automatic robots) were created to address the issue but each of them has its own limitation. Here we have examined to beat the above constraint by building up a self-governing robot [2]. Fig. 1. shows the Climber climbing the arecanut tree.

As of now, the shortage of workers has become one of the major challenges in arecanut cultivation. Areca trees grow to a maximum height of around 60-70 feet [3]. It is compulsory to climb the trees around four to five times each year for an effective reap. Only trained workers can do these activities. They need to climb the trees using muscle power. In a hectare of land, around 500 arecanut trees can be grown and a worker needs to climb at least 100 to 150 trees per day to harvest the yield. As this involves real hard physical exertion, youths are losing interest in such risky job resulting in emerging demand for the skilled labourers [4][5].

Fig. 1: Climber climbing the Arecanut tree.

II. Related Works

A. Semi-automatic Robot.

To cut arecanut from trees, Wonder Climber [1] was invented, which is shown in Fig. 2. Skilled workers are required to cut the arecanuts by utilizing this hardware. The greatest advantage of this machine is it can be shifted to anyplace on one's shoulders since it weighs about 6.5 kilograms. This machine can be made to climb the tree and do the hard work related to arecanut tree climbing and cutting. Wonder climber is operated by the assistance of a pulley and rope. With the assistance of two U clamps, the machine can be fitted to any arecanut tree. Once it is fixed, the rope is pulled to climb up. Once it reaches the tree top, by pulling the rope in the correct direction the blade edge can be adjusted to pluck the arecanuts.

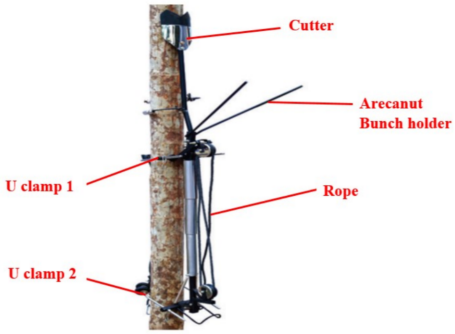

Fig. 2: Wonder climber.

B. Automatic Arecanut Plucking Robot.

The tree climber has two rings, two pulleys, rollers, rope, spring, cutter, collector and the main frame. The power from the motor is transmitted by rope pulley instrument. The machine is placed around the tree and clamped to it by utilizing two rings. Rotation of the motor allows rope to wind and rewind on to the drum. Cutting will happen along the movement of the machine. There is no separate mechanism for cutting operation. Control of the robot is done by a Bluetooth connected via mobile. The upper and lower rings are used to mount the machine onto the arecanut tree. These two rings are fixed to the main frame with the help of pins to arecanut tree. The ring is provided with holes of different diameters so as to climb arecanut trees of different diameter. During the winding operation, the upper ring will be locked to the tree and lower ring will be free to move thus creating an upward movement of the lower ring. After the winding operation, the lower pulley gets locked and upper pulley becomes free. During the unwinding operation the upper pulley displaces and creates a displacement. The cutting operation is carried out by the cutting tool during the unwinding operation. A motor is used for this operation. This operation gives enough power for the cutting tool to produce a cutting action. The remote controlled arecanut plucking machine is shown in Fig. 3.

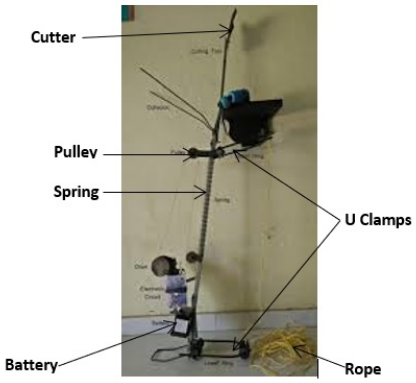

Fig. 3: Remote controlled arecanut plucking robot

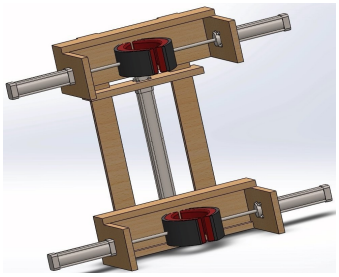
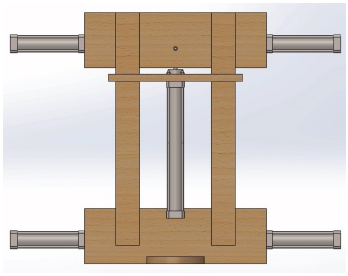


(a) Front view of a Model.



(b) Back view of a Model.

Fig. 4: Design of the Model.

III. Model Design

To address the above issue, the model was designed utilizing the SOLID WORK software as shown in Fig. 4. This design had the capacity to climb up and climb down the tree by considering some mechanisms which will be discussed in the upcoming area. The fundamental material utilized in this robot includes Pneumatic actuators for development of the cylinder bars, to move up and down, Cylinder bars to hold the tree firmly, Grippers to maintain a strategic distance from the scratches on tree and sharper to cut the matured arecanuts, wooden sheets for supporting the cylinders and Pneumatic Poly Urethane (PU) HOSE tube pipe to supply compressed air to pneumatic cylinders [6].

A. Working of Robot(Climbing up)

A Smart Arecanut Plucking Robot is designed and implemented using pneumatic operations. Here, a robot is designed to climb the tree automatically or by manual operation.
The automated robot contains five cylinders in which four cylinders are used for holding the tree and another one cylinder used to climb the tree up and down. There are four stages in climbing the tree.

Subdivision in stages.

1) Stage 1: During the first stage, the cylinder 1 and cylinder 2 holds the tree tightly with the help of piston and gripper by moving the piston forward using compressed air pressure as shown in Fig. 5.

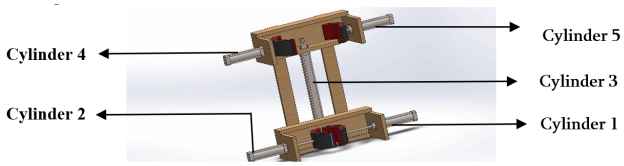


Fig. 5: Movement of the Piston of Cylinder 1 & 2.

2) Stage 2: In the second stage, the third cylinder expands horizontally by the support of cylinder two and three and using compressed air pressure. The cylinder expands almost double in its size by elaborating piston as shown in the above Fig. 6. Hence it is an efficient approach to climb the tree in a short period of time.

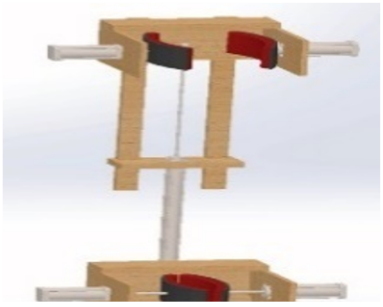

Fig. 6: Movement of the Piston of Cylinder 3 (Climbing Up).

3) Stage 3: In the third stage, cylinder four and five holds the tree with the help of air pressure and third cylinder as shown in the above Fig. 7. The compressed air is passed through the compressor through PU HOSE tube pipe and the cylinders one and two piston gets compressed.

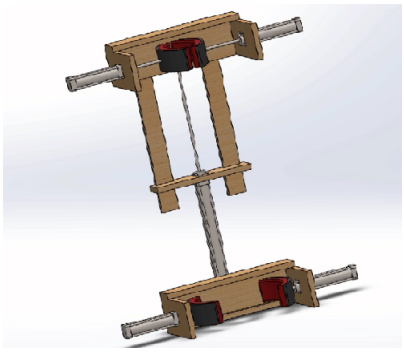

Fig. 7: Compression of the Piston of Cylinder 4 & 5.

4) Stage 4: During the fourth stage, the third cylinder gets compressed hence the robot moves upwards this process continues until the robot reaches the top of the tree were arecanuts are present. Each stage is repeated sequentially with the help of the controlling unit. The fourth stage is shown in Fig. 8.

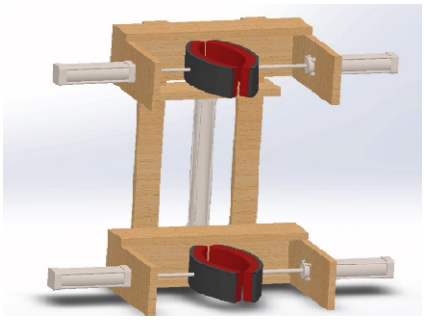

Fig. 8: Piston Movement of Cylinder 3.

B. Climbing Down

When the robot completes cutting of the arecanut bunch it moves down utilizing a similar procedure which is followed during climbing up of the tree but in reverse order.

C. Proposed Arecanut robot

This model is designed to overcome the issue occurred during manual climbing. The robot can be operated by farmers from the ground without manual climbing. This robot is more efficient with different frameworks as far as speed. Farmers can easily operate this robot by understanding the movement of the cylinders.
The designed robot can climb up and climb down the arecanut tree with live video streaming. Depending on the user instructions, the robot cuts the arecanut bunch.

IV. System Description

The block diagram of the robot is shown in Fig. 9. The system comprises of two units in particular Mechanical Unit and User Control Unit. The Automated unit comprises of Pneumatic cylinder, Air compressor, Solenoid valve, Air filter, Control unit and cutter. The user control unit comprise of Raspberry Pi 3, camera, transmitter and receiver.

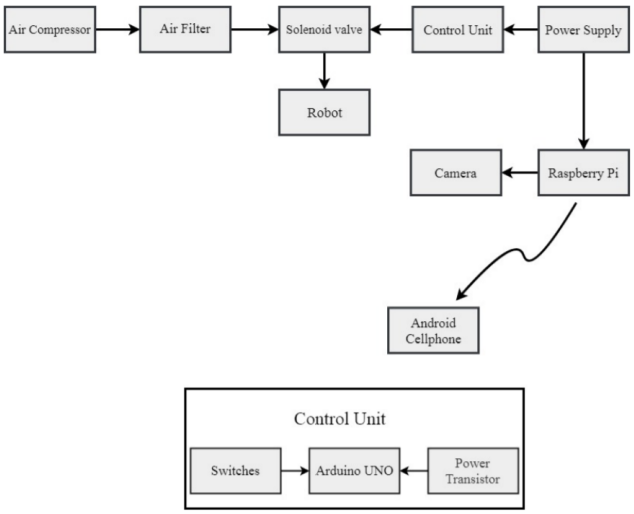

Fig. 9: Block Diagram of Arecanut Plucking Robot.

A compressor can compress air to the required pressure. It can convert mechanical energy from motors into the potential energy in the form of compressed air. At the point when tank weight achieves its built maximum capacity, the air compressor closes off. The packed air is connected to the air channel so as to expel the contaminants from the compacted air [7]. A solenoid valve is a 5/3 solenoid valve series 4-Way solenoid operated valves feature single or double 12v DC, 1Watt solenoids, commonly used to control the stream or heading of air in the framework. The camera associated with the robot will keep track the development of robot and can screen the cutting procedure by giving the guidelines through the control unit to the robot sends the live video streaming through a camera mounted on it. The video can be seen in the Android mobile. The system of the working of the robot is controlled with Pneumatic cylinder. In this task, 5 Pneumatic cylinders are utilized. They will give the appropriate movement to the robot for climbing up or down. Raspberry Pi 3 is the primary useful unit in this undertaking. The cutter which is mounted on the robot cuts the arecanuts dependent on the guidance is given by the user [8].

A. Double acting Pneumatic cylinder

The construction features of a double acting cylinder is shown in Fig 10. The construction of a double acting cylinder is similar to that of a single cylinder. In the double-acting cylinder, a pneumatic force can be connected to either side

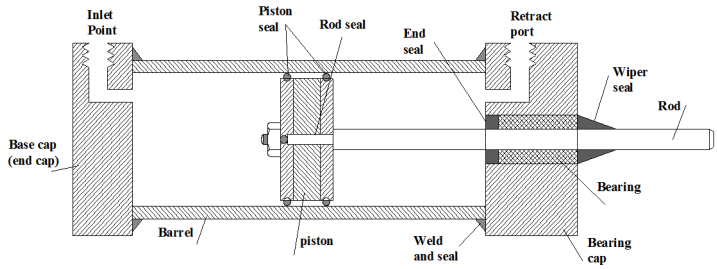

Fig. 10: Double acting Pneumatic Cylinder.

(supply and exhaust) of the cylinder [9]. The double-acting cylinders are normally used in the application where greater stroke length is required.

B. Pneumatic cylinder / Actuator

Pneumatic actuators are the machine used to convert compressed air into the mechanical energy to perform valuable work. In other words, these actuators are used to supply the required power towards the end of the stroke or used to make displacement of the piston [10]. The pressurized air from the compressor is supplied to the pneumatic actuator to move the piston. The pneumatic cylinder is shown in Fig.11.

Fig. 11: Outer View of Pneumatic Cylinder.

C. Flow Chart

The flowchart of the robot operating in automatic mode is shown in Fig. 12. The user needs to press switch SW 1 in order to select the robot to move UP or DOWN. If the user presses the switch SW 1 as ON, the robot starts to climb UP the tree automatically. If the user presses the switch SW 6 as OFF, the robot starts to climbs DOWN the tree automatically. Whenever user press the switch SW 2 (Exit Button) ON, the robot enters in to STOP mode. The cylinder 4, cylinder 5 pistons move forward and holds the areca tree. If user press the switch SW 7 OFF, the robot enters in to IDLE mode.

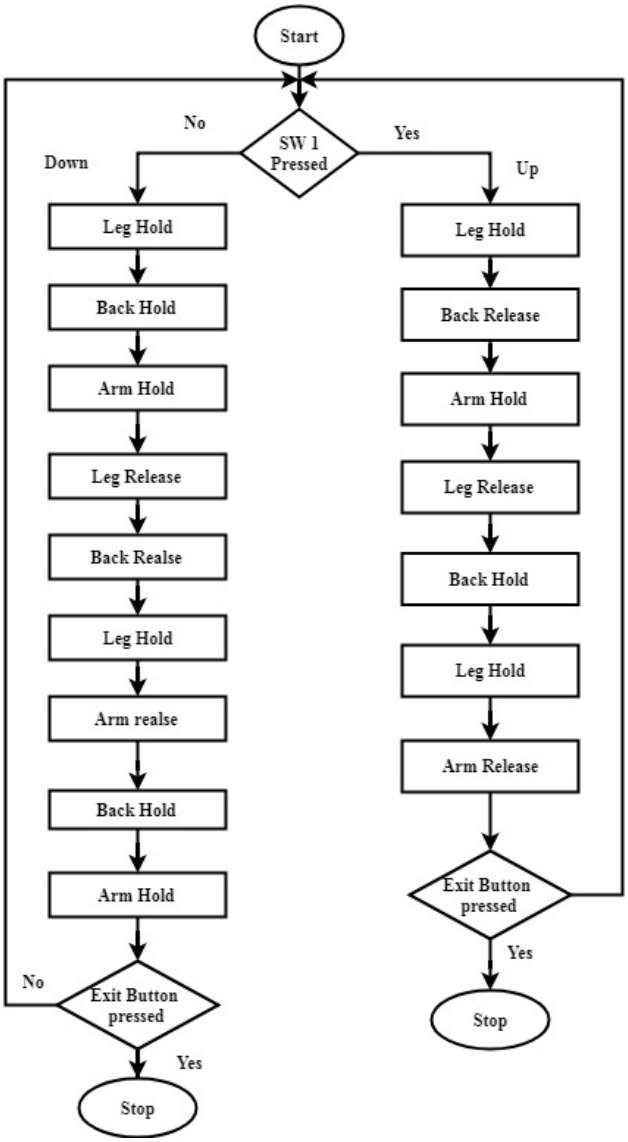

Fig. 12: Flow chart of Automatic Mode.

V. System Software

In this part, programming and working framework utilized for design the robot are discussed. Python is a programming language utilized for controlling the automated unit. For Raspberry Pi 3B, the Raspbian OS is the Linux based working framework which is dependent on Debian streamlined package [11]. Python is the language utilized for coding. Arduino UNO is used for controlling the solenoid valve, Raspberry pi is used for live video streaming of the robot [12].

The Logitech webcam c270 is connected to USB port 1 of Raspberry-Pi through USB cable. The Android mobile is connected to Raspberry-Pi by turning on WiFi. The corresponding IP address of the devices named as Raspberry is entered in RaspiCAM Remote App after that live video streaming of the robot can be observed in the Android mobile.

TABLE I: Control operations or Commands.

Control operations of Robot	
Operations	Digital I/O pins of Arduino
Leg Hold	1 1 0
Back Release	1 0 1
Arm Hold	1 0 0
Leg Release	0 1 1
Back Hold	0 1 0
Arm Release	0 0 1

Table 1 shows different combination of digital inputs from the pins of Arduino to control the robotic actions. When I/O pin is made logic 1 the transistor connected to that I/O pin turns ON and the corresponding valve of the solenoid opens and pressurized air enters the cylinder through this valve moving the piston in one direction. If I/O pin is made logic 0 the transistor connected to that pin turns OFF and closes the valve and stops the movement of piston.

VI. Results Analysis

A Smart Arecanut Plucking Robot is designed and implemented using pneumatic operations. In this paper, a robot is designed to climb the tree automatically or by manual operation.

The robot is constructed using six Pneumatic cylinders.Out of six cylinders, two cylinders are used for the upper arm and 2 cylinders are used for the lower arm to grip the tree. One cylinder is used for the movement of the robot and one more cylinder is used to control the movement of the cutter. The snapshot of the robot with a cutter is shown in Fig. 13. There are six stages in climbing the tree.

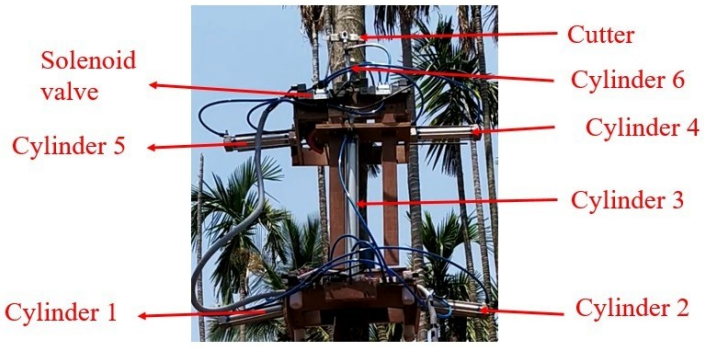

Fig. 13: Snapshot of the Robot with Cutter.

Through these six stages of the operations, the robot moves one step upwards and this process continues until the robot reaches the top of the tree. Each stage is repeated sequentially with the help of the controller. Similarly, to climb down the tree all the stages mentioned in the above section have to be performed in reverse order. The sixth cylinder gets expanded when the user gives the instruction to cut the arecanut. The cutter with piston mounted on the robot is shown in Fig. 14.

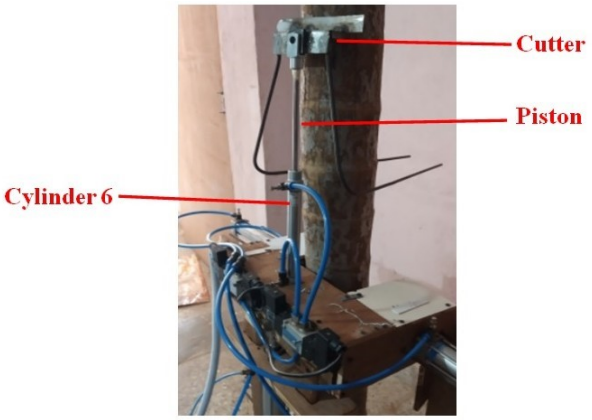

Fig. 14: Movement of the Piston of Cylinder 6 to Cut the Arecanut Bunch.

The robot designed is tested in areca plantation farm. It has successfully climbed up and down the tree and also cut the arecanut bunch. The Fig. 15. shows a picture of the robot while climbing an areca tree.

Fig. 15: Robot Climbing the Tree.

VII. CONCLUSION AND FUTURE WORK

The robot designed in this paper successfully climbed up and climbed down the arecanut tree and cut the arecanuts automatically with minimum manpower. Hence, it reduces the demand for skilled labours. The robot is simple in design and user-friendly. It can climb arecanut trees of varying sizes. The robot is operated in two modes namely Manual mode and Automatic mode. The camera which is interfaced to Raspberry Pi mounted on the robot successfully sent the live video streaming. The video streaming is observed in RaspiCAM Remote App installed in the user's android phone. By watching the video stream, the user can give instruction to the robot to cut the arecanuts. The robot takes around 6 to 8 minutes to climb up, cut the arecanuts and climb down a 45 feet arecanut tree of varying trunk diameter (around 5.5 to 8 inches).

For future work the speed of the robot can be increased by increasing the pressure given to cylinders. The position of the cutter can be made controllable by the user. Image processing can be used for automatic identification of the ripened arecanuts. Wireless connectivity can also be implemented between user and the robot.

***Abstract*—A lattice filter has multiple applications in adaptive receivers for communication. The design and implementation using high level synthesis has been explored here for trade off between use of conventional computational units and distributed arithmetic. The aim of our work is to implement a digital lattice filter using Schur polynomial. Schur polynomial is an efficient method through which orthonormal polynomials used to compute the lattice coefficients. We have implemented a digital lattice filter in Vivado HLS with regular arithmetic and also with distributed arithmetic, which provides a multiplier-less architecture. By synthesizing the codes in Vivado HLS, The implementation results in the architectures that are compared for resource utilization and latency and delay has been compared for the conventional and distributed arithmetic multiplier less architectures the design based on Schur polynomials.**

Keywords—Lattice filter, High level synthesis, Distributed algorithm, Schur polynomial.

I. INTRODUCTION

Designers have to integrate software processors and application specific hardware that is customized for specific tasks. Describing these features using Hardware Description Language (HDL) allows the designer to adopt tools for Register Transfer Level (RTL) and then use that to burn into target hardware. But the problem faced here is that writing in HDL requires the designer to write in a low level language which is much harder to work with. To overcome this, in recent times, many designers are combining FPGA and HLS. HLS is much easier to work with as the designing can be done using high level languages. Also, the RTL is generated automatically. FPGA is usually reconfigurable and deployment is easier on FPGAs. However, different HLS tools have different specifications. Hence, it isn't easy for all the tools to follow any particular benchmark. High Level Synthesis tools are categorized into Domain Specific language and General Purpose programming language. Despite offering many more functionalities like allowing more input output languages and higher memory bank, it is still more robust than academic HLS tools [1].

In high level synthesis, interconnections are considered to be the key feature that affects performance of the integrated circuit or design. For example, the interconnections account for more than 50 percent of the total dynamic power of an Intel microprocessor. When trying to improve efficiency in terms of area, to minimize area, the complexity of the interconnections has to be minimized as well. In a case where fixed binding of functional units and registers are involved, there will be allocations between both the components through multiplexers. This allocation is called Port Assignment Problem. The main demands of a port assignment algorithm are producing an optimal solution and estimating interconnection complexity as quickly and accurately as possible. To achieve this in a more efficient way, an improvised matrix based algorithm is formulated. Spanning tree and conflict graph methods are used to compute feasible solutions. Elementary tree transformation is used to optimize the obtained feasible solutions. For this, matrix formulation is done using $\oplus$ and $\otimes$ which improves efficiency. Simplex method is used and pivoting is formed. Properties of pivoting are then studied and successive pivoting is proposed. The algorithm is then tested on real benchmarks to evaluate improvements in power, area and delay efficiency [2].

FPGA based digital filters are effective in digital signal processing because of the properties contributed by FPGA like parallelism and logic increases the speed of computation. Distributed arithmetic is based on this concept. FIR filters are widely used because their stability nature and linear response. Usually FIR filters are implemented sequentially incorporating multipliers and accumulators [3] [4].

Lattice filters are versatile architectures are suitable for VLSI design because of their regular and repeated structure. They can be designed for all-pass filter. Usually, filters tend to work only within a certain range of frequencies below or above which the magnitude level reduces. However, with lattice filters, there is no gain reduction and all frequencies can pass through, changing the phase relationship with the multitude of frequencies. Lattice filters scope is explored more in adaptive filter design and hence the applications are signal processing and in future communications of 5G wireless communication.

Distributive arithmetic is one of the most efficient ways to implement a filter. Lattice filter is implemented in High Level Synthesis using Vivado HLS by using Schur Algorithm. The filter is first designed using regular arithmetic and report is obtained through synthesis in Vivado HLS. This report is then compared to the report obtained by designing the filter once again using distributive arithmetic.

This paper has been divided into five parts. The first three parts give brief descriptions about high level synthesis, lattice digital filter and distributed arithmetic respectively. The fourth part gives a detailed explanation of the results obtained. The fifth part gives a conclusion for our findings.

II. HIGH LEVEL SYNTHESIS

RTL level based programming languages demands more work and knowledge on physical level registers and their states at each clock cycle. FPGA requires programming and when they are programmed with RTL level languages, it increases the level of complexity in terms of cost and time. This is because implementation of any function take into account about resources consumed and time taken. There are high possibility of errors occurring during developing and implementing and during testing. Hence it is required to implement at high level of abstraction [5].

Technology like HLS evidently provides the required high level abstraction by incorporating high level programming languages like C or CPP. It has the capability of generating RTL simulations automatically. Test bench are used in verification and validation. These can be written in high level languages in HLS, which can be used validate RTL through co-simulation. Hence it decreases design time and increases productivity [6].

An important application of the high level synthesis is that it allows the designer to write the code easily and use more transformations before the final RTL is generated for design space explorations [13]. Also as mentioned in [14], the methodology used there helps to utilize various design possibilities using timing constraint from the input given.

III. LATTICE DIGITAL FILTER

Digital lattice filter is widely used in digital signal processing. A lattice filter is an example of an all-pass filter. Usually implementation of lattice filters on FPGA involves usage of adders, multipliers, and delayers. The most common implementation technique is array based implementation. To improve the speed and performance lattice structure can be pipelined [7]. The filter coefficients can be found by Schur algorithm [8]. The coefficients can be found by using MATLAB.

Lattice filter has the advantage of frequency insensitivity compared to the other form of digital filters [9]. Lattice filter can be scaled to the required order by iterating the basic structure containing multipliers, adders and delayers. The rounding off of multiplier coefficients can cause error and increase sensitivity. To combat that effect higher word length is chosen for filter realization [10].

IV. DISTRIBUTED ARITHMETIC

Digital lattice filter can be realized by incorporating the concept of distributed arithmetic. Here multiplication can be seen as convolution. The idea is to reduce the number of resources used. This concept takes care of errors caused by rounding off of the multiplication coefficient as well [11].

It follows a mechanism wherein it recognizes values of a multiply then accumulate that occur multiple times and then stores them to a lookup table or a LUT. The values stored in LUTs can be accessed faster from the computer storage than any other external medium. So because of this, the overall cost due to components will reduce by a lot. However this multiplier-less architecture can only follow where there is a multiply and accumulate operation. This makes it perfect for usage in digital lattice filters wherein each module requires a multiplier. With the usage of distributive arithmetic, the architecture becomes multiplier-less which brings down the number of components used, thereby reducing the overall cost as well. The area used by the filter will depend on the number of bits given as input.

Through multiple analysis and experiments conducted, it was found that the implementation using distributive arithmetic, about 86.90% of hardware resources and 67.92% of power consumption was saved [12]. Architectures and design space exploration are implemented for achieving low power implementations[13]. High level synthesis techniques are applicable to be used in determining optimal designs [14].

V. METHODOLOGY AND SYSTEM RESULTS

The code was first written in MATLAB to obtain the lattice coefficients needed while building the filter. For an FIR filter, the Schur Polynomials are derived from the denominator so using that, the required lattice coefficients are obtained.

To implement the filter, the code was written in regular arithmetic at first. In Vivado, the code was written using C++. The same code was written in MATLAB again, and also manual calculation was done to justify the accuracy of the written program and the obtained output.

The filter that we have implemented is of third order. Output has been recorded at the end of every module of the filter, so the final output is the output obtained at the end of the third lattice module. According to the equation being modeled here, the input is split into two, where one is same as the input and the other one is same as input with a delay. Similarly, we have two outputs from the filter, FOUT and GOUT.

After synthesizing the code for a third order filter in Vivado, the utilization estimates were obtained.

LATENCY ESTIMATES OF THIRD ORDER FILTER USING CONVENTIONAL ARITHMETIC

Latency		**Interval**	
Min	Max	Min	Max
21	21	22	22

TABLE I. UTILIZATION ESTIMATES OF THIRD ORDER FILTER USING CONVENTIONAL ARITHMETIC

Name	BRAM_18K	DSP48E	FF	LUT
Expression	-	-	0	12
Instance	-	5	355	727
Memory	0	-	128	6
Multiplexer	-	-	-	53
Register	-	-	121	-
Total	0	5	604	798
Available	650	600	202800	101400
Utilization (%)	0	0.83	0.29	0.78

Similarly, the code is written in Vivado HLS and synthesized for a third order filter using distributive arithmetic to produce the following report.

TABLE II. LATENCY ESTIMATES OF THIRD ORDER FILTER USING DISTRIBUTED ARITHMETIC

Latency		Interval	
Min	Max	Min	Max
118	124	119	125

Total	0	10	1777	3172
Available	650	600	202800	101400
Utilization (%)	0	1.67	0.87	3.12

VI. CONCLUSION AND FUTURE SCOPE

To summarize the process, we have implemented a digital lattice filter using Schur Polynomial on Vivado HLS using conventional arithmetic and using distributed arithmetic, to synthesize and generate reports accordingly.

The reports that we have obtained display the estimates of resource utilization. From the obtained reports, we can see that the claim about distributed arithmetic needing no memory holds true. However, the implementation using regular arithmetic needs memory resources as well to function. So we can see that using distributive arithmetic requires lesser resources making it more area efficient depending on the number of bits of the input. Also, from the literature survey done on lattice adders, we also know that distributive arithmetic is power efficient and requires lesser power than normal.

Even though distributive arithmetic uses lesser resources, there is a trade off with speed. Since it is bit serial in nature, the latency increases and the total speed reduces. With the addition of more bits, the area used increases and the speed decreases.

Distributive arithmetic is preferred by many especially for filter implementations because the pros weigh out the cons. Power consumption has always been a problem but with this multiplier-less architecture, the efficiency based on area and power has improved. Hence, we can conclude that distributive arithmetic proves better when compared to regular arithmetic, in the ever improving field of technology today.

The filter can be improved in terms of speed by carrying out research to convert bit serial computing to parallel computing. Also further research on multiplier less architectures may help in improving area efficiency as well.

***Abstract*—Wireless Sensor Network (WSN) is the collection of already deployed motes which sense the physical phenomena and pass the sensed information to the sink node . Sink node stores information and send that information to users according to the user needs. Wireless Sensor Network (WSN) have self directed, tiny, low powered devices called sensors. Major issue in wireless network is coverage of area . It checks how the sensing area is monitored by motes. Strategy for coverage needs simultaneous activation of multiple sensor nodes as every location get covered by at least n sensors. Therefore scheduling technique alternatively activate the sensor nodes to reduce energy consumption. Due to battery limitation, utilization of energy is an extensive challenge in sensor network .Only few nodes may determine the network-lifetime in existing approach .The main role of sensor is sending and receiving the whole traffic so their "energy efficient coverage " is biggest challenge in sensor network. Sensor localization is used to find the x ,y coordinates of unknown nodes so that scheduling will get easy to cover the area using that particular nodes location. Scheduling is main concept in which sequence of nodes is important which increases the energy efficiency and network lifetime.**

Keywords— Wireless sensor network (WSN), Sensor Localization, Prediction, Scheduling.

I. INTRODUCTION

A. Wireless Sensor Network

Wireless Sensor Network (WSN) is a distributed network of interconnected devices called motes which are connected wirelessly. A mote have multiple sensor modules, for sensing the information of light, information of temperature and report it to the weather forecast. Humidity, pressure and sound each mote have four different components named as processing ,memory, battery modules and communication. Multiple applications like laptop , PC,mobiles are accessing data from internet then sink node access that information from various nodes and send that data to the satellite

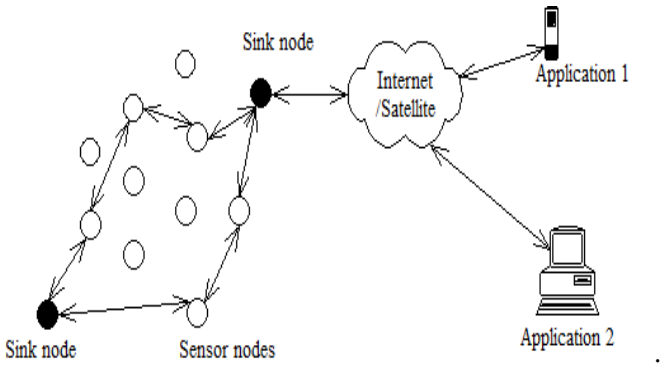

Fig 1. Architecture of wireless sensor network

B. Energy Efficiency

Wireless Sensor Network(WSN) includes many motes with different parameters which have battery power, frequency ,range and accordingly they cover the assigned area. While covering the area they should consider the energy efficiency metric as very important issue as it means that sensor should cover the assigned area in less battery power so that energy ingestion will be less and it will cover the area efficiently. Motes have been used in various fields like engineering, structural health monitoring, health and environment where energy efficiency is very important. There are multiple tasks like data aggregation, receiving and sending data ,data processing which utilizes resources including CPU power ,memory and most important is energy to increase the lifetime of network and productivity.

C. Sensor Localization

Localization is used to find the location of motes which is important to do scheduling of that motes for energy efficient coverage . Distance Orientation method is used to calculate the distance of unknown mote from sink node whose location is already known. This paper is organized such a way that first is discussion on localization literature papers and second covers papers on scheduling concept.

Finding the coordinates of unknown node(x_u,y_u):
Anchor nodes(known) x, y co-ordinates,

(x_1,y_1)=(2,1), (x_2,y_2)=(5,4), (x_3,y_3)=(8,2) with the distance between anchors and node of unknown position $r_1 = \sqrt{10}$, $r_1 = 2$, $r_1 = 3$.

$$2\begin{bmatrix}6 & 1\\ 3 & -2\end{bmatrix}\begin{bmatrix}x_u\\ y_u\end{bmatrix} = \begin{bmatrix}64\\ 22\end{bmatrix} \text{ ……..(1)}$$

Resulting in x_u=5, y_u=2 as the positions of unknown nodes.
The paper is organized as follows:
Section 2 is literature survey and section 3 is proposed work in which some methodologies like localization and formulas are stated. Section 4 presents analysis of simulation results. Finally section 5 concludes the paper.

II. Literature Survey

Sensor Localization: In this following literature, multiple papers on localization are discussed in which sensor localization is important concept which is used to find the location of sensor. Using that location ,sensor can communicate easily in distributed network and increase the accuracy.

R. Jin, Y. Ma, Y. Li, J. Zhao and F. Zhou,(2018), "**High accuracy localization scheme based on time-of-flight (TOF) and directional antenna in WSNs**[1]". In this paper ,they present "high accuracy estimation method" for node localization. Here a sink node contains an antenna having directional information which sends beacons periodically and it has sink nodes position and the location of unknown nodes is find out using antenna orientation . By considering the observations, variations in received signal strength indicates time of flight values and values of beacons , an unknown node calculate the distance relative to the beacon node simultaneously.

I. Strumberger, E. Tuba, N. Bacanin, M. Beko and M. Tuba,(2018), "**Monarch butterfly optimization algorithm for localization in WSNs**[2] ". In this paper they studied about "Optimization Algorithm" which comes in "NP hard " problem. Localization is about finding coordinates which are geograhphically considered for each and every mote which have unidentified position which are deployed accidentally in the observing area. Here the location of anchor node is identified by Global Positioning system(GPS).Distance is calculated using radio signal strength between unknown nodes and neighbour sink nodes .Trilateration method used to get know the (x,y) coordinates of unknown motes which uses the information of motes position.

Lu Dai,Bang Wang, Xianjun Deng ,Laurence T.Yang,(2017)," **An Improved Immune algorithm for Node Relocation to maximize confident information coverage in Hybrid Sensor Network**[3]". This paper studies that the movable mote relocation problem to increase area assured information coverage and reducing the movement cost where it consist the stationary as well as mobile nodes. Stationary nodes can not relocated after initial deployment and mobile nodes minimize the movement cost , maintaining network connectivity and exploit area coverage through moveable node repositioning.

Scheduling: In this following literature papers Scheduling is considered which first uses prediction for classification of sensors according to residual energy, frequency and range which then used by the Scheduling .It is used to give sequence to the motes so that they can activate alternatively and cover the area which they have already assigned .

Manel Chenait, Bahia Zebbane, Chafika Benzaid, Nadjib Badache,(2017),"**Energy-Efficient Coverage Protocol Based on Stable and Predictive Scheduling In WSNs**[4]". Main problem in WSNs is reporting. It says that how well much area is covered by less sensors ,every position must enclosed in at least k motes .Some sensors cover the same,That's why Scheduling alternatively active the sensors so that energy consumption should get reduce hence in this paper SPEC protocol is used. It reduces scheduling energy waste and also prolongs the reporting period.SPEC exactly eliminates unusable switches so that it increases the energy proficiency and network lifetime.

Jia Yufu,Lia Hongjun,(2015**)**,"**Node Scheduling Scheme Based on Coverage Preserving for WSN**[5]". In this paper , Monte Carlo algorithm scheme is used to test whether the nodes deployed are repeated or not. It uses back off mechanism for coverage collision detection. The results shows that the motes covers all concerned zone with minimum motes.

P. Chaturvedi and A. K. Daniel,(2012), "**An Energy Efficient Node Scheduling Protocol for Target Coverage in WSNs**[6]". The major issue faced by WSNs is the energy proficiency and network lifetime. Coverage problem is defines as how well the motes monitor the given area. Scheduling is the most preserving way to remain the motes in active or sleep states. Trust metrics is most important concept for increasing the confidence level that each area is covered by at least one mote. The performance is increased by the aggregation mechanism based on link stability and residual energy of the mote.

III. Proposed Work

Localization is nothing but finding the physical location of sensor nodes as transferring packets to destination will be easier if sensor locations are known. Global positioning system(GPS) is easy method used to find the location of sensor nodes. It is difficult when there is huge number of sensor nodes.

A. Trilateration

Trilateration is nothing but localization of sensor nodes using the distance metric. Node location is estimated through distance calculation from three anchor nodes. Here,

intersection of coverage range of anchor nodes is calculated, which gives a single point as a position of unknown node.
Using the distance calculation equation. If the unknown coordinates are (x, y) and known node coordinates are (x_i, y_i) which are having r_i distance from unknown spot, three equations will be:

$$(x - x1)^2 + (y - y1)^2 = r1^2$$
$$(x - x2)^2 + (y - y2)^2 = r2^2$$
$$(x - x3)^2 + (y - y3)^2 = r3^2$$

Expand out the squares and do minus the second equation from the first and third equation from second, we get

$$2(x2 - x1)x + 2(y2 - y1)y = r1^2 - r2^2 + x2^2 - x1^2 + y2^2 - y1^2$$

$$2(x3 - x2)x + 2(y3 - y2)y = r2^2 - r3^2 + x3^2 - x2^2 + y3^2 - y2^2$$

This is a system of two equations with two unknowns:

$$Ax + By = C$$

$$Dx + Ey = F$$

The values of x and y is obtained from the below equations:

$$x = (CE - FB) / (EA - BD)$$

$$y = (CD - AF) / (BD - AE)$$

B. Distance calculation using Euclidean distance formula

$$\text{Error} = \frac{1}{N_t}\sum_{i=0}^{N_t}\sqrt{(x\hat{}\,i - x)^2 + (y\hat{}\,i - y)^2}$$

where N_t is the network size.
(x,y) is the true location of the unknown node or source. ($x\hat{}_i - y\hat{}_i$) is the estimated location.

C. Ad hoc on-demand distance vector routing protocol (AODV)

AODV is an on-demand distance vector routing protocol which uses routing tables having one entry per target .It is on demand protocol as it creates routes when it is requested by source. while packets are going along the multiple routes from the source to the destination routes will stay active. When the source will not send packets , the routes will get time out and close.

AODV is used as we need routing table to have all information of the nodes instead of having frequent switching to getting information While covering the area routing table should have all the information about sensor nodes as which sensor is available and not while traversing the route for area coverage and accordingly prediction procedure will be applied for the efficient network coverage so it will reduce time consumption and increase energy efficiency and network lifetime.

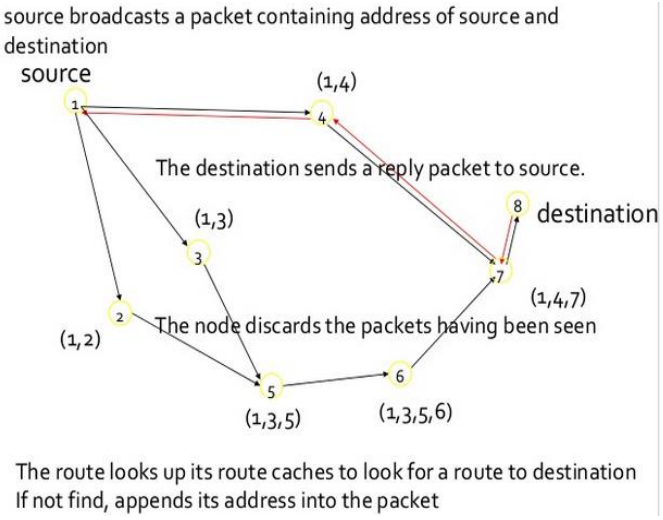

Fig.2 Packet Broadcast Through AODV

D. Network Lifetime

$$\text{Lifetime_Rate}_{(t)} = \frac{N_nodes_{(E>0)}}{N_nodes_{(t=0)}}$$

Network lifetime rate will get changed when no of active sensor value will be changed. Having more no of active sensors will increase the network lifetime as they will cover the maximum area in less energy and increases the energy efficiency.

E. Prediction Procedure

Prediction procedure will check if coverage redundancy algo to apply or not exact after active message.Active Message(AM) have two types of senders.

i)Internal Sender located inside S_i sensing disk.
ii)External ,located between r and $2r^4$, where,r is the redius of s_i sensing disk
iii)Opposite external ,which is an external sender located at the opposite quadrant of another external sender.

F. SPEC (Stable and Predictive Energy-aware Coverage Scheduling)
SPEC is the one way evaluation technique in which routing table have all the information related to sensors using that information sensors get selected to activate. Frequent switching is avoided by SPEC which reduces the energy consumption.

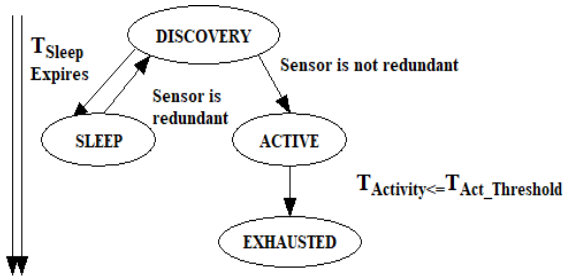

Fig.3 One way evaluation of SPEC protocol.

One way evaluation is used to minimize the frequent switching energy. Here, multiple switches are reduced because of continuous sensor activation.
Wake up method is used to adjust the sleep and active timers considering the energy of motes.
Prediction is to minimize the computation energy loss it reduces the energy required to frequent switches.
Multiple states of SPEC are:

i)Discovery-It will check how many sensors are active right now.
ii)Active-After discovery of sensor node it will get decided to active that particular sensor or not and if that sensor has covered the same area already or not.
iii)Exhausted- sensor will have one threshold value after that limit sensor will go to the exhaust state.
iv)Sleep: sensor will go to the sleep state after its particular timer.

IV. Results and Analysis

Localization is the process of finding the physical or relative location of a sensor node as data and information are useless if the nodes have no idea of their geographical positions. Here, we can give any number to any node and we can make anchor node , any one of them it is not necessary that sequencing is important .

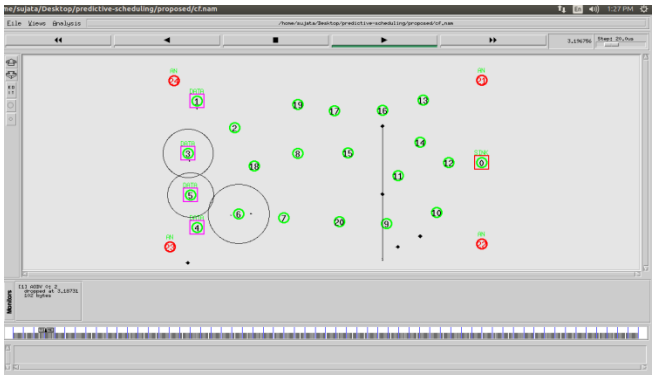

Fig.4 Localization of sensors

Here ,according to the anchor nodes location (x,y) coordinates it will calculate the distance between two nodes and find the location of unknown nodes.

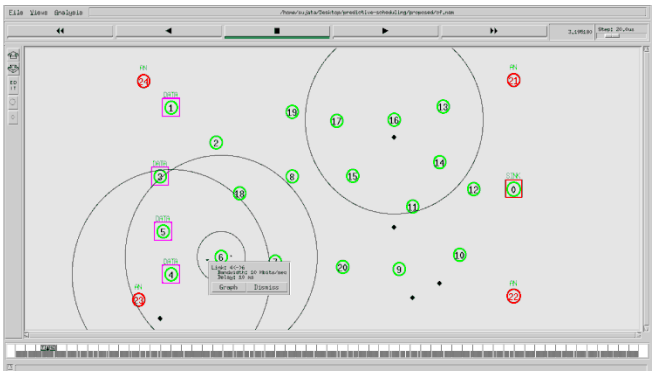

Fig. 5 Communication Links between nodes

While finding the routes,it will select the sensor node having more energy remaining to get active to cover the maximum area.

AODV(Adhoc on Demand Distance Vector Routing protocol)

Here, monitoring of coverage area is done where CBR(Constant Bit Rate),no of bytes transferred per second is calculated.

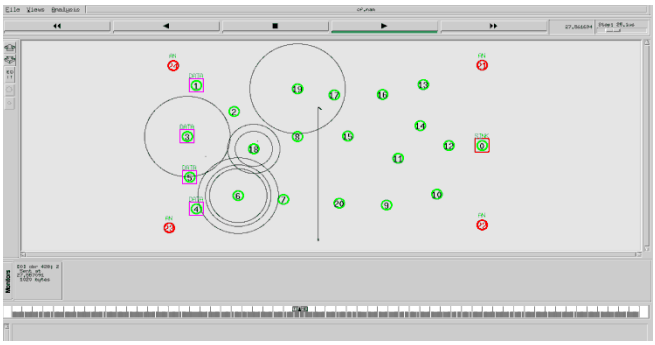

Fig 6 Monitioring of sensors ,CBR(Constant bit rate)

Here, no.of bytes transferred per second is calculated. According to the energy remaining node will demand to pass the packet through it and it will find the route to send the packet to destination.

TABLE I

simulation configuration

Simulation parameters	***Values***
Simulator	NS 2.35
Routing protocol	AODV
Simulation Time	10 Minutes
Transmission Range	100 m
Operating system	Ubuntu 16.04

Energy Consumption in previous systems vs proposed systems.

Energy consumption is nothing but how much more energy is required to cover the assigned area.As there is no frequent switching in proposed systems it reduces the energy consumption.

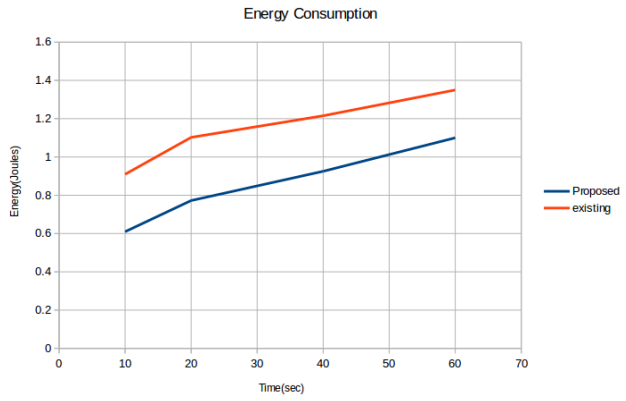

Fig 7 Energy consumption in existing and proposed systems.

In existing systems energy required to cover the area is very much as sensor nodes doesn't have the information if assigned area is overlapped or not .In proposed systems that drawback is overcomed as AODV is having routing table having all the information in the routing table. hence energy consumption is less in proposed system.

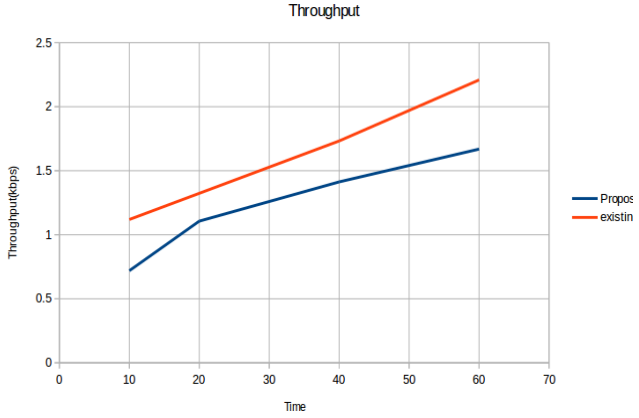

Fig.8 Existing vs Proposed packet throughput

As energy required is less in proposed systems throughput is more.

CONCLUSION

In this paper sensor localization is used to improve the accuracy of sensor location so that activation of motes will be easy for area coverage. Prediction is used for predicting the mote according to its battery power, frequency and range so that more battery powered sensor will activate first and cover the more area proficiently and for activation of motes

Scheduling is used so the sequentially sensor gets activated and cover the area without redundancy of same area coverage and hence it increases the network lifetime and energy proficiency. Future scope is to validate mathematical model for the stability and prediction strategies.

An Improvement in Performance and Computational Cost of ANN Based Wind Speed Prediction System

Shashank Sinha, S. Tiwari
Dept. of Instrumentation and Control Engg.
Dr. B. R. Ambedkar National Institute of Technology
Jalandhar, India

***Abstract*-Wind speed prediction is very important as it influences the wind energy and hence wind farm applications. An accurate wind speed prediction will be helpful in scheduling and management of the wind farms. In this work, empirical mode distribution (EMD) and ensemble empirical mode distribution (EEMD) have been used for decomposition of wind speed data into IMFs. An ANN has been proposed to predict the wind speed with IMFS given as the inputs. The accuracy of prediction by the ANN is further increased by using the actual wind speed at the previous instant along with the IMFs as the input to the ANN. This increase in accuracy in prediction was also accompanied by a reduction in the total computational cost.**

***Keywords*- ANN, Wind Speed, Prediction, EMD, EEMD.**

I. INTRODUCTION

The continuously increasing demand of electric power gives rise to the option of use of wind energy s it is abundantly available and clean in nature [1]. But the wind energy comes with a bigger disadvantage of being highly random in nature. To overcome this disadvantage of wind energy, continuous efforts are being made to devise methods for accurate prediction of wind energy [2].

Over past few years many researches have been done to predict the wind speed, Kavasseri [3] has used f-ARIMA model to predict the wind speed, Zhang [4] has used ANN-based and SVM based models for predicting wind speed. Zhou [5] has proposed an improved SVM based model for forecasting short term wind speed. Sun [6] has used Fast EEMD (FEEMD) and regularized extreme learning machine for predicting wind speed. Wang [7] has used a hybrid model of consisting EEMD and Genetic Algorithm and back propagation for the same purpose. Hybrid models for predictions have shown some better results for forecasting wind speed [8]. WD (wavelet decomposition) is also used for decomposing the wind speed data for hybrid model for improving the performance of the system [9] and [10]. Hui Liu [11] has shown and compared various decomposition techniques along with various neural network techniques for prediction of short term wind speed for one to three step ahead.

This work studies the effect of using previous instant wind speed along with IMFs of the wind speed data generated through EMD and EEMD for prediction of wind speed at next instant.

II. WIND SPEED AND ITS EFFECT ON WIND ENERGY

Wind flow is a general phenomenon generally caused by atmospheric air pressure difference. Wind generally flow from high to low atmospheric pressure, and the speed of wind flow is known as wind speed.

The flow of wind contains energy within it which can be further converted into any other form of energy, so the energy of the wind can be defined as[2]:

$$E = \frac{1}{2}mv^2 \quad (1)$$

where m is the mass of wind and v is the wind speed. The mass of the wind (m) can be defined as:

$$m=\rho Av \quad (2)$$

so

$$E = \frac{1}{2}\rho Av^3 \quad (3)$$

where ρ is the air density, A is the cross sectional area of the object on which the wind is falling on.

So because wind speed (v) is variable and random in nature so the wind energy become highly variable and random in nature.

III. DECOMPOSITION OF WIND SPEED DATA

In this paper EMD and EEMD have been used to decompose the wind data. The procedures to do so are as follows.

A. EMD-

The EMD is explained in detail by Huang [12], it is a technique to adaptively decompose a given signal, by means of a process called the sifting algorithm, into a finite set of AM/FM modulated components. These components, called 'intrinsic mode functions' (IMFs), represent the oscillation modes embedded in the data[13]. To find IMF of any time series via EMD steps are as follows[14]-

- Find the local extrema (maxima and minima) of the signal.
- Find the upper envelope $s_+(t)$ and lower envelope $s_-(t)$ by interpolating maxima and minima by cubic spline method.
- Calculate the mean of the envelopes.

$$s(t) = \frac{s_+(t)+s_-(t)}{2} \quad (4)$$

- Subtract the mean from the signal and repeat the process until the resulted signal obtain the criterion of an IMF.

$$c(t) = x(t) - s(t) \quad (5)$$

- Repeat the whole process until the remaining signal is able to decompose i.e. it will have two or more nos. of extremas.
- The remaining signal is called as residue or the trend component.

The IMF should have two properties-

- The no. of zero crossing and no. of extrema should either be equal or at most differ by1.
- The average of the envelope (maxima and minima) should be zero.

But the EMD consist the problem of mode mixing [15] which further was removed by EEMD.

B. EEMD-

To overcome the problem of mode mixing EEMD was proposed in this method different realizations of white noise are added to the signal [14] and [16].

$$S_i(t)=x(t)+w_i(t) \quad (6)$$

where x(t) is the original time series signal and $w_i(t)$ are the different realizations of white noise and i=1,2…..n. Then the IMFs are computed as follows

$$IMF_j = \frac{1}{n}\sum_{i=1}^{n} IMF_j^i \quad (7)$$

So the power of the added noise is consider by the sound to noise ratio of the signal is decided by the formula

$$SNR = 10log_{10}\frac{P_1}{P_2} \quad (8)$$

Where P_1 is the signal power and P_2 is the power of the noise. The SNR should remain in between 50 to 60 dB for successful EEMD [17].

IV. ANN FOR WIND SPEED PREDICTION

Over the past few years artificial neural network have been found to be very much suitable for nonlinear systems and for time series application. In the current work, an ANN with one hidden layer is proposed to predict the wind speed on the basis of the IMFs of the wind speed data. Two different types of activation functions namely *logarithmic sigmoid (logsig)* activation function having a transfer function as-

$$logsig(n) = \frac{1}{1+e^{-n}} \quad (9)$$

and *Tan-sigmoid (tansig)* activation function having transfer function as-

$$tansig(n) = 2/(1+\exp(-2*n))-1 \quad (10)$$

were considered and the best of the two was used. The output layer has a pure linear transfer function.

The ANN use Levenberg-Marquardt back propagation for training. The training algorithm calculates the network parameter as follows [18] to [20]:

$$J = \frac{\partial E(W_k\}}{\partial W_k} \quad (11)$$

$$W_{k+1} = W_k - [J^T J + \mu I]^{-1} J^T E \quad (12)$$

Where J is the jacobian matrix which contains the error with respect to network weights and biases. E is the vector of network error and μ is learning parameter.

The training data set comprised of 100 sec. of wind data. the performance of this ANN is then compared with another ANN using the previous instant actual wind speed as an input in addition to the IMFs.

The comparison of results obtained for predicting wind speed using different methods have been made by using three parameters MAE, MAPE and RMSE by Zhang et al [3]. Therefore, the same parameters have been used to compare results in this work. The computation of these parameter can be done as follows -

$$MAPE = \frac{1}{n}\left(\sum_{i=0}^{n}\frac{|x(t)-x'(t)|}{x(t)}\right) * 100 \quad (13)$$

$$MAE = \sum_{i=1}^{n}|x(t) - X'(t)|/_n \quad (14)$$

$$RMSE = \sqrt{\left(x(t) - x'(t)\right)^2/(n-1)} \quad (15)$$

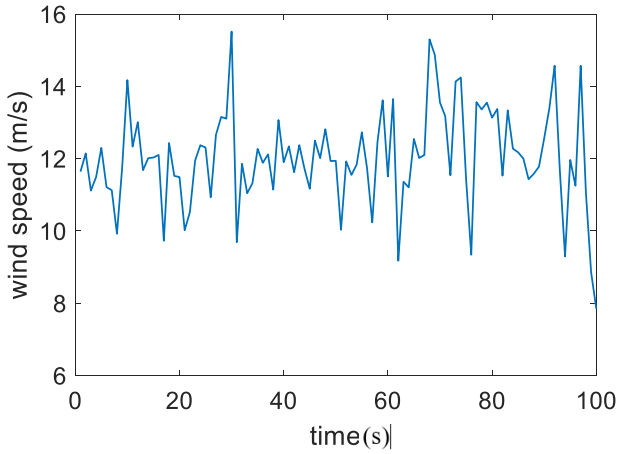

Fig 1 Test Data #1

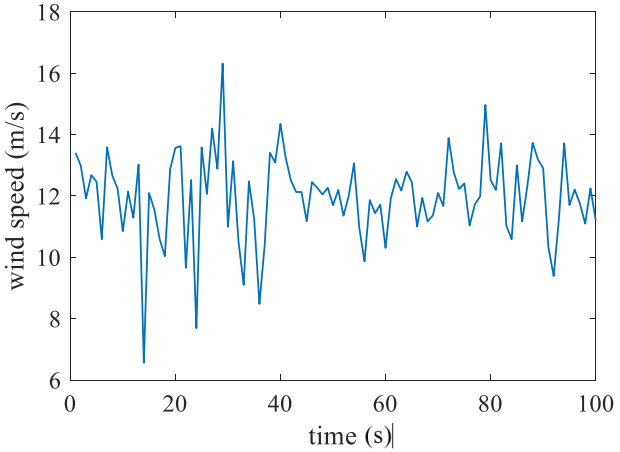

Fig 2 Test Data #2

Where x(t) is the actual value of wind speed, x'(t) is the predicted value.

V. SIMULATION AND RESULTS

The two ANN models were trained using wind speed for 100 sec. The nos. of neurons in the hidden layer was decided using trial and error method. The better of the TANSIG and LOGSIG based on the simulation result was taken as activation function.

These ANNs were then tested using two sets of testing data sets, i.e. Test Data #1 and Test Data #2 (shown in Fig 1 and 2 respectively) each comprise of 100 sec. data.

These data sets were decomposed by EMD and EEMD methods, figure 3 and 4 show the EMD and EEMD of test data #1 and figure 5 and 6 show EMD and EEMD of test data #2.

The architecture of the ANNs and a comparison of their performances are given in Table I and Table II.

Figure 7 and 8 shows a comparison between the wind speed predicted on the basis of IMFs generated using EMD and EEMD without considering the actual wind speed as an input for Test Data #1 and Test Data #2 respectively.

A comparison between the wind speed predicted on the basis of IMFs generated using EMD and EEMD along with the actual wind speed at the previous instant as an additional input for Test Data #1 and Test Data #2 is shown in fig. 9 and 10.

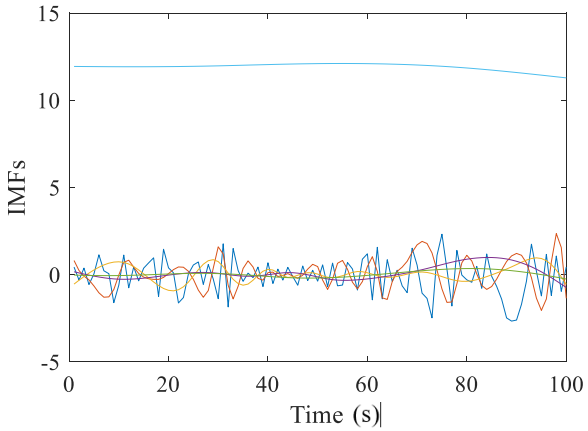

Fig. 3 EMD of Test Data #1

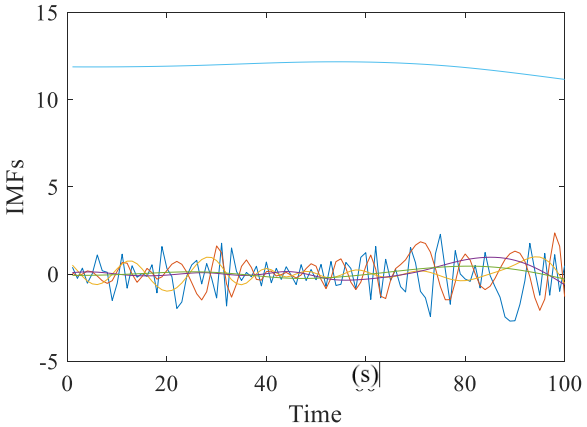

Fig. 4 EEMD of Test Data #1

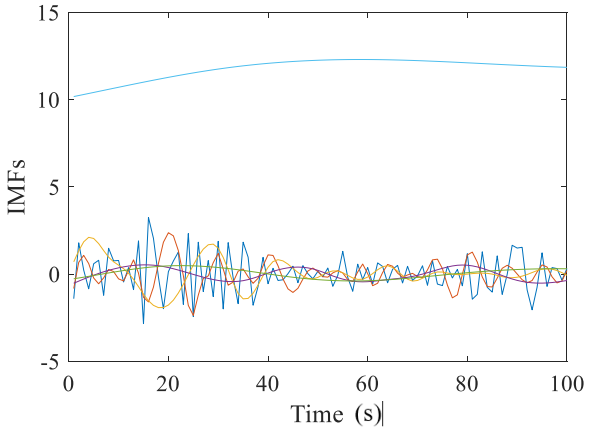

Fig. 5 EMD of Test Data #2

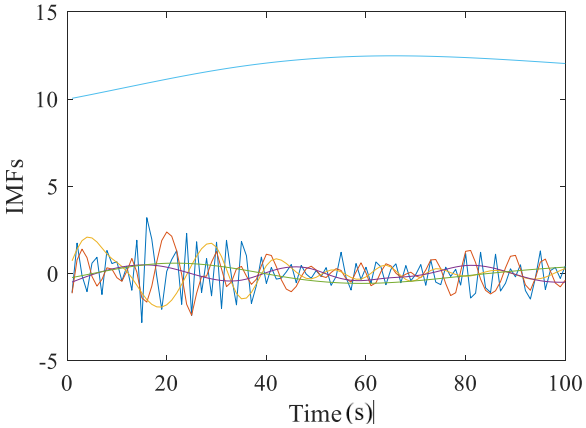

Fig. 6 EEMD of Test Data #2

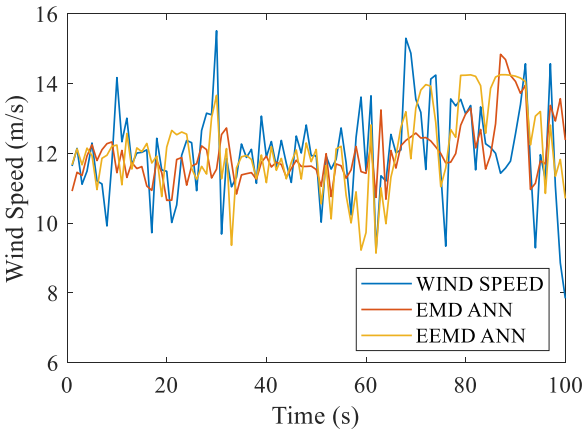

Fig. 7 Results of EMD and EEMD based prediction for Test Data #1

From table I it can be seen that in case of EMD when only IMFs of the wind speed are used for prediction then the error parameters (MAE, MAPE and RMSE) are 1.0408, 8.99 and 1.4216 respectively, but when previous instant wind speed is incorporated along with the IMFs for the prediction then the corresponding error parameters are 1.0236, 8.68 and 1.2971 respectively. So the error parameters are reduced by 1.65%, 3.44% and 8.75% respectively. Similarly, in case

of EEMD when only IMFs of the wind speed are used for prediction the error parameters are 1.0034, 8.65 and 1.3638 but when the wind speed is used along with the IMFs, then the corresponding error parameters are 0.8865, 7.68 and 1.2152 hence the error parameters are reduced by 11.65%, 11.21% and 10.89% respectively.

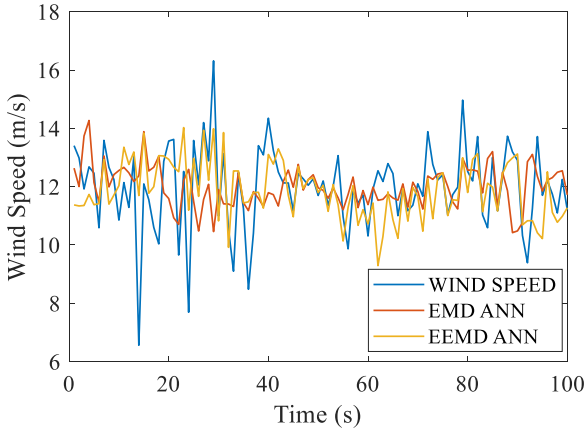

Fig. 8 Results of EMD and EEMD based prediction for Test Data #2

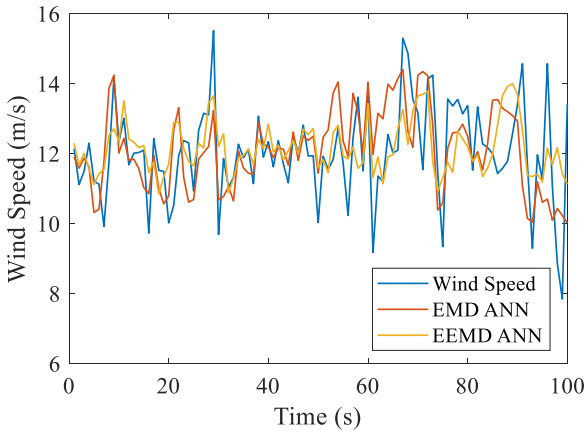

Fig. 9 Results of EMD, EEMD and previous movement wind speed based prediction for Test Data #1

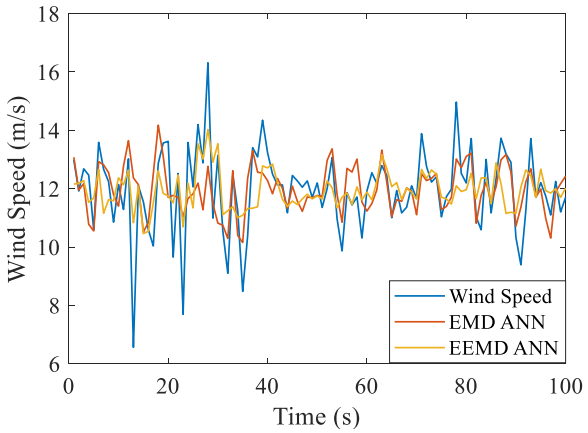

Fig. 10 Results of EMD, EEMD and previous instant wind speed based prediction for Test Data #2

Table I ANALYSIS of TEST DATA #1

Method		ANN Architecture		Performance Analysis		
		No. of hidden layer neuron	Activation Function	MAE	MAPE %	RMSE
EMD	IMF only	14	TANSIG	1.0408	8.99	1.4216
	IMF+ previous instant speed	8	LOGSIG	1.0236	8.68	1.2971
EEMD	IMF only	8	LOGSIG	1.0034	8.65	1.3638
	IMF+ previous instant speed	6	TANSIG	0.8859	7.68	1.2152

Table II ANALYSIS of TEST DATA #2

Method		ANN Architecture		Performance Analysis		
		No. of hidden layer neuron	Activation Function	MAE	MAPE %	RMSE
EMD	IMF only	14	TANSIG	1.1255	10.01	1.5909
	IMF+ previous instant speed	8	LOGSIG	0.8385	7.58	1.2040
EEMD	IMF only	8	LOGSIG	0.9666	8.71	1.3501
	IMF+ previous instant speed	6	TANSIG	0.8551	7.66	1.1631

Table III ANALYSIS of TEST DATA #3

Method		ANN Architecture		Performance Analysis		
		No. of hidden layer neuron	Activation Function	MAE	MAPE %	RMSE
EMD	IMF only	14	TANSIG	1.1753	9.57	1.5484
	IMF+ previous instant speed	8	LOGSIG	1.1108	9.25	1.4024
EEMD	IMF only	8	LOGSIG	1.0007	8.27	1.2998
	IMF+ previous instant speed	6	TANSIG	0.8496	7.15	1.1655

Table IV ANALYSIS of TEST DATA #4

Method		ANN Architecture		Performance Analysis		
		No. of hidden layer neuron	Activation Function	MAE	MAPE %	RMSE
EMD	IMF only	14	TANSIG	1.0092	8.48	1.2704
	IMF+ previous instant speed	8	LOGSIG	0.8389	6.77	1.1122
EEMD	IMF only	8	LOGSIG	0.9373	7.46	1.3423
	IMF+ previous instant speed	6	TANSIG	0.8105	6.76	1.0879

Similarly from Table II it can be seen that in case of EMD when only IMFs of the wind speed are used for prediction, the error parameters are 1.1255, 10.01 and 1.5909 but when the previous instant wind speed is incorporated with the IMFs for the prediction then the corresponding error parameters are 0.8385, 7.58 and 1.2040, so the error parameters are reduced by 25.45%, 24.27% and 24.31% respectively. Similarly for EEMD when only IMFs of the wind speed are used then the error parameters are 0.9666, 8.71 and 1.3505 respectively but when previous instant wind speed is incorporated with the IMFs for the prediction then the corresponding error parameters are 0.8551, 7.66 and 1.1631, so the error parameters are reduced by 11.53%, 12.05% and 10.88% respectively.

Two more data sets, Test Data #3 and Test Data #4, each comprising of 100 sec. data were then used to investigate the prediction accuracy of the ANNs already used for Test Data #1 and Test Data #2. The results obtained are as given in tables III and IV. The results in Table III and IV are in conformity with results reported in Table I and II for Test Data #1 and Test Data #2 respectively.

It is clear from the results in Table I-IV that when previous instant wind speed is incorporated with IMFs (for both EMD and EEMD) the error parameters are reduced (for all Test Data sets). Hence the performance (accuracy) of the prediction is increased when previous instant wind speed is incorporated with IMFs for prediction of wind speed.

From Tables I-IV it can also be seen that the no. of hidden layer neurons are also getting decreased from 14 to 8 in case of EMD and from 8 to 6 in case of EEMD when previous instant wind speed is incorporated with IMFs for wind speed prediction. So because of the reduction in the number of hidden layer neurons the computational cost of the ANN prediction system is also decreasing significantly.

VI. CONCLUSION

The simulation result establish that by incorporating previous instant wind speed along with the decompositions of wind data, not only the accuracy of the prediction improves but the computational cost of the system is also reduced. This reduction in computational cost has a great significance in case of short term wind speed prediction for real time control applications in wind farms.

An Improved Inverter Control for Grid-Connected PV System

Varun Kumar Mahawar and S. Tiwari
Department of Instrumentation and Control Engineering
Dr. B. R. Ambedkar National Institute of Technology
Jalandhar, India

***Abstract*—The grid-connected solar panel is a distributed power generation device which is connected through an inverter that converts DC power from photovoltaic array to AC power. The voltage regulator to maintain the capacitor voltage at a certain reference level along with a current regulator are required to control the inverter. This paper mainly focuses on control of the inverter with an objective of extracting the maximum power from the solar panel. A fractional order proportional integral controller is proposed to control the inverter in this work. The performance of this controller is compared with the conventionally used PI and PID controllers on the basis of simulation result obtained using MATLAB Simulink.**

Keywords—FOPI, Inverter, PV system, MPPT

I. INTRODUCTION

From the last decades, due to the high increase in the consumption of energy, environment and reserve issues are emerging [1]. It is necessary to find different alternatives for energy consumption. Renewable energy is a good alternative because it is gathered from renewable resources. The most common technologies in renewable energy are Wind power, Hydropower, Solar energy, Geo-thermal energy, Bioenergy, Wave energy. Solar energy is gaining high interest from governments, academia, and industry because it is sustainable and green [2]. Solar energy is an efficient and more feasible alternative option for renewable energy because it is available abundantly. A photovoltaic array is used for generating electricity from the sun. The starting development of solar energy was in space application where cost was not a big issue [3]. Then the photovoltaic (PV) system was started to be used for home application. The multifunctional inverters were proposed in 1998, which have a fuel cell or battery as an auxiliary system [4]. If the storage device such as battery is not connected to the system, the system called as standalone system. PV system was subsequently, connected to the grid and its functionality was monitored in different climate conditions. It has been observed that if the grid is connect to the PV system, the battery size is reduced by 0.5-0.7 factor as compared to standalone system for the same load and solar capacity [5]. In grid-connected PV system, it is important to maintain the capacitor voltage or inverter input voltage at a certain reference level. If it is not set at the reference level, circulating current may flow in the system. Circulating current affects the maximum power of the PV system and it may also damage the system. For increasing the efficiency of the photovoltaic system when PV array is not working, Wu et al suggested a method by using a three-phase rectifier with grid-connected inverter [6]. The maximum power point tracking of PV array is necessary for efficient implementation and operation of the solar system. The quality analysis of the 3.6 KW rooftop solar system in Cairo, Egypt, which is connected to the 220V 50Hz grid is presented in 2011. The system validates the capability of grid-connected photovoltaic in Egypt. The result was analyzed with other studies, which shows the solar system's yearly average production is higher than others [7]. A large scale grid connected photovoltaic plant is installed in Ramagundam, India, where the performance of annual weather variation effect in solar output is observed using SCADA and the actual energy consumption is compared with simulated result in SCADA system [8]. A 91 KW rooftop photovoltaic system was set up on the National Water Research Centre (NWRC), Egypt. A MATLAB Simulink work is proposed mimicking the description of that PV system and Maximum power extract from the solar array has 85% efficiency [9].

The goal of this paper is designing an efficient simulating model, which provides the maximum power from the solar panel while maintaining the capacitor voltage at reference level. The Fractional-Order-Proportional-Integral (FOPI) controller is almost as simple as the conventional PI controller with additional advantage due to the fractional integral. Therefore, the current work envisages to employ FOPI for maintaining the inverter input voltage and compare the performance of the FOPI controller with that of the conventional PI and PID controller on the basis of the simulation results.

II. MODEL DISCRIPTION

The system under consideration is a grid connected solar system consisting of a PV array, DC-DC boost converter, Perturb & Observer Maximum Power Point Tracking (MPPT) controller, 3 phase DC-AC converter, grid and 3 phase resistive load [10]. This system has no storage device such as a battery. The irradiance and temperature values are applied to the solar panel as input. Then DC-DC boost converter is controlled by using Perturb and Observe (P&O) MPPT algorithm and maximum power is extracted from PV panel. Then inverter

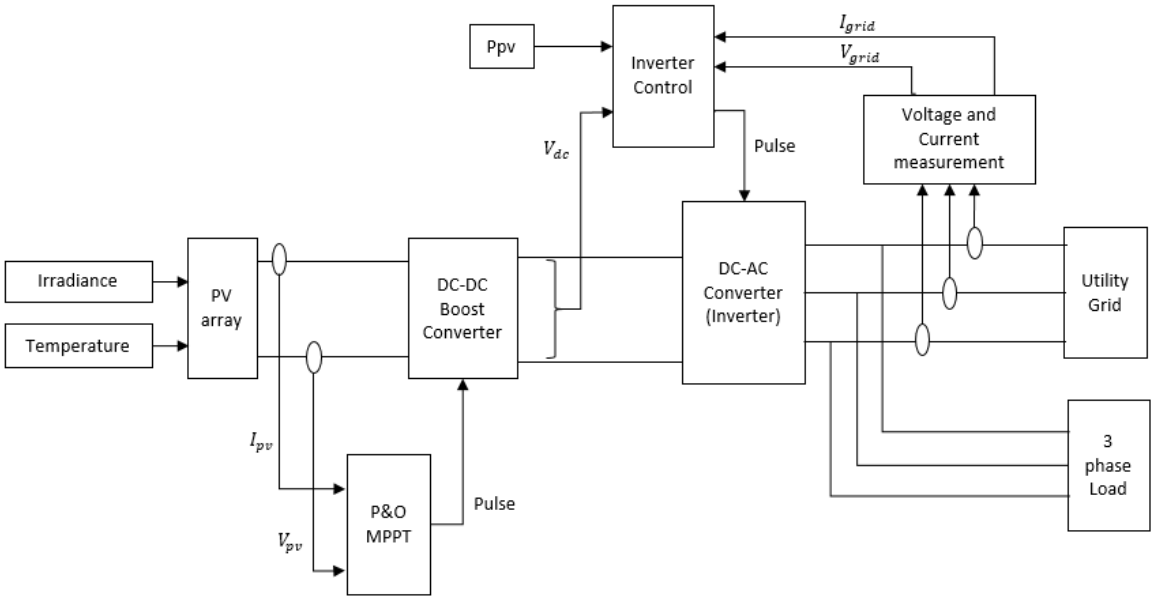

Figure 1 Schematic representation of grid-connected PV system

control scheme is applied to the DC-AC converter (Inverter) for converting DC power to 3-phase AC power. The load is absorbing the power from the inverter and grid both. The simplified configuration is shown in fig (1). This system is modeled and simulated using MATLAB Simulink.

A. PV system

The equivalent circuit for ideal PV cell and practical PV cell are proposed [11] and shown in fig (2) and (3).

The equations (1) and (2) are for ideal PV cell. A series resistance (R_s) and a shunt resistance (R_{sh}) are combined with the ideal equivalent circuit to represent a practical PV cell [11].

$$I = I_{pv} - I_d \quad (1)$$

$$I = I_{pv} - I_0\left[e^{\frac{qv}{aKT}} - 1\right] \quad (2)$$

Where I is current supplied through load (Amp), I_d is current supplied through diode (Amp), I_{pv} is current supplied from PV (Amp), I_0 is reverse saturation current (Amp), q is charge $= 1.602176565 \times 10^{-19}$ Coulomb , v is thermal voltage (Volt), a is diode ideality factor, K is Boltzmann's constant $= 1.3806488 \times 10^{-23}\, JK^{-1}$, T is absolute temperature of p-n junction (Kelvin).

In the PV cell model, the current source is parallel connected with the diode. PV cell act like a diode if there is no irradiance.

$$I = I_{pv} - I_d - I_{sh} \quad (3)$$

$$V_{sh} = V + IR_s \quad (4)$$

$$I_{sh} = \frac{V_{sh}}{R_{sh}} = \frac{V+IR_s}{R_{sh}} \quad (5)$$

$$I_d = I_0[e^{\frac{qV_{sh}}{KT}} - 1] \quad (6)$$

By substituting equation (5) and (6) in equation (3)

$$I = I_{pv} - I_0\left[e^{\frac{q(V+IR_s)}{KT}} - 1\right] - \frac{V+IR_s}{R_{sh}} \quad (7)$$

Where I_{sh} is current supplied through shunt resistor (Amp), R_s is series resistance (Ω), R_{sh} is shunt resistance (Ω), V is load voltage (Volt), V_{sh} is voltage at shunt resistor (Volt) [11].

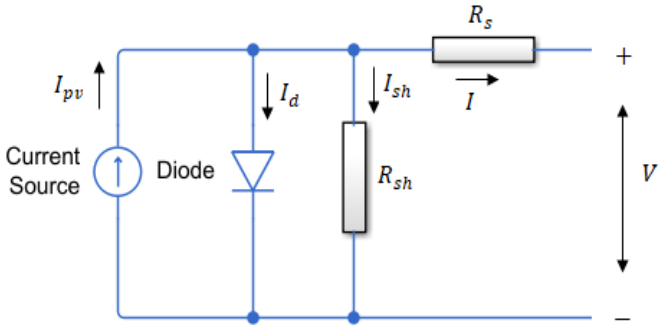

Figure 3 Equivalent circuit of practical PV cell

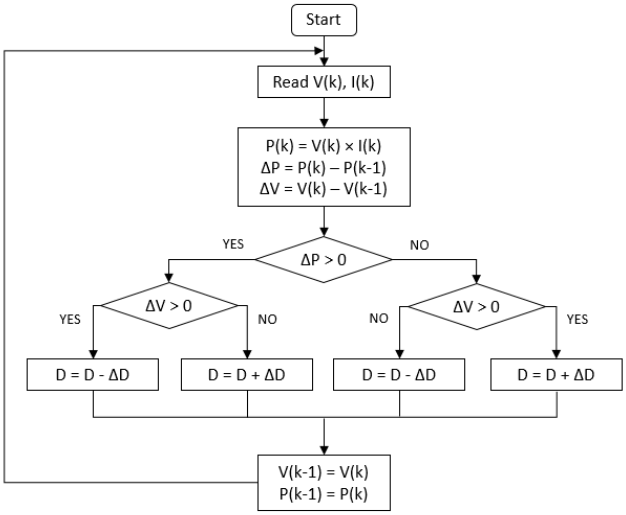

Figure 4 Flowchart of P&O MPPT algorithm

B. Maximum Power Point Tracking (MPPT)

For tracking of maximum power, perturb & observe technique is the most popular because of the low cost and ease to the DC-DC boost converter. In this method, the voltage and current of solar panel are read at time k and the solar power at time instant k is calculated. The voltage and power at time instant k are compared with the sample at time instant (k-1). Voltage from PV array is adjusted by a small amount and the power change is observed. If $\frac{dP}{dV} > 0$, positive sign indicates that the MPP is greater than solar power and the perturbation D is decreased to obtain the MPP. If $\frac{dP}{dV} < 0$, negative sign shows that the MPP is lesser than solar power and the perturbation D is increased to obtain the MPP [14]. If power is increasing continuously with increase in PV voltage, the voltage is increased until $\frac{dP}{dV} = 0$ [14] [15] [16]. The flowchart of the P&O MPPT is shown in Fig. (4), where D is the perturbation step-size.

The MPPT technique requires the knowledge of solar panel parameters. V_{oc} is the open circuit voltage of PV array. Maximum power point voltage (V_{MPP}) and open circuit voltage (V_{oc}) have a linear relationship as shown below

$$V_{MPP} = k \times V_{oc} \tag{8}$$

Where k is constant, and the value of k depends upon the characteristics of the PV cell. The value of k varies between 0.73 to 0.85 [17]. The maximum power at the actual maximum power point (MPP) is calculated by

$$P_{max} = V_{MPP} \times No.of\ series\ modules \times I_{MPP} \times No.of\ parallel\ string \tag{9}$$

Where P_{max} is maximum power at actual MPP, V_{MPP} is the voltage at MPP, I_{MPP} is current at MPP. The efficiency is calculated by the following

$$\eta = \left(\frac{P_{\max tracked}}{P_{max}}\right) \times 100 \tag{10}$$

$$P_{\max tracked} = P_{pv} \tag{11}$$

$$\eta = \left(\frac{P_{pv}}{P_{max}}\right) \times 100 \tag{12}$$

Where η is the efficiency of the MPPT method, $P_{\max tracked}$ is maximum power tracked by the MPPT method [9].

C. Controllers

PI controller is a feedback-based controller. It calculates the output by the received error signal. The function of PI controller is eliminating the steady state error, which are insensitive to system variation [18]. The basic equation of PI controller is given by

$$G_c(s) = K_p + \frac{K_i}{s} \tag{13}$$

PID controller modifies the output based on proportional gain(K_p), integral gain(K_i) and derivative gain(K_d). PID controller make the system stable and more accurate, as it reduces the oscillation present in the system [18]. The equation for PID controller is as follows-

$$G_c(s) = K_p + \frac{K_i}{s} + sK_d \tag{14}$$

FOPI controller is used for improving the performance of the system. As it has three parameters K_p, K_i and λ to tune [19]. The transfer function of FOPI is given by

$$G_c(s) = K_p + \frac{K_i}{s^{\lambda}} \tag{15}$$

The FOPI controller has better control, more flexibility and excellent robustness over PI and PID controller [19]. Ziegler-Nichols method is used for tuning the controller parameters. The

Table I Tuning parameters for controllers

Parameters	PI controller	PID controller	FOPI controller
K_p	112.5	150	112.5
K_i	22500	50000	22500
K_d	-	0.00075	-
λ	-	-	0.6

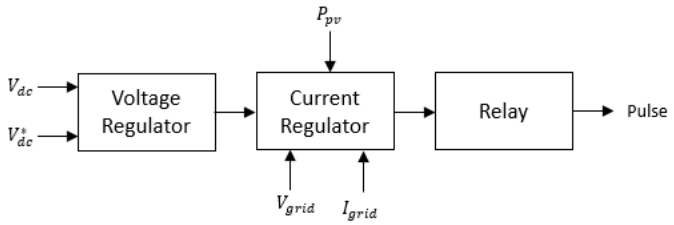

Figure 5 Inverter Pulse Control Scheme

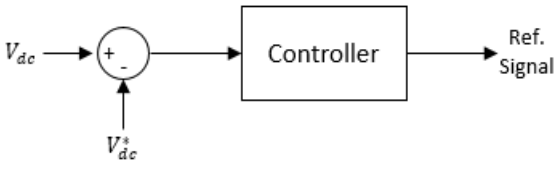

Figure 6 Voltage Regulator

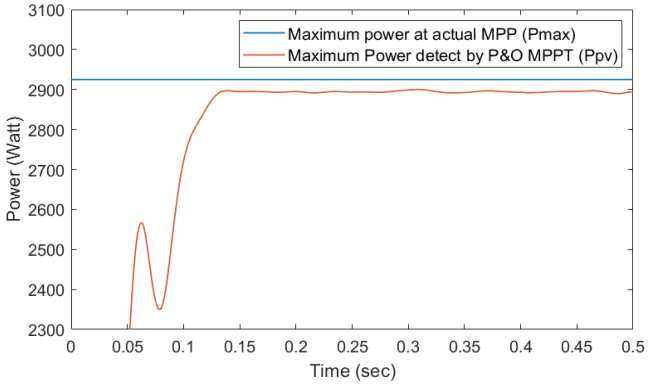

Figure 7 Maximum power extract from Simulink model

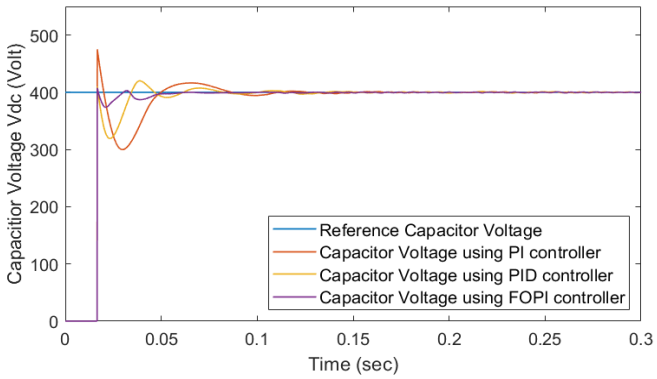

Figure 8 Response of Capacitor Voltage V_{dc}

values of the gains for the different controllers are as given in Table I.

D. Inverter

After extracting the maximum DC power from the solar array, that DC power is converting into 3 phase AC power to supply the demand power to 3 phase load. 3 phase 3 wire inverter is used for converting DC to AC power. 3 phase 3 wire inverter consists of six MOSFET devices. The simplified method for controlling the MOSFET devices is shown in fig (5).

The voltage regulator is designed for maintaining capacitor voltage(V_{dc}) at a certain reference level(V_{dc}^{*}) Fig. The error and signal generated by comparing capacitor voltage(V_{dc}) reference voltage(V_{dc}^{*}). The controller generates a reference signal for the current regulator, which is shown in fig (6). Three controllers PI, PID, and FOPI are used to produce reference signal one by one to control the inerter and their performances are compared. This reference signal is compared with the solar power P_{pv} and a reference power signal is achieved.

Table II Step response parameters for V_{dc}

Parameters	PI controller	PID controller	FOPI controller
Rise Time ($\times 10^{-16}$)	1.5266	1.7347	1.7347
Settling Time (sec)	0.0784	0.0566	0.0440
Peak Overshoot (Watt)	18.7236	4.6681	2.1154
Peak Time (sec)	0.0167	0.0388	0.0167

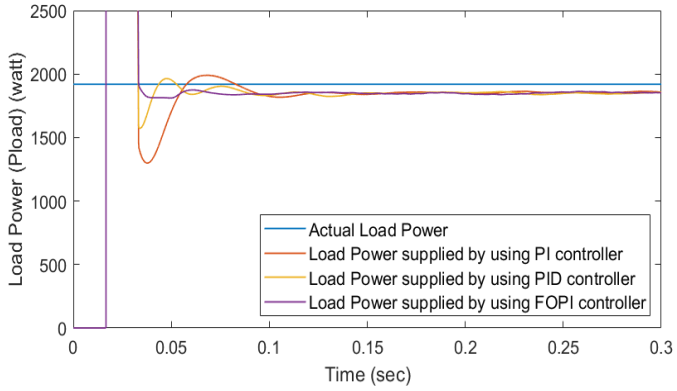

Figure 9 Response of Load Power at 1940W

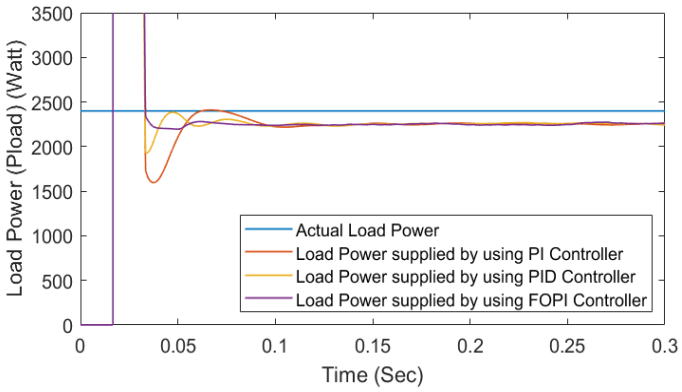

Figure 10 Response of Load Power at 2400W

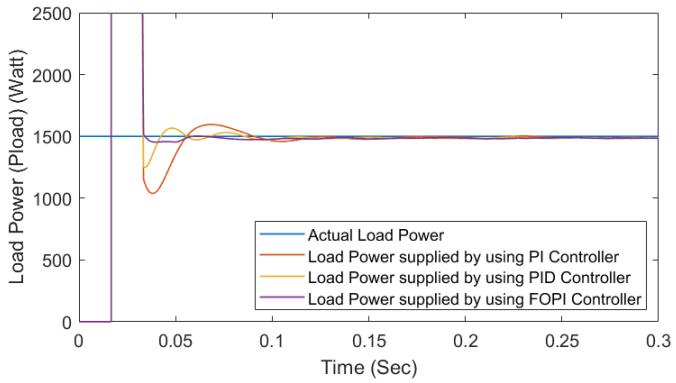

Figure 11 Response of Load Power at 1500W

The phase-locked-loop (PLL) is used to find the phase angle of the grid voltage(V_{grid}). The phase angle is used for park transformation, in which the three-phase grid voltage (abc) reference frame transforms to the grid voltage (dq0) reference frame.

By using the reference power signal and d-axis component of grid voltage, a current reference (I_d^{*}) is generated. An inverse park transformation converts this current reference(I_d^{*}) from the (dq0) reference frame (I_{dq0}) to (abc) reference frame(I_{abc}). Then I_{abc} is compared with the grid current (I_{grid}) and the control pulses for 3 phase 3 wire inverter are generated by using a relay.

III. RESULT

The model is worked in Standard Temperature Conditions (STC). The corresponding values of irradiance and temperature are $1000\ W/m^2$ and 25^0C respectively. The maximum power tracked from the P&O MPPT is compared with the calculated maximum power (2925 W) from (9). The voltage V_{MPP} and current I_{MPP} at calculated maximum power are 37.5 V and 7.8 A respectively.

Fig (7) shows the maximum power tracked by the P&O MPPT. The efficiency of P&O MPPT technique is 98.94% calculated by (12).

The performance of the three controllers in the system are investigated at different levels of 3-phase resistive load. The capacitor voltage is determined by the DC-DC boost converter parameters and hence is kept at 400V and the actual power demand of load in figure (9), (10) and (11) is 1920W, 2400W and 1500W respectively. The capacitor voltage(V_{dc}) and load power for the system equipped with FOPI, PI and PID controllers are shown in figure (8), (9), (10) and (11).

The performance of these controllers in maintaining the capacitor reference voltage in terms of settling time and peak overshoot is given in Table II.

The figure (8), (9), (10) and (11) along with the observations in Table II clearly shows that the PID controller performs better that the PI controller as it takes lesser time to attain the reference target and overshoot value is also very less. However, the least settling time and overshoot are obtain by using for FOPI controller.

IV. CONCLUSION

In this work, a grid-connected PV system is suggested. The P&O tracking method is a precise tracking method and can be used for MPP tracking with an efficiency of 98.94%. A comparative study in to the performances of the FOPI, and the conventional PI and PID controllers for controlling the inverter establishes the superior performance of the proposed FOPI controller in terms of both, the settling time and the peak overshoot that also reduces the distortion in the system. This work can further be expanded by including battery in the grid connected PV system. The future scope includes investigation into hardware implementation of the same.

***Abstract*—The emergence of Internet of Things (IoT), has increased the demand for design of energy-efficient and secure IoT devices. For example, IoT devices such as Wireless Sensor Nodes (WSN) and Radio Frequency Identification (RFID) tags employ AES cryptographic module which are susceptible to Differential Power Analysis (DPA) attacks. With the scaling of technology, leakage power in the cryptographic device increases, which increases their vulnerability to DPA attack. The FinFET based Adiabatic Logic Circuits are energy efficient and consume low power as compared to normal FinFET circuits. The proposed adiabatic logic is used to design logic gates such as buffers, XOR/XNOR, and AND/NAND circuits. The circuits have been designed using FinFET 18nm technology. The average power of the circuits has been computed and also the output Energy loss of the circuits has been calculated. For the Buffer the Average power consumption was found to be 4.331uW without adiabatic logic and 1.840uW with Adiabatic logic. The reduction of power is 57.51 %. For the AND/NAND circuit Average power consumption was found to be 4.479uW without Adiabatic logic and 2.356uW with Adiabatic logic. The reduction of power is 47.39 %. For the XOR/XNOR circuit Average power consumption was found to be 7.778uW without adiabatic logic and 4.428uW with Adiabatic logic. The reduction of power is 43.07 %.**

Keywords— Adiabatic Logic, FinFET, Low Power VLSI Design

I. INTRODUCTION

Adiabatic logic is a widely used method to design circuits that are energy-efficient and secure. It has been proved that adiabatic logic is one of the most the promising techniques when it comes to dealing with DPA attacks [6],[7],[8],[9]. Techniques such as Symmetric Pass Gate Adiabatic Logic (SPGAL) are used in the design of hardware that is secure and the same time consumes minimum power. These systems are most suitable to be implemented in IoT based devices [1]. When compared to the other widely used DPA resistant families of adiabatic logic, one of the drawbacks of SPGAL is its high leakage power at lower technology nodes. Therefore, with scaling the designer has to deal with the challenges of leakage current. The energy-efficiency of the computing circuits decreases with increase in leakage current. This in turn makes the device more vulnerable to DPA attacks. Low leakage devices such as FinFET can be used for the investigation of crypto circuits. In [1] the design of cryptographic processors, one of the main threats is the DPA attack. To determine the relationship between cipher texts and keys, S-Box is used in cryptographic algorithms like AES and DES [10]. However, due to its high-power consumption, S box is prone to DPA attacks. Due to its resistance against DPA attacks, an 8-bit S-Box circuit has been designed using Symmetric Pass Gate Adiabatic Logic (SPGAL). The verification of results has been performed through SPICE simulations in 180nm technology. As compared to and Secured Quasi-Adiabatic Logic (SQAL) and conventional CMOS, this circuit saves up to 67% and 92% energy. Wireless Sensor Network (WSN) and its sensing applications are of great importance in the present day [2]. With the internet of things, these sensors sense various parameters from the environment and share information across various platforms. Various key technologies and domains that motivate research in IoT have been thoroughly discussed. A cloud centric vision for world-wide implementation of IoT is presented in this paper. A cloud implementation using Aneka has been performed. This is based on the interaction of public and private clouds. There is an emphasis on the need for convergence of WSN, distributed computing and Internet. Paper [3] presents an overview of various radio frequency identification techniques. Traditional ID technologies and RFID techniques have been compared. Various applications of the same have been presented. Each of these applications have their own techniques of which some of them are tag energy supply, frequency range and tag writing capabilities. A circuit contains various components such as transistors and other components. Each of these consume an amount of power which contributes to the overall power consumption of the circuit. Information is leaked through power consumption. Secret keys can be extracted by analysis of side channels. Approaches to prevent DPA attacks and cryptosystems that are secure even when implemented in hardware that leaks have been presented [4]. To reduce power consumption from many charge recovery logic families have been designed. This paper presents a new charge recovery logic style for resistance against side-channel attacks (SDA), especially against DPA attacks. This logic style proves to have better in DPA-resistance level and lower power consumption compared to existing DPA styles proposed this far [5]. Mechanisms such as usage of DC bias instead of ground in the source of NMOS transistors and Pass transistors to discharge the internal parasitic capacitances of function blocks have been proposed to reduce the data dependent power consumption. These methods decrease the dynamic power consumption. This method is more DPA resistant than other proposed styles such as TDPL and SALB. There is also reduced power consumption From the Literature Survey it is observed that most of the Hybrid Full Adder designs employ CMOS Technology. FINFET is known for its high speed of operation. Hence an implementation

of Hybrid Adder using FINFET would further reduce the Delay of circuits [11].

II. Basic of FinFET Based Adiabatic Logic

Adiabatic logic is an efficient method to recycle the charge stored in the load capacitor using power clocks. The main advantage of this method is the reduced dynamic switching energy loss due to charge recycling. The adiabatic charging/discharging of the load capacitors is shown in Fig. 1.

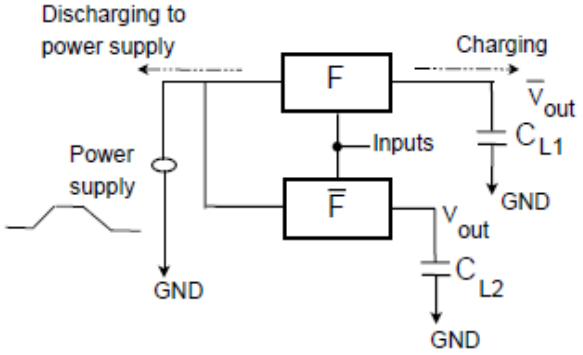

Fig. 1. Adiabatic charging/discharging [1]

Considering that a constant current source is supplying the charge, the energy dissipated in an adiabatic circuit is given by

$$E_{diss} = \frac{RC}{T} CV_{DD}^2 \quad (1)$$

In equation 1, the load capacitor is denoted by C. Vdd is the full swing of the power clock. The charging and discharging time of the capacitor is given by T, Vdd was the full swing of the power clock. Energy dissipation in adiabatic circuits is lesser than, conventional CMOS. As T approaches infinity, energy dissipation tends to zero.

FinFET Device

The FinFET has the gate wrapping the channel in all the three directions. The silicon body is perpendicular to the plane of the wafer. The strudture of the FinFET device is shown in Fig. 2.

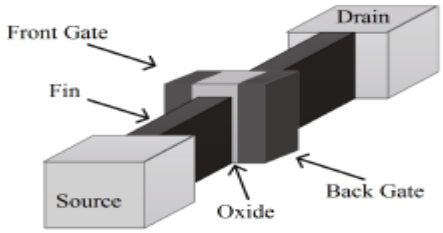

Fig. 2. FinFET Device structure [1]

The main advantage of FinFETs is the effective gate control over the channel. This reduces the threshold current, gate dielectric leakage currents and the short-channel effects than MOSFETs. Higher on state current,lower leakage and faster switching are the advantages obtained from the same. FinFET has different working modes due to its multigate structure. The FinFET has two main working modes. The Independent-Gate (IG) mode and the Shorted-Gate (SG) mode. The two gates are tied together in the Shorted gate mode and the device acts as a three terminal device in SG mode.

III. Implementation of FinFET Based Adiabatic Logic Circuits And Results

The Schematics of FinSAL Buffer, FinSAL AND/NAND gate and FinSAL XOR/XNOR gate were designed using Cadence Virtuoso Tool. The test benches were created, and the working of the Adder was verified through simulations. FINFET 18nm technology was used in the design. The Transient Analysis was performed, and the energy consumption of the circuits was calculated. The Basic Methodology is shown in Fig. 3.

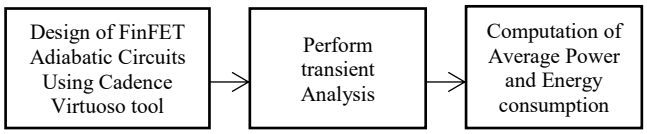

Fig. 3. Basic Overview of Implementation

Table I shows the Basic Overview of Implementation.

TABLE I Different Energy Sources and Their Objectives

Tool Used	**Technology**	**Parameters computed**
Cadence Virtuoso	FinFET 18nm	Energy Average Power

A. Design of Buffer

The Schematic of the buffer with FinFETs in the IG (Independent Gate) mode has been designed as follows. The 18nm technology FINFETs has been used. The n1lvt and p1lvt transistors have been used. The Schematic has been designed in Cadence Virtuoso using FINFETS. Fig. 4 shows the schematic of the buffer. When A is high, capacitor C_L charges and out is pulled up to VDD, while A- bar and out-bar is low.

a. Design of a buffer without Adiabatic Logic

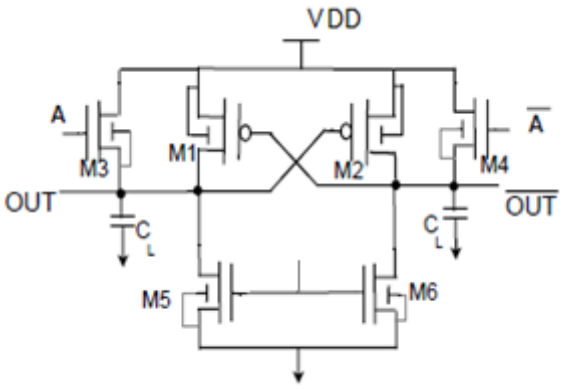

Fig 4. The Schematic of FinFET Buffer

TABLE II SPECIFICATIONS FOR PERFORMING SIMULATION

Library	Model name	Pin Name	Specification
cds_ff_mpt	p1lvt n1lvt	A, Ab	L = 18nm VDD = 1V
analogLib	vdd	Not applicable	1V
	vdc	Not applicable	1V
	gnd	Not applicable	-
	vpulse	Clk	Period = 80ns, Pulse width = 40ns DC Voltage = 1V
	vpulse	A	Period = 80ns, Pulse width = 20ns DC Voltage = 1V

Table II lists the specifications for performing simulation. It contains details about the libraries that are used, the input pins, the model names and the specifications. The average power of the design is computed by performing transient Analysis. The transient analysis waveforms of the buffer is shown in Fig 5.

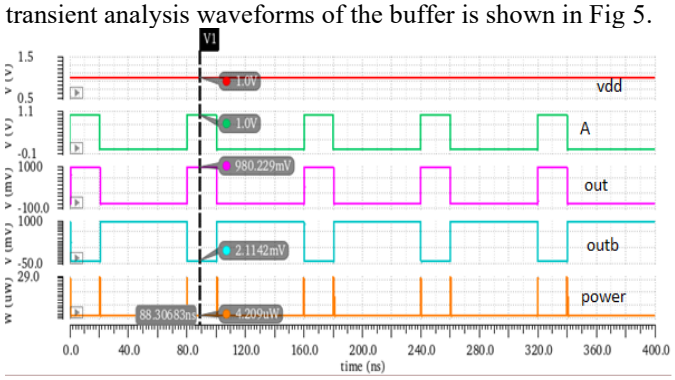

Fig. 5. Waveforms of FinFET Buffer

The maximum output voltage is found to be 980.23mV. The average power consumed by the circuit is 4.331 uW.

b. Design of FinFET Buffer with Adiabatic Logic

The Schematic of the FinFET buffer with Adiabatic logic has been designed as follows. The 18nm technology FINFETs have been used. The n1lvt and p1lvt FINFET transistors have been used. The Schematic has been designed in Cadence Virtuoso using FINFETS. Fig. 6 shows the schematic of the buffer. As compared to the previous design a Vclk pulse is applied as as the supply.

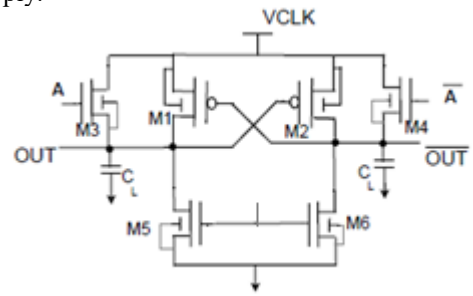

Fig 6. The Schematic of FinFET Buffer with Adiabatic Logic

The specifications for performing synthesis have been shown in Table III.

TABLE III SPECIFICATIONS FOR PERFORMING TRANSIENT ANALYSIS

Analysis	Specification
Transient	Analysis: tran Stop time: 400ns Accuracy defaults: conservative

The transient Analysis was performed, and the working of the Buffer was verified. The stop time was taken to be 400ns. Accuracy defaults were set to conservative.

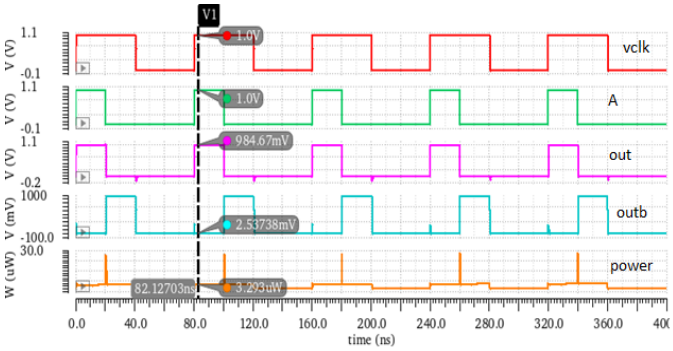

Fig.7. Waveforms of transient Analysis of FinFET Buffer with Adiabatic Logic

Fig. 7 shows the transient analysis waveforms of the FinFET Buffer with Adiabatic logic. The maximum output voltage is found to be 984.66 mV. Average power consumption of the circuit is computed to be 1.84 uW.

B. Design of AND/NAND Gate

The Schematic of the FinSAL AND/NAND gate has been designed as follows. The 18nm technologies FINFETs have been used. The n1lvt and p1lvt FINFET transistors have been used. The Schematic has been designed in Cadence Virtuoso using FINFETS. The specifications remain the same as for the buffer however the period and pulse widths have been changed.

The Waveforms of FinFET XOR/XNOR Logic without Adiabatic Logic is shown in Fig. 13. The maximum output voltage is 955.36mV. The Average Power consumption is 7.778uW.

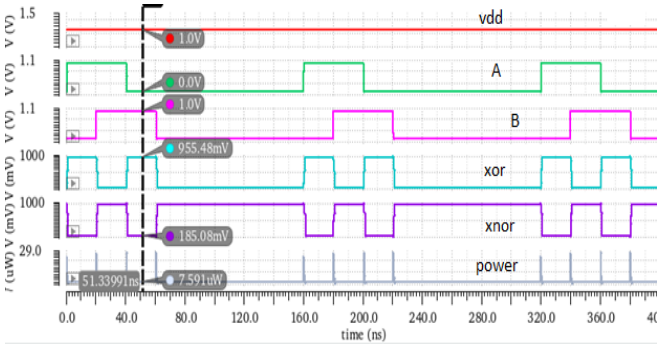

Fig. 13. Waveforms of FinFET XOR/XNOR Logic without Adiabatic Logic

b. *XOR/XNOR Circuit with Adiabatic Logic.*

Fig. 14. shows the schematic of the XOR/XNOR Circuit with Adiabatic Logic.

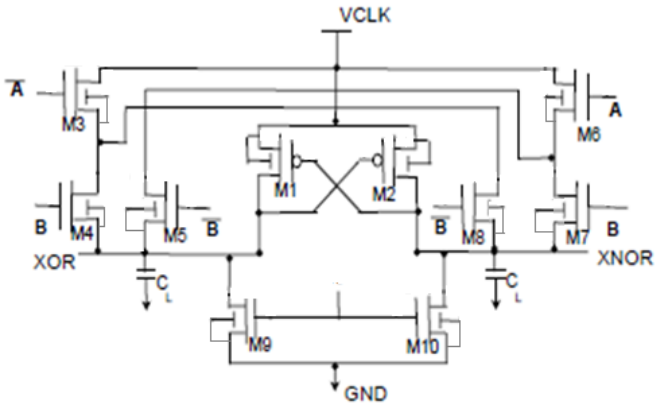

Fig. 14. The Schematic of FinSAL XOR/XNOR with Adiabatic Logic

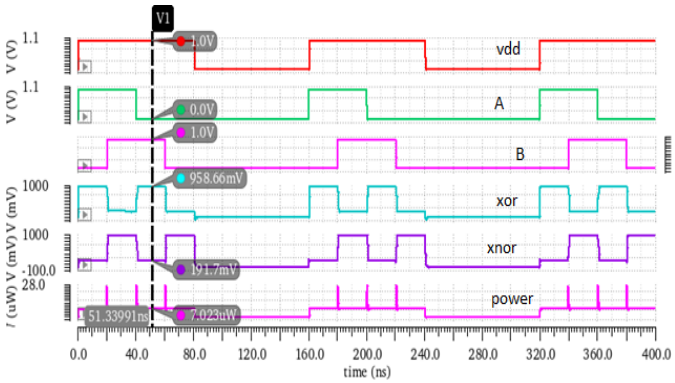

Fig. 15. Waveforms of FinFET XOR/XNOR with Adiabatic Logic

The Waveforms of FinFET XOR/XNOR Logic with Adiabatic Logic is shown in Fig. 15. The maximum output voltage is 958.662mV. The Average Power consumption is 4.428uW.

.

IV. Conclusion

Three circuits were designed using FinFETs – Buffer, AND/NAND circuit and XOR/XNOR circuit. They were designed using FinFET 18nm technology. The Average power and Energy of the three circuits was computed. For the Buffer the Average power consumption was found to be 4.331uW without adiabatic logic and 1.840uW with Adiabatic logic. The reduction of power is 57.51 %. For the AND/NAND circuit Average power consumption was found to be 4.479uW without Adiabatic logic and 2.356uW with Adiabatic logic. The reduction of power is 47.39 %. For the XOR/XNOR circuit Average power consumption was found to be 7.778uW without adiabatic logic and 4.428uW with Adiabatic logic. The reduction of power is 43.07 %.

For the Buffer the Maximum output voltage is 980.23mV without adiabatic logic and 984.66mV with adiabatic logic. The energy of the output signal is is 0.4804 pJ without adiabatic logic and 0.4808 pJ with adiabatic logic. The energy loss is reduced from 3.92 % to 3.84 %. For the AND/NAND circuit the Maximum output voltage is 980.193mV without adiabatic logic and 985.22mV with adiabatic logic. The energy consumption is 0.4803 pJ without adiabatic logic and 0.4853 pJ with adiabatic logic. The energy loss is reduced from 3.94 % to 2.94 %. For the XOR/XNOR circuit, the Maximum output voltage is 955.36mV without adiabatic logic and 958.662mV with adiabatic logic. The energy consumption is 0.4563 pJ without adiabatic logic and 0.4595 pJ with adiabatic logic. The energy loss is reduced from 8.74 % to 8.10 %.

***Abstract*—A simple four port antenna with Ultra-wide band (UWB) and multiple- input multiple-output(MIMO) behavior is proposed using two shared radiators. the two shared radiators are making 180^0 angle to each other. The problem of interference in broad-band of UWB from other sources is avoided by forming notch band at 5.5GHz center frequency. The proposed design is of size 48X48mm^2 using FR4 Substrate (dielectric constant 4.4) and fed by micro strip line. The two shared radiator multiple-input multiple-output antenna provides a bandwidth of 2.9 to 11.4 GHz with reflection coefficients S_{11}, S_{22}, S_{33}, S_{44} very less than -10dB and all the mutual coupling coefficients for respective antenna elements are less than or equal to -22 dB. The design also provides triple frequency bands characteristics with wide band behavior. Also, In order to achieve low mutual coupling, the meandered line stub is utilized at the end of the ground plane. The stimulated outcomes of proposed design are shown.**

Keywords—UWB, notch, MIMO

I. INTRODUCTION

UWB antennas has many Characteristics like extremely low transmission energy(less than 1mV), FCC given license of very high bandwidth but with short range, Extremely difficult to intercept, Low cost, use for multiple frequency ranges(3.1GHz to 10.6GHz)- satellite communication, tracking a radar, Mobile devices, sensor, GPS and Bluetooth are narrowband technologies(1.6 and 2.4 GHz respectively). To increase the transmission capacity, we need to reduce the multipath fading. Basically, combination of UWB and MIMO Technology solve the issue of fadedness of signals. In portable MIMO devices, close packing of several antennas degrade diversity performance by introducing mutual coupling between antenna elements. The first major challenge now-a-days is need of small UWB MIMO antenna with minimum coupling for smart and small Electronic devices such as WLAN and UMTS. The UWB MIMO antenna design also affected due to interference from other communication systems radiating at same frequency. The solution for this interference is creation of notch band at that particular frequency. The second major challenge is design of notched compact UWB MIMO antenna. Basically, the main idea from above discussion is to make a small UWB MIMO antenna having stop band behavior as well as low mutual coupling so that channel capacity can be maximize and minimize the cause of interference from other bands.

In Literature, Micro strip antennas accomplished various shapes such as square, rectangular, circular and octagonal proposed for obtaining Ultra-wide band [1-4]. The methods that are study in literature to design UWB MIMO antennas with minimum coupling are defected ground structures, rectangular stubs and tree like structures. T-shaped stub extruded in rectangular ground plane for decoupling in eye shaped UWB MIMO antenna and two antenna elements are orthogonal[3]. In this, concept of orthogonal placement of antenna elements used that provide low coupling between elements. By increasing branches of tree like structure, high isolation is achieved [5]. Fork shaped slot is placed between the antenna elements to enhance isolation and L-shaped slot cut from radiators to create notch band[6]. A shared radiator utilizing meandered line stub with ground plane[7]. T-shaped slot in pentagonal radiator with extending branch of ground plane for improving isolation has been discussed[8]. Method of Double layer slit-patch EBG structure between radiators for low coupling enhance the size of antenna[9]. Dual band MIMO antenna consist of shorted metal strips with ground plane for mutual coupling reduction and "L" slot in radiating patch for dual band[10]. The literature also provide designing methods of UWB antennas with notch band and low mutual coupling like Tapered Micro strip fed compact MIMO UWB antenna consist of two notches using two L shaped slits in patch and T shaped stubs for low coupling[11]. Orthogonally fed slot antennas for UWB systems utilizing uniplanar nature of coplanar waveguide using a diagonal strip on ground plane for maintaining isolation and arc shaped slot resonators in feed structure to reject the desired band[12]. A printed folded monopole UWB antenna uses an open stub to reject the desired WLAN band that interferes with the UWB band[13]. In Literature, two modified coplanar waveguides along with staircase-shaped radiating patches for orthogonal radiation patterns, with a rectangle stub placed at an angle between the feed to get low coupling in entire UWB and by using two split-ring shaped slots over the antenna elements respectively, the stop-band property is achieved[14]. A two CPW-fed floral radiating elements provides ultra wide band along with a decoupling structure to ensure high isolation and the stop-band at the WLAN frequency is obtained through single U-shaped slot on each antenna element [15]. Shared radiator symmetrically shared by two tapered micro strip feed lines placed at an angle of 135° from *X*-axis makes an UWB system and the utilization of meandered line stub with modified ground structure provides maximum amount of isolation between the antenna ports[16]. Many 2x2 port UWB diversity antennas reported in literature[11-16] lack in enhancing the communication channel quality. Therefore, many MIMO UWB antennas are proposed with more than 2-ports recently

[17-22] (consider Table1). Three port antenna design consists of staircase-shaped radiating elements constituting UWB band and also the antennas give stable gain, directional radiation patterns and favorable radiation efficiencies[17]. A four port CPW fed UWB MIMO system with high isolation and stop band behavior[18]. The design of antennas with high radiation efficiencies for UWB signaling and for development of UWB impulse radio communication systems is a most difficult task, especially when these signals and systems exist with previously standardized narrowband services. So, to avoid this problem, an antenna design with quad-element and dual stop-band is communicated in literature[19]. In MIMO UWB Technology, it has been seen that placement of disposed antenna elements orthogonally is the most familiar methodology to maximize isolation of MIMO antenna elements[20]. The orthogonal arrangement of antennas helps to accomplish polarization diversity performance where isolation factor is mainly affected by spacing of individual elements. Also, miniaturization is achieved in UWB MIMO antenna by utilizing the benefit of symmetry property of planar antennas[20]. A design with four circular patches, defected ground structure(DGS) and a mushroom-like electromagnetic band gap structure uses metallic vias method reported in [21]. In this, four ring-shaped slots on the radiators are etched to get stop band behavior[21]. The antenna structure with four triangular monopoles connected symmetrically and orthogonally improves the diversity performance, and by combining a rectangular ring with a straight line further reduces the coupling due to interoperation of the elements[22]. An Koch Fractral geometry is used for UWB performance with C-shaped slot for band rejection and rectangular stub attached to ground plane for mutual coupling reduction [23]. However, many MIMO antennas has been proposed with and without notch bands, and mostly with two ports but they have relatively big size, weak MIMO performance and high coupling in whole band of UWB in comparison with the proposed structure. Many nonconventional shape antenna design that provide compactness are often optimized using different optimization techniques such as genetic algorithm, particle swarm optimization, etc. These antennas offer better impedance matching over wide frequency band. In this communication, a miniaturized MIMO antenna with simple geometry, ultra-wide band and high isolation is proposed. Two shared radiator with two port each designed on 48X48 mm^2. The substrate used for design is FR4_epoxy with 1.6 thickness and relative permittivity of 4.4. The shape of the shared radiator is hexagonal and is fed by perpendicular micro strip line structures of width 1.5mm and height 23.65mm. Each feed line structure consist of two feeds of same width 1.5mm but feed 1 has length 9.9mm and feed 2 has length 13.75mm. feed 1 and feed 2 are orthogonal to each other. The isolation in shared elements is obtained by extending the branch of the ground plane in the symmetry axis of two antenna elements. To get stop band at 5.5GHz, the presented antenna has a slot with inverted L-shaped geometry in Ground plane near feed line of patch. The dimensions of the slot is optimized using Genetic optimization alogorithm in order to achieve sharp notch. This simulated design has ultra-wide impedance bandwidth, the gain is moderate and radiation pattern is omni-directional. The compact size antenna designed due to shared radiator and has stop band at 5GHz to 6.2 GHz. A comparison of other reported UWB MIMO antenna with proposed simulated antenna design is presented in Table 1.

This article is planned as follows: In Section II, Layout for proposed system is discussed with simulation results followed by stop band behavior of MIMO. Experimental results are presented in Section III including isolation, radiation characteristics, and MIMO parameters. Finally, Section IV concludes the Article.

TABLE 1. COMPARISON OF PROPOSED LAYOUT OF UWB MIMO WITH OTHER REPORTED

Reference	Size(WxL geometry) (in mm^2)	Number of Elements	Operating band(in GHz)	Isolation (in dB)	Peak Gain (in dBi)	Notch band (in GHz)

II. ANTENNA LAYOUT

The planned layout is demonstrated in figure 1, has two identical shared patches 180^0 apart with common modified ground structure as represented in figure 2. Two regular

shared Hexagonal radiators are fed by 50Ω Micro strip lines of size (L_F x W_F) where L_F= L_{F1}+L_{F2}. The proposed antenna design has total area of 48x48 mm^2 (i.e. denoted as L_G x W_G) and has printed on low loss FR4 substrate with 4.4 relative permittivity, .02 loss tangent and 1.6mm thickness. The overall MIMO antenna volume is reduced by layout of two shared radiators. One of the major issue in UWB MIMO antenna design is to get resonance at lower cut off frequency i.e. 3.1 GHz and keeping compactness of the layout with it. This can be obtained by increasing current path in radiator so we take hexagonal shared radiator.

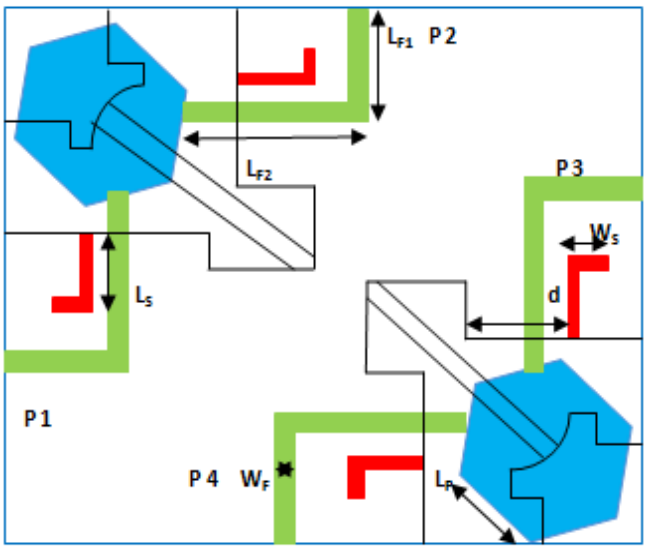

Figure 1: Proposed Geometry

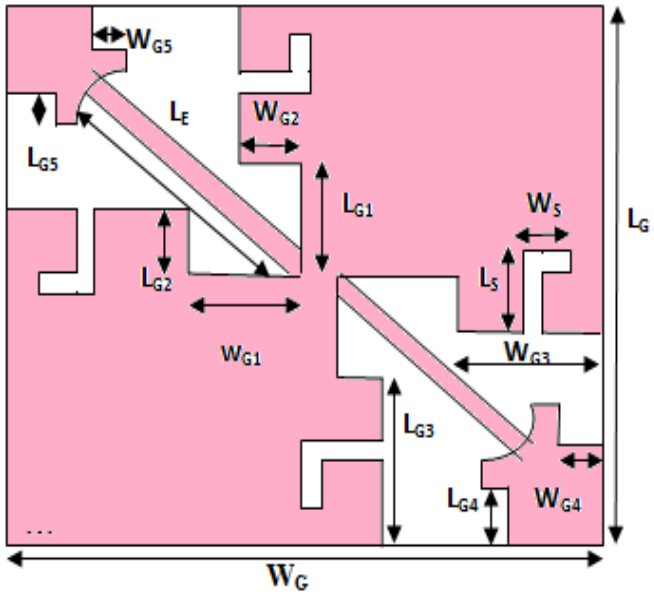

Figure 2: Geometry Of Ground Plane

This design provides wide band of 2.9-11.4 GHz with triple band characteristics and also maintain compactness of the design. In Portable devices, high level of coupling occurs if we utilize multiple radiators that degrades diversity performance. Another major issue is to reduce this coupling between the ports and maintain the compactness of the antenna. In literature, decoupling structure (occupies larger space) is the approach carried out to maximize isolation. The issue of high coupling between ports is minimize by utilizing concept of increasing the distance between respective ports. So, to obtain high isolation between four ports of respective shared radiators , two simple metal branches of length L_E that act as respective reflectors are extended on ground plane on both sides of radiators. These metal branches can also decrease the current on the ground structure flowing between two elements of respective radiators. Further improvement in isolation can be obtained by increasing effective length of the ground. This is accomplished by creating slot in the ground plane. Band stop characteristics in WLAN band also achieve in this design. A inverted L-shaped slot (L_S x W_S) is cut from ground plane near each feed line to create stop band in the region 5.1 - 6 GHz. L-shaped geometry is chosen because of its broad band rejection characteristics. Designing and Optimization process is done by High Frequency Structure Simulator(HFSS). The optimized parameters are given in Table 2.

TABLE 2. PARAMETERS VAUES USED FOR PROPOSED ANTENNA

Parameter	Value(in mm)	Parameter	Value(in mm)
L_G	48	L_{G5}	6.48
W_G	48	W_{G5}	6.7
L_{G1}	9.5	L_S	2.5
W_{G1}	9.5	W_S	5
L_{G2}	5.5	L_E	17.8
W_{G2}	5.5	L_{F1}	9.9
L_{G3}	14	L_{F2}	13.75
W_{G3}	14	W_F	1.5
L_{G4}	6	L_P	8.48
W_{G4}	6	d	7.1

III. OUTCOMES AND DISCUSSION

A. Outcomes

Figure 3 represents the return loss characteristics (S11 and S22 in XY Plot 1, S33 and S44 in XY Plot 2) of the 4-port UWB MIMO proposed design. All reflection coefficients S11, S22, S33 and S44 are < -10dB for entire ultra-wide band (2.9 GHz to 11.4 GHz). These reflection coefficients show triple band characteristics. In XY plot 1, S11 parameter show maximum return loss of -20dB, -25dB and -24dB at 4.1GHz, 7.5GHz and 8.8GHz respectively whereas, S22 has maximum return loss of -27dB, -38dB and -24dB at the respective frequencies. In XY plot 2, return loss(S33) of -28dB, -36dB and -24dB observed at 4.1GHz, 7.5GHz and 8.8GHz respectively whereas, S44 drops to -20dB, -24dB and -23.5dB at these frequencies respectively. It is also shown that, the simulated resonant frequency is given by 7.5 GHz. The existence of L-slot in ground is responsible for notch at frequency of 5.5 GHz. The various mutual coupling parameters S12,S13 and S14 are shown in Figure 4. They all are almost less than -22dB. This shows that the presence of meandered line stub in ground plane avoids the interference between shared patches.

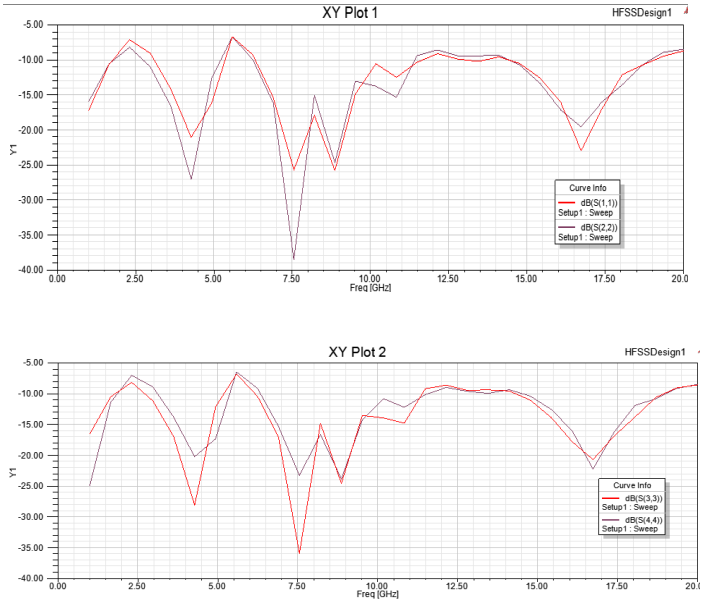

Figure 3: Simulated Results For Return Loss

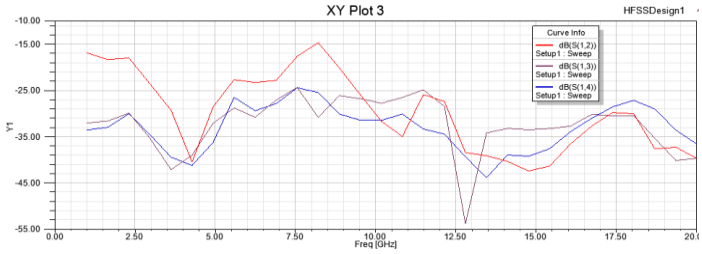

Figure 4: Simulated Results For Isolation Of UWB MIMO Design

B. Stop band behavior

The proposed antenna has simple ground plane represented as Antenna I of Figure 5. This ground plane design show low mutual coupling between shared radiators.

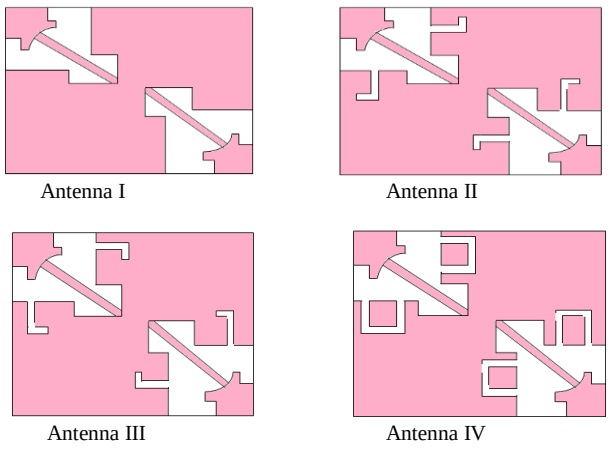

Figure 5. Evolution Of Ground Plane

In order to get rid of interference from other bands, various techniques are displayed in Figure 5 (Antenna II, Antenna III and Antenna IV) to create notch band keeping mutual coupling as low as in Antenna I. Through the comparison in Figure 6, we observed that notch band at 5.5GHz is created using inverted L shaped slot of .7mm thickness with parameter d=7.1mm, using L shaped slots of .7mm thickness at 4.9 GHz(notch center frequency created) keeping distance d= 10.8mm, L_S= 4mm, W_s = 3.1mm and U- shaped slot also create notch at 5.5GHz with distance d=6.2mm, L_S= 4mm, W_s = 3.1mm. The best suitable geometry for notch creation is Antenna II with lower cut off frequency 2.9GHz because in case of Antenna III and Antenna IV, it is difficult to maintain lower cut off frequency that is 3.1GHz as per FCC. The lower cut off frequency in later two cases is 3.2GHz because of different surface current distribution due to different geometry of slots created in ground plane. The upper cut off frequency for Antenna I is 11.4 GHz and in later cases, it is 11.5GHz. So, we concluded that Return loss graph shifted slightly towards right due to either L pattern or U pattern slot in ground.

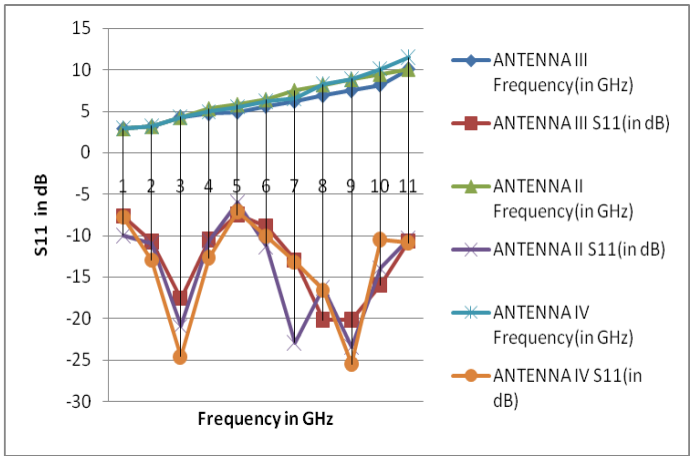

Figure 6. Comparison Of Return Loss For Different Notch Techniques

The comparison of Mutual coupling is shown in Figure4 and it is obtained almost less than -22dB. This shows that the presence of meandered line stub in ground plane avoids the interference between shared patches.

IV. CONCLUSION

A novel micro strip line fed 4X4 UWB-MIMO Layout contain a shared patch and modified ground is communicated. The Layout of antenna has very small size of 48 × 48 mm^2 that makes it best solution for portable devices. By cutting an inverted L-shaped slot in the ground plane, stop band from 5.1 GHz to 6 GHz is created. The meandered line extension in ground plane also has a great impact on the −10 dB bandwidth for entire UWB and on the isolation factor. The simulated results displays consistency where the working bandwidth of the MIMO antenna is from 2.9-11.4 GHz with coupling as low as -22 dB.

***Abstract*—Power transfer (WPT) without wires in electric vehicle charging is a relevant topic in the present day scenario. From the year of Tesla, the basic method of WPT using magnetic resonance has been developed. The main advantage of WPT is that it does not need any wires and can charge dynamically. So this method is very useful in the case of stationary and dynamic charging of the electric vehicle. WPT can be also used in biomedical types of equipment, electronics appliances charging. This paper proposes a third harmonic WPT system with improved input power factor. The advantage of selecting third harmonics for the power transfer is that it will increase the system frequency up to 3 times without rising the switching frequency. Also, the bigness of the passive components lowered into one by third and thereby the reduction in cost. Reasons for neglecting high order harmonics are also discussed in this paper. The major flaw of ordinary WPT is the poor power factor. So the proposed topology uses a boost PWM rectifier along with hysteresis control, it will increase the input power factor up to 0.9.**

Keywords: Wireless power transfer(WPT), inductive magnetic resonance, Inductive Power Transfer(IPT), Electric vehicle.

I. Introduction

Nowadays the government authorities provide subsidies and reduce taxes to enhance the marketing of the electric vehicle. The shortage of fossil fuels is the major reason for this and also the unlimited emission of pollution from petroleum vehicles. But the charging of the electric vehicle is very difficult. Also, there will be chances for a shock if there are any cracks in the plugged wire. So the concept of WPT for charging will eliminate all these problems[1].

Firstly,Discussing what is the conventional wireless power transfer arrangement done in the electric vehicle. Fig. 1 displays a conventional resonance inductive power transfer arrangement[2] used in EV. There is diode bridge rectifier and high-frequency inverter on the primary part which will draw the power from the grid. The rectifier converts the AC supply into DC. The inverter used is a quasi-square wave inverter having the output of rich in harmonics. The inverter stage transforms DC waveform into a high-frequency square wave. The frequency should be as high as possible in order to boost the efficiency and to limit the losses in transmitting

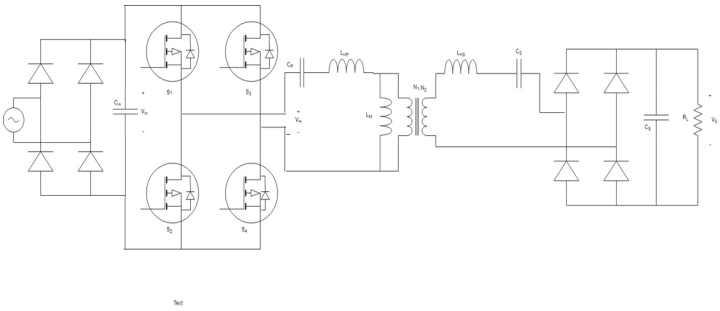

Fig. 1. A Conventional Resonance Inductive Power Transfer system

side. In the primary side transmitter, there is an inductor and a compensating capacitor. These are used to convert a high-frequency square wave into a high-frequency sine wave. Likewise, there is an inductor and a compensating capacitor on the secondary part. So that frequency of the receiver secondary side is made to match with transmitting coil in order to increase the productivity of power transfer. That is the transmitter and receiver are in resonance. The switches used is IGBT for high-power application. Normally, the IGBT carry up to 20 KHz. The power carried from the primary is rectified into dc again in the secondary side, and it is used for charging the battery[3].

Charging of the electric vehicle via WPT is by two types; static and dynamic(in motion)charging. In dynamic charging, the transmitting coil is placed beneath the road, while the receiving coil is placed in the vehicle. So that when the vehicle is passed over the road the battery gets charged[4]. The major parts of the system are a utility grid, a rectifier, a high-frequency H-bridge DC-AC inverter, and two series attached transmitting helices with their series resonant adjusting capacitors, beneath the road. The automobile part of the arrangement contains a receiver helices placed below of the automobile with a resonant adjusting capacitor, a diode bridge rectifier with a DC draining capacitor and the automobile battery. In stationary charging, the primary coil is placed in a particular area, and when the vehicle comes over directly the primary coil, power is transferred through the secondary coil which is placed in the vehicle.
The other advancement in wireless charging is that the

selection of the higher harmonics for the power transfer. The main feature is that the bandpass filter nature of the resonant structure. The resonant network is tuned to pass only one harmonic current to the secondary side. As a result, only the selected resonant component frequency is passed into the secondary side. If the third harmonic frequency of H-bridge inverter is identical to the resonant frequency, then the energy transfer to the second part is the third harmonic frequency. If we change the resonant frequency into fifth, seventh then that component will only transfer to the secondary side. Third harmonic system is introduced by Hulong Zeng. The advantage of this system is that here instead of fundamental frequency 3rd harmonics[5] is selected for the power transfer from primary to secondary. An advantage is that without varying the switching frequency, we can use a large system frequency for the power transfer with the reduced size of the passive components. Also, the cost is reduced due to the dimension cutback of the passive components. Here the output of quasi-square wave inverter contains fundamental, third, fifth harmonics. The receiving side is tuned in such a way that the receiving frequency matches with the third harmonic frequency. As a result the efficiency of third harmonic system is greater than fundamental system.

The major problem of all these systems is that the conventional rectifier on the primary side leads to distorted sinusoidal waveform and a poor power factor. The reduction in power factor affects system performance and efficiency. So the initiated technology is a third harmonic WPT with PWM boost rectifier along with hysteresis control. It will reduces the THD and improve the power factor up to 0.9.

II. Proposed Topology in IPT

Conventional switching power supplies are operated by rectifying the ac line supply and the rectified ac supply is again filtered by large electrolytic capacitors[6]. The main problem behind is that the input current waveform gets largely distorted and input power factor will be very poor(0.35). In order to get best efficiency and the best performance, it is desirable to get a large input power factor and reduction in harmonics. Many of the switching regulator topologies can be used for the power factor advancement and harmonic current deduction[7]. The most used is the boost topology. A high power factor rectifier can be established by using a dc to dc boost rectifier shown in fig 2. The rectifier with a simple circuit is perceived by using an integration of incontinent diode with a boost chopper[8]. This topology has several disadvantages:

- There is a series diode D_S in the power flow path. It will lead to voltage dip, large power damage, poor accuracy.
- At a time, 3 semiconductor losses occur in the power current path.
- There is a particular design required for the inductor on the dc side to bring dc current.
- The essential frequency of the boost switch is very eminent. This will increase the losses in switching and reduce the productivity.

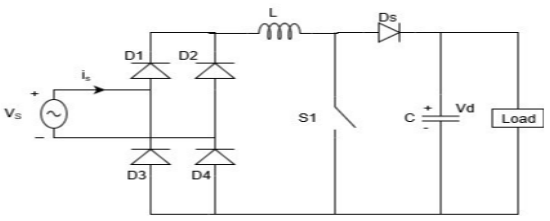

Fig. 2. Boost type rectifier

So by using a simple circuit, which is relevant in the case of ac to dc energy conversion(fig 3). A full bridge pulse width modulated(PWM) boost rectifier using four active switches, that provides controllable dc link voltage, controllable power factor and nearly sinusoidal input current. The overall wireless power transfer with a PWM boost rectifier circuit is shown in figure 3.

In the initiated single-phase power factor correction

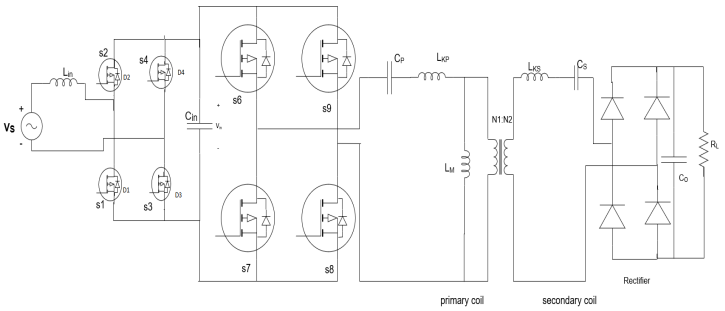

Fig. 3. proposed system

procedure, series diode Ds in the boost topology has been vanished. Another important fact is that instead of the dc-side inductor, an ac-side inductor is used. The merits of the initiated approach are:

- Input current gets sinusoidal and input power factor improved.
- At any time there is two semiconductor drop occurs in the power flow path instead there are 3 semiconductor drop occurs in the power flow path in case of conventional boost topology.
- The ac side boost inductor, L_{in} reduces electromagnetic interference.

A. Working of PWM Boost Rectifier With Power factor improvement

Due to the non-linear characteristics of diode rectifier, there are power quality issues. The THD of the rectifier with filter is having a 10% ripple and THD of 260.46%. In order to

reduce THD and improve power quality, introducing the PWM rectifier fig 3. The PWM converter draws a near sinusoidal input and providing a controlled dc voltage at the output side. It can work both in first and second quadrants of the voltage-current plane. So it will be bidirectional and after the control, the current will be purely sinusoidal.
From the figure, it is clear that the PWM boost rectifier consists of 4 IGBT make a full bridge and input inductance. Its working is discussed here: It has 4 modes
1.Mode 1: When the source voltage is positive and switch S_1 and S_4 are on. During this mode inductor, L is charged through V_S-L-S_1-D_3 or V_S-L-D_2-S_4. The capacitor discharges through the load.

$$V_S = L\frac{di}{dt} \tag{1}$$

2.Mode 2: When the source voltage is positive and S_1 and S_4 are OFF. In this mode, the diode D_2 and D_3 conducts and others remain inactive. Source and inductor feed energy to the capacitor and load.

3.Mode 3: When the source voltage is negative and switch S_2 and S_3 are on. During this mode inductor, L is charged through V_S-L-D_1-S_3 orV_S-L-S_2-D_4. The capacitor discharges through the load.

4.Mode 4: When the source voltage is negative and S_2 and S_3 are off. In this mode the diode D_1 and D_4 conduct, others remain inactive. Source and inductor feed energy to the capacitor and load.

The rectified DC voltage from the PWM rectifier is converted into high-frequency AC by using an inverter. Here the quasi-square wave inverter is used.

The main aim of the paper is that reduce THD and make current in phase with the voltage. So that input power factor can be improved. So we need current control schemes. There are mainly 2 different techniques:

- Hysteresis control
- Sinusoidal PWM [11]

But in this paper, Hysteresis control is used.

III. Control Strategy

By using the proposed boost topology, will get a nearly sinusoidal input current. In order to get a fair sinusoidal input current and improved power factor, a control strategy for PWM rectifier is used. The voltage source rectifier operates by keeping the dc link voltage at a preferred reference value, using a closed loop control[9]. Here the output voltage of the load is compared with a reference value. Then this inaccuracy is given to a PI controller. The output from the PI controller is multiplied with a unity sine. The unity sine will be the ratio of $V_m \sin wt$ to the peak value of the voltageV_m. The resulting output will be reference current. This reference current is compared with the actual current producing switching pulses to the PWM rectifier through a hysteresis controller. The switching signal is used to ON and OFF the four switches of the rectifier[10]. So that the power can come or return to the ac source according to dc link voltage requirements. The control strategy using hysteresis is shown in figure 4.
This control strategy provides almost sinusoidal input current

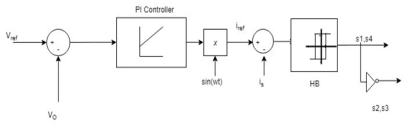

Fig. 4. Block Diagram of Closed Loop Control Strategy

and a high input power factor with THD of 2.59 %.

IV. Power from Harmonics In H-bridge Inverter

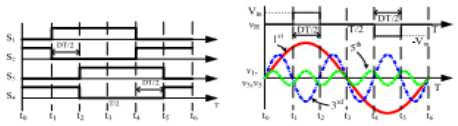

Fig. 5. PWM waveforms, H-bridge output voltage vH , and H-bridge output voltage harmonics.

Now coming into the working of quasi-square wave inverter, each phase leg of the quasi-square-inverter handle under 50 % duty cycle. There is a phase shift among the two legs that manage the outgoing voltage of the inverter V_H. When the switches s_6 and s_8 are on, V_H is the incoming voltage, V_{in}. While if the switches s_7 and s_9 are on then the outgoing voltage V_H equals $-V_{in}$. As there is an energy interchange among the dc source and resonant converter, these states are called active states. There is another condition where both upper switches or lower switches are on state. These states are called zero states as there are energy moves continuously through a closed path within the resonant network. At the same time load continually utilizing the power under zero states. The switching pulses and inverter output is shown in fig.5.

The output of H bridge inverter, V_H is a quasi-square waveform, which contains all the harmonic contents i.e, fundamental,third ,fifth etc. Fourier series representation of quasi-square wave inverter is expressed as[11], Where D is the duty ratio.:

$$v_H = \sum \frac{4V_{in}}{n\pi} \sin(n\pi D) \sin(nt) \tag{2}$$

V. Third Harmonic Selection and Transformer Design

A. Third Harmonic Selection

From the inverter, will get a high-frequency square wave. The power transfer from transmitter to receiver is done by the transformer and the selection of harmonics to transfer power is done by the compensating capacitors and inductors. Third harmonics are selected for the power transfer in this paper. The selection of third harmonics for the power transfer is studied here. It is clear that the switching frequency has a role on the size of the passive components. If the frequency increases three times then the size of the passive components reduced to one by third. Likewise higher harmonic frequency further reduce the size of the passive components. Usually, the electric vehicles are in the kiloWatt range, so that IGBT is used instead of MOSFET. But the maximum frequency that can be carried by IGBT is 20kHz. One way to increase the system frequency is by using the harmonic current to transfer power. The bandpass filter characteristics of inductive power transfer can be used to increase the system frequency by fixing the switching frequency constant. Here a 3rd harmonic frequency is transferred to the secondary side. As a result, the 3rd series resonance compensation(SRC) has merit in volume, weight contrast to the fundamental system. The change from fundamental to the third harmonic system is the frequency of resonance of the resonant network, while the topology used is the same for both. The advantage of High order harmonic system is the small size and low weight. But the dc bus voltage use will be less in higher harmonics and the switches undergoes large current force even if the primary ampere turns is same. The merits of 3rd harmonic discussed below
The power losses in the system mainly are:

- Switching loss P_s. That is the H-bridge inverter loss.
- Capacitor damage P_c.
- Secondary rectifier loss P_d. Diode bridge conduction loss.
- Winding copper loss P_w.
- Transformer Core loss P_t.

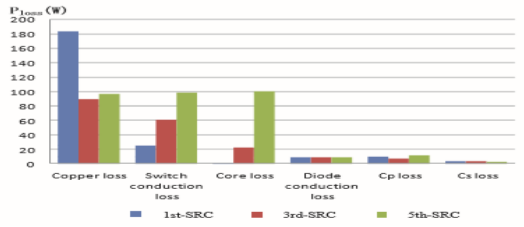

Fig. 6. Loss Comparison of Three IPT Systems

The graph, fig.6 shows a comparison of three IPT systems [12]. P_s is the H-bridge inverter loss. The switching loss, Ps depends upon the switching frequency. As the harmonic order increases, the switching loss increases. Considering the case of copper loss, less number of spins on the windings in higher order harmonic system , as the turns ratio decreases for higher order harmonics. At the same instant, it requires additional winding in analogue to manage the larger primary current. In order to get a good correlation, the three IPT systems current density is calculated to be same. The overall outcome display that copper loss will reduced in higher harmonic system. But from the graph, it is acquit that 5th SRC has over copper loss compared to 3rd SRC. The reason behind is that 5th SRC does not show good performance because it requires a fractional number of turns. As the frequency increases, there is a chance for turns ratio becomes fractional. even with harmonic order more than 5th SRC, this issue will come and effects in a cheaper scheme. The secondary position destruction that are diode loss and secondary side compensation capacitor loss are nearly the same. It means the secondary part only consider resonant component stimulation from the primary part and do not consider which grade of harmonic is selected for the transfer. The copper loss, switching loss, and primary capacitor loss all depends upon primary part current magnitude. As the harmonic order increases, the amplitude of the primary side current increase thereby these losses get increased. In the case of higher order harmonics, there is a chance of a fractional number of turns that affect the overall performance, which leads to an increase in the core loss in higher order harmonics. In WPT application the primary and secondary part are split apart and the form of the core changes a lot. So here window utilization factor expressed in terms of complete winding length(CWL) and winding isolation voltage. CWL is the total of all wires length that is used in the transformer. In case of a higher order, the turns get reduced so that the CWL get reduced. In the case of higher order harmonic system the voltage force on the inductor terminal will be less as the total number of spins get reduced. But the voltage force between the adjacent spins will be higher in the higher order harmonic system. So that 5th SRC having large adjacent voltage stress than 1st and 3rd SRC.
In short, the main reason for selecting the harmonic component is the reduction of copper loss and winding spins.So that it will contract the bigness of the resonant structure. But some limitations are there. There will be higher switching loss and higher insulation voltage between the adjacent spins. There is a need for selecting various core substance for various harmonic order. It limits the higher order harmonic system. Also in the higher order harmonic system, there is a chance for a fractional number of turns in the transformer. It will affect the selection of high grade harmonics.

B. Transformer Design

From the fig 1, it is clear that the ac power is changed into dc power by a PWM rectifier with power factor correction. Then the dc power is changed into high-frequency ac through a high frequency-inverter. A high frequency-inverter is placed between inverter and secondary side with primary

and secondary compensation. The high-frequency current produces an alternating magnetic field in transmitting coil, that induces a voltage on the secondary. By the resonance of secondary compensation, we will get high efficiency. Lastly, the ac is again rectified into dc for charging the battery. The difference from a wired charger is that there is loosely coupled coils in the wireless charger[13].

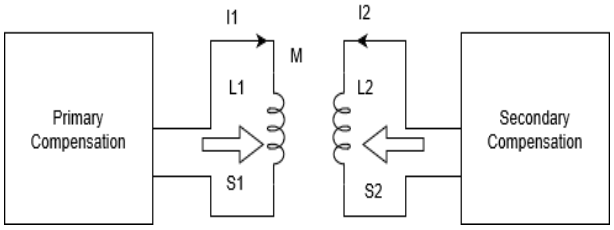

Fig. 7. Two Coil WPT system

To get an idea of WPT principle, the coil and the compensation network is shown in fig 7, where L_1 and L_2 shows the self-inductance of primary side transmitting coil and secondary side receiving coil respectively. I_1 and I_2 are the currents in the primary and secondary side. S_1 and S_2 are the apparent power go into L_1 and L_2 respectively. M is the mutual inductance. For designing we consider only the active power P_{12} transfer from primary to secondary:[3]

$$p_{12} = wMI_1I_2sin\varphi_{12} \tag{3}$$

Taking 400W power transfer from primary to secondary for 230V, 50 Hz supply.we are first calculating the values of passive components for a fundamental frequency. The turns ratio is taken as 15:20 for the fundamental frequency. Assuming 70% efficiency ,can be calculate input power and input current. The secondary current can be calculated by (4)

$$I_1 = I_2k \tag{4}$$

Where k is the ratio of secondary to primary turns. φ_{12} is the phase difference between primary and secondary current, which is taken as 90° for maximum power transfer. From (3), by substituting all values, M will get. The switching frequency is taken as 18kHz. From the M value, primary side inductance can be calculated using(5). From primary side inductance secondary side inductance can be calculated.

$$M = k1\sqrt{L_1L_2} \tag{5}$$

For a WPT, the value of k1 will be very less(0.01) and L_2 is taken as$L_2 = L_1k^2$. From the primary inductance, secondary inductance can be calculated. The compensation capacitor values of primary and secondary can be calculated by 6 & 7 respectively:

$$C_1 = \frac{1}{4\pi^2 f^2 L_1} \tag{6}$$

$$C_2 = \frac{1}{4\pi^2 f^2 L_2} \tag{7}$$

TABLE I
PARAMETERS FOR 1ST AND 3RD SRC

1st SRC	3rd SRC
Turns ratio= 15:20	5:20
L_1=164.5mH	L_1=54.83mH
L_2=291mH	L_2=96.6mH
L_m=2.1884mH	L_m=2.1884mH
C_p=475.2pF	C_p=158.4pF
C_s=269.5pF	C_s=89.83pF
Resonant frequency=18kHz	54kHz

similarly, the values for third harmonics can find out using these equations by changing the turns ratio into 5:20 and the switching frequency becomes three times the fundamental frequency, i.e, 54kHz. The fundamental and third harmonic values are listed in Table1:

VI. SIMULATION RESULTS

The Simulink diagram of the proposed topology is shown in fig.8. In which primary side, there is PWM rectifier along with a hysteresis control is used to enhance the power factor and a high-frequency inverter for converting high-frequency AC. The primary and secondary side inductors and capacitors are for compensation. The secondary side of the transformer is in resonance with the primary side. Again, there is rectification in the secondary side to charge the battery.

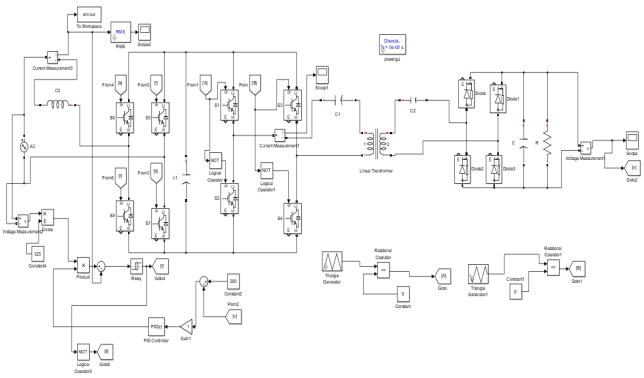

Fig. 8. Simulink Diagram Of the Topology

The parameters used in the simulation are shown in table 2. The switching pulses for the inverter are generated by comparing triangular and a dc value and also there is 90° phase shift between the two legs that is shown clearly in fig.9. The switching pulses and inverter output is shown in the fig.10.

Fig.11 shows the input current waveform and its THD in a conventional rectifier WPT. The THD is 260.46% and pf is 0.35.

Fig.12 shows the inverter output and fundamental current for the selection of fundamental frequency as the resonance frequency. While fig.13 shows the inverter output and third harmonic current for the selection third harmonic frequency

TABLE II
PARAMETERS USED FOR SIMULATION

Components	Values
Input inductor	10.4mH
Input capacitor	266μF
Primary inductor	54.83mH
Secondary inductor	96.6mH
Primary capacitor	158.4pF
Secondary capacitor	89.83pF
Output capacitor	100μF
Load resistor	100Ω
Harmonics	Third

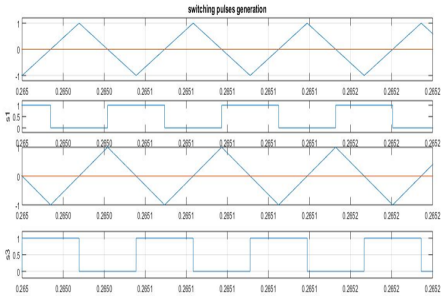

Fig. 9. Switching Pulses For Inverter

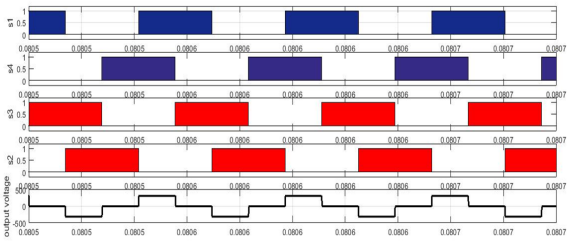

Fig. 10. Switching Pulses And Inverter Output Voltage

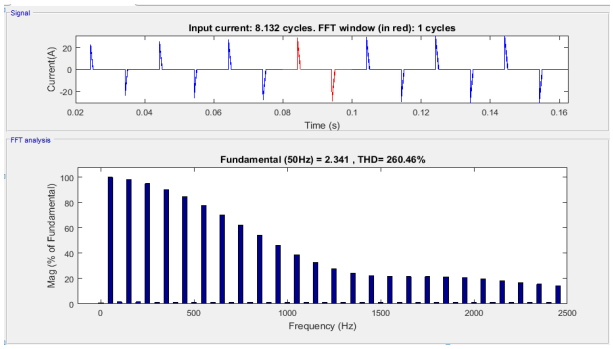

Fig. 11. Input current and its THD in conventional rectifier WPT.

The PWM rectifier control is used to draw a sinusoidal current with improved power factor. From the graph, fig.14 shows the incoming current is sinusoidal which is in phase with incoming voltage having THD 2.59% and a power factor

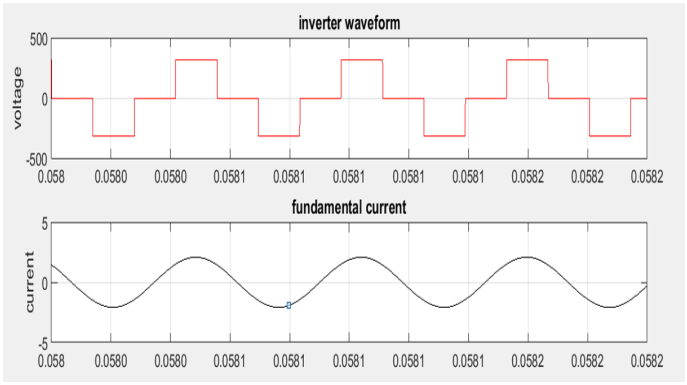

Fig. 12. Inverter Output And Fundamental Current

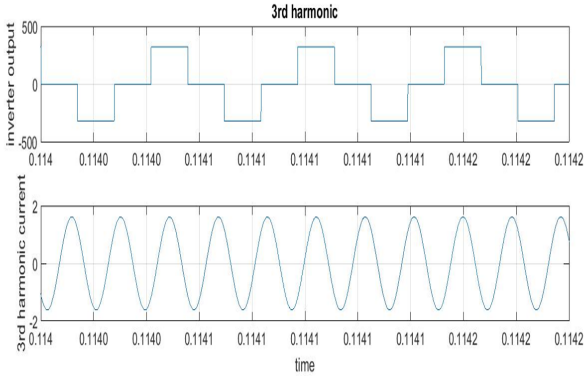

Fig. 13. Inverter Output And Third Harmonic Current

of 0.99.

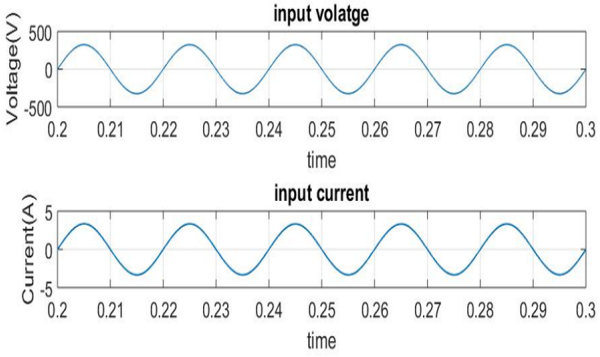

Fig. 14. Input current and Voltage in the Proposed Topology

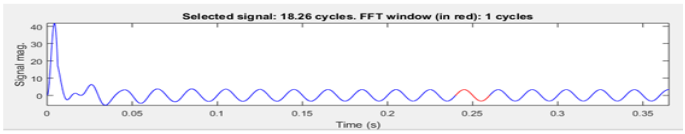
The FFT analysis of the input current is shown in the fig.15 along with power factor and THD. The power factor is improved greatly.



THD	DF	ϕ	COSϕ	PF
0.0259	0.999	0.2	0.999	0.998

Fig. 15. FFT Analysis Of Input Current

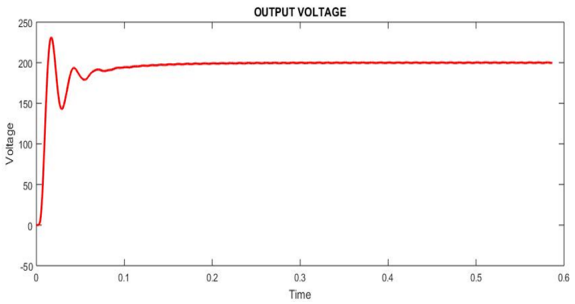


Fig. 16. Output Voltage

The load is regulated by a constant voltage mode. Here making 200V as the output voltage for the battery as shown in fig.16.

VII. Conclusions

In this paper, we are discussed about the wireless power transfer system using third harmonics with input power factor correction. The advantage of using third harmonics for power transfer instead of fundamental is that it decreases the size and volume of the passive components and decreases the overall copper loss. But the input current is not sinusoidal , so that the power factor will be very poor. The PWM rectifier with hysteresis control is used to improve the sinusoidal shape and power factor.

When using a controlled rectifier with 10% ripple filter for rectification, it produces a THD of 260.46% i.e, pf is 0.35. Where as the PWM rectifier with hysteresis control improve the power factor into 0.99 and the THD is 2.59%. Here a 400W, 20cm distance between primary and secondary is introduced with high input power factor and low total harmonic distortion.

***Abstract*— The human brain produces different electrical signals in response to the thinking process. These signals are captured using different techniques such as EEG, ECG, EMG, etc. Electroencephalography (EEG) is one of the technique which is being used widely. The data can be detected using EEG Caps, Neurosky Headset. The device used for the project under discussion is Neurosky Headset. The EEG signals Can be used to detect epilepsy, sleep disorders, stroke, head injury, dementia. The EEG signals captured by the headset are transmitted via Bluetooth to the laptop and interfaced with the MATLAB. The obtained signals are deduced to the required parameters which can help us to identify whether a patient is having insomnia or not.**

***Index Terms*—Electroencephalogram(EEG), Non-invasive, Neurosky Mindwave, MATLAB.**

I. INTRODUCTION

No system will continuously work whether it is living or mechanical. Rest plays major role in living organisms to get revitalize. Sleep is the place where every living organism gets rest and the life energy is accumulated. Sleep is the thing which has been harmed in the process of human development. Because of the artificial lights the sleep got troubled and humans started to feel that the sleep is unnecessary thing because of obsession in using gadgets. This the predominant reason for all the disorders and illness in human's life. The international classification of sleep disorders (ICSD, ed 2) lists eight categories of sleep disorders along with appendix A and Appendix B, the four major sleep complaints include excessive daytime sleepiness, insomnia, abnormal movements or behavior during sleep and inability to sleep at the desired time [1].

Insomnia is hassle falling asleep through the night, or arousal too early within the morning. The symptoms of the insomnia include difficulty in starting sleep and maintaining it, early morning awakening and non-restorative sleep at any given time. Among 8 to 40 percent of the general population are suffering from insomnia, 30 to 40 percent are having poor sleep and 8 to 10 percent are suffering from chronic insomnia [2, 3]. Also, about 4% of the population use sleeping pills on a regular basis [4].

Neurons in the human brain produces a voltage of 70 millivolts and the potential difference can be measured using different techniques. Electroencephalogram (EEG) is a technique to measure and record that potential difference in the form of a signal by placing electrodes on the scalp or in the tissue of the brain. There are two methods in EEG, one is invasive and other is non-invasive technique. In invasive method the electrodes are placed inside the brain tissue which will cause problems. The sophisticated non-invasive technique will help to avoid those problems in which the electrodes are placed on the scalp using conventional 10-20 system. Alpha, beta, theta and delta are the four main kinds of the EEG waves which will be used to diagnose diseases like insomnia, epilepsy, Alzheimer's and many other diseases [5]. Similarly, advancements in technology have led to the genesis of many sophisticated devices that can capture the brain waves without wet electrodes. Mind wave headset, Muse, etc. are few of such devices. The mind wave headset is the apparatus used here to serve the purpose. It consists of two dry electrodes namely Fp1 and CAR (according to the 10-20 system). As it consists of only one pair of electrodes it is referred to as a single channel device. The data is wirelessly transmitted via Bluetooth and the signal is mapped at receiver 'send using MATLAB.

II. RELATED WORKS

The literature survey of the work is discussed in this section. The research paper [6] describes about diagnosis of autism based on electroencephalography signal analysis in which discrete wavelet transform is used to obtain major types of EEG waves. Shannon entropy values are calculated for each EEG subband using the feature vector and based on the extracted features artificial neural network classifies the EEG signal into normal or abnormal. In paper [7] Dry electrode is used to get the EEG signal which replaces the conventional 10-20 system and the collected data is sent wirelessly to the cloud from headset where the doctor can examine it in live to interpret the meaning of EEG signal. A single channel EEG signal is used to diagnose insomnia in [8] using PSD approach, the data of insomnia patients and normal patients taken from physiobank and the normalized

power of the EEG subbands is calculated. The working of Neurosky headset is described in [9] [10] [11] and [12].

III. SYSTEM DESIGN

A. *Block Diagram*

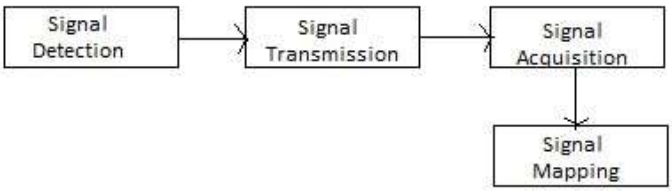

Fig. 1. Block diagram

The block diagram for proposed system is shown in Fig. 1. This system is classified into four stages. These four stages are Signal detection, Signal acquisition, Signal transmission, and Mapping Signal.

1)Signal Detection:

Fig. 2. Headset

In this stage EEG signal is detected through the Neurosky Mindwave headset by placing it on head using a methodology called electroencephalography(EEG). The trifling potential generated by a single neuron is difficult to detect using noninvasive methods. So, the aggregate of electrical potential generated by a cluster of neurons is detected with the single dry electrode which is placed on the forehead. Although, the amplitude of EEG signal varies from 1 micro volts to 100 micro volts in a normal adult, it is amplified and sampled by the headset whose strength is good enough to transmit wirelessly via Bluetooth.

Brainwave Type	Frequency range	Mental states and conditions
Delta	0.1Hz to 3Hz	Deep, dreamless, non-REM sleep, unconscious
Theta	4Hz to 7Hz	Intuitive, recall, fantasy, imaginary, dream
Low Beta	13Hz to 15Hz	Formerly SMR, relaxed yet focused, integrated
Midrange Beta	16Hz to 20Hz	Thinking, aware of self & surroundings
High Beta	21Hz to 30Hz	Alertness, agitation
Gamma	31Hz & above	Cognition, information processing

Table 1. Frequency range for different EEG subbands

2)Signal Transmission:

The detected signal is processed and converted into digital form by the headset. The headset has a thinkgear chip which helps in transferring the aided signal to personal computer or laptop via Bluetooth. 3)Signal Acquisition:

The signal is acquired into laptop where the MATLAB is used as a platform to run code to get the required raw EEG signals.

4)Signal mapping:

The MATLAB uses thinkgear.dll file to access the signal from the headset and the required signal in the form of graph. The raw EEG signal is further classified into delta, theta, alpha and beta from which normalized power is obtained and compared to reference values.

B. *Methodology*

The thinkgear connecter will automatically starts the application when it is installed, unless we stop it. The headset is connected to the laptop via Bluetooth. The thinkgear.dll file should be loaded in MATLAB and the code is executed. The above mentioned steps are basic to run any neurosky applications.

The dry electrode is placed on the forehead of the person through headset to get the raw EEG data. The raw EEG data is filtered using Daubechies wavelet to get delta, theta, alpha and beta. Energy of each segment is calculated using

$$\text{Energy} = \sum_((j=1)^n)\ CDj \quad (1)$$

where CDj is segment of raw EEG signal. Then Normalized power is calculated and compared with the reference values from [9].

Normalized Power = Energy / number of samples

If the obtained values are falling in the rage of the reference values, we can say that the person might be suffering from insomnia and there is a need to consult doctor.

IV. SYSTEM IMPLEMENTATION AND EXPERIMENTAL RESULT

The Normalized power of each segment of raw EEG data, each of 20 samples is obtained from three persons.

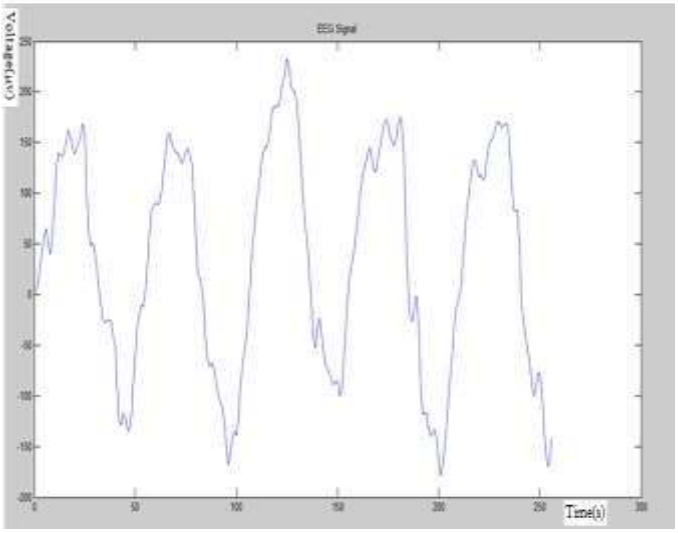

Fig. 4. Raw EEG signal

Fig 4 shows the obtained raw EEG signal from the patient. EEG headset has been used to obtain the signal. The graph was plotted against voltage and time.

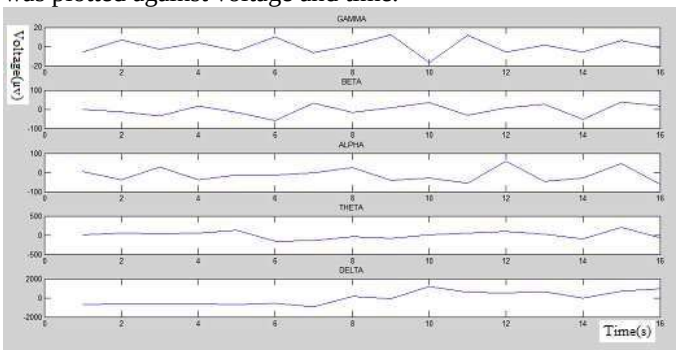

Fig. 5. Different Segments of EEG signal in time domain

The obtained signal (Fig 4) is characterized into four types i.e., Delta, Theta, Alpha, Beta. These signals are plotted in fig 5

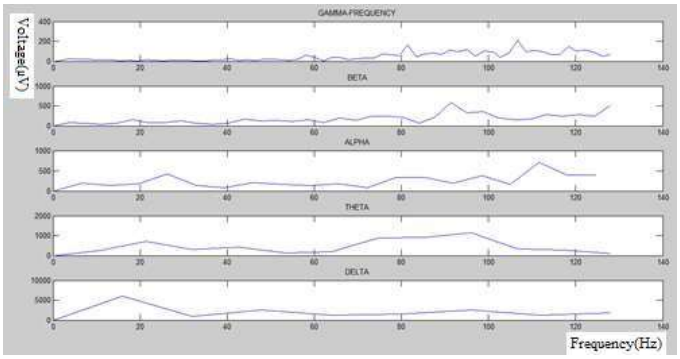

Fig. 6. Segments of EEG signal in frequency domain

Fig 6 shows the signals in frequency domain which are used to calculate the normalized power.

The obtained values are listed in below table

Wave	Person1	Person2	Person3	Reference Value
Delta	0.533	0.086	0.145	0.81-0.89
Theta	0.660	0.080	0.199	0.0078-0.16
Alpha	0.727	0.113	0.1162	0.006-0.02
Beta	0.650	0.122	0.177	0.0005-0.0007

Table 2. Results

From the above results we can say that person2 might be suffering from insomnia.

V. FUTURE SCOPE

This system can be further Developed to diagnose different kinds of illness or disorders and can improved to get the approval for clinical use, which will be useful to doctors and also the people live in remote areas.

VI. CONCLUSION

The proposed system uses the brain signals in the form of raw EEG data to diagnose insomnia.as we are using non-invasive method of electroencephalography, it is easy and harmless to use the headset. MATLAB serves as the platform to obtain the normalized power which helps to diagnose the person.

***Abstract*—Present time, everybody uses on-line social network for his or her totally different purpose. Mediate dissimilar on-line SMN a few private information is splited any on online SMN. That divided data has abused by fraud person. Fraud person gather the knowledge, use fraudulently it as intimidation to someone, produce sensible relevancy to gain users trust and create some crimes. That occurs gradually. To unravel that drawback cross platform exploration might facilitate in social computing in every theory and real time. Some technique accustomed fraud person targeted on users public profile information, place and temporal property of persons content still as in depth vogue. Existing user identification supported on network structure aren't effective. To discover fraud person, structure projected proposal for FRUI algorithmic program .also use profile and content based identification algorithm. Projected work take a look at 2 on-line social media networks-Facebook and LinkedIn.**

Keywords— SMN, FRUI, Cross Platform, Content and Profile based Algorithm.

I. INTRODUCTION

Currently, large no of on-line social media networking sites are available like Facebook, Twitter, LinkedIn, Instagram, etc. People use this SMN Sites for their different purposes means getting important information, sharing ideas, posting their thoughts, entertainment and always attach with friends. At this time peoples have a no of accounts on on-line SMN same users. Who all are victimization the many accounts on various on-line social media they're victimization those accounts for various purpose. Like obtaining private info of some people, creating fraudulence victimization it and for black mailing reason. In this days fraud peoples toll on-line social media network become greater incessantly.

Facebook is an online social media network. User use the Facebook easily by using internet on computers , laptops mobile phones like smartphones. User first register on Facebook [2]. After doining registration, user can make their account on Facebook by giving personal data like profile picture, birth date, gender etc. Users easily use this account for entertainment, connected with people. User can makes no of friends on Facebook. Users will post their photos, thoughts, and ideas etc on Facebook. People will use varied insert apps, also collect notifications other people's activities. Peoples might part of familiar -interest team. Facebook had over a pair of.3 billion monthly active users as of December 2018 Facebook collect distinguished media coverage, together with several contentious like users account privacy and theoretical impact. Twitter one, the biggest activity service on a social media network. Where people tweets their thoughts [3]. LinkedIn is a professional site. On this site users can post their CV. This site is also used business. LinkedIn allow user to create their profile and connection to connect with each other in on-line SMN [4]. User can make professional relationship using LinkedIn social media network.in planned system used Facebook and LinkedIn social media network. Sina Microblog, the first Chinese microblog social media web site, has over five hundred million accounts and originate run over a hundred million tweets per day [5]

Recently user's interest is increasing on social media network platform on the net, the cross-platform approach has unified utterly completely Different SMN platforms to create richer data and extra and additional complete SMNs for social computing tasks [1]. The cross-platform system finds users on multiple SMN.there are two varieties of SMN connection: single following connections and mutual following connections. If person 1 follows person 2, then person 1 and person 2 have single manner fan during which one is aware of the opposite, however not the other way around. This relationship are common in Twitter and Sina Microblog., mutual manner connections are called friend relationships. The mutual following friend relationship makes as long as a devotee request is shipped only if a friend request is sent by one person and Confirmed by the opposite person. Mutual Friend relationships are terribly tough to pretend by mischievous person[1]. This relationship are common in Facebook, WeChat SMN.

This planned System Projected approach for friend relationship based algorithm. This method is identifying anonymous user in multiple SMN using FRUI algorithm, content and profile based technique .system is applied on two SMN Facebook and LinkedIn. Rest of paper is containing below section: section section II discuss related work, section III introduce proposed work, and section IV introduce result and discussion section VI presenting conclusion and future work.

II. RELATED WORK

Now a days everybody is attracting or using online social media network .between this some social crimes happens by fake user.to identity fake user there are number of methods presented. In this section we discuss some of them.

In [6] M. Motoyama and G Varghese authors present method which is find out a user by using matching and searching account info. This method use three dimension like profile base, connection base and content base to identify users. This presented method check out in two social media network: Facebook and Myspace.

In [7] Author Reza Zafarani presented another method using communities which is connected user identities. This method is called as join analysis algorithm. The connection joining usernames designated by one user in numerous SMN, and on a number of online as regards usernames and communities

In [8] author's. M.A. Kaafar D.Perito, C. Castelluccia, and P. Manils, this methodology traverse the connection users account exclusively by viewing their usernames. The instinct is that the prospect that try of usernames refers to the identical physical person powerfully depends on the entropy of the username string itself.

In [9] Author's presented approach in which users correlation account was used to find the users .authors check out a correlation of users accounts between a five social media networks Facebook ,Flickr, twitter, Google and Myspace.

In [10] Authors Paridhi Jain, et al presented approach was used users account data. Presented system author use users account information like profile photo, date of birth, gender etc .writing style and network structure created by user.

In [11] Authors introduce "Identifying users across social tagging systems". Authours use 2 types of user account info like user id and their tags. This method presented questions and explore either users will determine across social tagging systems.

In [12] in this paper author's Reza Zafarani, et al presented another method which is based on users a behavioral-modeling approach.

III. Proposed work

In this paper System projected a proposal for FRUI (Friend Relationship based User Identification algorithm). During projected model FRUI applied first to detect fake user. On this result of Friend Relationship based User Identification applied two types of technique i.e. content and profile based technique. Lastly this fake person are going to identify.

Below fig1 shows the proposed system architecture.

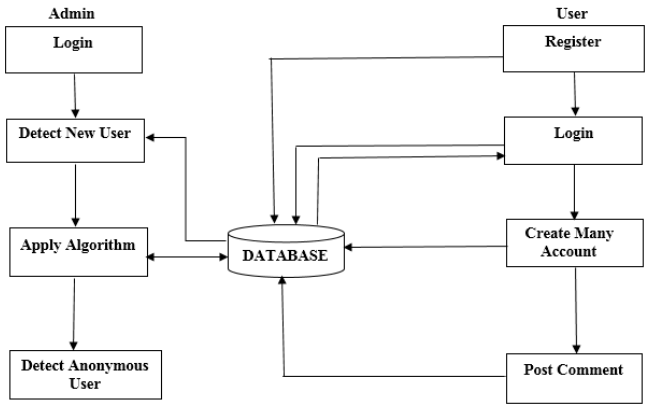

Figure1. Architecture of proposed system

As shown in above Figure (Fig1) there are two roles in the system one is Admin and another is User who have accounts on Social Media. New User can register to Social media network with all details then by using these log in details user can log in into social media. These all details will be saved in database which are entered while registering on social media. One user can create multiple accounts with different name.

After log in into system user can share post, send request, accept request, like and comment the post these all activities of user will be recorded in the database.Admin can log in and see all the details of both social media network Facebook and Linked In.When new account is created admin can see the newly added accounts of user i.e. admin can see registered user. Admin can apply Content based, Profile Based and FRUI algorithms to detect the Anonymous User in system. By using there profile details, Friend list, posts, comments algorithms will find the probable anonymous user of social media and at the end give list of that users.

Content based identification Algorithm-

Content based identification technique detect a fraud user on on-line social media network content based technique used. This planned system used post content which is posted publically by user.

Profile based identification Algorithm-

Profile based identification technique is Identify a fraud user on a SMN involving collection of profile attributes likes profile photo,gender,date of birth, username etc. Profile information is very important in projected system. In this planned system use only two profile attribute birth date and mobile no.

Below algorithm used in this system.

ALGORITHM: FRUI

Input: SMNA, SMNB, Priori UMPs: PUMPs
Output: Identified UMPs: UMPs
1: function FRUI (SMNA, SMNB, PUMP)
2: T= {}, R= dist ( ), S=PUMPs, L= [ ], max=0, FA= [ ], FB= [ ]
3: while Sis not empty **do**
4: Add S to T

5: if max>0 do
6: Remove S from L[max]
7: while L[max] is empty
8: max=max-1
9: if max= =0 **do**
10: return UMPs
11: Remove UMPs with mapped UE from L[max]
12: for each UMPa~B (i, j) in S do
13: for each UEAa in the unmapped neighbors of UEAi **do**
14: FA[i] =FA[i] +1
15: for each UEAb in the unmapped neighbors of UEAj **do**
16: R [UMPA~B (a, b)] +=1, FB[j] =FB[j] +1
17: Add UMPA~B (a, b) to L[R [UMPA~B (a, b)]]
18: if R [UMPA~B (a, b)]>max **do**
19: max=R [UMPA~B (a, b)]
20: m=max, S= {}
21: while s is empty do
22: Remove UMPs with mapped UE from L[max]
23: $C = L[m]$, $m = m - 1$, $n = 0$
24: S = {un-Controversial UMPs in *C}*
25: while *S* is empty do
26: $n = n + 1$, I = {UMPs with top n *Mij* in C using (5)}
27: S = {un-Controversial UMPs in *I}*
28: if $I == C$ do
29: break
30: return T

IV. RESULT AND DISCUSSION

The experimental analysis done using the java programming with set of Facebook and LinkedIn users account .the performance is measured using input user and search time of proposed system.

In this paper an application was developed through which can perform anonymous user identification .To Register this Application, user selects type of social network (Facebook, LinkedIn), gives their user name, password and basic information of user (i.e., mobile no, email, gender and birth date). After the registration process, the user can login their account by giving their user name and password. After login process user can view their profile, add friends and view their friend list, search friends, send friend request etc. The Admin has right to identifies the anonymous user.

Table. 1 and fig. 2 shows the performance analysis of FRUI, Profile and Content based technique with input user and search time (milliseconds).

Technique	Input user	Searching time (milliseconds)
FRUI	600	69868
Profile base	350	4045
content base	50	3067

Table1. Input user and Searching Time.

As shown in above table.1. This system have been tested for 300 users of Facebook and 300 users of LinkedIn accounts (total 600). On this 600 input users, first FRUI algorithm is applied. After that got 350 users as an output of FRUI. Then using this output as an input for profile base, got 50 users as an output of profile base. On this output, content base algorithm is applied and got 3 anonymous users as output.

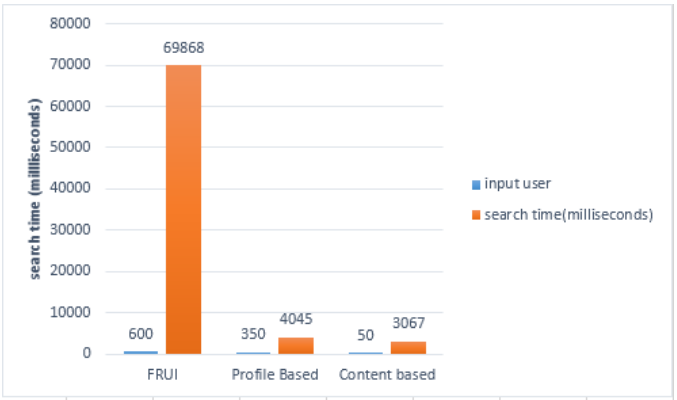

Fig.2 Analysis graph of proposed system.

V. Acknowledgement

After the completion of this work, words aren't enough to specific feelings regarding all people who helped me to achieve my goal. It's an excellent pleasure and moment of huge satisfaction on behalf of me to specific my profound feeling to my guide **Prof. Vaishali Jadhav** and my co-guide academician **Prof. Sujata Bhairnallykar** whose constant encouragement enabled Pine Tree State to figure sky-high. Her perpetual motivation, patience Associate in Nursing glorious experience in discussion throughout progress of the planned work have benefited Pine Tree State, that is on the far side and all members of Computer Engineering department who are giving support to done my work .

VI. CONCLUTION AND FUTURE SCOPE

In this paper finds the difficulty to identify the fraud user's identification in multiple SMN. In SMN network structure is main part. It is help to sort out user identification tasks downside. The planned system for FRUI algorithm. This algorithm finds fraud users by using two another profile based and content based technique (algorithm) to identify fake users. In future work, system have a tendency to aim to assign with that various challenges that system sweet-faced throughout that course of analysis. As an example there are several cases whenever same username doesn't essentially guarantee the identical identity.

***Abstract*—Due to wide application range in remote areas, Wireless Sensor Network (WSN) is an emerging field of research to prolong the lifetime. Since the battery is not replaceable so there is a need of efficient communication to prolong the lifetime. For this, many techniques are provided by many researchers like: clustering, routing, data aggregation etc. In clustering technique, the whole area is divided into many parts known as clusters. But clustering should be efficient to effect positively. Our aim is to provide load balancing with higher coverage of nodes. So, we have proposed a clustering algorithm based on three conflicting factors using fuzzy. The results positively support the algorithm in order to prolong the network lifetime.**

***Index Terms*—Wireless sensor network (WSN); Clustering; Coverage; Average Lifetime of CHs; Standard Deviation of Lifetime CH; Fuzzy**

I. Introduction

Wireless Sensor Network (WSN) is a collection of tiny sensors [1] having the capability of sensing the surroundings. There may be one or more onboard sensors attached with a node. WSN is having many applications in many areas like: healthcare, military, whether forecasting, agriculture etc. The communication of data may be wired or wireless according to the application of WSN. Sensor can also have chargeable or non-chargeable battery. But most of the applications use wireless communication due to the use in remote areas, so also contains non-rechargeable battery with many other issues like: reliability, security, fault tolerance etc [3] [4] [9]. Due to this there is always a need of efficient utilization of battery to gain data for more time. So our aim is to maximize the lifetime of network. For this many routing [7], clustering [2] [8] etc algorithms have been proposed by many authors. Initially the transmission was direct transmission where the sensor directly transfers the data to the Base Station (BS). After this, data transmission changes to indirect as multi-hop transmission, which reduces the energy consumption by a node and distribute it among all nodes. After it, Clustering algorithm comes into existence that divides the whole network into some clusters and each cluster is having one CH that is responsible for data collection and transmission after processing.

Energy Model We have utilized the same energy model used by [12]. The energy consumption according to this model can be shown as:

$$E_T = \begin{cases} p * E_{electronic} + p * \varepsilon_{fs} D^2_{length}, & \text{if } D_{length} < d_0 \\ p * E_{electronic} + p * \varepsilon_{mp} D^4_{length}, & \text{if } D_{length} \geq d_0 \end{cases} \quad (1)$$

E_T - known as transmission energy utilization in transmission p packets at distance D_{length}. $E_{electronic}$ shows energy in initialization of transmitter.
'd_0'- threshold length
ϵ_{mp}- Transmission with amplification
ϵ_{fs}- Transmission without amplification

Energy utilization in p packet receiving:

$$E_{p_{Rec}}(k) = E_{(Rec-electronic)} * p = p * E_{electronic} \tag{2}$$

We have proposed a clustering algorithm using fuzzy with three conflicting attributes. We have taken heterogeneous WSN where the characteristics of nodes are different to each other. Results verify the superiority of proposed algorithm.
The remaining paper is as follows: Section II explains some previous work done for the lifetime maximization of WSN. Section III explained the proposed algorithm in detail. Section IV shows the comparison of proposed technique with LEACH and base algorithm. Finally the conclusion is given in Section V.

II. Related Work

Clustering is one of the main approaches used for the lifetime maximization by topology controlling and dividing the work among the nodes. The total area is divided into some part and each part is known as cluster. Each cluster is having one CH that is known as the leader of that cluster, whereas, all other nodes work as member nodes. Member nodes sense the data and transmit it to the CH and CH process the data and forward it to the BS either directly or by intermediate CHs. Heinzelman [12] provided LEACH protocol in 2000. LEACH is one of the famous clustering algorithms that work on probabilistic model. It used the probability concept in such a way so that each node would work as a CH after particular number of rounds means it divides the responsibility of CH among the nodes. All remaining nodes join the CHs on the basis of signal distance that shows the corresponding distance. But due to randomness it unbalances the energy consumption. LEACH-C [13] is one of the extended versions of LEACH that specified a restriction that a node is able to be a CH only if its energy is greater than the average of total network energy. Due to this it confirms the division of nodes with higher residual energy. But the energy consumption remains unbalance in this algorithm.
After this H-LEACH [27] came into existence that divides the whole area into some predefine partitions and each LEACH algorithm is applied in each partition to select the CH in each partition. Aaditya et al. [28] provided Hybrid H-LEACH with updating the CH selection process by making it based on distance and residual energy and also using re-clustering phase that validates the minimum distance of member node to the respective CH. Some techniques used centralized control for CHs selection [14] [15]. Yang [19] and Wnag [20] is provided a dynamic approach for clustering and tracking the target. Sharma [21] provided clustering and routing technique using multi-hop path. Many other solutions [5] [6] [10] [11] [23] [24] [25] [26] have been provided for WSN applications to prolong the lifetime.
In our last papers, we have proposed many attributes [30] [31] that can effect to the energy consumption rate and also proposed a multi-attribute based clustering [29] that provided efficient clustering by enhancing the technique given by Elma et al. [27]. As improvement of our previous work, we have proposed fuzzy based clustering using multi-attributes.

III. Proposed Work

The complete proposed algorithm can be described in following steps:
Step 1: First, we find the nodes having remaining energy greater than the total average of network:

$$Energy_{res}(node) > Energy_{res}(Net_avg) \tag{3}$$

Step 2: Now, we made twenty populations from the node. These populations are generated using k-means clustering and contain only nodes having high residual energy. So here we have used the concept of LEACH-C algorithm to select the CHs from the set of nodes with high amount of energy. It increases the chance that the selected CH will be able to collect data and transmit it to the BS or next CH.
Step 3: Compute Node Coverage: It shows how many normal nodes in the clustered network are within the d0 distance. Its value shows that how many of nodes are within the range where no amplification or regeneration of signal is required. This is calculated for each set of CH or for each population. It is computed as:

$$Node_Cover = \frac{(Count_Nodes_k(Distance_{(Node_k - CH)}) \leq d_0)}{n-1} * 100 \tag{4}$$

Step 4: Compute Average Lifetime of CHs: It shows the average of number of rounds till a CH is able to survive or we can say that it shows the time period till the CH is able to collect the data from normal or member nodes and send it to the BS or CH next in the path. It also helps us maintain the same clustering for more time so that there will be no need for frequent clustering. It means we can proceed with the same clusters for next few rounds. It is computed as:

$$Avg_CHs_lifetime = \frac{\sum_{c=1}^{CHs_{count}} (Erem_CH_c / E_{Tran_Req})}{CHs_{count}} \tag{5}$$

Step 5: Compute Standard Deviation of Lifetime CH: It verifies the load balancing among the CHs. It shows the deviation of lifetime of CHs and lower value helps us to maintain equal energy dissipation and balance lifetime of each CH. Population with lower standard deviation verify the equal energy dissipation in homogeneous WSN and maintain the equal remaining lifetime in both heterogeneous and homogeneous WSN. It plays critical role in where the dead of single node affect the data collection process and we need

whole network to work simultaneously for maximum time. It is computed as:

$$Std_CH_life = \sqrt{\frac{\sum_{c=1}^{CHs_{count}} (Lifetime_c - Avg_CHs_lifetime)^2}{CHs_{count}}} \quad (6)$$

Step 6: In this step, we use the fuzzy logic to calculate the fitness value for each set of CH or population. All input values are normalized first and then provided as the input. For defuzzification, total 27 rules are generated by us to find the fitness value of a population. The figure explains the fuzzy rules generated by us. We have used triangular membership function for fuzzy calculation.

Fuzzy Description: We have used triangular membership function as shown in Figures 1 and 2 for every input and output.

Fuzzy Rules: We define total twenty one rules as shown in Figures 3 and 4.

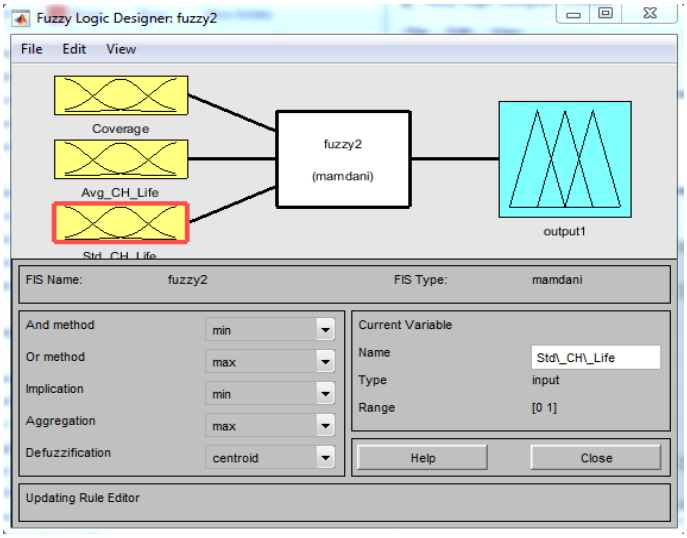

Fig. 1: Fuzzy logic formation

Step 7: Now the population having maximum fitness value selects as the best set of CHs and the nodes in that set select as the final CHs for the data collection.

Step 8: Cluster Formation: All other nodes are known as member nodes and join the nearest CH according to the received signal strength.

IV. Result and Experimental Simulation

We have used MATLAB to simulate all the data collection process with realistic view and better understanding. We have compared with LEACH protocol and our old proposed algorithm. We have processed the whole process in number of rounds and compared all the algorithms. The comparison is done on the basis of number of dead nodes and residual energy and it is shown by Figures 7, 9, 6, and 8.

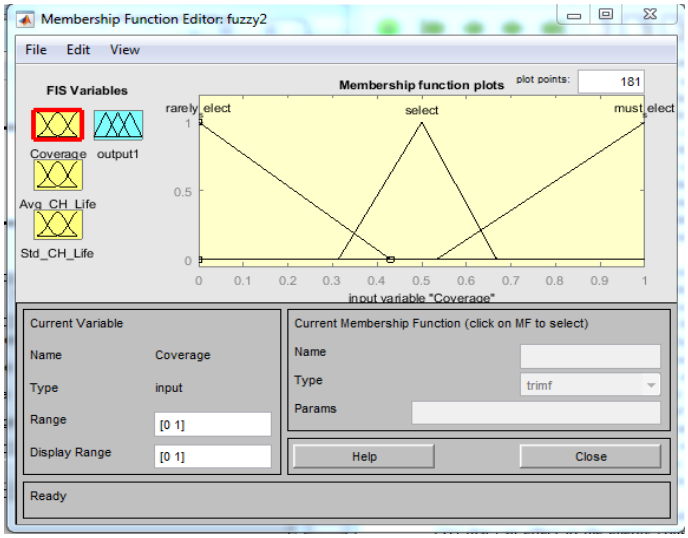

Fig. 2: Membership function for input coverage

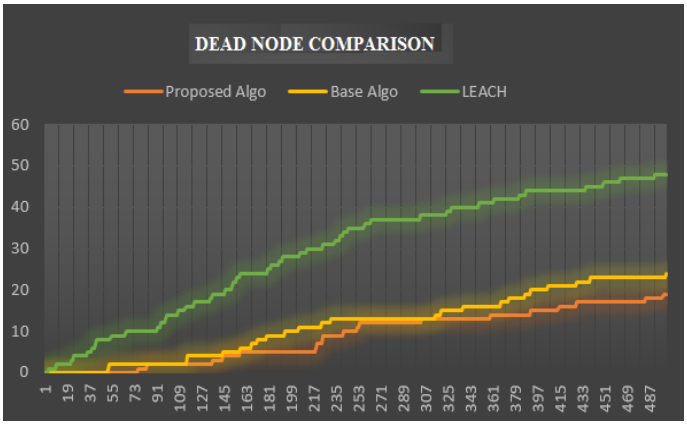

Fig. 8: Dead sensors compare at Rmax=500

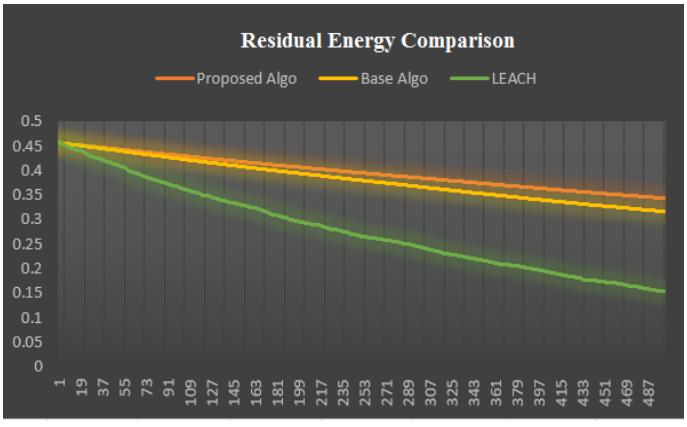

Fig. 9: Residual power compare at Rmax=500

Conclusion

High value of coverage verifies that the member nodes can easily communicate with the chosen CH with out need of amplification of signal. Average lifetime of CHs shows that best nodes are chosen for CHs and they can survive for more period of time. Low standard deviation verifies the load balancing among the CHs. The proposed technique provides us a fuzzy based fitness value generation and selection of set of best CHs among available according to the optimal value of fitness value for the population. This technique removes the manual computation of fitness calculation as was done in our last paper and provides a better approach for the fitness value calculation and selection of CHs based on the fuzzy calculation. Results and simulation part support that our proposed technique provides higher lifetime for network.

***Abstract*—Wireless Sensor Network is having large number of sensors that sense the surrounding area. Sensing coverage of each nodes are limited that depends on their hardware designing. There is a Base Station (BS) that collects all the packets from sensors and then further processing is done on the collected that are used by the authentic users for taking decision. These information are stored in repository that may be used in future for business models too. Generally these sensors nodes are deployed in remote areas that are not easily reachable so energy is one of the main problem since batteries are not going to be frequently changed once they are deployed. There are lots of proposed work given by many authors and researchers for prolonging the WSNs lifetime. Some of the popular algorithms are LEACH, LEACH-C, HEED etc. Clustering is one of the strategy in which clusters are formed and there is a Cluster Head (CH) in each cluster and the other members nodes transmit data to their respective CHs. In our proposed algorithm we have consider four factors for the selection of CHs.**

***Index Terms*—Wireless sensor network (WSN); Clustering; Delay; Network Lifetime; Maximum power of nodes required; Lifetime of CH; Maximum power of CHs required**

I. Introduction

WSN is a network in which sensors are used in each devices and they all are connected to each other by wireless medium. Each sensor senses the surrounding area. Sensors are used as per our demand that what kind of environment we have to sense. WSN has lots of application in field of medical, agriculture, military and also natural disaster management for the prediction of any tragedy.

In WSN each sensor nodes have their own battery that are treated as non-replaceable since it is not possible to change their batteries frequently once they are deployed. Lifetime of WSN should be as long as possible so we have proposed an approach for prolonging lifetime of whole network. We have used clustering approach in which clusters are formed and in each cluster a CH is selected that receives data from all its member nodes falling under same cluster. After receiving data from all member nodes CHs perform some computation and calculation than further processed data are sent to the sink node i.e. base node that are assumed to having infinite energy since their batteries are easily replaceable because they are easily reachable.

Selection of CHs are our main concern since they have more responsibility with respect to other member nodes. If perfect suitable nodes are chosen as CHs than it may be possible that they dead before time and it will affect our whole network, even whole network may go down. It must be taken care that CHs have to receive data from all nodes after that it must be processed for further processing then it is sent to BS means that more operation that will use more energy so the energy of selected CH must be high. Apart from this the distance of CH to BS will also play a measure role so this distance should be low. We also want to minimize the delay so all the factors that may affect it will be also taken care while selecting CH. We have considered four factors from some previously proposed factors [1] [2] for the selection of CHs. It will select best CHs among all possible nodes that will help us in prolonging lifetime of our network. These factors are:-

1. Delay
2. Maximum power of nodes required
3. Maximum power of CHs required
4. Average lifetime of CH

After considering all these factors a fitness function will be used to calculate fitness value of each nodes. The nodes who has maximum fitness value will be selected as CH and they will work as CHs for some rounds. After some rounds CHs are changed since there fitness value are not perfect to work as CH.

Once CHs are selected they have to collect data from its member's node and forward it to BS. The route followed by CHs to send this data to BS should also be perfect since it may leads to cause delay and more energy consumption too. CH may directly sent data to BS that is called as single hop transmission, no doubt it will take more energy with respect to multi hop transmission. We will select the shortest route for transmission of data from CHs to BS.

Organization of rest of the paper is as: review is described in section 2. Section 3 determines about proposed work whereas the results and comparisons are shown in section 4. Finally, conclusion is explained in section 5.

II. Related Work

Energy is the main concerned in WSN, for this many researches have been done to find its solution [3] [7] [8] [13] [14] - [16]. Topology management [8] - [12] and route analysis [3] - [6] is the main solutions to various issues in

WSN. Low Energy Adaptive Clustering Hierarchy (LEACH) [19] is the main algorithm in field of clustering. It is utilizes probabilistic approach for choosing the CHs in such a way so that every node can become a CH after particular rounds. The selected CHs broadcast a message of selection as a CH so that the normal nodes can find the nearest CH and join that cluster. A TDMA schedule is assign for the data transmission process so that each node can send its available data in its slot. In this way, it distributes the load among the nodes and enhances the lifetime of network. But the selection among the available nodes becomes randomly that creates the unbalance of energy consumption and lead to early dead sometimes.

Centralized control [21], [22] in LEACH can also be given to BS. Here, the BS knows the information about the nodes like: its location and its remaining power and BS selects the CHs for enhancement of lifetime. But this approach is limited to the small WSN.

LEACH-B [23] is an expansion of LEACH algorithm, it optimized number of CHs based on the available remaining energy. Archimedes spiral model is utilized by Halder et al. [24] to optimize the distance between sensors to utilize the energy. LEACH-C [25] applies restriction to LEACH so that no node be able to take a part in CH selection that would have energy less than network's average energy. H-LEACH [26] divides the whole network into many part and LEACH is applied in each part independently. H-LEACH is modified by Aditya et al. [27] by providing dynamic partition that changes after each round of CH selection.

Neetu et al. [29] gave an efficient information collection about abnormal activity in gas pipeline. We have also proposed solution using some factors [30]. Position of nodes may affect the network utility [32] and aggregation of data is also helpful in energy optimization by reducing the redundancy in data packets. Best population selection can be done as the form of next generation [28] and can be applied where many objectives need to fulfill simultaneously. In this paper, we have suggested an algorithm taking a property of LEACH-C that only those nodes take part in CHs selection which will have energy greater than total average energy of WSN. It also utilizes many attributes including some suggested [30] and some new attributes for selecting the CHs.

III. Proposed Work

We designed an algorithm specified as energy optimization using a protocol based on multi parameters of WSNs. The proposed algorithm increases the lifetime of the network by calculating the optimized cluster heads which is the root for lifetime maximization of WSN. The population generated in the network consist of sensor nodes which have the fixed energy and power and cannot be recharged. This energy of sensor nodes gets reduced after certain transmissions of data. So, there is a need to suggest a method or an algorithm which could maximize the lifetime of the sensors. The given algorithm is based on the procedure that, from given nodes, we select certain sets of nodes to be selected as CH. For every set, we generate the fitness function value and the set with the best fitness value is selected. the nodes opted in the set are considered to be final CHs.

Eres represents the total power left in the nodes. more the residual energy less will be the delay as the delay is contrary to Eres. The efficiency of the network depends upon the CHs. selected. CH determination is accomplished by the fitness function explored in the methodology section. Cluster formation is done after the CH determination. The CHs broadcasts the message that they have been selected as final CH and nodes can join them to form the cluster. In return, the nodes send the join message depending upon the signal strength and distance of a node from the CH. A Connection is established among the nodes. CH and base station and the communication starts with the transfer of data. This fitness function proposed is applied to the sets of node periodically so as to maintain the non-uniform distribution of energy nodes considering their residual energy. For the packet delivery to BS from CHs, we require the shortest path which is calculated through Route identification theorem.

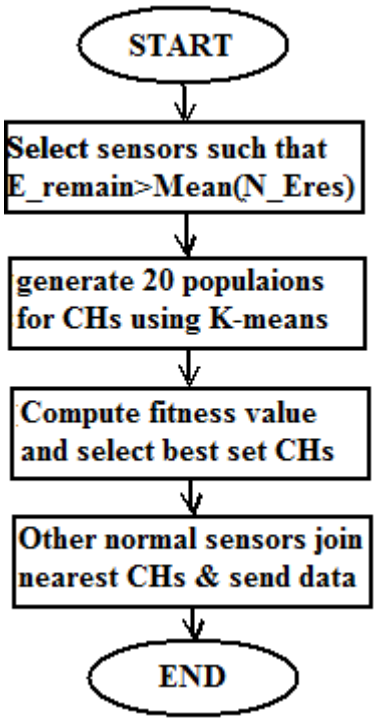

Fig. 1. Proposed Approach for Clustering

A. *An enhanced approach for energy optimization using protocol based on multi factors*

Sensor nodes are distributed in the network in a random manner. The proposed algorithm EOPMF calculates the fitness function value, determines the CHs.

*1) **CH Investigation:**:* As there are n nodes deployed in the network in a random fashion, we take all n nodes and compare their residual energy(remaining energy) with the

total average energy of the network. we select sensors having $E_{res} > E_{avg}$. according to the need of CHs, we choose the sets of nodes to be elected as CHs and apply the fitness function on these sets. The set with the best fitness value is supposed to have the best CHs. The steps involved in the process of CH determination are:

*a) **Step 1**:* **Evaluation of Delay:**
The greater is the residual energy lesser is the delay. Delay evaluation can be given as:

$$Total_Delay = (\frac{(E_{preliminary} - E_{remaining})}{E_{preliminary}} + random_num) * RoundTripDelay \quad (1)$$

*b) **Step 2**:* **Evaluation of Maximum power of required by members:**
It determines the max energy dissipation by any one member node. Its evaluation can be given as:

$$P_Max_mem = Max(Transmission_E(Member_j - CH)) \quad (2)$$

*c) **Step 3**:* **Evaluation of Maximum power of CHs required:**

$$CH_Power_Max = Maximum(Trans_E(CH_c - BS)) \quad (3)$$

*d) **Step 4**:* **Evaluation of Average Lifetime of CH:**

$$Avg_ClustHd_Life = \frac{\sum_{k=1}^{CHs_Num}(E_{res} - E_{Trans(CH_k - BS)})}{CHs_Num} \quad (4)$$

*e) **Step 5**:* **Determination of fitness function:**

$$Fitness = 0.4 * F1 + 0.15 * F2 + 0.2 * F3 + 0.25 * F4 \quad (5)$$

Where factor F1 = Delay, F2 = Maximum power of nodes required, F3 = Maximum power of CH required, and F4 = average lifetime of CH.

*f) **Step 6**:* All the steps described above are rephrased for distinct times and finally, the best CHs are selected based on the optimized fitness value.

*2) **Cluster Formation**:* Once the final set of CH is obtained, all the normal nodes send the join message to the nearest CH depending upon signal strength. These nodes percept the information from their vicinity and transfer information to CH. The CH after receiving information, passes it to the BS through the shortest path algorithm described in the base paper.

Algorithm 1: Proposed CH investigation method

```
Data: Initial Energy E(i), variables values
Result: CHs
Begin
for each sensor n do
    if(E_left(n) > E_left(net))
    add sensor to CH_group
end
originate Q sets in CH_group
for all sets Q in CH_group do
    for all CH Investigation round do
        Enumerate the Delay;
        Enumerate Maximum power of nodes required;
        Enumerate Maximum power of Ch required;
        Enumerate average lifetime of CH for all sets Q;
    end
end
Pick r in (0,1);
Suppose M(Fit_Opt), N(Fit_Opt) are optimization
parameter for two sets M and N;
for each CH set Q do
    if ((M(Fit_Opt) < N(Fit_Opt))
    {
    N is optimal set of CHs
    }
end
End
```

B. Packet Forwarding Process:

Route identification algorithm is required to get the shortest path from CH to BS so that the minimum energy is utilized for the transmission. The Algorithm is discussed in the base paper. The data is transmitted from the CH to base station in a single or multi-hop manner considering the shortest path and minimum energy constraint required.

IV. Result and Experimental Simulation

We have pre-owned the MATLAB software for the simulation of the algorithm and generate the results. the study of different cases visualizes a better picture of base paper and proposed approach comparison. Net Eres and dead nodes are taken as the comparison attributes. The network assumes to be dead when 3/4 of total sensor dies. Dead comparison is is done as 2, 4, and 6 and residual comparison is done as: 3, 5, and 7. The proposed algorithm's results outperforms to the base algorithm by imparting maximized lifetime to the network.

CASE 2: When Node count = 100, sink position (20,20)

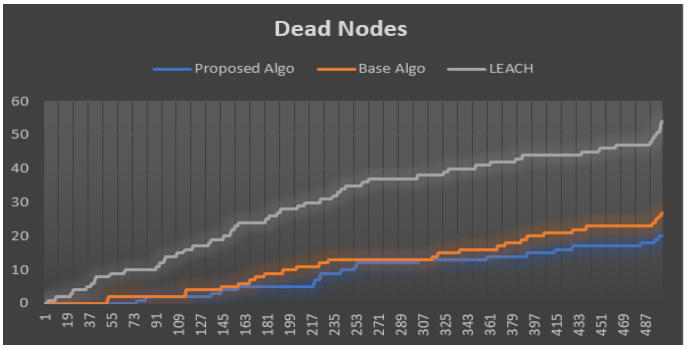

Fig. 4. Dead sensors graph for Rmax=100

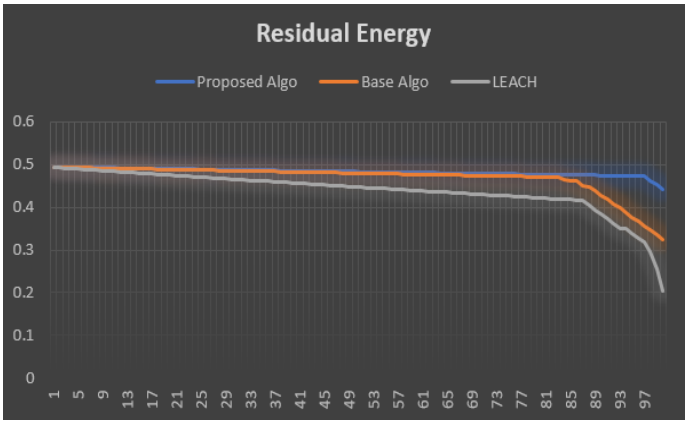

Fig. 7. E_{res} graph for Rmax=100

V. Conclusion

In wireless sensor network our main goal is to collect information from sensor nodes. We have fulfilled our main

motive to prolong lifetime since sensor node batteries are not changed frequently once they are deployed and there is limited power. For our proposed algorithm we have considered the heterogeneous network apart from homogeneous in which sensor nodes are of different configuration with respect to energy and other factors. Proposed method makes information collection process efficient and make higher lifetime. Comparison of the proposed algorithm with the LEACH and base paper assists our concept.

***Abstract*— This paper presents various input impedance matching networks that can be used for cascode common source LNA with inductive degeneration topology in 45 nm CMOS technology. We review the matching networks being used and analyze their performance using simulations. Based on our simulation results, we further conclude that T-Matching network is the best input impedance matching network for cascode common source LNA with inductive degeneration topology in 45 nm CMOS technology.**

I. INTRODUCTION

It is an era of amazing developments in technologies. Wireless technologies are improving faster than anything. Alternate options are being explored and efforts are being done to design devices that would save energy. The advancements in technology aim to create sustainable future and are focused on creating devices that are reduced in size and consume less resources. Market for wireless technologies is increasing at a rate faster than one can imagine. Emerging wireless technologies require a receiver system that is compatible with the latest methodologies of wireless systems. Wireless technologies demand a receiver system that provides an optimum performance and consumes low power; which makes it suitable to run for a longer duration of time. Low power receivers are in demand because they also felicitate battery less operation [1]. Recent wireless technologies include ZigBee, Bluetooth, Bluetooth low energy (BLE), etc. which aim at providing a solution for obtaining low energy solutions and also making IoT a future possibility in every aspect of life. With brisk increase in communication technology, additional burden of larger integration also follows up. Better performance delivering integrated circuits are in demand with spectacular improvements in technology. CMOS scaling technologies are also improving day by day which is able to provide better performance at a lower cost and lower chip area. These developments in CMOS process technologies have made realizing a system on chip feasible, for use in almost all domains of life [2]. With scaling of technology integration of circuit is more compact i.e., more no of elements can be placed in a smaller area. This increases the complexity of the circuits. Digital circuits can be easily redesigned according to the changes in the CMOS technology. However redesign of analog circuits to cope up with the advancements in technology has become a challenge for the researchers [3]. This paper is organized in 5 sections. Section I gives a brief review about the recent technologies in wireless communication. Section II of the paper discusses about the Low Noise Amplifier (LNA), its importance in wireless communications and its utility in other domains as well. Further in section III, we discuss the design aspects of the LNA with reference to matching networks and other design parameters as well. Section IV is about the simulation results obtained and further in Section V, we select the preferred matching network based on our analysis.

II. LNA IN WIRELESS COMMUNICATION

A. Low Noise Amplifier(LNA)

At the receiver block, the signal needs to be received and processed further which includes filtering the undesired frequencies, amplification of the signal while maintaining a good value of signal-to-noise ratio (SNR). Signal-to-Noise ratio gives an idea of extent up-to which the signal is affected by noise. A large value of SNR signifies good signal strength and low value of SNR signifies poor signal strength. In most of the receiver architectures, first block in the receiver after the antenna is the Low Noise Amplifier [4]. A low-noise amplifier is an electronic amplifier that amplifies a very low-power signal without significantly degrading its signal-to-noise ratio. It may be preceded by a band select filter in some architectures. LNA is responsible for the overall performance of the receiver to a large extent as it is the first block in the receiver chain and its noise performance dominates the noise performance of the complete receiver. LNA amplifies the signal present at its input and adds a very little noise by the virtue of its components. Hence, it is preferred in many receiver architectures and other domains as well. LNA should provide a high gain, low noise figure, high linearity, low power consumption, etc. LNA's performance is determined by the value of these design parameters [5]. LNA needs to be connected to other components of the receiver system, so input and output impedance should be high enough to prevent loading effect on other components connected. Loading effect tends to decrease the gain of the amplifier as effective load resistance of the amplifier decreases as a consequence of low resistance of the adjacent components. A fully-integrated LNA is the best option. Finally, power consumption is a concern, especially for portable devices. LNA with all parameters perfectly within the limit cannot be designed as trade-off always exists between the different parameters of a LNA. Based on our application area, we need to focus on the parameter to be optimized and accordingly the LNA design procedure is carried out further.

B. LNA in wireless communication

Applications of low noise amplifier involve different frequency ranges but when we want to implement it for

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

wireless applications, the frequency that is to be considered is 2.4 GHz or a higher frequency than this as well. Wireless communication is carried out using a narrow band of frequencies or single frequency. Hence we do not need to focus obtaining an optimum performance over a wide range of frequencies. However, there are applications which require wideband LNA's i.e., optimum performance over a wider range of frequency. Darlington amplifier proves to be best for applications for wideband performance [6].

C. Applications of LNA

Applications of LNA also decide the components that can be utilized in the circuit design. If we require a system on chip, we should avoid components which occupy larger chip area, etc. LNAs are used in many applications like industrial scientific and medical band (ISM band), cellular telephones, biomedical applications (at low frequency), satellite communications, etc. For biomedical applications, the low noise amplifier should be designed such that the power consumed by it is within the limit because it may increase the temperature of the tissues; and higher temperature may damage the brain tissues.

III. DESIGN PROCESS

The first step in the design of any circuit or system is creating an outline of expected performance of the circuit or the system. Application for which the circuit is to be designed is the most crucial factor that determines the design process. Unless application is specified, the design process cannot be initiated as the application determines the parameters of concern and we need to proceed with the design following those parameters. The trade-offs like impedance matching, choosing the amplifier technology (such as low-noise component) and selecting the low noise biasing conditions are important parameters for designing a low noise amplifier. Apart from this, low power consumption, small chip area and low cost are also desirable [7]. LNA design process can be categorised into 4 major parts that can be listed as: topology, matching networks, transistor selection and biasing [8].

A. Topology

LNA can be implemented using many topologies such as common-gate, common-source, cascode, etc. Out of all these available topologies, most widely used topology is cascode i.e., common source connected in cascade with common gate transistor [9]. This topology provides an improved performance over others and also improved bandwidth. These topologies can further be enhanced with additional circuitry to provide an improved performance. Common- Gate topology provides a highly linear circuit but noise performance of this topology is relatively low [10]. Inspite of a high noise figure, it can be utilized in wireless communication as it satisfies the standards of the wireless systems. Moreover, with the help of different techniques, desired noise performance can also be achieved by this topology.

B. Matching Networks

LNA is generally placed after the antenna which denotes an impedance of 50Ω. For maximum power transfer between two stages, the output impedance of the first stage should be matched with the input impedance of the second stage. If impedance mismatch occurs between the two stages, maximum power transfer will not take place and reflections are ought to occur. Hence, LNA's input impedance needs to be matched with antenna's output impedance to achieve complete power transfer. This can be achieved by using an input matching network that performs this task of matching the input impedance and it is very crucial for LNA's performance. Matching networks also have different topologies and numerous components are available that can provide matching between two stages. However, choosing a proper matching network that enhances the performance of the circuit is a tedious task that needs to be done properly. A change in matching network affects the circuit performance and hence, a comparison can be done to find which matching network is best for our circuit design.

Similar to the input stage, output matching also needs to be accomplished in order to transfer maximum power to the next stage after the LNA in the receiver block. Different output matching circuits also affect circuit performance.

C. Transistor Selection

Proper selection of transistor is crucial for performance of the circuit. Fabrication process also affects the circuit performance to a large extent. Basically, MOSFET (Metal Oxide Semiconductor Field Effect Transistor) is used to realise LNA, along with additional components.

D. Biasing

After the accumulation of the circuit components as desired, we need to provide biasing to give the device a stable operating point. If the biasing provided to the circuit is not able to provide a stable operating point, it will ruin the circuit performance at the desired frequency, and the circuit will become prone to oscillations and this may destroy the circuit completely. Hence, stability analysis is very crucial for a device's proper operation. Many methods are used to provide biasing to the circuit such as resistive divider biasing, current mirror, etc. Out of these methods, we prefer current mirror biasing as MOSFET current mirror tends to reduce the chip area of the circuit and also provides a good stable operating point to our device. After the design process is complete, we need to convert our design into end-product which can be achieved by fabrication of the circuit. Before fabrication process start,s we need to perform simulations and analyze the stability of the circuit in real time.

IV. SIMULATION RESULTS

We performed the simulations in ADS (Advanced Design System) software and obtained the results required. ADS is a tool which is used by RF designers to simulate circuits and analyze their performance before process of fabrication begins. It helps to reduce the cost of device as its properties can be studied before fabrication, saving unnecessary cost of fabrication. Different from other digital circuits, the value of RLC in RF circuits must be extremely precise due to the sensitivity of the frequency response. A slight change of the value of the circuit components such as inductor, capacitor, etc. within the RF circuit can cause a considerable effect that ruins the expected performance. LNA implemented uses a cascode pair in its basic circuit and a tank circuit is used as a load as it is ought to offer better performance than other

available output loads. We simulate the LNA circuit using 3 different input impedance matching networks and analyze the results obtained, on the basis of LNA parameter specifications. Cascode configuration provides better performance than other configurations and using inductive degeneration enhances the noise performance as well as the gain of the LNA [11]. Input impedance matching is achieved using different input impedance matching circuits and the circuits are simulated.

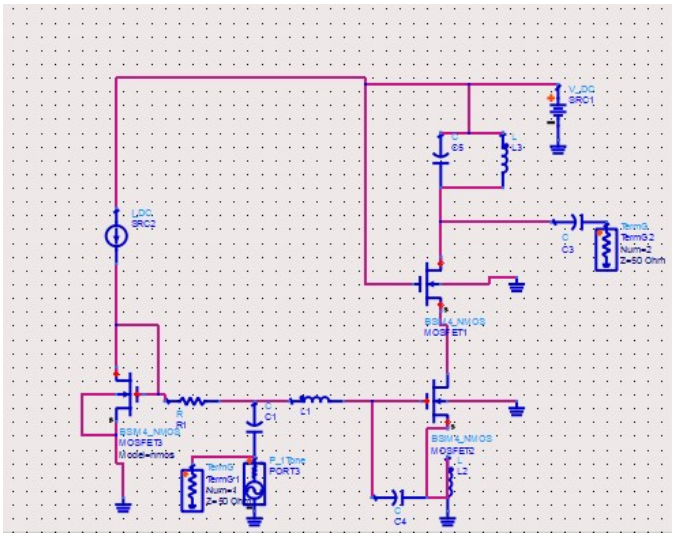

Fig. 1:Implemented LNA

LNA design cannot be perfect in all parameter values a s a trade-off will always exist between the parameters. Input impedance matching circuit can be designed in many configurations such as L matching, T-matching, π-matching, etc. Apart from these configurations, any matching network can be formed using components available that may include inductor, capacitor, transmisson line, stub-matching, etc. For LNA matching, we avoid using matching networks consisting of transmission lines as it may give rise to crosstalk, as the system being designed is going to be fabricated on a chip. Matching networks chosen for analysis are L matching network, T- matching network and third matching network is designed with different configuration than the available matching networks.

A measure of linearity of circuit is obtained by value of its Input Third Order Intercept point (IIP3). A high value of IIP3 implies a high linearity circuit. From the simulation results obtained, we infer that T matching provides a highly linear circuit than the other two combinations.

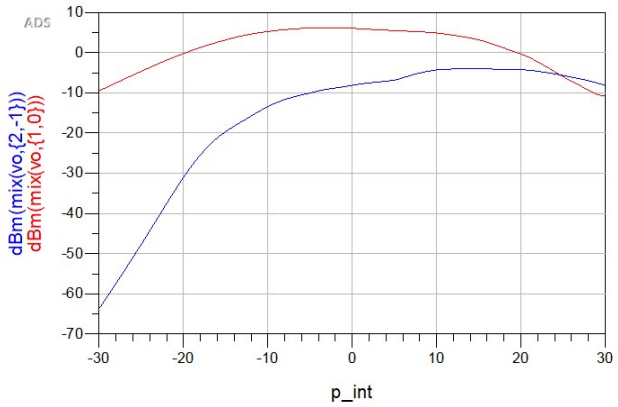

Fig. 2: IIP3 for the LNA circuit with matching network 1

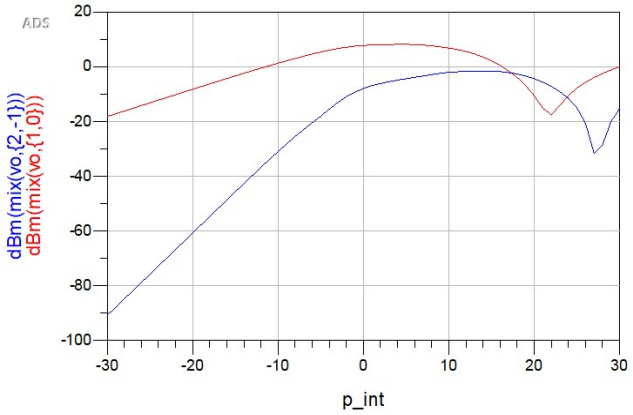

Fig. 3: IIP3 for the LNA circuit with matching network 2

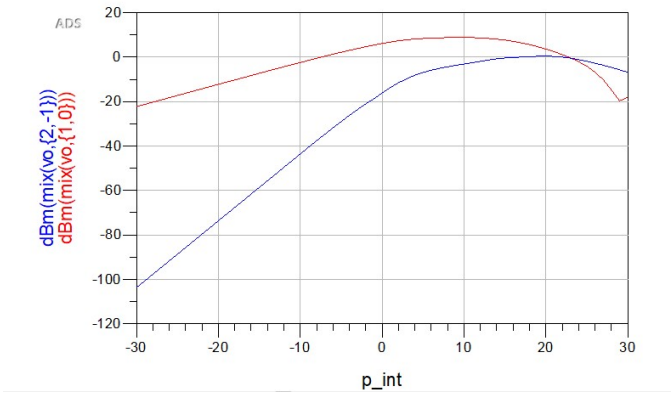

Fig. 4: IIP3 for the LNA circuit with matching network 3

An important parameter in LNA design is the gain offered by the amplifier. In many applications, where the signal to be processed is very weak, gain offered by the circuit is very crucial for the receiver performance. Gain of the system should be sufficiently high so that the effect of noise is suppressed and the SNR maintains a good value. L matching i.e., matching network 1, offers the maximum gain out of the three matching networks. Gain offered by this circuit is sufficiently high with a value of 26.52 dB which is good enough to process signals with very weak amplitudes. Gain offered by matching network 3 was the lowest and hence we conclude that it is not preferable for processing signals which are very weak.

Noise performance of the low noise amplifier is a very critical parameter. As the name implies, the LNA circuit should have a very low noise figure i.e., a good noise performance. It determines the overall noise performance of the receiver system, hence considering this parameter is essential during our design. On the basis of results obtained by simulations, we conclude that the noise figure of the circuit using matching network 2 and 3 is better than using matching network 1.

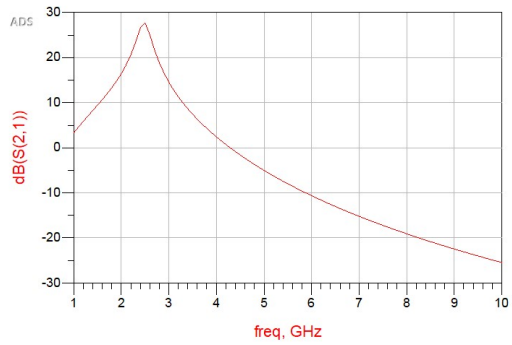

Fig. 5: S_{21} (Gain) of the LNA circuit with matching network 1

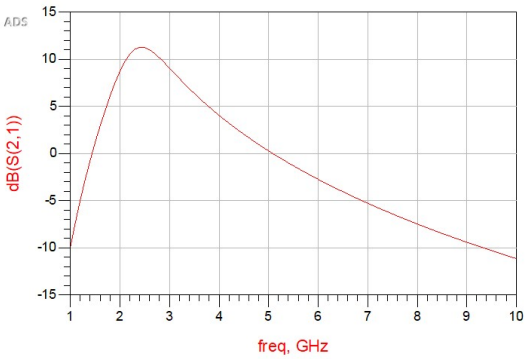

Fig. 6: S_{21} (Gain) of the LNA circuit with matching network 2

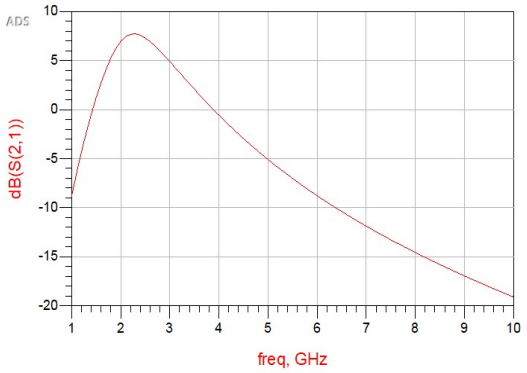

Fig. 7: S_{21} (Gain) of the LNA circuit with matching network 3

.

Either of the two circuits provides a good noise performance. Noise performance of the device is determined by the components being used in the circuit design.

V. CONCLUSION

It is very difficult to design a LNA with all the parameter values perfectly within the limits, which creates a restriction on choosing best circuit among given choices. If we require high gain in our system, while compromising with the noise performance, we can adopt L matching network in our design. On the other hand if we want a circuit with better noise performance, we can adopt T- matching network.

Fig. 8: Noise Figure of the LNA circuit with matching network 1

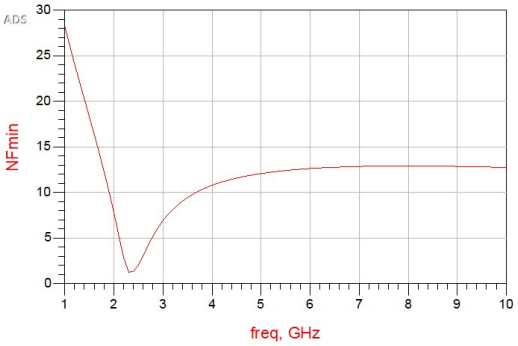

Fig. 9: Noise Figure of the LNA circuit with matching network 2

The results obtained are summarized in tabular form in the table 1.

Table 1: Results obtained for Cascode Common Source LNA with Inductive Degeneration Topology utilizing different input matching circuits

Parameters	Matching network 1 (L matching)	Matching network 2 (T matching)	Matching network 3
Technology	45nm	45nm	45nm
S_{11} (dB)	-12.041	-4.146	-36.5
S_{21}(dB)	26.52	11.281	7.705
S_{22}(dB)	-0.08	-1.202	-1.452
S_{12}(dB)	-51.28	-54.259	-63.25
Noise Figure (dB)	7.464	1.293	1.124
IIP3 (dB)	4.774	9.785	8.765
Power Consumption (mW)	5.45	8.91	9.37

We have simulated and analyzed Cascode Common Source LNA with Inductive Degeneration Topology in 45 nm technology using three different input matching networks and on the basis of the results obtained, we infer that T-matching network provides better overall performance when compared to the other matching networks.

***Abstract*— One of the most essential component of transceivers is Low Noise Amplifier (LNA). LNA is placed at the initial stage of the receivers and hence, it governs the overall performance of the receiver. This paper compares Cascode Common Source LNA with Inductive Degeneration Topology utilizing different output matching circuits. We list the specific application domains of the different circuits analyzed, on the basis of the results obtained through simulations. We further conclude that RLC circuit is the best one to be used as an output matching network in terms of minimum power consumption and highest linearity.**

Keywords— IoT, Wireless, LNA, Cascode, Inductive Degeneration

I. INTRODUCTION

One of the hottest topics of research nowadays is 'Internet of Things' (IoT) i.e., connecting everything to the Internet to make the dream of smart homes come true. Researchers are working in order to design devices which can be made compatible with the IoT standards. Connecting everything to Internet puts an additional constraint on the components that are being designed. Researchers work to achieve best results using minimum resources in order to make a component that is able to cope up with the rapid growth in technologies day by day. Ability to communicate by the means of wireless medium is the most important feature required in the systems nowadays. For this we require a receiver which should be capable of providing an optimum performance when implemented in real-time systems. LNA is generally the first block in most of the receiver's architectures and hence its performance is crucial for the entire receiver system [1]. Choosing an LNA which is best in terms of performance parameters increases the efficiency of the receiver's system. However with expeditious growth in wireless communication industry, manufacturers aim to design a circuit which is able to deliver best results among the already available hardware at present. In case of LNA performance, target is to achieve a low noise figure, high gain, low loss, high IIP3, etc. [2]. RF circuits have created a tremendous scope of research and this comes due to advancements in semiconductor technologies which makes system level integration more flexible. These have also gained popularity due to their low cost which makes RF more attractive technology to work on. CMOS technology advancements have proved to be beneficial for both analog and digital circuits. However redesign of digital circuits for a newer technology is an uncomplicated process. This is not so in case of redesigning an analog circuit for a newer technology. It is a challenge to redesign analog circuits for newer technologies [3]. The paper is organized into 5 sections. Section I being the introduction followed by Section II that gives a brief about LNA in wireless communication. Further we move to Section III that discusses the topologies prominent for implementing LNA and in Section IV, we discuss the results achieved by us during simulations. In the last section of the paper, we summarize our results and state the application areas depending on the topology being discussed.

II. LNA IN WIRELESS COMMUNICATION

In recent times, focus on technologies consuming low-power has increased and these are being utilized in wireless communications as well. Low power consumption, high gain, low noise figure, etc. are the constraints that are the most important for implementing LNA in wireless communication. Apart from bluetooth communication, low power wireless devices are in demand for other application areas as well. These application areas include neural signal analysis, medical applications, etc. [4]. Since LNA determines the receiver performance, designing a LNA with consideration of all parameters within specified limits presents a demanding situation for all the researchers. Most of the LNA's are generally single band LNA i.e., they are designed to operate at a single frequency. However multiple band LNA's are also being introduced i.e., they are capable of operation at more than one frequency. Operating a single LNA over multiple frequencies increases the complexity of the circuit but it also makes it versatile for multi-standard applications. However LNA's are reported that operate at two frequencies i.e., they are dual band LNA's. Multiple band LNA's are less common as achieving optimum performance at multiple frequencies increases the overheads as well as increases the cost of the LNA. Moreover, it also results in increase in power requirements of the circuit as well as increase in the chip area occupied by the circuit [5]. If we wish to design a broadband LNA, we generally use a single transistor which is being used in common-source configuration [6]. Darlington amplifier is used in case of broadband applications i.e. optimum performance over a larger bandwidth [7]. Wireless communication is generally limited to short distances as compared to other forms of communication. Designing a LNA for short distance communication (up-to 10m) is a smooth process in comparison to designing a LNA for long distance communication (more than 10 m). LNA for long distance communication where the distance between the transmitter and receiver is more than the specified range requires high sensitivity which in turn leads to increase in complex design process. LNA for short distance communication where the distance between the transmitter and receiver module is less than 10 m drives the next block into compression because of the signal at the input being strong in amplitude. This signal leads to an output signal which is distorted. In this scenario we need a LNA that can overcome this problem by

suppressing the input signal to prevent this condition [8]. Bluetooth is also a form of wireless communication which is more prevalent and everybody is more familiar with this form of wireless communication. For Bluetooth communication also, we need a transmitter and receiver and the receiver end utilizes an LNA as the first block of the system. LNA for this particular application will have different characteristics than the LNA for other forms of communication as LNA parameters depend on the application for which they are being designed. More specifically a LNA for Bluetooth applications should provide a higher gain and consume less power than others. Bluetooth Low Energy (BLE) focuses on reducing the power consumption of the circuit and is apt for IoT applications. BLE devices can work for longer hours as they consume less power.

III. LNA TOPOLOGIES

LNA's utilize configurations that were used traditionally to design amplifiers. Other than configuration, additional steps need to be taken to achieve the desired performance. The desired performance can be obtained by introducing a change in the biasing network or it can be through a change in matching networks being used. Most common LNA topologies are common-gate, common-source, cascode, etc. Each of the above topology has its own advantages and disadvantages. In-spite of their own merits and demerits, the cascode configuration is the most common configuration used for implementing LNA. Common source configuration can be used with resistive load as well as inductive load. Resistive load offers less gain and also it does not provide proper matching, which at higher frequency creates a hindrance to the proper functioning of the circuit. Inductive load overcomes the disadvantages offered by resistive load configuration. In the common source configuration, the inductor placed at the output node is responsible for output matching. We also need to provide input matching network to match the input impedance of the amplifier with that of the antenna. In this configuration, a capacitor is also connected across the gate and drain of the transistor which denotes the gate-drain overlap capacitance. The effect of the capacitor is nullified by using an inductor in parallel with the resistance. Since the capacitor is of smaller value, the inductor that should be connected across it should be of a higher value. Using an inductor of large value introduces parasitic capacitances at the ouput node and input node of the circuit and thus degrades the performance of the amplifier. Hence, this topology is rarely used in practical LNA design. Common source stage with resistive feedback is also a possible topology that can be used to implement low noise amplifier. In this topology, a resistor is connected across the output and input nodes i.e., R_F provides a feedback from the output node to the input node. R_F sends a current signal as a feedback to the gate terminal of the transistor depending on the voltage at the output node. This topology does not suffer from the drawbacks as that of common source stage with resistive load. Gain offered by this topology is not restricted by the supply voltage as in case of resistive load. The trade-off between the gain and supply voltage is overcome in this particular topology and hence it is preferable over common source stage with resistive load. Resistive load in case of any transistor configuration i.e., common source or common gate, always creates a trade-off between the supply voltage and the gain of the circuit. Hence, resistive load is not preferred in any practical application, unless required.

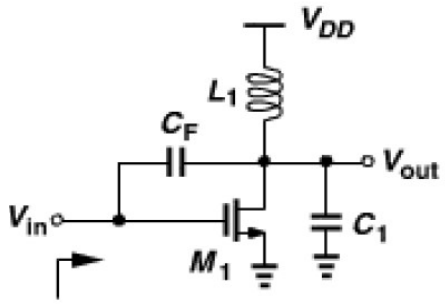

Fig. 1: Common Source Stage in presence of capacitance (reproduced from [9])

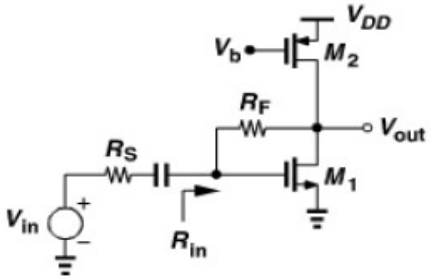

Fig. 2: Common Source Stage with resistive feedback (reproduced from [9])

Apart from common source configuration, common gate configuration can also be used to implement LNA for practical applications. Low input impedance offered by this configuration makes it suitable for practical applications. Inductor is used as a load in this configuration. If the inductor possesses ideal characteristics, it can be connected across the output terminals but if a practical inductor is to be used, a resistor should also be connected across it to model the losses offered by the inductor. Noise performance of this configuration is not optimum as it accounts for a lower gain i.e., better noise efficiency will result in a lower gain. Most widely used configuration is cascode common source stage. This configuration tries to overcome the drawbacks of the topologies discussed so far by introducing certain changes in the circuit. In this configuration, we use active devices to achieve input impedance matching of 50Ω, which limits the noise contribution that was added due to the passive devices in the circuit. One method to achieve this is inductive degeneration that is most widely used in LNA design. The value of the degenerative inductor is crucial in this design process. To achieve an impedance matching of 50Ω, an inductor having a value of about 50 pH, is to be realized. It is difficult to realize an inductor with this value accurately. Hence, in order to realize this inductor, a different method is used. If we wish to achieve impedance matching using degenerative inductor, we need to reduce the f_T of the transistor which can be done by adding an additional

capacitance across the MOSFET terminals. When we start the design process of the cascode LNA, we need to find out the value of the degeneration inductor according to the design specifications.

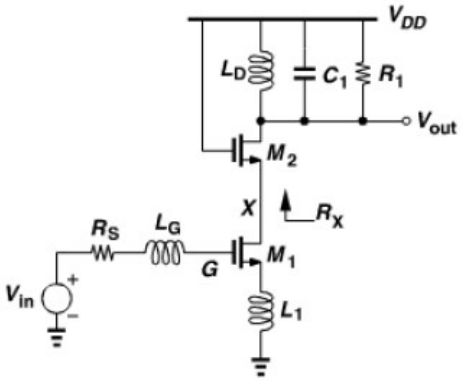

Fig. 3: Cascode Common Source Stage with Inductive Degeneration (reproduced from [9])

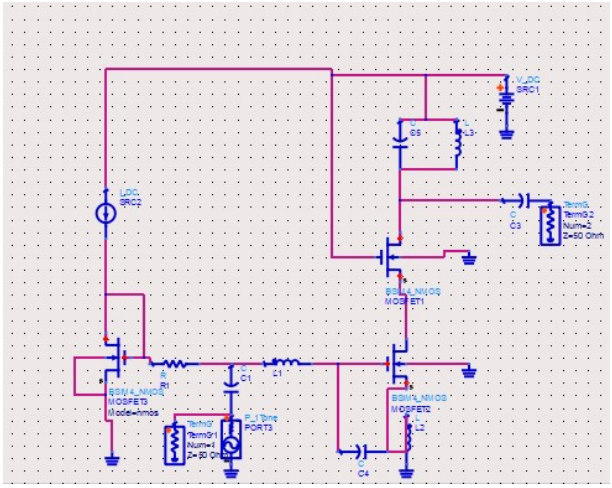

Fig. 4: Implemented LNA

Many other configurations also exist for LNA implementation but they are not widely used in practical applications as their design process is much more complex than these basic configurations. These topologies can be used if we want to design an application specific LNA. Noise cancelling LNA's are available i.e., their design process focuses on improving the noise performance of the LNA, etc.

IV. SIMULATION RESULTS

We can use different circuits as load in our low noise amplifier design and these circuits play a major role in the performance of the low noise amplifier. We have implemented four major output matching networks in our LNA and compared the simulation results obtained to find out the best output matching network for LNA circuits. We observe a trade-off between the various parameters of the LNA. Change in one parameter of the LNA affects the other parameters as well. We observe a trade-off between the gain of the LNA and the linearity of the circuit. We desire a high gain LNA; however a higher gain affects the linearity of the subsequent stages of the receiver. Hence, we need to confine our gain so that the non-linearity of the subsequent stages of the receiver does not become prominent. Generally a pre-select filter is placed before the LNA. This filter is sensitive to the impedance matching at its output terminals [10]. Hence, in our circuit design, we need to focus on impedance matching networks at the input terminal also. Cascode configuration implemented by us incorporates inductors and capacitors to provide this input matching. Inductor placed at the input terminal and the inductor placed at the source end of the MOSFET along-with the capacitance (C_{gs}) creates an input matching network for our configuration. Using a cascode configuration also has a benefit of providing required isolation between the input and output nodes. Isolation is necessary in circuits so that the signals from the output do not leak back to the input terminal. If proper isolation is not provided, signals may leak back and this creates a hindrance in proper operation of the circuit.

Using a resistance as a load is the most common practice but is does not prove to be the best output matching network based on our analysis. When resistance is used as a load, it is observed that it does not provide proper matching and maximum power is not delivered to the output node, which in turn results in more reflected power and losses.

$$|A_V| = g_m.R_D \qquad \text{..... (1)}$$

After substituting the values, we get the gain in terms of voltages as:

$$|A_V| = 2.VRD$$
$$V_{GS}-V_{TH} \qquad \text{.....(2)}$$

Gain obtained in this circuit is lower as it depends on the supply voltage and the voltage drop across the resistance. For new technologies, we work on lower voltages and hence, the gain is further reduced if we use resistance in our circuit. On the basis of results obtained, we conclude that using R as a load in our circuit is not preferable as it ought to increase the noise figure of the circuit as well as it is observed to provide a low value of IIP3. High frequency operation of the circuit is also restricted as the resistance does not provide proper matching at frequency of interest. Thus, this circuit does not provide optimum performance. Using an inductor as a load, overcomes the disadvantages offered by resistive network. Inductor sustains a lower voltage drop than a resistor and hence it can operate at a lower supply voltage as well. Moreover, inductor resonates with the capacitor at the load to offer matching at higher frequency. Value of the inductor is chosen first and then accordingly, the value of the output or load capacitance is chosen such that it will provide matching for desired frequency. Hence, using an inductor in our circuit solves the issue of obtaining matching at our frequency of interest. Using L as a load in our amplifier design overcomes the disadvantages that are observed in circuit with resistance as a load; and it is better to use an inductor in our circuit than using resistance because using a resistance limits the circuit performance and may not deliver the required results.

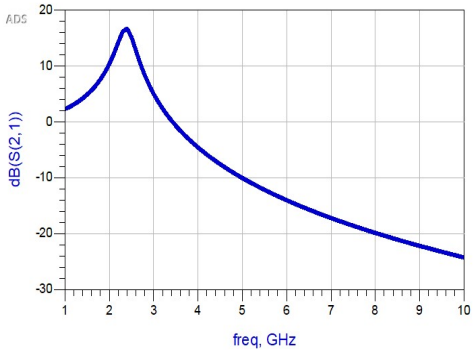

Fig. 5: Gain (S_{21}) obtained when R is used as load

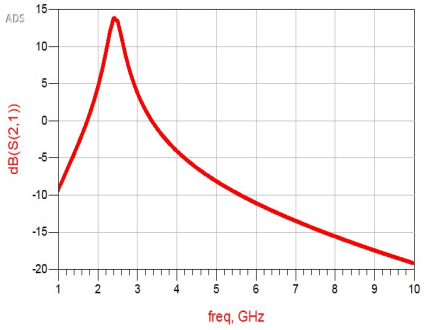

Fig. 6: Gain (S_{21}) obtained when L is used as load

Using LC as a load provides even better results as the inductor being used to realize the circuit is assumed to be a real inductor. Practical inductors suffer from losses which can be modeled by placing a resistor in parallel with the configuration of L and C. It can also be verified from the results obtained during simulation that when a practical inductor is being used in our circuit, the results get downgraded as the inductor being used to achieve output matching is not ideal inductor. Practical inductor properties are also being considered.

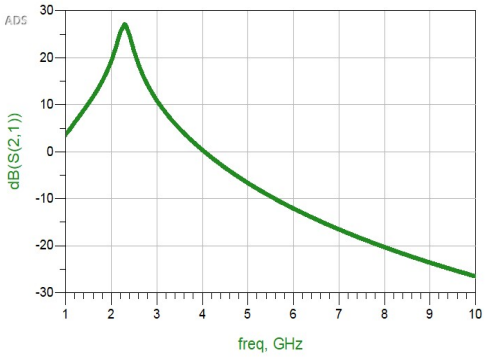

Fig. 7: Gain (S_{21}) obtained when LC is used as load

We know that ideal characteristics never exist. We should prefer the configuration that takes practical aspects into consideration. Using circuit design that is more close to the practical values, is always more realistic to use, as it always provides a better understanding of the real time performance of the circuit. Design process following practical aspects always yields results which are more close to real-time performance of the circuits.

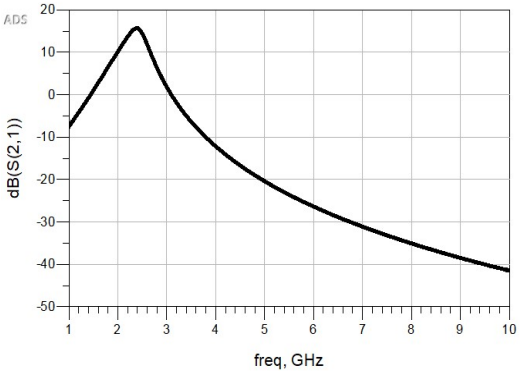

Fig. 8: Gain (S_{21}) obtained when RLC is used as load

We summarize the results obtained in tabular form. However, we compare the performance only on the basis of the gain provided by the circuit. Other parameters can also be used to compare different circuits; and analyze their performance on the basis of parameter values obtained. We need to make a choice of optimizing only one design parameter, keeping others at stake. While implementing these circuits practically, wire bound inductors can be used to realize the given inductance values. Using these inductors reduces the chip area occupied by our circuit design but at the cost of an additional overhead of placing the inductor off-chip rather than integrating on chip [11]. LNA design involves higher level of integration with minimum cost but it also creates a challenge to achieve a better noise performance. MOSFET is being used to implement LNA which possesses a noisy nature; and the noise sources in the MOSET are many. Dominant noise sources are channel noise, gate noise generated due to distributed gate resistance of the MOSFET, etc. These sources degrade the noise efficiency of the LNA. These can be controlled by properly choosing the size of the transistor which provides minimum noise figure. Cascode LNA with inductive degeneration configuration is ought to provide better noise performance and higher gain as compared to other configurations [12].

V. CONCLUSION

We cannot come to a conclusion stating that a particular circuit proves to be the best in terms of all parameters. Every circuit design possesses its own pros and cons making it suitable for one application and not suitable for a different application. This comes forward as a consequence of trade-off between the parameter values of LNA, which makes it a bit difficult to design a circuit with all values perfectly within the limits. On analysis of the results obtained after simulations, we can see the fact come true that there is always a trade-off between the LNA parameters. We observe that one circuit is suitable for application requiring high gain while other circuit is suitable for an application where low noise figure is required. Henceforth, every circuit has its own utility in one application or the other. We need to make a preference in terms of which parameter needs to be optimized and proceed with that aim to design.

Table 1: Results obtained for Cascode Common Source LNA with Inductive Degeneration Topology utilizing different output matching circuits

Parameter	R as load	L as load	LC as Load	RLC as Load
S_{11} (dB)	-13.44	-12.79	-12.041	-14.58
S_{22} (dB)	-11.26	-0.006	-0.08	-19.5
S_{12} (dB)	-47.44	-50.96	-51.28	-50.02
S_{21} (dB)	16.65	13.91	26.52	15.84
Noise Figure (dB)	7.802	8.419	7.464	7.784
IIP3 (dB)	7.023	4.026	5.243	9.783
Power Consumed (mW)	2.95	2.51	5.011	1.98

If we restrict our analysis by considering the gain of the system, LC as a load is observed to be the best design as it offers the maximum gain out of all the above configurations. Even RLC as load offers a sufficient amount of gain. Both these configurations are considered suitable to be utilized in any low noise amplifier design. If we desire a circuit which is highly linear, we need to consider IIP3 value of the circuit. For applications which require a highly linear amplifier, RLC can be utilized as the output matching network as it is observed to provide a higher value of IIP3. Based on our results, we also conclude that if we want to restrict the power consumption of the circuit, we should utilize RLC network in our circuit design, which is observed to consume less power as compared to others. Application specific LNA's are designed by optimizing one parameter and keeping others in the specified limit as trade-off cannot be ignored completely.

Abstract—**Wireless Sensor Network (WSN) could be presently exploitation technology for the data gathering from the hostile surroundings. WSN is consists of an outsized variety of sensing nodes, they are known as sensors. This kind of network is employed to gather the data through base stations (BS). However, it works on restricted batteries consumes lot of loads and power, limited energy is the bottleneck. The data collected from different nodes may give redundant information. To reduce the redundant information data fusion is needed, which will increase the accuracy and robustness of the information. LEACH protocol is one of the typical data fusion algorithms, which will reduce the energy consumption and extend the life cycle of the network. The research results were analyzed and benchmarked with the well-known LEACH and GSTEB protocols. The outcome shows a major improvement within the WSN in terms of energy potency. The results show the overall network energy consumption by scrutiny with existing algorithms.**

Keywords—WSN-Wireless Sensor Networks; LEACH-Low Energy Adaptive Clustering Hierarchy; GSTEB, Data Fusion

I. INTRODUCTION

[1]Wireless is consists of thousands restricted batteries operated nodes. Nodes are unit created of radio transmission and receiving, sensing, storage, processing, mobilize and world positioning system (GPS). These nodes area unit localized in massive geographic region. These nodes area units are localized in massive geographic region. These sensors area unit gift close them then they transform the information into electrical Signals then these signals area unit processed to urge Characteristics remotely gift space wherever sensors unit. The Sensor interconnections have thought-about as promising tool for analysing the physical world, utilize self-organized nodes will sense, method and communicate area unit battery high-powered. In lifetime sensor interconnections node, energy must be a main yet vital resource, wherever exhibits have a restricted characteristic. So that, it is often necessary to optimize specification therefore resources consumed is decreased. Their boundaries kind their style and protocols each stimulating completely different. WSNs are unit shaped by an outsized variety of sensing element.

Depending on the sensors with restricted battery power cannot be superimposed balanced energy exhausting ought be thought-about because the reason for energy-efficient management. The current system has been enforced by the not high Energy adjective bundle Hierarchy (LEACH) theme permits role of collection head evolved among sensing element and makes an attempt distribute energy usage though all buds. It utilizes irregular rotation native base equally distribute energy load among senses within the track though out set-up part, all nodes are unit at instant buds through human action with short messages one lump is chosen as a bunch head per bunch head choice rule. Here we proposed a General Self organized Tree Based Energy Balance routing protocol (GSTEB). We have a tendency to take into account a scenario within which interconnections collects info sporadically from parcel wherever every node regularly senses atmosphere and sends data back to central Station. Commonly parte unit two definitions for lifetime interconnection are time from the beginning of interconnections operation to the death of the primary node within interconnections and also the time from the start of interconnections operation death of last node within interconnections.

The main aim of GSTEB is to do attain extended interconnections a time period various applications. Every spherical, Base station (BS) allots a root hub and communicates its ID and its coordinates to all or any device nodes. Then interconnections computes trail either by transmission of trail data or BS to device nodes or by having identical tree structure being dynamically and singly designed by every node. For each case, GSTEB will amendment foundation reconstruct tree with short delay with low energy exhaustion. Thus, a balanced load is achieved compared with the protocols. The task of GSTEB is part into Initial part, Tree-Constructing part, Self- Organized information aggregation and transmission part, and knowledge Exchanging part.

This paper is organized as following, Section II contains the related works, section III reviews about routing protocol, section IV contains working principles, section V contains results and discussion and section VI concludes the paper.

II. RELATED WORK

In[2] Hongjun Wang, Huiqing Yangtze, Hui Zhao, and YoujunYue projected an formula to balance energy exhaustion of detector nodes in WSN, in order network life additionally gets extended. [3]Zhang Shiyue, Jiande Wu, Xiaodong Wang projected LEACH Cluster

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

routing formula for wireless detector Network information Fusion thereby reducing the energy exhaustion and quantity of knowledge communication. In[4] Wei-Qi bird genus ; Bin-Jie Hu projected fusion formula with the gauss distribution characteristic chart therefore the gauss membership operate will improve the information preciseness and measuring stability. In[5] Diksha.J. Ramteke, Amol Boke projected a way supported ICH-LEACH wherever, there'll be hierarchy which is able to encompass Master and slave bunch head thus on enhance life of Master bunch head and lifelong of specific network. In[6] the developing enthusiasm in wireless sensor networks and emerging trend in recent field motivated for measuring the characteristics, operations and communication protocols for a different areas. In[7] proposed the Low Energy Adaptive Clustering Hierarchy to distribute the energy evenly between the sensors in the network. Data fusion is incorporated with routing protocols to reduce the information content that could be transmitted to the base station. Life time also gets extended. In paper [8] redundant data can be eliminated, which will improve the performance. So that energy consumed and network life time also increased. All these done by Improved LEACH algorithm. In[9] Measurement stability and data precision is improved by applying gauss membership function of fuzzy theory and improved leach protocol.

III. HIERARCHICAL ROUTING PROTOCOL

A. Leach

a) LEACH is a simple routing protocol used to reduce energy exhaustion data improve lifetime interconnections nodes. The buds in the LEACH plus cluster buds and bunch head to polling is minimum. Clustering optimization problem in single hop networks: are used to predict lifetime reliability wireless sensor interconnections .Small energy exhaustion data report of distance closer to base clustering in large scale. The distance from the base station far smaller cluster. Every cluster divides into mini clusters and they are organized for each mini cluster define the other mini bunch head. It communicated directly with the bunch head and collects the information about the other nodes to connect and concentrates all nodes for data transmission used resolves some nodes coverage problems.

[10] Each cluster head is having a responsibility to create and manipulate a TDMA schedule during communication process. To transmit the data packets schedule table is used by its cluster member nodes. If any emergency happens in the monitoring environment the sensing elements are triggered to send the information to their own cluster head rather than remote BS by themselves. The data from different nodes are collected by the cluster head and remove the redundant data, then transmits the remaining information to BS. Transmission distance between the nodes will be reduced by the member node with the help of cluster head. Because of this energy consumed.

In [11] To reduce energy consumption in WSN, data fusion is the best solution. Due to sensor failure interruption may occur, by using data fusion techniques we can reduce the redundant data. By doing this entire network energy will be consumed, so that life time of that entire network will be increased.

GSTEB and LEACH is the best suitable algorithm to perform the energy consumption.

The communication process have two different phases such as, Setup phase:

[12]The node which is used to broadcast the message to its surrounding sensing node whose number larger than threshold number will select itself as a bunch head. A node will receive more than one broadcast message from different bunch head, and also judge its distance by the strength of received broadcast message. So, the buds whose number is smaller the threshold will only send request message containing its Broadcast ID to the cluster. Which has the strongest signal strength for saving energy. It records the nodes ID. The CH creates a TDMA schedule slots and broadcast it to all the cluster members and each nodes get their idle slots for transmitting the data, and then the steady state phase starts.

a) *Steady-state phase*

Cluster nodes will form them and send to BS. The formation on the bunch head can reduce the unnecessary bandwidth cost and communication traffic and also a positive reflection to the energy exhaustion where the data transmission distance becomes shorter comparing with transmitting to BS separately which is used to save some energy for the group of nodes.

A. GSTEB

GSTEB protocol is mainly proposed for wireless sensor networks the operation will be divided into phase. They are initial phase, [13]Tree constructing phase, Self-Organized data collecting and transmitting phase and information exchange phase.

a) Initial phase

[14]In the first stage of GSTEB operation data packet to is broadcasted to all the node or few nodes by BS to share the data created time. Every node sends its data to a particular radius. Nearest node's information will be available with the packet. So that packet will be received by its nearest node.It also receives and record the data info in memory. It operates in round, each round generates the data for BS and receives the information of nodes, once all the sensors information is received by the BS then round will be finished.

b) *Tree constructing phase*

Root node will be selected by the BS and broadcast the root id to coordinate with other nodes. Each and every round highest residual energy node will be selected as root node. So the data will be collected by the particular root node and transmits the fused data to the BS. The nodes will choose the parent and its neighbours using vitality. Repeating this process until the tree is constructed. After constructing the tree, sensors will collect the information and transmits the fused data. During the transmission state each child node sends their root id to its parent by choosing them considering their distance.

c) Information exchange phase

Each and every node should generates and transmits a data packet in every round, before its energy goes down. It can persuade the topology. So the node which is about to die need to share their data with other node. This process is

performed based on the time slots, in each time slot random delay will be computed by the node whose energy will certainly be exhausted. This will help to make another broadcasting node in a new time slot. This particular node will broadcast the data packet to the complete network. Mean time remaining nodes will monitor the channel. Root id will be verified based on the data packet received from the node. In order to transfer the information securely the cluster head will be selected based on the degree of energy.

IV. WORKING PRINCIPLE

GSTEB is hierarchical routing algorithm which is most popular for sensor networks. GSTEB sensor nodes are combined in order to form clusters on the basis of received signal strength. The cluster head will act as routers to the sink node. [14]Transmission can be only done by bunch heads instead of all other nodes which will save energy. Existing routing protocol consider balanced energy exhaustion of nodes ignoring elaborative data processing between the sensor nodes. LEACH protocols needs base stations with uneven distribution of bunch heads. Since, the sensor consumes high energy, it should be considered as the issue for energy efficient management. The observation of energy level over sensor network provide as issues in the transmission.

The methodology performs the detector network and selects bunch heads space to the bottom station. The bunch heads are chosen by comparison their crucial values, rather than the crucial values, rather than the standard methodology of choosing bunch heads, during this bunch formula within GSTEB will perform knowledge fusion. The method will acquire higher convergence and price lower message overhead. Clustering in sensing aspect network is economical good topology that encourage planning energy efficient protocols to develop sensing element buds with low price.

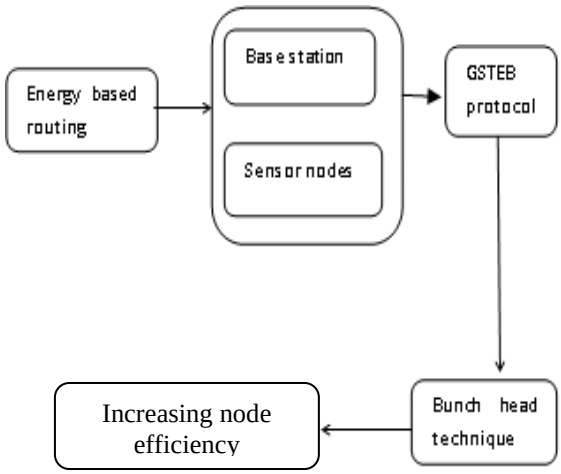

Fig. 1. GSTEB Architecture

A. Low Energy Adaptive Clustering

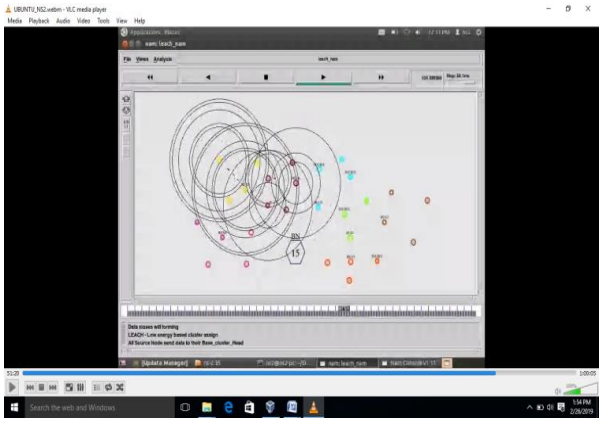

Fig. 2. Source node data to their base head

LEACH is an simple efficiency routing protocol in WSNs. It is integrated with clustering is to lower the energy exhaustion for creating the nodes. It maintains the clusters to improve the lifetime. The performance of LEACH is slightly lower than the proposed method GSTEB.

LEACH will divide the Wireless Sensor network in to number of cluster. Each and every cluster will have a cluster head. The cluster head is responsible to colletct all the data from the other sensing nodes which is shown in fig 2 and fig 3.

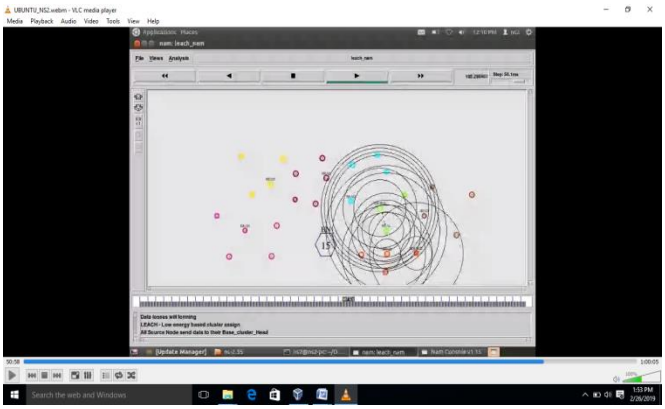

Fig. 3. Implementing LEACH algorithm

B. Tree Based Energy Balance Routing Protocol

G GSTEB is a popular energy balancing routing protocol. For each bunch head process, the base station purposes a node for each bunch head and own its neighbouring ID information which node has highest weight. It is mainly used to balance the energy exhaustion and load.

STEPS OF LEACH ALGORITHM

Step 1: Begin and construct WSS and WSN
Step 2: Send node locations and residual energy information from nodes to base station
Step 3: if Node Energy> Threshold Energy then Wait for cluster
Step 4A: Send join request to CH and wait for TDMA schedule for head announcement

Step 4 B: Node is selected as bunch head.
Step 5: Search for clusters in interconnections
Calculates the modularity (Q) of the clusters
Step 6: if Q>Qmax then
Calculate the centroid of interconnections and its distance from the nodes closest to it
Step 7: Assign highest weights to the nodes close to the centroid having residual energy than others.
Step 8: Compute the estimated (normalized data accuracy) for the sensor nodes in interconnections. Plugin the weights of the nodes in terms of Energy and Precision constraints.
Step 9: In the weights matrix obtain the best set of cluster.

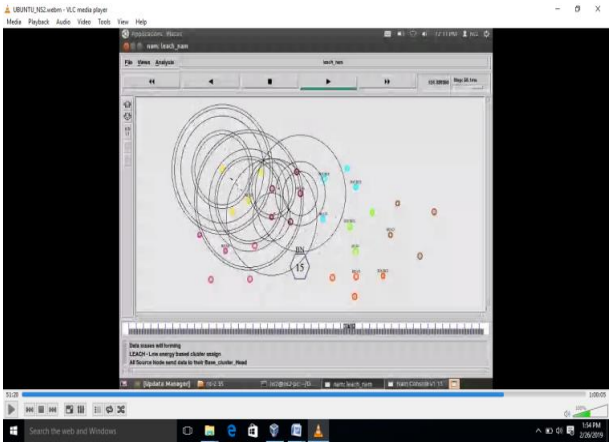

Fig. 4. Group Identification Access

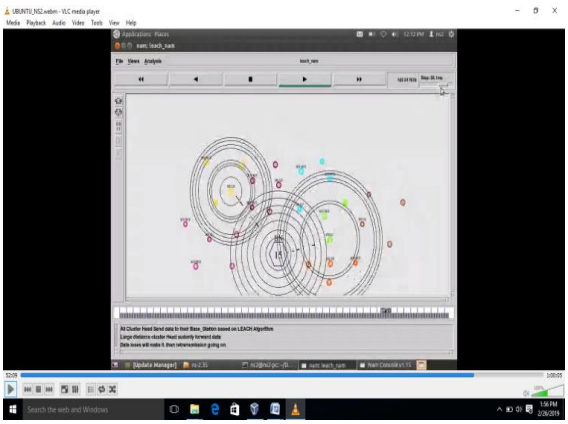

Fig. 5. Bunch head send data to bunch head

STEPS OF GSTEB ALGORITHM

Step 1: Create node
i=nodeid;
Set the routing channel;
Set inienergy, resenergy;
Set rad_range as default;
Step 2: If((node in rad_range) && (next hop!=NULL)
then
Capture data load (node all);
Step3:Create a node and configure
(rreq,rrep,tsend,trev,tdrop, inienergy, resenergy)
Step 4: For i=0 to n
con_energy [i]=inienergy[i]-finalenergy [i]
total_energy[i]=<con_energy [i])
Step 5: if(max_energy[i] <con_energy[i]) then
max_energy = con_energy[i]
nodeid=i;
step 6: If (distance<300 &&max_energy [nodeid]
>energy_neighbor [nodeid]) then
step 7: Max energy node is the cluster head;

V. RESULT AND DISCUSSION

In LEACH, based on the distance the sensor energy consumption was reduced. The nodes will concentrate all the nodes. It only concentrate on specific nodes that transmit the data and information to the other node. It will load the data nodes more and more as shown on figure 4 and figure 5.

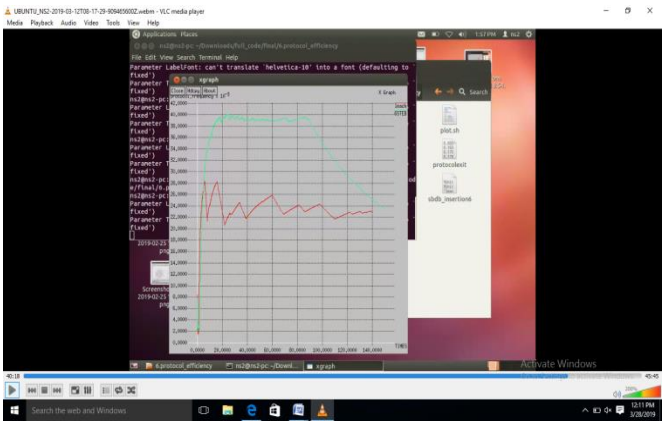

Fig. 6. Delay xgraph loss

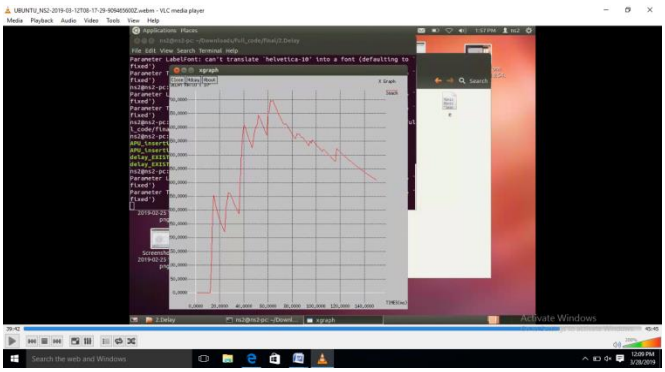

Fig. 7. Delay xgraph loss 1

In GSTEB, the nodes will concentrate all the nodes and do the data processing even though bandwidth is high and minimize energy consumption efficiently compared to LEACH on shown in figure 6 and figure 9. It reduces load. We have used E-GSTEB type of GSTEB for minimizing energy consumption

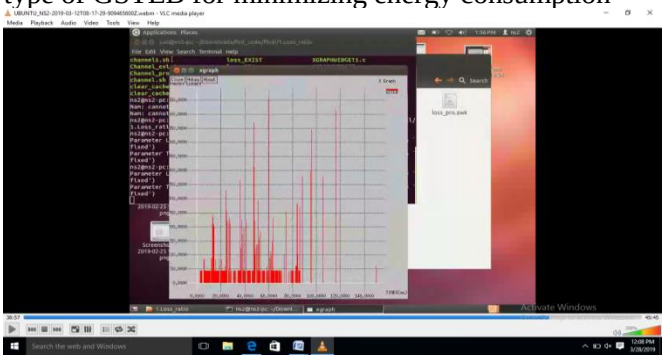

Fig. 8. Parameter xgraph loss

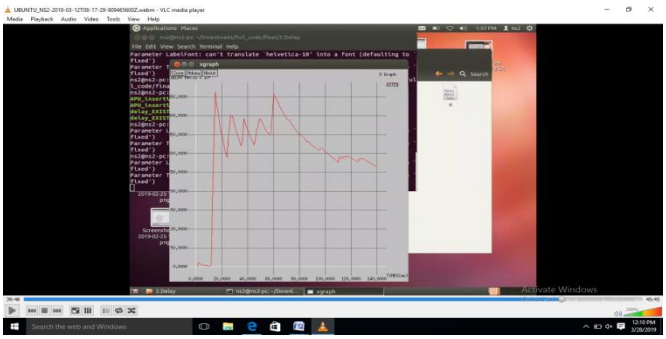

Fig. 9. Parameter xgraph

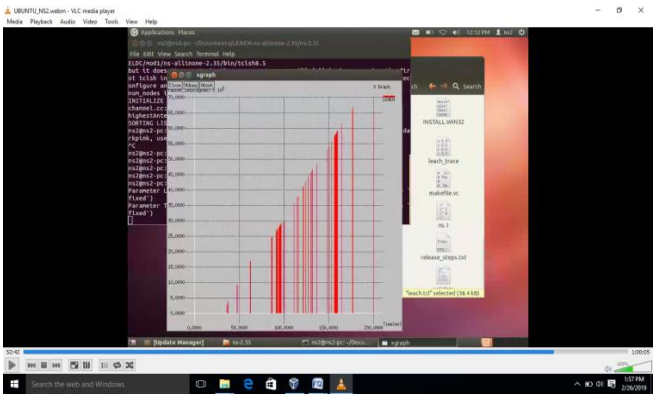

Fig. 10. Xgraph loss 1

The Base station allocates nodes coordinates in each round. Interconnections transmit the data information being dynamically and individually

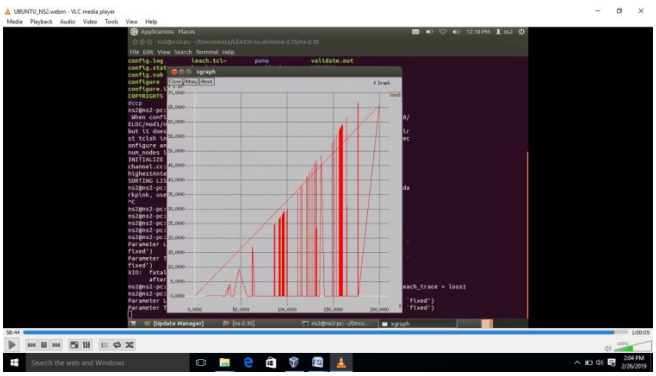

Fig. 11. Xgraph loss 2

The GSTEB chooses the nodes with residual energy to transmission the data information. The allocation of nodes will performed by the Base Station based area unit distance with the radius clusters are shaped. All the nodes will be covered with the other nodes.

VI. CONCLUSION

In this paper, we proposed an enhanced cluster head technique for energy consumption in data fusion. Data from different sensors are grouped and performed cluster heading. The simulation results show the minimized energy with enhanced (E-GSTEB) technique. Because of this energy reduction, network life time will get improve. This clustering techniques gives the more accurate data and data transmission is more efficient. This is done by using a particular data fusion technique.

ACKNOWLEDGMENT

We are thankful to our management Sathyabama Institute of Science and Technology for providing us all the necessary support and facilities required for preparing this manuscript.

***Abstract*—The major problem faced by the paralyzed people is their mobility. The quadriplegia, one of the serious disabilities affects all the four limbs and such persons need an external help to perform their daily activities. The main objective of this project is to provide an automated system for such people. Abstract discusses the possibility of developing a wheelchair whose motion can be controlled using eye blinks. User's eye gestures are translated to screen position using optical sensing in MATLAB. A camera mounted on the wheel chair recognizes the eye gaze/blinks and if it matches with the gestures in memory, motion control commands are generated by the micro controller depending on the coding. These commands drive the motors of the wheelchair.**

Keywords—Arduino UNO, Hough Transform, MATLAB, Webcam.

1. INTRODUCTION:

Wheel chair is a versatility-based gadget for people with cutting edge/extreme physical disabilities. Different control interfaces have been created for wheelchair control, for example, joystick or head control. These types of interface are not accessible to the general population practically. Now, using eye squint and mouth signal, an alternate type of wheelchair control is conceivable.

This report exhibits the plan, advancement and medicinal effect of a wheelchair with eye control. Individuals with tetraplegia cannot work a wheelchair with joysticks. In any case, a few people truly feel hard to control the bearing of the wheelchair with their hands because of loss of motion, the old, impaired. A wide scope of help gadgets and current hardware have been created to help improve their personal satisfaction. This innovation is a mix of an individual with incapacities in the public eye.

Since all individuals cannot utilize the conventional electric wheelchair, there must be some correspondence between the client and the wheelchair to control it. It is extremely hard for the handicapped client to drive the wheelchair with their arms.Some commonly used methods are mentioned such as: Voice Operated Wheelchair System[1],Head and Finger based Automated Wheelchair System[2], Eye Movement based Electronic Wheelchair System which uses MATLAB[3],Eye Movement based Electronic Wheelchair System which uses Raspberry Pi[5], Hand Gesture based Wheelchair System[4].

- Voice operated Wheelchair System[1] works based on input voice command delivered by the disable person.
- Head and Finger based Automated Wheelchair System[2] works based on head and finger movements.
- Eye Movement based Electronic Wheelchair System which uses MATLAB[3] works based on EOG (Electro-Oculogram).
- Hand Gesture based Wheelchair System[4] works based on EMG (Electromyogram).

In this paper our work mainly emphasizes on the eye blinks with help of mouth gestures. By adding these mouth features number of instructions will be increased as shown in below Table:1. In 'CascadeObjectDetector', to detect eyes we used "Eye Pair Small" and to detect mouth we used "Mouth" in CascadeObjectDetector.

1.1 Model Design algorithm:

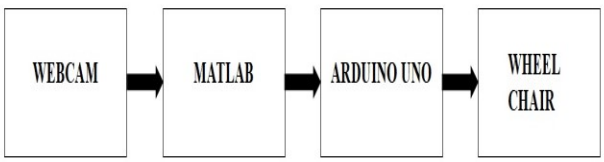

Fig.1- Wheelchair control system block diagram

As shown in Fig.1 Facial features are recorded by the webcam and it is feed to the MATLAB as input. In MATLAB we will use Viola Jones algorithm for detecting facial features and to detect the pupil we will use HOUGH transform. Now to interface the MATLAB with Arduino UNO there presents Arduino packages in the MATLAB toolbox. To run MATLAB code in Arduino, Arduino packages must be installed. Now Arduino is connected to L298N motor diver prototype for wheel moment. This L298N motor diver has

dual full bridge design. An Obstacle detection sensor is used to detect obstacle, when it detects then buzzer sound will be activated.

2. PROPOSED METHODOLOGY :

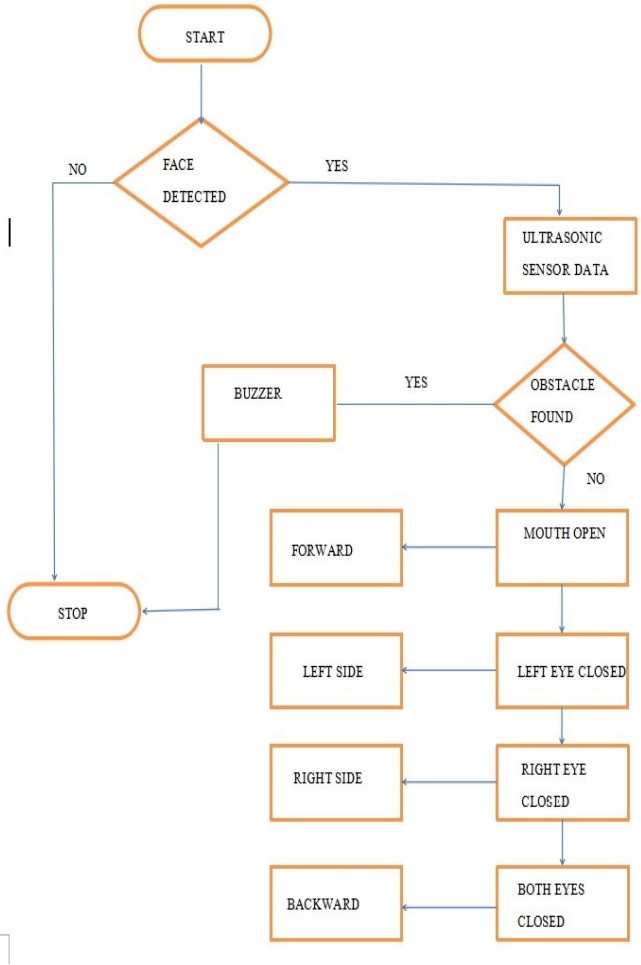

Fig.2-Flow chart

Step by step working :

- Web cam starts recording the facial features. If face is not detected then the program will be stopped, else ultrasonic modulo will be activated.
- If obstacle is found then buzzer will ring otherwise further process will be takes place.
- When mouth is open and 2 eyes are open then wheelchair starts moving forward.
- When left eye is closed, right eye is open and mouth is closed then wheelchair starts moving left.
- When left eye is open, right eye is closed and mouth is closed then wheelchair starts moving right.
- When mouth and 2eyes are closed then wheelchair will move backwards.

2.1 Working:

Working of this project divided into 2 parts:

- Detecting face using Viola Jones algorithm.
- Continuous capturing of eyeball blinks with help of webcam and it is fed to MATLAB and Interfaced with Arduino board.

2.1.1 Detecting face using Viola Jones algorithm :

Using 'CascadeObjectDetector' we will detect eye-shaped objects based on their structure, Viola Jones Algorithm detect similar objects. Continuous snapshots of every 24 frame are taken and feature points are saved.we capture 1 snapshot every second and process it based on the position of the object. Previous snapshot and current snapshot, features are detected and this is communicated to the wheelchair through the serial port.

Viola Jones Algorithm is to scan a sub-window in the detection of a face for the given input. Standard image processing approach will re-scale the input image for different sizes and then run the fixed sized detectors through these images. This approach is taking time instead of being pictures of large sizes. According to the standard perspective, Viola Jones re-measure the detectors rather than the input image and often with different sizes run the detectors with a picture. At first it seems both methods execution will take more time, but Viola Jones has devised a wide-ranging revealing that requires the same number of calculations of any size image. If webcam detects many faces, the program will be stopped because it is difficult to recognize the original input. The above figure is not for example, to detect multiple face or face, it will not come to know the face.

2.1.2 Continuous capturing of eyeball blinks with help of webcam and it is fed to MATLAB and Interfaced with Arduino board:

Continuous snapshots are taken and is given as input to the MATLAB. Using HOUGH transform we will find arbitrary shapes such as circles and ellipses. For detecting eye pupil HOUGH transform is useful. If pupil detected then consider that eye is open, else eye is closed. Where step by step process regarding the moment of wheel chair is discussed in above flow chart. Now the output of MATLAB is given to Arduino through serial communication. Here Arduino UNO board is used to perform moment of wheel chair. It takes around 2 seconds(delay time) of time for each instruction to get executed and display the corresponding output results. Table.1 describes input instructions to the wheelchair.Designed prototype is shown in Fig.3.

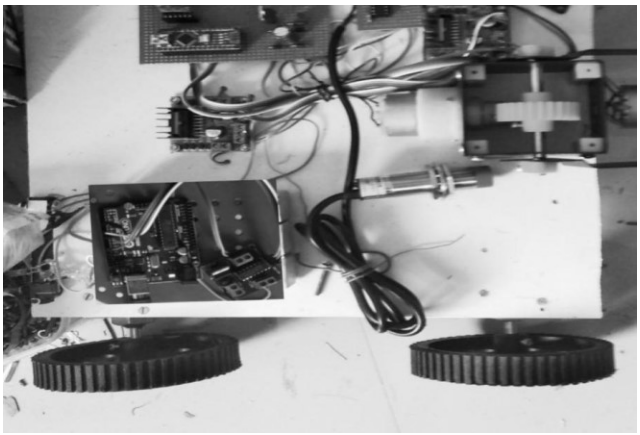

Fig.3-designed prototype

Right eye	Left eye	Mouth	Wheelchair
Open	Open	Open	Forward
Open	Close	Close	Left side
Close	Open	Close	Right side
Close	Close	Close	Backward

3. RESULTS:

The following cases of above table outputs are shown in the below.

- When 2eyes are open and mouth is also open then wheel chair moves forward as shown in Fig.4.
- When left eye is closed, right eye is open and mouth is closed then wheelchair moves left side as shown in Fig.5.
- When left eye is open, right eye is closed and mouth is closed then wheelchair moves right side as shown in Fig.6.
- When 2 eyes are closed and mouth is closed then wheelchair moves backward as shown Fig.7.

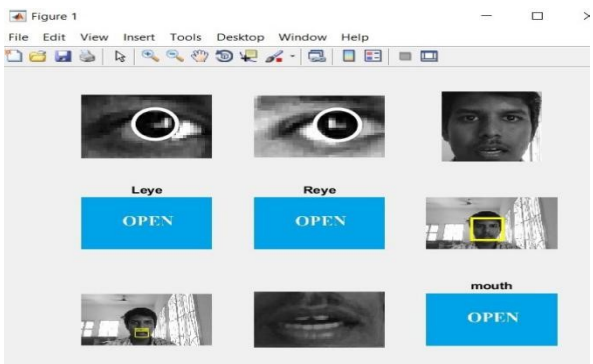

Fig.4- Forward Movement

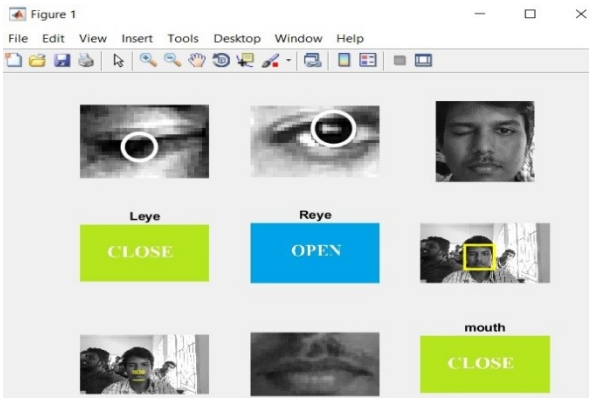

Fig.5- Wheelchair moves left side

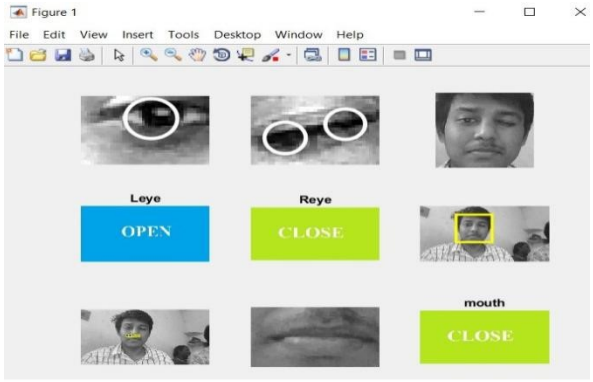

Fig.6-Wheelchair moves right side

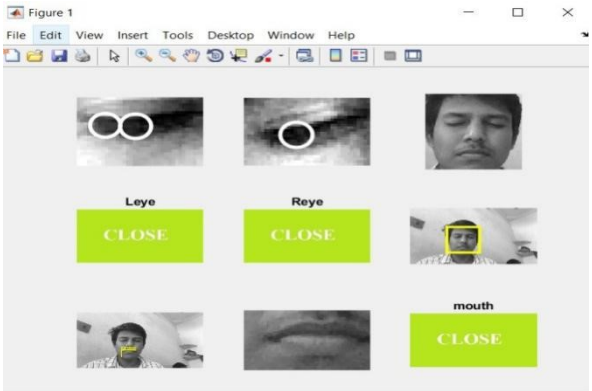

Fig.7-Moves backwards

3.1 Accuracy table:

We conducted different trails on normal and disable people and those results are tabulated in Table.2 and Table.3. The results are quite impressive and percentage of exactness is varied with person to person, but in each case the chances of positive detection are impressive.

Attempts done by normal persons:

Serial no	Total attempts	Favourable outcomes	Percentage of exactness
1	9	8	88.88
2	7	5	71.42
3	9	7	77.77
4	6	6	100
5	5	4	80

Table.2- Percentage of exactness for normal person

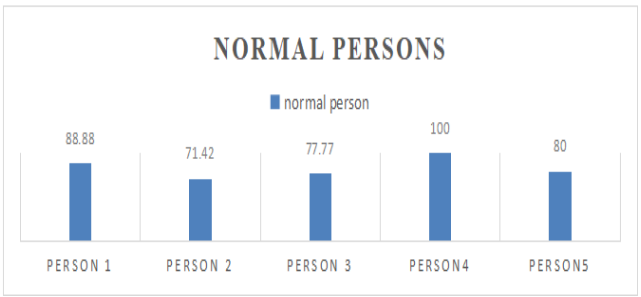
Attempts done by disable persons:

Serial no	Total attempts	Favourable outcomes	Percentage of exactness
1	6	4	66.66
2	9	7	77.77
3	4	3	75
4	7	5	71.42

Table.3- Percentage of exactness for disable person

The above data for normal and disabled people are represented in graphical form as show in Graph:1 and Graph:2.
Graph:1 describes number of successful attempts made by the normal people. Graph:2 describes number of successful attempts made by the disable people. X axis describes the person and Y axis describe about the percentage of accuracy

.



Graph:1

Graph:2

4. Conclusion:

This paper's work has been successful in developing an enhanced wheelchair movement system using facial gestures for the quadriplegia, disabled people. The primary purpose of this work is to develop a prototype that can detect obstacle and make disables self-dependent by increasing their range of mobility through the use of their own facial gestures including both eye and mouth movements. Wheelchair movement system has shown appreciable results with favorable outcomes and the efficiency of this new system is better than the previous developed prototypes for the disables. Future work for this system could be extended by improving speed and power controls of the system for developing a whole optimized systemfor disables.

***Abstract* — Data transformation is converting input data from one form to another form. Normalization is a standard data transformation techniques which can be used to transform data. There are many types of normalization techniques, like Min-Max normalization, Cube Root normalization, etc. In this paper, we implement a two-phase normalization process. In the first phase, the data is normalized using Cube Root normalization. Next, the normalized data is still more scaled by applying the logarithmic transformation. Finally, the performance of the transformed values is evaluated against standard metrics.**

Keywords— Data Transformation; Mean Absolute Error; Normalization; ROC Curve;

I. INTRODUCTION

Data Transformation is an integral part of data preprocessing phase in data mining lifecycle. In data transformation, data is converted from the existing form to a form appropriate for mining [1]. Better mining results are yielded if the data in the dataset are appropriately preprocessed and transformed. There are four major categories of transformation techniques. They are smoothing, aggregation, generalization, and normalization [2]. In this paper, we implement a novel normalization strategy by using log values. This normalization strategy can be used by any data mining application of any industry to produce more accurate results.

II. RELATED RESEARCH WORKS

In the research work of Gopal Krishna, a normalization technique named Integer Scaling normalization was introduced. Integer scaling normalization was tested on three datasets. This normalization technique produces values between 0 and 1 effectively [3]. Three normalization technique was compared in the research work of Saranya and Manikandan. Their work normalized the age attribute in the dataset. K-Means clustering was used to test the normalized datasets. This research work reveals that Min Max normalization performed well than other normalization techniques [4]. In the next work of Zuriani and Yuhanis existing normalization techniques was analyzed to predict dengue fever outbreak. Two dengue dataset and one sample dataset for rainfall prediction dataset were used in their work. Maximum accuracy achieved after normalization was 83.4%. In their work, it was found out that decimal scaling normalization performed well than other techniques [5].

III. DESIGN AND IMPLEMENTATION

The required dataset is downloaded from the UCI repository. The dataset used in this work is students academic dataset [6]. This dataset is used to predict the performance of the students. This dataset contains 33 attributes of personal, academic, social, demographic traits of a student. This work mainly focuses on three main attributes in the data set namely grade 1, grade 2 and grade 3. In this work, we implement a two-phase normalization process.

A. Phase 1: Cube Root Normalization

In the first phase, the grade values in grade 1, grade 2 and grade 3 is normalized using cube root normalization. i.e., we take each mark (x) in grade 1, grade 2 and grade 3 find out its cube root value.

Let X be the mark acquired by the students

$$X1 = \sqrt[3]{X}$$

X1 is the output of Phase 1.

B. Phase 2: Log Normalization

In the second stage, we take X1 values and scale it further more by finding log values of X1.

$$X2 = \log (X2)$$

X2 is the output of Phase 2. To the X2 values, we apply decision tree classifier to determine the accuracy and AUC values.

C. Software Implementation

Phase 1 and Phase 2 of this work is carried out in Matlab 2018a. First the dataset is imported. Cube root values (X1) of grade 1, grade 2,grade 3 are found out using the cube root formula, X1 = (sign(x).*abs(x.^(1/3))) [7]. Then we find out log values (X2) of X1 using the log formula (X2=log(X1)). Then we use the classification learner app to determine the effectiveness of the normalized dataset. In the classification learner app, we use Fine Tree classifier to determine the accuracy and AUC values of the normalized datasets.

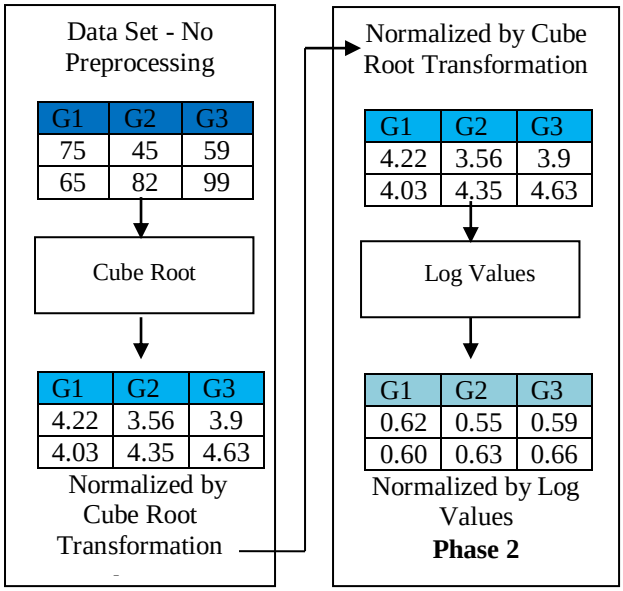

Fig 1: Working Principle

The above figure shows the working principle of this research work. In Phase 1, we perform cube root transformation and Phase 2 perform log normalization.

IV. RESULTS AND DISCUSSIONS

The performance of this proposed work is analyzed in terms three metrics. The metrics are Accuracy, Mean Absolute Error [8] and Roc curve. The experimental values of the metrics are as follows.

A. *Accuracy*

Accuracy of the dataset before preprocessing is 85.6%.
Accuracy after cube root normalization is 85.1 %.
Accuracy after log - cube root normalization is 86.6 %.

B. *ROC Curve*

ROC Curve of the datasets is given below. AUC Value indicated the capability of the model in distinguishing between two groups [9]. The following figures shows the ROC Curve with AUV values of the datasets.

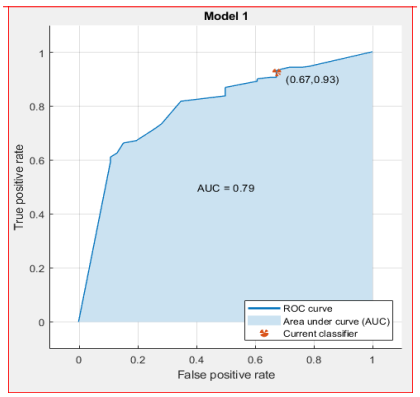

Fig 2: No Preprocessing

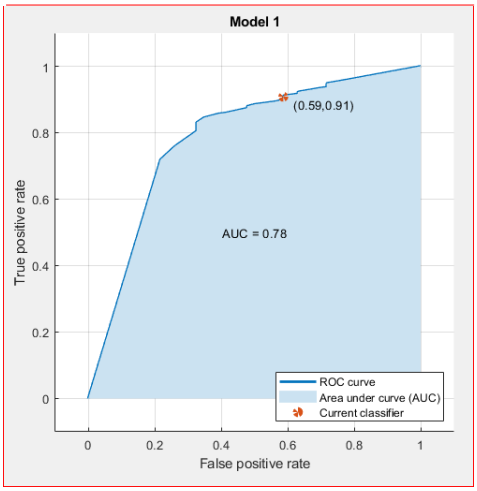

Fig 3: Cube Root Normalization

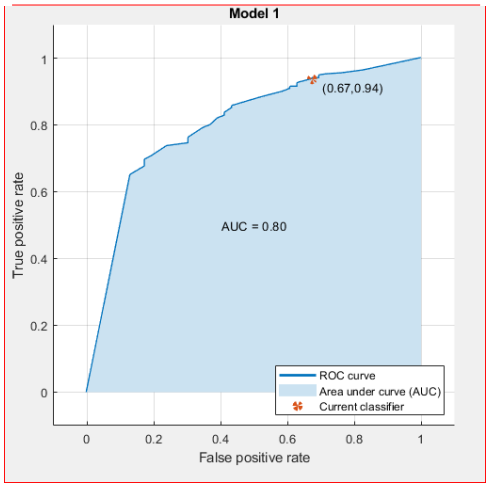

Fig 4: Log - Cube Root Normalization

C. *Mean Absolute Error (MAE)*

MAE before preprocessing is 9.10 %.
MAE after cube root normalization is 0.52 %.
MAE after log - cube root normalization is 0.07 %.

In all the comparisons it is found out that, academic dataset which undergoes two phase normalization performed well than academic dataset with no preprocessing or dataset preprocessed with cube root normalization. Comparing the accuracies, it can be found that high accuracy of 86.6% is achieved by the academic dataset after log cube root normalization. The Mean absolute error is also less (0.07) and AUC value is higher (0.80) for the academic dataset which underwent two-phase normalization. Hence it can be seen, that the proposed normalization strategy decreases the mean absolute error and increases the accuracy and AUC value of academic dataset. It can be taken from here that log - cube root normalization is very effective in improving the performance of mining works related to academic datasets. So, researchers working on academic datasets can use log - cube root normalization to improve the performance of their works.

V. CONCLUSION

In this paper, we introduce a two-phase normalization strategy using the log and cube root values. The academic dataset from the UCI repository is used in this work. From the experimental results of this work, we can conclude that our normalization strategy produces better results in terms of accuracy and mean absolute error. So, for preprocessing academic datasets, it is highly recommended to use log - cube root normalization. As future directions, we can implement log-square root normalization or implement multi phase normalization technique using max min normalization, cube root normalization and square root normalization together.

***Abstract*—Super resolution algorithms always used as a trade-off between the cost of the high definition (HD) cameras and the quality and/or clarity of the image obtained. There are various predefined algorithms that obtain Super Resolved images from Low Resolution (LR) images, some (such as, Convolutional Neural Network (CNN), Deep learning, Sparse Representation based algorithms) gives better results for e.g. deburring of zoomed part, removal of noise, color enhancement and so on but are computationally complex or hard to implement in real-time environment whereas some are very simple to use (such as, interpolation based, wavelet based algorithms) but lack quality for e.g. ringing artifacts, edge blurs, poor image quality etc. In this paper, we proposed a method that combines advantages of some of the above mentioned methods. Our proposed method obtains High Resolution (HR) image using saliency model for detection of visually dominant regions, Discrete Wavelet Transform (DWT) for extraction of high frequency details, finally Multi-layer Perceptron (MLP) and Particle Swarm Optimization (PSO) for interpolation. Experimental results visually and quantitatively show that for considered test images our proposed super resolution method appears to be most promising compared to bi-cubic, Chopade *et al.*, Yu *et al.* and Man *et al.* methods.**

Keywords—resolution; saliency; wavelet transform; particle swarm optimization; multi-layer perceptron

I. INTRODUCTION

Nowadays many applications and systems entirely depend upon images for processing, e.g., different biometric systems as, iris recognition system which uses unique patterns of a person's eye veins for recognition, fingerprint scanner that uses physical differences in bridges and valleys or medical imaging systems, radiography, tomography, MRI, ultrasound, elastography, etc. that used for medical diagnosis or surveillance systems and many more. Such applications require very minute details for processing and the outcome relies entirely on the input images therefore quality is the basic necessity for such applications, LR images cannot be used as an input for such applications because these images appear pixelated and contain very less details and we cannot extract required details like, edge information, color information, etc. from such images. High quality images can be obtained using High Definition (HD) cameras but, cost of such cameras is high and cannot be always used as a preferable solution and here come the super resolution (SR) algorithms into the picture. SR algorithms can convert Low Resolution (LR) images into HR images with much less expenses as compared with the cost of HD cameras [1].

Researchers have proposed several solutions for SR problem in both frequency as well as in spatial domain. Frequency domain consists of Complex Wavelet Transform (CWT), Discrete Wavelet Transform (DWT), Stationary Wavelet Transform (SWT), Fast Fourier Transform (FFT), Discrete Fourier Transform (DFT), etc. Eason *et al.* in [2] combined CWT, Wavelet zero padding (WZP) and Cycle Spinning (CS) for obtaining HR image. Gajjar *et al.* [3] used DWT so as to extract high frequency details to reduce edge blurs in combination with learning and maximum a posteriori (MAP) approach, finally gradient descent method is used for minimization of the cost function and the image obtained is the HR image. Anbarjafari *et al.* [4] proposed a method in which high frequency sub bands obtained after DWT and the original LR image are interpolated then Inverse DWT is used in order to obtain the final HR image. Chopade *et al.* [5] proposed SR method that uses SWT in combination with DWT to avoid information loss that occurs due to down sampling in DWT. The extraction of neighbouring information required for the interpolation process is more effective if we are using the decomposed image compared to the use of the original LR image therefore we have used DWT in our proposed method.

Spatial domain methods include interpolation, reconstruction, filtering, sparse representation, learning, optimization etc. Interpolation based techniques are generally categorized as classical interpolations and edge based interpolations [6, 7]. Classical interpolations include linear i.e. nearest neighbour, bi-linear and non-linear i.e. cubic, bi-cubic and spline interpolation methods but mostly these methods are combined with other methods like wavelet based, learning based optimization based methods for obtaining better results because if used alone these methods suffer from reconstruction artifacts like jaggings, saw tooth edges, edge breaks, ringing effects etc. In edge based interpolation techniques recognition of edge region is done and then interpolation is used accordingly therefore such methods provide better results in edge regions. Although edge directed interpolations provide better results than classical interpolations, all these methods use duplication of available information for missing pixel calculation and therefore suffer from jagging, ringing and blurring effects.

To overcome the shortcomings of interpolation based methods several learning based methods have been introduced

[7-10]. CNNs and Deep learning algorithms provide excellent results [7] but are computationally complex to avoid this complexity simple networks like multi-layer perceptron (MLP), Radial Basis Function (RBF), Backpropagation network etc. are widely used [8-10]. San *et al*. [8] have used MLP and RBF in combination with wavelet packet transform for high frequency extraction whereas Man *et al*. [9] have proposed a method that uses registration process for estimation of relative motion between different LR images and then three layer MLP is used for interpolation. Hasan *et al*. [10] have used one of the algorithm from nearest neighbour, bi-linear and bi-cubic interpolation for the upscaling method and then feed forward backpropagation network is used for increasing quality of the interpolation. Instead of duplicating the neighbouring information, learning based methods actually learns to create a new pixel using available neighbouring information this enhances the quality of the resulting HR image therefore in our proposed method we have used learning based interpolation using MLP instead of classical interpolations.

PSO is used to optimize complex and non-convex cost functions obtained after various learning or reconstruction based methods and also for enhancement of the SR results in many algorithms along with classical interpolations or cutting edge learning based methods [11-14]. Gajjar *et al.* [11] have used PSO for final optimization of the cost function obtained after wavelet based learning and Maximum a posteriori markov random field (MAP-MRF). Quraishi *et al.* [12] have evolved a method which uses DWT and linear interpolation for obtaining HR images from input LR images subsequently PSO is used for enhancement of the results whereas Chen *et al*. [13] have used PSO only for the edge region, saliency model is used for the estimation of the edge region, and later, to obtain the HR image Artificial Neural Network-PSO (ANN-PSO) is applied in the estimated edge region and bi-linear interpolation is applied in non-edge region. Yu *et al.* [14] have proposed a mixed PSO algorithm for reconstruction based SR process to avoid shortcomings of basic PSO. Inspired by advantages of PSO, we have used it in our proposed method for visually dominant regions so as to avoid cracked, jagged or blurred edges and indirectly to enhance the interpolation process in that particular region.

Considering above mentioned points, we proposed an approach that integrates benefits of saliency model, DWT and PSO and MLP based interpolation to obtain HR images. The rest of the paper is organized as: In section II proposed method is discussed briefly. In section III experimental results (quantitative as well as visual) are presented for considered test images and section IV concludes the paper.

II. Proposed Method

Saw tooth or cracked edges is the most common problem in classical bi-cubic interpolation however some researchers tried to address this problem, combination of SWT with DWT proved to be better up to certain extent [5, 9], whereas Yu *et al.*'s method uses mixed PSO only for enhancement to overcome problems of all these methods we have proposed saliency guided SR method. In our proposed method Phase Spectrum of Quaternion Fourier Transfer (PQFT) saliency model is used to detect visually dominant regions and to generate the saliency map, DWT is used for extraction of the high frequency details, Missing HR pixel calculation is done with the help of MLP based interpolation in background region and using PSO based interpolation in visually dominant region. In-depth flow of our proposed method is given in the following section and the schematic diagram for obtaining HR image is shown in Fig.1.

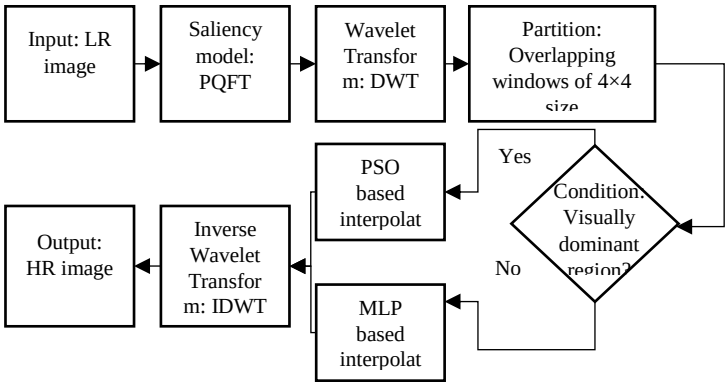

Fig. 1. Schematic diagram of our proposed SR method

A. *Saliency Model: Phase Spectrum of Quaternion Fourier Transform*

Saliency model is used to detect and extract visually dominant regions from an image [15]. Broadly saliency detection methods can be divided as spatial and frequency domain methods. Spatial domain methods are, Classical Itti model, AC algorithm, Region based Contrast (RC) model, Histogram based Contrast (HC) model, Context based CA (Context Aware) model, Graph Theory based algorithm, etc. but shortcomings of these spatial domain based saliency detection methods are these have very high computational complexity and are very sensitive to parameter selections therefore not very useful for real-time systems whereas frequency domain based saliency detection methods have comparatively low computational complexity and feature extraction is easier as compared with spatial domain methods therefore we have chosen frequency domain based saliency detection. Frequency domain based saliency detection methods include, PQFT, Spectral Residual, MSS (Maximum Symmetric Surrounded) and FT (Frequency Tuned) methods.

In our proposed method saliency is used as a sort of image segmentation that segments image into visually important and background part and output of this process is a saliency map. This acquired saliency map is then used for selection of the interpolation process. We have used PQFT algorithm for saliency detection, which uses only the phase spectrum of the input image after application of the Fourier transform but discards the magnitude spectrum and then by applying inverse Fourier transform obtained output is a saliency map of the input image. This saliency map contains only binary values, 1 for visually important regions and 0 for background regions.

Edges play a very vital role in the image. Interpolation process causes smoothing of the edges which degrades the quality of the resultant HR image, therefore to preserve the edge information extraction of high frequency details is essential and

we have used wavelet transform for this. Original LR image is used as an input for DWT and not the saliency map.

B. Wavelet Transform: Discrete Wavelet Transform

Wavelet Transforms decompose signals into both time and frequency domains that means it uses functions localized in both real and Fourier space. There are two main categories of wavelet transform one is a Continues Wavelet Transform (CWT) and other one is a Discrete Wavelet Transform (DWT). When wavelet transform uses discrete set of wavelets it is known as DWT, which fragments image into four mutually orthogonal set of components i.e. one low frequency sub band: LL known as approximation component which can be used for further decomposition and three high frequency sub bands LH, HL and HH represent vertical, horizontal and diagonal details respectively [16]. One – level decomposition using DWT is shown in Fig. 2.

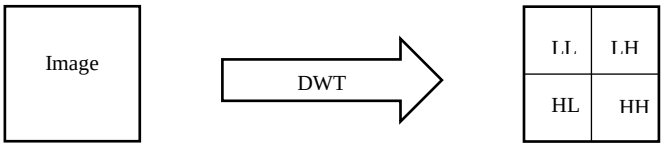

Fig. 2. One - level decomposition of an image using DWT

Haar, Daubechies, Morlets, Symlets, Meyer, Coeiflets and other real wavelets are different kinds of mother wavelets, among these wavelets, Haar wavelet is the simplest and since it is less smooth than other wavelets, it provides better results for the area with sharp edges. Therefore we have chosen Haar wavelet in our proposed method.

Each sub band obtained after DWT is divided into overlapping windows of 4×4 size and compared against the corresponding saliency map to check whether that window falls under the visually dominant region or not. If out of 16 pixels 8 or more pixels are having value 1 in the respective saliency map then that window falls under the visually dominant region and processed using PSO based interpolation otherwise it falls under the background region and processed using MLP based interpolation.

C. Optimization: Particle Swarm Optimization

The particle swarm optimization is a search algorithm motivated by the social behaviour of birds within a swarm and therefore the name is particle swarm. In PSO each particle modifies its position and velocity according to the neighbouring information, which indicates that each particle within the swarm is influenced by other particles [17]. Based on the fitness function, position and velocity updation of each particle is done respectively, by following equations.

$$p_i(t+1) = p_i(t) + v_i(t+1) \tag{1}$$

$$v_i(t+1) = v_i(t) + c \times r_1(t)[b_i(t) - p_i(t)] + s \times r_2(t)\left[\hat{b}(t) - p_i(t)\right] \tag{2}$$

Where $p_i(t)$ and $v_i(t)$ are position and velocity of the particle 'i' at time step 't' respectively, c and s are cognitive and social components respectively, r_1 and r_2 are any random numbers between 0 to 1, $b_i(t)$ is the personal best position which is the best position of the particle from the first iteration/time step till the current time step and $\hat{b}(t)$ is the global best position within the swarm i.e. the best of the personal best.

In our proposed method swarm is a window of size 4×4 and each pixel within the window is a particle. As our proposed method uses PSO only for the visually dominant region, only those particles having value 1 in the corresponding saliency map are considered while modifying position and velocity based on the fitness function. The fitness function is defined as:

$$f = min\left(\left|h_{window} - \frac{p_i \times \hat{b}_{window}}{\sum_{j=0}^{16} p_{j(iff\ p'_j=1)}}\right|\right) \tag{3}$$

Where h_{window} is the actual HR coefficient from the original HR image that is to be calculated, $\hat{y}_{window}$ is the global best for that particular window. Updation of position and velocity using (7) and (8) is done until there is no change in the global bests for continuous five iterations.

D. Learning: Multi-layer Perceptron

MLP is a feed forward neural network that uses supervised type of learning. That means for the learning process target vector is required for each of its input vector, this pair of input and target vector is called as training pair [18]. Number of hidden layers are variable and the values of hidden layer neurons are calculated using following equation.

$$z_j = b_j + \sum_{i=0}^{n} x_i w_i \tag{4}$$

Where, z_j is a hidden layer neuron, b_j is a bias, x_i is an input and w_i is a weight between input layer and hidden layer.

Output of MLP is calculated using

$$y = b + \sum_{j=0}^{m} z_j v_j \tag{5}$$

Where, y is a value of output neuron and v_j is a weight between hidden layer and an output layer.

Learning process of any neural network is associated with the weight updation and in MLP weight updation and bias updation is done using following equations respectively,

$$w_j(new) = w_j(old) + \alpha t x_j \tag{6}$$

$$b_j(new) = b_j(old) + \alpha t \tag{7}$$

Where, α is a learning factor and t is a target pixel value.

In our proposed method we have used two hidden layers for MLP. Input layer consists of 16 pixels which are taken from 4×4 window, first hidden layer also contains 16 pixels which are

calculated using (3), second hidden layer contains 4 pixels which are also calculated using (3), output layer contains only one pixel which is calculated using (4) and this output value is our calculated HR coefficient. This calculated HR value is then compared with the actual HR image's corresponding coefficient and difference is calculated. If this difference is greater than 25 % then weight and bias updation is done using (5) and (6) respectively otherwise no weight updation is required. Fig. 3 shows structure of used MLP in proposed method.

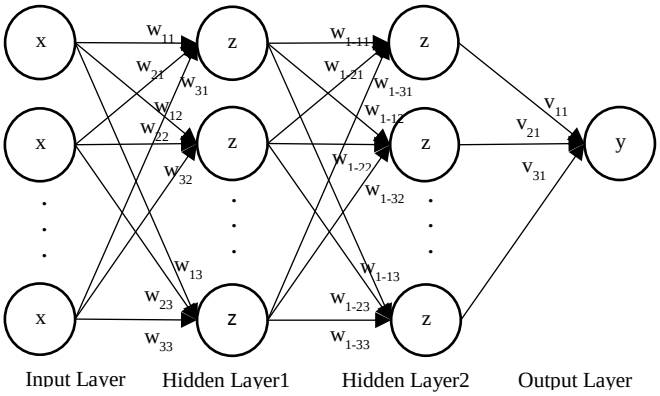

Fig. 3. Structure of the MLP used in proposed method

E. *Interpolation*

Interpolation is a process that uses known neighbouring pixel values for insertion of the new data at unknown points. In a procedure of conversion from LR image to HR image interpolation is used for calculation and insertion of unknown HR pixel with the help of neighbouring known LR pixels [6].

In proposed method interpolation is done using both learning i.e. MLP and optimization i.e. PSO methods, for this bi-cubic interpolation is taken as a base. In bi-cubic interpolation 16 neighbouring pixels of unknown pixel are used for weighted average as shown in Fig. 4.

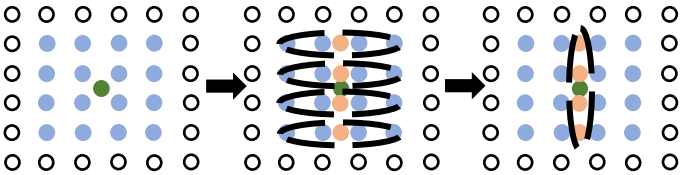

Fig. 4. Process of bi-cubic interpolation

In Fig.4 left most figure represents 16 known LR pixels, middle figure represents intermediate value calculation and final HR pixel calculation is shown in the right most figure. Blue coloured pixels are known LR pixels, as shown in the middle image, using weighted average of these pixels, 4 red coloured pixel values i.e. intermediate values are calculated horizontally, after that as shown in the right most image, vertical weighted average of these 4 intermediate values gives value of HR pixel.

F. *Inverse Discrete Wavelet Transform*

The Inverse of the DWT process is known as IDWT, and it is used to reconstruct the processed sub bands [16]. In our proposed method after PSO and MLP based interpolation, these interpolated high frequency sub bands and the interpolated LR image are combined using IDWT. First-level IDWT is shown in Fig. 5.

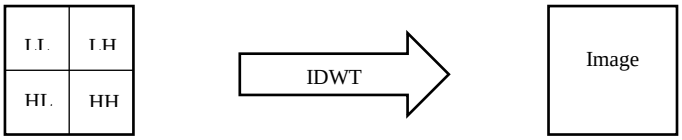

Fig. 5. Inverse Discrete Wavelet Transform of an image

III. Results And Discussions

Here, we have used "Football", "Baboon", "House", "Letters", "Parrot", "Monarch", "Foreman", "Peppers", "Texture 1" and "Texture 2" as test images for experimental purpose, as shown in Fig. 6. Experiments are performed on Intel core 3, 2.3 GHz processor with 4 GB RAM using MATLAB 2016a.

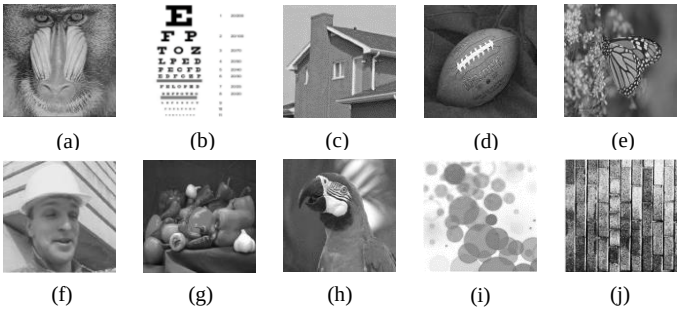

Fig. 6. LR Test images: (a) Baboon, (b) Letters, (c) House, (d) Football, (e) Monarch, (f) Foreman, (g) Peppers, (h) Parrot, (i) Texture1 and (j) Texture2

Performance evaluation of our proposed method with four predefined methods viz., bi-cubic method [6], Chopade *et al.* [5], Yu *et al.* [14], and Man *et al*. [9] using our considered test images is shown visually (as shown in Figs. 7-16) as well as quantitatively. For quantitative performance evaluation, we have used three full reference image quality estimation parameters viz., Peak Signal to Noise Ratio (PSNR), Structural Similarity Index (SSIM) and Normalized Cross Correlation (NCC) [19, 20]. Experimental results of these quality assessment parameters for all the considered methods and for our proposed method are listed in Table I also, Bar charts for each of the quality assessment parameters are shown in Figs. 17 (a-c).

In this paper, we have concentrated our work in the visually dominant region and for that saliency model and DWT are used. Therefore from the cropped part of Figs. 7-16 (e) we can see that our method gives better results in both edge as well as in non-edge region. Also, Results of quality assessment parameters of our proposed method for considered test images are high compared to bi-cubic, Chopade *et al.*, Yu *et al.* and Man *et al.* methods as shown in Table I.

IV. CONCLUSION

In this paper we proposed Saliency guided Image Super resolution using PSO and MLP based interpolation in wavelet domain, and therefore tried to combine advantages of all these methods. Though interpolation based methods produce processing artifacts, combining them with DWT, MLP and PSO avoids this problem also complexity of interpolation based methods is less than other SR methods therefore our proposed method acts as a mid-way between the complexity and the quality. Experimental results for considered test images show that our method gives a promising solution for SR problem and outperforms other considered methods.

However, selection of window for PSO or MLP based interpolation is based on the fixed condition i.e. if window contains 8 or more occurrences of 1 in its corresponding saliency model, then that region is considered as visually dominant region. This condition can be automated, but complexity of the solution will increase subsequently therefore, there is a need to

find a solution that will automate the process but will also not increase the complexity.

***Abstract*— Because of man-made occasions and regular causes, numerous areas on the land are experiencing quick and wide-running changes in vegetation spread. Vegetation is the significant piece of land spread and its progressions have a significant effect on the vitality and mass biochemical cycles. It is also a key marker of territorial natural condition change. Change discovery alludes to the way toward recognizing contrasts in the condition of a state by watching it at various occasions. The Multi Spectral Remote Sensing pictures are proficient for acquiring a superior comprehension of the earth condition and its changes. A Convolution Neural Network (CNN) plays a prominent role in classifying the images more accurately, compared to other Machine Learning algorithms. This paper concentrates on identifying the vegetation change in Bapatla region of Andhra Pradesh state, India between the years 2015 to 2017 using multi spectral Landsat images and deep learning techniques and the experimental results shown a decrease in vegetation land in approximately 240 square kilo meters.**

Keywords*— *Change Detection; Convolution Neural Network; Multi spectral; Vegetation Cover

I. INTRODUCTION

Due to the normal catastrophes and the occasions made by man on nature, fast changes are being seen on the society in numerous countries[1]. To get by on the earth, vegetation is one of the major source and profitable asset accessible on the earth. In order to understand and manage environment at large variety of temporal and spatial scales, up-to-date and reliable information is required all the time.

So as to spare these assets, one way is to gather the satellite pictures of those specific territories amid various timespans and investigate the progressions before they get vanished. Remotely detected information like aerial photos and satellite pictures are the main alternative that permits identifying land spread changes on a vast scale [2].

Satellite pictures have the capability of offering the most exact and most recent data contrasted with measurable, topographic or land use maps.

Manually, the changes cannot be identified from those images. Therefore, advanced techniques and systems are required to find out them. At present the Deep Learning Methods are very commonly used to trace out these changes [3]. In this paper, the vegetation land change in Bapatla region of Andhra Pradesh state, India between the years 2015 to 2017 was identified using Convolution Neural Network (CNN) [4] and to cross-check the acquired outcomes, Natural Difference Vegetation Index (NDVI) [5] concept was used.

The changes obtained through both the concepts were compared and it was observed a decrease of vegetation land in nearly 240 sq. km from both the methods.

II. LITERATURE REVIEW

Kevin and Louis de Jong [6] proposed an effective unsupervised technique for recognizing pertinent changes between two unique images of the equivalent scene. A CNN for semantic division is executed to separate compacted picture highlights, just as to group the identified changes into the right semantic classes. A difference picture is made utilizing the element map data created by the CNN, without unequivocally training on the target contrast pictures.

Kyungsun and Lim [7] proposed a novel change calculation for high goals satellite pictures utilizing CNNs, which does not require any preprocessing, for example, ortho-amendment and classification was proposed. They planned three encoder-decoder-organized CNNs, which yield change maps from an info pair of RGB satellite pictures.

Antonio Mazza [8] proposed a little sans cloud division of the objective picture, a smaller CNN is prepared to play out the ideal estimation. To approve the proposed methodology, they centered around the estimation of the NDVI, utilizing coupled Sentinel-1 and Sentinel-2 time-arrangement obtained over a rural area.

Meera Gandhi. G [9] presented an upgraded Change Detection technique for the examination of Satellite picture dependent on NDVI. NDVI differencing was used as change detection method.

Majed and Ibrahim [10] proposed that Remote Sensing information in blend with the fitting multispectral groups, for example, Landsat OLI/TIR and TM information were utilized to change discovery of vegetation spread utilizing vegetation records for the times of 1990 – 2015 in Ajloun zone, where this investigation zone has the most forest cover in Jordan.

III. THEORETICAL BACKGROUND

Different Algorithms are available in Machine learning and deep Learning for classification. Here CNN was used for accurate classification. And NDVI was used to validate the results obtained from CNN.

A. CNN

Convolutional Neural Networks are complex feed forward neural systems [4]. CNNs are utilized for image classification and recognition in view of its high accuracy. Major steps in classifying the images in the present work are as follows.

Input: Training Data, Output: Classified image
Step-1: Take the image dataset.
Step-2: Pass the data set through the first layer called convolutional layer (Conv2D) with activation function relu and filter of size (1,1).
Step-3: Flatten the output from conv2D layer.
Step-4: Give the flattened image to the Dense layer with 64 neurons and activation function, relu.
Step-5: Repeat Step 4 again with 32, 16 neurons and with same activation function.
Step-6: Give the output from step 5 again to the Dense layer with softmax activation function for 5 classes.
Step-7: Obtain final classified image output.

B. NDVI

The Chlorophyll in the plant observes visible light and transmits the Infrared light. The vegetation rate can be determined dependent on this wonder. NDVI evaluates vegetation by estimating the distinction between near infrared (which vegetation emphatically reflects) and red light (which vegetation assimilates). NDVI dependably extends from - 1 to +1. Negative quantities near -1 represent water bodies, values near +1 represent thick green leaves and NDVI near Zero indicate urban land [5].

NDVI will be calculated using equation 1

$$\text{NDVI} = \frac{\text{NIR}-\text{Red}}{\text{NIR}+\text{Red}} \quad (1)$$

where Red and NIR are the spectral reflectance measurements obtained in the red (visible) and near- infrared regions.

C. Accuracy

Accuracy is the most natural execution measure and it is essentially a proportion of effectively anticipated observation to all observations. The accuracy can be calculated using equation 2 [11].

$$\text{Accuracy} = \frac{\text{TP}+\text{TN}}{\text{TP}+\text{FP}+\text{FN}+\text{TN}} \quad (2)$$

Where, True Positives (TP) and True Negatives (TN) are the effectively predicted positive and negative classes which imply that the predicted positive and negative classes are same as actual positive and negatives. Whereas False Positives (FP) and False Positives (FP) occur when the actual and predicted values are different.

IV. EXPERIMENTAL RESULTS

The essential purpose for this research work is to discover whether the vegetation has expanded or diminished amid various timeframes. Figure 1 indicates the flow involved in this work.

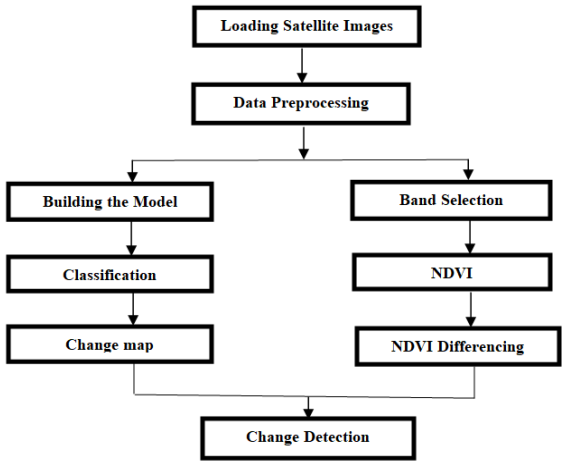

Fig.1. Architecture diagram

A. Dataset and Software used

The Source for the Dataset is US government Earth Explorer website (http://earthexplorer.usgs. gov/) [12]. Here Landsat 7 ETM scenes containing Bapatla, Guntur District, Andhra Pradesh, India Datasets with Latitude 15° 53' 47.8392" N and Longitude 80° 27' 37.5624" E. were considered. These are the multi-spectral images, comprising of 8 bands, for the years 2015 and 2017. To achieve this study, experimentation was done using Anaconda3 Installer version 5.3.0 with Python version 3.7.

B. Data Preprocessing

The aim of Pre-processing is an improvement of the image data that suppresses unwanted distortions or upgrades some image features for further processing. Data preprocessing here involves the Normalization, which evacuate the radiometric errors and effects of atmosphere by 'atmospheric correction' on the satellite images [13]. Next, image cleaning, which involves the removal of noise and Brightness corrections were performed.

C. *Building the Model*

Before building the model, image stacking, combining all bands into a solitary image was done. This was accomplished for both the years independently. There are various CNN architectures/models for image classification [14].

Here a model, which incorporates convolution and dense layers with activation functions 'Rectified Linear Unit (relu)' and 'softmax' were used. Relu [15] is to be used for nonlinear objects and soft max [16] in the case of multi class classification. The convolution layer is the first layer through which the image in the form of matrix of pixel values is passed into it. Then, by passing the channel filter to all positions, a matrix is acquired.

Dense layers perform classification on the features extricated by the convolutional layers. Commonly, a CNN is made out of a heap of modules that include feature extraction. The last module is trailed by at least one dense layer. The last dense layer in a CNN contains one node for each target class in the model, with a softmax function to create a value between 0– 1 for each node.

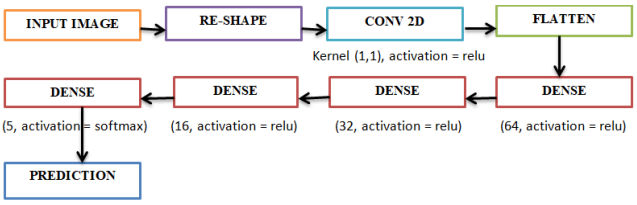

Fig.2. Model for Classification

The Model for classification used in this work is shown in the figure 2. Here the input image is reshaped and given to the Convolutional layer. Then, the software selects a filter with size (1,1) and the activation function used was relu. Next, the image is flattened and given to the dense layers. Initially, 64 neurons were given with relu activation function, followed by 32 and 16 neurons. Here, 5 classes namely Vegetation, Water, Roads, Buildings, Soil were considered. So, 5 neurons were given, one for each target class with soft max activation function in the dense layer. Thus, the image when passed through this model gets classified.

D. *Classification*

Since, a supervised CNN was used, training should be provided for it. The pictures from a similar territory, as shown in the figure 3 and figure 4 were considered as input for training the model. To know how precisely the model is functioning, the entire input was isolated as pixels into 70 percent train data and 30 percent test data. At first, the model was trained with 70 percent of the train data. Next, the test information was given to it. After getting the ideal accuracy, the two satellite pictures of the years 2015, 2017 were given as contribution to the model for classification. In this work, 5 classes, Vegetation, Water, Roads, Buildings, Soil were considered.

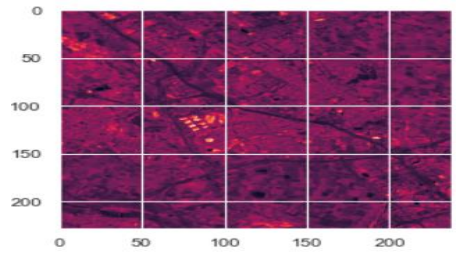

Fig.3. Sample Training Image1

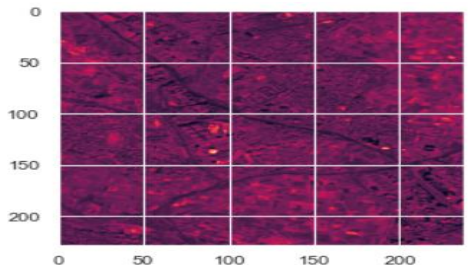

Fig.4. Sample Training Image2

E. *Change Map*

The change map was obtained by differencing the classified images one from the other pixel-by-pixel. The change map contains the changes in all the classes. By isolating each class from the change map, the change can be acquired independently for each class.

F. *Band Selection*

The 8 bands for Landsat 7 ETM are Blue, Green, Red, Near Infrared, Shortwave Infrared 1, Thermal, Shortwave Infrared 2, Panchromatic [17]. For calculating the NDVI, only red and near infrared bands are required [18]. In the Satellite sensor considered here, band 3 represents the red and band 4 represents the infrared. So, these bands were used to calculate the NDVI.

G. *NDVI Differencing*

NDVI Differencing is the process of subtracting one NDVI image from the other NDVI image. The NDVI images were produced by applying the NDVI to 2015, 2017 datasets separately by considering the red and infrared bands using equation 1. Since the Vegetation values of NDVI ranges from 0.3 to 0.8, only those pixel values were considered in the image obtained from NDVI Differencing and the change was calculated [5].

V. Experimental Results

A. *Confusion* Matrix

After training the model, a confusion matrix along with heat map[19], for the pictures used in classification was drawn between the actual and predicted values to know how accurately the model is working. Figure 5 shows the confusion matrix and the heat map for 5 classes. Here 1800, 1000, 3463, 3083, 577 pixels respectively in each class were correctly classified into the corresponding classes.

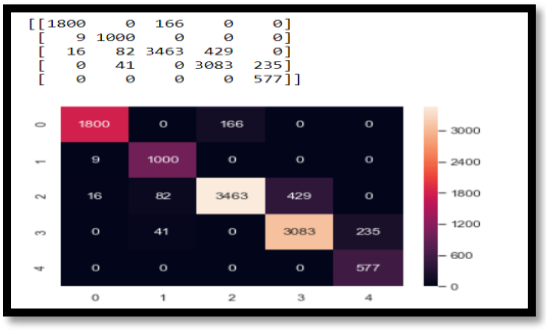

Fig.5. Confusion Matrix and Heat Map

B. *Accuracy of the Model*

By increasing the number of epochs from 1 to 15, the Accuracy of the Model increased from 82% to 92% and the loss decreased from 42% to 17% as shown in the figure 6.

```
Epoch 1/15

```

Fig.6. Accuracy of the Model

C. *Classified Image*

The 8 bands of Landsat 7 ETM Satellite were stacked together into a single image and then processed. The stacked images of 2015 and 2017 were passed to the model for classification. The classified images were shown in the figure 7 and figure 8.

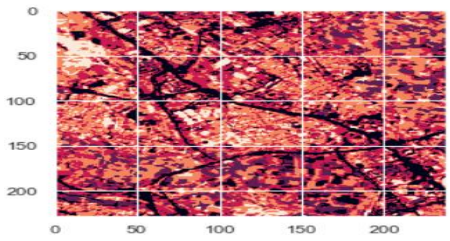

Fig.7. Classified Image of the year 2015

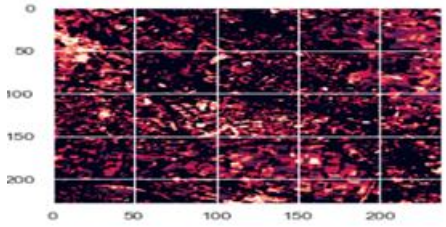

Fig.8. Classified Image of the year 2017

D. *Change in Vegetation*

The Change map was obtained by subtracting the classified images of 2015 and 2017 from one another The 5 classes from the change map were separated and change in each class was found out. Figure 9 shows the change in vegetation.

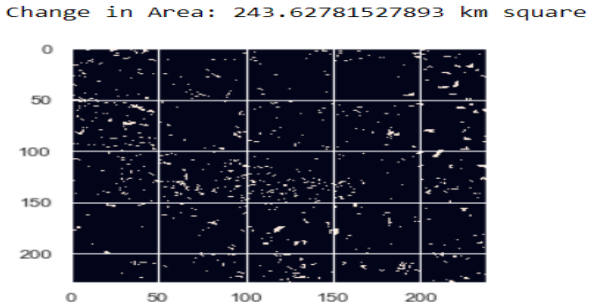

Fig.9. Change in Vegetation

E. *NDVI Images*

The NDVI images of the years 2015 and 2017 images were shown in the figures 10 and 11.

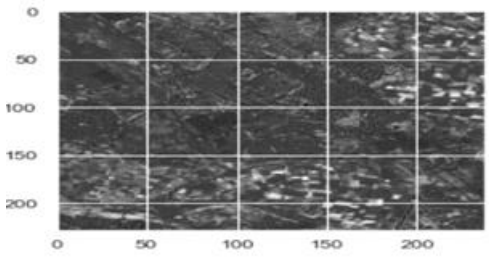

Fig.10. 2015 NDVI Image

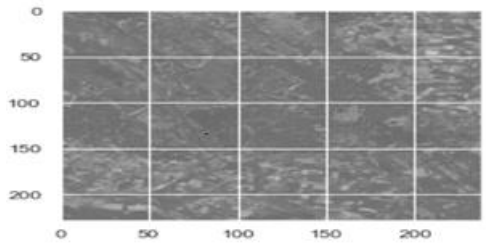

Fig.11. 2017 NDVI Image

F. *NDVI Differencing and Change Detection*

The NDVI Differencing was done through subtracting 2017 NDVI image from 2015 NDVI image. As vegetation index ranges from 0.3 to 0.8, by fixing a threshold as 0.3 to 0.8, the change in Vegetation was calculated and it was observed as 239.35 sq km as shown in the figure 12.

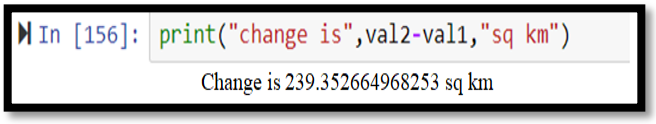

Fig.12. Change obtained through NDVI.

VI. CONCLUSION

The Change discovery is a proficient method to identify the changes in the regular assets and make vital strides before they become evaporated. For recognizing changes over various timespans, Remote Sensing will be extremely useful. This paper identified the change in Vegetation for the years 2015 and 2017 in Bapatla, Guntur District of Andhra Pradesh, India utilizing CNN and NDVI ideas. It has been seen that the Vegetation was diminished from 2015 to 2017. The reduction in vegetation got through CNN with an accuracy of 92 percent was 243.62 square kilometers and through NDVI was 239.35 square kilometers. The change acquired through both the ideas was almost equivalent.

Design of quadrature error correction loop for communication

Bhagyashri D.Kale

Student of YCCE,Nagpur

Dr.U.S.Ghodeswar

Asso.Prof.YCCE,Nagpur

***Abstract*— The proposed circuit is analog closed loop circuit which corrects quadrature error over high frequency range. The exhibited circuit comprises of stage bolted circle type engineering and it is helpful for quadrature blunder redress. Simple shut circle is utilized to address quadrature mistake for advanced clock. It consumes 1.99mA current from 1v supply over high frequency range. The circuit was design in cadence virtuoso software in 90nm technology file. The circuit works over high frequency range that is 100MHz to 2GHz. In presented method impact of duty cycle distortion due to mismatch in input clocks also discussed. The proposed technique works on high frequency as well as low frequency.**

Keywords— analog closed loop, duty cycle mismatch, quadrature, quadrature correction, quadrature error, phase locked loop,

I INTRODUCTION

Quadrature signal is the pair of periodic signal are said to be in quadrature when they differ in phase by 90 degree. This Quadrature phase separation is critical task, but quadrature separation is very important for wireless and wired communication. Presently a days advance in cmos innovation empower the usage of high recurrence quadrature signal generator, however quadrature partition is in charge of jumble in sign produce quadrature mistake after cautious format dealing with. Imbalance occurs in quadrature clock while separation those are phase imbalance and amplitude imbalance. The sufficiency awkwardness in quadrature clock is effectively cured by utilizing advanced cushion which act as plentifulness modulator and right the adequacy befuddle in clock. If there should arise an occurrence of stage unevenness requires stage change circuit to address it.

Quadrature error leads to different types of errors in different types of communication systems such as poor error vector magnitude performance in wireless transmitter and in wireless receiver it increase bit error rate ratio and wired communication it worsen the jitter which can affect eye parameter.[1] If quadrature error is present it also reduce the image rejection ratio because circuit is depend on the phase separation to achieve good image rejection ratio.

In this paper we present a simple circuit that constantly right the confounds in quadrature signal over the high recurrence extend. This analog circuit is based on phase locked loop type architecture. Low frequency and high frequency challenges are address in this paper. The present circuit is only design for wired and wireless communication. This system is targeted for the application of software define radio(SDR) and cognitive radio(CR).

(a)xor based doubler output when clocks are in perfect quadrature[1]
(b)xor based doubler output when quadrature error is present[1]

II RELATED WORK

Immual raja, student member ,ieee ,Vishal khatri , Zaira zahir and Gulab Banerjee proposed A 0.1-2GHz Quadrature amendment circle for advanced multiphase check age circuits in 130 nm cmos (2017) this paper shows a simple circuit that can persistently address quadrature mistake over high recurrence run. Here this analog circuit is based on the phase locked loop architecture. Both challenges at high frequency and low frequency are addressed in this paper.[1]

Immanuel Raja ,Gaurab Banerjee, Mohamad A. zeidan, jacob A. Abraham A 0.1-3.5 GHz Duty cycle measurement and correction technique in 130nm CMOS (2016) this paper presents a DCC (duty cycle corrector) technique by using PMC to correct duty cycle of the square wave over the frequency range of 100MHz to 3.5GHz this circuit works over frequency where most of the system fails.[2]

B.Kang Plan and examination of a ultra-wideband programmed self aligning upconverter in 65nm cmos (2012) here ultra-wideband phase interpolator is used to correct quadrature mismatches .ultra-wideband means it use very low energy for short range, high bandwidth

communications over high frequency. Phase interpolator is a circuit in the receiver of the serial link.[3]

Notten, Maxime BeMarc nard, A CMOS quadrature down-conversion mixer with analog i/q correction (2006) in this paper i/q gain and mismatches are corrected for down -conversion mixer with the help of variable resistance over the frequency of 470 MHz to 720MHz.[4]

S.Navid, F.Behbahani, A.Fotowat A Hajimiri Level bolted circle a strategy for broadband quadrature clock age (1997) In this paper mistake right between two quadrature signal a predisposition created by circle to move the dc dimension of info clock over the recurrence scope of 40 to 500 MHz [5]

III BLOCK DIAGRAM DESCRIPTION

A simple shut circle that having negative criticism which is utilized to address quadrature mistake between two clock stage Fig 1(a) describe two clocks that having 50% duty cycle and both are exactly quadrature so after XORing at output we get twice the input frequency and 50% duty cycle. In (b) both clocks are not perfectly quadrature and also not 50% duty cycle so after XORing output will be non 50% duty cycle means quadrature error is present in second case.

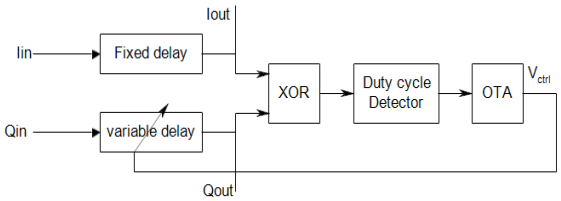

Fig 2 Block diagram of the quadrature correction loop

In Fig2 fixed delay which presented I way and variable delay is presented in Q way here fixed deferral is utilized here in light of the fact that it enables the circle to work over bigger scope of sign. Timekeepers from variable deferral and fixed postpone go to xor and quadrature blunder location is done at the yield of the xor. This yield go to DCD which produce voltage which is corresponding to obligation cycle at the info. Same voltage go to OTA which give addition to circle and create control voltage for variable deferral, as indicated by this control voltage variable postpone will fluctuate and quadrature mistake get remedied. In the event that edge partition between the I and Q tickers is not exactly $\pi/2$, at that point circle will deliver vctrl with the end goal that Q clock will be got more deferral than fixed postponement in I way. What's more, in the event that point partition is more than $\pi/2$, then vctrl produces littler than the fixed postpone way.

IV CIRCUIT LEVEL DISCRIPTION

A.Variable delay:-

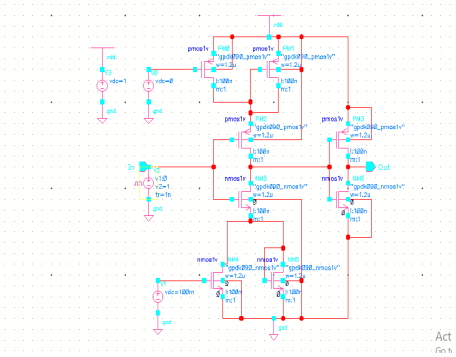

Fig 3 delay used in loop

Delay cell contain two inverter one current starved inverter and is followed by digital inverter. The current kept inverter comprises from a maneatis load for both Nmos and Pmos. Maneatis load gives surety of wide tuning of range, which helps in lessening the quantity of defer cells prompting territory and power saving. between input and output two inverters are present. The charging and discharging current of output capacitance is depends on first inverter i.e current starved inverter. The second stage inverter is for improving the ascent and fall time of circuit. The variety in deferral happen regarding control voltage.

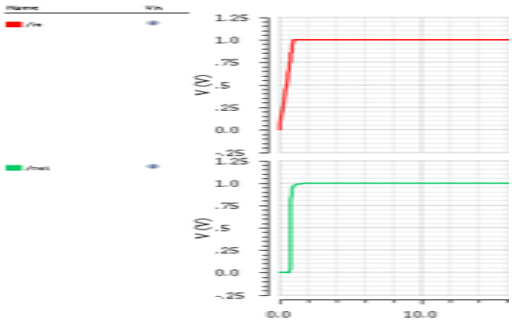

Fig4 output of delay

In presented output, output of delay will be same as input but gives some delay at output. If control voltage will vary then distortion of output will change and get proper output.

B. Current mode logic XOR

The xor rationale is use to change over quadrature blunder to obligation cycle mistake implies at the yield of xor quadrature detecting is performed whether responsibility cycle is half or not. It gives yield as double the information recurrence. For high recurrence input timekeepers it is beyond the realm of imagination to expect to execute with straightforward xor on account of that cml xor is utilized.

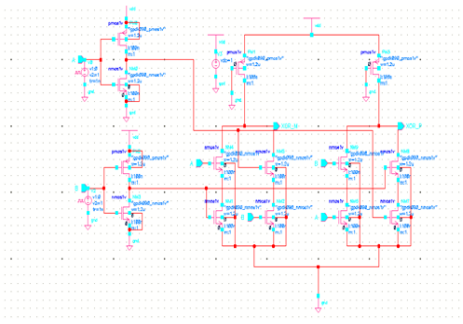

Fig5 schematic of CML-based XOR

In usage Nmos transistors with Pmos load as appeared in the fig. The proportion of the time length for which the sign is more prominent than the regular mode voltage to the all out time is taken as obligation cycle

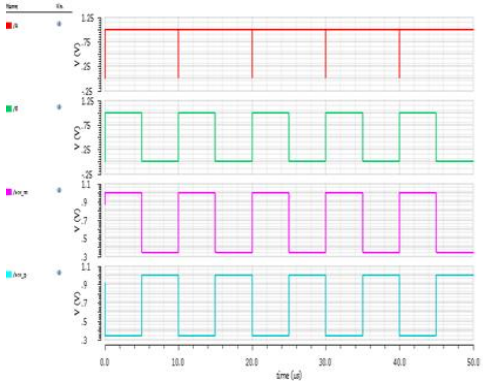

Fig 6.Output of cml xor

Here in output of cml xor will get two output one is xor and another one is xnor output which is totally opposite to the xor output and here useful output is xor.

C. *Duty cycle detector*

DCD is a DA (differential enhancer) based channel ,here current guided through one arm or other by the yield of cml xor . At yield of dcd two capacitors are available on each arm. It is dynamic low pass channel which create differential dc normal voltage yield of xor. This yield is corresponding to the yield of xor. DCD is differential amplifier which produce output difference of two input signal.

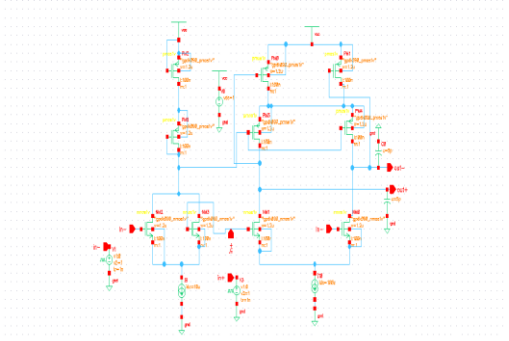

Fig 7. DCD schematics

Output of DCD

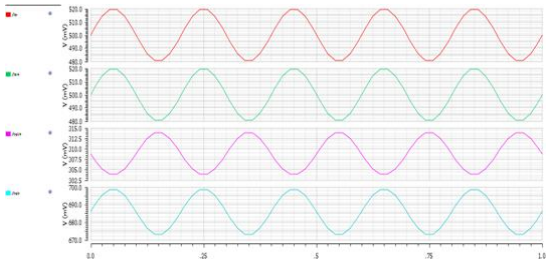

Fig 8 waveform of DCD

The output of DCD is based on differential amplifier, here both input having same phase so at the output we are getting opposite cycles it means difference of both input is zero. If at the output of DCD both the cycle is in same phase that means duty cycle is of 50%

D. *Operational trans- conductance amplifier*

OTA is use to give increase to the circuit and it create control voltage. Ota provide control voltage to variable delay with the help of bias translational circuit. The circuit is biased at 100uA.

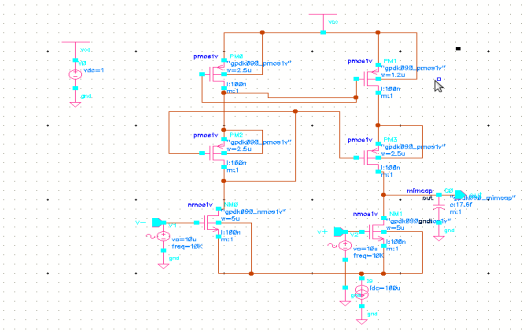

Fig 9. Schematic of OTA

Capacitor is set at the yield of OTA for additionally separating for the control voltage. Here OTA provide gain 21dB. Voltage of OTA transfer to variable delay and according to this voltage variable delay vary and quadrature error will get corrected

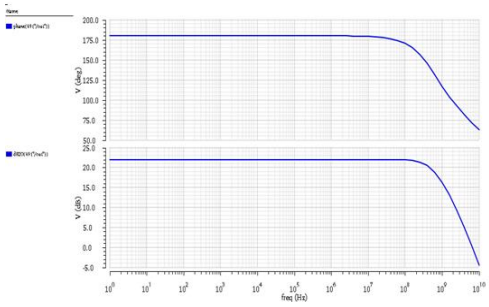

Fig 10 waveform of OTA

From AC analysis we can say that circuit will work 10^9 Hz frequency shows in first waveform and second waveform shows that it gives gain of 21dB.

E. *Bias-translational circuit*

Two voltages for variable delay are send from bias translational circuit. The output voltage of OTA are provided to bias translational circuit. The output voltage is provides for nmos and pmos of control voltage.

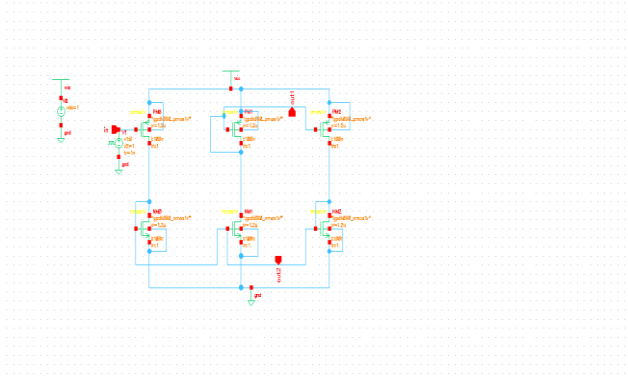

Fig 11 Bias translational circuit schematic

Input to the bias translational circuit is vpulse and at the output we will get two equal voltages. This bias translational circuit gives for 1v at output is 500mv and 500mv of two voltages

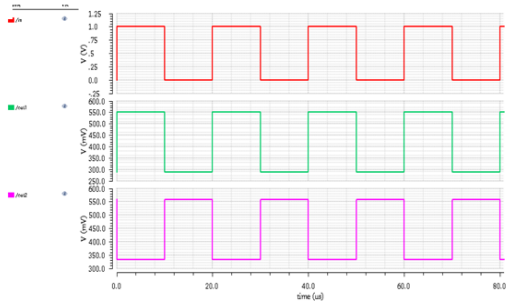

Fig 12 output of bias translational circuit

V MATHEMATICAL ANALYSIS OF THE QUADRATURE LOOP

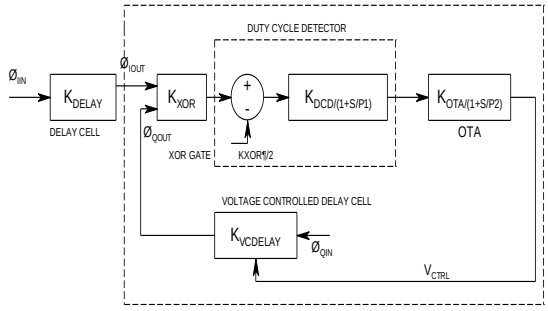

Fig 13. Mathematical representation of quadrature correction loop

Let ΦIin is the period of the information I clock and ΦQin is the period of Q clock. ΦIout is the yield from fixed deferral while ΦQout is yield from variable postponement. The quadrature mistake among ΦIin and ΦQout is limited by second request negative input circle which produce control voltage for the voltage controlled defer cell. Φqe is the quadrature mistake between the ΦIout and ΦQout. The XOR square has gain Kxor and it convert quadrature blunder Φqe into obligation cycle deviation. In the event that obligation cycle is half, at that point at the yield of xor it spoken to by KXOR(π/2).If duty is non 50% then DCD will detect and generate voltage corresponding to duty cycle. DCD is used as low pass filter having pole p1 and gain $K_{DC.}$ This voltage pass to the OTA and it will amplify the voltage. It has dc gain K_{OTA} and pole p2 generate voltage $V_{CTRL.}$ This voltage pass to variable delay introduce some delay in ΦQin and generate ΦQout.
So yield period of quadrature clock ΦQout is given by

$$\phi_{Qout} = K_{xor}.\phi_{Iin} - K_{xor}.\phi_{Qout} - K_{xor.\Pi/2}.\frac{K_{DC}}{(1+s/p1)}.\frac{K_{OTA}}{(1+s/p2)}.K_{VCDELAY}$$

……(1)
Take K_{XOR} common

$$\phi_{Qout} = K_{xor}\left(\phi_{in} - \phi_{Out} - \frac{\Pi}{2}\right).\frac{K_{DC}.K_{OTA}.K_{VCDELAY}}{\left(1+\frac{s}{p1}\right)\left(1+\frac{s}{p2}\right)} \quad \text{……..(2)}$$

Let $K_{xor}.K_{DC}.K_{OTA}.K_{VCDELAY}$ = K
Then closed loop equation for ϕ_{Qout}

$$\phi_{Qout} = \frac{K\left(\phi_{in} - \phi_{Out} - \frac{\Pi}{2}\right)}{\left(1+\frac{s}{p1}\right)\left(1+\frac{s}{p2}\right)} \quad \text{……(3)}$$

After solving equation

$$\phi_{Qout} = \frac{p1p2\left(K\phi_{in} - K\phi_{Out} - K\frac{\Pi}{2}\right)}{p1p2\left(1+\frac{s}{p2}+\frac{s}{p1}+\frac{s^2}{p1p2}\right)} \quad \text{……(4)}$$

Multiply p1p2 to bracket at denominator

$$\phi_{Qout} = \frac{p1p2\left(K\phi_{in} - K\phi_{Out} - K\frac{\Pi}{2}\right)}{p1p2 + p1s + p2s + s^2}$$

$$\phi_{Qout} = \frac{p1p2\left(K\phi_{in} - K\phi_{Out} - K\frac{\Pi}{2}\right)}{s^2 + (p1+p2)s + p1p2} \quad \text{……}$$

..(5)
Multiply denominator with ϕ_{Qout}

$$\phi_{Qout}\left(s^2 + (p1+p2)s + p1p2\right) = p1p2\left(K\phi_{in} - K\phi_{Out} - K\frac{\Pi}{2}\right)$$

$$\phi_{Qout}s^2 + \phi_{Qout}(p1+p2)s + \phi_{Qout}p1p2 + p1p2K\phi_{Out} = p1p2\left(K\phi_{in} - K\frac{\Pi}{2}\right) \ldots$$

……..(6)
Take ϕ_{Qout} common and will get

$$\phi_{Qout} = \frac{K\left(\phi_{in} - \frac{\Pi}{2}\right)p1p2}{s^2 + (p1+p2)s + (p1p2 + p1p2K)}$$

$$\phi_{Qout} = \frac{K\left(\phi_{in} - \frac{\Pi}{2}\right) p1p2}{s^2 + (p1+p2)s + p1p2(1+K)} \quad \text{……..(7)}$$

ω_η is the common recurrence and ξ is the damping coefficient of the framework

$$\omega_\eta = \sqrt{(K+1)\,p1p2}, \quad \xi = \frac{p1+p2}{2\sqrt{(K+1)(p1p2)}}$$

$$\omega_\eta \xi = \frac{p1+p2}{2} \quad [1]$$

The shafts p1 and p2 avoid the middle to limit the settling time. In any case, separate between p1and p2 posts choose the abundancy of the swell on control voltage this presents jitter in the clock. In the event that p1 and p2 are keep nearer to focus, at that point low pass activity is better and control voltage is exceptionally slick. To limit the quadrature mistake a high estimation of K is required.

VI IMPACT OF DUTY CYCLE DETECTOR

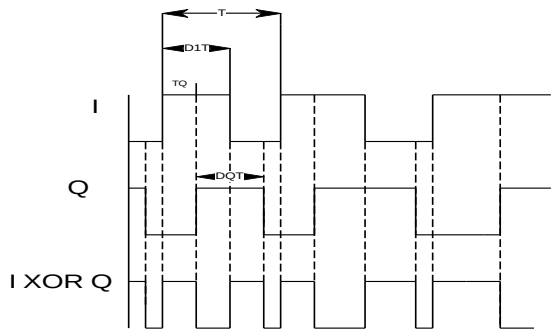

Fig 14. Impact on duty cycle

In above fig I and Q the two tickers having T timeframe and flipping somewhere in the range of 0 and 1. The time slack between two tickers is TQ. At the point when this apply to quadrature circle then non half obligation cycle sway the amendment execution of circle . this system is valuable for location of quadrature mistake. The circles accuracy is rely upon the quadrature finder. Henceforth sway on obligation cycle is broke down.

The output of xor is given to DCD which generate the dc normal of yield of xor

So

$$x(t) = i(t) \oplus q(t) \quad \text{……..(1)}$$

Let d(t) is output of the DCD

$$d(t) = \frac{1}{T}\int_T x(t)dt \quad \text{……..(2)}$$

$$= \frac{1}{T}\left(\int_0^{T_Q} 1dt + \int_{D_I T}^{T_Q + D_Q T} 1dt\right)$$

$$= \frac{1}{T}(T_Q + T_Q + D_Q T - D_I T)$$

$$= \frac{2 \times T_Q}{T} + (D_Q - D_I) \quad \text{……..(3)}$$

To analyze the quadrature error, we can write

$$T_Q = \frac{T}{4} + Q_e \quad \text{……(4)}$$

Here Q_e is quadrature error between I and Q clocks so d(t) can be write

$$d(t) = \frac{1}{2} + \frac{2 \times T_Q}{T} + (D_Q - D_I) \quad \text{….(5)}$$

In above condition demonstrates change of quadrature mistake and obligation cycle blunder in the yield of DCD

On the off chance that the two checks are in ideal quadrature there is no contortion in obligation cycle

$$d(t) = \frac{1}{2}$$

Here is the dc average of a 50% duty cycle .

A nonzero quadrature error (Q_e) result is

$$d(t) = \frac{1}{2} + \frac{2 \times Q_e}{T}.[1] \quad \text{……(6)}$$

VII IMPLEMENTATION CIRCUIT AND RESULTS

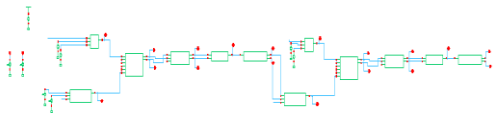

Fig 15.implemented quadrature correction loop

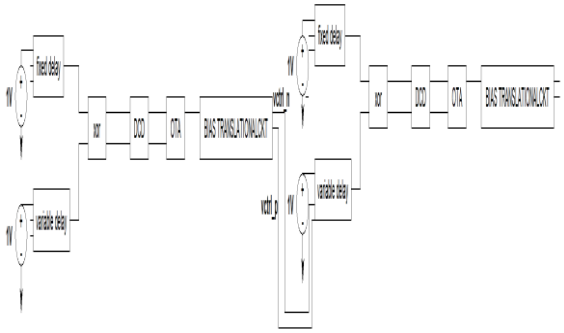

In implemented circuit all modules are combined and voltage provide to the circuit is 1v and the same circuit is built in 90nm technology file. First two block is of delay blocks one is fixed delay and second is of variable delay. Fixed delay inputs are vpulse for main input and other input contains 0v supply and output is given to xor. Variable delay again contain vpulse to main input another input is comes from bias translational circuit. The output of variable delay is given to second input of xor. At the output of xor quadrature sensing is done same output is given to DCD and DCD generate voltage according to input. The same output of DCD is pass to input of OTA and OTA gives amplified voltage to bias translational input and bias translational dive this voltage and pass to variable delay.
The output of this loop is as below

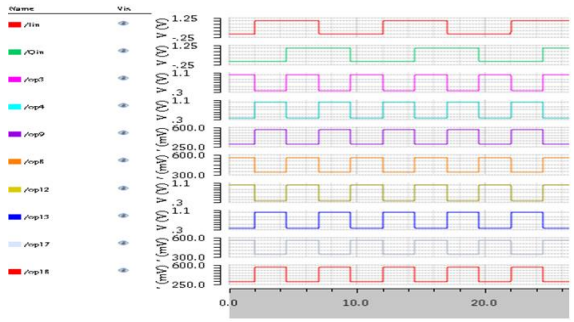

Fig 16. Exact quadrature clock

In fig 16 shows exact quadrature clock here angle between Iin and Qin is 90 degree and therefore at output we are getting 50% of duty cycle it means there is no error present in the clocks.

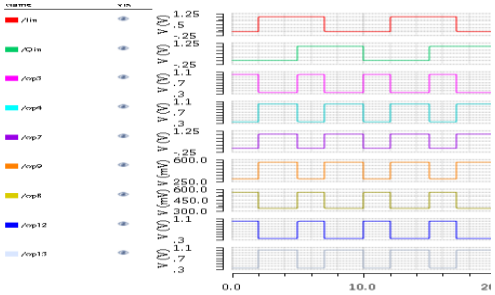

Fig 17. Angle between Iin and Qin is greater than 90 degree.

The above fig 17 shows that angle between Iin and Qin is greater than 90 degree so at the output we are not getting 50% of duty cycle it means here quadrature error is present so after correction the waveform will look like below waveform

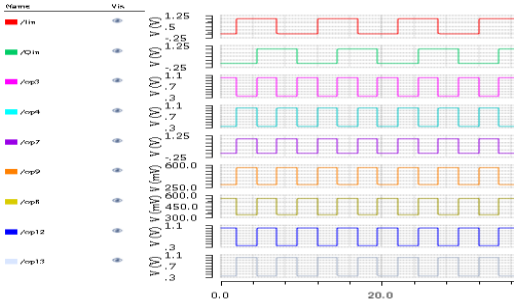

Fig 18 corrected waveform for greater than 90deg.

Now in above fig we can see that duty cycle is of 50% means error is removed in this clocks signal and both clocks in perfect quadrature. Here variable delay get vary it will be less than the fixed delay and before variable delay was greater then it will become less than previous delay

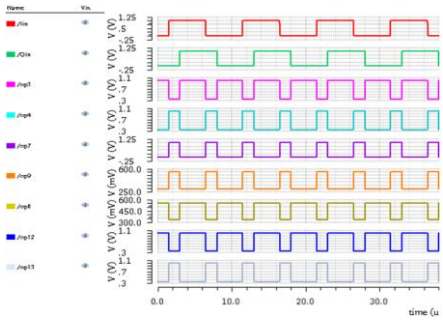

Fig 19. Angle between Iin and Qin is less than 90degree

In above angle between Iin and Qin is less than 90 degree so in output we are getting non 50% duty cycle it means there is quadrature error is present so corrected output waveform is given below

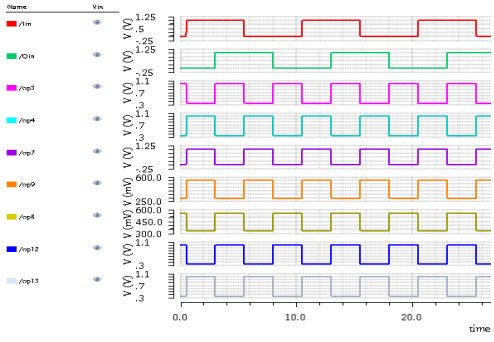

Fig 20. Corrected waveform from less than 90 degree

In above fig quadrature error get corrected because at output we are getting 50% duty cycle. So here variable delay vary and error get corrected. Variable delay is greater than fixed delay means previous variable delay was greater than the after corrected waveform.

Table1 Comparison with previous circuit

Specifications	Previous method	Present method
Technology	130nm	90nm
Power dissipation	4.49 mw	1.19mw
Voltage required	1.2v	1v
Current required	5.4mA	1.99mA

VIII CONCLUSION

In proposed method quadrature error of signal is corrected with the help of analog closed loop circuit the loop is based on the phase loked loop architecture.If angle between two clock signal is greater than 90 deg then variable delay will be less than the fixed delay and when angle between two clock signal is less than 90 deg then variable delay is greater than the fixed delay. power dissipation also minimized as compare to previous technology.

IX FUTURE SCOPE

Through the performancee of the system in terms of quality is satisfactory for the application of quadrature error correction loop that is analog closed loop. But for specific angle measurement and correction is also required for duty cycle correction so this kind of improvement is required
.

Abstract **— Lower voltage as well as high-speed subthreshold logic circuits are becoming important factors in modern VLSI technology. At subthreshold region, the effects of the process variations and the diminished ratio of active current to ideal current can introduce timing errors. These timing errors are responsible in the vandalism of the working capacity of the circuits operated at subthreshold region. An increase in propagation delay is observed when the threshold voltage of MOSFET is more than the supply voltage. This paper proposes a circuit to reduce the timing errors keeping the energy consumption to minimum amount. The proposed circuit uses a multiplexer implemented using transmission gates, to be used in the longest delay path of the logic circuit which is operated at subthreshold region. Forward body biasing notion is used to lower the MOSFET's threshold voltage and is incorporated in the proposed circuit, thus, reducing the switching time of the MOSFETs. The proposed circuit is implemented using Cadence Virtuoso at 45 nm technology and compared with the circuit studied from literature survey. The supply voltage for the combinational circuit and the proposed circuit and the D flip-flop was 287 mV. The forward body biasing voltage V_{SB} for NMOS and PMOS MOSFET was equal to 287 mV. The proposed circuit is applied to the longest delay path of the 64-bit ripple carry adder operated at subthreshold region and the switching delay for high going and low going transition are measured and are reduced by 48.14% and 26.60% respectively. Also, the slope of transition of the output signal has been increased by 53.08% & 8.14% for rise and fall respectively. The total propagation delay diminished by 30.12% as compared to existing technique. The energy per cycle and energy-delay product (EDP) turned down by 33.10% and 53.31% respectively, over the existing technique.**

Keywords **— Body biasing, subthreshold logic circuits, critical path delay, transmission gate, multiplexer**

I. INTRODUCTION

In modern VLSI technology, for low-power appliances sub-threshold digital circuits are becoming more important. Dynamic energy used by the digital subthreshold logic circuits can be reduced by decreasing supply voltage. But, whenever supply voltage becomes less than the threshold voltage of MOSFETs, it increases propagation delay. Digital logic circuits endure the process variation effect, whenever they are operated at the subthreshold region.

Furthermore, the subthreshold circuits endure diminished active to idle current ratio. This diminished current ratio and process variations effects encountered at subthreshold circuits can introduce timing errors. These timing errors damages the working ability of the subthreshold circuits.

In this work, a circuit is proposed which is to be used in the longest delay path (critical path) of the logic circuit operated at subthreshold region. The circuit uses multiplexer implemented using transmission gate. As an application, the proposed circuit is used in the critical path of the ripple carry adder with 64 bits to bring down the longest path delay. The MOSFETs using in the transmission gate of the proposed circuits are forward body biased so as to vary the threshold voltage that brings about variation in the switching characteristics of the circuit. Body biasing technique uses the body terminal for changing the threshold voltage of MOSFET. The proposed circuit that is applied to 64-bit ripple carry adder operated at subthreshold region, is implemented in Cadence Virtuoso at 45 nm technology and is compared with the existing circuit.

As an overview of the paper, Section II records the similar work to bring down the delay in critical path of subthreshold logic circuits. Section III, proposes multiplexer based circuit to be used to minimize the critical path delay whereas Section IV explore the implementation of the proposed circuit and its usage in 64-bit ripple carry adder as an application along with the simulation and comparative results with reference to the existing circuit. Section V deals with conclusion and future scope.

II. RELATED WORK

Certain methods to minimize critical path delay and energy for subthreshold circuits that require extremely low power are discussed in this section. Adaptive feedback equalized technique proposed in [1] reduces the critical path delay and provides energy improvement in subthreshold digital circuits. In this, the author used a feedback equalization technique using a variable threshold inverter as shown in Fig. 1(a). The inverter's threshold voltage is also called as mid-point voltage of the voltage transfer characteristics. This technique causes a change in the inverter's threshold voltage based on the output of the logic circuit, so as to introduce faster switching. Changes in the inverter's threshold voltage, in turn, changes the range for logic '0' and logic '1' quickly, based on the variation in the output available in the critical path of the logic circuit operated at subthreshold region of operation. The critical path delay signal is registered in the flip-flop. This feedback equalization circuit improves the switching range at a faster rate, using more number of MOSFETs in the used two feedback paths.

Feedback equalized technique proposed [2] reduces the critical path delay and energy of the circuit operated at

subthreshold. Here, authors have proposed only one feedback path. This technique is not applicable, if previous output and present output of combinational logic block are same. [3] presents the use of feedback equalization technique for the non-subthreshold circuit, using Schmitt-trigger to reduce the switching time. Transistor sizing methodology is proposed in [4] decreases the effect of process-variations. This approach introduces more MOSFET parasitic leading to increase in propagation delay of subthreshold logic circuit.

III. Proposed Model for Critical Path Delay Improvement

The proposed circuit shown in Fig. 1(b), uses a multiplexer implemented using transmission gate to minimize the delay along the critical path. The critical path is the longest path of the logic circuit and is used when operated at subthreshold region to improve the switching characteristics so that the output of the combinational logic circuit is registered in a flip-flop at a faster rate. The shown combinational logic block is operated at subthreshold region, that increases the delay in the generation of the output signal. The suggested circuit is used to improve the working of combinational circuits along the critical path by lowering the delay.

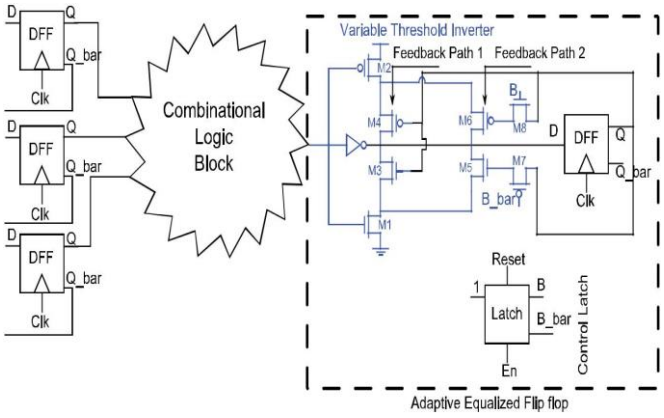

Fig. 1(a). Existing logic design using feedback equalization to improve the critical delay through logic circuit operated at subthreshold region [1].

The multiplexer based circuit uses two transmission gates TG1 and TG2 [5]. A single transmission gate is the parallel connection of PMOSFET and NMOSFET. The input to the NMOSFET of TG1 and TG2 are complement of each other. The MOSFETs used in the transmission gate are body biased. The forward body bias technique is used to reduce the threshold voltage of n-type and p-type MOSFETs. In this circuit, data inputs provided to multiplexer are constant logic '0' and '1'. The select line of the multiplexer is the critical path signal of the logic circuit operated at the subthreshold region. The advantage of transmission gate is that they provide strong '1' and '0' values.

When the TG (transmission gate) is ON, both n-type and p-type MOSFETs are ON and they are in OFF state when the transmission gate is turned OFF.

When the critical path output C_{out} of the logic circuit operated at subthreshold region is equal to zero, TG_1 will be in ON mode (MOSFET M_1 and M_2 are ON as shown in Fig. 1(b).) and at the same time, TG2 will be in OFF mode (MOSFET M_3 and M4 are OFF as shown in Fig. 1(b).), causing the multiplexer output to be strong logic '0'.

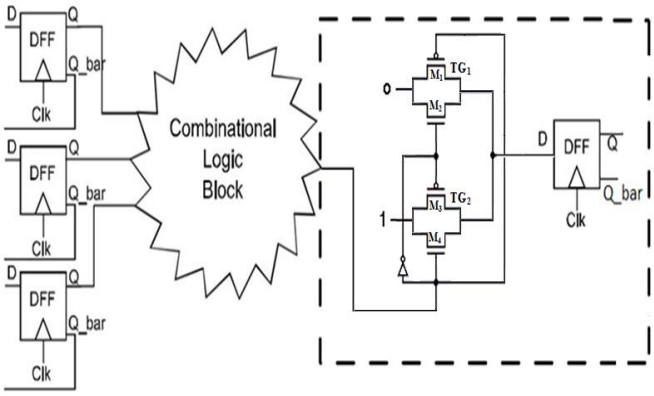

Fig. 1(b). Proposed circuit to improve the working of logic circuit along the critical path.

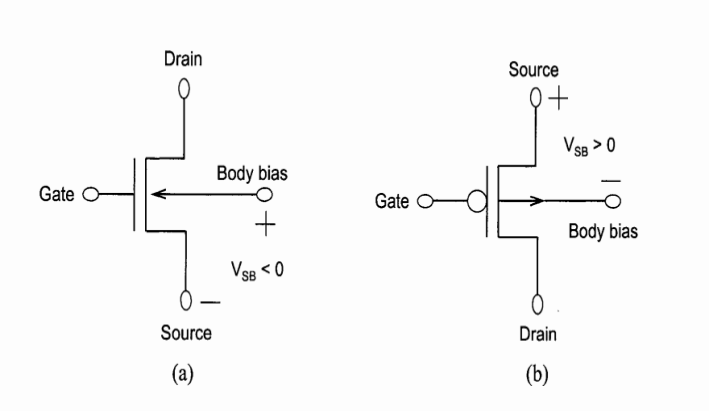

Fig. 1(c). Forward body-biased MOSFETs. (a) NMOS. (b) PMOS [7].

When the critical path output C_{out} of the logic circuit operated at subthreshold region is equal to logic one, TG_1 will be in OFF condition (MOSFET M_1 and M_2 are OFF as observed in Fig. 1(b).) and at the same time the TG2 will be in ON (MOSFET M_1 and M_2 are ON as observed in Fig. 1(b).), producing the multiplexer output as strong logic '1'. The MOSFETs used in the transmission gate are forward body-biased to decrease the threshold voltage of MOSFETs. The idea here is, though the C_{out} switches to the other logic level with higher delay, the MOSFETs used in the transmission gates are made more sensitive to the signal C_{out}, since their threshold voltage is reduced and causes the output of the multiplexer to switch faster. The proposed design can scale-down the transition time of MOSFETs and in turn bringing down the critical path delay of any logic circuit operated at subthreshold region.

The body terminal is used to change the threshold voltage of MOSFETs at the time of circuit operation. The change in threshold voltage of MOSFET using body biasing totally depends on the voltage polarity at source and body terminals (V_{SB}) as shown in Fig. 1(c). Source-substrate p-n junction of MOSFET when reverse or forward biased, increases or decreases the threshold voltage of MOSFET respectively [6]. The width of the depletion region below the gate is reduced by operating MOSFET in the forward-body biasing. Ionic charge in the depletion region will be decreased by reducing the depletion width. To keep up the charge

balance, the mobile charge (number of electrons for an NMOSFET) within the inversion layer increases. After increasing the number of mobile charges within the inversion layer, the gate voltage of the MOSFET required reduces to reach a similar level of the inversion as compared to a zero body biased MOSFET. Therefore, after applying forward body biasing in the MOSFET, the threshold voltage will decrease [7].

Drivability of the MOSFET becomes better with forward body biasing [8-9]. Operating at subthreshold voltage lowers the power consumed [10]. Turning down the supply voltage to near threshold voltage in devices with short channel length, is a constructive solution for ultra-low power applications [11].

IV. Simulation Resuls

The proposed circuit using multiplexer and the existing adaptive feedback equalization circuit are individually applied to 64-bit ripple carry adder operated at subthreshold region, are implemented in Cadence Virtuoso that uses 45 nm technology and results are compared for the two designs for various parameters. Both the designs are operated at 287 mV of supply voltage. 64-bit ripple carry adder has been selected as an application of the proposed delay minimization circuit. The critical path of 64-bit ripple carry adder is found on the final carry output generated at last. Hence, the proposed multiplexer based circuit is used for this carry output signal, C_{out} of the ripple carry adder with 64 bits to decrease the delay along critical path in terms of switching the signal faster so that it can be captured by flip-flop at a faster rate. The supply voltage for the combinational circuit and the proposed circuit and the D flip-flop was 287 mV for both the designs. The forward body biasing voltage, V_{SB} for NMOS and PMOS MOSFET was equal to 287 mV. The threshold voltage of p-type and n-type MOSFETs before body biasing was measured to be 441 mV and 496 mV respectively. The threshold voltage of PMOS and NMOS MOSFET after body biasing was measured to be 387 mV and 455 mV respectively.

A. *Implementation of 64-bit Ripple-carry Adder*

The ripple-carry adder with 64 bits is implemented at 45 nm technology and operated at subthreshold region. Sixty-four full-adder cells are cascaded so that output carry of current stage full-adder is carry forward as an input carry to the consecutive stage full-adder and so on. The block diagram of a ripple-carry adder that can perform operations with 64 bits as input is as shown in Fig. 2. Here, sixty-four inputs A_{63} to A_0 and B_{63} to B_0 are provided to full adder cells 63 to 0. S_{63} to S_0 are the sum outputs of the sixty-four stages of the full-adder. Here, C_{in} acts as initial carry input for the beginning stage full adder and C_{out} is the carry output signal in the final stage of 64-bit ripple carry adder.

B. *Implementation of Proposed Multiplexer-based circuit using forward body-biasing*

The existing circuit of adaptive feedback equalization is implemented and applied to 64-bit ripple carry adder operated at subthreshold region. The entire circuit has been implemented in Cadence Virtuoso at 45 nm technology operating at 287 mV of supply voltage. Fig. 3(a) shows output of this implementation which uses adaptive feedback equalization idea to improve the critical path delay. Here, to bring out more clarity on the analysis, the input applied on A_{63} to A_0 have same input signal and B_{63} to B_0 have same input signal. A_0, B_0 and C_{in} are the input signal of first 1-bit full adder while, C_{out} is the final output carry signal of the combinational logic block. E_Out signal is the output signal of the adaptive feedback equalization technique before reaching the D flip-flop.

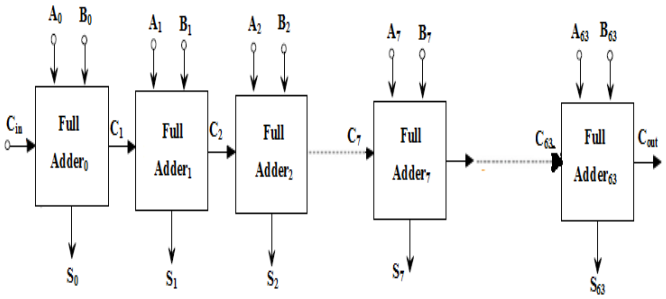

Fig.2. Block diagram of ripple carry adder with 64 bits.

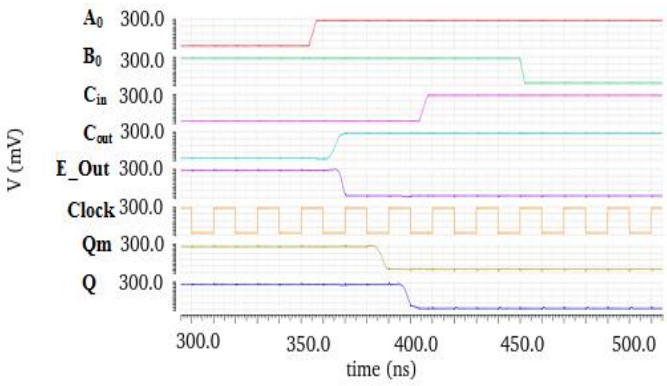

Fig. 3(a) Functionality of existing logic circuit using adaptive feedback equalization technique applied for 64-bit ripple carry adder to improve the critical path delay.

The proposed circuit to decrease the critical path delay uses multiplexer. The multiplexer is implemented using two transmission gates. The select line of the multiplexer is the critical path output signal of the combinational logic block whose delay need to be minimized. The signal that goes to the transmission gates NMOS MOSFETs is complementary of each other, so that when TG1 is ON, TG2 is OFF and vice versa. The MOSFETs used in the transmission gates are forward body biased so as to reduce the threshold voltage of these MOSFETs making them more sensitive to the signal having higher switching delay characteristics. Therefore, this leads to the increase in the slope of the switching characteristics of the signal i. e. rising slope and falling slope of the signal.

The transient analysis showing the functionality of the 64-bit ripple carry adder when used with the proposed circuit to minimize the critical delay is shown in Fig 3(b).

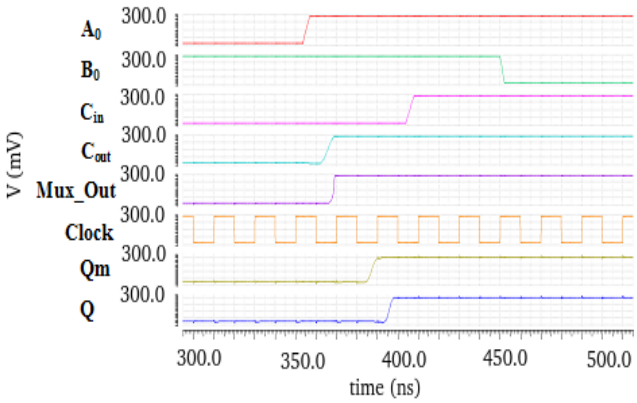

Fig. 3(b). Functionality of proposed logic circuit using multiplexer with forward body biasing technique applied for 64-bit ripple carry adder to improve the critical path delay

Here, to bring out more clarity on the analysis, the input applied on A_{63} to A_0 have same input signal and B_{63} to B_0 have same input signal. A_0, B_0 and C_{in} are the input signal of first 1-bit full adder while, C_{out} is the final output carry signal of the combinational logic block. The Mux-Out signal shown in Fig. 3(b), is the output of multiplexer that gets registered in the followed flip-flop after a clock cycle. The results are measured with respect to the rise time or fall time and the slope associated with the two signals Mux-Out and Q which forms the output of the multiplexer and the output of the flip-flop respectively.

Switching delay of E_Out signal (Fig. 3(a)) is higher than the switching delay of Mux_Out signal (Fig. 3(b)). Reduction in rise or fall time and increase in the slope of these signals indicates the faster switching. The energy per cycle is measured having 33.10 % improvement.

C. Master-slave Positive-edge Trigger D Flip-flop

Fig. 4 shows the used schematic of D flip-flop with positive edge trigger [12] in the design to register the output of multiplexer. The flip-flop uses transmission gates. There is no body biasing technique applied for any of the MOSFET in this circuit of the flip-flop. Master latch becomes active whenever clock goes to lower state and it samples input data signal into Q_m with the slave latch is in hold condition and it retains previous value with the help of feedback. Slave becomes active, when clock goes to higher state and samples the master output (Q_m) into final output (Q).

D. Comparison Between Timing Characteristics of 64-bit ripple carry adder using existing technique and using proposed circuit to lower the delay along the critical path

The supply voltage for the combinational circuit and the proposed circuit and the D flip-flop was 287 mV. The forward body biasing voltage V_{SB} for NMOS and PMOS MOSFET was equal to 287 mV. The threshold voltage of p-channel and n-channel MOSFETs before body biasing was measured as 441 mV and 496 mV respectively. The threshold voltage of p-channel and n-channel MOSFETs after body biasing was measured as 387 mV and 455 mV respectively.

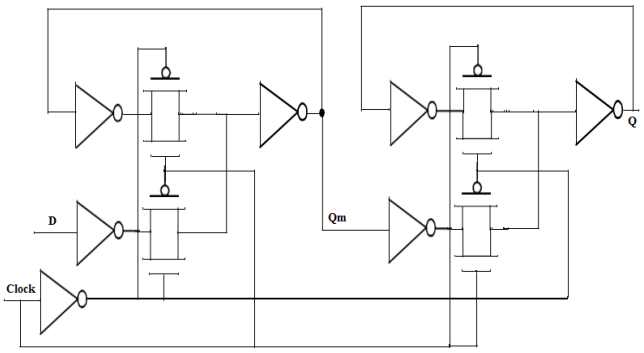

Fig. 4. Schematic view of simple Master-Slave positive edge triggering Flip-Flop [12].

Table I shows the comparison of rise & fall time at the output of the existing technique and the proposed circuit when applied to ripple carry adder with 64 bits. C_{out} is the final output of the critical path of the combinational logic circuit operated at subthreshold region. Table II shows the comparison of rise & fall slopes between the existing technique and the proposed circuit when applied for 64-bit ripple carry adder. Table III shows the comparison of total propagation delay, energy per cycle, energy-delay product (EDP) and corresponding achieved operating frequency of the D flip-flop of the existing technique and the proposed circuit when applied to ripple carry adder with 64 bits.

After providing forward-body biasing in proposed mux-based logic design threshold voltage is lowered-down as compared to zero biased MOSFET. So, MOSFET sensitivity is increased. It has reduced switching delay from logic high to low and low to high (Table I). Therefore, this leads to decrease in total propagation delay of combinational logic block with mux-based logic design. Proposed mux-based logic design gives opportunity to increase clock frequency of the D flip-flop. Total energy per cycle of the proposed mux-based logic design applied for 64-bit ripple carry adder is reduced as compared to existing logic design using adaptive feedback equalization technique applied for 64-bit ripple carry adder. Energy-Delay product has also been lowered down as compared to existing circuit of adaptive feedback equalization when applied to 64-bit ripple carry adder.

V. Conclusion and Future Scope

This paper proposes a circuit to improve the switching characteristic of the longest path (critical path) of the logic circuit operated at subthreshold region of the operation. The proposed circuit comprises of a multiplexer that is implemented using transmission gates and is used in the critical delay path of the logic circuit when operated at subthreshold region. Forward body biasing notion is incorporated in the proposed circuit to lower the threshold voltage of the MOSFETs so as to reduce the switching time of the MOSFETs. The proposed circuit is implemented using Cadence Virtuoso at 45 nm technology and compared with the circuit studied from literature survey at 287 mV. The supply voltage for the combinational circuit and the proposed circuit and the D flip-flop was 287 mV. The forward body biasing voltage V_{SB} for NMOS and PMOS MOSFET was equal to 287 mV.

TABLE I COMPARISONS OF RISE TIME AND FALL TIME AT THE OUTPUT OF THE EXISTING CIRCUIT AND PROPOSED CIRCUIT USING MULTIPLEXER USED TO MINIMIZE THE DELAY ALONG CRITICAL PATH DELAY IN RIPPLE CARRY ADDER WITH 64 BITS

Design Methodology	**Rise time of the flip-flop input signal (ns)**	**Fall time of the flip-flop input signal (ns)**
Existing Adaptive Feedback equalization Circuit applied to 64-bit ripple carry adder [1]	1.99 (at the output of Adaptive feedback equalizer circuit)	1.838 (at output of Adaptive feedback equalizer circuit)
Proposed Circuit Using Multiplexer applied to 64-bit ripple carry adder	1.032 (at the output of the multiplexer)	1.349 (at the output of the multiplexer)

TABLE II COMPARISONS OF RISING SLOPE TIME AND FALLING SLOPE OF THE OUTPUT OF THE EXISTING CIRCUIT AND PROPOSED CIRCUIT USING MULTIPLEXER TO MINIMIZE THE DELAY ALONG THE CRITICAL PATH IN 64 BITS RIPPLE CARRY ADDER

Design Methodology	**Rising Slope of the flip-flop input signal**	**Falling Slope of the flip-flop input signal**
Existing Adaptive Feedback equalization Circuit applied to 64-bit ripple carry adder [1]	61.99	69.96
Proposed Circuit Using Multiplexer applied to 64-bit ripple carry adder	94.90	75.66

TABLE III COMPARISONS OF TOTAL PROPAGATION DELAY, MINIMUM ENERGY POINT, ENERGY DELAY PRODUCT AND CORRESPONDING OPERATING FREQUENCYOF THE OUTPUT OF THE EXISTING CIRCUIT AND PROPOSED CIRCUIT USING MULTIPLEXER TO MINIMIZE THE DELAY ALONG CRITICAL PATH DELAY FOR 64 BITS RIPPLE CARRY ADDER

Parameters	**Existing Adaptive Feedback equalization Circuit applied to 64-bit ripple carry adder [1]**	**Proposed Circuit Using Multiplexer applied to 64-bit ripple carry adder**
Total propagation delay	41.8 ns	29.17 ns
Energy/cycle	1.4048 fJ/cycle	0.9398 fJ/cycle
Energy-Delay product (EDP)	58.72 x 10^{-24} J.s	27.41 x 10^{-24} J.s
Achieved Operating frequency of the D flip-flop	25 MHz	50 MHz

The threshold voltage of p-channel and n-channel MOSFETs before body biasing was measured as 441 mV and 496 mV respectively. The threshold voltage of of p-channel and n-channel MOSFETs after body biasing was measured as 387 mV and 455 mV respectively. The proposed circuit is applied to the critical path of ripple carry adder with 64 bits operated in subthreshold region. The switching delay for high going and low going transition time at the signal given as input to D flip-flop is same as signal produced as output by the proposed circuit using multiplexer and are measured and are reduced by 48.14% and 26.60% respectively. Also, the slope of the transition of the output signal has been increased by 53.08% & 8.14% for rise and fall respectively. The total propagation delay diminished by 30.12%, as compared to existing technique. The energy per cycle and energy-delay product (EDP) turned down by 33.10% and 53.31% respectively, over the existing technique. The operating frequency of the proposed mux-based logic design can increase by 50% as compared to the existing logic design keeping the same supply voltage. The flip-flop used can also be modified to make it more sensitive to detect and capture the critical delay path signal at a faster rate.

***Abstract*—Security defies one of the galactic barrier when pondering the use of cloud services. Data outsourcing in the cloud (DOC) is conventionally based on data encryption, which imparts impregnable security, but deteriorating the efficiency and rimming the functionalities of cloud. In this proposal we aim to possess them by proposing a secret sharing scheme that depends on partitioning the data and distributed storage over multi-clouds. The scheme used in the proposal uses a combination of symmetric (AES) and asymmetric (RSA) encryption techniques to share the data among the peers in the cloud environment. The proficiency of the suggested scheme has been demonstrated by the empirical results.**

***Index Terms*—multi-clouds, special key, AES, RSA, SISA.**

I. Introduction

The digital revolution has yielded massive amounts of multimedia stats that has become difficult to oversee, thus ultimately induced many organizations to switch to cloud-based solutions. Nevertheless, these cloud-based solutions seem to be economical but there dwells a numerous issue like reliability, accessibility, security & covertness of the content that is being assigned to these Cloud Service Providers (CSPs). Accidental breaches in the cloud services owing to the inadequacy of fault tolerance or server downtime have contributed to formidable forfeit and financial losses in the past.

Multi-clouds have bloomed as a compelling way in offering an eminent cloud service, as it entails outsourcing of data to multiple cloud storage (MCS) servers which are sovereign as a result sealing the data leakage issues. Nevertheless, archiving the data at third-party servers will endanger its security, thus encryption methods are implemented on the information to retain its confidentiality. Encryption methods have been implemented that split the data files into multiple chunks and then archive these shares at distributed cloud server. However, another vital aspect is storage volume at the servers, one such approach is eliminating the data redundancy over the cloud server. Thus, encryption of data will scramble the data so that the hostile will not be able to read it, while removing of redundant data will intend to locate coincident data.

Here in this proposal the data (.pdf, .jpg, .xlsx, .mp3) is converted to its corresponding binary value which further divided into 32-byte blocks. This 32-byte blocks is then encrypted by using a *hybrid encryption* and stored over multi-clouds.

II. Background

Storing data on cloud using a single encryption algorithm became a traditional approach and the system possess various vulnerabilities. Instead of storing data, the trend of uploading files on multiple clouds gathered attention as the data was pretended to be safe as the intruder found it difficult to retrieve data from multiple cloud. Storing the data by splitting it into different chunks and uploading it on cloud was proposed in [1] along with this encrypting the chunks increased integrity authentication of the system to a greater extent also it removed the flaws of encrypting information and uploading it on single cloud.

MCS is a vital service of cloud computing, this grants user to lay in the chunks of encrypted data at distinct cloud drives. Thus, it endorses various CSPs to utilize a single interface in lieu of traditional unique cloud service. Cloud security in the first place aims to the subjects that link to information privacy and protection facets of cloud computing. Such paradigm hubs to the malign insider's ingress to stored information, safeguard from malicious files, elimination of the centralized division of data storage, obsolete files and downloaded files often. The proprietor of the data is less anxious for the future of data stored in such cloud service model. Another aspect is the ingress command on the data, the proposed scheme seeks to ensure the CIA triad which pares malign insider's and file threats with an algorithm that enhances data sharing covertness in MCS services. The proprietor can store and

recover the data in the absence of merging conflicts to procure significant information. The empirical outcomes specify that the suggested model is apt for adopting the MCS services.

III. Related Work

Ken Yang *et al.* [1] found that the use of clouds for storing crucial data in distinct organizations is practiced these days. The data was stored on the server and retrieved at any time and from anywhere. It was made more secure in cloud storage with proper security algorithms and authentication. The analysis increased the availability and security of data at any time at the receiver. For an intruder dealing with the single cloud system is easier than multi-clouds. From this the idea of multi-clouds gathered attention in cloud computing.

Jing Jang Hwang *et al.* [2] introduced the data sharing techniques that were used in the cloud infrastructure were susceptible to various kinds of attacks as many traditional cryptographic techniques fail to provide essential authentication and data integrity for the user. Emphasis was done on using data slicing using AES encryption. The parts of the data were maintained on different clouds servers.

Xiao hua Jiae *et al.* [3] outlined the decline in employing single clouds as the MCS elevated swiftly in CSPs arena. Cloud computing imparts many gains in terms expenditure and uptime. Guaranteeing the security of cloud computing is a prime constituent in the cloud computing environment, as end-user often stores delicate information on CSP which may be untrustworthy. Single cloud became less popular among CSPs as it fails to thrive the CIA triad, thus CSPs moved towards MCS to store important information. It concluded on recent research related to single and multi-cloud security and addressed the use of multi-cloud providers to maintain security. This work motivated to promote the use of multi-clouds due to its ability to reduce security risks that affect the single cloud to the application.

The summary of these papers augmented to storing the data in multi- clouds rather than single cloud. The data should be sliced and each unique chunk is stored in different cloud servers. There was a supreme need of data encryption of data using an optimum and mutually compatible cryptographic algorithms. Finally not acquiescing the available encrypted data to be easily procurable by focusing on encrypting the special symmetric key. The multimedia data used was encrypted using AES algorithm and the special key is being encrypted using an asymmetric public key and all this information is stored in clouds, which strengthens the data integrity of the infrastructure.

IV. Proposed Work

The application built is a secure data sharing application that let us to take advantage of cloud computing using enhanced encryption standards. The application strips away all the redundancies and reduce the complexities of existing systems, acting as a secure endpoint where users can share data securely and in more meticulous way. In this proposal we use *hybrid encryption* which guarantees improved security, confidentiality, integrity of the application. One of the main reason why we use *hybrid encryption* because the public-key cryptosystems often confides to complicated mathematical computations which is generally inefficient in contrast to symmetric-key cryptosystems. A *hybrid cryptosystem* blends the ease of public-key cryptosystem with the efficacy of symmetric-key cryptosystem. The framework of the *SISA* application is shown Fig. 1, here initially the data files (.pdf, .jpg, .xlsx, .mp3) are converted to 32-byte array before performing the AES encryption discussed latter.

TABLE I: Existing vs Proposed

Existing work	Limitations	Proposed work
Data is divided and stored on single cloud	No better encryption	Data is encrypted as well as divided and stored on multiple clouds
Data is encrypted using AES algorithm	Key produced by AES algorithm is not secured	Encryption of Data Using AES algorithm and then splitted.
Data is encrypted using RSA algorithm	RSA is old Algorithm and is not safer for data encryption.	Encryption of AES key using RSA algorithm

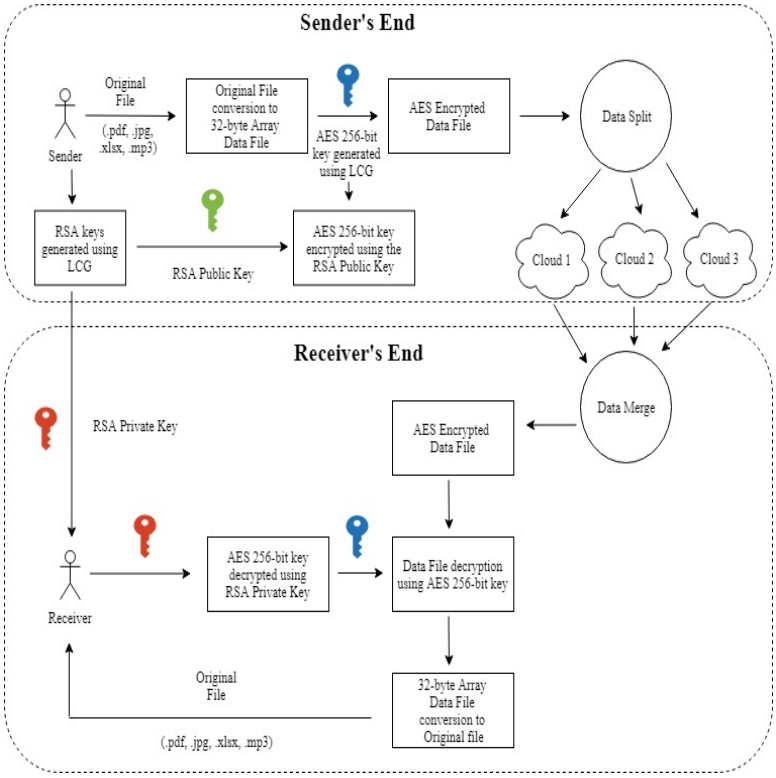

Fig. 1: Framework of SISA

A. Advanced Encryption Standard (AES) Cryptosystem

AES is a symmetric block cipher cryptographic algorithm which is hypothetically impenetrable in a non-trivial time, discussed in algorithm 1. AES allows three variations in key

lengths i.e 128, 192 & 256 bits where the encryption consists of 10, 12 & 14 rounds respectively. All the rounds in each case are identical besides the last round. For encryption, each round consists of four steps : 1) Substitute bytes, 2) Shift rows, 3) Mix columns & Add round key. The last step consists of XORing the output of the previous three steps with four words from the key schedule, the Fig. 2 shows the basic structure of AES cryptosystem. Here we use the AES encryption technique to encrypt the input data file (256 bits), this AES 256-bit encryption key is a *special key* as in our case. In this proposal the AES 256-bit key can be used to encrypt multimedia data (text, audio, pdf, jpg). The integrity of data is ensured by the *special key* which is further encrypted by using an asymmetric key (RSA), thus resulting an *hybrid encryption*. This can be formally realised by the given equations 1 , Let 'P' be the plaintext, K_{AES} be the *special key* which is generated at a real-time using a pseudorandom number generator called Linear Congruential Generator and K_{pri} & K_{pub} be the receiver's private and public RSA keys respectively.

$$\begin{aligned} C_1 &= E_{AES}(P, K_{AES}) \\ C_2 &= E_{RSA}(K_{AES}, K_{pub}) \end{aligned} \tag{1}$$

Then, send both the ciphertexts C_1 & C_2 to the receiver. The receiver can then recover the plaintext as shown in equations 2,

$$\begin{aligned} K_{AES} &= D_{RSA}(C_2, K_{pri}) \\ P &= D_{AES}(C_1, K_{AES}) \end{aligned} \tag{2}$$

B. Linear Congruential Generator (LCG)

Linear congruential generators (LCGs) are class of pseudorandom number (PRNG) algorithms used for generating sequences of random-like numbers. They are prevalent among the other prng's primarily due to their ease of implementation, speed and memory usage. LCGs are defined by the recurrence relation as shown in equation 3 [11]:

$$X_{n+1} = (aX_n + c) \, mod \, m \tag{3}$$

where,
m : the modulus ; a : the multiplier; c : the incrementer; X_0 the starting value, or seed.

Thus, for example if we consider a = 11, c = 37, X_0 = 1 and m = 100 then we can get, X_0 = 1 , X_1 = 48, X_2 = 65, X_3= 52, X_4 = 9 and so on. In this proposal AES 256-bit key is generated in this fashion and stored in 16 $\times$ 16 matrix which is then used in the AES encryption process as discussed above.

C. Rivest–Shamir–Adleman (RSA) Cryptosystem

It is asymmetric cryptographic algorithm popularly used over internet to encrypt data. Generally, RSA algorithm relies on the fact that the factorization of large integer is computationally complex. Here the public-key & private-key both consists of two numbers of which one is the multiplication of the two large prime numbers. So if the private-key is compromised then the encryption fails, thus the encryption strength entirely depends on the key size. Hence, if this key size is doubled or tripled then the encryption strength increases exponentially. Typically, RSA keys are of 1024-bits or 2048-bits so if we used to encrypt large amount of data files (.pdf, .jpg, .xlsx, .mp3) it will consume tremendous amount

11:    temp=SubWord (RotWord (temp)) xor Rcon [i / Nk]
12:    else if (Nk = 8 and i mod Nk = 4)
13:    temp SubWord (temp)
14:    end if
15:    w[i] = w[i - Nk] xor temp
16:    i=i+1
17:    end while
18: end procedure
```

Algorithm 2 Data Splitting Algorithm [10].

procedure MAIN
  Initiate db connection from user to application interface.
  Convert the data to binary
  Generate a Secret key
  Encrypt the data with Secret key.
  Apply Rijndael key Schedule & derive RoundKey
  BitXOR(state of byte, Block(RoundKey))
  Apply Non-linear substitution step
  SubByte: $\frac{oldByte}{newByte}$ (LookUpTable)
  ShiftRow: Transpose(state of Row)
  MixColumn: Mix(state of column)
  Add all the RoundKey
  Check the size of data
  Evaluate remainder = size % cloud no
  Estimate the size of split data (S) = $\frac{Size\,of\,data - remainder}{cloud\,no.}$
  Last data size = S + remainder
  Insert key values to random cloud
end procedure

Algorithm 3 AES key encryption using RSA algorithm [9].

procedure MAIN
  Generate two different primes p and q
  Calculate the modulus$n = p * q$
  Calculate the euler's totient function $\Phi(n) = (p-1) * (q-1)$
  Select for public exponent an integer e such that $1 < e < \Phi(n)$ and $gcd(\Phi(n), e) = 1$
  Calculate for the private exponent a value for d such that $d = e^{-1} mod \Phi(n)$
  Public Key = [e, n]
  Private Key = [d, n]
end procedure

of time. In this proposal, the RSA algorithm provides security to the AES 256-bit key by encrypting it with its public key as shown in equations 1. This encryption of the AES 256-bit key remains anonymous to any intruder, thus provides an one layer additional security. The receiver can decrypt the *special key* using the private-key sent by the admin as shown in equations 2. This enhances the compatibility and efficiency of the *SISA* application and the system guarantees the superior security of the encrypted data stored on the MCS [3].

RSA Key Generation

RSA required two large prime numbers 'p' and 'q' to generate public and private keys. These prime numbers are generated using the Linear Congruential Generator as discussed in subsection IV-B. This LCG algorithm is deterministic and therefore produce sequences of numbers that are not statistically random.

- Generate large random numbers of desired magnitude using LCG.
- Check whether these numbers are prime, otherwise pick successive random numbers.
- Generate the public-key 'e' & the private-key 'd' which are then selected based on the conditions as discussed in the algorithm 3.

Thus, these RSA public-key & private-key of key size 1024-bits is generated and is further used to encrypt-decrypt *special key* as shown in equations 1,2.

D. Working of SISA Application

The application is a client-server based cloud infrastructure where the files can be uploaded, downloaded, shared among the connected server and clients. Initially, the sender / user uploads the data files (.pdf, .jpg, .xlsx, .mp3) to the application which is then converted to 32-byte array. This 32-byte array (i.e. data file) is encrypted by using the AES 256-bit key (i.e. *special key*). Now, before uploading this AES encrypted data file on to the cloud servers the number of blocks are created on to the encrypted data file which are then splitted symmetrically into three parts and are then stored on to the three different cloud servers, discussed in algorithm 2. Thus each cloud server contains the unique part of a file.

The second part of the application is encrypting the *special key* used for data file encryption using the RSA public-key. The system encrypts the *special key* with the RSA public-key and the generated private-key is sent to the receiver by the system. Now, the data as well as the symmetric key is encrypted. This enables hybrid encryption standards which are very difficult to detect and computationally complex to attack easily.

At the receiver's end, the sender first sends the RSA private-key to the receiver only after which he can be able to download the data file. The use of private-key here acts as a obstruction for the decryption of data file using *special key* as it is encrypted using the RSA public-key. Hence, the system first decrypts the special key using RSA private-key and then the data file is decrypted using that *special key*. Finally, 32-byte array is converted back to the original data file (.pdf, .jpg, .xlsx, .mp3) is downloaded at the receiver's end.

Need for Hybrid Cryptosystem

1) Symmetric ciphers are significantly faster than asymmetric in encrypting the files with larger size.
2) Asymmetric ciphers enables key exchange system but at the cost of speed.
3) Asymmetric encryption decelerates the encryption process, but with the concurrent use of symmetric encryption the overall system performance is enhanced.

V. Result Analysis

A. Performance Measurements

The cycle count values for encryption or decryption which depicts the the number of system clock cycles required to en-

crypt or decrypt bytes of data. The amount of time required to execute one of these routines for any system-clock frequency can easily be calculated by using the following formula given in equation 4 [13] :

$$Time = \frac{Cycle\,Count}{System\,Clock\,Frequency} \tag{4}$$

The following are the parameters used for the encryption algorithm performance :

1) **Encryption Time (T_E):** It is the time taken to convert the plaintext (in KB) to ciphertext.
2) **Encryption Throughput (Th_E):** It is defined as the total size of input file (in KB) over the total encryption time (in seconds) as shown in equation 5.

$$Th_E(KB/sec) = \frac{\sum size\,of\,input\,files}{\sum T_E} \tag{5}$$

3) **Decryption Time (T_D):** It is the time taken to convert the ciphertext (in KB) to plaintext.
4) **Decryption Throughput (Th_D):** It is defined as the total size of input file (in KB) over the total decryption time (in seconds) as shown in equation 6 [12].

$$Th_D(KB/sec) = \frac{\sum size\,of\,input\,files}{\sum T_D} \tag{6}$$

5) **Average Time (T_{avg}) :** It is defined as the ratio of total encryption / decryption time over the total number of files as shown in equation 7.

$$T_{avg} = \frac{\sum T_E\ or\ \sum T_D}{\sum number\,of\,input\,files} \tag{7}$$

B. Graphical Analysis

The following Tables II & III shows the comparison of AES & RSA cryptosystem with our proposed system. It is observed that our proposed hybrid encryption is significantly overlapping with the performance of AES algorithm. The graphs 3a & 4a clearly depicts that the *hybrid encryption* is as effective as the AES cryptosystem. On the other hand, in RSA cryptosystem the time take taken for encryption and decryption increases exponentially with the increase of the file size as shown in the graphs 3b & 4b, which is not feasible. Hence, in the proposal the RSA (1024) cryptosystem is used to encrypt the AES 256-bit key which reduces the cost of encrypting the much larger size data files. Thus, the proposal gets the advantage of encrypting the large files using AES which is comparatively faster than RSA and then by encrypting the *special key* with RSA (1024) will computationally complex the decryption process. This will ensure the integrity of the data file.

VI. Conclusion

Despite the benefits of cloud storage of availability, less computation time, etc. in the today's digital world '*data security*' remains the primary focus among the tech giants. This led in the emerging of adapting the cryptographic techniques to the data uploaded over the cloud. In the context, various

TABLE II: Encryption Time (in Milliseconds) [13] [14]

File Size (in KB)	AES	RSA	Proposed System

symmetric and asymmetric key encryption techniques were used to store data on cloud over the period of time. A *hybrid* of symmetric and asymmetric key encryption (i.e. AES and RSA) is proposed which focused on the encryption of data file using symmetric key followed by the encryption of symmetric key with asymmetric key, and storing this crucial data and symmetric key in distributed cloud in encrypted scheme. Encrypting the symmetric key was implemented as the encryption of the key remained anonymous to any intruder and it made the key to be decrypted first before decrypting the data. The asymmetric key was used to further reduce the cost of encrypting symmetric key using another symmetric key algorithm which shows the compatibility of AES and RSA in cryptography is superior.

Performance Evaluation and Analysis of various Network Security tools

Sinchana K, Sinchana C, Gururaj H L, Vidyavardhaka College of Engineering, Mysore,
Sunil Kumar B R, Adichunchanagiri University, Mandya

***Abstract*— With the developments in the internet and the rise of ecommerce applications and social networks, there is a lot of data generated daily. Thus, the transmission of this data safely through the web is an issue. Also, network security is gaining a greater importance as more and more people are moving towards the age of digital information. As the number of users increase, the cyber-attacks are becoming critical. There are various network security tools which deal with a lot of functions in contributing to the security of network. These network security tools help in finding the vulnerabilities in a website or a web application, to secure wi-fi networks, to crack passwords, to ensure message encryption etc. This paper describes some of such tools, which deal with vulnerability check in a website, wi-fi security, network scanning, network or protocol analyzing.**

***Index Terms*—Network security, Zed Attack Proxy, Aircrack-ng, Wireshark, NMAP**

I. INTRODUCTION

THE fast developments in the internet has attracted a huge number of users, increasing the data production rate. As more and more people are moving towards the digitalized information, this information has to be safely transmitted. The safe transmission of such data is an issue. Along with this, the network security has got a greater importance as there is an increase in the number of users day by day. Due to increase in the number of users, cyber-attacks have become a major threat[1].

Thus, in order to ensure the safe transmission of data and network security, there are various network security tools available. These network security tools perform different functions. There are various types of tools which are used for different purposes[2]. These tools perform variety of operations to contribute to the network security.
Some of them help in sniffing the network or analyzing a protocol, some of them deal in securing a wi-fi network, some of them deal with password security, some check for the website security etc.

In this paper, we describe four such tools which perform certain tasks contributing to the network security[3]. We discuss about Zed Attack Proxy (ZAP) tool which deals in checking for the vulnerabilities in the websites or web application. How the threats in the websites are discovered and solutions are found using ZAP.

Then we discuss about Aircrack-ng tool which deals with password cracking of Wi-fi network. How this helps in discovering the effectiveness in the security of wi-fi network.
Next, we discuss about the NMAP tool that is Network mapper which is a network scanner that helps in finding out the hosts and servers in a computer network. It sends packets and analyses the responses.

The next tool is Wireshark tool, which is a packet analyzer. It is used for network troubleshooting and analyzing the network, development of software and communication protocols.

We discuss how these tools work and their important contributions to ensure network security.

II. ZED ATTACK PROXY

Zed Attack Proxy is an open source web application security scanner which is a free network security tool. It is an OWASP (Open Web Application Security Project) with the flagship status. It is completely free and open source[4]. ZAP is used for penetration testing of your website or a web application. It is ideal for the use of both beginners to the application security as well as professional penetration testers. It is becoming a framework for advanced testing.

A. ZAP PRINCIPLES

- It is free, open source which means anyone can access and use it.
- It's also cross platform that is it works on Linux, Windows and Macs.
- It is easy to use; any user be it beginner or a professional can use it easily.
- It is easy to install; it requires Java Runtime Environment but everything else is included in standard downloads.
- It is fully internationalized, i.e., it's been translated to many other languages.
- It is fully documented, set of useful documents and helpline files are included.
- It works well with other tools, so that we can use other tools in conjunction with zap if we need to.
- It supports the use of well-regarded components.

B. ZAP MAIN FEATURES

- *Intercepting proxy*: we configure the browser to proxy through zap so that zap can see through all the requests and responses.
- *Active and passive scanners*: it provides both the active and passive scanners, so that passive scanners just examine through requests and responses and still recognise the types of problems just on that basis. But the active scanners are different and these can perform wide range of attacks only on applications that you have permission to test.
- *Spider:* it is used to crawl the application, say for example to find the missed-out pages or hidden pages.
- *Report generation*: zap can prepare reports based on the issues found including more advices and links on how to solve that particular problem.
- *Brute force component*: it can also find files even if there are no links to them using brute force component, which is based on owasp dirbuster tool.
- *Fuzzing***:** it can also fuzz parameters and includes fuzzing libraries from the jbrofuzz and fuzz db tools. You can use fuzzing to find more subtle vulnerabilities that the automated scanners cannot find.
- *Extensibility***:** zap can be easily extended

Any web application has to be tested and security testing plays a vital role in it. There are many security threats that a website or a web application may face, like SQL injection, Broken authentication and session management, cross sight scripting, broken access control, security misconfiguration, sensitive data exposure, insufficient data protection, cross site request forgery etc. Zap helps in detecting all such threats and vulnerabilities, and possibly give solutions to the problems[5].

C. WORKING OF ZAP

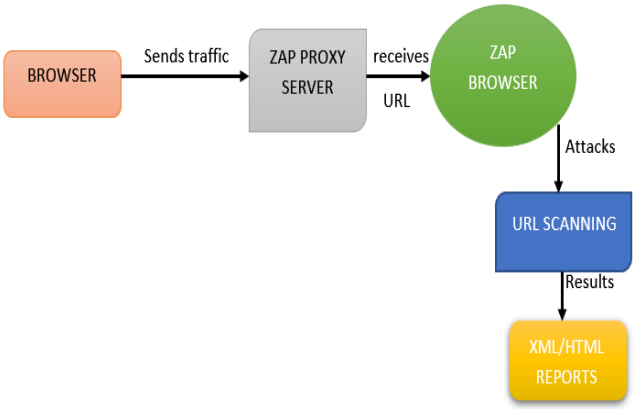

Fig. 1. Block diagram of working of ZAP

Initially, zap creates a proxy server. The browser sends the traffic to pass through the zap proxy server, then the zap browser receives the URL and the attacks on URL with help of auto scanners that helps to find out the vulnerabilities in a website. Finally, a report is generated with the respective problem, its reason and also the solution for it.

E. A SIMPLE PENETRATION TEST

Firstly, configure your browser to proxy through ZAP. Then, explore the application manually. Next, use spider to find 'hidden' content. See what issues the passive scanner has found. Finally, use the active scanner to find vulnerabilities

F. WORKING SCENARIO

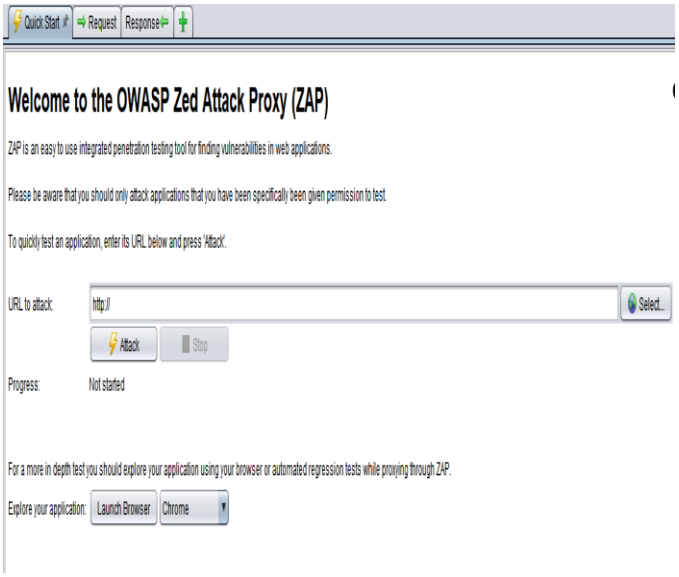

Fig. 2. Initial window of ZAP before entering URL to attack

Initially the zap window looks like this as shown in the above figure.

We give a URL to attack in order to check for the possible vulnerabilities and then the scanning process starts. It is as shown in the below figure.

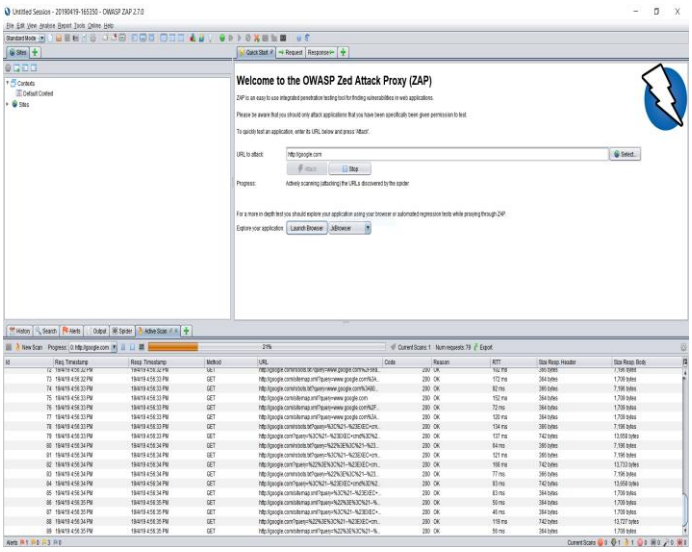

Fig. 3. The scanning process in ZAP.

Once the scanning process is done, the threats or the vulnerabilities discovered through scanning are listed in the alert section.

Fig. 4. The description, type and other details of a threat scanned in scanning process.

The description of the problem and also the possible solution for the threat is also given as shown in figure.

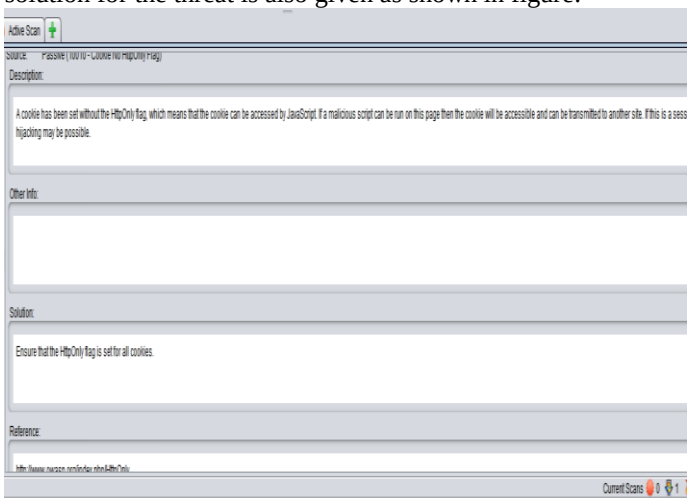

Fig. 5. The solution for the problem given after the description of the vulnerability.

Thus, Zed Attack Proxy is an effective tool to ensure security of the web applications or websites.

III. AIRCRACK-NG

A. FEATURES

It contains a suite of tools for the purpose of checking wireless networks. It is mainly used for:

- *Monitoring:* Packet capturing and exporting of data to text files which is further used for processing by third party tools
- *Attacking:* Replaying attacks, de-authentication, fake access points and others through packet injection
- *Testing:* Checking driver capabilities and Wi-Fi cards (capture and injection)
- *Cracking:* WEP and WPA PSK

It contains four necessary parts [6]:

- *Airodump-ng:* it records the coordinates of the entry or access points and captures the raw 802.11 packets.
- *Aireplay-ng:* it is used for injecting frames into wireless networks.
- *Aircrack-ng:* it is used for recovering keys once enough packets have been captured.
- *Airdecap-ng:* it is used for decrypting the encrypted capture files.

Aircrack-ng is used mainly to test the weaknesses of wireless networks by accessing the network using WEP and WPA-PSK keys by decrypting encrypted packets stored.

B. WORKING OF AIRCRACK-NG

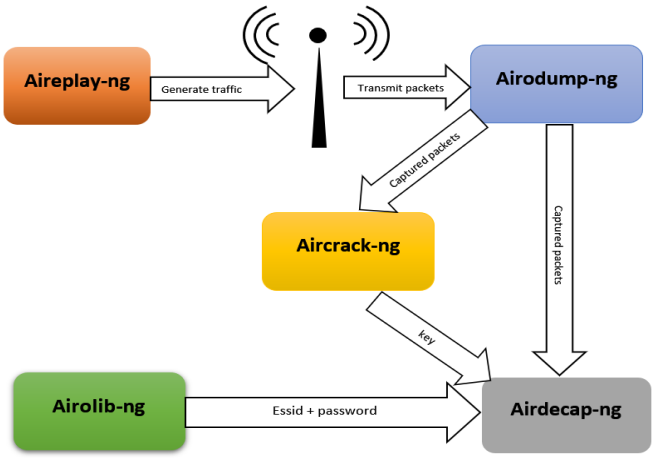

Fig. 6. Block diagram of working of aircrack-ng

Firstly , the aireplay-ng tool generates packets for simulating the traffic. Then the traffic generated, transmits packets and sends it to the airodump-ng tool. The airodump-ng tool captures the packets and then classifies them. Along with this tool, airmon-ng tool changes the adapter to monitor mode to capture all the packets[7]. Once, enough packets are captured, aircrack-ng recovers the key from captured packets. Finally, the airdecap-ng starts decrypting the contents of packets using the recovered key. The airolib-ng tool helps in fastening the password cracking process by precomputing the pairwise master keys[8].

C. WORKING SCENARIO

The password is cracked by checking out all the possibilities in the password list. The output during the cracking process is as shown in fig. 7.

Once the password is cracked, the aircrack-ng tool shows the respective password with the message as “KEY FOUND!”.

The following figures show the output screen while aircracking takes place.

The current passphrase represents the currently parsed password in the password list [9].

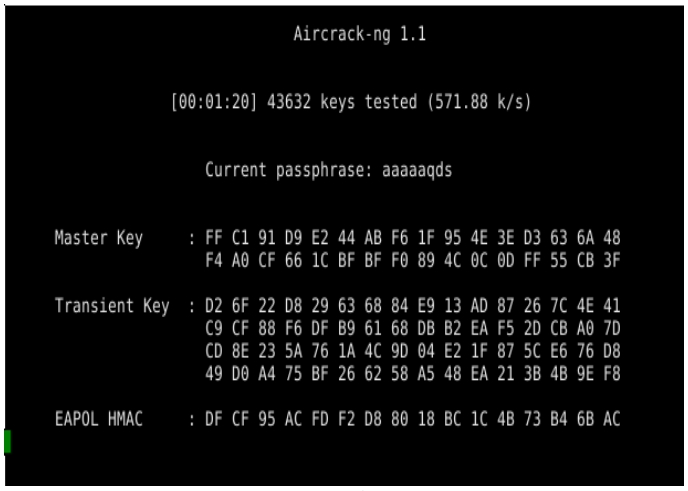

Fig. 7. Output screen while checking for password in the password list.

Once the password is cracked, the output screen is as shown.

Fig. 8. The final output screen when the password is cracked with the message as KEY FOUND and the respective password.

IV. NMAP

Nmap is basically known as foot printing tool or recognisant tool. This is the first step to find information about the target or the IP or the website. Nmap in normally the tool used with Linux, OS and the nmap for windows is known as zenmap.

Nmap is expanded as Network Mapper. It uses innovative raw IP packets to determine which hosts are available on the network, which hosts the services (application name and version), the operating system (and OS versions) that they work on, what packet filters or firewalls are in use and many other characters. It was initially designed to scan large networks quickly. Vulnerability detection, penetration testing, host discovery. The main use is for network exploration and security audits. We will also get to know what the flaws in our network are. It will help us find available ports and services. It will likewise be utilized for finding and abusing vulnerabilities in a system[10]. Nmap supports dozens of advanced techniques to map the network filled with IP filters, firewalls, routers and other hurdles. Many post scanning procedures (both UDP and TCP), OS detection, version detection, ping scraping etc. Nmap is a port scanner and is a tool used by system administrators and attackers (s) to identify vulnerability in operating systems[11]. This takes an IP address or host name and finds the source information associated with it. If an IP address is provided, it then finds the host to which it belongs to[12]. Nmap comes into use when we need to scan huge networks, nearly hundreds of thousands of machines. Nmap is a tool that can be used to find services that operate on Internet connection systems. It could potentially be used for black hat hacking as any other device, as precursor attempts to gain unauthorized access to computer equipment. Nmap is often used by security and systems administration to access the network for impairment.

A. WORKING OF NMAP

Traditional command line and graphical (GUI) versions are available to suit our priorities. Binaries are also available for those who do not want to compile the NMP from the source.Nmap can be used for advanced ethical hacking as well as for scanning a network by using a command line “nmap –v –A target host”.

In the fig 9 the TCP scanning that is done using Nmap. First the command line “nmap –sS 192.168.86.1” is used to syn scan the TCP. This command sends a syn message to the target system (Responder in figure1) using the TCP IP stack, then the responder sends a syn+ack message to the initiator and the initiator sends the ack message which confirms the 3-way hand shake.

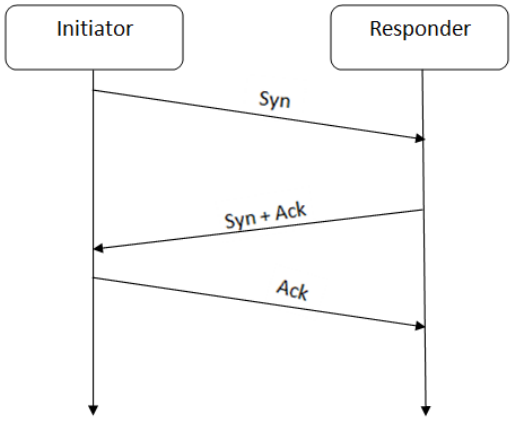

Fig. 9. TCP scanning using nmap.

B. WORKING SCENARIO

Fig 10 shows the initial window of Nmap. Since Nmap is a scanning tool let us take the example of the tcp scanning and show the working scenario of Nmap.

Fig 10 is the initial window of the nmap and this is how it looks when we first open the window. To scan the TCP IP, we need to enter the command line “nmap –v –sn 192.168.0.0” in the command space as shown in fig 11. And once the scanning

of the TCP is done the final window looks like the fig 12 which is the window that shows the entire scanning of TCP.

This is basically just an example to make us understand about the working of nmap. Similarly using the command lines, we can scan any network as shown in the example.

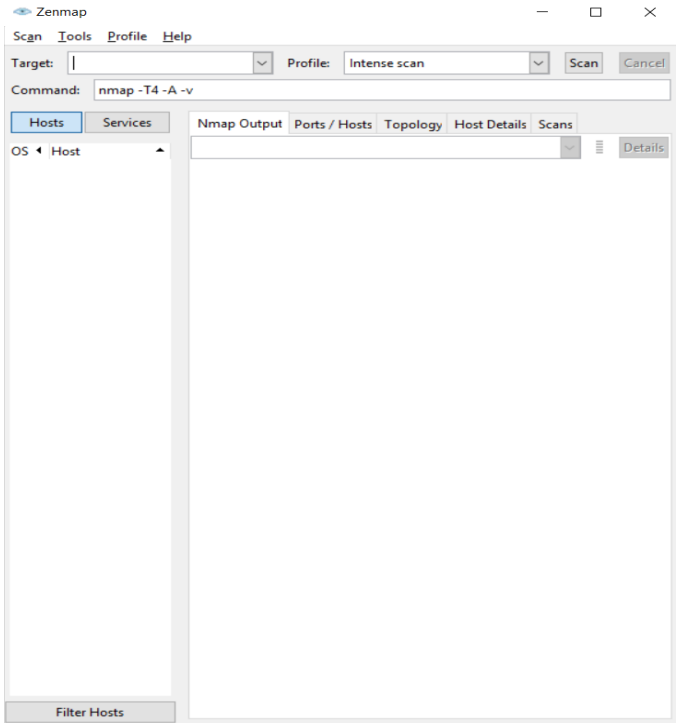

Fig 10. Initial window of nmap.

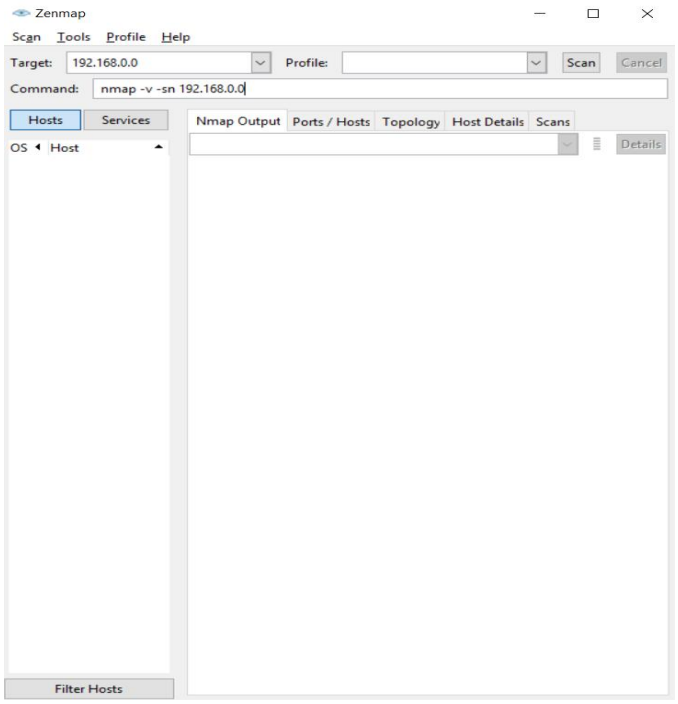

Fig 11: command entering

Command line should be entered to scan the TCP, this is done by using the command line “nmap –v –sn 192.168.0.0”

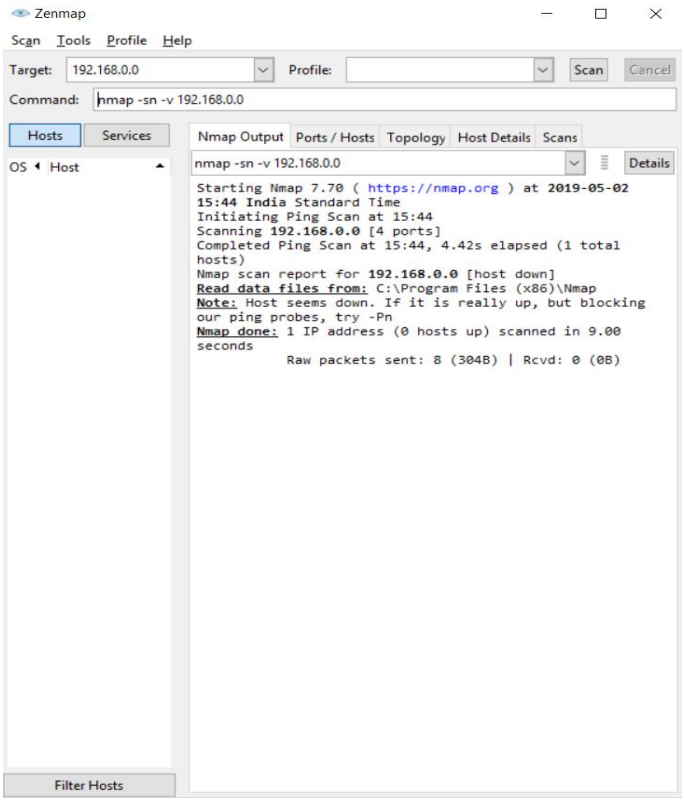

Fig 12:Final window after scanning.

V. WIRESHARK

Wireshark is an open-source and open packet analyzer. It is used for network analysis, software and communications protocol development, troubleshooting and education. It puts the network card into promiscuous mode. This basically means it can intercept packets into the network, it is done by using libraries called as winpcap and libpcap. These winpcap and libpcap provide capture and filter capabilities on different platforms. Wireshark is a free and open-source protocol/ packet tracer[13]. Network attacks are almost identifiable by observing incoming and outgoing traffic, because unusual behavior is caused by the suspicious pattern of packets[14].

A. FEATURES OF WIRESHARK

- The main feature of wireshark is, it has live capture and offline analysis.
- It is a multiplatform i.e., it runs on multiple flatforms like windows, OS, linux etc.
- Captured network data can be browsed through a graphical interface.
- For dissecting new protocols, plug-ins can be created.
- Most importantly it is a data capturing tool and a packet analyzer.

B. WORKING OF WIRESHARK

The first thing we see is the list of all the network interfaces. We have to choose which interface we want

wireshark to capture on. Most of the time it will be the Ethernet or Wi-Fi interface. Once we select the interface the wireshark starts capturing the packets.

Let us take an example of ping packet. Ping packets are a type of internet control message or part of the ICMP protocol. We can ask the wireshark to give us only ICMP packets.

The top part of the screen wireshark shows a list of all the packets seen and gives a brief information about them.
The middle section of the wireshark window shows the lines that corresponds to one of the layers of the internet. Each of the layer is represented by the header that is contained by that packet. So, whenever the wireshark intercepts the packet it looks at all of the header on that packet so that we get complete information about the packet-ed every step of the network stack.

The bottom most part of the wireshark window shows the actual bits of the packets and what their encoding means.

C. WORKING SCENARIO

Fig 13. shows the initial window of wireshark where all the network interfaces are present.

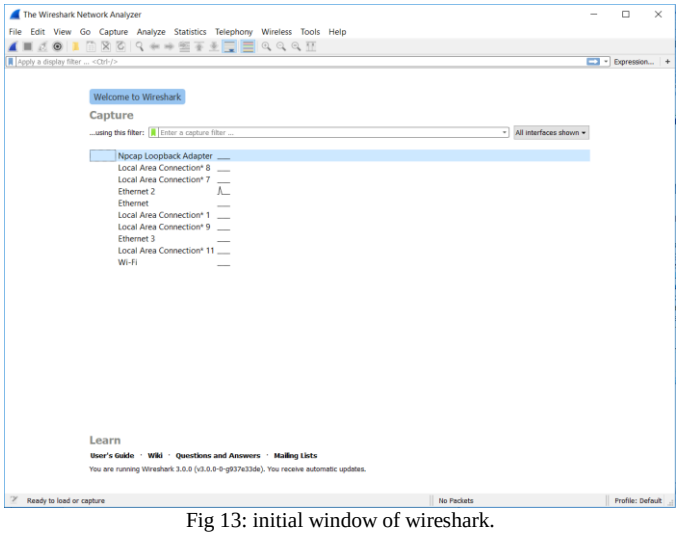

Fig 13: initial window of wireshark.

Fig 14 shows that the packets are being scanned. Here as for the example we have taken i.e., TCP, the packets are being scanned for that.

We can also get the input output graph for this TCP packet analyzer. This option is found in the statistics option and the graph is as shown in fig 15.

Statistics also has many options such as packet length, end points, resolved addresses etc and one such option is capture file properties and this is shown in fig 16.

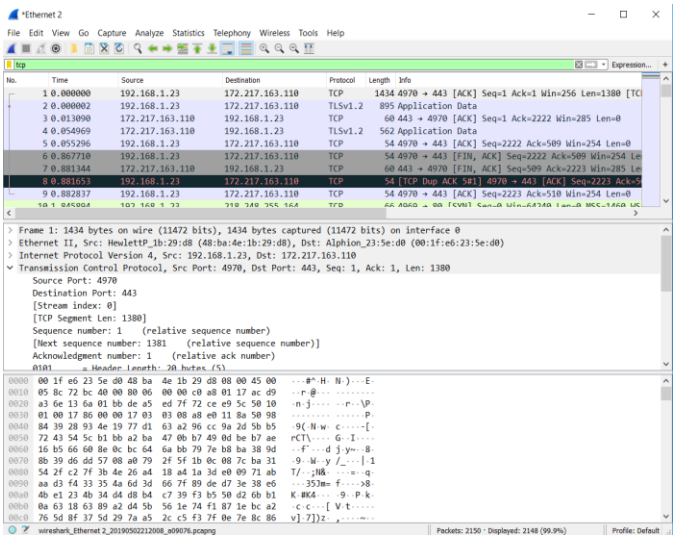

Fig 14: Packet scanning.

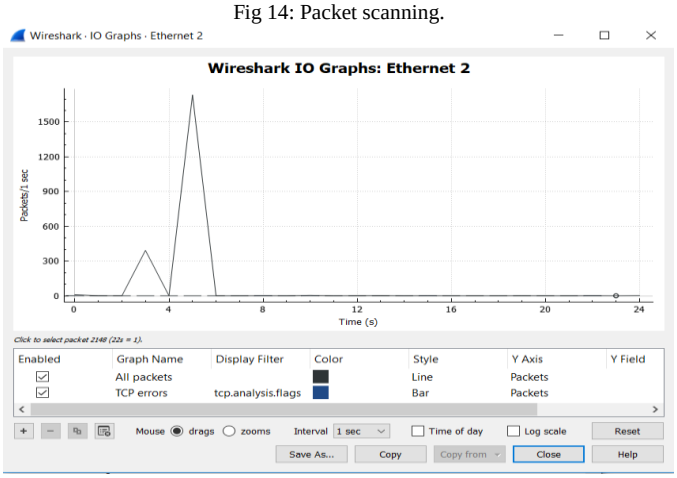

Fig 15: i/o graph.

Under ideal conditions, the graph represents a line develops over time indicating efficient performance the TCP connection [15].

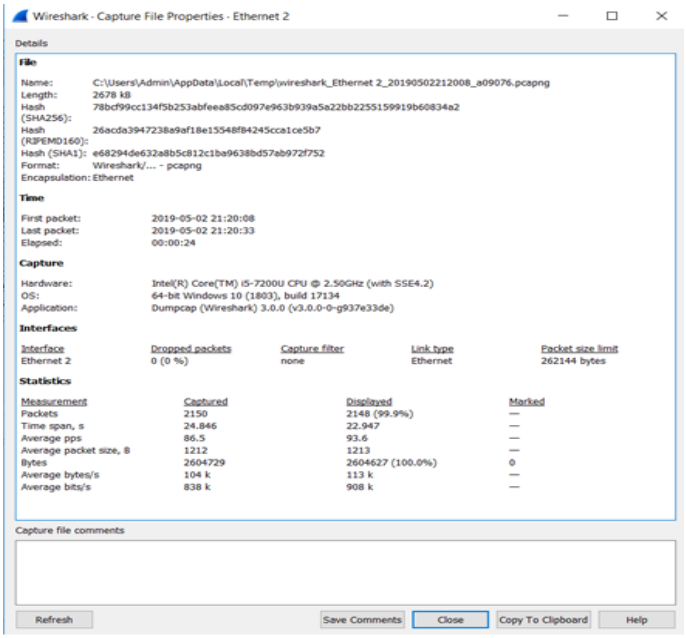

Fig 16: capture file properties.

VI. COMPARISON TABLE OF THE NETWORK SECURITY TOOLS

NO.	TOOL	FUNCTION	USES
1.	Zed Attack Proxy	Web application security scanner	Scans vulnerabilities in a web application, and gives solutions to those problems.
2.	Aircrack-ng	Wi-fi network security checker	used to test the weaknesses of wireless networks by accessing the network.
3.	NMAP	Network mapper	Gives all the information about a network about hosts, operating systems etc.
4.	Wireshark	Packet analyzer	used for network analysis, software and communications protocol development, troubleshooting and education.

VII. CONCLUSION

Here we have exhibited the subject of Network Security and some of the Network Security Tools that will help us in finding the vulnerabilities in a website. In this paper we see the usage, main features, principles and the working scenarios of network security tools like zap, aircrack-ng, Nmap and Wireshark. Thus, all these tools help us in securing the network and preventing it to be vulnerable from any third-party system.

Abstract- Piezoelectric devices are the alternative potential source for energy. The main focus of this paper is to maximize the output voltage in different shapes of piezoelectric cantilever beam with the same dimensions. In this paper we compare the power output between conventional structure and modified structure (E-shape) and conclude that modified structure has more possibilities in generating maximum power. The prototype E-shaped structure shows maximum deflection than the conventional one. This energy harvester is able to remove the battery problem in various fields like wireless, biomedical and so on. The various structure of cantilever beam is designed by using COMSOL multi-physics 5.1. The obtained results are compared using MATLAB simulation.

Keywords- Cantilever, Unimorph Piezoelectric, Energy Harvesting.

1. INTRODUCTION

Advancements in wireless sensors in recent years have had major strides in the piezoelectric domain. When we realize the fundamental properties of piezoelectric effect, we can state that the amount of electric energy produced is directly proportional to the mechanical stress applied. Many researchers have tried to increase the amount of power generated through the use of cantilevers pertaining to the amount of stress and displacement caused by the cantilever beam which has lead to unique design modules like rectangular (cardinal form), step, trapezoidal and much more. Keeping the main focus about structural integrity this paper mainly showcases a new unique form of a cantilever beam design known as the modified E-structure which produces substantial displacement in turn increasing the sensitivity. Here an unimorph cantilever beam is utilized, unimorph has only one piezoelectric layer [4] attached to the substrate. Since energy harvesting is our primary objective, unimorph cantilever is viable choice. Given that the cantilever beam focuses on fundamental modes of frequency [1], the accuracy is tested using MATLAB of different transfer functions pertaining to the E structured cantilever beam [Fig 2]. Basically, there are two model of cantilever that can be used in two different modes-33 mode and 31 mode, where 33 mode (compressive mode) means the voltage is obtained in the 3-direction parallel to the direction of applied force and the 31 mode (Transverse mode) means the voltage is obtained in 1 direction perpendicular to the direction of applied force [5]. The one end of the unimorph cantilever beam is fixed while other end is suspended freely for motion. When the cantilever beam is deflected up and down from the vibrations produced by a mechanical force in the cantilever beam. This mechanical energy of the beam will get converted into electrical energy due to piezoelectric properties [8].

Piezoelectric energy harvesting can be used as the alternative source of energy for the removal of battery problem. PZT materials that can convert the ambient vibration energy surrounding them into electrical energy. This electrical energy can be stored and used to power others devices. Due to advance technology of wireless and MEMS technology the wireless sensor which are in remote area, this piezoelectric electric energy harvesting plays a vital role. In case of biomedical field to power sensors which are implant inside human body, this energy harvesting contributes to supply the power for example the artificial pacemaker.

2. CLASSIFICATION OF CANTILEVERS

This section presents the case study using finite element analysis in COMSOL Multiphysics to compare the traditional rectangular piezoelectric cantilever beam as shown in fig 1 and the derived E shaped as shown in fig 2.

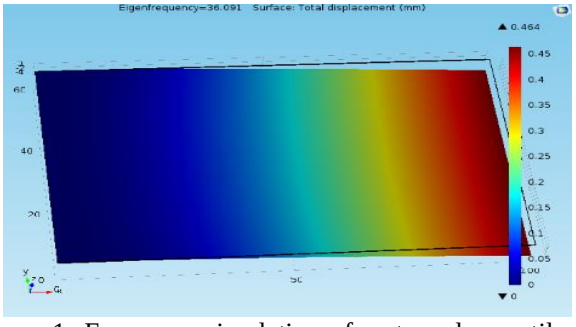

Figure 1: Frequency simulation of rectangular cantilever beam

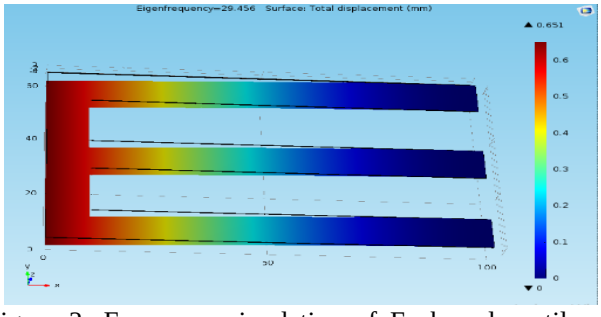

Figure 2: Frequency simulation of E shaped cantilever beam

In order to perform a fair comparison, we need to keep the dimensions of both the beams equivalent as shown in Table 1. The required parameters are compared as shown in Table 2. When the length of piezoelectric and non-piezoelectric are equal the maximum power is generated [11]. The mechanics module of COMSOL Multiphysics is used to simulate the mechanical domains and the piezoelectric devices module to simulate the piezoelectric properties of the PZT5H layer [6].

Table 1: CANTILEVER PARAMETERS

Layer	length (mm)	Width (mm)	Thickness (mm)
Silicon	100	60	0.276
PZT-5H	100	60	0.222

Table 2:MATERIALS PROPERTIES

Material properties	PZT-5H	Silicon
Young's Modulus (GPa)	63	170
Density (kg/m^3)	7500	2329
Poisons Ratio	0.31	0.28

Lead Zirconate Titanate (PZT) is a perovskite ceramic material that shows marked piezoelectric effect[2]. PZT can be prepared in many different forms depending on the application. Here with an approach to create an universal cantilever beam which could be used in multiple ways, we choose PZT based on the conclusions made in the paper[2]. Where temperature change above 20°C does affect the output voltage(PZT-5H). Piezoelectric material works really well under the curie temp (200 °C) and the energy produced increases as the loading increases while the temperature decreases[2].
Table 3 shows comparison of different shapes used for analysis.

Table 3: COMPARISON OF RECTANGULAR AND E-SHAPED BEAMS.

Geometry	Stress, (N/m^2)	Piezoelectric voltage (V)
Rectangular	1.32*10^5	0.278
E-Shaped	1.64*10^5	0.32

3. MESHING

3.1 Meshing

The finite element mesh is used to subdivide the Computer Aided Drawing (CAD) model into smaller domains called *elements*, over which a set of equations are solved. These equations approximately represent the superintended equation of interest via a set of polynomial functions defined over each element. As these elements are fragmented down into figuratively smaller modules, as the mesh is refined, the computed solution will approach the true solution

Meshing is a basic procedure to produce a physical simulation through a grid structure than maps every part of the model to be fabricated. Here the model is meshed with physics control mesh and element size fine. Meshing can be done in many different forms namely tetrahedral [Fig 3] hexahedral and polyhedral. Tetrahedral form is adopted to construct the E cantilever (Fig 4) as it has 4 vertices, 6 edges, and is bounded by 4 triangular faces which provides an immense amount of structural integrity. Tetrahedral meshing is easier to compute than hexahedral, as it simplifies complex geometry. Also another key feature is that tetrahedral can be transitioned into another form of meshing easily when compared hexahedral.

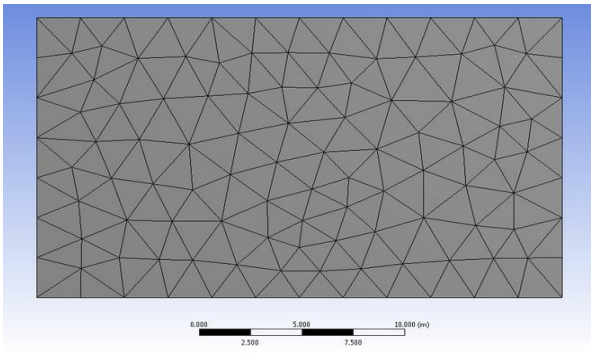

Figure3: Typical Tetrahedral meshing (Comsol)

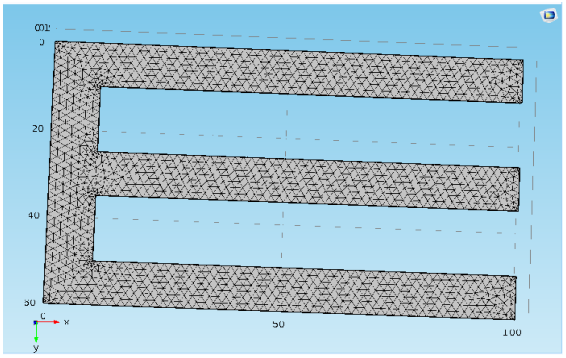

Figure 4: Tetrahedral meshing applied for E cantilever

3.2 Mathematical modelling

A definite system can be represented by different peripherals which may be physical or not depending on its application. A mathematical model as the name states represents this in a mathematical concept. A schematic of converting kinetic energy into electrical energy is represented in figure 5 [1] based on linear elasticity.

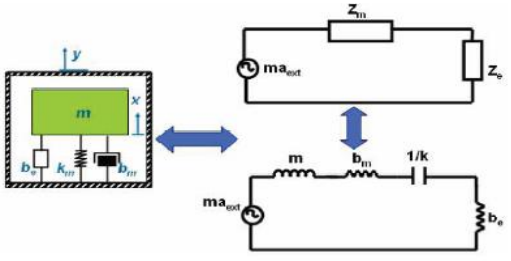

Figure 5: Schematic of a generic vibration energy harvester.

When control system analogy of translating mechanical models to electrical models is applied to the system in

[Fig 5] we get:

$$m\frac{d^2x(t)}{dt^2}+(b_e+b_m)x(t)+kx(t)=f(x)\ldots. (1)$$

$$\frac{X(s)}{F(s)}=TF=\frac{1}{mS^2+k} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(2)$$

The above obtained transfer function is used to verify the frequency values using MATLAB.
General equations pertaining to a unimorph cantilever beam are as follows [3]:

$$K=\frac{Ewt^3}{4t^3}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

$$fr=\omega/2\pi=\frac{1}{2\pi}\sqrt{\frac{K}{m_e}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\

Multiphysics we acquire the following average values:

Table 4: COMPARISON OF RESULTS

Geometry	Eigen frequency (Hz)	Displacement (mm)
Rectangular	36.091	0.464
E shaped	29.456	0.651

4.2 Verification using MATLAB

Taking in consideration of the possible errors caused as the number of iterations are more, the following values were verified in MATLAB using bode plot concept. The frequency obtained from the COMSOL simulation is compared with the frequency obtained from matlab simulation which is shown in figure 7. As the frequency obtained from COMSOL simulation is 29.45 while the frequency obtained from matlab simulation is 32.

Using equation (2) where the following substitutions are made:
m=0.006923 kg
Damping coefficient(B) = 0 (assumption)
Stiffness(K) = 6.8

We get a graph as shown in figure 7, from which we can draw that the eigen frequency value is 29.123Hz.

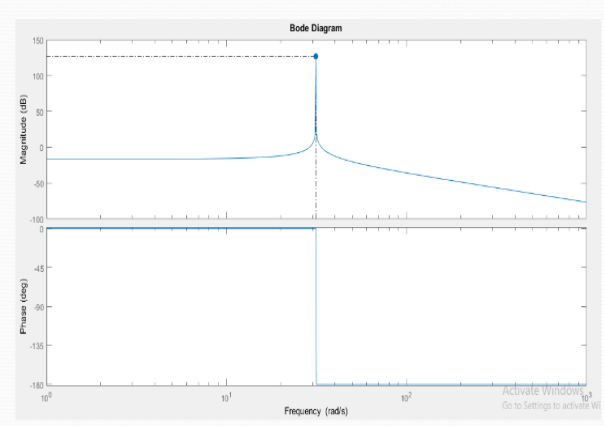

Figure 7: Bode plot obtained from MATLAB simulation

5. CONCLUSION

From the results obtained and verified it is evident that the new formulated E shaped cantilever beam produces more displacement when compared with the traditional Rectangular shaped beam. Since the output power generated is more in this particular prototype as compared to other structures, it can used in bio sensors, wireless sensors, ultrasonic imaging and so on.

5.1 Future scope

The performance of the beams can be estimated by incorporating residual stress of the beams. Mesh less tools can be used to evaluate the performance of the structures. As, it is observed the displacement of the E shaped cantilever beam is considerably more than the conventional structures, different types of structures can be derived to increase the efficiency of this module.

***Abstract*—Solid state transformer (SST) is an alternative concept of traditional line frequency transformer in the distribution circuits. It has expedience such as small volume, less weight, high power density, controlled power factor etc. It is very beneficial for future power system. This paper encompasses the system design and demonstration of a high voltage SST laboratory prototype model for smart grid applications. The high voltage high frequency 5KVA SST operating at 3 kHz designs are the prime segments of the system, including power stage are highlighted. Transformers magnetic core materials are compare and selected. The high voltage high frequency 5KVA, 3 KHz transformer prototype are designed and integrate with load.**

Keywords – High frequency transformer, dc to dc converter, inverter, rectifier, solid state transformer.

I. INTRODUCTION

Nowadays, power electronics is one of the advance technologies in the power system which has been focused on the improvement of power density and efficiency simultaneously minimising the weight, cost with volume [1]. Varieties of redevelopment technologies are present incorporating high frequency system employed with attachments, such as battery storage system, flexible alternative current transmission system, high voltage dc transmission system, and fuel cell system and power management for computers [2].

We are using SST as an alternative to the traditional line frequency transformer because to overcome the disadvantages of traditional transformer such as bulky size and heavy weight, transformer oil can be harmful when exposed to the environment which are used in traditional transformer cooling as well as insulating purpose, large magnetic inrush current produces harmonics, undesirable results at the input side such as fluctuations effects output waveform with impressions of power deficit at average loads, Voltage regulation is not optimum etc. SST has discriminative characteristics than traditional, as less weight, low volume, high power density, high power factor. Controlled power factor, reactive power compensation, metering or advanced distribution automation, harmonic filtering etc. [9]

Recently, SST is another one high frequency link power conversion system to use in distribution systems with the development of the high voltage power device technology [1].SST exhibits good features such as small weight and volume, controlled power factor, high power density, voltage sag etc. compare to traditional transformer [2]. SST is combination of different materials such as boron, silicon, iron and phosphorus. SST is oil free and dry type insulated high voltage high frequency transformer is mostly preferred due to its safety and environmental consideration; it is one of the advantages of solid state transformer. When line frequency transformer are used in the system then FACTS devices are used to compensating purpose but its alternative SST are used then there will be automatically compensation takes place which is in built in the system.

The remaining part of the paper is drafted as follows. In section II, configuration of SST are explained. In section III, design of high frequency transformer are presented. In section IV, selection of power devices are presented. In section V, summarization of SST function are presented. Finally, conclusion of the paper is given by in section VI.

II. CONFIGURATION OF SST

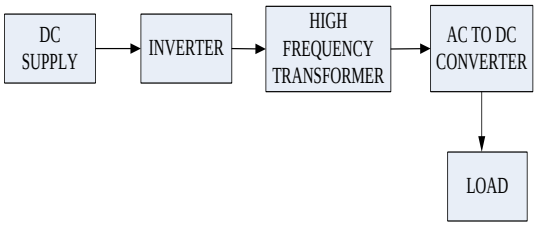

Fig. 1. Configuration of SST

In the recent decade, high power converter is named as power electronics transformer or solid state transformer, has getting more attention and used in the distribution system. Configuration of solid state transformer (SST) are shown in figure 1.

Solid state transformer is one of the best power electronics device which is a coil free, self-regulating, and able to correct the power quality problems, prevents system form load disturbances as well as fault from primary supply side, converts ac to ac, dc to dc, dc to ac with any desired frequency [3].

The basic operation of SST is shown in figure 1. In this operation dc suppy220 volt is given to the system then inverter is the one of the power electronics device used to convert dc to ac and ac supply 230 volt is supply to the high frequency transformer, rating of high frequency transformer is 5KVA and frequency is 3 KHz so size as well as weight will be reduces then output of the high frequency transformer is 48 volt given to rectifier and convert 48 volt ac to 48 volt dc. Output of the rectifier is dc connected to dc load like battery charging, electronic workshop and electrical vehicle charging [1]. If input supply is ac then that time firstly converting 50 Hz ac voltage into dc voltage by using the rectifier. The output of the rectifier is provided to dc to dc dual active bridge converter, in which firstly inverter are used to convert dc voltage into ac voltage at high frequency and supply to high frequency transformer where step up or step down the voltage and output of transformer is provided to rectifier an again convert to dc voltage, finally integrate with dc micro grid as well as ac micro grid [2]. Due to high frequency volume and weight are reduced, so power ratings are required high to reduces weight and volume of transformer effectively.

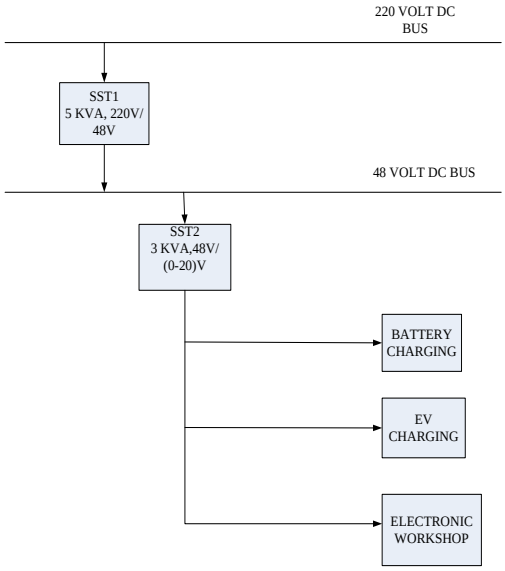

Fig. 2. Innovative architecture of project

Innovative distribution architecture proposed in the project is shown in fig.2.it is proposed to use two solid state transformers. Ratings of these transformers are 5KVA and 3KVA respectively. Input supply is 220V dc and output voltage is variable from 0 to 20V dc. The output is provided to electric vehicle charging, battery charging, and electronic workshop. Also interaction of 48V photovoltaic supply system is proposed for supply to loads through solid state transformer 2, use of this transformer is unidirectional. But when supply is not available then use of main input supply is proposed, which will be provided through solid state transformer 1 as shown in figure 2 and this transformer is bidirectional transformer.

SST is a very beneficial for future distribution power system means in future increases residential load demand and that time required high power rating distribution transformer to improve capacity of the system [2]. If there is a limited space to install transformer, that time SST is a one of the best solution.

The prior work on SST was either components eccentric or had restricted functionality designed for traction systems. Despite of all the distribution system remained destitute from this technique [1].

The concept of solid state transformer is very straight forward and also challenging. High power density power electronic circuit are required, so the operation of SST challenges for both hardware as well as control design. SST contains many components such as high frequency transformer, gate drive, power devices, heat sink, cooling system, control circuit, etc.

The paper can be summarized as follows,

1. Design of solid state transformer
2. Design of high performance system controller for solid state transformer.
3. The demonstration of prototype for loads like as electrical vehicle charging, battery charging, electrical vehicle etc.

III. DESIGN OF HIGH FREQUENCY TRANSFORMER

Table1 shows the specification of 5 KVA solid state transformer. Different parameters are defined like input voltage, output voltage, input current, output current and switching frequency which is the basic parameters required to design the solid state transformer.

A. Specifications of SST :

Table I - Specifications of SST

Power rating	5 KVA	Frequency	3KHz
Input DC voltage	220V	Primary side current	23.92A
Output DC voltage	48V	Secondary side current	104.16A
Primary AC voltage	230V	Secondary AC voltage	48V

B. Selection of Core material :

There are different types of core material are available such as ferrite, amorphous and nanocrystalline and silicon steel. By comparing all materials characteristics, we are selected amorphous core material it has also many advantages as well as disadvantages. Amorphous core material has the highest saturation flux density (1.56T) than

other materials and losses taking place in the core are marginally accepted for a band of several kilohertz. The subjected core is cheaper therefore, it shows the requisite operational cost ratio performance in terms of switching frequency less than 5-10 kHz [5]. Table 2 shows the comparison between different core materials. Core materials are comparing and selected amorphous core material in the c core shape and it has high permeability with 25 micrometre strip thickness.

At the time of transformer design core losses are very important factor to be considered and these are find out by using Steinmetz equation. [1]

$$P_{cv} = K \times f^{\alpha} \times {B_{ac}}^{\beta}$$

Where, P_{cv}= time average power loss per unit volume

B_{ac}= peak flux amplitude

K, α, β = Steinmetz constant

f = frequency of sinusoidal excitation

For different core material has different Steinmetz constant and core losses at 3 KHz frequency which are shown in table 2. Amorphous core material has less core losses than silicon steel.

C. Selection of wire:

Selection of the conducting wire depends on the rating of current. We are selected copper conducting wire for winding purpose at different size for primary and secondary side because primary current is 23.92 A, 10 SWG wire are used and secondary current is 104.16 A, 6×3 fibre glass enamel coating copper foil are used.[4]

D. Calculations :

To find out the different parameters we are using following formulae's [4], [7];

$$\sum VA = \left[\frac{1}{\eta \times \cos\varphi_1} + \frac{1}{\cos\varphi_2}\right] \qquad (1)$$

Equation 1 are used to find out VA rating of a transformer which is 10390.955VA and optimal flux density are calculated by using equation 2. Optimal flux density is less than saturation flux density which is 0.8066T.

$$B_o = \left[\frac{1 \times \sqrt{\Delta T}}{{K_o}^{7/8} \times K_t \times K_f \times K_u}\right] \times \left[\frac{K \times f \times \Delta T}{\sum VA}\right]^{1/6} \times \left[\frac{1}{(\rho_c \times K_c \times f^{\alpha})^{7/12}}\right] \qquad (2)$$

$$A_p = K_o \times \left[\frac{\Sigma VA}{K \times f \times \Delta T}\right]^{4/3} \times [\rho_c K_c f^{\alpha}]^{2/3} \qquad (3)$$

As per [4], all constants and product of area are calculated to selection of core. By using equation (2) product of area 135.1419 cm^4, so we are selected AMCC-160 amorphous c core to high frequency transformer. [5]

$$N_p = \frac{V_p}{k_v \times k_f \times A_c \times B_o \times f} \qquad (4)$$

$$N_s = \frac{V_s}{k_v \times k_f \times A_c \times B_o \times f} \qquad (5)$$

By using equations (4) and (5) we are calculated primary and secondary side number of turns 36 and 8 respectively. Turns ratio are 4.5: 1.

$$\text{MLT} = \frac{\text{Volume of winding}(V_w)}{Window\ area(W_a)} \qquad (6)$$

$$\text{But, } V_w = k_w \times {A_p}^{3/4} \qquad (7)$$

By using equations (6) and (7), calculated mean length of winding are 19 cm. also theoretically core and copper losses are calculated by using (8) and (9). Which are 12.6779 W and 15.1121 W respectively. [4]

$$P_{cu} = \rho_w \times V_w \times k_u \times J^2 \qquad (8)$$

$$P_{fe} = m \times K_c \times f^{\alpha} \times {B_m}^{\beta} \qquad (9)$$

In equations current density J are used which is calculated by equation (10).

$$J = \left[\frac{\beta \times h \times A_t \times \Delta T}{(\beta + 2) \times \rho_w \times k_u \times V_w}\right]^{1/2} = K_t \left[\frac{\Delta T}{{A_p}^{1/4}}\right]^{1/2} \qquad (10)$$

High frequency transformer core AMCC-160 and core with winding are shown in figure 2. [5]

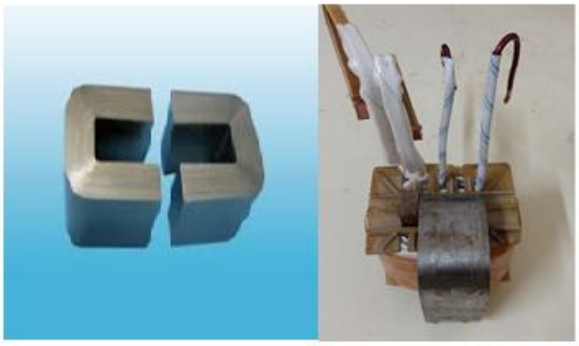

Fig. 3. Core AMCC160 and core type transformer

Table 2 – Comparison between different core materials and Steinmetz equation constant

IV. SELECTION OF POWER DEVICES

The input to the transformer should be high voltage and low current means 220-volt dc voltage and 23.92 ampere current. Faster and low loss switching at the high voltage side should be shows satisfactory performance by SiC power devices, however SiC power devices are not commercialized yet and the cost of the devices are higher than Si devices [1].In this project for high voltage side FNB34060T intelligent power module are used for inverting purpose which are shown in fig.4 pin configuration as per datasheet [6]. It is an advance module providing a fully featured, high performance inverter output stage for AC induction, BLDC and PMSM motors. These modules integrate optimized gate drive of the built in IGBT to minimize losses, while also providing multiple protections like under voltage lock out, over current shutdown, thermal monitoring of drive IC and fault reporting. It can support up to 20 KHz. All connections are as per datasheet [6].

For low voltage and high current side means 48-volt 104.166 ampere current side two level H-bridge converter are used to convert 48 ac voltage to 48-volt dc voltage. There are four IRFB3077PbF MOSFEET are used which has rating 75 V/210 A. [1] From the control objective, the phase shift PWM strategy is employed during rectification to cancel harmonics and minimizes size of filter.

Fig. 4. FNB34060T IPM

The switching frequency is selected N times that of rectification stage and boost converter stage. To diminishes the size of passive components higher switching frequency selected. To improve efficiency and thermal design switching losses are big challenge. Between 5 to 20 KHz frequencies are selected for switching the power devices. There are 3 KHz switching frequency are selected which is multiple of 60 Hz.

Zero voltage switching is obtained by dual active bridge converter [11]. In this condition the turn on losses of IGBT and reverse recovery energy losses of parallel connected diode will be very small and turn off losses of the dual active bridge converter remains high due to its inherent operations.

Gate driver design is one of the important parts in the SST design system which are used to high voltage side mosfet into which short circuit protection, active clamping circuit, fault isolation circuit, under voltage protection circuit are integrated. Pulse width modulation technique are used. [9]

V. SUMMARIZATION OF SST FUNCTION

SST are used for different functions such as rejection of load disturbance, rejection of source disturbance, VAR compensation, dc micro-grid integration, ac micro-grid integration etc. All these described characteristics will be evaluated in SST prototype. The advantages over the conventional transformer.

a) SST integrate with both AC and DC micro-grid
b) SST shares both voltage and current
c) Efficiency is good ac as well as dc load condition
d) Source voltage sag means source disturbance rejection capability in SST
e) Load disturbance rejection capabiltity in SST

VI. CONCLUSION

This paper highlights the concept of design and demonstration of 5 KVA SST when input is 220-volt DC and output is 48-volt dc. Also required calculations and selection of material are explained in details. SST has many advantages than conventional line frequency transformer is deeply explained.

Abstract*---ADC are the important blocks of signal processing systems. Depending on the type of ADC, the blocks involved in the design of an ADC will vary. This paper gives an insight to the design of comparator which will be used in different types of ADC's. This paper also presents design of AND gate, digital counter and DAC used in Ramp ADC. The implementation of 8-bit Ramp ADC is carried out using 45 nm technology in Cadence virtuoso tool and the consumed power is estimated.

Keywords-Analog to Digital Converter (ADC), Digital to Analog Converter (DAC), comparator, digital counter, Operational Amplifier (Op-Amp), Toggle Flip-Flip (TFF), Multi Section Capacitive Digital to Analog Converter (MS-CDAC).

I. INTRODUCTION

Data converters are important building blocks in modern mixed signal processing. The circuit of data converters acts as a link between the analog and digital worlds. Data converters are devices converting analog signals into digital signals and vice versa. It forms the critical components of all the systems. Data converters can be implemented in a number of ways, each taking a different performance parameters in terms of resolution, speed, power consumption, area, etc.

II. REVIEW ON VARIOUS DESIGN TECHNIQUES OF ADC

S. Bashir et al., [1] have proposed different types of ADC's that are used in different application requirements. Different performance parameters like power consumption of different ADC's are compared.

D. Prashanth et al., [2] have designed a dynamic latch based comparator that further provides input and output separation. Thus kickback noise effect is reduced.

P. M. Figueiredo et al., [3] have proposed a different types of comparators out of which latched comparator is one of them. One of the most commonly used comparator is dynamic latched comparator due to its speed.

K. M. Abozeid et al., [4] have designed a dynamic latched comparators, which is power efficient because, in regeneration phase they consume power and absence of static power consumption in reset phase .

Yan Huang et al., [5] have presented the different types of latched comparators like static latched comparator, class AB latched comparator. The fabrication of the comparators are processed using 130 nm technology with power dissipation of 0.75 mW

Raghava Katreepalli et al., [6] have proposed design of synchronous counters which is energy efficient and the power consumption also reduced because clock is applied to different flip-flops simultaneously.

Babita Diana K et al., [7] have designed a SAR ADC using a capacitive array DAC, which works based on charge redistribution principle.

Savitha.M et al., [8] have designed 14 bit SAR ADC. ADC performance is analyzed by using the two split capacitiv e array DAC method to obtain power consumption.

Shinwoong Park et al., [9] have presented a paper that examines the concept of MS-CDAC's, which allows for a broader range of CDAC section segmentation options beyond split - CDAC and C–2C.

Nikhil A. Bobade et al., [10] have presented a modified DAC structure. Hence modification is proposed in modified DAC structure has good power efficiency.

III. Ramp ADC

Ramp ADC is the type of counter ADC. It includes comparator, an AND gate, digital counter, and a DAC. The DAC output is taken as an input to the comparator where it is compared to the analog input signal and produces the comparative output from the designed comparator [2]. If output of the comparator is high then that gives a high input to the digital counter that act as a clock signal. The digital counter makes use of a Toggle Flip-Flop (TFF). Counter starts to count which will be further given as an input to the DAC. Ramp ADC block diagram is shown in Fig. 1. This block is incorporated from [1] and the comparator design is taken from [2]. In this work separate blocks are designed and interconnection between the individual blocks is done.

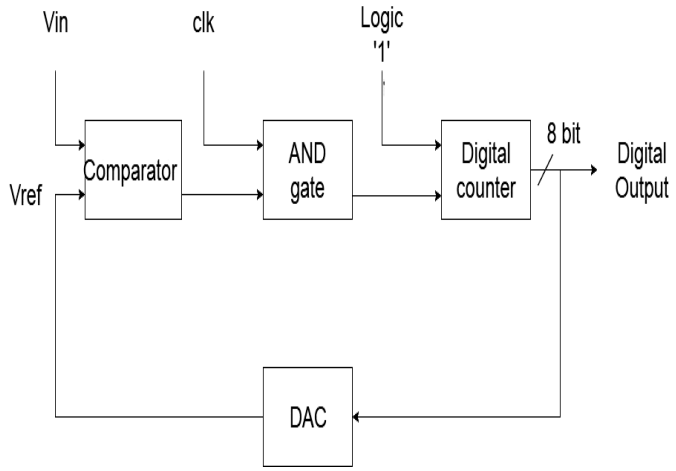

Fig. 1. Ramp ADC block diagram

IV. COMPARATOR

A comparator is a circuit which is used to compare two voltages and it produces the output as either one or a zero, depending on the voltage whether it is at the positive side or at the negative side. The fundamental functionality of the comparator is to find out if an applied input is greater or smaller than the reference signal and, depending on comparison, the binary output is generated.

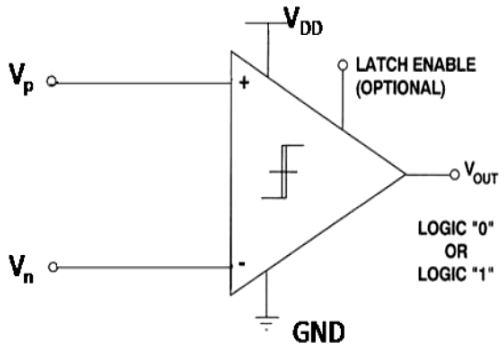

Fig. 2. Symbol of comparator

Fig. 2 displays the comparator symbol. The input voltage is applied to the Vp terminal and Vn is supplied with reference voltage. If Vp terminal input voltage is higher than Vn, then the comparator output is logical '1', where, as if the Vp terminal input voltage is lower than Vn, then the comparator output is none.

ADC's can be implemented using different types of comparators namely Op-Amp based comparator, Static latched comparator, Class-AB latched comparator [11]. Static and Class AB latched comparators are more power efficient, but after regeneration and reset phase there are some supply currents. That problem can be overcome by using Dynamic latched comparator [13]. It allows flow of current only during the regeneration phase [4]. Therefore, due to its high speed and minimized power consumption, Dynamic latched comparator is used in this work.

V. DYNAMIC LATCHED COMPARATOR

The comparator involves two phases of the operation. The output nodes of the comparators are discharged or charged to the source or ground respectively, depending on the architecture in the reset phase. In regeneration phase the digital value is generated at the comparator output. Hence there is power consumption. One of the benefit of Dynamic latched comparator is the absence of static power consumption in the reset phase [4]. Fig. 3 demonstrates the Dynamic latched comparator circuit diagram.

When clk=low, transistors M4 and M3 are in ON state, that precharges the terminal Di+ and Di- to V_{DD} such that transistors M5 and M6 are turned ON. This will discharges the OUT+ and OUT- to ground. When clk=high, M3 and M4 are in OFF state and transistor M15 turned ON, due to which Di node starts to discharge. The difference between voltages Di+ and Di- are applied to transistors M5 and M6. Initially transistors M6 and M5 are in ON state and gradually they becomes OFF. So the output nodes OUT+ and OUT- start regenerating when M5 and M6 are unable to ground the outputs. Power consumed by Dynamic latched comparator is 75.94 pW.

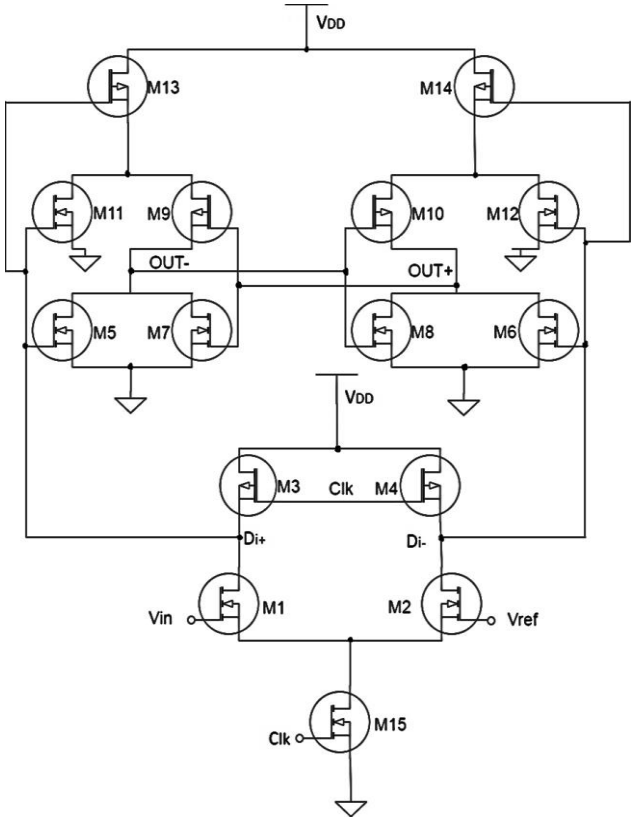

Fig. 3. Circuit Diagram of Dynamic latched comparator

VI. AND GATE

In Ramp ADC, control signal is provided using AND gate. One of AND inputs is the comparator output and another is a clock. The digital counter value increases depending on the AND gate output. Fig. 4 shows the AND Gate schematic.

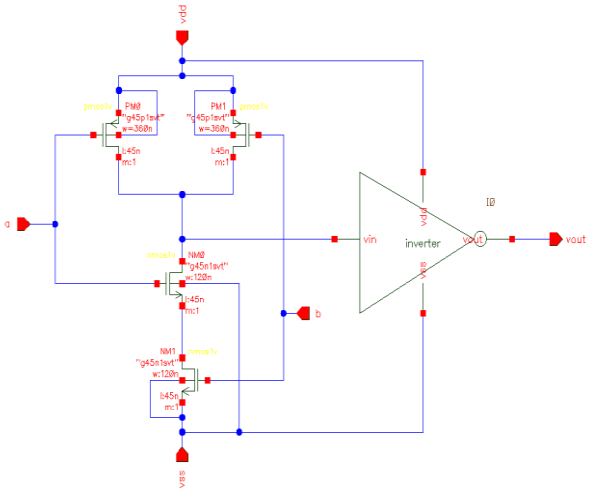

Fig. 4. Schematic of AND gate

VII. Digital Counter

Two types, namely asynchronous counter and synchronous counter, are available. Asynchronous counters are having large propagation. But synchronous counters are more reliable and they can operate at high speed because the same clock is used for all flip-flops, which ensures that every output is changed at the same time. There is therefore more use of synchronous counters. Design of the counters should have high reliability and low power consumption [6]. Hence synchronous counters are used.

Digital counter plays major role in Ramp ADC. When output of the AND gate is applied to digital counter, the digital counter value increases until it becomes equal to sampled input value. The obtained digital output is applied to DAC. The 8-bit digital counter is designed by using TFF [6]. The schematic diagram of digital counter is shown in Fig. 5.

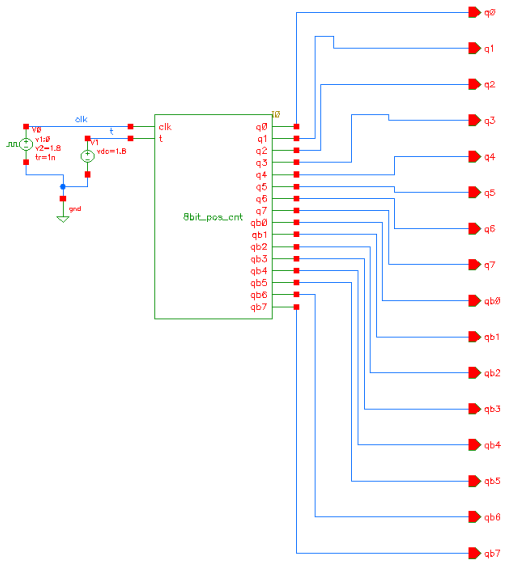

Fig. 5. Schematic of digital counter

VIII. Digital to Analog Converter (DAC)

DAC types are different [8]. Binary weighted and R-2R ladder structure is one of the easiest structures [12]. These structures of the DAC transform digital input into analog output. R-2R ladder type DAC is superior than Binary weighted resistor DAC [12]. Because the resistance changes depending on the binary bit in the Binary weighted resistor DAC. As the number of bits increases, therefore, the resistance will increase causing the effect of loading [11]. Besides that, dissipation of power and non-linearity will also increase. DAC is widely used with capacitor arrays [8]. Compared to conventional R-2R voltage driven techniques, capacitor arrays are easier to manufacture with fewer errors of mismatch [9]. It saves more power based on techniques of charge-redistribution [8]. It is noted that Charge redistribution DAC has a low power consumption of 1.315 µW compared to other DAC types.

Fig 6 shows 8-bit Charge redistribution DAC. It consists of capacitors and switches. The circuit has two modes of operation. One is the reset mode and other is the conversion mode. In reset mode, the bottom plate of the capacitors gets discharge since all the switches are connected to ground. In conversion mode, the switch connection changes from ground to VREF [7], depending on the digital code.

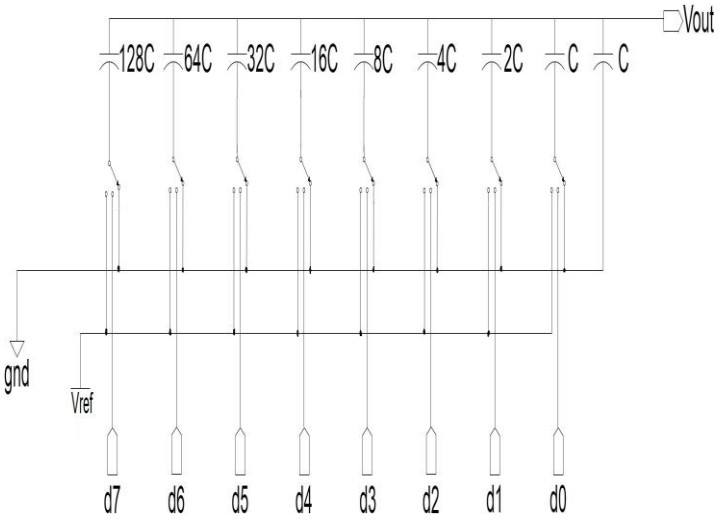

Fig. 6. Schematic of 8-bit charge redistribution DAC

IX. Result

Fig. 7. shows the output of comparator which is simulated in Cadence virtuoso tool with 45 nm technology. Likewise Fig. 8 and Fig. 9 shows the output of AND gate and digital counter respectively.

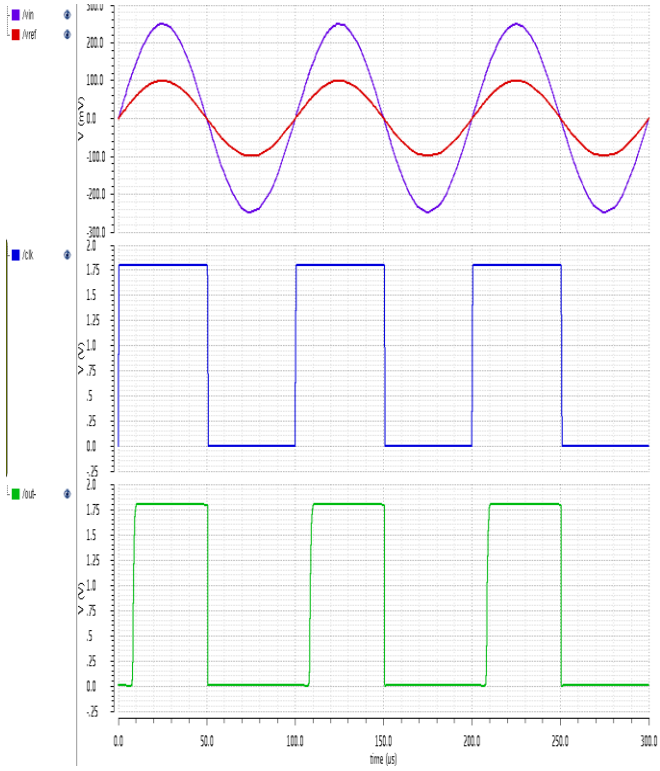

Fig. 7. Output of Dynamic Latched comparator

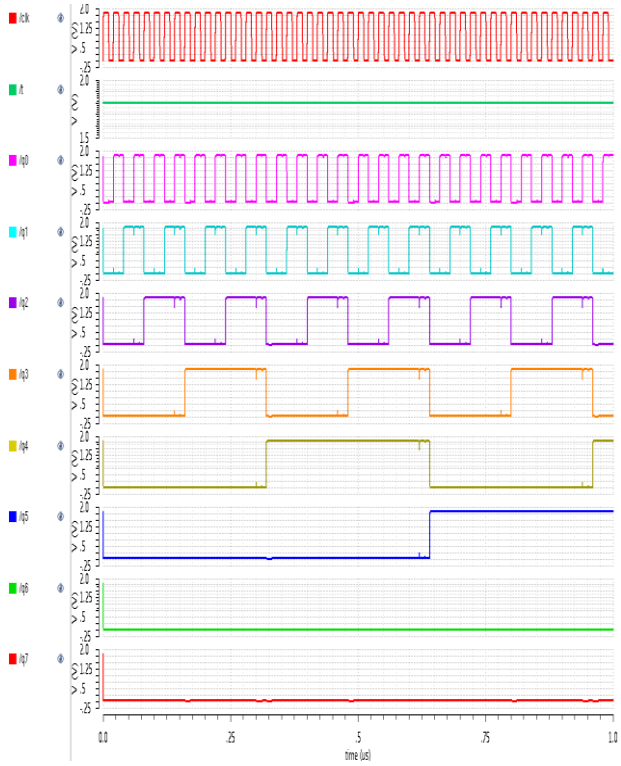

Fig. 9. Output of digital counter

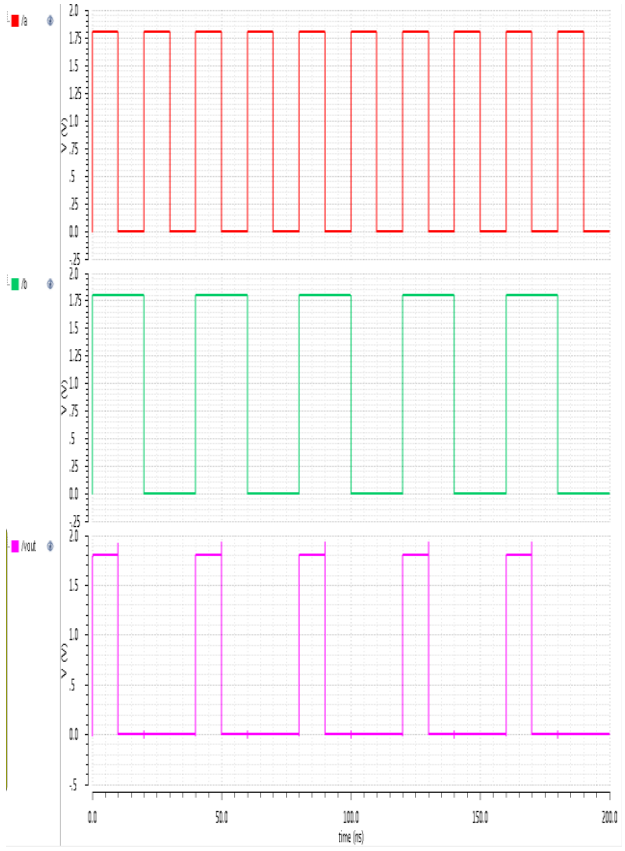

Fig. 8. Output of AND gate

Output of the 8-bit charge redistribution DAC is shown in Fig. 10. It is observed that the digital value ranging from 0 to 255 are converted into analog voltage of 0 to 1.793V.

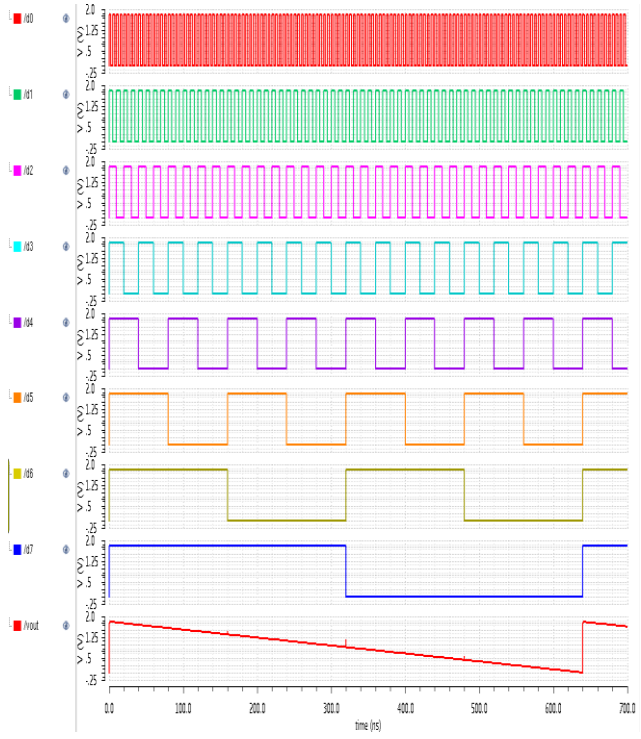

Fig. 10. Output of 8-bit charge redistribution DAC

Transient response of 8-bit Ramp ADC is shown in Fig. 11. Output of the DAC is compared with input voltage. If the comparator output is high, the clock signal to the counter will be provided.Therefore counter value increases, that increased value is again fedback to the DAC. DAC will produce the digital output.

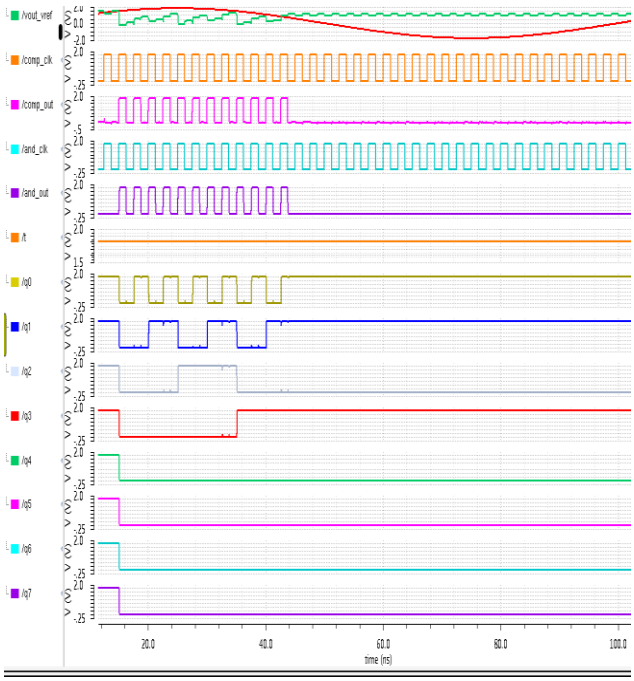

Fig. 11. Output of 8-bit Ramp ADC

The power consumed by 8-bit Ramp ADC is shown in Fig. 12. It is observed that 8-bit Ramp ADC consumes power of 3.247 mW.

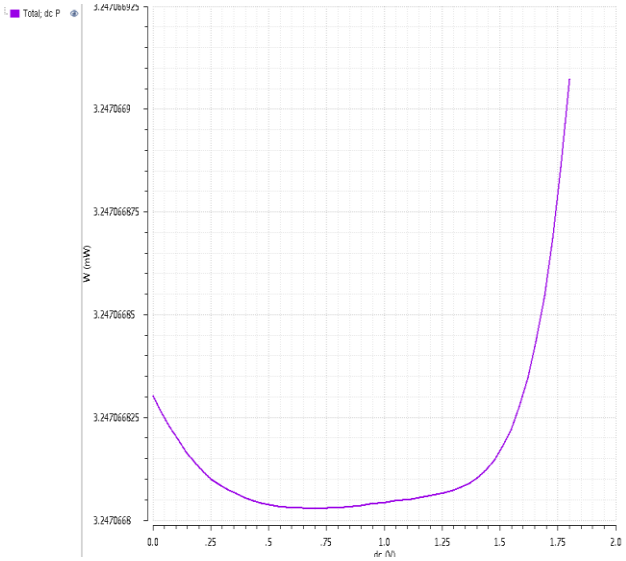

Fig. 12. Power plot of 8-bit Ramp ADC

X. CONCLUSION

The implementation of dynamic latched comparator, AND gate, Digital counter and DAC for Ramp ADC are designed using 45 nm technology and power analysis is made. The power consumed by the 8-bit Ramp ADC is 3.247 mW.

***Abstract*—Routing Protocol for Low power and Lossy Network (RPL) is a light weight routing protocol designed for LLN (Low Power Lossy Networks). It is a source routing protocol. Due to constrained nature of resources in LLN, RPL is exposed to various attacks such as blackhole attack, wormhole attack, rank attack, version attack, etc. IDS (Intrusion Detection System) is one of the countermeasures for detection and prevention of attacks for RPL based IoT. Traditional IDS techniques are not suitable for LLN due to certain characteristics like different protocol stack, standards and constrained resources. In this paper, we have presented various IDS research contribution for RPL based routing attacks. We have also classified the proposed IDS in the literature, according to the detection techniques. Therefore, this comparison will be an eye-opening stuff for future research in mitigating routing attacks for RPL based IoT.**

Key Words - IoT, RPL, IDS, attacks, countermeasures, security, attacks, blackhole, wormhole, knowledge driven approach

I. INTRODUCTION:

IoT is a collection of heterogeneous things or devices that are connected to the Internet. The devices will have a uniquely identity in the network. The devices can be RFID tags, sensors, actuators, smart phones and wide variety of smart devices. The emergence of IoT has led to the connection of people, devices, services and many objects [1]. It is deployed in wide range of applications from smart city to healthcare and intelligent transport systems. There are other domains in which IoT plays a remarkable role to improve the quality of our lives. The IoT has transformed the objects or things from traditional to smart device with the help of Cloud Computing, Big Data, Communication Protocol, WSN and the Embedded Systems.[2]

IoT=Sensing + Communication + Storage + Analysis

The devices in IoT are heterogeneous and so they use various standards. There are many protocols used for communication. 6LoWPAN is one among them. It is a simple low-cost communication protocol. It provides communication in applications where the resources are constrained. The throughput of LLN is not much considered [3]. LoWPAN include devices that work together to connect the physical environment to real time applications. Example of LoWPAN is Wireless Sensors. The main characteristics of LoWPANs are low bandwidth and data rate, star and mesh topology, small sized packets. The architecture of 6LoWPAN is depicted in Fig.1

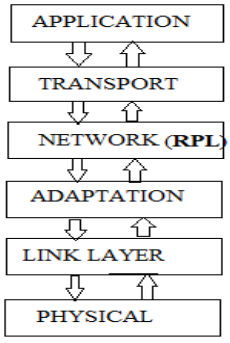

Fig.1. 6LoWPAN Architecture

The major difference in the architecture of 6LoWPAN is the incorporation of a new layer. The new layer is called Adaptation Layer. The main functions of the adaptation layer [4] are: (i) Compression and Decompression of network (IPv6) and transport (UDP) header (ii) fragmentation and reassembly of packets and (iii) routing of packets. The routing can be taken care by Network Layer and Adaptation layer. The routing protocols used in traditional network and WSN are not suitable for IoT. The routing challenges of IoT are: heterogeneous devices, diverse networking, deployment of nodes, intermittent connectivity between nodes, multi-hop communication, fault tolerance, security and context awareness [5]. There

are many standards for IoT. RPL is one of the IoT standards.

The remaining of this paper is organized as follows: Section- II presents the overview of the RPL protocol. Section-III rigorously discusses the classification of recent countermeasures for RPL based routing attacks in IoT. In section-IV, we have provided the concerns, challenges and opportunities related to RPL. The comparison is concluded in section-V.

II. RPL OVERVIEW:

RPLis a routing protocol designed for resource constrained networks. It is a Distance Vector routing protocol. RPL protocol has to find links and select nodes efficiently. It is also a source routing protocol. It allows the sender of a packet to specify the complete or partial route of a packet. The routes of the RPL are enhanced for traffic in both the directions. The root nodes will be a sink node for the topology. Finally, RPL constructs the DAG topology. The DAG consists of one or many DODAGs. There will be one DODAG for every sink node. RPL uses four values for maintaining and identifying a topology. They are RPLInstanceID, DODAGVersionNumber, DODAGID and Rank. RPL protocol and its operation is elaborated in [28].

A. Identifiers of RPL:

- RPLInstanceID: It is used to identify the DODAGs. LLN consists of numerous RPLInstanceIDs. Each of it defines a group of DODAGs that are enhanced for different Objective Functions (OF).
- DODAGID: It uniquely identifies the DODAG in the network. One instance of RPL can have many DODAGs but each have unique ID. (RPLInstanceID, DODAGID) represents a single DODAG uniquely.
- DODAGVersionNumber: A DODAG is rebuild from the root occasionally. The reconstructed DODAG have a version number incremented from the previous one.
- Rank: It determines the location of individual node with respect to the root of DODAG. Fig.2. depicts the DODAG that consists of nodes with various rank.

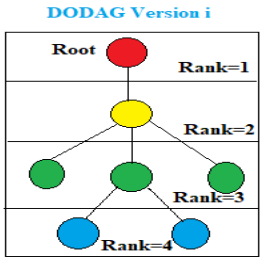

Fig.2. RPL Rank

B. Objective Function (OF):

The objective function [6] defines (i) How the metrics of routing, objectives of optimization and related functions are used in the computation of Rank (ii) Selection of parents during the formation of (iii) Translation of one or more metrics into Rank. The various objective Functions are OF0, MRHOF [7], ETXOF [8], LBOF, TAOF

C. RPL securtiy features:

According to the specification of RPL, the implementation of security features is optional. It provides confidentiality and integrity of messages. RPL can use the link layer security mechanism and in their absences RPL can use its security modes: (i) Unsecured mode: In this mode, RPL message is sent using link layer security to meet the security requirements of applications. (ii)Pre-Installed mode: In this mode, if a node wishes to join an instance of RPL then it should have a pre-installed key. Using that it can generate and process secured message of RPL. (iii)Authenticated mode: As in the pre-installed mode, the nodes will have pre-installed keys in this mode also. Node can use the pre-installed keys to join as leaf in the instance of RPL. If it wishes to join as a router in the RPL instance, it should obtain a key from the authority of authentication. The process of authentication and obtaining keys are based on the implementation. The nodes in the RPL will send CC (Consistency check) message for protecting replay attacks.

III. CLASSIFICATION OF COUNTERMEASURES FOR RPL BASED ROUTING ATTACKS:

The resource constrained nature of nodes and links in the RPL has led to various attacks. IDS is one of the countermeasures for RPL based attacks. Various IDS based countermeasures, knowledge driven technologies approaches are discussed. Fig.3. depicts the classification of IDS. We have reviewed in depth about the detection technique-based IDS for attacks in RPL. The placement strategy of IDS is discussed in [27].

A. NETWORK BASED APPROACH:

The network-based IDS is used for monitoring the traffic in the network. It is also used for analyzing the traffic to protect the system from threats which are based on the networks. NIDS will read all the packets inbound to the network and searches for the pattern that are suspicious. If the threats are detected or discovered, based on the severity, the system can take action such as the IP of the source can be barred from accessing the network, the administrator can be notified, etc.,

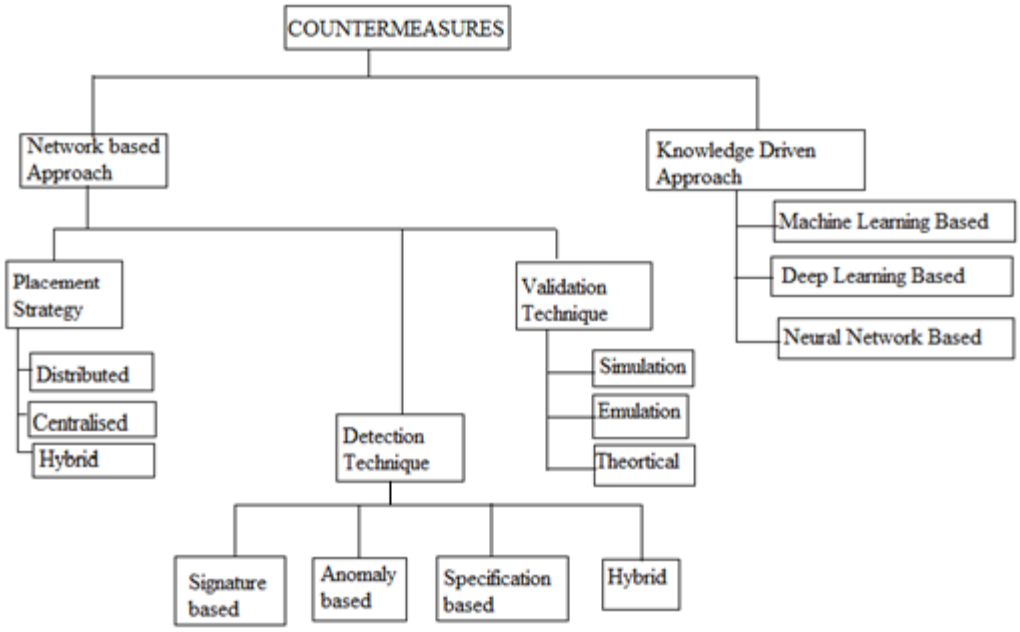

Fig.3. Classification of IDS for RPL Based attacks

1) SIGNATURE BASED DETECTION: In signature-based approach, the signature or pattern of the attack is stored in the IDS internal database. If any network or system activity maps with the stored pattern then the alert will be generated. These IDS are effective in detecting the known threats.

a) Liu [9] et al proposed an IDS based on Immunity Theory. The data in the IoT network is filtered using the immune mechanism. The IoT data is mapped to the elements of the immune environment. The concept of Artificial Immune System (AIS) and the proposed IDS is based on the artificial immunity. The detection element in the proposed IDS evolve dynamically for the purpose of self-learning and self-adaptation.

b) As a large number of devices are connected to the Internet, providing security is a critical challenge. It is difficult to adapt traditional security measures to the nodes since they are constrained in resources, processing power, etc., Oh et al [10] proposed an IDS which operates on the resource constraints. It is a light weight security system which could operate on resource constrained devices. They proposed two techniques: auxiliary shifting and early detection to reduce the number of matchings performed on the constrained systems. The proposed light-weight system also achieved a good performance for a large number of patterns.

c) Pongle [23] et al proposed an Intrusion detection system for real time. It is used for detection of wormhole and the attacker who performs the attack. It uses the location and neighbor information for the detection of worm hole attack. Based on the strength of the received signal, the attacker is identified. This system consumes only fixed number of packets of UDP. So, it is beneficial for resource constrained environment. The centralized module is performing heavy processing and the light weight module will be running on all the sensor nodes. Since it is light weight, it saves energy on the sensor nodes. Based on the placement strategy, it is hybrid placement of IDS. Since the location information of nodes are added, the system is more efficient with less overhead and high detection rate. The memory consumption is also less. The proposed method yields 94% of detection rate.

2) ANAMOLY BASED DETECTION: In anomaly-based IDS, at any instance the activity of a system will be compared with the normal behavior profile. If there is any deviation from the normal behavior i.e., if it exceeds the threshold value then the alert is generated. It is also efficient detect new kinds of attacks. The attacks related to wastage of resources can also be detected using this approach.

a) Gupta et al [12] proposed an IDS based on the computational Intelligence. The malicious activities and intrusion can be detected in less duration. The proposed IDS is a three-tier

architecture. It is Anomaly based IDS. It is suited for both NIDs and HIDS. The majority flaws in the security is also presented in the paper.

b) Cervantes et al [13] proposed Intrusion detection of SiNkhole attacks on 6LoWPAN for InterneT of Things (INTI). It is used for detection of sinkhole attack in the routing services of IoT. The proposed system combines trust, reputation strategies, watch dogs for analyzing the device behavior of the devices. Based on the behavior of the devices the nodes can be classified as attackers or not. The mobility of the node and self-repair mechanism of network are taken into consideration in the proposed INTI intrusion detection system. The effectiveness of the proposed system is measured in terms of detection rate, false positive and false negative rate. The system provided less false positive and negative rate. Since the placement of IDS changes over the time, it consumes more resources. The author in this paper does not discuss the impact of proposed solutions for low power devices.

3) SPECIFICATION BASED APPROACH: In this scheme, specification represents the set of rules or the thresholds which are used to define the behavior of the network components. The network components can be routing tables, protocols and nodes. If there is any deviation from the defined specification, then the alert is generated. This is also similar to anomaly-based approach i.e., identifying the deviation from the normal behavior. But the difference between the two is that in this the specifications are defined manually and there is no need for training phase. Since the specifications are defined manually, it provides lower false positive rate in comparison with the anomaly detection.

a) Le et al [14] proposed a Specification Based IDS for detecting topology attack (local repair and rank attack) in RPL. In the proposed system, the monitoring mechanism is described based on the finite state machine of RPL. The system can detect the threats in the routing operation. The overhead of the system is reasonable. The normal operation of the network is taken as an abstract(specification). This is done manually. If there is any malicious behavior, then that will break the specification. From that it is understood that attack is performed on the routing operation.

b) Surendar et al [15] proposed a detection technique based on the specifications. The specifications are defined considering the constraints of resources. The limitations of INTI and SVELTE are improved. The consumption of energy by the proposed system is also low. It provides quick response against the detected attack. In the proposed system, the nodes in the network will be clustered and a leader will be elected based on the probability. [16] The nodes in the cluster will forward their rank value to the cluster head. Dempster-shaffer theory based on evidence is used to combine evidence from different nodes. The belief degree of the node is derived from it. The cluster head will detect the attack and notify it to the root of DODAG. Once the attacker is detected, the reconstruction of DODAG will be done by the root node without including the attacker node. The proposed system is evaluated by the NS2 simulator.

4) HYBRID APPROACHES: This approach takes the advantage of the scheme and minimize the influence of the drawbacks of the above schemes.

a) The above proposed Intrusion Detection Systems can detect only specific attacks but not the attacks if they are combined. Napiah [17] et al proposed CHA-IDS (Compression Header Analyser) for the detection of combined attacks in 6LoWPAN. The proposed system is a multi-agent system that captures the raw data, manages it and perform analysis based on it. Based on the analysis, the system will take action. The features are selected based on correlation. It also utilizes Best First and Greedy Stepwise to identify the significant features. Only the significant features are identified for detection of attack. Then the features are tested using 6 machine learning algorithms for classifying malicious node and the good ones. The six machine learning algorithms are (i) MLP (ii) J48 (iii)SVM (iv) Navie Bayes (v) Logistic and (vi) Random forest. Among these algorithm J48 shows the better performance in detecting the attacks. So, J48 is used in CHA-IDS which provided 99% of true positive rate. The rule or the signature will be created by the ML algorithm and it is placed at 6BR. It is updated when new signatures are available. It is a hybrid IDS (Anomaly and signature based). The proposed system identifies the following attacks: (i) Flood attack (ii) Sinkhole attack (iii) Wormhole attack when they are combined also.

b) Midi et al [18] proposed Kalis: Knowledge Driven Intrusion Detection System for detecting attacks in real time scenarios of IoT. It is designed for less constrained nodes. The system does not require any changes to the existing IoT system. Based on the IDS detection scheme, the proposed architecture is a hybrid approach (signature and anomaly based) and based on the placement strategy of IDS also it is a hybrid

approach (centralized and distributed). The system is able to detect attacks in various IoT protocols. The evaluation result shows that it is effective in detecting many attacks such as routing attacks, DoS, traditional attacks, etc.,

c) Raza [19] et al proposed an IDS for the detection of various routing attacks (sinkhole, spoofing and selective forwarding attack). The IDS is a hybrid one since it is based on both Anomaly and Signature. It is a light weight effective IDs for constrained nodes. The IDS is also provided with mini firewall. It filters the traffic that are from malicious node before they reach the combined nodes. The IDS is placed in 6BR and all the constrained node. The advantages of the proposed IDS are:(i) The constrains of resources in 6LoWPAN network is taken into consideration. (ii) There is an integrated mini-firewall for the filtering the traffic (iii) It is flexible and it can also be used for the detection of other attacks. The limitation is that the proposed IDS will be affected by Denial of Service (DoS) attack.

B. KNOWLEDGE DRIVEN APPROACH:

a) Geethapriya et al [20] proposed Deep Learning [DL] based IDS for IoT network. The intelligent IDS is tailored into the IoT network. DL is used for detection of malicious traffic. The proposed system provides security as a service. The IDS is implemented in a stand-alone device which is easy to integrate into IoT network. There are three phases in the proposed IDS: (i) Connection phase (ii) Anomaly phase (iii) Mitigation Phase. The DNN (Deep Neural Network) is implemented using Keras. Through this paper, the author has concluded that the usage of DL algorithms for detection of anomaly (blackhole attack, sinkhole attack, DDoS attack, wormhole attack) in IoT environment is feasible and practical. The average precision rate is 95% and the recall rate is 97% for different scenarios of attack.

b) Verma [21] et al proposed NIDS for IoT which are based on RPL. NIDS will be acting as a first line of defense for the networks. There are no reliable datasets for IoT. So, IDS will be suffering in the advancement of accurate performance. RPL-NIDDIS 17 dataset is a synthetic dataset created by NetSim Simulation Platform. The authors have used this dataset for network IDS. They have also discussed 22 attributes that may compromise the IoT network. Correlation analysis is used for the determination of relationship in the future. The dataset developed is evaluated using Machine Learning techniques.

c) Kfoury [22] et al proposed a Self-Organizing Map (SOM) neural network for clustering routing attacks that are inherited from WSN. It is used for notifying the administrator in the early stage itself. It reduces the power consumption of the node and the interruption in the network. SOM is a kind of neural network. It uses unsupervised learning for the conversion of high dimensional space into low dimensional space. This conversion is done for better visualization on a map. In this method, each and every node calculates its distance to the input vector. The Best matching unit holds the node that are closest to the input. Wireshark is used for capturing the traffic and the power tracer module of Contiki is used to get the power consumption of each node during the attacks. Thus, the SOM classified the sample in input training into: sink hole attack, Version attack, Hello Flood attack and clean data. TABLE I represents the summary of the review IDS along with its limitation and challenges.

IV. CONCERNS, CHALLENGES & OPPORTUNITIES:

From the review, it is understood that vast number of researches has been conducted for providing detection and prevention of attacks in RPL. The following issues are discussed below:

- The implementation of security features of RPL remains unexplored.
- There are large numbers of options available in RPL. Most of them remain unused.
- As the number of devices in IoT increases daily, then new security and routing features are also need to be addressed.
- Large number of tools and testbeds should be investigated for evaluation.
- From the review, it is clear that IDS has been serving as one of the countermeasures for the attacks in RPL. The nodes in RPL are resource constrained but IDS need more computation. So, the expandability of IDS for RPL needs to be considered.
- More researches were conducted in simulators especially Cooja. Hence, large number of tools (hardware and software) and testbeds should be investigated for evaluation.

TABLE I. COMPARISON OF IDS DETECTION TECHNIQUES FOR RPL BASED IOT ATTACKS:

References	Intrusion Detection Technique	Threats addressed	Advantages	Limitations	Countermeasure
Cervantes et al [13]	Hybrid (Reputation and trust strategies)	Routing attack	* Node mobility is taken into consideration * The self -repairing mechanism is also taken into account	*More consumption of resources since IDS changes over time	Self repairing mechanism
Lee et al [24]	Anomaly	DoS	*Light weight Intrusion detection system *Detection is accurate	*Only energy of node is considered *Other parameters can be included	-
Wallgren et al [25]	-	Routing attack	*Resource constraints is considered *Less energy consumption in other nodes	*Overhead is high in 6BR *Detection accuracy is less	-
Bhosale et al [26]	Anomaly	Wormhole attack	*Detection rate is high *Different wormhole attacks are considered	*Energy consumption is high *Extended to other attacks also	Real time IDS
Pongle et al [23]	Anomaly	Routing attack	*Packet overhead is low *Resource consumption is low	* Only one type of attack is detected *False positive rate is high	Real time IDS based on Received Signal Strength
Liu et al [9]	Signature	-	*High adaptability *Detection rate is high	*Efficiency decreases with high volume data	Immunity Thoery
Oh et al [10]	Signature	Multiple attacks	* Highly Scalable * Less usage of memory	* Not suitable for real time * Less detection rate	Auxilary shifting & early detection
Gupta et al [12]	Anomaly	-	*Suitable for both NIDS and HIDS *Majority flaws in security is addressed	*Energy consumption is more	Computational Intelligence
Le et al [14]	Specification	None	*Less computation and storage overhead *Energy efficiency is high	*More overhead	Finite State Machine
Surendar et al [15]	Hybrid (Anomaly and signature)	Sinkhole attack	*Constraints of resources are considered *Less drop in the packet *Immediate response against detected attack	*Unknown attacks can't be detected * It is not suitable for real time	InDReS
Napiah et al [17]	Hybrid	Combined attacks	* Detects both individual and combined attack * High detection rate	*Can be extended to detect more attacks	Compression Header analyser
Midi et al [18]	Hybrid (Anomaly and signature)	Routing, DoS attack	*Less usage of CPU and RAM * IDS is Self-adapting * Different IoT protocols are taken into account	* It is not suitable for constrained nodes. * Computational overhead is high	Knowledge driven Technique
Raza [19]	Hybrid	Routing attack	*Constraints of resources are considered * Flexible	*SVELTE can be affected by DoS attack * Less detection rate	Light weight IDS
Geethapriya et al [20]	Deep Learning	Multiple attacks	*Average precision and recall rate are high for different scenarios *Energy efficient	*Large processing power is required *Requires more dataset	Deep Neural Networks
Verma et al [21]	Machine Learning	Modern Routing attack	*False positive rate *Accuracy is high	*More time consumption *Requires more dataset to train	Correlation analysis
Kfoury et al [22]	Neural network	Multiple attacks	*Attacker is detected at the early stage *Power consumption is less *Less interruption of network	*Computationally intensive	Self Organising Map

V. CONCLUSION:

Through this review paper, we have rigorously reviewed recent IDS based countermeasures for the detection and prevention of RPL based attacks. Since, the nodes in LLN are resource constrained, they are easily prone to attacks. The various attacks involved in RPL were discussed. Many investigations should be done to make IDS suitable for resource constrained nodes. The security features that are available in RPL should be explored and implemented for detection of attackers. Thus, this comparison will be an eye-opening stuff for the researches, who conduct further investigation on attacks and countermeasures related to RPL.

***Abstract*—The rapid development on the field of communication require a secure exchange of information between the sender and the reciepient. Information hiding techniques are widely used in the field of communication such as military applications, scientific research etc. Information hiding is a general process or term which deals with embedding the message for communication in the content.Otherwise we can say that it refers to either producing the data to be hidden making the existence of secret information to be unnoticeable.This process leads to prevent unauthorized access.There are two inputs in the steganography process, one is the cover object and the other is secret object, both these inputs may be image, video, audio e.t.c. Depending upon these cover objects, it can be categorized into image steganography, video steganography, audio steganography e.t.c. In this paper both cover and secret objects are image.**

In this paper image steganography is performed with IWT (Integer Wavelet Transform).Normally the steganography process is performed with DWT (Discrete Wavelet Transform), while applying this transform there exists floating point coefficients,which leads to floating point truncation results in loss of information, to avoid this problem we choose IWT. Arnold transform is an image scrambling technique applied to the secret image to ensure security to it.

***Index Terms*—Integer Wavelet Transform, Arnold Transform, DWT**

I. Introduction

There are some basic criteria to categorize the steganography process. The steganography classification based on the cover objects are image steganography, video steganography, audio steganography and network steganography[14]. The two main process or algorithm in steganography is embedding and extracting. These embedding and extracting processes are performed on certain domains, based on these domains we can classify into six main types. They are spatial domain techniques, transform domain techniques, spread spectrum based domain techniques, masking-filtering technique and cover generation techniques[15].

The steganography processes are generally performed on spatial domain and transform domain. The most frequently used domain is spatial type, where it is easy for implementation (embedding and extracting processes), but security in this domain is less as compared to the transform domain because the unauthorized accessibility will be very high. The transform domain is very difficult for implementation but security will be very high as compared to the spatial domain.

In this paper, two main transforms are used in this steganography process. One is the integer wavelet transform (IWT) and Arnold transform. The IWT is applied to the cover object to transform it for hiding the secret object, where integer to integer or bit to bit mapping takes place. The Arnold transform is implemented to provide secrecy to the secret image , since it is an image scrambling transform.when it is applied to an image, it becomes a diffused form where it is not able to identify the image correctly. The diffused form of secret image is embedded on the sub-bands cH, cV and cD, since the sub-bands are invisible to human eye. This is the entire steganography system. The strength of proposed steganography system is analyzed by security analysis. The security analysis is performed through cryptanalysis.

II. Literature Survey

The techniques for hiding information from an unauthorized access is known as steganography, hence the nature or property of steganography is invisible to human eyes [1]. This paper put forward a secure embedding steganography algorithm that hides the secret object into the least significant bits (LSBs) of integer wavelet transformed cover image in the form of bits or bitstream. This indicates the two level decomposition on LL band, where LL band is similar to the cA band. When decomposition is performed on the image, produces or decomposes to sub-bands are LL, LH, HL and HH sub-bands, in which information on LL sub-band is homogeneous to the original one and is visible to the human eye, because it is the low frequency sub-band and remaining are high frequency sub-bands, not highly visible to the human eye [17].Due to this low frequency, LL sub-band is visible in nature,so the image available from this band appears close to the original image and the sub-bands LH, HL and HH are invisible for human eyes due to its high frequency. These sub-bands are close to cA, cH, cV and cD components or coefficients of the image, where cA is the approximation coefficient of an image and cH, cV and cD are detail coefficients of an image, they are invisible to human eyes. This paper gives idea about choosing IWT instead of DWT.

Based on [2] it was stated that encrypting for hiding an image in another gray image file using Least Significant Bit (LSB) based Steganography and Arnolds transformation algorithm based Cryptography. Here hiding process of secret image into the cover image with minimum distortion made to the cover image.

Steganography methods have many challenges such as high hiding capacity and imperceptibility [3]. Here it proposes integer wavelet transform (IWT) for increasing high hiding capacity and Optimum Pixel value Adjustment algorithm (OPA) for elevating the image quality.The lead of Steganography, over cryptography is that message do not engage attention to themselves.

In [4] steganography is the practice of masking objects like a file, message, image or video within another digital image, simply the purpose of data hiding.Here conceal the secret messages using integer wavelet transform (IWT). IWT is mainly used for signalling tehniques.

According to [5] the main application of DWT (Discrete Wavelet Transform) is image compression. The disadvantage of the DWT is that the wavelet coefficients are real numbers. In this case efficient lossless coding is not possible for linear transforms. Integer Wavelet Transform (IWT) is a fundamental modification of linear transforms, where each filter output is rounded to the nearest integers. IWT can be a unified lossy and lossless codec. The use of IWT is to reduce the memory demands of the compression algorithms as integers are used alternative to real numbers.

In [7] Cryptography and steganography are the two prime fields for information reliability. Cryptography means technique in which the information is unsystematic in a dense rubbish fashion during transference, steganography focuses on masking the existence of the information. Combining both technique gives a higher level of security in which even if the use of covert channel is revealed, the real documentation will not be opened. This paper gives attentiveness on concealing multiple secret images in a single 24-bit cover image using LSB substitution based image steganography. Each secret image is encoded before hiding in the cover image using Arnold Transform. Outputs disclose that the proposed method successfully secures the high capacity data keeping the visual quality of transmitted image satisfactory.

In [8] copyrights protection of plain texts is still a remaining issue that must be improved in order to provide authentication of proprietorship and obtain the desired validity. During the last decade, digital watermarking and steganography techniques have been used as option to block tampering, distortion, and media forgery and also to protect both copyright and authentication. This paper presents a comparative analysis of information hiding techniques, especially on those ones which are focused on modifying the structure and content of digital texts.

In [18] it is a technique, where presence of secret message cannot be detected, so it act as a tool for security purpose to transmit the confidential information in a secure way.There are varity of information hiding approaches exist and they differs from each other depending upon message to be embedded, usage of file types as a carrier or compression method etc. Uncompressed file formats like BMP, GIFF, TIFF e.t.c based on lossless compression provides high data hiding capacity, that means the hiding capacity depends on types of cover images used.

III. PROPOSED TECHNIQUE IN THIS PAPER

The paper proposes steganography based on image with IWT and Arnold transform, here both cover object and secret object are of different images. Both transforms are used namely, IWT and Arnold transform is applied to cover image and the secret image.

A. INTEGER WAVELET TRANSFORM

Widely used wavelet transform in steganography process is DWT (Discrete Wavelet Transform). When it is applied on the image, there exist floating point coefficients, leads to floating point truncation, which may cause loss of information. To avoid this problem, a new transform known as IWT (Integer Wavelet Transform) is utilized in this work. Both the transforms DWT and IWT leads to image compression process. DWT leads to lossy data compression, in which compresses data by discarding some of it. Its aim is to minimize the amount of data that needs to be held. But in IWT it is lossless data compression that allow original data to be perfectly reconstructed from the compressed version.

B. ARNOLD TRANSFORM

Arnold transform is an image scrambling technique, which scrambles the pixels of the image so we can say that it is an image encryption method. When this transform is applied to an image, the pixel location of the image gets changed thus the image appears like a diffused form. We can say that it is an iteration process which leads to change in position of the pixel location, hence this transform depends on the number of iterations and act as a key. The Arnold transform is an image scrambling technique performed on the square image, which shifts the pixel location from (x, y) to (x, y) without changing its size.This transform change the pixel position of the image without removing any information from the image. This transform is area preserving and invertible without loss of information. Let the pixel image be S=(x,y), where [x,y] = [0,1,2,.....N-1] N implies size of the square image [18].

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = A \begin{bmatrix} x \\ y \end{bmatrix} (mod N)$$

$$A = \begin{bmatrix} 1 & p \\ q & pq+1 \end{bmatrix}$$

The values of p and q act as key points in this transform

Generally matrix A is written as

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix}$$

Another important 'key' used in this transform is 'N', the number of iterations.For the same matrix A, different number of iterations can be performed on an image, which results in diffused form of image. The real image can be obtained by taking contrary of Arnold transform through correct number of iterations, if the number of iterations is incorrect we can't obtain the correct version of the original image.If the number of iterations is very high, the transform takes more time to obtain the output as well as in reverse stage.

Fig. 1. Arnold Transformed image

C. CRYPTANALYSIS

The cryptanalysis is applied to the entire steganography system to analyze its strength for hiding the information. The cryptanalysis is performed by providing certain attacks to the entire steganography system. In this paper there are three keys, p,q and number of iterations. Based on these keys cryptanalysis is performed. The attacks preferred to this steganogrphy system is brute force.

1) Brute Force Attack: Brute force attack is performed by applying trial and error method through all possible keys.In this paper the analysis of this attack should be performed on extracting algorithm.Only the Arnold transformed image is available to the attacker, so to obtain the original secret image by the attacker he/she want to take the inverse of that image.From this it is clear that all possible keys should be applied to the inverse part of the Arnold transform.That is the brute force attack should be performed on inverse Arnold transform of an image by applying all possible keys.

Arnold transform is performed by iteration process on an image to scramble it to obtain the diffused nature however it is not at all clear, where we can perform many number of iterations on the image .An attacker can easily access the original secret image by applying all possible number of iterations on an image, thus the attack can happen easily. To avoid this we introduce new keys rather than the iteration or repetition number. Let p and q are the newly introduced keys along with the iteration or repetition number.By using the values of p, q and iteration number we are performing Arnold transform, thus the combined version of p,q and iteration number act as keys in encryption and decryption. The only source available to the attacker is the stego image, then he/she has to perform extracting process by these three combinations of keys together to obtain the original secret image. The attacker can attack if and only if the combinations of keys should be similar to that used in the embedding process. By this we can say that, Brute force attack is performed by applying trial and error method through all possible combinations of keys. In this paper the analysis of this attack should be performed on extracting algorithm. In extraction algorithm,after extracting the secret image we have to perform inverse Arnold transform by applying the three combinations of keys to extract the original secret image. Only the Arnold transformed image is available to the attacker, so to obtain the exact image by the attacker he/she want to take the inverse of that image.From this it is clear that all possible keys should be applied to the inverse part of the Arnold transform.That is the brute force attack should be performed on inverse Arnold transform of an image by applying all possible keys.As per the experimental analysis, some of the extracted images from different sets of keys results similar images which makes the attacker confused,which is shown in figure 2 and figure 3 . Hence it is the another advantage while analyzing brute force attack.

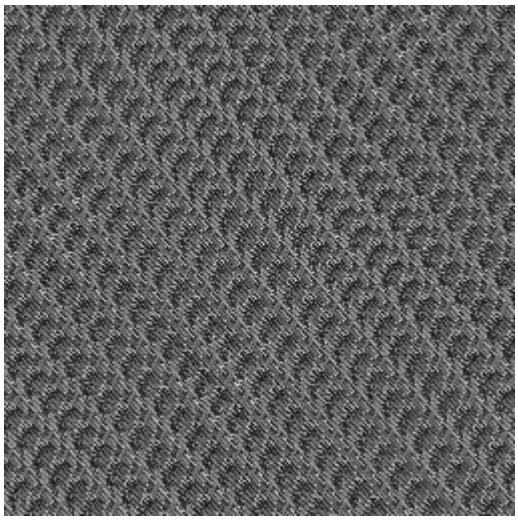

Fig. 2. Extracted image with iteration number=1,p=1 and q=1

IV. ALGORITHMS

There are two phases in image steganography algorithms, the embedding and the extracting phases.

A. Embedding process

There are two inputs in the embedding algorithm or process, one input is cover image and other input is secret image.The cover image is send to the IWT (Integer Wavelet Transform) to obtain the transformed image for embedding the secret image .The secret image is send for the Arnold transform to obtain the scrambled image in diffused nature in order to enhance security or secrecy to the secret image. The output produced in the embedding process is the stego image.The algorithm for embedding process is given below.

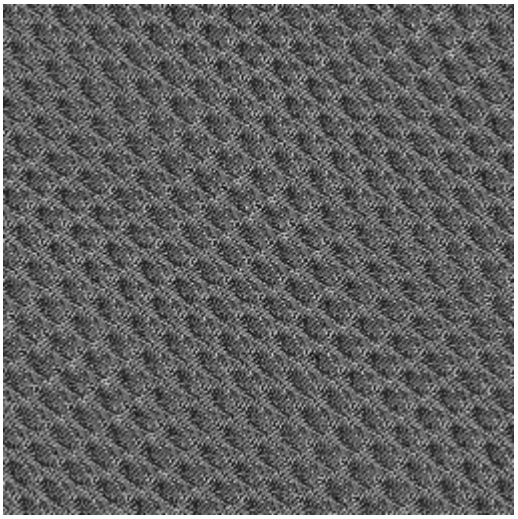

Fig. 3. Extracted image with iteration number=1,p=1 and q=2

- In the embedding phase the IWT (integer wavelet transform) is applied to the cover image (gray scale image)
- Obtained sub-bands of low and high frequencies, LL (low-frequency sub-band), LH, HL and HH (high- frequency sub-bands). These sub-bands can be termed as coefficient bands such as approximation coefficient band (cA) and detail coefficient bands (cV, cH, cD).The three detail coefficients are vertical coefficient (cV), horizontal coefficient (cH) and diagonal coefficient (cD)
- Apply Arnold transform on secret image
- Embed Arnold transformed secret image on the detail coefficient bands of the IWT transformed cover image, since the detail coefficient bands are invisible to the human eye
- After embedding process, perform inverse (IWT) integer wavelet transform to obtain the stego image.

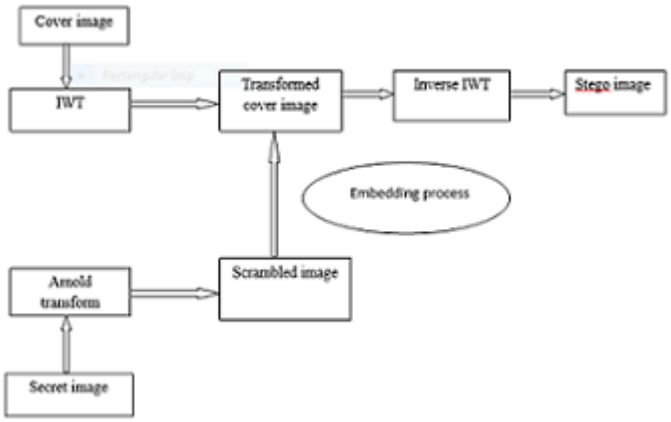

Fig. 4. Embedding Process

B. Extracting Process

The extracting process or algorithm consist of one input as the stego image and two outputs while the cover image and secret image.The stego image is send to IWT to obtain the transformed image from where we have to withdraw the scrambled secret image.The extraction process produces two sets of output as cover image and scrambled image. The scrambled image is send for inverse Arnold transform to obtain the original secret image. The algorithm for extracting process is given below.

- In the extracting phase the IWT (integer wavelet transform) is applied to the stego image
- Extract the secret image from the detail coefficient bands (cV, cH, cD), this secret image is in the form of an Arnold catmap and the transformed cover image
- Apply inverse Arnold transform on extracted image, in order to obtain the real secret image
- Apply inverse IWT to obtain the original cover image

Fig. 5. Extracting Process

V. EXPERIMENTAL ANALYSIS

The proposed steganography algorithm is based on IWT and Arnold Transform. The advantage of this system is analyzed based on its comparison with steganography system based on DWT and Arnold Transform. Mainly the information is available on LL sub band, the figure given below shows the difference in LL sub band applied with IWT and DWT on the same image.

Fig. 6. Difference in LL sub band

From this above figure it is clear that the steganography with IWT is the better one.Comparing IWT and DWT steganography system, clarity on stego image is more in IWT than in DWT. While comparing the performance evaluation PSNR (Peak Signal to Noise Ratio), SNR (Signal to Noise Ratio) of IWT steganography system is higher than DWT steganography system. But in the case of MSE (Mean Squared Error), it is lower in IWT than in DWT. Based on all these criteria we can conclude that the steganography system with IWT and Arnold Transform is the best one. The strength

of entire information hiding system should be analysed by cryptanalysis. The cryptanalysis is performed by taking the possible number of iterations for the iteration matrix A with p and q values. Thus we can say that iteration number, p and q values act as the combination of three keys for encryption and decryption.

VI. PERFORMANCE EVALUATION

A. MSE-Mean Squared Error

It is square of error between original image and stego image image.Mainly used to measure distortion in the image

$$MSE(O,\tilde{S}) = 1/U * V \sum_{i=0}^{U}\sum_{j=0}^{V}(O(i,j) - (\tilde{S}(i,j))^2$$

O(i,j)=Original image
$\tilde{S}(i,j)$=Stego image In this paper a comparison of MSE is made between DWT-Arnold steganography system and IWT-Arnold steganography system. While comparing MSE, it is high in DWT-Arnold steganography system than in IWT-Arnold steganography system.From this it is clear that since MSE is less in the case of IWT, the distortion of the image is less.

B. PSNR-Peak Signal to Noise Ratio

(PSNR) is the ratio between the original cover image and the stego image, in order to compare its quality.

$$PSNR(O,\tilde{S}) = 10log_{10}\frac{(L-1)^2}{MSE(O,\tilde{S})}$$

O=Original image
$\tilde{S}$=Stego image
L=grey-level number On comparing PSNR values of IWT and DWT steganography system,the IWT system have better quality than the DWT-Arnold steganography system.

C. SNR-Signal to Noise Ratio

SNR is calculated as ratio of original image to affected noise. Noise indicates difference between original image and stego image

$$SNR(O,\hat{S}) = 10log\Big(\frac{\sum_{i=1}^{U}\sum_{j=1}^{V}(O_{i,j})^2}{UVMSE}\Big) \quad (1)$$

Transforms	MSE	PSNR	SNR
IWT	6.0900	106.7000	36.1110
DWT	35.5685	89.0519	18.4798

Performance analysis between two transforms

Images	MSE	PSNR	SNR
Cameraman	6.0893	106.7012	36.1122
Lena	6.0900	106.7000	36.1110
Apple	6.0900	106.7000	36.1110
Baboon	6.0900	106.7000	36.1110

Performance analysis on different images

VII. CONCLUSION

The proposed steganography system is based on IWT (Integer Wavelet Transform) and Arnold transform .The developed steganography system is analyzed through cryptanalysis, by introducing simulation attack and brute force attack. Mainly the attack is performed on stego image or cipher text by the attacker. In this work a comparison is made between IWT and DWT steganography system to prove IWT is the best one for hiding the information. Here Arnold transform is used for ensuring security on secret image before hiding. A combination of three keys is used for embedding Arnold transformed secret image to the cover image, to provide high security to the secret image .The combination of three keys are obtained from the Arnold transform in the form of bits .From these keys we can measure the strength of the steganography system in terms of bits by analyzing its computation complexity.The proposed steganography system withstand both simulation and brute force attacks.Simulation attack is performed in extraction section by providing the combination of keys entirely different from the embedding process.The usage of different keys cannot extract the original secret image, thus conclude that the developed steganography system have the ability to withstand the attacks based on simulation.Brute force attack is performed by applying trial and error method through all possible combination of three keys, the steganography medium would be very strong in data hiding.

aritroroyarko@gmail.com, ksaadat09@gmail.com, md.saiful.islam@bracu.ac.bd

***Abstract*—Health and security for cows have been an alarming concern over the South-Asian countries as many people depend on cows for a living. Cows are used for various purposes. For example: It can be used for milk production, crop farming and meat production. It is evident that the health of cows depend on what they eat and where they eat. Many measures can assess the quality of the food. One such way of providing reliable food is by the measurement of pH and temperature of the food. The environment in which the cows stay has significant effects in the wellbeing of the cows. Foot diseases can occur if the cows stay near its own dung for too long. Sadly, no farm takes any measurements during the provision of food. Moreover, farms neither check the environmental conditions nor do they maintain it regularly. Furthermore, the security of cows inside the farm is very tough to maintain, as constant labor need to keep eyes on the cows. Our system looks after the health of cows by measuring pH and temperature of food. It keeps the environment clean by spraying water on the farm at regular intervals of time and security is kept in check by detecting whether the cows have crossed the gate of the farm. The system does all these processes automatically by using pH, temperature, RFID sensors, Arduino micro-controllers, water pump and a 9V battery to power up the pump.**

Keywords—Health, Security, Environment, pH, Temperature, Arduino, RFID, Sensors, Water pump, Cows.

I. INTRODUCTION

Health for cows has always been an important topic for the farmers and is still a difficult issue that needs to be addressed. Our system is the result of a research to help the farmers of any agriculture-based country. The system has undergone thorough revision for quite a number of times after the initial plan. It incorporates three different dimensions which includes the food monitoring system, environment monitoring system and antitheft system of cows. All these components need to be inside the farm. The food monitoring system measures the pH and temperature of the food for the cows and compares the data to a standard chart. If the values are inside the range of the chart, then the food is marked as edible and can be fed to the cows in the farm. The environment monitoring system consists of a water pump which sprays water at frequent intervals of time, generally 4 hours, to drain out all sorts of dirt and wastes produced by cows. If this is not done, it could lead to serious diseases and health hazards for the cows. The anti-theft system consists of RFID tags which is placed on the neck of cows and a RFID sensor placed on the gate of the farm. If any cow escapes the gate or anyone steals a cow, the RFID system will trigger an alarm in the farm, letting all the farmers know that a cow has escaped from the boundaries of the farm. The system is designed to do all the following things mentioned above and we believe that this will not only make the lives of farmers easier but also help farmers to stay away from big losses such as the death of cows, escape of cows or the theft of cows from farms.

II. LITERATURE REVIEW

A lot of work has taken place on the topic of RFID based automatic anti-theft system. Geeth Jayendra, Sisil Kumarawadu and Lasantha Meegahapola have worked rigorously on the topic of RFID based anti-theft auto security system with an immobilizer [1]. Researchers have constantly focused on providing more security that would be efficient. We are now at an era of technology, where RFID systems can track livestock. Nabil Kannouf, Yousef Douzi, Mohammed Benabdellah, Abdelmalek Azizi have written a paper on RFID being used as a security measure on livestock [2]. Rand A. Mahmood has also written about the uses of RFID as a measure of security, starting from security of livestock to library books and personal identification documents [3]. Furthermore, there has also been work and an article on the topic of "CATTLE RFID & TRACKING SYSTEM" [4].

Ensuring food quality is something that is very crucial and many articles provide information on the quality of food provided to cattle. It is very evident that the enzymes can only work most properly in the time of digestion at a suitable pH and temperature range. M.B.de Ondarza added to their website that the enzymes need a pH of 5.7-7.3 and an optimum temperature of 39 degrees to work properly during digestion [5].

Lastly, we can frequently see the use of water pumps where microcontrollers have complete control due to different needs. Madhurima Santra implemented a system to turn on a water pump when the water level of a tank goes beneath a level [6]. Moreover, J. E. Okhaifoh, C. K. Igbinoba, and K. O. Eriaganoma also completed work on the topic of microcontroller based automatic control for water pumping machine with water level indicators using ultrasonic sensor [7]. Furthermore, water wastage from motor pump is a big issue. O Bamigboye, F. Ehiagwina, E. O. Seluwa and K. O. Gbadamosi have also worked together to design a microcontroller based

water pump that works in a way which reduces the water wastage [8].

III. PROPOSED MODEL

The system is designed in such a way that it takes data as input from the sensors according to the environment that the cows are in and then passes the data to the Arduino. The Arduino then computes and converts these electrical readings to scaled values like pH and temperature, which are understandable by humans. The interfaced software compares the computed values with a standard dataset to decide whether the food is appropriate for the cattle. If the pH value lies within the range 5.7-7.3, then it is within the acceptable range. Similarly, if the temperature lies within 38.5-39.5 degrees centigrade, then the temperature is also in the acceptable range. The food can be fed to the cows if and only if both the temperature and pH of the food are within the appropriate range. Lastly, if the temperature and pH are within the standard range, then the system will turn on the green light. Otherwise, it will turn the red light on.

Similarly, the antitheft system detects any RFID card/tag close to the receiver. The cows have RFID tags wrapped around their neck. Any presence of the tag nearby the receiver would indicate that a cow is close to the gate and is about to escape. The RFID receiver would then dump information about the tag to the system, alarming the farmers about the escape.

In addition, the environment monitoring system maintains a clean environment for the cows to live and grow. The motor pump sprays water on the surface of the farm to remove all sorts of wastes and dirt at frequent intervals of time.

A. Flow chart of the system

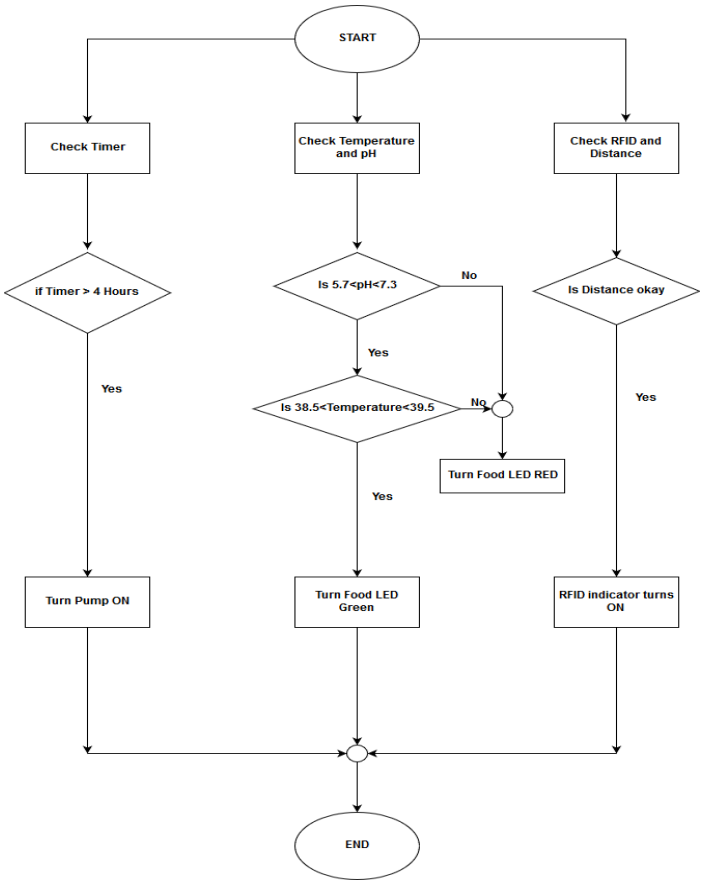

Fig. 1. Flowchart of the system.

The flowchart above represents the overall processes and activities within the system. The system is primarily divided into three parts. Firstly, for the environment management part, there is a timer which checks whether the time that the water pump was last turned on exceeds more than 4 hours. If the condition is true, then the pump automatically turns on to clean the surrounding area. Secondly, the temperature and pH of food is checked regularly. If the pH is within the normal range of 5.7-7.3, then the temperature is checked. The temperature needs to be within 38.5 to 39.5 degree centigrade to be considered normal. If both of them are ok, then the food is good to be fed to the cows and a green light turns on. Otherwise, the red light turns on to warn the farmer that the food is not ok. Lastly, for the antitheft system, if the distance between the tag and receiver is less than the threshold value, it means that the cow is about to escape and the red light or alarm system turns on to warn about the escape.

IV. RELATABLE EQUATIONS

We used the following equation to convert the analog voltage readings taken as input from sensors to digital pH values.

$$pH\ reading = \left(5 - \left(analog\ reading \times \frac{5}{1023}\right)\right) \times \frac{14}{5} \quad (1)$$

V. HARDWARE DETAILS

The overall description of the hardware components are as follows:

A. Arduino Uno R3

In our project, we have used Arduino which is a board to interface between the hardware components, such as the temperature and pH sensors, and the computer. The system uses two Arduino Uno R3 boards in order to serve its needs. One Arduino Uno R3 board controls the pH, temperature, RFID sensors and another one controls the water pump. The latter Arduino also acts as a timer that allows the water pump to spray water on the surface at regular intervals. This is possible by using a delay in our code. The fact that this Arduino deals with only one component, allows the Arduino delay to work exactly like a clock.

B. pH Sensor—SEN0161

The pH sensor's use for our research is to get an analog voltage from the solution that we are using as the food for cattle. The system is designed in the following way. The sensor is placed inside the solution which is the cow food over here. Readings from the sensor pass to the Arduino where it is processed. The sensor produces electric voltages based on the concentration of hydrogen ions in the solution. Furthermore, the pH sensor calculates the pH and gives us the actual reflection about the acidity of the food. The pH reading is obtained by converting the analog voltage using a suitable equation. If the pH lies within the actual range then we can say that the food is okay for the cattle to eat or else it is discarded.

C. Temperature Sensor—DS18B20

For our system, the temperature sensor gives us electric voltages just like the pH sensor. The voltage is directly proportional to the temperature, meaning that the reading is dependent on the temperature of the food. The reading is converted to a suitable temperature value by calling a built in function called getTemp (). Just like the process of collecting temperature, the working methodology is also very much the same. The temperature sensor gives us readings and if the readings are okay i.e. if they lie within the range, the food is accepted. The sensor gives us a reflection of the warmth of the food and whether it is suitable for the cows. However, for the food to be accepted, the temperature and pH should both be within the range. The food will not be accepted if any one of the tests fails.

D. RFID sensor—MFRC522

RFID tag is placed around the cow's neck and RFID receiver is kept on the side of the gate of the farm, which is further connected to the Arduino Uno R3. In general, the RFID receiver module gives a signal to the Arduino board whenever it sees any tag energizing the receiver module at a particular Radio Frequency. This means that whenever a cow passes or escapes through the gate, the RFID receiver module detects the tag and dumps information of the tag to the Arduino. Once information is dumped into the software system, the Red light for the "Cow stolen" signal is turned on in the maintenance room. This would let the farmers know that something is wrong inside indicating either a cow has escaped or someone has entered the farm and is running away with the cow. The RFID system was chosen over many other security systems because it is very cost efficient.

TABLE I. COMPARISON OF RFID SENSORS

Items	Passive RFID	Active RFID	Active RFID new version
Communication. Range	70cm / 3m-7m	Greater than 10m	Approximately 10m
Life of Battery	No battery present	Approximately 1 year	Around 1 year
Security	Weak	N/A , or weak	Strong
Cost	Less than $1	Less than $10	Around $10
Application	Distribution, inventory, tracking of goods	Tracking person (restricted area)	Tracking person

The above table represents how different RFID sensors vary with their applications, cost, battery life and security. This also shows us that the use of RFID sensors for farming purposes is very economic [9].

E. Water pump

Water pump is there to spray water and maintain a clean environment. A 9V potential difference with ample amount of current turns on the water pump. The Arduino controls the water pump via a mosfet which acts as the switch to turn the water pump on and off at regular intervals. The water pump sprays over the surface, cleans off dirt and dung produced cows.

VI. BLOCK DIAGRAM OF THE SYSTEM

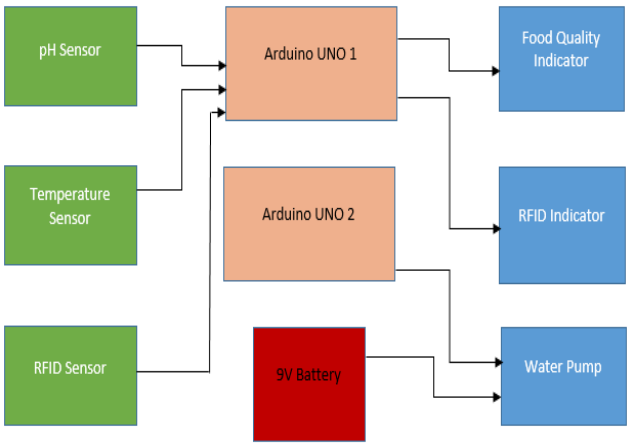

Fig. 2. Block diagram explaining the process

The block diagram above represents the main functions of our system in terms of blocks. There are a total of two Arduinos and a 9V battery. The first arduino has inputs from

pH sensor, temperature sensor and RFID sensor respectively. The arduino mainly processes the inputs. Based on the rules set, it shows appropriate outputs that indicates the food quality and security status of the farm. The second Arduino's output is connected to a water pump which is further driven by a 9V battery. It mainly acts as a switch and is programmed in such a way that when the time that the pump was last turned on becomes greater than 4 hours, the output becomes high and the 9V battery starts driving the water pump for a specific amount of time.

VII. SCHEMATIC DIAGRAM OF THE SYSTEM

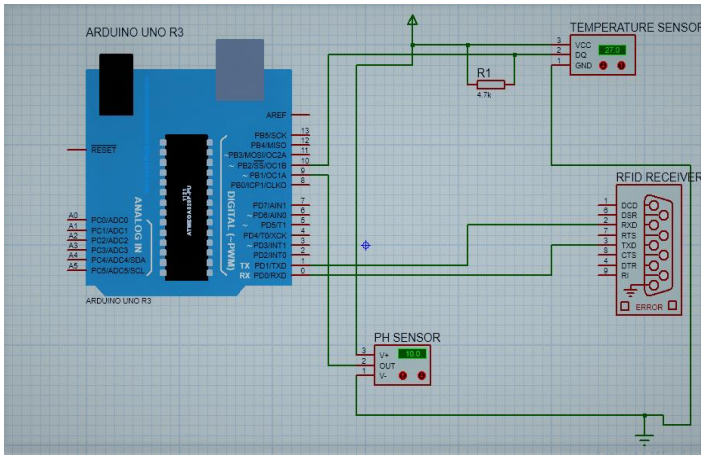

Fig. 3. Schematic diagram of Arduino 1 and corresponding connections

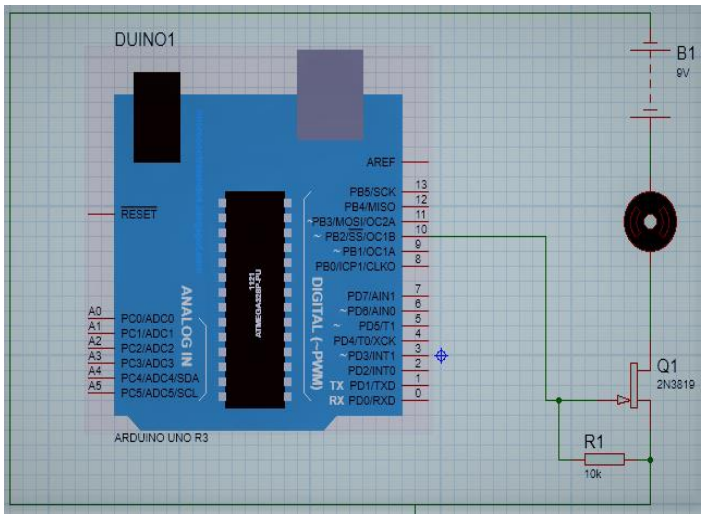

Fig. 4. Schematic diagram of Arduino 2 and corresponding connections

The two schematic diagrams above represent the elements which are connected to the two separate Arduinos in graphical format. Fig. 3 represents the circuit diagram of Arduino 1. This arduino is connected to a pH sensor, temperature sensor and RFID receiver respectively. All the sensors are connected to 5V and ground. There is a 4.7 kilo ohm resistor between the VCC and output of the temperature sensor. Moreover, in Fig. 4, the arduino acts as a switch. The output is connected to the gate of a nmos Q1. The drain is connected to the negative terminal of the pump. The pump is driven by a 9V battery. There is a resistor between the gate and source of Q1. All the components are grounded commonly.

VIII. STATE OF THE SYSTEM

The following table shows the state of the system at different conditions:

TABLE II. STATE OF THE SYSTEM

pH	Temperature range (^{0}C)	RFID range	LED for Food	RFID Indicator
<5.7	<38.5	Not close	Red	X
>7.3	>39.5	Not Close	Red	X
5.7<ph<7.3	38.5<t<39.5	Close	Green	Red

The following figures show the state of the system at different conditions.

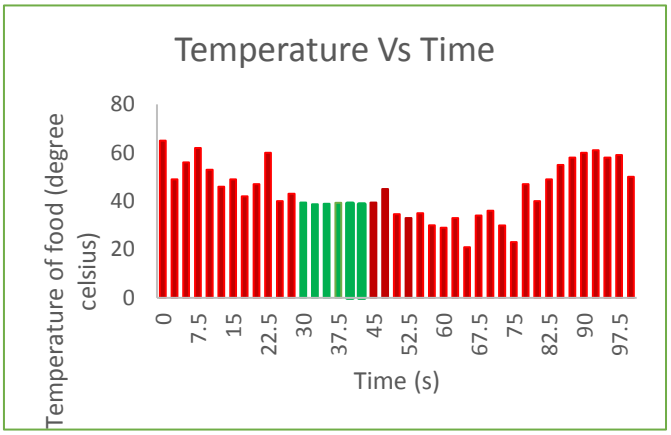

Fig. 5. Temperature vs Time graph

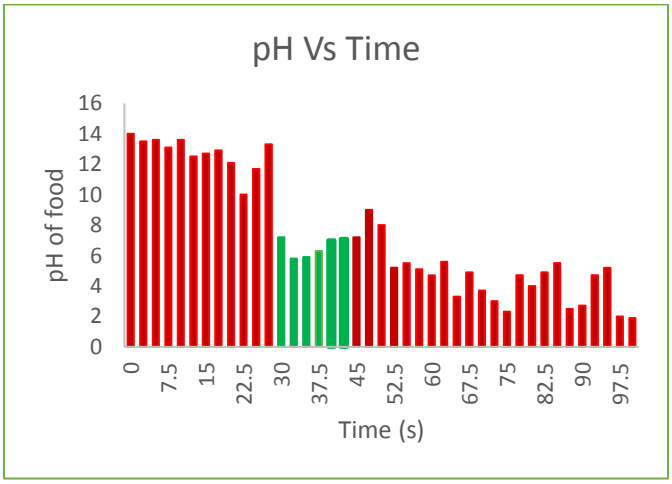

Fig. 6. pH vs Time graph

The green bars in both Figure 5 and 6 show the temperature and ph range of food which is ok to be fed to the cows, whereas the red portion is the range which is unacceptable. If the temperature is within 38.5 to 39.5 degrees celsius, then the food is ok. Moreover, a pH range of 5.7 to 7.3 is acceptable to be fed to the cows.

A. The Overview Of The System

The design and architectural model of our system is as follows. There are two maintenance rooms on either side of the main area, where the cows reside. The room on the left contains a water pump which is powered by a 9V battery. The pump sprays water around the cows at regular period of time to clean any kind of dirt and waste produced by the cows, maintaining a hygienic environment. The room on the right has three main sensors connected to the Arduino inside it. They are: 1) Temperature sensor 2) pH sensor 3) RFID receiver. The temperature and pH sensors are both placed inside the food that will be served to the cow so that the right quality is ensured. The RFID receiver is placed near the exit to notify the owner about the escape of any cow from the farm.

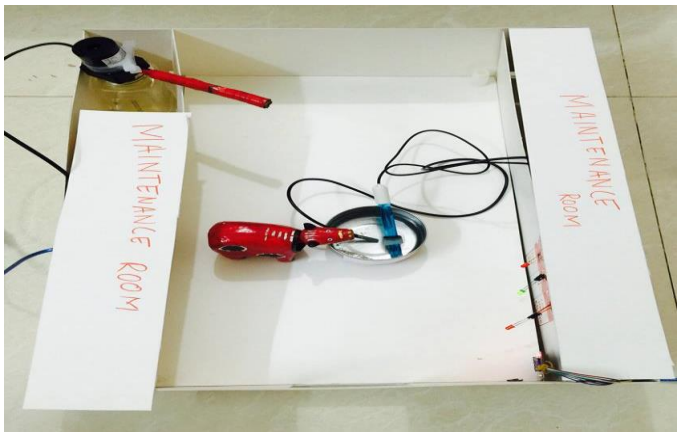

Fig. 7. Overall architecture of the System

B. When The Food Is Okay

When the food that has been provided is within the pH and temperature range, a green light is seen to be turned on. This gives farmers the sign that they can continue to feed the cows.

Fig. 8. Green light turned on , when the food is okay

C. When The Food Is Not okay

If the pH and temperature of the food is outside the standard range, a red light is turned on, meaning that the food cannot be fed to the cows. For example: If the temperature is above 39.5 or below 38.5 or the pH is above 7.3 or below 5.7, then the red light will automatically turn on to tell the farmer that the food provided must be changed.

Fig. 9. Red light turned on, when the food is not okay

D. When Cow Tries to Escape

If the cow tries to escape then a red light would be turned on under the “COW HAS ESCAPED” section, alarming the farmers that the cow has been stolen or escaped and they should look for the cow in the nearby areas.

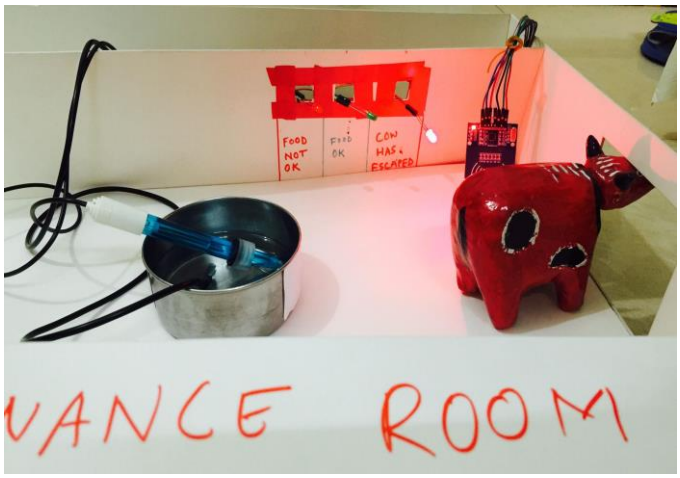

Fig. 10. Red light turned on as cow tries to escape

VI. Conclusion and Future Direction

The design and implementation of smart security, food and environment monitoring system for cows using microcontroller is discussed in this paper. There are some new innovations in our system. For example: Previously, there were very less works on how to check the quality of food which should be provided to cows. In our system, we identified the parameters that can affect the quality of food and then implemented a system that automatically checks whether the food being provided to the cow is healthy, maintains a clean environment around cow's living area and alerts the farmer of any security breach. Another advantage that our system has is that it minimizes big losses for farmers. Although there is an initial installation cost for farmers, the system reduces overall loss through prevention of unhealthy growth and theft of cows. Furthermore, the size of our system is very small, which is a major benefit.

However, there is room for improvement. The system has used less variety of sensors and components in order to measure food quality. Different sensors can be used in order to get measurements that are more accurate and reliable. One such sensor is the turbidity sensor to get a better picture of the quality of the food [10]. It also gives a better understanding of the quality of water [11]. In addition, we are not checking the quality by measuring the vitamin and mineral content of the food. This is something which can be looked after for further research.

A GPS system can also be used in the system to keep track of all the cows and monitor the position of each cow [12]. Hence, it will not only help us to alarm the farmers whether a cow has been escaped or stolen, but also track the exact position of where the cows are.

A heart rate sensor can come in handy to measure the heart rate of all the cows. Records can be kept in the database. This would serve as an indicator to predict any expected disease or attack even beforehand [13].

***Abstract*—This paper describes the implementation of automatic generation control (AGC) and automatic voltage regulator (AVR) under generation rate constraint (GRC) and coupling between automatic generation control and automatic voltage regulator while considering generation rate constrain of two areas for improve and better performance characteristic of load frequency control (LFC) problem. our control aim has to normalize the area control error (ACE), frequency error and tie-line power error in spite of the presences of system uncertainties and external load disturbance, So that the required frequency and power interchange with adjacent structures are maintained in order to reduce the transient deviations and to provide zero steady state error in proper short time, the behavior of the planned is checked by MATLAB SIMULINK software.**

Keywords— Automatic Generation Control (AGC); Automatic Voltage Regulator (AVR); Generation Rate Constraint (GRC); Area Control Error (ACE)

I. INTRODUCTION

Automatic generation control maintains a balance between the whole power generation and load demand, to keep the system frequency (normally 50 or 60 Hz) and regular power interchange with neighboring systems [1].

Load frequency control (LFC) performs a vital role for energy stability between load and era sides. In recent years, several robust design strategies have been delivered for LFC [2]–[4] The dynamic behavior of many industrial plants is heavily influenced by disturbances and, in particular , by change The dynamic conduct of many industrial flowers is closely influenced by disturbances and, in particular, by adjustments in the running point. This is commonly the case for electricity structures [5].

In an electrical grid, many synchronous turbines with different voltage rankings are connected to bus terminals which have the identical frequency and segment sequence as the generators. All generators linked in parallel ought to be run at the suitable capacity to meet the demand. If a generator loses synchrony there'll be changes within the voltage and frequency offer. It's essential to synchronize the bus with the generators for the period of transmission for secure operation. also recognized as synchronous balance refers to the capability of a system to return to synchronism after any disturbance such as a sudden exchange in loading conditions offer frequency and voltage should frequently be among a positive prohibit to confirm safe and reliable operation of electrical instrumentation and equipment every at the client premises and throughout transmission and distribution. So it's crucial to be in an exceedingly position to screen and hold the voltage and frequency among limits. After an annoyance involving a net exchange in power, the System will enter a transient state which is regularly oscillatory and reflected by means of fluctuations in the energy flow over transmission lines. This is referred to as the dynamic system performance. In a tie-line connecting one team of turbines to another, these oscillation can also construct up and be mirrored via excessive fluctuations in power flow in the tie line. This will motive protective equipment to day trip [6].

The goal of this paper is to sketch a controller to perform LFC. At first an evaluation of one of a kind systems from previous research works was performed. The end result obtained. The Matlap/Simulink platform was used for all simulation outcomes obtained. The balance of the systems used to be investigated and the transient and constant country response of the systems have been simulated before any controller used to be designed. The manipulate goal is to minimize overshoot, settling time and steady state error. In LFC, deviation in frequency and tie line strength must return to zero in the minimal time and with minimal overshoot after a load alternate [7]. Controllers had been designed and tested to obtain this. Different kinds of controllers had been simulated in Simulink for the device specifically the PID, Fuzzy, Neuro-Fuzzy and Fuzzy-PID [8]–[11] to enhance its performance. Finally a comparative evaluation of the consequences from the unique

controllers was once achieved and the most appropriate one was once chosen.

II. TWO AREA POWER SYSTEM

Power systems have complex and multi-variable structures. Also, they consist of many one of a kind control blocks. Most of them are nonlinear and/or non-minimum segment systems [12]. Power systems are divided into manipulate areas related by tie lines. All generators are supposed to represent a coherent crew in every manipulate area. From experiments on electricity systems, it can be viewed that every place wants its gadget frequency and tie line strength go with the flow to be managed [3].

In intention of control at this point is to regulate the frequency of each area and at same time to regulate the tie-line power as per inter area power contract. In case of frequency proportional plus integral control is used to get zero steady state error in tie-line power flow as compared to the contracted power, consider that each control area can be represented by an equivalent turbine, generator and governor system. Consider that case of an isolated control area here the incremental power $^{\Delta P_G - \Delta P_D}$ was accounted for the rate of rise of kinetic energy stored, and increase in area load caused due to rise in frequency. A tie-line transmits power in or out an area, so this fact must be taken into the incremental power equation of each individual area.

Power transported out of area-1 is given by

$$P_{tie1} = \frac{|V_1||V2|}{X_{12}} \sin\left(\delta_1^0 - \delta_2^0\right) \tag{1}$$

δ_1^0, δ_2^0 = power angle of equivalent machine of the two area

For incremental change in δ_1^0, δ_2^0 the incremental tie-line power is expressed as follows

$$\Delta P_{tie1}(pu) = T_{12}\left(\Delta\delta_1 - \Delta\delta_2\right)$$

Where

$$T_{12} = \frac{|V_1||V2|}{P_{r1}X_{12}} \cos\left(\delta_1^0 - \delta_2^0\right) = \left[\frac{P_{r1}}{P_{r2}}\right] T_{12} = \partial T_{12} \tag{2}$$

=Synchronizing coefficient

As the incremental power angel are integral of incremental frequencies the equation is written as

$$\Delta P_{tie1} = 2\pi T_{12}\left(\int \Delta f_1 dt - \int \Delta f_2 dt\right) \tag{3}$$

Where Δf_1 and Δf_2 are incremental frequency change in area-1 and area-2 respectively.

In the same way, the incremental tie-line power out of area-2 is given by following equation

$$\Delta P_{tie1} = 2\pi T_{21}\left(\int \Delta f_2 dt - \int \Delta f_1 dt\right) \tag{4}$$

Where

$$T_{12} = \frac{|V_1||V2|}{P_{r1}X_{12}} \cos\left(\delta_1^0 - \delta_2^0\right) = \left[\frac{P_{r1}}{P_{r2}}\right] T_{12} = \partial T_{12} \tag{5}$$

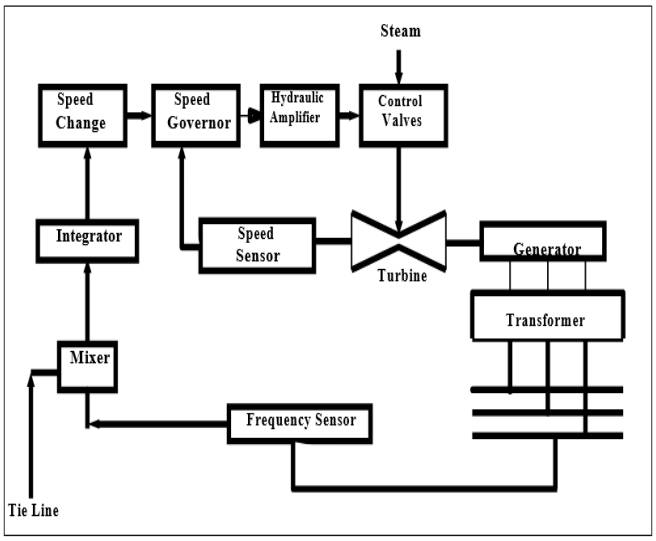

Fig.1. Block diagram of ALFC

Similarly, the incremental power balance equation for area-1 is written as follow

$$\Delta P_{G1} - \Delta P_{D1} = \frac{2H_1}{f_1^0}\frac{d}{dt}\left(\Delta f_1\right) + B_1\Delta f_1 + \Delta P_{tie1} \tag{6}$$

It may be noted that all quantities other than frequency are in per unit in equation, taking Laplace transform of equation and recognizing, the equation is given as

$$\Delta F_1(s) = \left[\Delta P_{G1}(s) - \Delta P_{D1}(s) - \Delta P_{tie1}(s)\right] \times \frac{K_{ps1}}{1 + T_{ps1}S} \tag{7}$$

Where as

$$K_p s1 = \frac{1}{B_1}, T_{ps1} = \frac{2H_1}{B_1 f^0} \tag{8}$$

When compared to the equation of isolated control area case, the only variation in the appearance of the signal $\Delta P_{tie1}(s)$ is shown in fig (1).

Taking Laplace transform of equation (3) the signal $\Delta P_{tie1}(s)$ is obtained as

$$\Delta P_{tie1}(s) = \frac{2\pi T_{12}}{S}\left[\Delta F_1(s) - \Delta F_2(s)\right] \tag{9}$$

From the control area-2, $\Delta P_{tie2}(s)$ is given by taking the Laplace of the equation (9)

$$\Delta P_{tie2}(s) = \frac{-2\pi\partial_{12}T_{12}}{S}\left[\Delta F_1(s) - \Delta F_2(s)\right] \tag{10}$$

III. RESPONSE OF TWO AREA SYSTEM UN CONTROLLED CASE

A. Static Response

The change or deviation result in the frequency.
Tie-line power under steady state conditions flow sudden step changes in load in two area.

Say ΔP_{G1}, ΔP_{G2} are the incremental changes in the generation in area-1 and area-2 owing to the load changes.

Δf Is the static change in frequency, which is same for both the areas, ΔP_{TL} is the static change in the tie-line power that is transmitted from area-1 to area-2 .
For the two areas, the dynamics are described by

$$\left(\Delta P_{G1}-\Delta P_{D1}\right)=\frac{2H_1}{f^0}\frac{d}{dt}\left(\Delta f_1\right)+B_1\,\Delta f_1+\Delta P_{TL1} \tag{11}$$

$$\left(\Delta P_{G2}-\Delta P_{D2}\right)=\frac{2H_2}{f^0}\frac{d}{dt}\left(\Delta f_2\right)+B_2\,\Delta f_2+\Delta P_{TL2} \tag{12}$$

B. Dynamic Response

A power system of two identical control areas is considered for analysis $\tau_{gt}=\tau_t='0'$ for both the areas,

The damping constants of two areas are neglected

$$\mathrm{B}_1=\mathrm{B}_2=0$$

By virtue the second assumption equation (11) and (12) become

$$\left(\Delta P_{G1}-\Delta P_{D1}\right)=\frac{2H_1}{f^0}\frac{d}{dt}\left(\Delta f\right)+P_{TL1} \tag{13}$$

$$\left(\Delta P_{G2}-\Delta P_{D2}\right)=\frac{2H_2}{f^0}\frac{d}{dt}\left(\Delta f_2\right)+P_{TL2} \tag{14}$$

Laplace transformation on both sides of equations (13) and (14)

$$\Delta F_1(s)=\frac{f^0}{2H_1}\left[\left(\Delta P_{G1}(s)-\Delta P_{D1}(s)-P_{TL1}(s)\right)\right]$$

$$\Delta F_2(s)=\frac{f^0}{2H_2}\left[\left(\Delta P_{G2}(s)-\Delta P_{D2}(s)-P_{TL2}(s)\right)\right]$$

From the block diagram, the following equations can be obtained

$$\Delta P_{G1}(s)=\frac{\Delta F_1(s)}{R} \tag{15}$$

$$\Delta P_{G2}(s)=\frac{\Delta F_2(s)}{R} \tag{16}$$

$$\Delta P_{TL1}(s)=\frac{-2\pi\partial_{12}T_{12}}{s}\left[\Delta F_1(s)-\Delta F_2(s)\right]$$

$$\Delta P_{TL2}(s)=-\Delta P_{TL1}(s) \tag{17}$$

From the above equations, the following observations can be made

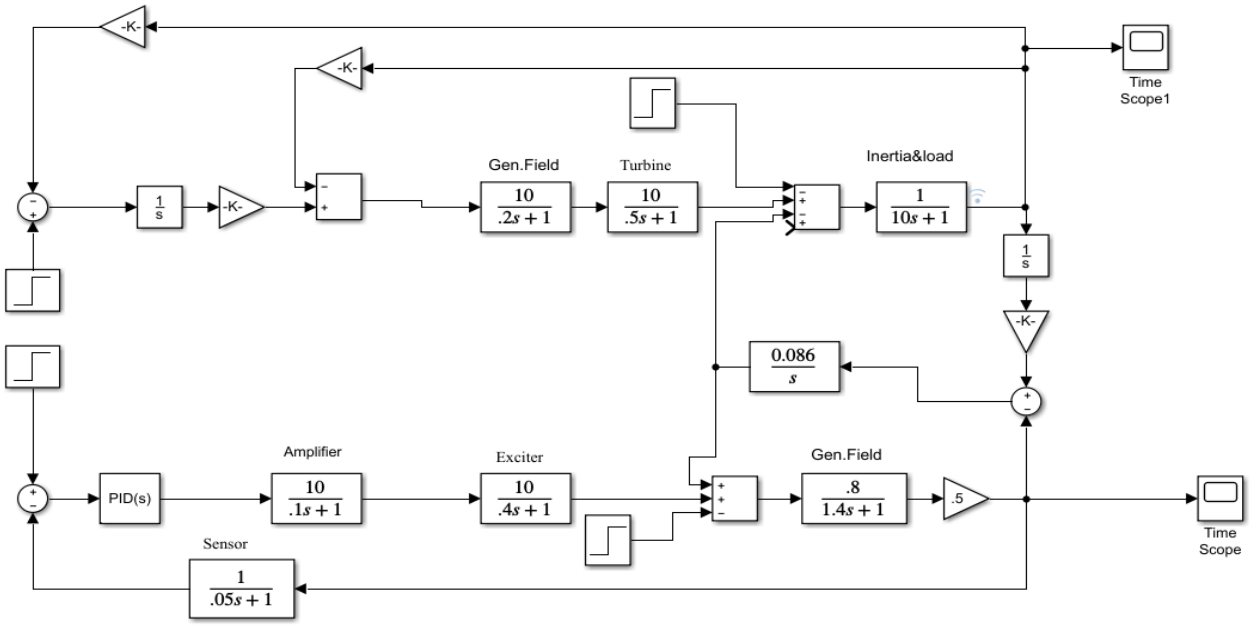

Fig. 2. SIMULINK model of two areas of AGC and AVR considering GRC

IV. SIMULATION STUDY

The AGC and AVR are implementation according to high speed loop of the , since commotion control of generator have little time fixed contributed by field winding, where AGC loop is slow motion loop be forced major time constant take part by turbine and generator determination of inertia. So that the existing transient in excitation control loop mask many fast or does not influence the AGC loop. Practically these two are not non- interacting, the interaction exists but in opposite direction. Since AVR loop influence the magnitude of generated emf this model located in the magnitude of real power and hence AVR loop felt was existed in AGC loop.

In this section develop AGC scheme is employed with AVR and considering generation rate constraint. Here coupling between AGC and AVR scheme is employed. The interaction between frequency domain and voltage cross coupling was exist and can some time disturbing. AVR loop impact the magnitude of generated emf and the internal emf magnitude of the real power. It is complemented that changes in AVR loop is felt in AGC loop. Generation rate constraint is not effect on the terminal voltage because the GRC is applied only from the speed governor system.

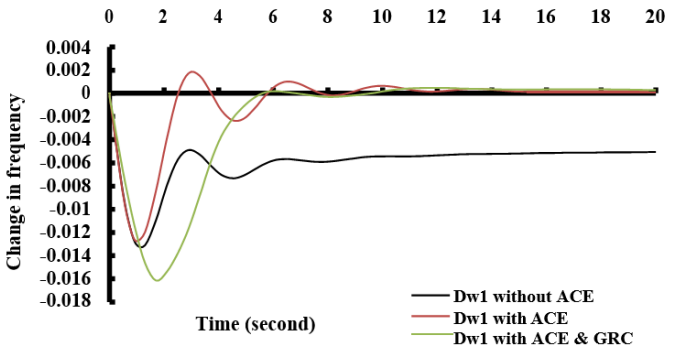

Fig. 3. Comparisons between Dw1 with and without ACE &GRC

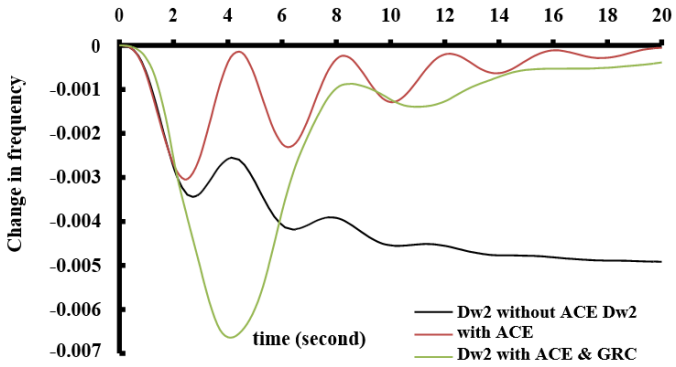

Fig. 4. Comparisons between Dw2 with and without ACE and GRC

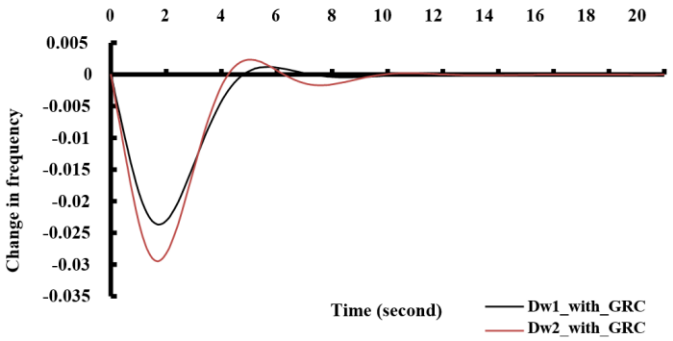

Fig.5. Change frequency of two areas AGC, AVR and GRC

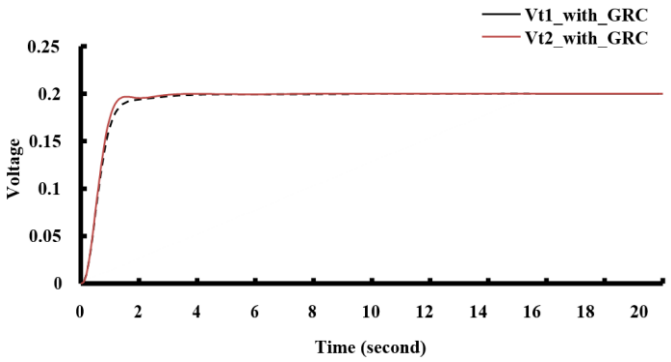

Fig.6. Terminal voltage of two areas AGC, AVR and GRC

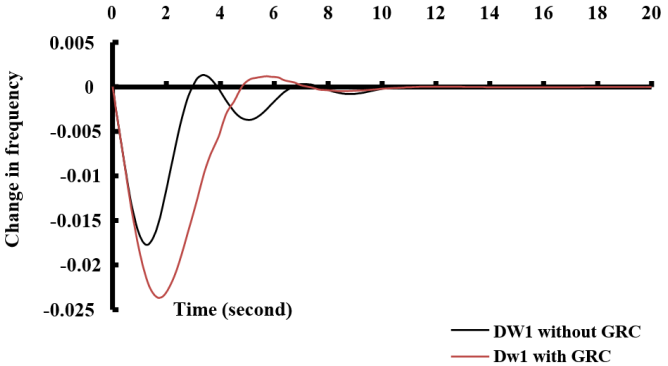

Fig.7. Comparison of change in frequency of area one

In Fig. 5 develop AGC scheme with AVR and considering generation rate constraint of two areas. Here coupling between AGC and AVR scheme is employed. The interaction between frequency and voltage exists and cross coupling does exist and can some time troublesome. AVR loop affect the magnitude of generated emf. The internal emf determines the magnitude of real power. It is concluded that changes in AVR loop is felt in AGC loop.

Fig. 6 represent the change in frequency of area 1 and area 2 the time settling and steady state error is less when coupling, Fig. 7 represent the comparison between frequency of area 1 its clear that the steady state and settling time is less but the over shoot is increase because that the GRC give the real state. Fig. 14 represent the generation rate constraint is not effect on the terminal voltage because the GRC is applied only from the speed governor system.

V. CONCLUSIONS

The two major loops that are AVR loop and ALFC loop has been studied for two areas power system. The frequency of the system is dependent on real power output and is taken care of by ALFC. Terminal voltage of the system is dependent on the reactive power of the system and is taken care of by AVR loop. The cross coupling effects between the two loops are studied that are associated with low-frequency oscillations. It has been observed that even with GRCs the system stays stable and that the response are not much different with and without Generation Rate Constraints.

Abstract*— Cognitive radio network (CRN) is the most emerging technology in wireless communication paradigm. The various components of CRNs include secondary user or cognitive user (CU), primary user or licensed user (LU), and spectrum holes. The CU is an unlicensed user which does not have license to access the spectrum. The license of the spectrum is hold by the LU. The CU nodes exploit the spectrum in an opportunistic manner in the radio environment of LU. The CU node vacates the band if LU appears and starts searching for other available unutilized band. Due to this, the researchers has experienced CRN is a highly dynamic environment. Therefore, one of generic problem coined in CRN is the coordination among the CUs for their resources. It can be viewed as, one, coordination among the CU nodes activities and, other, the channel assignment. To do this, a node may be designated as a special node called coordinator or leader that figure out which bit of the range is accessible, select the best accessible channel, facilitate access to this channel with other node, and clear the channel when another node is identified. Thus, the present contribution proposes a diffusion based coordinator election algorithm, a process to identify a coordinator in CRN. The works also illustrates flow of the algorithm using suitable examples.

Keywords*— cognitive radio network; coordinator; diffusion computation; CU; LU

I. INTRODUCTION

The radio spectrum plays most vital role in the rapid growth of wireless communication technology. In limited availability, various research studies in [1, 2] has observed that the 15% to 85% spectrum are underutilized which imposing credential rip-off in the developments of wireless industries. The cognitive radio networks (CRN) is the emerging technology that ensure the effective utilization of radio spectrum and increases efficiency. The fundamental motivation behind subjective radio system innovation is to move the underutilized authorized range which has a place with the LU which should be possible entrepreneurially. The user(s) in CRNs identifies spectrum range called white space using predefined range task technique for communication. Along these lines, in addition, there is a need of new innovation for better use of range in remote system.

CRNs have two sorts of user; one is primary user or license user (LU) which has the specialist to utilize the specific spectrum. Second is secondary user or cognitive user (CU) which not has the specialist to utilize the specific range band. There ought not to be any obstruction CU within the sight of LU. CU utilizes the spectrum range just without LU interference, artfully. In literature(s), the spectrum of CU is also called as free band or unutilized band of LU. The CRN identifies free band using following fundamental functionalities; spectrum sensing, spectrum detecting, spectrum sharing and spectrum mobility [2, 3]. The CU node keeps up a rundown of edges called local edge set (LES). From LES, few edges are used for control purposes, called public control edges (PCE), which is association set up with neighbors.

A. Problem elucidation

In CRN, a CU node is furnished with an assortment of abilities, for example, learning, proficiency, insight, believability, and working to filter for similarity and enhanced channels. The requirements of a CU node for the spectrum band changes dynamically. This may leads sporadically changes to the radio environment. Usually, the random appearance of LU plays vital impact and adds unique challenges to the CRN. The CU may observe frequent specific spectrum mismatch and hence also adds dynamicity. Therefore, the synchronization of the node(s) activity and channels is examined relative area of research in CRN like other traditional wireless ad hoc networks. The coordinator election process elect a coordinator or leader nodes which may takes care of all synchronization related jobs. In this paper, we present a dynamic coordinator selection protocol for CRN. The coordinator is significant in a CRN in light of the fact that it guarantees better spectrum usage and keeps up the quality of services (QoS). The portrayal of issues present in coordinator choice can be comprehended with the accompanying fig.1. The conduct of the CU node changes quickly to discover the range free from the LU in radio situations. The edges in fig. 1, edge(a, b), edge(a, c, d) , edge(c, d) and edge(c, d) are the free which are detected by CUs nodes 1, 2, 3 and 4 individually. The CU nodes are called neighbors anytime in the event that they have at any rate one public control edge (PCE). Diverse neighborhood look conventions can be utilize to discover a neighbor node in the cognitive radio system [8, 9]. Here, PCE of CU node of 1 and 2 is edge (a) and PCE of nodes 2, 3 and 4 are edge(c, d). The edge list can switch randomly and cause alterations to the topology because the LU can randomly arrive on its license edge at any moment.

For LU interference prediction, on LES, efficient detection method can be used [10]. If CUs have more number of PCE, their links are more stable. For example, links from 2, 3 and 4 are more stable than from 1 to 2. In CRNs CUs can move out of scope or just next to the network. However, PCE may not present because required edge is presently occupies by LU. The monitoring of CU nodes and the allocation of edges in CRNs is therefore highly challenging. We need a suitable network coordinator to ensure stronger cooperation among CUs and assign spectrum holes or edge. Due to significant functional and operational difference with the traditional wireless networks, it is not possible to apply the present coordinator election procedures in CRN. We therefore need to develop a coordinator election technique appropriate for cognitive radio networks.

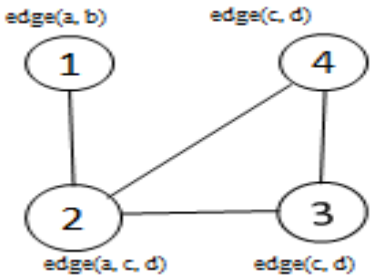

Fig. 1 Example scenario

B. Coordinator election in cognitive radio networks

By and large, coordinator elections are a solitary procedure. Once, the coordinator election computation algorithm is over, there is just a single chief in the networks. The special node act as the coordinator of the allotted task and the rest of the nodes will work ordinarily. The available coordinator can guarantee better coordination among CUs and proficient channel portion as portrayed above.

C. Proposed model

In our proposed framework, we consider a cognitive radio networks which comprises of *m* nodes and *p* edges. The CU is represented using unique *id* for portrayal in the system. Our coordinator decision protocol is based on diffusion computation [11] for extrema finding. Eventually, the proposed algorithm finds the max *id* node as the coordinator. The computation gets started as soon as departure of a leader is observed by any node. The node will be treated as source or initiator *(initial_node)*. As the diffusion method spreads, it creates the spanning tree. In case if multiple nodes start diffusion computation simultaneously, only higher *id* diffusion node survives. If a node receives election message, it is acknowledges using acknowledgement message. On receiving multiple acknowledgements, the initial node selects the highest *id* node as a leader and informs other. If a node *i* observe the presence of LU in the channel, the node removes immediately from the network.

II. RELATED WORK

There are several conventions for ad hoc networks focused on diffusion computation found in literature [12-14]. TORA [18] is a well-known directing convention dependent on diffusion computation. The messages can be tracked among remote system nodes. In CRN, not many coordinator decision conventions have been suggested. Bansal et al. [16] suggested two election coordinator conventions for a single multi-channel jump radio scheme without any identification of effect, one probabilistic and one randomly assigned. The election of the coordinator of this convention takes place at various phases. The measurement of name room is reduced by a factor of 2 in every span of the previous round. The selected node will be proclaimed as the system coordinator at the end of the specific phase. The entire round number depends on the amount of nodes in the scheme. The method used by randomization is probabilistic. In the final phase, only the CU node is dynamic and tuned in. In particular, as a system coordinator, a CU node, involved in the last phase of communication, is declared. In a fully-connected cognitive radio system, Arachchige et al.[17] suggested an unequal strategy to coordinator choice. Furthermore, the designers have used the neighboring revelation coordinator node. Exactly, the scheme coordinator of a CU node participating in the last phase is declared. The neighboring CU node dependably stay associated with one another with at any rate one normal edge. The CU nodes interface in different methods of activity trading control messages so as to play out the decision. Mittal et al.[8] shows a crash-considered cognitive radio system election convention. The assessment suggested in [16] is an extension of the diffusion. The designers anticipate the scheme to be uniform. There might be more than one coordinator in the instinctual systems of size. Two coordinator are 2x times separated.

In the event that two chiefs exist inside the inclusion zone, the determination of a coordinator is performed based on [16]. The work in [18] depicts list strategy for coordinator decision. The creators have figured an articulation for processing sampling components (SF). The parameters include amount of energy (E), CU quantity (Z) and free links (K). The aim is to determine the estimated CU nodes for the sample components (SC). As cognitive radio coordinator a CU node with the highest notable sampling component (SC) value pronounces itself. Author in [15], proposed leader election protocol for CRNs in which diffusion computation technique and message passing is used. A bio-inspired coordination election protocol for CRNs is proposed in [19], the protocol utilizes ant's intelligence to investigate the radio spectrum.

III. SYSTEM MODEL

We assume a cognitive radio networks consists of *m* CUs and *p* correspondence channel. The CU user communicates with each other using communication channel. The communication channels are also termed as links or edges. The edges are bidirectional and not really FIFO.. Every CU has unique identification number(*id*) which is used to

represent by natural number system. We use diffusion computation method and message passing approach to find the maximum identity node in the network. Every node is assumed to maintain some set of data structure during message passing in leader election process. The quantity of all edges acquaints by all CUs is known as the global edge set (GES). We consider various information and message, given in table I. Other assumptions are listed as follows which have been used in our algorithm.

A. Communication edges

The CU nodes are associated intelligently through the correspondence edges.

B. Unique identification number

id is the natural numbers.

C. Diffusion computation

In diffusion computation process, election instance is generated. The election message is spread over the network. This is also called as the expansion of the spanning tree.

D. Highest id node finding

The algorithm finds maximum *id* node as the coordinator in the networks. If we observe more than one initiators, the node with highest *id* will give higher preference.

E. Communication network

CUs are associated in the correspondence organize. We utilize radio range or edges *(channel*) for the system creation in the cognitive radio networks. The communication networks reveal spanning tree while coordination process is in progress.

F. Interference of primary user

When LU appears, the CU needs to disengage itself from that specific edge, immediately, if single PCE present. This situation can be taken care of by *prob_reply ()* function.

IV. PROPOSED ALGRITHM

A. Description of data structure and messages

The following table I and II listed various data structures and message used in the algorithm.

TABLE I.

Abbreviation	***Description***
Buffer	*Stores id of initial node received in Election message*
Count_ (child)	*Signifies number of election message received by ith node.*
Parent_id	*Signifies current parent node for computation.*
Child_id	*Signifies current child node for computation.*
Involve	*Signifies whether node i is participating in election or coordinator.*
Initial_node	*Signifies current node id who started election.*
Ack_buffer	*Stores nodes from where A_ck have to come*
Max_id	*Stores highest downstream node including that particular node*
E_M	*Message to expand the spanning tree*
A_ck	*Message to recognize receipt of an E_M*
Lead_id	*Message to declare the new coordinator*
probe	*Message to decide whether a hub is as yet associated*
Reply	*Message sent because of a Probe message*
Nbl	*Stores neighbor of a node*

TABLE II

Function	***Explanation***
Initiat_prob( )	*If reply from child doesn't come parent remove the child from Ack_buffer* *If probe from parent doesn't come child announce leader*

B. Text of proposed algorithm

The present coordinator election algorithm has been shown in the three procedural steps as following.

Procedure 1: initialization and broadcasting

1. *Node observe departure of leader, initial_node=node_id*
2. *Init(initial_node)*
3. *Involve(initial_node)=1, parent_id=node _id, max_id= node _id, Ack_buffer=Nbl_initial_node*
4. *Broadcast E_M(initial_node,Lead_id ,parent_id) to child*

5. *While parent_id.Lid==child_id.Lid*
    a. *Involve(child_id)=1*
    b. *Max=child_id*
    c. *Initiate_probe(parent_id, child_id)*
    d. *While received E_M*
        i. *Count(child_id)++*
        ii. *Buffer[]=initial_node*
    e. *End While*
    f. *If(count(child_id)>1)*
    g. *Compute_max_initial_node_using_buffer(child_id)*
    h. *Ack_buffer=Nbl_child except parent*
    i. *Parent_node=child_node*
    j. *Broadcast E_M(initial_node, Lid,Parent_node)to child*
6. *End While*
7. *Discard E_M and send N_Ack as node has different leader OR same E_M originator*

Procedure 2: Receiving Acknowledgement

1. *Upon receiving A_ck from node j, Remove j from Ack_buffer compute max_ id*
2. *While ack buffer is empty*
3. *If node is initial node then lead_id=max_id and broadcast lead message(lead_id) to the child*
4. *Else send A_ck(max_id) to parent*
5. *End if*
6. *End while*

Procedure 3: Announcing leader in network

1. *Upon receiving lead message(lead_id)*
2. *While node.involve==1*
3. *Node.lead=lead_id and set Node.Involve=0*
4. *Broadcast leader message to child*
5. *End while*
6. *If node.involve=0*
7. *Then find max leader and broadcast lead message (lead_id)to smaller leader sub network*
8. *End if.*

C. Description of algorithm

The proposed convention is given in content. This convention contains three system procedures: Iinitialization and broadcasting, Receiving Acknowledgment, and Aannouncing leader in the networks. For appraisal of figuring, we use a couple of data structure and messages which are given in the table I. In the midst of the count system every node keeps up that data structure. On amid the computation procedure, every node may reach in any procedure and acts the states of the system, accordingly.

Essentially, we will depict the convention in three cases; in first, there is no interference of LU impedance or node portability and node crashes. In next, it will contain states of disappointment because of LU impedance or node versatility and node crashes. The progress of protocol in first case is appeared in text. Thus, in our proposed convention when any node observe departure of its coordinator, it will begin the computation by instating itself as an initial node, and communicate the election message to its child or neighbor by keeping up the every one of the data structure. The *E_M* message advances data structure, for example, *id* of the initial node for particularly called initiator node. In the event that various elections *E_M* message received by any node *i* from initiator, the message is simply discarded and *N_Ack* send to the parent. The *A_ck* message is utilized to recognize the *E_M* message so as to recoil the spreading over tree. The *A_ck* message answers *Max_id* of node *i*. At the point when the initial node receives acknowledgement *(A_ck)* from all neighbors, the initiator node presently has the most noteworthy *id* put away in *Max_id*. The initiator node declared most extreme node as a coordinator for the associated CU node *i* in cognitive radio networks.

Leader message is used to declare the coordinator. If LU intrude on the channel, the influenced node leaves the channel and this situation can be dealt with by *initial_probe( )*. In this, if reply of child does not come in finite time, the parent will expel child from its *ack_buffer* list. On the off chance that prob from parent does not come in fix measure of time, child node will report the leader in sub network going about as a virtual initiator in light of the fact that in the long run it will have most extreme *id* in its sub network. The partaking CU node *i* have exceptional identifier esteem go from 1….*m*. In the event when node with *involve= 0*, represent it has leader. Otherwise, it is 1 and starts to search for a coordinator. At the point when any node receives *E_M* and on the off chance that its leader and parent leader is same and involve is 0, at that point node involve in the computation. Each time, on receiving *E_M*, every node will augment its *count(child)*. At the point when count of node more noteworthy than 1 node chooses highest *id* CU as initiator node and rest of the nodes are consider as ordinary CU. After getting the *E_M* if node have its leader *(involve=0)* or originator of election message is same node will basically dispose of the message and send *N_Ack*. Otherwise node will take an interest all the while and communicate the election message to neighbor aside from the parent node in the wake of introducing the *Ack_buffer*. Second part of calculation is getting of affirmation. At the point when any node gets the *A_ck* or *N_Ack* from node j it will expel j from the *Ack_buffer* list. Node need to figure the maximum *id* and update *Maxi_id* if *A_ck* got. In the event that *Ack_buffer* is vacant and node isn't starting node it will send the *A_ck* to its parent with most extreme id node of downstream network. Third procedure is receiving the leader message. After accepting leader message there will be two possibilities the node is either have its coordinator or it is hanging tight for the leader. On the off chance that node has its leader, at that point most extreme *leader_id* node will be chosen as leader and new leader will be declared to littler leader sub network otherwise node will store its new leader. The working of algorithm is given in fig. 2, 3, and 4.

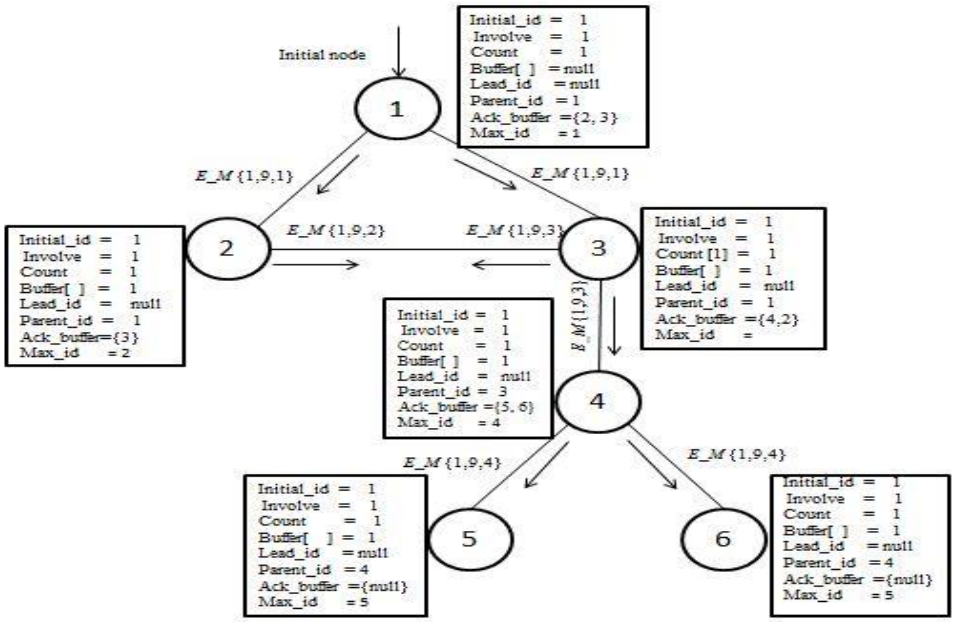

Fig. 2 Initialization and *E_M* broadcasting

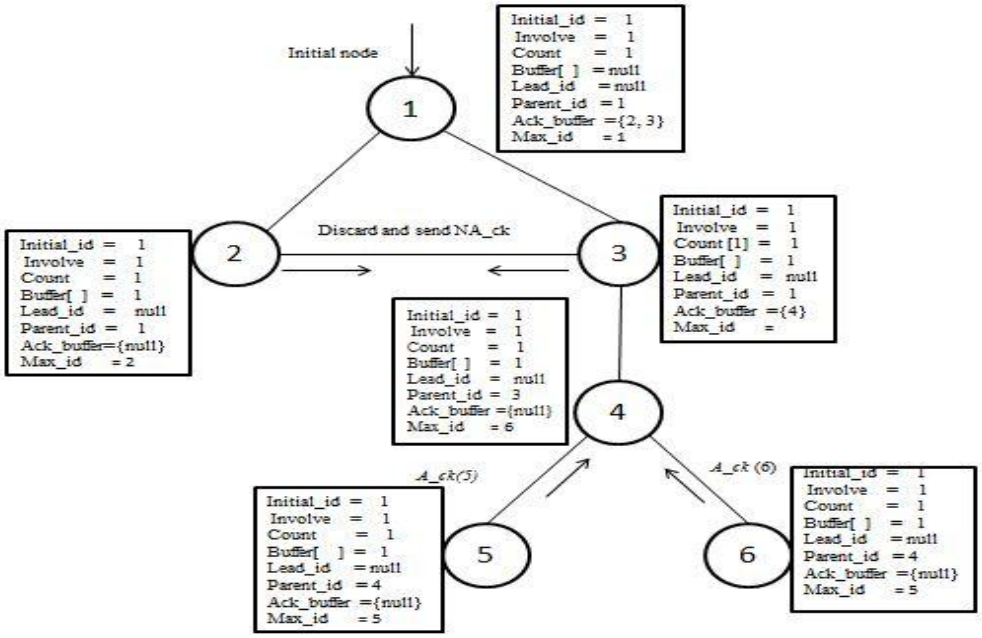

Fig. 3 Acknowledgement delivering

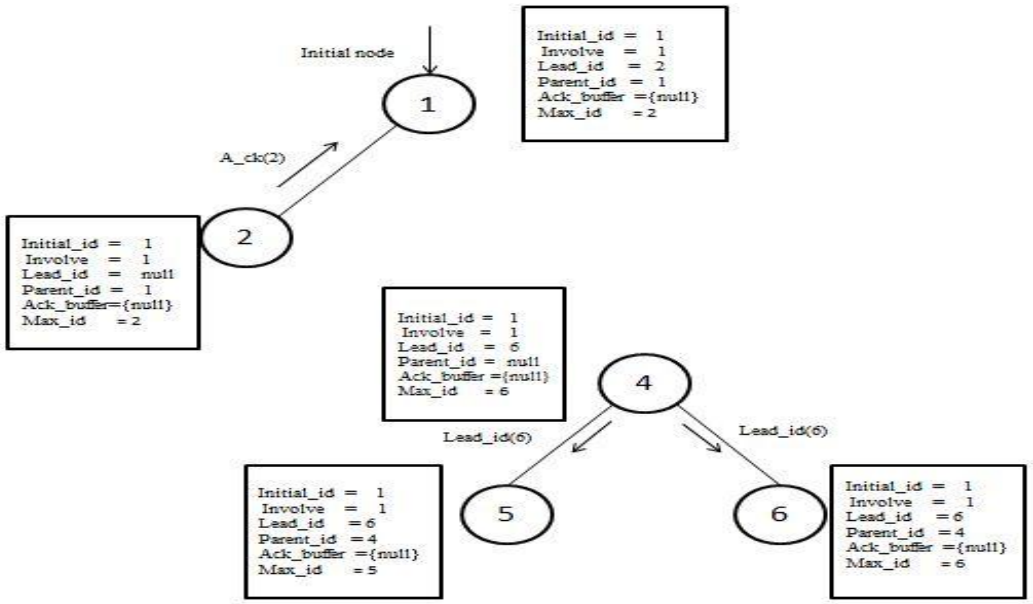

Fig. 4 Handling failure condition and announce leader

V. CONCLUSION

We proposed a coordinator election algorithm to find a maximum *id* node in cognitive radio networks. We have used diffusion computation method to find a coordinator node. The illustration of the algorithm has been included to verify the fairness of the protocol. It is an improved version of the diffusion based leader election protocol in CRN. The example demonstration claims its dynamicity while performing coordination election in cognitive radio networks.

({debasis.cse14, mps, rajat160454}@nitp.ac.in)

***Abstract*— The proposed model, Multi-Hop Low Duty Cycle Medium Access Control (MLDC-MAC) protocol, assumes that the deployment area is composed of equal-sized grids. The sensor nodes that fall within a grid are considered to be the part of the same cluster. The base station appoints the node with the highest residual energy as the cluster head in each grid. The base station also establishes multi-hop paths for communicating with the cluster heads and broadcasts the schedule for inter-cluster communication in the network. After receiving this information, each cluster head broadcasts a schedule for intra-cluster communication within its cluster. When a cluster head receives data from the source nodes in its cluster, it computes the aggregate and sends it to the base station. The simulation results show that MLDC-MAC increases the network lifetime compared with Low Duty Cycle MAC (LDC-MAC) protocol and Bit-Map-Assisted MAC (BMA-MAC) protocol.**

Keywords*— *Data Slot, Control Slot, Energy, Radio, Communication.

I. INTRODUCTION

A Wireless Sensor Network (WSN) is a collection of numerous autonomous devices (sensor nodes) that are deployed in a region to monitor the physical or environmental conditions and report it to a Base Station (BS) [1], [2]. Once deployed, a WSN may be required to provide uninterrupted services for several days or even years. Nonetheless, sensor nodes are powered by small batteries which have low energy storage capacities. Moreover, if the geographic or climatic conditions are not favourable, replacing or recharging the batteries is not a feasible solution. Hence, Medium Access Control (MAC) protocols that are designed for WSNs, inherently include one or more energy saving schemes to meet the network objectives [3], [4].

Usually, the radio/transceiver of a sensor node consumes the maximum amount of energy in its lifetime. It has been found that the radio drains a considerable amount of energy even when it is idle (neither transmitting nor receiving) [5], [6]. To this end, most of the MAC protocols turn OFF the radio when it is not working. In Time Division Multiple Access (TDMA) based MAC protocols, each node is allotted one or more slots in a periodically repeating time frame during which it can send/receive data. At all other times, the node keeps its radio OFF to conserve energy. This helps in minimizing energy consuming factors like overhearing, idle listening and collision.

Clustering is another technique to conserve the energy of sensor nodes in which nodes are grouped into clusters and one node in each cluster is appointed as the cluster-head (CH). The function of the CH is to collect data from all the non-cluster-head (non-CH) nodes and forward it to the BS. Hence, non-CH nodes are involved in short-range communications only.

This paper presents a cluster-based multi-hop routing protocol named Multi-Hop Low Duty Cycle MAC (MLDC-MAC) in which the deployment area is composed of *n* equal-sized grids. Sensor nodes falling within a grid are considered to be the part of the same cluster. The BS appoints the node with the highest residual energy as the CH in each cluster. All the CHs communicate with the BS via multi-hop paths that are established during the setup phase of the protocol. MLDC-MAC adopts a centralized CH election scheme which results in uniform distribution of CHs in the network. An efficient CH rotation scheme (enforced by the rule to appoint the node with the highest residual energy as the CH in each cluster) ensures even distribution of load among the nodes in the network.

This paper is organized as follows. Section II discusses the related work. Section III describes the working of the proposed model. Section IV discusses the results of the simulations and section V concludes the paper.

II. RELATED WORK

In BMA-RR [7], the cluster formation process is same as LEACH [8]. The overall working of BMA-RR is same as BMA-MAC [9]. However, a source node can claim multiple data slots as per its requirement. After receiving control messages from all the source nodes, the CH gets to know how many data slots each source node requires. Based on this information, the CH sets up and broadcasts a TDMA schedule. A one-bit S/R flag informs the node whether it should go into sending mode or receiving mode during the allocated slots. As the name suggests, data slot(s) are allotted on a round-robin basis. A node turns its radio ON during the allocated data slot(s) to perform the assigned task. A one-bit data mode flag informs the CH if the destination is any other node. If the data is for any other node, CH will forward it to that node in the next session. In BMA-RR, nodes with multiple data slots toggle their radios between ON and OFF numerous times within a frame.

BS-MAC [10] follows the same procedure during the set-up phase as discussed above. Towards the end of the set-up phase, each CH broadcasts a Control Slot allocation (CS_ALLOC) message in which it assigns one control slot to each non-CH. This message also contains unique 1-byte short

addresses for the CH and its members to communicate among themselves. A source node sends a control message in its control slot whereas a non-source node keeps its radio OFF to save energy. Each CH uses Shortest Job First (SJF) Algorithm to assign data slots to the source nodes and this information is broadcast through a data slot announcement (ADS_ANN) message. A source node wakes up during the allotted data slot(s) to transmit/receive data to/from its CH. If a node wants to send data to another node, it has to be sent to the CH in the current session. In the next session, the CH will forward the data to the destination node.

BEST-MAC [11] is a modification of BS-MAC in which a Contention Access Period (CAP) is introduced after the control slots. The nodes which could not join the network during the set-up phase send join-request messages during this period. A CH acknowledges the receipt of these messages but does not assign control slots to such nodes. They are allocated control slots in the announcement period when the CH allocates data slots to the source nodes. Data slot allocation is done on the basis of the Knapsack Optimization Algorithm. BEST-MAC also uses shorter time slots which can lead to frequent reservation and scheduling. The CAP may lead to idle listening of CHs after a few sessions. This is so because all the left-out nodes may have joined the network by then.

In LDC-MAC [12], the setup phase is same as LEACH. After the formation of clusters, each CH broadcasts a schedule in its cluster. Every non-CH node is allotted one control slot and one data slot. A source node transmits a control message and a data message in the allocated control slot and data slot respectively. A non-source node keeps its radio OFF for the entire duration of the frame. A CH identifies the source nodes by the control messages received from them and stays awake during the corresponding data slots. However, in this process the CH may have to toggle its radio between ON and OFF multiple times within a frame. Moreover, data slots that are not used by their owners are wasted.

The proposed model is a modification of LDC-MAC in which CHs are appointed by the BS. They communicate with the BS via multi-hop paths that are established during the set-up phase of the protocol. In the next section, the proposed model has been discussed in detail.

III. PROPOSED MODEL

The proposed model assumes that the deployment area is composed of *n* equal-sized grids. Sensor nodes lying in a grid are considered to be the part of the same cluster. All the sensor nodes are homogenous, stationary, and fitted with GPS devices that can be used to know their locations. It is assumed that each node in the deployment area can transmit to the BS directly. It is also assumed that all the nodes are time synchronized. This can be achieved by having the BS broadcast a synchronization pulse at the start of each round. The proposed model divides a round into two phases: Set-up Phase and Steady-state Phase. Fig. 1 shows the working of MLDC-MAC protocol.

A. Set-up Phase

After deployment, each sensor node transmits a HELLO message to the BS. This message contains information which is in the following format – (SN_{id}, SN_{loc}, SN_{re}). Here SN_{id} represents the sensor node ID, SN_{loc} represents its location, and SN_{re} represents its residual energy. After receiving HELLO messages from all the sensor nodes, BS chooses the node which has the highest SN_{re} as the CH in each grid. If two or more nodes fulfil this criterion, then any node can be elected CH randomly. A node whose SN_{re} is below a predefined threshold is not considered in the CH election process.

After CH election, BS broadcasts a duty allocation (DUTY) message that contains information for each node which is in the following format- (SN_{id}, CH_{id}, SN_{loc}). Here, CH_{id} is the ID of the node's CH. If the CH_{id} for a node matches the ID of the node, then the node itself has been elected as a CH for the current round. The DUTY message informs each non-CH node about the allotted CH. It also informs each CH about the non-CH nodes in its cluster.

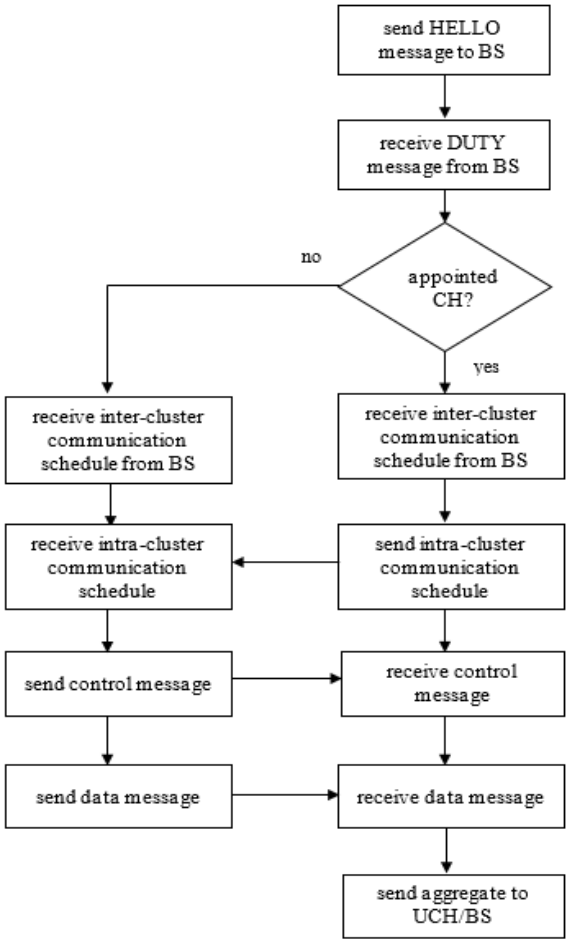

Fig. 1. Working of MLDC-MAC protocol

After a timeout period, BS broadcasts the schedule for inter-cluster communication (SCH_{bs}) in the network. This message contains information about the locations and sizes of control slots and data slots in a frame. The message also contains information for each CH which is in the following format – (SN_{id}, UCH_{id}, DS_{num}, UCH_{loc}). Here, SN_{id} represents the ID of a CH and not a non-CH node. Here, UCH_{id}

represents the ID of the upstream CH, DS_{num} represents the data slot number in which the CH should communicate with its upstream CH, and UCH_{loc} represents the location of the upstream CH. Each CH can identify its upstream CH and the data slot allocated for inter-cluster communication from SCH_{bs} message.

After receiving SCH_{bs} message, each CH broadcasts the schedule for intra-cluster communication (SCH_{ch}) in its cluster. This message contains information for each non-CH node which is in the following format – (SN_{id}, CS_{num}, DS_{num}). Here, SN_{id} represents the ID of a non-CH node, CS_{num} represents the control slot that has been allotted to it, and DS_{num} represents the data slot that has been allotted to it. Each non- CH node identifies the allotted control slot and data slot from SCH_{ch} message. The number of control slots and data slots within the intra-cluster communication period of a frame is fixed. Hence, some data slots and control slots may go unused depending on the size of the cluster.

B. Steady-state Phase

The steady-state phase consists of *k* equal-sized frames. A source node sends a control packet to its CH in the allocated control slot. The control packet informs the CH that the non-CH node will be using its data slot to send a data packet. So, the CH keeps its radio ON during the corresponding data slot. The CH computes the aggregate of all the collected data, and sends it to its upstream CH/BS during the slot allocated in the inter-cluster communication period. A new round begins after k frames in which each sensor node sends a HELLO message and the whole process is repeated again.

IV. Results and Analysis

All the protocols, MLDC-MAC, LDC-MAC, and BMA-MAC are simulated using the Python Programming Language. In all the simulations, the First Order Radio Model [8] is used to calculate the energy consumption in sensor nodes. Table I shows the parameters that are used in the simulations. Here, E_{elec} represents the energy spent in running the transmitter or receiver circuitry, E_{idle} represents the energy spent in idle mode and ϵ_{amp} represents the energy spent in running the transmit amplifier. The BS is assumed to be located outside the deployment area but very close to it. The result shown for a simulation is the average of the results generated in 10 iterations of that simulation.

TABLE I. Simulation Parameters

Parameters	***Values***
Deployment area (A)	50×50 m^2, 100×100 m^2
Initial energy of node	10 Joules
E_{elec}	50 nJ/bit
E_{idle}	40 nJ/bit
ϵ_{amp}	100 pJ/bit/m^2
Threshold energy	0.1 Joules
Data/Schedule message size	500 Bytes
Control message size	20 Bytes
Number of frames in a round	20
Number of CHs (C)	16, 25
Number of nodes (N)	100, 200

Each simulation result is followed by a table that represents the result in terms of RF (round number in which the first node dies) and RL (round number in which the last node dies) for each protocol that is simulated. For each protocol, the RF value is assumed to be the network lifetime in the protocol. Hence, the percentage increase/decrease in the network lifetime can be calculated by comparing the RF value in one protocol with the RF value in another.

For the first simulation, 100 nodes are randomly deployed in a 100×100m^2 area and the number of CHs is 16. Fig. 2 shows the graph that is generated after the first simulation. Table II shows when the first node and the last node of each protocol dies in the first simulation.

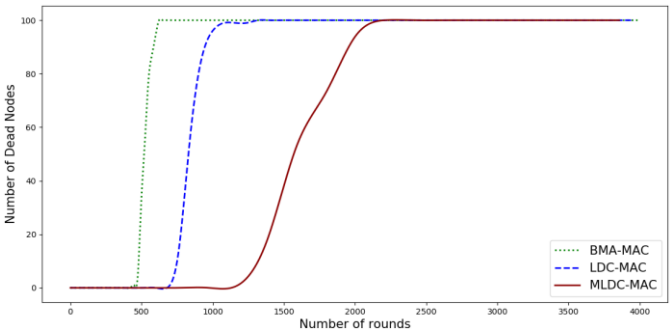

Fig. 2. First Simulation: N=100, A=100×100m^2, C=16.

TABLE II. Results of First Simulation in terms of RF and RL

Protocol	***RF***	***RL***
BMA-MAC	446	600
LDC-MAC	719	1264
MLDC-MAC	1119	2073

For the second simulation, 200 nodes are randomly deployed in a 100×100m^2 area and the number of CHs is 16. Fig. 3 shows the graph that is generated after the second simulation. Table III shows when the first node and the last node of each protocol dies in the second simulation.

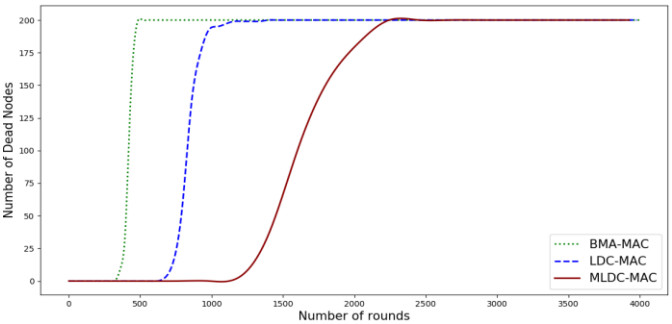

Fig. 3. Second Simulation: N=200, A=100×100m^2, C=16.

TABLE III. Results of Second Simulation in terms of RF and RL

Protocol	***RF***	***RL***
BMA-MAC	312	478
LDC-MAC	636	1350
MLDC-MAC	1126	2106

It is seen that MLDC-MAC saves more energy than BMA-MAC and LDC-MAC in the first and second simulations. Further, the performance of MLDC-MAC is better when 200 nodes are deployed in a 100×100m^2 area than when 100 nodes are deployed in the same area. This is evident from the fact that the RF value in MLDC-MAC is higher in the second simulation than the first simulation.

For the third simulation, 100 nodes are randomly deployed in a 100×100m^2 area and the number of CHs is 25. Fig. 4 shows the graph that is generated after the third simulation. Table IV shows when the first node and the last node of each protocol dies in the third simulation.

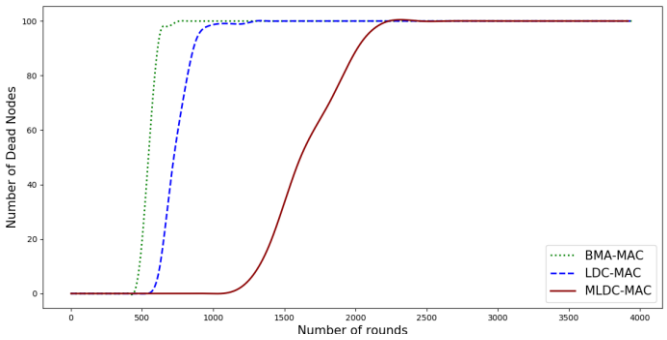

Fig. 4. Third Simulation: N=100, A=100×100m^2, C=25.

TABLE IV. RESULTS OF THIRD SIMULATION IN TERMS OF RF AND RL

Protocol	*RF*	*RL*
BMA-MAC	448	720
LDC-MAC	556	1244
MLDC-MAC	1110	2103

For the fourth simulation, 200 nodes are randomly deployed in a 100×100m^2 area and the number of CHs is 25. Fig. 5 shows the graph that is generated after the fourth simulation. Table V shows when the first node and the last node of each protocol dies in the fourth simulation.

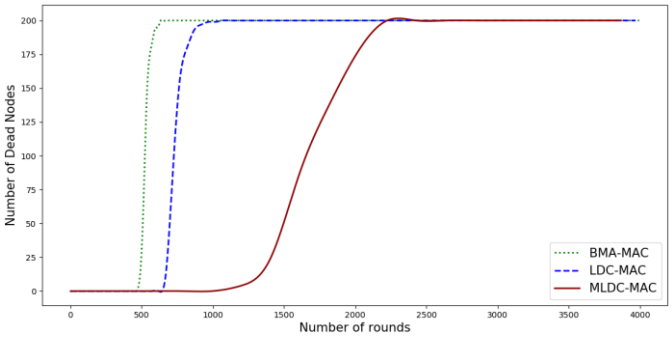

Fig. 5. Fourth Simulation: N=200, A=100×100m^2, C=25.

TABLE V. RESULTS OF FOURTH SIMULATION IN TERMS OF RF AND RL

Protocol	*RF*	*RL*
BMA-MAC	468	618
LDC-MAC	638	1024
MLDC-MAC	1167	2100

It is seen that MLDC-MAC saves more energy than BMA-MAC and LDC-MAC in the third and fourth simulations also. Additionally, the RF value in MLDC-MAC is higher in the fourth simulation than the third simulation. Hence, it can be concluded again that performance of MLDC-MAC is better when 200 nodes are deployed in a 100×100m2 area than when 100 nodes are deployed in the same area.

For the fifth simulation, 100 nodes are randomly deployed in a 50×50m^2 area and the number of CHs is 25. Fig. 6 shows the graph that is generated after the fifth simulation. Table VI shows when the first node and the last node of each protocol dies in the fifth simulation.

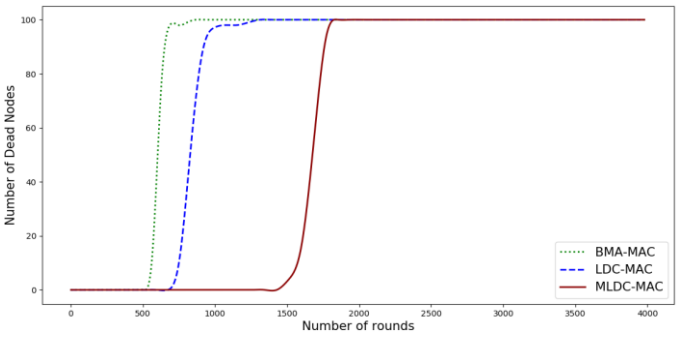

Fig. 6. Fifth Simulation: N=100, A=50×50m^2, C=25.

TABLE VI. RESULTS OF FIFTH SIMULATION IN TERMS OF RF AND RL

Protocol	*RF*	*RL*
BMA-MAC	534	828
LDC-MAC	706	1308
MLDC-MAC	1496	1785

For the sixth simulation, 200 nodes are randomly deployed in a 50×50m^2 area and the number of CHs is 25. Fig. 7 shows the graph that is generated after the sixth simulation. Table VII shows when the first node and the last node of each protocol dies in the sixth simulation.

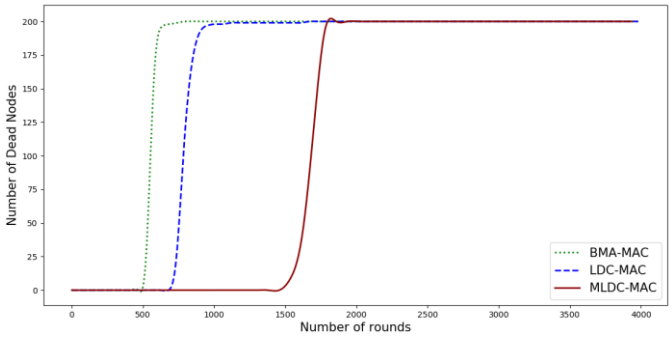

Fig. 7. Sixth Simulation: N=200, A=50×50m^2, C=25.

TABLE VII. RESULTS OF SIXTH SIMULATION IN TERMS OF RF AND RL

Protocol	*RF*	*RL*
BMA-MAC	495	784
LDC-MAC	700	1624
MLDC-MAC	1474	1783

It can be concluded from the results of the fifth and sixth simulations that MLDC-MAC saves more energy than LDC-MAC and BMA-MAC in both the simulations. When the results of the third and fifth simulations are compared, it is found that MLDC-MAC performs better when 100 nodes are deployed in a 50×50 m^2 area than when they are deployed in a 100×100 m^2 area. Similarly, on comparing the results of fourth and sixth simulations, it is found that MLDC-MAC performs better when 200 nodes are deployed in a 50×50 m^2 area than when they are deployed in a 100×100 m^2 area.

V. Conclusion and Future Scope

MLDC-MAC has a centralized approach towards cluster head election unlike LDC-MAC and BMA-MAC. In MLDC-MAC, the BS is responsible for electing cluster heads in the network. This ensures that the cluster heads are evenly distributed throughout the network. MLDC-MAC establishes multi-hop paths between cluster heads and the BS. This eliminates the requirement of long-range communications that are inevitable in LDC-MAC and BMA-MAC. The simulation results show that MLDC-MAC saves more energy than LDC-MAC and BMA-MAC. The performance of the proposed protocol can be further enhanced by dynamically varying the size of grids for even distribution of load.

***Abstract*—Solutions for both constrained and unconstrained problems of optimization pose a challenge from the past till date. The genetic algorithm is a technique for solving such optimization problems based on biological laws of evolution particularly natural selection. In simple terms, a genetic algorithm is a successor to the traditional evolutionary algorithm where at each step it will select random solutions from the present population and labels those as parents and uses them to reproduce to the next generation as children with a series of biological operations, namely reproduction, selection, crossover and mutation.**

***Keywords*—Genetic Algorithm, Travelling Salesman, Grammar Induction, Minimal Vertex Cover, Optimization, Evolutionary Algorithms.**

I. Introduction

The use of Genetic Algorithm is not something that started in recently[1]. Genetic Algorithms have been prevalent for more than half a century. Genetic algorithms first came as a result of the research of John Holland in the University of Michigan around 1960, but were unpopular until the 90s. The main purpose is to be used to solve problems in which deterministic algorithms or other traditional algorithms are too costly (time or processing). In simple terms problems which were considered hard or impossible in terms of computation were solved using genetic algorithms in record time and processing capacities. Thanks to the latest advances in research and development of artificial intelligence and soft computing the advancement in genetic algorithm has been enormous. Scientists from using genetic algorithm in their research for optimization have now started to dedicate their total research for the advancement of this very subject.

The Genetic Algorithm (GA) follows the Darwinian theory of Natural Selection[1] which is based upon a bigger class of Evolutionary Algorithms. As mentioned above, Genetic Algorithms are mostly used for optimization of the conventional problems. The genetic algorithm has biologically inspired operations such as mutations, crossover and selection. The "Survival of the fittest" theory of the Darwinian theory is the basis of the Genetic Algorithm[5].

In any genetic algorithm problem, it is started by taking a population of candidate solutions (possible solutions not necessarily the best solution) called individuals or creatures or phenotypes for the problem to be optimized in the given context. Each solution is made up of one or more individual set of properties (called chromosomes or genotype) which undergoes the above operations to be crossed or mutated to arrive at new solutions for the same problem.

This paper is basically divided into three parts. (1)The first part of the paper deals with the introduction of Genetic Algorithm and a brief history of how it all started. (2)The second part will be dealing with the all the operations and the theory which is used in genetic transformations and the (3)final part will include a detailed application of genetic algorithm to three classical problems one an algorithmic problem, one a graph based problem and one finally a Formal language based problem and also we will be looking at how it optimized the solution methodology and also the current and future research applications of GA in some of the most popular machine learning areas.

II. Background

The genetic algorithm is developed from Evolutionary algorithms (EA)[1] which is a 'generic population-based' meta heuristic optimization algorithm. An EA n which the GA is based upon uses biologically inspired mechanisms such as reproduction, mutation, recombination, and selection[7]. The algorithm believes in the theory that the fittest offspring give either the most suitable solution or will produce the fittest set of offspring. This way the EA applies the concept of natural selection.

Like an EA the GA also works similarly[16]. The evolution usually starts with a population of randomly generated solutions or individuals called the initial population. This process is iterative and each iterations population is called a generation.In each of the generations a fitness evaluation is done of all the newly generated population as well as the currently existing chromosomes from the previous generations. The value obtained by an objective function in the optimization problem under consideration is called the fitness. A stochastic selection of the more fit individuals is done from the current population, and modifying the genome of each individual (recombined or mutated randomly) to form a new generation. The newly generated candidate solutions are utilized in the next generation (or iteration) of the genetic algorithm. Commonly, the algorithm comes to a halt if a maximum number(set by the user) of generations specified beforehand has reached, or a fitness level which is considered as optimum or nearly optimum(satisfactory) has been reached for the population[5]. The basic flow of a GA solution will be something as follows:

Algorithm 1: Generic GA

```
Start
Initialize population randomly (say P)
Define fitness function of the problem
Determine the fitness of the population
while !Converging or Optimum not achieved do
    Parent selection from population
    Crossover operation for new population generation
    Perform mutation on the new population
    Calculate fitness of new population
end
If optimum achieved, display the final result
Stop
```

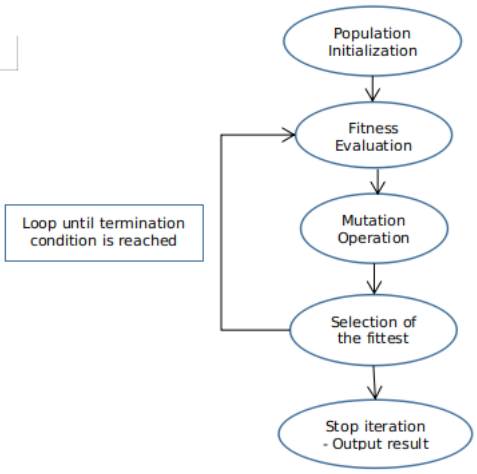

Fig. 1: Flow Chart of a GA

1) A genetically suitable representationx of the solution domain in a format suitable for computation preferably binary representation (0 and 1)[2].
2) A function to evaluate the fitness of the solution or the population generated (fitness function).
3) Data Initialization.

Each candidate solution is usually represented as an array of bits. Arrays or other forms of data structures can be similarly used[16]. The main characteristic of these genetic representations that makes it convenient is the easy alignment of parts, which makes crossover operations simpler. Representations of variable lengths can also be used, but it makes crossover implementations a bit more complex.

III. Initial Population Assignment

The first step in any GA problem is the initialization of population[11] which is a part of the current generation. A generation (say P, P0 is the initial population and Pt is at iteration t) P0 is the initial population which is usually generated randomly. In an iterative process the next generation of population P1, P2... are constituted. When a population for a GA is selected it is made sure that the population diversity (a wide range of possible solutions) is maintained. A failure to maintain population diversity may lead to a condition called Premature Convergence[14].

A. Premature Convergence

Premature Convergence in Genetic Algorithm is analogous to under-fitting in Artificial Neural Networks. The premature convergence in a genetic algorithm is when the algorithm reaches a minimum before it reaches the global optimum solution. Usually, when a genetic algorithm per say any evolutionary algorithm is trapped into a local maxima and doesn't move forward, it's called a condition of premature convergence.

1) Reasons for Premature Convergence

label=

a) Loss of Diversity: Diversity is how many numbers of different solutions are there and how different they are. The loss of diversity refers to how uniform the solutions and thus all solutions are similar to the best one, so the GA is stuck finding the weak and the strong ones.
b) Increased selective pressure to converge to best solution.
c) Over exploitation of the currently existing building blocks from the current generation of population.

2) Prevention of Premature Convergence:

There are certain strategies to prevent the condition of premature convergence

a) Increase the size of the population of the algorithm.
b) Uniform Crossover.
c) Replacing the population's similar individuals
d) Segmentation of chromosomes of similar fitness called fitness sharing

The population size is a crucial parameter to be kept in mind. It shouldn't be too large which might slow down the algorithm and a very small population size might be small for the genetic operations. The optimal size of the population is found by a trial-and-error method.

B. Methods of Initialization

There are two methods of population initialization for a Genetic Algorithm:

Random Initialization: In this method, the initial population is populated with a bunch of totally random solutions.

Heuristic Initialization: This method populates the initial population based on a known heuristic of the problem.

IV. Genetic Operations

Genetic operators are those operators which are applied on the population pool to edit or create new genes from currently existing genes. There are quite a few genetic operators. Their uses, properties and types are discussed below:

Selection: After the initial population initialization then the next step in GA is the selection operation. This is the first genetic operation. There are two types of selections:

a) Selection from the current generation to take part in this generation's reproduction. This is also called the parent selection.

b) Selections from the current generation's parents and offspring to go to the next generation. This is the selection of survivors.

In this step, a single individual chromosome is to be selected as a parent for the next generation of population, based on fitness.

A. Fitness Proportionate Selection

This is a very popular way to select a parent. In this method the parents are chosen on the basis of probability which is proportional to their fitness. This means, higher the fitness of the individuals, the higher chance of being selected to reproduce and propagating the features to the next generation.

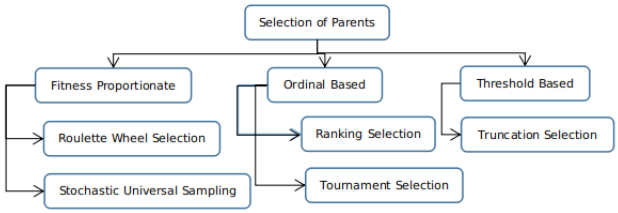

Fig. 2: Different methods to select parents for next generation

There are two ways of implementing the Fitness Proportionate Selection:

1) Routlette Wheel Selection

This selection in this method is based on the proportionality of the fitness of an individual chromosome. The fitter the individual chromosome the higher the chances of the chromosome being selected as a parent. The roulette selection follows a principle of searching linearly through a wheel with slots, where the slots of the wheel weighted proportional to the fitness of the individual chromosomes. Then a chance is taken by throwing a marble in the wheel and selects the chromosome. Chromosome with bigger fitness will be selected more times. A higher the fitness of the individual, greater the size of the area on the pie and so it has a much higher chance of landing in front of the fixed point when the wheel is spun. Therefore, an individual is more probable to be selected if it has a higher fitness value. This implements the " survival of the fittest " law directly. The roulette wheel selection method is show in Fig 3.

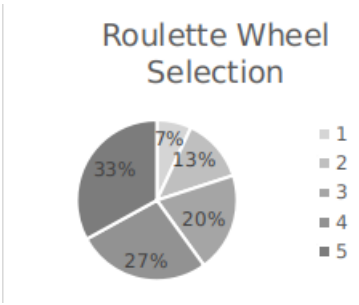

Fig. 3: Roulette Wheel Selection for a sample of 5

There are two main approaches to Roulette Wheel Selection:

a) Approach 1 : Stochastic Sampling with Replacement

This approach selects individual pairs for crossover with probability proportional to their fitness values. Consider a simple fitness and probability of 4 chromosomes. The example as shown in table 1.

TABLE I: Stochastic sampling with 4 Chromosomes

No.	Fitness(f_i)	Probability(P_i)
1	132	0.083
2	521	0.32
3	56	0.035
4	879	0.55
Total	1588	1.0

In this example the probability that an individual is chosen as a parent for crossover is given by:

$$P(i) = \frac{f(i)}{\Sigma f(i)} \tag{1}$$

f(i) : fitness of individual i

P(i) : Probability that individual i is chosen

b) Approcah 2 : This approach has a specific approach which is very similar to the roulette wheel:

It follows a few steps

a) The chromosomes are mapped to a contiguous line such that the length of each individual segment is equal to the size which is proportional to its fitness.

b) A number is generated in random and that chromosome who has a segment falling in the selected random number, is finally selected as parents.

This is done till the number of selected individuals to the required number is obtained.

TABLE II: The table shows the data with some sample population

No.	Rank	Fitness(f_i)	Probability(P_i)
1	9	1.6	0.19
2	8	1.4	0.15
3	7	1.2	0.13
4	6	1.0	0.11
5	5	0.8	0.08
6	4	0.6	0.07
7	3	0.4	0.0.3
8	2	0.2	0.02
9	1	0.0	0.00

Stochastic Universal Sampling : The first step is similar to the approach 2 of the Roulette Wheel Selection. In this the second step there are equally spaced pointers placed over the lines as many individuals are to be selected.

2) Rank-Based Selection

This is an objectively selected selection method[14]. The fitness is dependent on the individual's rank Ranking introduces a sense of uniformity among the individuals and acts as a simple method to control selective pressure. The probability of each chromosome selected is based upon its fitness normalized by the total fitness of the population. There are two types of ranking: Linear and Non-Linear ranking. Linear ranking ranks the individual in population is ranked from 1 to n in the

order of how fit the chromosomes are. Linear ranking assigns a probability proportional to the individuals rank. In the non-linear ranking method, it uses non-linear distribution. Like the linear ranking but the rank is based on but not proportional to the individual's rank.

Tournament Based Selection : This is the simplest of all the selection methods. In this method a K (say =2) is taken and k chromosomes are selected in random and the fittest of the selected k chromosomes is permitted to reproduce.

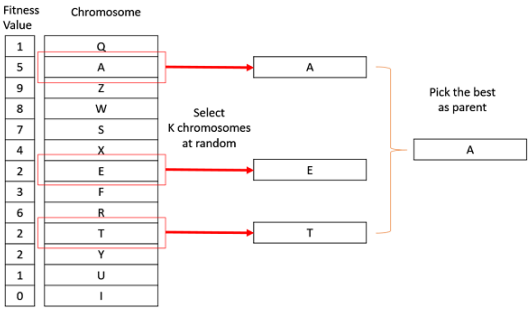

Fig. 4: Tournamen Based Selection

3) Threshold based Selection

a) Truncation Selection

It is an artificial method used to select parents for a large set of chromosomes. A parameter called Trunc is used as a parameter for this method. Trunc indicates what part or fraction of the existing population of chromosomes are to be selected as a parent, The Trunc has a value ranging from 10% - 50%. The chromosomes which are below the limit of the threshold are not allowed to reproduce.

b) Survivor Selection

This selection method is the one which decides which individuals are to be kept for the next generation and which are to be kicked out. This process is known as replacement. This type of selection reduces a population of (N+L) to N where N is the number of parents or population size and L is the number of off springs at the end of a generation. The survivor selection is divided into 2 types as shown below:

c) Age Based Selection

In this method the fitness of the chromosome is not taken into consideration. In this method a certain chromosome is allowed to reproduce for a certain number of generations and then it is kicked out even if it has the highest fitness.

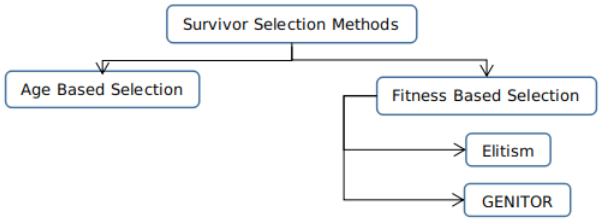

Fig. 5: Survivor selection method and its types

d) Fitness-Based Selection

In this selection, children tend to replace the least fit chromosomes in the population. The selection process followed for the least-fit individuals can be done using one of the above specified methods like tournament selection, fairness proportionate selection etc. In this Elitism is the method which helps preserve the fittest chromosomes during crossover or mutation. In this method there are first copies of the best chromosomes made to the new population. This method increases the performance of the GA drastically.

V. Crossover

Crossover or recombination is an method using in genetic and evolutionary algorithms which is based on the biological process of crossover done during reproduction. This method is one of the few ways to generate new solutions from present population existing by combining the genetic information of parent chromosomes to generate new population or offspring. There are other ways of generating solutions, from a single parent where the parent is cloned as the offspring of the next generation. Mutation of the newly generated off springs are done before being added to the gene pool of the next generation. The different algorithms in evolutionary computing may store the genetic information in different of data structures. It generally uses bit arrays, trees or vectors of real numbers so each genetic representation can be operated with crossover operators of various types.

A. Single-Point Crossover

Both the parents' chromosomes are taken and one point known as the 'crossover point' is randomly assigned. The gene information (bits) to the right of the selected point of one parent chromosome is exchanged with the other parent chromosome shown in fig 6. This results in a child chromosome or offspring which contains genetic material from both the parent chromosomes.

B. Two point and K-point crossover

In this type of crossover, two points are selected from the parent chromosomes randomly. The bits from both the parents between the crossover points are swapped creating new child chromosomes

Fig. 6: Single Point Crossover Method

C. Uniform crossover

The uniform crossover is another type of crossover operation to generate offspring from parent chromosomes. In this, according to a fixed uniform distribution, the child's genetic data is chosen independently from the two parents. In this type of crossover not segments but individual bits are exchanged during the crossover operation unlike the k-point method. Usually the bit chosen from either parent have almost equal probability of being chosen. There are other ways to make the

offspring inherit the genetic information of one parent more than the other by mixing the selection ratios.

VI. Mutation

The Mutation operator is one of the operators used in a genetic algorithm to genetically diversify the genetic population from one generation to the next. This operation of mutation in a genetic algorithm is analogous to biological mutation. In the process of mutation, one or a few values of the genetic information stored in the chromosome are edited or changed. In mutation, there is a probability of the new gene being very similar to the previous configuration or being completely different. So, by the use of mutation, the GA can get a better diversity of population to in turn getting a better solution set in the next generations in comparison to the previous one. This occurs in accordance to the probability of mutation which is set by the user itself. It is recommended that the probability is set low; if set too high the algorithm would work as a primitive random search rather than in an evolutionary manner. There are different types of mutation:

A. Bit Flip Mutation

The mutation of bit strings ensure through bit flips at random positions

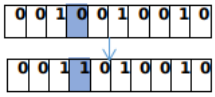

Fig. 7: Bit Flip Mutation

The probability of mutation of a bit is 1/L where L is the length of the binary vector.

B. Flip Bit

This type of mutation takes the selected gene or the chromosome and inverts the bits of the gene. If the bit in a gene is 1 it is inverted to 0 and if it is 0 it is changed to 1

C. Boundary

This type of genetic mutation is useful in integer of float types. In this the operator replaces the chromosome's genetic value with a random value of a lower or an upper bound.

D. Non Uniform

d.The use of non-uniform operators for the mutation operations will increase the probability that the amount of mutation will go to 0 in the next generation. It helps the gene population to grow and evolve rather than staying dormant in the initial stage of the evolutionary timeline. It is also helpful to tune the solution in the later stages but with a price. This operator is limited to integer and float type genes.

E. Uniform

e.This mutation operator inputs an upper and lower bound from the user and replaces value of a selected gene with uniform random values lying between those two bounds. This is also limited to integer and float type gene population

F. Gaussian

f.This operator selects a unit Gaussian Distributed random value and adds it to the selected gene. The obtained gene value is snipped if the added value falls out of the set upper or lower limit specified by the user. This operator is also limited to integer and float genes

VII. Termination

The basic requirement of a genetic algorithm just like any algorithm in computer science has to terminate after a certain amount of time. The rate of progression of a GA is high until it reaches close to the optimum solution and the pace reduces. So the termination condition has to be designed in a way that it stops close to the termination condition as no algorithm can be 100% accurate. Usually, the termination condition is one of the following termination conditions—

a) When there is no improvements in the population for the X iterations
b) We reach an absolute number of iterations.
c) When the objective function value has reached a certain value defined earlier (probable optimum solution)

VIII. Fitness Function

A Fitness function also called as an Evaluation function evaluates how close to the optimum solution or the desires solution has the GA reached[15]. According to the natural selection rule the fittest of the assumed chromosomes are sent to the next level and the rest are killed off. The chromosomes which pass on to the next generation act as parent chromosomes which will be further used for reproduction of new child chromosomes by two methods namely crossover and mutation. But how will the fittest of the chromosomes found. It is done by giving each chromosome a fitness value at the end of each generation. This fitness value will be given by a function known as the fitness function. Each chromosome will award a score and thus indicating how close the chromosome came to the optimum solution. There are a few generic requirements of a fitness function. They are as follows:

a) The fitness function should be clearly defined and the reader should be able to understand clearly how the score for the fitness function is calculated.
b) The optimization of the fitness function is of the prime priority. If the fitness function becomes a bottleneck of the whole algorithm, then the efficiency of the algorithm will be greatly affected.
c) The fitness function should quantitatively measure how fit the given solution is in solving the problem at hand.
d) The fitness functions should give intuitive results. The best and worst chromosomes should be given the best and worst fitness scores.

IX. Applications

The following sections will talk about the different applications of Genetic Algorithm

A. Application 1: Solving the travelling salesman problem with genetic algorithm

The travelling salesman problem always considered as one of the classical problems of computer science optimization theory. It is regarded as an NP-complete problem[3]. This problem serves as an abstract to problems in many engineering fields in the current era. There are two ways of solving this travelling salesman problem in the conventional method which is global and local search. Solving the travelling salesman for a small search space with the traditional methods is easy but the same for a huge search space with the traditional methods is not so efficient. So the genetic algorithms give the problem a biological intelligence simulation and makes it a much more efficient approach to solve the same[4]. The travelling salesman problem will have a GA approach flowchart similar to the one in Fig 1.

As said above the traditional methods are suitable for small number of cities, but when it comes to cities in number of hundreds as it is in the real life scenario the genetic algorithm approach is faster and will take much less time. For the travelling salesman problem we have considered a series of 15 cities and also their latitude and longitudes in table 3

Like any basic GA problem we start by randomly initializing a set of population referred to as a gene pool[11]. This gene pool will be used in the further mutation and crossover to hopefully produce better population for the successive generation. There will be three basic functions followed, namely, reproduction, mutation and crossover.

The first step in this will be reproduction where string from the current generation are copied with the probability based on objective function value. The second operation is crossover where randomly selected pairs of strings are mated which will result in new string.

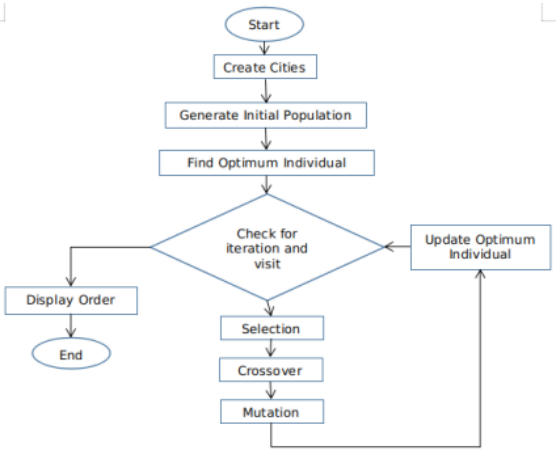

Fig. 8: Solving the Travelling Salesman Problem using GA

The third and final operations in this is mutation Mutation can be done in any one of the methods in the above section but in this we will be following a method of altering the value of a string in random position in some of the population[6]. Mutation is a method by which we can create a diverse population which can protect the genetic material which can probably lost during reproduction or crossover.

TABLE III: Example of cities and their coordinates

Cities	latitude	longitude
City 1	-27.6126	-51.0233
City 2	-26.5716	-52.3229
City 3	-27.4087	-49.822
City 4	-27.2662	-49.708
City 5	-26.9985	-51.5528
City 6	-27.0754	-52.9808
City 7	-26.8794	-52.8568
City 8	-27.6963	-48.8243
City 9	-26.843	-53.5758
City 10	-26.781	-49.3593
City 11	-27.496	-48.6598
City 12	-26.9155	-49.0709
City 13	-27.7455	-49.9423
City 14	-28.3377	-49.6373
City 15	-26.7326	-52.3919

The population which is generated in every generation is checked with the fitness function after the genetic operations to find the fittest of the population for the next generation. In this, we are using a fitness function f(x), where f(x) is defined as:

$$f(x) = \frac{1}{t(x)} \tag{2}$$

Fig. 9: Plot of cities according to Table III

Where t(x) is the objective function. As the travelling salesman problem is a minimization problem t(x) calculates the cost of travelling the cities represented by a chromosomes. This fitness function helps to maintain the darwinian Survival-Of-the-Fittest rule. In our method we also use the Elitism method where the first copies of the best chromosomes are sent to the next generation. This method helps to increase the performance of a GA as it prevents it from losing the best found solution of a particular generation.

The next step of the model is the crossover operation. This method is a very crucial step of the GA. Firstly two chromosomes are randomly selected from the gene pool and then a common crossover length is selected and the both chromosomes are broken at that point and crossed. The crossover operation can be done with a series of steps as follows:

a) Start from the first node c(first node in chromosome C1 and C2)
b) Search both the parent chromosome C1 and C2 and consider the first legit node after the first node in the

parent chromosomes C1 and C2

c) If $C_{px} < C_{py}$ select node X else select node Y
d) If the selected node is node X as the next string in the partially constructed chromosome then copy the remaining genes from the parent C_2 else copy everything from C_1

1) Results

In the example problem we have taken 15 cities. And for the ease of processing we have taken a initial population of 500 chromosomes. Once the program executes the shortest path is represented as in the fig 10. It has to be noted that there is a possibility of the existence of more that one correct answers ,i.e. in this case more than one optimum path for some Travelling Salesman Problems. This depends on the random solutions generated and mutation and the crossover operations.

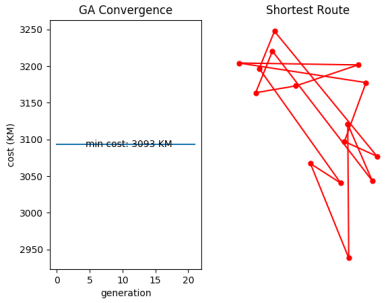

Fig. 10: Final Shortest path calculated using the GA

2) Comparison to other methods

a) Genetic Algorithm

Genetic algorithm is an algorithm with exponential time complexity with a worse case time complexity of O(Kmn). The advantages of using the GA is that the best solution is achieved by the fitness criteria but the disadvantage is that there is no optimum solution,i.e. an approximate solution is reached but an optimum solution is not reached.

b) Greedy Approach

This takes a time of 5 seconds for just a problem with 15 cities. This has a logarithmic time complexity, i.e. the time complexity of the worst case is O(log(n)). This only disadvantage is that there is no best case so no accuracy is reached.

c) Dynamic Programming

3.This is also a slower method of achieving the shortest path. But this takes around 9 seconds for a problem with 15 cities. This has a worst case time complexity of O($n^2 2^n$). The advantage in the method is that this method can achieve a global optimum solution but the biggest disadvantage of this method is that it is inefficient for both memory and time.

B. Application 2 : Grammar Induction

A grammar induction is a method of deciding or finding out a grammar from a set of sample strings collected from the language generated by the grammar[10]. Similar to the travelling salesman problem the grammar induction is also an NP-complete problem for Finite State Grammars. GA has been successfully used for Grammar Induction for Finite State Grammar[13].

Given a set of equivalent and non-equivalent grammars, we use GA to find out a grammar which can successfully parse the given language. Let the initial gene pool be G and next generation be G_{New}. Mutation is performed repeatedly and consists of replacement of an old chromosome by a new one. Steps to use GA for grammar induction[12]:

a) Select one grammar from the initial gene pool G and find the fitness value of the selected grammar
b) Sort the selected grammar in descending order of fitness value
c) Apply the crossover operation between 2 random pairs
d) Sort the resulted new grammar in GNew and find the fitness value of the newly generated grammar
e) If the new grammar successfully finds the positive and negatives, end the iteration
f) Else replace the gene pool G with fitter members from G_{New}. Finally mutate the outputs if repeated
g) Else jump to step (e)

C. Application 3 : Minimal Vertex Cover using GA

Graph-Theory states, " the vertex cover is a term referring to a set of vertices such that every edge of the graph is incident to at least one of the vertices from the set. It can be stated as, G=(V,E), S $\subseteq$ V is a vertex cover if $\forall\{u,v\} \in E : u \in S \vee v \in S$"[9]. Minimum vertex cover for the graph G will be equal to the vertex cover S that minimizes $\|S\|$.

The main issue in finding the minimum vertex cover from a given set of points has been one the most important and classical problems of both graph theory as well as computer science. Unlike both the travelling salesman and the grammar induction problem, the minimal vertex cover problem is said to be an NP-hard problem and this is a very typical example of an NP-hard optimization problem.

Procedure to find the minimum vertex cover using a GA is as follows:

Algorithm 2: Algorithm for finding the Minimum Vertex Cover

```
Input : Graph G
V_c = {}
E^P = E[G]
while E^P !empty do
    Let (x,y) be an arbitraty edge of E^P
    V_c = V_c
    Pop from E^P every edge incident on either x or y
end
Return V_c
```

Using the above methods in combination with the genetic operations we will be able to find out the minimum vertex cover of a set of points in a graph.

X. Conclusion

The research on the field of Genetic and Evolutionary algorithms and also taking into consideration the results obtained in the above experiments and the past work on the same, gives sufficient evidence that the GA has proven to be much more faster and very much efficient in finding solutions to real world problems in comparison to the traditional methods as showing the three applications. The GA also gives rise to new solutions which might not be able to be found by traditional methods.

***Abstract*— wireless sensor network (WSN) is the group of sensing computing and communication components that gives ability to sense a physical phenomenon in a specified environment. The main problem of WSN is energy consumption or battery power, to avoid such problems different type of routing protocols is used. LEACH routing protocol is used to reduce the energy consumption and enhance the battery power and network lifetime. LEACH is a homogeneous WSN protocol and it has some limitations. So there are few version of LEACH homogeneous protocol such as A-LEACH, B-LEACH, T-LEACH and MOD-LEACH. To overcome limitation of homogeneous LEACH protocol heterogeneous LEACH protocol is used. In a heterogeneous LEACH two or more different types of nodes with different battery power and functionality are used. Sink node is a sensor node which has large energy capacity and it collects data from other node. Sometime sink node affected by different type of attack such as sinkhole, black hole attack etc. to avoid these types of attack various technique are used such as intrusion detection, watchdog scenario etc. The sensor has small tiny OS having a capability of sensing physical phenomena and transfer to its base station to convert the sensing information into the human-readable form via internet.**

Keywords— LEACH protocol, Clustering, Heterogeneous WSN, energy Consumption, Network lifetime CH (Cluster Head), BS (Base Station).

I.INTRODUCTION

WSN is the collection of small sensor node also called as a mote. Sensor node (mote) senses the physical phenomena from environment. The battery is an essential part of the sensor. LEACH is standard homogeneous protocol and also it has some version with particular modification. Such as A-LEACH, C-LEACH, M-LEACH, T-LEACH etc.

LEACH protocol has advantages of clustering to reduce energy consumption and enhance the network lifespan. Whereas network lifespan is a time interval or time span from starting of a network to first node death. TDMA scheduling used to reduce the energy consumption because TDMA scheduling allocate some time span to each sensor node then each and every sensor send the data to the CH in particular cluster within allocated time slot. So the data redundancy will be reduced and efficiency will be increased.

LEACH has some drawback such as all sensor nodes have same functionality, parameter, and characteristics. If one of the sensor nodes is destroyed or crashed then the whole network is affected. When we choose the CH if low energy sensor node is chosen then the network lifespan and performance of a particular task will be reduced. Sometimes the distance factor between the sensor nodes in the network will be affected on the performance of the whole sensor network.

The difference between homogeneous and heterogeneous LEACH.

Homogeneous Network	Heterogeneous Network
WSN contain sensor same energy level and almost same parameter such as range, battery power, also all sensor node are identical then such type of network is called as a homogenous WSNs	In heterogeneous WSN, nodes are deployed with different initial energy levels, range, battery power than such type of network is called as a heterogeneous network
It saves energy but does not help in prolonging network lifetime	As compared to homogeneous it saves more energy and helps in prolonging the network lifetime
They are less suitable for real-life applications cause it has some limitation due to homogeneity.	They are more suitable for real-life applications cause its maintain heterogeneity.
Examples-LEACH, PEGASIS	Examples:- DEEC, EDDIEC

Table No.1.comparison of Homo and Hetero LEACH

The work defined in the literature of LEACH Protocol on Homogeneous network which is having sensor nodes with the same parameter which doesn't work efficiently and it has some limitation over a distributed area.

Existing approaches in this area reside big-challenges like the situation where the Sink node affected by a different type of attacks. Due to these limitations, existing approaches are not suitable for sink node security.

In construct, take a LEACH Protocol on Heterogeneous Wireless Sensor Network. Propose the method for Heterogeneous Wireless Sensor Network with Sink Node to improve the security the rest of the paper is organized as follows. Section 2 shows a brief description of the related work performed on the LEACH protocol. Section 3 presents

Methodology. Simulation results discussed in Section 4. Finally, the conclusion introduced in Section 5.

II. Related Work

Salim EL Khedari, Nejah Nasari, Anne Wei, Abedennaceur Kachouri [1] in 2014 described the cluster selection based on different topology because when topology change the whole throughput of sensor network is change. They compare different version of LEACH on homogeneous sensor network and it optimizes performance by using parameter such as mobility, scalability, self-organization, distributed organization, centralized etc.

Reenakamal Kaur Gill, Priya Chawla, Monika Sachdeva [2] in 2014 described that LEACH protocol and its phase's advantages, disadvantages and possible attack on routing protocol. LEACH protocol contains no. of rounds to select the CH of particular cluster. After the formation of cluster no. rounds are divided into two phases one is a set-up phase and another is a steady state phase.

George W. kibirige [3] in 2014 described the total information about sinkhole attack means sinkhole attack is which type attack how it works on LEACH protocol how its affected on sink node and how this attack apply on node by using mint route protocol, challenges in detection of sinkhole attacks communication pattern, prediction or some existing approach such as rule-based, anomaly detection, statistical method anomaly detection method etc. also they detect the attack on sink node by using different detection mechanism.

R.K.Sundararajan, U Arumugam [**4] in 2015** described various threat affection on various layer for physical layer the jamming and tampering for data link layer collision, exhaustion, unfairness for network layer sinkhole black hole, selective forwarding, for transport layer flooding, false messages for application layer data aggregate on distortion etc. this type of threats for different layer and disturb the whole scenario of arranged WSN. Also, they discussed various launching technique to launch a sinkhole attack ex. IDS Architecture and its working or intrusion mechanism also to detect sinkhole attack.

Jitender Grover, Shikha Sharma [5] in 2016 described security requirement such as data confidentiality, data integrity, data authentication, data availability, source localization, self-organization, data freshness etc. to avoid attacks and challenges on the sensor network. They describe the classification of security thread which is based on routing. To avoid different attack some protocol is used such as SPIN, TINYSEC, LEAP, ZIGBEE etc. also they compare the all security protocol performance with all security requirements to verify the effective outcome i.e. they provide security to sink node.

Mohamed Elshrkawey, Samiam, Elsherief, M.Elsayed Wahid [6] in 2017 described that the overview of Homogeneous LEACH protocol i.e. what exact LEACH protocol does, total phase of LEACH protocol such as set up phase, steady-state phase, threshold value calculation formula and TDMA (Time Division Multiple Access) scheduling to improve the network lifespan.

K.Johny Elma, S.Meenakshi [7] in 2018 described that maximize the lifetime of the network by using clustering topology. Clustering is an important factor in the wireless sensor network. Also, they said about energy efficient heterogeneous network by using the sensor node having different functionality and parameter. Route identification technique has minimum time requires sending the packet from source to destination so energy consumption is reduced.

III. Methodology

LEACH protocol is self-adaptive routing protocol which adapts or observes a sudden change in environment. Homogeneous sensor network contain the sensor node which has the same functionality and characteristics. LEACH is fully implemented homogeneous sensor network routing protocol. The cluster has one CH and other is normal sensor node. According to residual energy CH is selected. All sensor nodes can sense the environmental phenomena and store on it then forward that data to CH. Formation of a cluster for LEACH protocol has purpose to reduce energy consumption Improve scalability and network lifespan. Every sensor node selects a random number between 0&1.if this random number is less than a threshold value T(n) that node is chosen as a CH for that current round. An equation of calculating the threshold value T(n) is-

$$\mathrm{t(n)} = \begin{cases} \dfrac{p}{1 - p * rmod\left(\dfrac{1}{p}\right)} & n \epsilon G \\ 0 \end{cases}$$

where:

p: is the percentage of choosing CHs.
r: is the current round.
G: is the set of sensor nodes that have not been CHs in $1/p$ rounds.
n- no. of the sensor node

Set-up phase- it consists cluster formation on randomly deployed sensor node in the sensor network. Each cluster consists one CH depends upon how much energy it contains. In this phase changes the information within sensor node such as node ID, location, energy etc.

Steady-state phase- it consists the data transmission among non CH node i.e. normal node and CH in the particular cluster the data transmission happened according to TDMA (Time Division Multiple Access) fashion. By using TDMA Scheduling CH allocate particular time slot to each and every sensor node in the cluster to transmit their data towards CH. So that all sensors remain inactive till their time slot does not allow to it then energy will less reduce and ultimately network lifespan will be more.

When these two states finish their work then network retreats into the set-up mode and begin an alternate round, starting with a choice of a new CH. In a cluster all sensors sense the physical phenomena in the environment collect it and transmit to the CH accordingly.

Cluster Formation-In LEACH protocol there are different methods w.r.t. attributes and algorithm to form a cluster such k-mean algorithm, fuzzy logic etc. but in LEACH protocol cluster formation in this way.

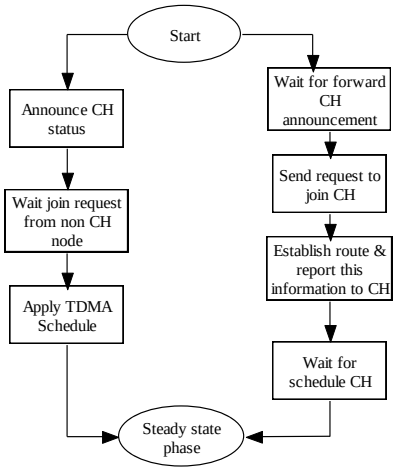

Fig No.1- CH formation.

above flow shows the activity of CH where suppose one node is CH if that node is really CH then he announces his current status i.e I am a CH of current round and he waits to join request from another normal node then he apply TDMA (Time Division Multiple Access) scheduling and send data to the BS.

In each round selected CH broadcast an advertise message to all the nodes in the network informing their new status after receiving this message each sensor node can determine to which cluster they belong to based on received signal strength according to no. of nodes in a given cluster the cluster head generates a TDMA schedule and set a transmission time slot to CH.

If the node is not CH then he waits for forwarding CH announcement from CH of that respective round then he sends the request to join the CH then he establishes the route and reports all information to CH then he waits for scheduling from CH. After doing this task from CH and non CH the whole scenario is going to steady-state phase.

TDMA Scheduling (Time Division Multiple Access)-

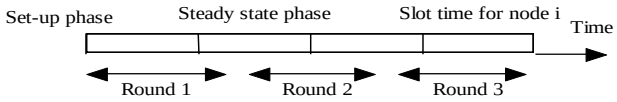

Fig No.2- Time Division Multiple Access.

it is a channel access method network for shared medium i.e. wireless sensor network it allow to share a same transmission medium so that all sensor node use same frequency channel and use it in their particular allotted time slot assigned by CH.by using TDMA scheduling all sensor node sense and transmit data one by one so data should be sent to CH in a uniform manner and it avoids the same data which come from two different node and CH also reduce the redundancy of data.it prevents an intra-cluster collision.

Energy Radio model-

First order radio model is used to calculate the energy consumption when bit data can transmit from sender to receiver. And this data can be transmitting from sensor node to CH and CH to BS.

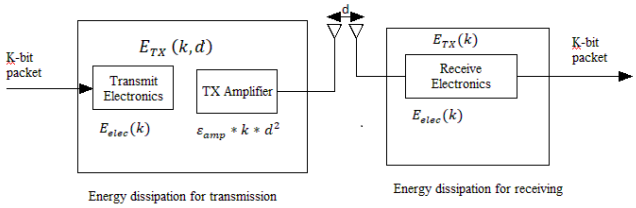

Fig No.3- Energy Radio Model

The radio energy model is shown in fig. 3. Hence to transmit a k- packet at a distance d the radio uses up is given as:

Where,

ETX: required energy utilization for packet transmission.

Eelec: is electronic energy that counts on the filtering, modulation the digital coding and spreading of the signal.

ERX: required energy utilization for packet receiving.

d_0: is equal to the square root of the dividing EDA free space model E_{fd} and multipath fading model Both ${E_{md}}^4$ models are relying on the distance between the receiver and transmitter.

Their value depends on the circuit amplifier model we use a first-order radio model. Whereas it calculates the distance in between two sensor node within a cluster and random function use for sensor distribution within a cluster.

In basic LEACH to find the distance between two hope i.e.

Threshold value distance-

$$d_0 = \sqrt{\frac{E_{fs}}{E_{mp}}}\ , E_{t=0}$$

$$s(i).x_d = rand(1,1) * x_m$$

$$s(i).y_d = rand(1,1) * y_m$$

Transmit amplifier type.

E_{fs} – Amplification coefficient of free space signal

E_{mp} – Multipath fading signal amplification co-efficient

E_{DA} -Data aggregation

Energy dissipation calculation-

Energy dissipation is degradation of energy and irecovareble energy where energy can transform from one phase to another phase. Energy dissipation calculates on the basis of amplifier and the signal transmission, modulation, distance in between transmitter and receiver, filtration bit error rate toleration etc.

$$if\ d > d_0$$

$$s(i).E = s(i).E - (E_{TX} + E_{DA}) * (3000) + E_{mp} * 3000 * (d^4)$$

$$d \leq= d_0$$

$$s(i).E = s(i).E - ((E_{TX} + E_{DA}) * (3000) + E_{mp} * 3000 * (d^2)$$

If adding transmition energy and data aggregation energy with each other w.r.t. no. of rounds then energy dissipated rate is calculated by transmit amplifier for the distance which is greater than threshold value(d_0) then it goes to multipath fading model(d^4)and if the distance which is less than threshold value(d_0) then it goes to free space model(d^2).

Election of associated CH for normal node-

$$\min_d = \sqrt{s(i).x_d} - (s(n+1).x_d))^2 + s(i).y_d\ (s(n+1).y_d))^2$$

CH can be elected with round by round to sending the data to BS.by using above formula associated CH for the normal node is elected.

This all technique or formulas used in Homo LEACH protocol. In Hetero LEACH there are two types of nodes are used one is a normal node and another one is an advanced node and that is the main difference between Homo and Hetero LEACH.

Random selection of normal node (Hetero LEACH)-

(temp_rand0>=m*n+1)

$E_t = E_t + s(i).E$

S(i).ENERGY=0;

Random election of advanced node (Hetero LEACH)-

(temp_rnd0<m*n+1)

S (i).E=$E_0 * (1 + a)$

$E_t = E_t + s(i).E$

In hetero LEACH protocol a normal and advanced node is elected by using above formulas whereas sensor node has assigned different initial energy and these sensor nodes are randomly elected with their respected energy level.

Sinkhole attack-

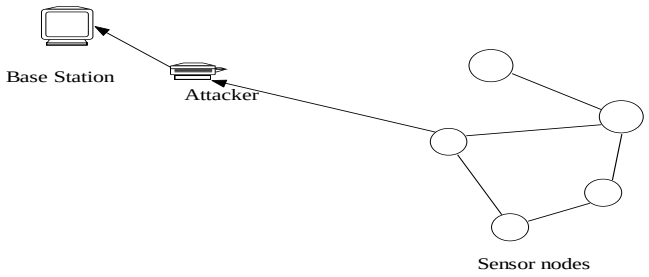

Fig No.4-Sinkhole Attack

Sinkhole attack is one type of active attack it alters information and changes the working of network. It gives the access of network to the unauthorized person and cracks the confidential information. It works on the network layer where one sensor node act as a malicious node which has high energy level and it attracts all remaining sensor node to send their packet towards it and sends fake routing information to all the sensor node and it grabs the packet or information about packet through routing table of any sensor node and also it resides in middle position in any network purposefully. So it works better and fast and it creates an environment in such a way that it attacks easily and fastly on the particular network.

For launching the sinkhole attack there are some method such as mint route protocol and TINY AODV protocol it totally depend upon routing metric so the attacker can make network vulnerable by altering the routing metric this is the most common drawback for routing protocol I.e. the routing metric and that's why all routing protocol can easily affected by the different type of network attack.

LEACH with the attack-

By using below formula attack can be performed on one node which is act as a malicious node whereas it collects data on itself and shows his status to all sensor nodes that is it has large battery power and drop the packet during the epoch.

$$epoch = mod(r, round\left(\frac{1}{p}\right) == 0)$$

The total no. of rounds in which all nodes have become CH once.

$E_{11}(r+1) = 0;$

For i=1:100

E_{11}(r+1)= $S_1(i) =. E + E_{11}(r+1)$

$E_1 =$ Energy left for the round.

After no. of round perform CH check what amount of energy is left to perform more operations.

Ec1(r+1)=Et-El1(r+1)

Et=total energy,

Ec=Energy consumed till previous round

(temp_rand<= (p/(1-p*mod(r,round(1/p)))))

This formula is used to election of CH for next round.

Attack is apply during epoch in different no. of rounds.

4. Simulation Result

Sr. No.	Parameter	Value
1	Simulation Area	100*100(m)
2	Energy model	First order energy radio model, battery
3	Initial node energy	0.5 joule
4	BS position	At center point
5	Node distribution	Random fashion
6	Channel type	Wireless(via signals)
8	Receiving Transmit energy(ERX & ETX)	$50*10^{-9}$

9	EDA data aggregation energy	$1.0*10^{-9}$
10	No.of rounds	3000
11	Network Simulator	MATLAB
12	Routing Protocol	LEACH

Table No.2- Simulation Result

Homogeneous LEACH-

These are the simulation result of Homogeneous LEACH which has the entire sensor node having same capacity and same parameter.

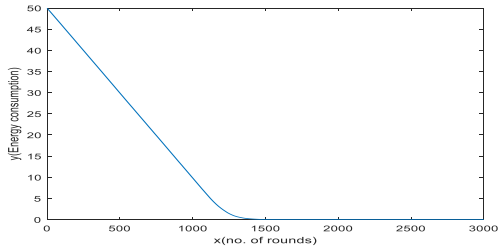

Fig No.5-Energy Consumption

In Homo LEACH this the resulting graph of energy consumption whereas all energy consumed within 50 sensor node then work of the particular cluster is stop because of lack of energy.

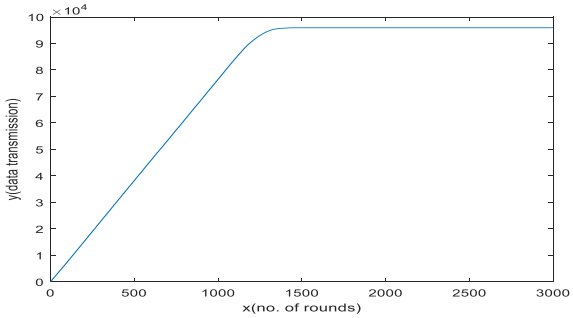

Fig No.6-Data transmission

In Homo LEACH this the resulting graph of Data Transmission whereas all data transmission in between sensor node to Base station can cover the sensing area is around 10*10^4 w.r.t. perticular no. of round.

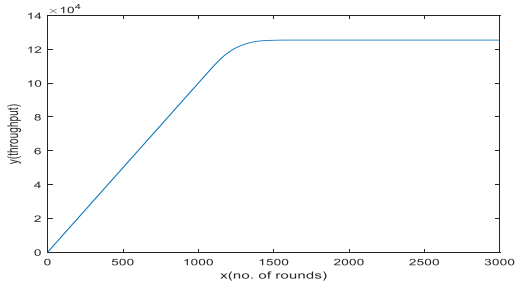

Fig No.7-Throughput

In Homo LEACH this the resulting graph of Throughput nothing but successful performance and packet delivery ratio in between sensor node to Base station can cover the sensing area is around 14*10^4 w.r.t. perticular no. of round

Heterogeneous LEACH-

In Hetero LEACH we use two type of sensor node one is a normal and another one is advanced sensor node having different type of battery power to increase the lifespan of the perticular network.

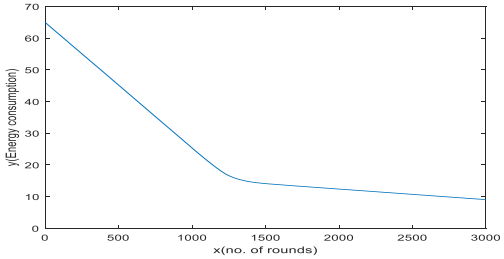

Fig no.8-Energy Consumption

In Hetero LEACH this the resulting graph of energy consumption whereas all energy consumed within 70 sensor node then work of the particular cluster is going to next round as compared to Homo LEACH Hetero LEACH can exceed their work 20 sensor more cause it use advanced node ultimately it gives more throughput.

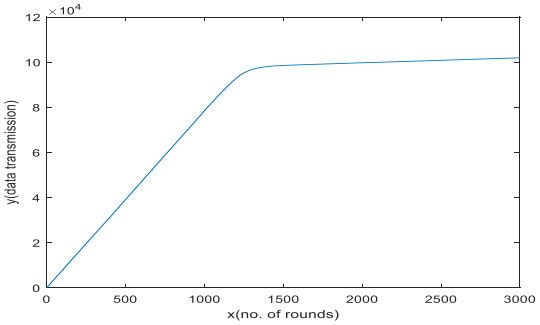

Fig No.9-Data transmission

In Hetero LEACH this the resulting graph of Data Transmission whereas all data transmission in between sensor node to Base station can cover the sensing area is around 12*10^4 w.r.t. particular no. of round.

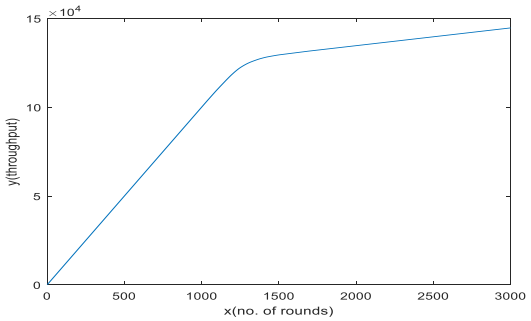

Fig No.10-Throughput

In Hetero LEACH this the resulting graph of Throughput i.e. successful performance and packet delivery ratio in between sensor node to Base station can cover the sensing area is around 15*10^4 w.r.t. perticular no. of round

LEACH with Attack-

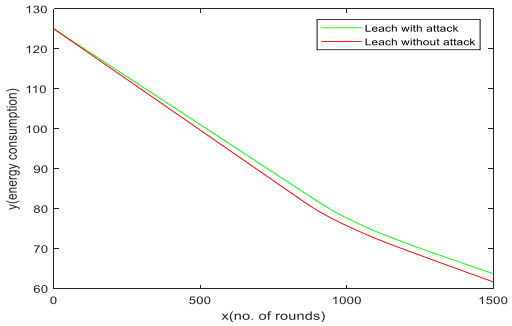

Fig No.11- Energy Consumption of Homo and Hetero LEACH with Attack

This the resulting graph of energy consumption of Homo and Hetero LEACH which is affected by sinkhole attack whereas LEACH with attack have high energy power than the LEACH without attack w.r.t. no. of rounds and energy in joule.

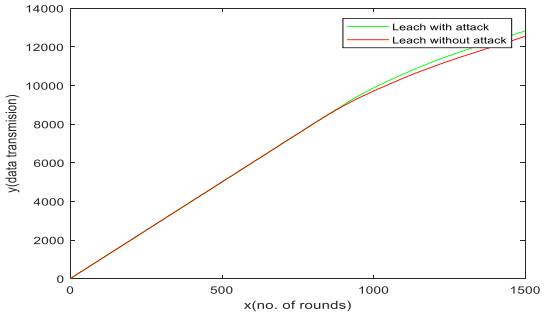

Fig No.12- Data Transmission of Homo and Hetero LEACH with Attack

This the resulting graph of Data transmission of Homo and Hetero LEACH which is affected by sinkhole attack whereas LEACH with attack have more data transmitted to the BS with minimum energy power than the LEACH without attack w.r.t. no. of rounds and energy in joule.
I.e. nothing but LEACH with attack is more data transmitted to the BS with minimum energy as compared to LEACH without attack.

CONCLUSION

This paper present LEACH hierarchical routing protocol and clustering topology on homogeneous WSN used to improve network lifespan and reduce the energy consumption. The basic homogeneous LEACH of WSN has some drawback so to overcome this drawback heterogeneous LEACH of WSN is used. For all parameter such as energy consumption, no. of sensor node (dead and alive node), throughput, data transmission also apply sinkhole attack on LEACH protocol.

***Abstract*— This paper deals with various parameter reduction methods of soft set theory. It has been found that the problem of uncertainty is too complicated to solve. This paper describes how decision making problem of uncertain and incomplete data solved using soft set theory concept. There are different soft set based parameter reduction methods to solve decision making problems that give optimal solution from big data. The purpose of this article is to explore the soft set theory with its approaches for parameter reduction, classification, clustering and association of rule generations. Comparison of various soft set methods for parameters reduction in terms of computational complexity, computational time and accuracy is provided.**

Keywords*— Soft set theory; uncertaint; parameter reduction; classification; clustering; association rule generation; big data analysis

I. INTRODUCTION

Uncertainty refers to some incomplete or unknown information. In decision making process of big data analysis, this uncertainty increases inaccuracy, which leads to wrong decisions. The problem of uncertainty in the field of engineering, social science and medical science cannot successfully solved by classical models as probability theory, interval mathematics, fuzzy set and rough set theory [1]. Each of this existing theory has their own difficulties as presented below:

A. Probability Theory

This theory is a branch of mathematics and deals with probability which is first investigated in sixteenth centaury by Gerolamo Cardano [1]. Stochastically stable phenomenon is the basis for this theory, where restriction on input is given by equation (1) is:

$$\mu_v = \frac{1}{n} \sum_{i=1}^{n} x_i \qquad (1)$$

If x_i is '1' then event occurs and absent when x_i is '0'. For the existence of limit more number of trials has to do but it is not possible for other field.

B. Interval Mathmatics

In this type of theory, interval is a collection of real numbers having feature that any number lies between '0' and '1'. But there is error while calculating the exact solution to the problem and this theory is unreliable, has partial aim and presents inadequate and defective information [1].

C. Fuzzy Set

In 1965, Lotfi A. Zadeh introduced another kind of set theory. Fuzzy set is a type of set whose elements have the degree of membership. Fuzzy set *F* allows regular assessment of the membership of element which is explained by membership function $\mu_F(x)$ between the interval of [0, 1]. But there is some problem in presenting the membership function for each different case [1].

D. Rough Set

Polish scientist Z. I. Pawlak [2] proposed some new concept over existing set theory with the lower and upper inference of the original set in 1991. But, decision features and conditional features are not directly connected. It means that decision values are not computed with regard to conditional attribute. This is the key difference in rough set and soft set theory.

E. Soft Set Theory

All the existing theories need some pre-specification of few parameter which result in incomplete and imperfect knowledge and leads to many problems. In classical theory there is a need to define mathematical model for exact solution but it is so complicated. The cause of above problem is the insufficiency of the parameterization tool of existing models. Noting such problem in existing theory new mathematical tool is developed by the D. Molodtsov in 1999 [1]. This theory is

free from the above difficulties and has the opposite approach by introducing concept of estimated solution. There is no restriction on estimated explanation in soft set so that this is extremely suitable and uses any parameterization using words, sentence, real numbers, functions and mapping. So difficulties in setting membership function or other difficulty is not available in the soft set theory.

In [2] author P. K. Maji *et al.* has presented how soft set can applied to resolve decision making difficulty for first time by example. Optimal selection can be done by choice value and weighted choice value. Various operations like equality, null, complement of two soft set and soft binary operation as AND, OR, NOT, Union and Intersection are defined in [3]. Soft set is defined in equation (2) is:

$$F: E \rightarrow P(U), \tag{2}$$

Where $P(U)$ is power set of U and pair (F, E) is a soft set if F is mapping of E which is shown in table 1. $\{e_1 \ldots e_5\}$ is set of parameter and $\{h_1 \ldots h_5\}$ be a group of conditional value. In soft set theory conditional value is calculated with respect to decision parameter value so that there is direct relation between these values.

Babitha and Sunil [4] presented definition of some relations and function of soft set such as Cartesian product, equivalence and partition relation and inverse function respectively. Aktas and Cagman [5] showed various characteristic of soft set and compared with rough set and fuzzy set theory and also provided definition of soft group and its soft group properties. U. Acar *et al.* [6] described new thought of soft ring with one more concept of soft ideals of soft ring using some basic algebraic structure of soft set theory.

The rest of this paper organized as follows. Section II presented the literature survey of various soft set based parameter reduction methods for uncertain and incomplete data and soft set based methods for data mining technique. Section III provides research motivation which includes how researcher get motivated because of limited research on soft set based methods for machine learning application is presented in literature survey. Finally Section IV gives conclusion.

II. LITERATURE SURVEY

Parameter reduction methods are described here as soft set algorithms for parameter reduction, soft set approach under incomplete data and soft set approaches for various data mining techniques. Comparative analysis of various methods of reduction of parameter is also given in table 4 and table 5.

A. Soft Set Based Parameter Reduction Methods

There is incorrect calculation in [2]. This is improved by reducing parameters of soft sets as presented by Degang Chen in [7] using parameterization reduction property of soft set. Improved algorithm for reduction of parameter is presented to give optimal solution in which decision value is calculated in accordance to parameters and this is the key difference between soft set theory and rough set theory. As shown in algorithm, Soft set (F, E) given as first input as shown in algorithm and second input is set of parameters P as $\{e_1 \ldots e_5\}$ and as shown in Table 1, it is obvious that h_1 is having highest choice value so h_1 is the optimal selection. But if data is more, then it is difficult to find solution so first find out reduct soft set which is third step of algorithm as by deleting e_1 and e_3 because having same value and it gets reduct soft set as $(F, P) = \{e_2, e_4, e_5\}$. From this reduct soft set optimal choice value h_1 or h_6 will get that has maximum choice value. Accordingly h_2 and h_3 are two suboptimal choices. So here problem of suboptimal choice is not solved by this method. The choice value is defined as follows in equation (3), which is last step of algorithm.

$$c_i = \sum_j h_{ij} \tag{3}$$

Where c_i is the choice value is given by summation of each h_{ij} entries in table and the selection of optimal value is made according to the maximum value of c_i as shown in table 1. The basic algorithmic steps to choose the optimal value is presented in [7] is as follow:

1. Input the soft set (F, E)
2. Input the set P of choice parameters which is a subset of E
3. Identify all reduct-soft-sets of (F, P)
4. Select one reduct-soft-set say (F, Q) of (F, P)
5. Obtain k, for which $Ck = max\ ci$.

Table 1: Binary table of soft set

U	e_1	e_2	e_3	e_4	e_5	Choice value *ci*
h_1	1	1	1	1	1	5
h_2	1	1	1	1	0	4
h_3	1	0	1	1	1	4
h_4	1	0	1	1	0	3
h_5	1	0	1	0	0	2
h_6	1	1	1	1	1	5

Zou and Chen [8] presented various operations for instance union and difference of two soft sets and also provided selection and projection in soft set theory which is based on relational algebra theory. Also it provides the definition of each above operations and applies this relational algebra operation for parameter reduction of soft set. M. I. Ali *et al.* [9] defined new operations because operations presented by [3] are not true generally, so author presented new notion of operations like restricted union, restricted difference, restricted intersection and relative complement in soft set theory for De Morgan's law. K. Gong *et al.* [10] proposed special type of soft set that is Bijective soft set and performed some operation such as relaxed AND, restricted AND, dependency of two Bijective soft set, reduction of soft set and significance of soft set. Z. kong *et al.* [11] presented the normal parameter reduction (NPR) algorithm for soft set in which above problem of suboptimal choice is solved by adding parameter set of soft set. This method computes the parameter importance degree and decision partition to give the optimal

solution for decision making. But this method is not easy to understand and needs more computation. NPR algorithm which is given in [11] is:

1. Input the soft set (*F, E*) along with parameter set *E*
2. Calculate parameter importance degree r_{e_i}, $1 \leq i \leq m$
3. Choose highest subset $A = \{e'_1, e'_2, \ldots, e'_p\}$ from *E* which satisfies total of $r_{e'_i}$ for $1 \leq i \leq p$ afterward place *A* in parameter reduction set.
4. Filter parameter reduction set if $f_A(h_1) = f_A(h_2) = \cdots = f_A(h_n)$ later calculate $E - A$ which is NPR *else A* is removed.
5. Find highest cardinality of *A*
6. Compute $E - A$ which is optimal NPR.

T. Herawan *et al.* [12] shown dimensionality reduction using multi-valued information which is to be transformed into multi-soft sets. AND, OR operations are used to reduct the attribute of soft set. Cagman and Enginoglu [13] explained soft matrices for soft set with its properties and presented soft max-min decision making method for soft decision making model that can be applied to solve uncertainty. So the problem of [11] is solved by X. Ma *et al.* [14] proposed new efficient normal parameter reduction (NENPR) algorithm of soft set without considering parameter important degree and decision partition. The NENPR algorithm proposed in [14] is:

1. Input the soft set (*F, E*) and the parameter set *E*
2. If $e^1{}_j$ and $e^0{}_j$ is occurs then it will becomes reduced parameter called as *C* and new soft set *(F,E')* is created without $e^1{}_j$ and $e^o{}_j$, where $U = \{h_1, h_2, \ldots, h_n\}$, $E = \{e_{1'}, e_{2'}, \ldots, e_{i'}\}$
3. Calculate oriented parameter sum $S(e_{j'})$for soft set *(F,E'), j'*=1',2',…*t'*.
4. Search the subset $A \subset E'$ where, S_A is a several of |U|, next place *A* toward candidate parameter reduction set
5. Examine each *A* in set, if $f_A(h_1) = f_A(h_2) = \cdots = f_A(h_n)$, it will be kept else *A* is obliterated.
6. Find highest cardinality of *A* in set then calculate *E - A- C* which is optimum NPR.

This algorithm takes less computation time as it compute only oriented-parameter sum to give the optimal value. X. Ma *et al.* [15] presented soft set algorithm based on parameterization value reduction that consider least parameter for optimal selection. Z. kong *et al.* [16] stated two cases of normal parameter reduction which is not given by [11] that is altering entries and adding object in soft set with positive and negative changed rates. M. I. Ali [17] has presented other idea on parameter reduction of soft set using classification to resolve the problems of decision making. Soft equivalence relation is introduced for soft set and rough set. Deng and wang [18] initiate idea of parameter significance with the two ideas such as degree of absolute dominance and relative dominance and proposed two algorithms called as pseudo parameter reduction and NPR of soft set. Kumar and Rengasamy [19] also present better decision for soft set theory using parameterization reduction by converting sample data into binary data without any loss of real data.

Han and Li [20] defined a soft set scheme that compile normal parameter reduction with three rules such as Core-Based, Inclusion-Based and Diagonal-Based rules. After combining these three rules one simplification algorithm is proposed. G. Zhang *et al.* [21] proposed algorithm for parameter reduction on soft equivalence relation of soft set. Z. Li *et al.* [22] proposed algorithms for reduction of parameter but using soft covering concept. Z. Liu *et al.* [23] shown the idea of induced soft set and define topology for soft set. T. Bakshi *et al.* [24] proposed several soft set algorithms for automated system of parameterization reduction. And complexity of this algorithm is better than above algorithms that is O (n^3).

Zhang and Wang [25] proposed new method for parameter reduction in soft set theory using the concept of important degrees of parameter that reduce complexity and performed more efficiently than above methods. N. Xie [26] presented attribute reduction in information system and define association among soft set and information system. V. Cetkin *et al.* [27] computed the decision making problems using inverse fuzzy soft set rather than fuzzy soft set so that, decision making process is very fast than existing methods. S. Danjuma *et al.* [28] proposed alternative approach to normal parameter reduction (ANPR) algorithm that overcome difficulty of existing NPR algorithms in terms of computational complexity but last choice not always consider and also give comparisons of NPR, NENPR and ANPR. The ANPR algorithm discussed in [28] is:

1. Input the soft set (*F, E*) and the parameter set *E*
2. If $e_i = e_j$ is present, then select one of them and put it in *Q*, if $e^1{}_j$ and $e^0{}_j$ is exists then it will becomes reduced parameter called as *C* and new soft set *(F,E')* is created without one of the $e_i = e_j$, $e^1{}_j$ and $e^o{}_j$, where $U = \{p_1, p_2, \ldots, p_n\}$, $E' = \{e_1, e_2, \ldots, e_m\}$
3. Calculate oriented parameter sum $S(e_{j'})$ for soft set *(F,E'), j'*=1',2',…*t'*.
4. Ensure each *A* in set, if $f_A(p_1) = f_A(p_2) = \cdots = f_A(p_n)$, also if there exist *B* $f_B(p_1) = f_B(p_2) = \cdots = f_B(p_n)$.
5. Calculate *(A∪B)-(A∩B)* intersection which is represented as *D*
6. Obtain highest cardinality of candidate parameter reduction set next compute *E -C -D -Q* as alternative NPR.

S. Danjuma *et al.* [29] presented analysis on different decision making methods of soft set by reducing parameters. Provide the analysis of different methods for soft set, rough set and for hybrid soft set and also gives real world application of soft set. J. Zhan *et al.* [30] presented survey of various algorithms for NPR, Bijective soft set decision and reduction method built on discernibility matrices in soft set theory. Ma and Qin [31] Distance based parameter reduction of fuzzy soft

set is proposed using distance matrix in which distance of two parameters is computed. And advantage is that low computation and high usability than NPR of fuzzy soft sets. The problem of NPR is overcome by Ma and Qin [32] that proposed new algorithms such as parameter value reduction (PVR), parameterization value reduction (PZVR) , maximal parameter value reduction (MPVR) and maximal parameter value reduction based on NPR (MPVR-NPR).

B. Soft Set Based Approach Under Incomplte Data

Zou and Xiao [33] shown data analysis approach of soft set for incomplete data. If in decision making incomplete data is present then it difficult to give optimal solution. In this, the choice value *ci* of object *hi* calculated as $ci = \sum_{j=1}^{y} hij$ in which *y* is number of parameter and *hij* are the entries in soft set. If there are m possible choice values of object *hi* then decision value *di* is calculated as $di = \sum_{i=1}^{m} kici$ where *ki* is weight of choice value *ci* which is calculated as follows so weighted average for all choice value is computed where, p_e *and* q_e are probability values, *d* is no. of incomplete data given in equation (4),

$$K = \begin{cases} \prod_{e \epsilon E_0^*} q_e \\ \sum_{c_d^x} \left(\left(\prod_{e_i \epsilon E_1^*} p_{e_i} \right) \left(\prod_{e_j \epsilon E_0^*} q_{e_j} \right) \right) \\ \prod_{e \epsilon E_1^*} p_e \end{cases} \quad (4)$$

Z. Kong *et al.* [34] gives the efficient decision making method of soft set for incomplete data which is more simplified than above method.

Table 2: Incomplete Soft Set

U	e_1	e_2	e_3	e_4
h_1	1	1	1	0
h_2	0	1	*	1
h3	0	*	1	1
h_4	*	0	1	*

In Table 2 * represent incomplete information which can be either '1' or '0' which indicates some values are unknown. For Big data analysis it is difficult to give optimal decision of incomplete data. In this method, instead of calculating weight value probability, value of that particular incomplete data is calculated in equation (5) is:

$$p_{e_j} = n_1 / (n_1 + n_0) \quad (5)$$

Where n_1 is the number of value 1 and n_0 is number of value 1. So calculate probability value for each incomplete data. For example for object h_2 in table 2 probability is calculated as $p_{e_j} = 3 / (3+0) = 3$, where n_1 is '3' and n_0 is '0', and then calculate decision value as given in equation (6):

$$d_i = \sum_{j=1}^{m} h_{ij} \quad (6)$$

In this way, optimal decision value will get using incomplete data as shown in table 3 where h_1 and h_2 are optimal selection.

Table 3: Incomplete soft set with decision value

U	e_1	e_2	e_3	e_4	d_i
h_1	1	1	1	0	3
h_2	0	1	3/3	1	3
h_3	0	2/3	1	1	2.67
h_4	1/3	0	1	2/3	2

M. S. Khan *et al.* [35] proposed new method for data filling for incomplete data called as ADFIS which focus on associations of parameters in which missing values are predicted. This method is implemented in Matlab for UCI dataset and overcome the problem of DFIS in terms of accuracy. On Average the performance of this method is improved by 4.44%. Alcantud and Garcia [36] proposed new algorithm to resolve decision making difficulty of incomplete data in Matlab tool. Also provides result in comparison with other methods for critical evaluation. L. Li *et al.* [37] presented the definition of soft incomplete discernibility matrix, soft parameter dominant incomplete discernibility matrix and last for weighted soft set also gives comparison with existing ones.

C. Soft Set Based Approaches for Various Data Mining Techniques

Jothi and Inbarani [38] recommended the soft set approach for unsupervised feature selection using AND operation and cardinality value is computed to give optimal solution. In this method classification is done using feature selection to select most prominent feature. J. Cai *et al.* [39] presented feature selection methods to reduce irrelevant data that result in less computation time and more accuracy. Proposed methods for supervised, unsupervised and semi- supervised which are applicable in machine learning problems such as classification and clustering.

H. Mohamed *et al.* [40] showed Bijective soft set method which include data pre-processing as first step and classification as second step for training and testing data which generate the decision rule using four classifiers to classify student learning pattern and obtain discernibility matrix for every feature. This method of soft set gives better accuracy than other theories. S. Sreedevi *et al.* [41] proposed a fuzzy soft set method that classifies mammogram images between malicious and regular images. Implementation is completed in different steps such as pre-processing, segmentation, feature extraction and selection, and classification. H. Qin *et al.* [42] proposed Novel Soft Set (NSS) method to select clustering attribute that gives faster decision and good scalability than Maximum Dependency Attribute (MDA) approach of rough set theory. This method compute equivalence classes for each attribute and then compute cardinality and degree of dependency to give optimal value. In this paper, cardinality of $a_i(e_j)$ calculated in equation (7) where, *D* is no. of equivalence classes for U/a_l parttions and $F_l(e_j)(X_K) \in \{0,1\}$.

$$|a_i(e_j)| = \sum_{k=D+1}^{D+|U/a_i|} F_1(e_j)(X_k) \times |X_k| \quad (7)$$

R. Mamat *et al.* [43] presented Maximum Attribute Relative (MAR) algorithm of soft set for categorical value to give clustering attribute that gives better performance in terms of execution time and scalability than existing method such as Total Roughness (TR), Min-Min Roughness (MMR), Maximum Dependency Attribute (MDA), Novel Soft Set (NSS). MAR is compared with above four old methods using fourteen datasets of UCI repository. D. Hartama *et al.* [44] proposed the new algorithm to select attribute called as Soft Set Fast Clustering (SSAA) for categorical data to obtain clustering attribute. This algorithm performs better than Maximum Degree of Dominance of Soft Set (MDDS) in terms of execution time using MATLAB software for six different UCI dataset. Herawan and Deris [45] presented soft set approaches for association rule mining from transactional data set. In this, soft regular and soft maximum association rules are defined to compare proposed work. B. Li *et al.* [46] presented association rule mining based on clustering by using Clustering by Fast Search and Find of Density Peaks (CFSFDP) clustering method and soft set to classify transactional database and generate association rule from big database. Results are shown for Adult data set. F. Feng *et al.* [47] defined soft set based association rule mining. Some algorithms are proposed to calculate Parameter taxonomic soft set, M- realization of parameter set and γ -M- reliable maximal association rule. Two case studies presented for Reuters and Web of Science data sets.

Ma and Qin [48] Proposed mixed type of soft set such as fuzzy soft set and interval-valued fuzzy soft set for decision making algorithm based on this hybrid type. F. Xiao [49] Proposed hybrid algorithms for fuzzy soft sets for decision-making by a fuzzy in medical diagnosis. In this algorithm, uncertainty is measured to generate credible value then calculate basic probability using dempster shafer evidence theory to give optimal value. Z. Kong *et al.* [50] proposed the new parameter reduction method based on score decision criteria for fuzzy soft set. At last comparison is given with previous parameter reduction based on choice value decision criteria and some dispensable set analyzes for different case.

Table 4: Comparisons of parameter reduction methods of soft set

Authors	Proposed method	Advantage	Disadvantage
P. K. Maji et al. [2] 2002	Design the algorithm for the selection of house by reducing the parameter with the choice value and the weight value. And give the optimal object selection.	Solve the decision making problems using parameterization property.	Gives incorrect computing in optimal selection of parameter.
H. Aktas [5] 2010	Introduce soft set group concept with its properties.	Overcome the problem of rough set theory.	Here soft ring is not defined which is overcome by [6]
D. Chen et al. [7] 2005	Presented latest method of parameterization reduction of soft set contrast with attribute selection of rough set theory.	Finding optimal decision on Boolean dataset without any influences on the final decision and solve problem in [2].	Problem in selecting sub optimal choice of object.
Y. Zou et al. [8] 2008	Proposed algorithm for parameter reduction using relational algebra and also define various operation like union, difference, selection, projection etc.	The method proves the invariability of optimal solution.	For more parameters, there is explosion of parameter with worst time complexity $O(2^h)$.
Z. Kong et al. [11] 2008	NPR algorithm is proposed to get minimized conclusion and suboptimal decision using added parameter soft set.	More efficient due to decision partitioned and parameter important degree.	Difficult to understand and require more time as computational complexity is $O(n^3)$.
T. Herawan et al. [12] 2009	Presented dimensionality reduction in multi-value information system via AND operation in soft set theory.	Attribute reduction is done for non-Boolean value.	Problems in data cleansing for large dataset and data clustering.
X. Ma et al. [14] 2011	NENPR soft set method that uses the oriented parameter sum exclusive of degree of parameter reduction and decision separation.	Decrease computational complexity by ignoring parameter reduction degree with decision partition and complexity is $O(n^2)$	Require to compute oriented parameter sum.
X. Ma et al. [15] 2011	Algorithm for parameterization value reduction using soft set theory is proposed.	Algorithm holds least parameter value for optimal selection.	Not useful for extended soft set.
Z. Kong et al. [16] 2012	Presents new definition for changing some entries and adding some objects in soft sets.	Problem of [9] varying entries and adding objects are solved.	Difficult for large dataset.

M. I. Ali [17] 2012	Proposed a new soft set for reduction of parameter and introduce the concept soft equivalence.	Reduction of parameter of soft set without distorting its original classification ability.	This method does not provide the algebraic structure.
D. Kumar et al. [19] 2013	Parameterization reduction algorithm converts sample data into Boolean data in information system using soft set theory.	Algorithm gives better decision making over uncertain data.	Difficult for large dataset.
Z. Li et al. [22] 2015	Algorithm for parameter reduction of soft covering is used to obtain lattice structure of soft set.	Attribute reduction for information system is provided.	Not useful for multisource information.
Z. Liu et al. [23] 2015	New definition for induced soft set is presented with topology for parameter reduction.	Soft set mapping is used for induced soft set which may be applicable for science field.	Difficult for large dataset.
S. Danjuma et al. [28] 2017	Propose an (ANPR) alternative normal parameter reduction algorithm for decision making based on soft set theory.	Algorithm reduces the computational complexity which is O (n^2); also execution time is less as existing techniques.	This method does not always consider the last choice.
S. Danjuma et al. [29] 2017	Different soft set based parameter reduction and decision making techniques for soft set is reviewed here with hybrid fuzzy soft sets and rough set.	Give the analysis of previous work and present real world application of soft set.	Problems of multiset on parameter reduction, multi criteria are not solved yet.
X. Ma et al. [32] 2019	PZVR, MPVR and MPVR-NPR algorithms are defined for normal parameter reduction (NPR).	MPVR algorithm gives redundant degree as 93.3% and lower complexity than NPR algorithm.	MPVR-NPR algorithm performance is not good as MPVR.

Table 5: Comparisons of soft set based approaches for incomplete data and data mining techniques

Authors	**Proposed method**	**Advantage**	**Disadvantage**
Y. Zou et al. [33] 2008	Weighted average method is used for optimal choice value of incomplete data for big data analysis purpose.	Problem of decision making using incomplete information is solved.	Not useful for extended soft set.
Z. Kong et al. [34] 2014	Present efficient probability data analysis approach on incomplete data, which is simplified weighted average for decision making.	Computational complexity is less than above method and it is implemented easily.	Not useful for extended soft set.
M. S. Khan et al. [35] 2016	ADFIS method is proposed for incomplete data with better accuracy over DFIS method for various dataset.	ADFIS gives improved performance on average of 4.44% than DIFS method.	Computational complexity is high than DIFS
L. Li et al. [37] 2018	Soft incomplete discernibility matrix and soft parameter dominant incomplete discernibility matrix is introduced.	Decision making problem of incomplete soft set is overcome.	Dost not provide the function mapping form of incomplete soft set.
G. Jothi et al. [38] 2012	For quick reduction of attributes unsupervised feature selection algorithm based on soft set is designed.	Speed and accuracy of the method is good and reduce computational time.	Not useful for extended soft set.
H. Mohamed et al. [40] 2014	To classify student learning fashion Bijective soft set is proposed using standard model.	Method gives good classification accuracy of 97.1%.	Use of more classifier that require more time.
S. Sreedevi et al. [41] 2016	Fuzzy soft set method is developed using fuzzy soft aggregation to classify the images.	Accuracy of algorithm is 94.09% for MIAS dataset.	Not useful for more set of parameters.
H. Qin et al. [42] 2012	NSS technique is proposed to cluster the attributes and compare on UCI dataset for various parameters.	Solved the problem of MDA method of rough set with good scalability.	Not for categorical dataset.
R. Mamat et al. [43] 2013	For the selection of cluster attribute MAR method in multi value information system is developed.	Execution time is less and scalability is good.	Method does not provide for categorical data.

D. Hartama et al. [44] 2016	Proposed the soft set based clustering attribute selection called selecting sub attribute algorithm (SSAA).	Solve the problem of maximum degree of dominance soft set.	Give only 67.56% average percentage of response time.
T. Herawan et al. [45] 2011	Soft set technique for association of rules using co-occurrence of parameters for Boolean dataset is designed.	Capturing of rules is faster than other.	Does not provide approximate reduct in information system.
B. Li et al. [46] 2015	CFSFDP clustering system for soft set is anticipated to reduce big dataset.	Effective technique to produce association rules from big databases	--
F. Feng et al. [47] 2016	Define soft set based association rule mining algorithm and conducted different case study.	Improve problem of transactional dataset	Dose not formalize proposed method in terms of logical formulas

III. RESEARCH MOTIVATION

Now a day's decision making for big data analysis is the most recent issue. Soft set theory is the new theory that solves the problem of previous theories using new property that is parameterization reduction and solve problem of decision making for big data analysis. Explore soft set approach with data mining techniques in machine learning platform is the new concept in artificial intelligence because limited research is done on the practical implementation of soft set method in data mining and machine learning field. Where the decision making problems will be solved by efficient soft set based parameter reduction algorithm for feature selection, classification, clustering and association rule generation to give the optimal selection considering the parameters such as computational complexity, computing time, accuracy, etc. Such algorithms will be implemented in Python platform by proposing the soft set based approach for machine learning with data mining techniques as shown in figure 1.

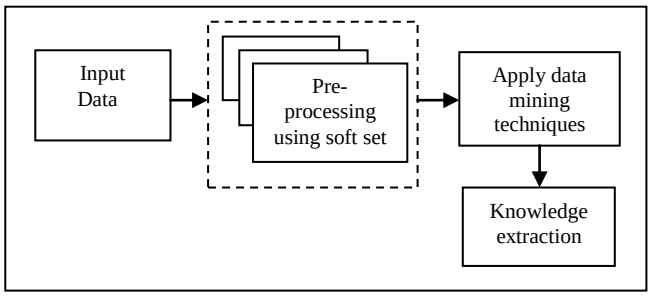

Figure 1: Conceptual framework of research work

Conceptual flow diagram shows the flow of research work in which decision making problem is solved by proposing parameter reduction algorithm using parameterization property of soft set theory, which include dimensionality reduction will be done by considering choice parameter for selecting prominent parameter from original data, then perform classification and clustering attribute selection using soft set concept after that classification based on association rule mining will be done to give the knowledge extraction over uncertain and incomplete data.

IV. CONCLUSION

The latest mathematical theory for parameter reduction is soft set theory that handle uncertainty problem of decision making to give the optimal solution. This theory performs better than existing theory as fuzzy set and rough set theory. Different methods are given in this paper for parameter reduction, few methods for incomplete data and some soft set based methods for various data mining techniques as feature selection, classification, clustering and association rule generation. Performance of these methods is calculated in terms of some parameters such as computational complexity, execution time, accuracy, memory used and scalability etc. Different parameter reductions techniques are relatively compared as shown in table 4 and table 5. As going through literature of soft set, it shown fewer researches on soft set based scheme for data mining techniques applicable for machine learning platform. Few realistic uses of soft set theory seen in literature survey but some of them faces some issues so in future, researcher can give more attention toward such problem. Still there is no such type of soft set method for big data analysis in machine learning platform, so in future researcher will more focus on such new concept.

***Abstract*: Specific learning disability is known as learning disorder (neurodevelopmental disorder). Learning disabilities refers to problems in one of three areas (reading called dyslexia, writing called dysgraphia and number related concepts or using the symbols and functions to perform math calculation called dyscalculia). Five to six percentage of school age children are predicted to have dyscalculia. Children are mostly affected by having difficulties in acquiring a basic mathematical skills and they might excellent in other area of interest. The lack of proper detection and assistance in early stages of development of children will affects them being mentally distress and vulnerable. They start to blame themselves for their situation. The proposed system is designed to identify the students whose are at the risk of dyscalculia in an effective manner. So that the students can be identified at their early stage, and by giving proper assistance, they can able to shine in their academics.**

Keywords: Dyscalculia, learning difficulty, detection, mentally distress

I. INTRODUCTION

Mathematics is an universal language which deals with an numbers ,arithmetic's, counting etc. Dyscalculia means having disorder in calculation. It says about the specific difficulty in learning mathematics. It provides difficulty in acquiring mathematical skills and it also involves having difficulty in understanding basic mathematical facts and inability to understand the meaning of number and quantities.

About 6% school going children are having the mathematics difficulties. Generally the basic problem starts at the age of 7. The early screening is an important step in diagnose process. Where the children are tested with the ability to read a number, to understand the number facts, to add and compare the numbers of one-digit and two-digit, ability to acquire basic multiplication skills, basic arithmetic skills, ability to count a number forward or backward, to find a greatest/smallest number, basic geometrical skills. These skill sets are considered for screening test that typically occurred in school children. The screening test is that is used to identify the children having difficulty in acquiring basic mathematical skills and those are need special care and remediation in learning. The diagnostic process of dyscalculia which is based on the test shows a latency between poor numerical ability and good numerical ability. To define a threshold for dyscalculia, there are different criteria has been proposed a difference of 1-2 standard deviation between a skills and mathematical performance. Children who are influenced by dyscalculia regularly feel desolate and they demotivate themselves that they can't do anything like others. This prompts extreme impacts in their grown-up life it might likewise make them drop out their studies. Moreover because of these learning troubles they frequently disregarded by their educators and peers. This cause a person to be frustrated, have the poor self-image. They face trouble in reviewing tables, identifying images, doing fundamental number juggling count, sequencing and so on.

Types of dyscalculia:

Children with developmental dyscalculia finds difficulties to count recognize the mathematical symbol, calculate. Some of the types are,

Acalculia: It is later stage, it occurs due to the injuries in brain. It leads to have difficulty in arithmetic skills like addition, subtraction, multiplication, Division.

Verbal dyscalculia: Children face difficulty in naming verbally, naming the symbol, counting of numbers and items.

Operational dyscalculia: Children find difficulty in applying the rules during the mathematical operations.

Sequential dyscalculia: Facing difficulty in counting according to the sequence.

To overcome the lack of screening tool for identifying dyscalculia and to acquire accurate results, the intelligent embedded system for identifying dyscalculia is proposed. The models consist of the set of test which concerned with basic arithmetic skills, counting numbers, basic geometrical skills.

II. LITERATURE SURVEY

Bane et al. (2012) taken the survey about the people who having learning disabilities on relationships. In this survey, 21 researchers with learning disabilities, 12 supporters and 7 university researchers were considered for the survey. This survey suggested that learning disabilities people have different experiences and views on relationships. This survey concluded that people with learning disabilities need more support from their friends, family, and faculty members to develop new relationships and keep their existing ones[1].

Boyle & Rivera (2012) examined various types of note-taking techniques used by students used during lectures. In this

study, 125 students who having varying disabilities are taken into the survey. This study proved that students those who used note-taking techniques got good score in an effective manner based on the measures of achievement and the quality and quantity of notes recorded[2].

Ho & Siegel (2012) conducted a survey on the identification of students who have reading disabilities, and also reading implications for Chinese Word Recognition and Instructional Methods in Hong Kong Primary Schools. The survey identified that students with dyslexic pattern made more phonological errors, and students with phonological dyslexic pattern made more semantic errors[3].

Kong (2012) conducted qualitative survey on six students with Dyslexia after starting their masters degrees. The students personal accounts were analyzed using thematic analysis. The major themes identified were distress, self-doubt, embarrassment, frustration, relief, confidence and motivation. This survey given better understanding about the consequences of a late diagnosis, and given the special attention for management techniques needed for specific needs of the individuals. The survey revealed that adults diagnosed with Dyslexia can be cathartic or devastating depending on the adults emotional status and personality[4].

Melby & Lervag (2012) given the attention to the students with dyslexia disability and students with non-word repetition. The study concluded that students with dyslexia disability have poorer non word repetition skills when compared to both chronological-age and reading-level controls. And also identified the severity of the non-word repetition problem, where the most important variability is oral language skills[5].

Rose & Rouhani (2012) conducted survey on text oral reading fluency of 64 adolescents who have dyslexia disability, and tested the their verbal working memory on text oral reading fluency. The survey suggested that many shortfalls associated with childhood dyslexia is much important in adolescence, but the nature of the relationships between cognitive and linguistic predictions, and reading fluency were identified to be different for every adolescence[6].

Berninger & May (2011) conducted a survey on evidence-based diagnosis and treatment for people who having learning disability in written and oral language, or both. This survey considered the individual planning differences and evaluation of response to the instruction and modification of the instruction when a student is not responding. And also the survey recognized that teaching alone cannot change heritable changes in gene expression at schooling stage, but not the suited for gene sequences which are vulnerable to complexity and volume in the upper grades[7].

Condition aggregates in variable based math led by Bhattacharya (1988) it was discovered that understudies had more learning inabilities in application than in the information of direct conditions and furthermore it was discovered that the disentangled strategy was more powerful than the technique for transposition in understanding straight condition wholes.

III. PROPOSED SYSTEM

The aim is to build an interactive and easy handling system with high accuracy in detecting the dyscalculia. The proposed system can able to test the children in the age between (8-10yrs), and used to identify the errors made by an individual on the basis of mathematic content prescribed for standard III and IV.

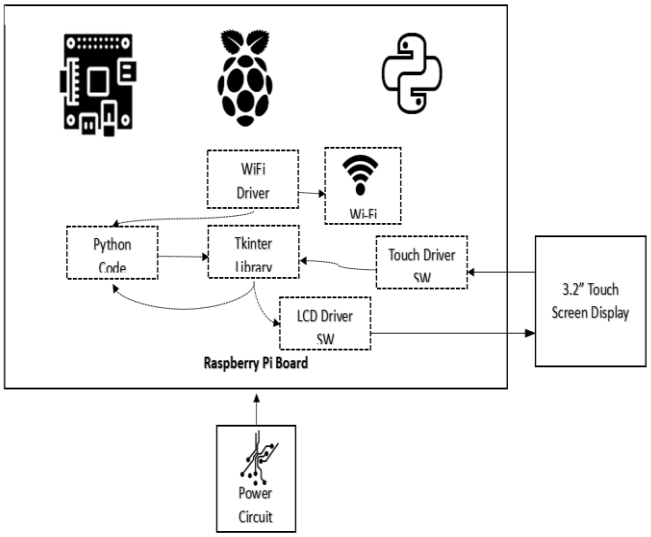

Fig. 1. Schematic diagram of Proposed system

The proposed system consists of raspberry pi board, LCD touch screen, and a power supply. The programming language which used is a python in which it consists of Tkinter and a GUI application for creating the buttons in the test screen. With the usage of Tkinter GUI, the questions will be created. The questions are based on testing the dyscalculia children. The children can able to answer the questions directly by clicking the LCD screen. This can be tested by comparing the latency between a child who suffered with dyscalculia and a normal child. After switching on the raspberry pi board, the result will be displayed on a display. It consist of set of questions for screening test, the children has to take a test for a period of time.

IV. METHODOLOGY

The skills that are checked by this method are given below.

A. Number and comparing:

In this section, the capabilities of the child to count the number in both forward and in reverse direction are checked (for example,1,2,3,4,5,6,7,8,9). And also this section can check whether the child can able to identify which number is odd

number, even number, greater, smaller number in a given questions

B. Basic addition and subtraction

In this section, the addition capability of the child to add the two numbers (example:1+1=2), and addition of doubles like(2+2=4), the subtraction skills (for example 1-2=1) are checked.

C. Basic multiplication skills:

In this section, the multiplication capability of the child (for example:2*3=6) is checked.

D. Missing numbers:

In this section, the missing numbers in given series (for example: 1,2,_,4,5) is checked. And the Identification of the missing number in even place and an odd place are also checked.

E. Place value:

This section involves to check whether the child can able to identify the underlined place value (for example:153=tens).It also involves to identify some of the geometry shapes like triangle, circle etc.

V. FLOW DIAGRAM

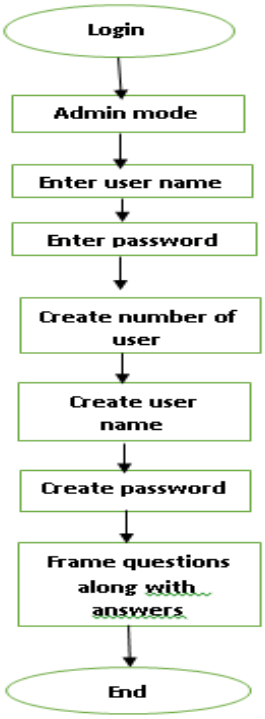

Fig 3. Flow diagram showing admin mode activity

Admin mode: The below flow diagram shows the operation activities carried out by the admin users. In this section, the we can change the type of the questions and we can put an multiple user .The multiple questions can be able to add in the admin section and we can also delete the questions. The number of user also can be created. The total score and the latency is displayed in admin mode. And we can also able to see the progress taken by the children in a parallel manner.

User mode: The below flow diagram shows the actions carried by the user. This section can be used for a children for taking up their test in order to identify whether they are suspected to have dyslexia or not.

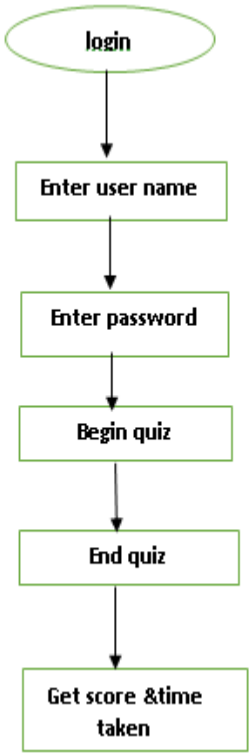

Fig 4. Flow diagram showing user mode activity

VI. EXPRIMENTAL RESULTS

The login page has different modes. They are user mode i.e. login created for normal child and a child suspected to have dyscalculia, and another mode is an admin mode. The user has to login in to the page. Once the child login into the page, they can started to attend the test.

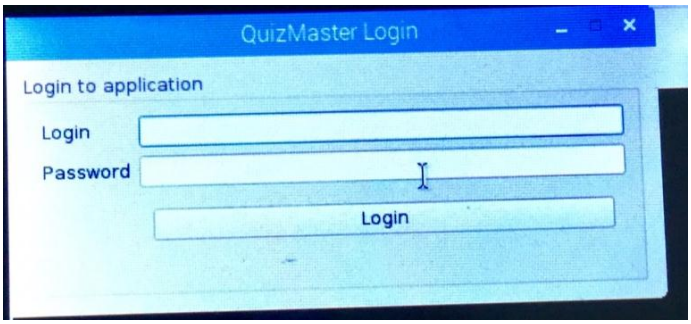

Fig. 5. Login page

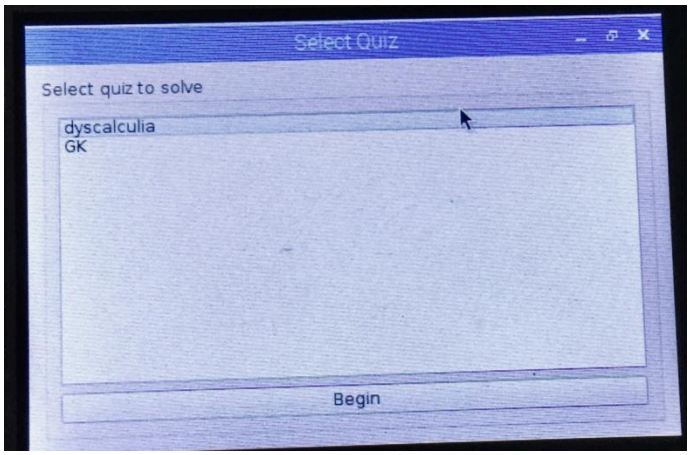

Fig 6. Selection of Quiz

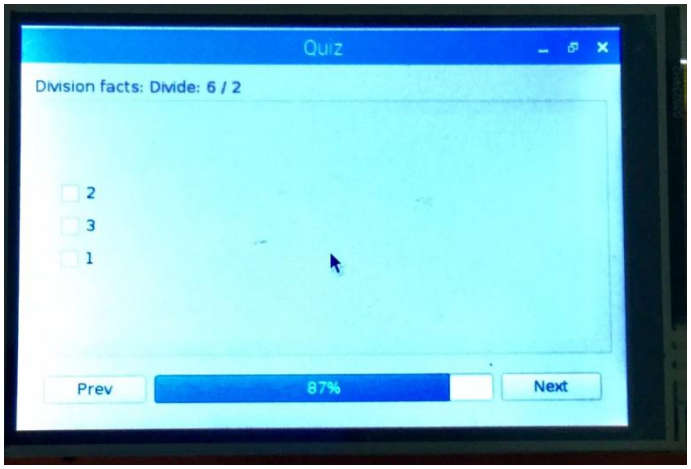

Fig 7a. Questions Set based on division

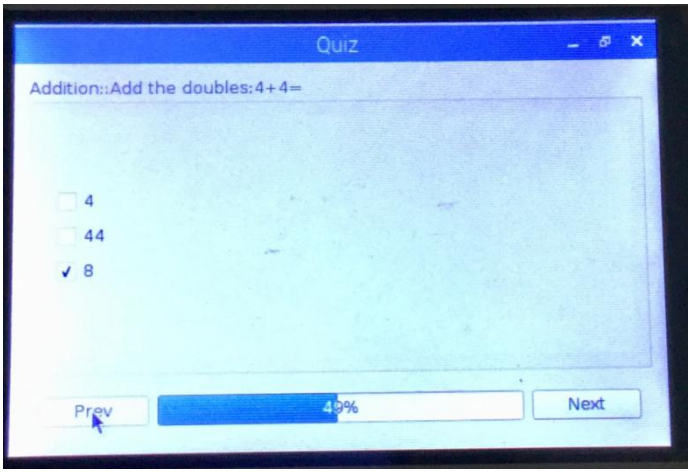

Fig.7b. Questions Set based on addition

Once the students have finished their test, the time taken by them will be displayed in the LCD screen. This is shown below.

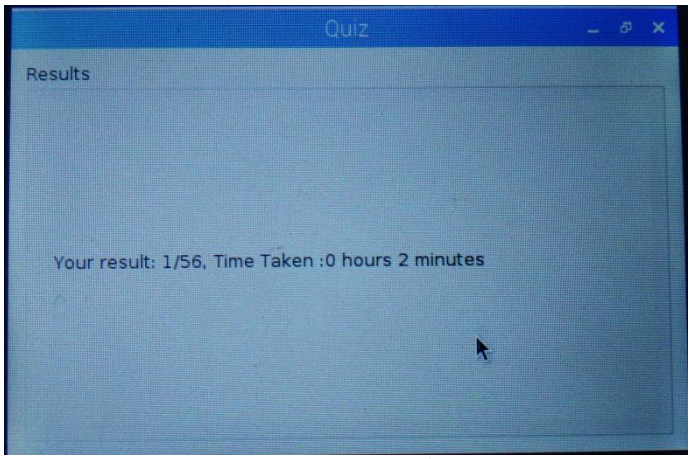

Fig 8. Latency and score of a child

Admin mode: Initially the number of user is created for taking the test. After that, multiple question sets can be added. Some of the question can also be deleted. The time taken for the test has been saved in the admin mode. So the admin can be logged in and the score of each child can be viewed as shown in below figure

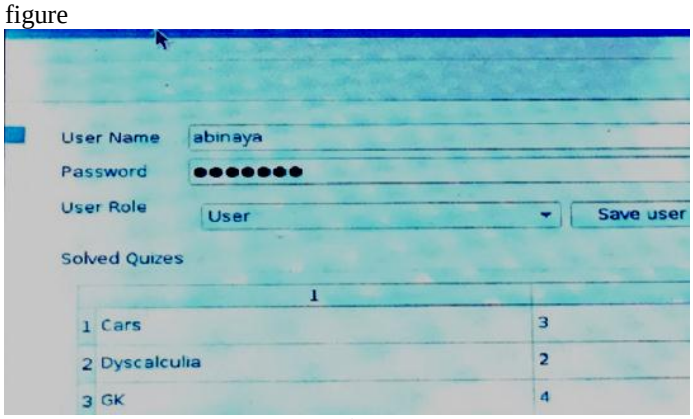

Fig. 9. Score of user statistics

The questions of the test can be updated periodically by using edit mode in the admin side.

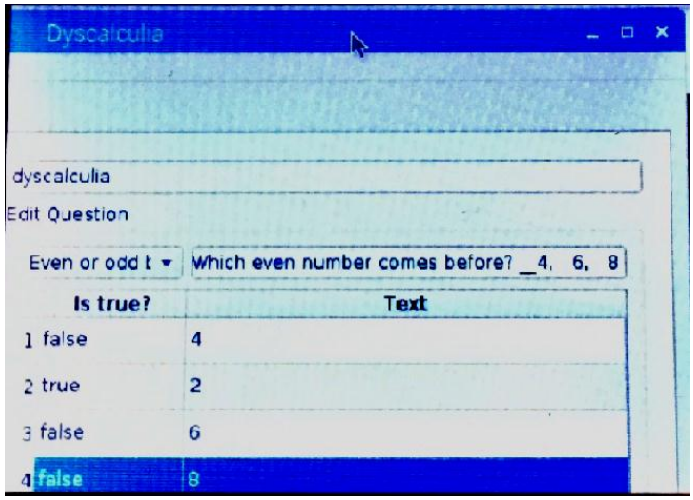

Fig 10. Questions addition page

The given model acts as prototype for the child studying class III. The questions are based on their normal ability. Since there were sixteen kids with two groups. One is normal children (control group) and another one is children (may be learning disabled). Both the groups of the children are allowed to take the test in a intelligent embedded system for identifying dyscalculia. Then the latency and a score of the children has to be calculated. The children are tested on the basis of relevant content.

VII. T- TEST CALCULATION

Sixteen kids of two groups are considered for taking the test. One is normal children (control group) and another one is abnormal children (may be learning disabled). Both groups of children are allowed to take the test in a intelligent system for identifying dyscalculia. Then the latency and a score of the children have to be calculated using T-test calculation. The test analysis of children was given below.

S.NO	Name	Correct answer Attended out of 10
1	Vino S	7
2	Sangeetha M	7
3	Akila K	6
4	vinay P	8
5	Lakshmi R	7
6	Priyanaga K	8
7	Swetha R	9
8	Anjali R	7
Mean		**7.375**

Table. 1 Correct responses of normal child

S.NO	Name	Correct answer Attended out of 10
1	Gayu K	2
2	Durga N	1
3	Gomathi T	4
4	Abinaya D	4
5	Gunaseeli V	5
6	Anusree M	3
7	latha U	2
8	Karthick K	5
Mean		**3.25**

Table. 2 Correct responses of abnormal child

S.NO	Name	Dyscalculia
1	Vino S	3.95
2	Sangeetha M	3.05
3	Akila K	3.07
4	vinay P	2.98
5	Lakshmi R	3.40
6	Priyanaga K	3.02
7	Swetha R	3.50
8	Anjali R	3.95
Mean		**3.365**

Table. 3 Latency of the normal child

VIII. CONCLUSION AND FUTURE SCOPE

The main purpose of this system is to identify the child with dyscalculia who may excel in other area. The main advantage of this system is to handle and use in an easy manner. The proposed is portable, and also it calculate the time taken by the children to answer and calculate the score and compare with the normal children score and latency and says whether the children having dyscalculia or not. The children with learning difficulty have less response for answering the questions. Those children are also taking more time delay when compared with other children's. These types of children should be identified earlier stage itself, and needs special care and guidance. Through practice, the dyscalculia disabilities in the child can be rectified.

The proposed system can be modified to identify the Dyslexia and Dysgraphia disabilities. The calculation of latency can be carried out with a help of screening tool automatically when the students are completing the test and the information can be sent to the parents Emil or mobile phone to aware about the children disability.

***Abstract*—Network virtualization encourages the assured resource management in which particular Virtual Network is allowed to be mapped on common or shared physical infrastructure. This mechanism termed as a problem of Virtual Network Embedding(VNE). It is considered to be NP-hard, and various heuristic, meta-heuristic, and exact solutions are proposed already in the past literature. In this paper study on different categories of VNE is presented. It also discusses multiple different approaches used to solve VNE among various networking environment like wireless networks, optical networks, cloud infrastructure, etc. The paper elaborates taxonomy of VNE optimization methods, considering dynamic or static, centralized or distributed and concise or redundant scenarios. Also focusses on a discussion of crucial algorithmic aspects and possible research directions.**

***Index Terms*—Network virtualization, Virtual network embedding, Embedding algorithms, Virtual networks**

I. Introduction

Network virtualization(NV) is a technique which defines a procedure of merging software as well as hardware network resources. It also performs network functionality into an individual, software-based executive entity, called a Virtual Network (VN). This domain is specific in collecting different virtual networks, that share the hidden resources of multiple substrate networks according to various resource allocation strategies. The physical network supplies network operators along with stretchability, variety, and tractability. Making NV one of the emerging automation in the advance internet architecture. The main advantages of NV are that it can provide more malleability and prevent internet petrification without requiring significant network modification. Network virtualization is made up of some form of network hypervisor, that virtualizes the physical network services to create virtual networks to serve various applications, and ultimately to provide the best possible outcomes, and the most efficient network access possible for the application and workloads. It is already used in business architecture like 4-WARD [1], CABO [2].

Virtualization is used to execute several applications (e.g., Operating System, servers, networking protocol) upon the same shared physical resources. These applications need cloud resources that are standard in the form of a virtual network including many virtual machines(VM) clusters attached by virtual links with undertaking bandwidth. In network tectonics infrastructure as a service (IAAS) [3] is used for defining future internet architecture. NV partition the role of the Internet service provider(ISP) in - 1)Infrastructure Provider (InP), and 2) providers of operation performing in-between the slices of the physical network known as a Service Provider (SP). InP employs and maintains the network appliances, and SP is the in charge of employment of networking protocols and enables end-to-end deployment of the latest networking technologies. There are various business models which are providing separation between InPs and SPs, eg. NetScript, Genesis, X-Bone, AGAVE, etc [4].

The traditional role of management and business of SP divided into three main players [1] (a) Physical Infrastructure Provider(PIP), (b)Virtual Network Operator(VNO)and (c) Virtual Network Provider(VNP). Information about each player is as follows:

1) **Physical Infrastructure Provider(PIP)**: PIP use to locate, command, and maintain the resources of a network such as routers, links, etc. They know the allocation strategy of physical resources assigned to VNP's request by excluding internal protocols. They provide information like prices of resources, the location of the physical network, and the Quality of Service offered. Which in turn, help VNP to build cost-effective decisions for the resources which are used to configure new Virtual networks.
2) **Virtual Network Provider(VNP)**: VNP is an intermediate group amid VNOs and PIPs. They discover practical resources from multiple InPs for granting VNOs requests. It is responsible for slicing and creation of empty containers in which VNOs form the protocol stacks required to configure the VN.
3) **Virtual Network Operator(VNO)**: They Operate the network architecture inside every slice of the virtual network. VNO install, manage, and operate the VN over the topology of VNP to serve the Quality of Service requirements of the client or end user. VNO set up the protocols, and networking infrastructure over the VN, isolated from technologies of the physical network. VNO then make use of VNs to provide services to the client.

A. Virtual Network Embedding

The primary entity in network virtualization comprised of a virtual network which is used to characterize many

network technologies like VPN, Overlay Networks, and Active and Programmable Networks. Virtual Network model defined as the interconnection of nodes and links along with their resource requirements. The requirement of a node is functional resources like Operating System capacity, energy, etc. that will not change with time. A link has a non-functional requirement like bandwidth, propagation delay, etc. that change throughout the time. Hence, this model termed as Virtual Network Request(VNR). Many VNRs with different node and link requirements enable to exist on the shared substrate network. The assignment of embedding VNs on the physical network is the major issue in network virtualization. This issue is known as Virtual Network Embedding problem (VNEP). The goal of VNE is proper utilization of primary resources by accepting many heterogeneous VNs to execute on the same SN. To complete this goal, VN mapped to specified nodes and links of the substrate infrastructure in the most favorable way. The Virtual Network Operator uses different embedding algorithms to determine which virtual resources to invoke from the Virtual Network Provider. Then Virtual Network Provider instantiates Infrastructure Providers substrate resources to handle various Virtual Network Requests. Hence, Virtual Network Embedding becomes an NP-hard problem. VNE is a topic of research in a couple of years because of the demand for network virtualization. In this way, multiple service provider can offer services on the same substrate network. It also can be used for network simulation architecture such as PlanetLab(a research network that supports the global evolution of new network facilities). Presently VNE problem is mainly classified into two subproblems, Virtual Node Mapping (VNoM) and Virtual Link Mapping (VLiM) [5]. The issue is further decomposed to solve the coordination between VNoM and VLiM.

1) VNE Problem Defination: VNE problem is explained as Assume substrate network as an undirected weighted graph G_S=(N, L), where N denotes the number of nodes and L denotes the number of links of the substrate network. Let VNR is represented by another graph $G_V = (N^{'}, L^{'})$, where $N^{'}$ and $L^{'}$ denote set of nodes and links associated to any $VNR^{'}$. Let us consider a function which allocates resources(bandwidth, CPU) to parts of the substrate network represented as equation 1.

$$capacity : [Nodes \bigcup Links \longrightarrow Resourcevectorspace] \tag{1}$$

Then for individual VNR we provide a function as in equation 2.

$$demand^{'} : [Nodes^{'} \bigcup Links^{'} \longrightarrow Resourcevectorspace] \tag{2}$$

This function allocate demand for resources to parts of all VNRs. Then a VNE is consists of two functions 3, 4 and :

$$F_1 : N^{'} \longrightarrow N \tag{3}$$

and

$$F_2 : L^{'} \longrightarrow G_V \subseteq G_s \tag{4}$$

for individual $VNR^{'}$ such that for all the nodes of any VNR and for all the links of any VNR

$$demand(L^{'}) \leq capacity(L) \tag{5}$$

Therefore equation 3 is a node mapping function(VNOM) and equation 4 is represented as link mapping function(VLiM). Model representing multiple VN and a single substrate is shown in figure 1.

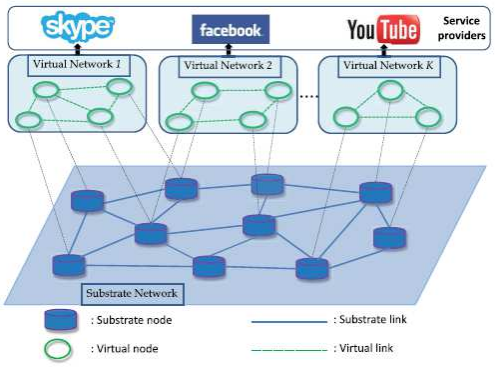

Fig. 1: Network virtualization model [6]

2) VNE problem description: Components of VNE are further described as follows:

1) **Substrate network(SN)**: SN has modeled with the help of a weighted undirected graph in VNE research literature. Substrate topology has formed with routers or switches defined on substrate nodes, and these nodes joined by substrate links such as coaxial cable or optical fiber. Each substrate node has specified by node capacity (CPU capacity) and the location of the node. Substrate links are defined by resources such as bandwidth and propagation delay.
2) **Virtual network(VN)**: The client formulates VN and supervised by the service provider. The task of Service Provider(SP) is to allocate computing resources of the network to a client, and resources hired from InP by using any VNE scheme. A weighted directed graph generally models VN with node and link requirement for computing power and bandwidth. VN termed with virtual network request which arrives from SP to SN in an online or offline manner.
3) **Virtual network mapping(VNE)**: VNEP is split into two subproblems - virtual node mapping (equation 3) and virtual link mapping (equation 4). There must be optimized coordination between these two subproblems. One scheme to achieve better coordination by solving each subproblem separately and output of VNoM termed as input for solving VLiM function. This permutation defined as uncoordinated VNE. Some solutions use coordinated VNE for better performance. Coordinated VNE will work in one stage or two stages. Some VNE approaches embed VNR into multiple adequate InPs by dividing a VNR into sub-requests. This variant termed as InterInP coordination.

The rest of this paper is organized as follows. Section II assesses a literature survey. Section III introduces some future research challenges. Section IV concludes the paper.

II. Taxonomy of VNE

VNE can be classified into six categories according to different objectives, as shown in figure 2. A static or dynamic approach used when modification of infrastructure is involved. VNE follow distributed Approach because virtual networks are placed on the physical network composed of multiple InPs. Otherwise, a centralized system is there. When there are no resources saved as a backup, then the Approach is concise otherwise redundant.

1) Scenario-based: Scenario-based approaches are classified as either static or dynamic. When there is a change in the substrate and virtual network with the evolution of the system, then the method is dynamic otherwise static.

Static: In the static category, VNRs arrive following an offline order and stay in the network queue for some time and mapped one by one. There is no reconfiguration of SN and VN involved. Hence it works better for a small-scale network. Limitation of static VNE approach is fragmentation as topologies of both VN and SN cannot be reorganized; due to this, no efficient resource utilization takes place.

Dynamic: Dynamic VNE approach overcomes the limitations of the static Approach by relocating already allocated resources. This Approach involves a change of infrastructure and VNRs arrive following an online manner. Dynamic VNE supports remapping of rejected VNR, which is called virtual network reconfiguration. This algorithm was introduced to improve the rejection rate and load balance. Limitations of dynamic VNE approach is that there is increased complexity of remapping.

2) Modification-based: Modification based approaches can take the form of centralized architecture when only one substrate entity involved for mapping. A Distributed architecture is considered when multiple objects are responsible for mapping the requests.

Centralized: These approaches follow soft programs that run on general computing platforms. The single entity of InP receive VNR and allocate resources to it. This separate entity has information about each resource allocation. In other words, it has global knowledge about the system. But the disadvantage of this Approach is if a single entity failure occurs, the complete process fails. It is tough to maintain scalability on an extensive scale network with this Approach.

Distributed: In this Approach, Virtual Network Requests are distributed over multiple substrate entities. Due to load distribution, every node participates in the embedding process, and it overcomes the limitation of scalability. These approaches provide better robustness compared to the centralized procedure. Deficiency of this Approach is there is communication overhead for maintaining synchronization among multiple InPs.

3) Relocation-based: Relocation based approaches consider the resource requirement. If resources are available only to satisfy the requests, then the method is concise. If resources are saved to handle any substrate failure, then the Approach is redundant.

Concise: In this approach substrate resources are not reserved as a backup when any entity fails. The concise Approach uses algorithms which use as many resources as required for completing the demands. The remaining resources which left after the embedding process they can be used for future VNRs. Failure recovery is not guaranteed in a virtual network. Most algorithms follow the assumption that every time SN is working; hence, most VNE solutions are concise in general.

Redundant: These approaches secure extra resources for virtual network requests in cases of runtime failure. Degree of reliability is directly proportional to the embedding cost. These approaches meant for fault sensitive systems. Substrate entities are monitored if any breakdown happens, so there are fall back resources for them, and switching from primary resource to backup support is performed.

According to the above context the approaches are mutually independent; hence, VNE algorithms are dynamic, distributed, redundant at the same time. Hence notation for identification of the class of the particular algorithm in which it belongs is described with the following syntax:

S—D/C—D/C—R

The first character denotes whether the Approach will work in a Static or Dynamic category. Next character indicates whether the algorithm is Centralized or Distributed. Finally, the third character aims to denote whether the Approach is Concise or Redundant. For instance, a VNE algorithm indicated as S/C/C represents that the algorithm is a static, centralized, and concise algorithm. Class distribution of different embedding approaches can be classified as follows:

A. Centralized/Static/Concise solutions

This section contains a literature survey of VNE algorithms belonging to S/C/C class, as shown in table I. This class is easy to model because virtual network requests arrive offline and processed in batches with a time window. There is only one substrate infrastructure to manage, and it has global knowledge about every component of the network. It works as a base to model the other seven classes described further in the paper. Many types of research have conducted in this class of VNE algorithms.

Limitations of S/C/C category such as:

- S/C/C solutions assume that substrate network remains operational through run time, but in today's substrate network such as MPLS(multi-protocol label switched networks), [13] and real-time system [14] the substrate node or link may fail. Hence, S/C/C solutions will not provide Virtual network survivability, and no extra resources saved for handling substrate failure.

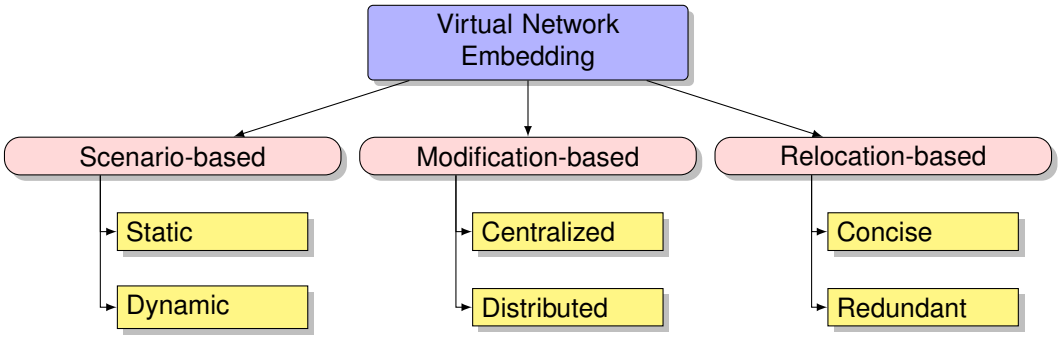

Fig. 2: Taxonomy of VNE

S.No.	References	Contribution	Merits	Limitations
1	Liu *et al.*[7]	virtual network embedding completed by 0-1 programming in one step.	Improved coordination based on nodes proximity	Not feasible for large-scale networks
2	Yu *et al.*[8]	Joint node mapping and link mapping in single stage	Reduced mapping cost and hop length	Not completely optimal
3	Feng*et al.*[9]	Considered multiple attributes of topology for embedding VN	Improved long-term average revenue, acceptance ratio, and revenue to cost ratio.	Does not provide fault tolerance
4	Jarray *et al.*[4]	JNLE column generation with branch and bound technique and auction-based mechanism	Increased infrastructure provider's profit up to 45%	Not able to maintain fairness among clients
5	Mano *et al.*[10]	Investigated trade-off of embedding time and reduced cost of virtual network	This Approach provides faster embedding by reducing dense Virtual Network into sparse.	The feasibility and capacity ratio were not analyzed.
6	Jahani and Khanli[11]	Core decomposition find subnetworks according to a degree of node	More revenue, acceptance ratio, and low embedding cost	It will not provide scalability in handling large complex graphs as memory size was unbounded. Additionally, Approach had more CPU and I/O cost due to inefficient utilization of memory.
7	Moura *et al.*[12]	Proposed A Branch and Price algorithm to solve Virtual network embedding problem of single path.	Fast running time hence memory usage was minimized	Further enhancement is required for performance of the algorithm and no. of nodes can be further reduced

TABLE I: Solution of S/C/C class

- The network scenario under this class of solutions is complicated because of the substantial computational burden on the central unit. Moreover, it is hard to analyze the network in this class.
- As the infrastructure is centralized, there is an issue of scalability arises while implementing S/C/C in large-scale networks. Moreover, static requests also cause fragmentation in the substrate network, which, on the other hand, cause reduced acceptance ratio and long term revenue.

B. Centralized/Dynamic/Concise solutions

C/D/C class includes another variant of S/C/C class by changing one characteristic as shown in table II. Here we are focused on the virtual network embedding with an evolving or dynamic system. The solutions belonging to this class has improved the rejection rate and balances the load of the substrate network efficiently.

D/C/C class provide VNE solutions with the reconfiguration of mapped virtual network requests and reorganize resource allocation. But, there are less number of solutions under this class as compared to S/C/C category. It has some merits as well as limitations.

Limitations are discussed below:

- Fewer VNE solutions are belonging to D/C/C class as compared to S/C/C class, due to the high migration cost of virtual nodes and links resulting in long service disconnection times. Hence, D/C/C solutions are not feasible for critical time applications.
- D/C/C solutions behave in a very complicated manner due to online characteristic; hence, they are more challenging than the static scheme.

C. Distributed/Static/Concise solutions

Above discussed two classes followed the centralized network topology. Where the central substrate entity is handling all VN requests from the clients and is responsible for choosing and assigning virtual nodes to the substrate nodes of the underlying physical network. But the centralized Approach has certain limitations like scalability among vast scaled network, and it is not easy to maintain. Another limitation is productivity and flexibility of VN requirement and management. This becomes challenging research when SN is dynamic with an evolving environment. As shown in table III the section deal with the analysis of distributed network topology which decentralizes the process of making decisions while mapping

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

S.No.	References	Contribution	Merits	Limitations
1	Shuhao *et al.*[15]	Proposed objective functions with both resource and security constraints	Addressed the security requirements of virtual network embedding	Not a traditional pay-as-to-go model.
2	Sun*et al.*[16]	Introduced a MILP model for embedding evolving VN requests	Reduced resource consumption as well as the cost of reconfiguration	Higher link mapping cost
3	Shakya *et al.*[17]	Focused on spectrum consecutiveness, relative loss, and spectrum alignment.	Achieved lower blocking probability for arriving VON requests and enhanced revenue for the Service Providers (SPs)	Alignment and Spectrum consecutiveness will cause excess link load of some region in the network, therefore blocking probability will increase.
4	Han *et al.*[18]	VNE in WiFi network	Increased InP profit and acceptance ratio	The average revenue as well as the average cost declined and RFD increases.
5	Han*et al.*[19]	Green virtual network embedding scheme in virtualized FiWi access network for 5G	Power consumption is reduced with guaranteeing Infrastructure Provider profit	No provisioning of virtual nodes with low flexibility.
6	Hejja and Hesselbach[20]	Embedding focused on peer-to-peer delay as a primary constraint	Reduced the average power consumptions in the physical network by 23.54%.	Non-direct edges are not considered

TABLE II: Solution of D/C/C class

VN on all substrate nodes. This work includes embedding of VN requests on a network which is shared and find optimal mapping with a balanced node on each node and link.

Limitations of S/D/C class of solutions:

- There is a lack in the group of S/D/C solutions in offering resiliency which can be provided by setting up backup resources at provisioning time in a centralized way.
- S/D/C groups algorithms that perform configuration of VNs across multiple substrate networks; hence, there is overhead of exchanging messages; therefore, for vast SNs evaluation is not optimal.

D. Centralized/Static/Redundant solutions

In a network virtualization environment, it is ensured that all virtual links should be unbroken in the presence of failure. As shown in table IV the section focuses on survivability approaches in NV environment. Resources are redundant to provide fault tolerance.

E. Distributed/Dynamic/Concise Solutions

VNE belonged to D/D/C class are grouped in this subsection, as shown in table V. These proposals can perform a dynamic reconfiguration of already mapped Virtual Network Requests when a new VNR arrives. Embedding is concise, and the algorithms run on a primary instance. Dynamic approaches are proactive, hence challenging. It leads to fewer publications in this category, compared to centralized, static methods.

Limitations of D/D/C VNE solutions:

- Distributed solutions for VNE are significantly harder to implement and more difficult to reach near to optimal solutions hence few D/D/C approaches are listed in this section.
- It is hard to find proper convergence direction in multiple Substrate networks.

F. Distributed/Dynamic/Redundant solutions

This subsection defined distributed and dynamic approaches, along with redundant resources to provide fault tolerant behavior. Nguyen *et al.*[6]defined resource allocation and routing in a wireless network environment. The objective of the framework was to prevent disruption caused by traffic for SPs. Provided operation cost for SN was low also it provided promising traffic reduction on link failure. As the formulated model was on a large-scale direct solving of optimization problem was not manageable. Hence, two algorithms were proposed by the application of ADMM (alternating direction method of multipliers) decomposition technique named parallel and distributed algorithm. Limitation of this multi-path addressing is that it also increases the redundant transmission of the target content and the node will exit network when the energy exhausted, and the QoS of the system will deteriorate.

Limitations of D/D/R VNE solutions:

- Most of the algorithms still run on a central instance, and few approaches try to combine redundancy and dynamicity.

G. Distributed/Static/Redundant solutions

This subsection deals with approaches having Decentralized infrastructure and resources are redundant to provide survivability. Order of arrival of VNR is offline

Chowdhury *et al.* [32] proposed PolyVINE allowed mapping of VN in a distributed way and each InP is involved in global competition. They proposed a location dissemination protocol(LAP)and hierarchical addressing system (COST) that allowed InPs to make informed forwarding decisions. Another direction involves modeling this problem as DCOP(distributed constrained optimization problem)[31] and for the solution, there should be minimal information exchange between InPs.

Beck*et al.*[33] proposed a parallel, generic, and distributed technique for mapping virtual networks. Proposed Approach provided minimization in communication than other decentralized VNE solutions. Regardless of its decentralized behavior, mapping costs of DPVNE remain persistent comparable to costs of centralized techniques.

Limitations of S/D/R VNE solutions:

- In S/D/R class of solutions SNs failure of any substrate element is considered thus complexity is higher than usual S/D/C solutins.

III. Future Research Challenges

VNE solutions are still an open field and cover many points. Some future directions in this respective domain are described below:

- **Complexity of VNE**: Static and rigid network systems cannot satisfy an increasingly large amount of mobile traffic. Therefore to leverage, the complexity and scalability of resource allocation in large-scale access networks, various multi-objective or distributed models are already introduced. There are many unresolved issues to resolve complexity in resource distribution.
- **Dynamic VNE**: In studies of static VNE, the assignment of network resources is persistent and excessive in the VNRs lifetime. However, in actual, the user's resource demands evolve with time; therefore, static VN embedding techniques leading to less usage of substrate resources and lowering of revenues. Dynamic methods provide flexibility in virtual and substrate network and provide multiple bandwidth connection in applications like E-health, virtual reality, etc. VNE algorithms with dynamical virtual network mapping for complex computation is an open research issue for future work.
- **VNE Survivability**: Protecting the Virtual Network layer is an uninvestigated spectrum for survivability. Providing survivability at the upper layer (e.g., Internet Protocol

978-1-7281-1261-9/19/$31.00 ©2019 IEEE

(IP)) of a multilayer network is crucial for VNE. Another advantage of giving survivability at the VN layer is that it capitulates more resource effective embedding as compared to providing the same level of survivability at the Substrate Network layer. Survivable VNE with VN level protection saves approximately 33% resources than survivable VNE with SN level protection. Allocation of resources to ensure survivability at the fabric level along with VN level is an essential future challenge to study further.

- **VNE in wireless network**: Operators of the wireless network are observing a considerable rise in data demand because of smart-phones and the abundance of supported Internet applications. Mobility is an important subject that has to be taken into account during the development of the VNE algorithm for wireless networks. Mainly, content caching at the network level is gaining interest as a technique which eases the generated data traffic at the base station and also reduces the access latency and the overall power usage. By caching accessible content along with the network, client requests can be satisfied by closely located mobile clients without the need to recover them from the source, which is assumed to be, in the best case scenario.

IV. CONCLUSION

Network virtualization is an encouraging tool to eliminate the rigidity of modern internet. Virtual Network Embedding is an important matter to resolve resource utilization in network virtualization. Embedding algorithms aimed are essentially exact, heuristic, and meta-heuristic to explain the available virtual network assignment in polynomial time. This paper presented a literature survey of a variety of approaches and also presented a study of many algorithms used to solve different aspects of VNE. A proper explanation and formulation of VNE are given, and a taxonomy is explained in an elaborated manner. As future work issues like InP interactions, reputation management, pricing models, and incentives for InP genuineness. Characteristics such as scalability, stability, and performance require further study

***Abstract*—Cooperative Communication (CC) allows the transmission of information by collaborating different nodes in the network by effective utilization of communication resources. In this paper, a new methodology for relay selection has been proposed where the relay is chosen based on the highest channel capacity of the node with the neighboring nodes as well as destination node. A new frame format ready to forward (RTF) has been proposed to enhance the communication by selecting the relay in a decentralized method. The existing RTS and CTS are modified to support cooperative ad-hoc network.**

Keywords—Cooperative communication, Ready to Forward, Decode-and-Forward.

I. INTRODUCTION

CC for wireless ad-hoc networks have a nature of broadcasting. Remaining nodes or terminals in the communication network behaves like a helping node for the exchange of information on receiving the broadcasted signal for the source node. It is used for improving network connectivity, communication reliability and reduce the signal fading effects.

CC supports both spatial diversity and timing diversity. There are three different types of protocols that are used in CC, namely Amplify and Forward (AF), Decode and Forward (DF) and coded cooperation. We used DF as it decodes the received information and filters the noise, then it encodes the information and broadcasts the information in the network. Whereas, in AF, the relay node will amplify the signal along with the noise which results in fading or loss in signal power and working of Coded cooperation is by transmission of various portions of a user's code-word using two different and independent fading paths.

The primary unit in CC is a three terminal network where the relay cooperates with the source by sharing its resources, to make successful communication between source and destination. Among the resources specified for cooperative communication in [1], relay is one of the important resources to be selected to improve the performance of the network.

CoopMAC was developed for wireless LANs to utilize the multi-datarate capability and reduce the throughput bottleneck that will be caused by the low data rate nodes, such that the throughput can be increased. High data rate stations in CoopMAC, are assisting low data rate stations in their data transmission by forwarding traffic. Each of the low data rate nodes maintained a list in the form of a table and called it CoopTable, of capable helper nodes that is capable of assisting in the transmissions which leads to memory constraints [2]. Relay-enabled DCF *(r*DCF) was developed which enabled packet relaying, in ad-hoc mode of IEEE 802.11 systems, by seeking each station to broadcast the datarate information among the stations explicitly[3].

Every station has to broadcast their rate information, this method consumes more bandwidth. In [4] and [7], authors proposed a new MAC protocol to make a betterment in the lifetime of the Wireless sensor network by considering residual energy information and channel state information of sensor nodes to select the cooperative nodes. A Cooperative Diversity MAC algorithm, which exploited the CC capability in the physical layer for the betterment in robustness of wireless ad hoc networks was investigated in [6].

A good amount of work was done to design cooperative protocols that define the selection of the relay candidate [8], it's coding [9], it's cooperative transmission [10] and it's power allocation schemes. From the recently proposed cooperative protocols, relay selection mechanisms only choose optimal relays among multiple relaying candidates to cooperate with communication links. Most of the research on cooperative communications models the wireless channel as a narrow band Raleigh fading channel with additive white Gaussian noise (AWGN) [11]. Among the relay selection algorithms developed so far, most of the researchers considered centralized relay selection method. Two papers [7] & [12] proposed decentralized relay selections methods, out of which one paper [7] considered location information of the users to

maximize the lifetime of the network by compromising with the reduction of throughput. Since throughput is an important parameter and it depends on the channel strength supported between the users, we propose a decentralized relay selection scheme by considering the location information of the users by modifying the existing IEEE 802.11b MAC protocol.

An effort is made to select the relay in decentralized manner as explained in section II and the proposed mathematical model is explained in III. Modified RTS & CTS frames and newly developed control frame known as Ready To Forward (RTF) for a 802.11b is described in section IV. The proposed model has been compared with wireless ad-hoc networks and an analysis is driven in section V and VI. Conclusion drawn from the proposed work has been explained in section VII along with the Future scope.

II. Relay Selection Model

In a cooperative ad-hoc network there are many nodes which are in range with the source node that may have better channel capacity when compared to the source node while transmitting to the desired destination node. In sequence, to choose the right Relay node, the following algorithm was developed.

Step 1: Source broadcasts RTS. It will be received by all the nodes which are in range (100m) with the source node. Modified RTS will contain the location information of the source.

Step 2: Destination will broadcast CTS, once the RTS is received at the destination The modified CTS frame format will contain the channel capacity supported between the selected source and the destination.

Step 3: The neighbouring nodes will calculate their channel capacity with respect to the destination node.

Step 4: If the channel capacity of the neighbouring node is greater than that supported between the selected source and the destination, a suitable relay with the highest channel capacity will be selected as explained in the mathematical model in section III.

Step 5: The selected relay node will now broadcast the RTF frame in the network to indicate that the other nodes need not be involved in further transmission.

Step 6: The selected relay node will be considered as the helping node to cooperate between the source and the destination.

Fig 1 specifies the methodology at the source node. The first step in the method is to sense the medium to check whether the required channel is free. If it finds the channel is free, then it broadcasts RTS frame i.e. source node broadcast RTS in the network. If the channel is busy then it will wait for the specific back off time.

After broadcasting RTS from the source node, it waits for short inter frame space (SIFS) i.e. the source node will be idle for some amount of time till it gets the response of a CTS frame from desired destination node.

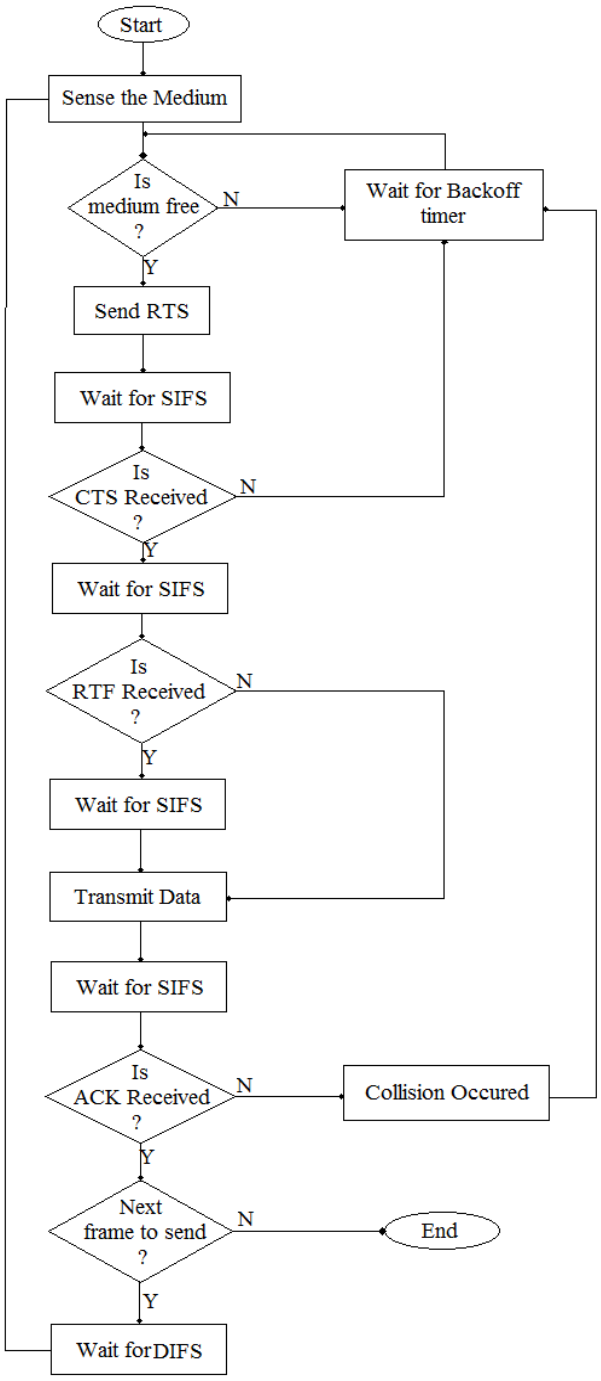

Fig.1: Methodology to be followed at the Source Node

If CTS is received by the source node in response to RTS then it waits for SIFS amount of time and checks for RTF. If RTF is received, then it waits for an SIFS time and transmits data to the destination node. If RTF is not received, it directly broadcasts the data to destination node. If CTS has not been received, then it waits for the specific back off time and makes a new attempt to access the channel.

After the data is transmitted from the source it waits for acknowledgement from the destination node. In the case when acknowledgement is received from the destination node and

there are no further frames to be transmitted then it terminates. If it has some more frames to transmit then it will hold on for a DIFS amount of time. If the acknowledgement has not been received by the source node, then it assumes that the collision has occurred and it waits for back off time and retransmits the data if the channel is free.

Fig 2 specifies the methodology at the relay node. Initially relay nodes are assumed to be in idle state. It receives RTS from the source node and also waits for CTS from the destination node. On receiving the CTS, every relay node computes the channel capacity, in which the relay checks whether the relay node channel capacity is greater than the channel capacity of destination node. If the relay node data rate is greater than that supported between source and destination, Difference between the maximum possible data rate and relay node data rate is assigned to x. The node with smallest value of x will be chosen as the relay node in order to broadcast RTF to remaining nodes.

After broadcasting the RTF it waits for the data transmitted from the source node which is to be transmitted to the destination node. Since the relay node follows the decode and forward mechanism, if first decodes the data and then it

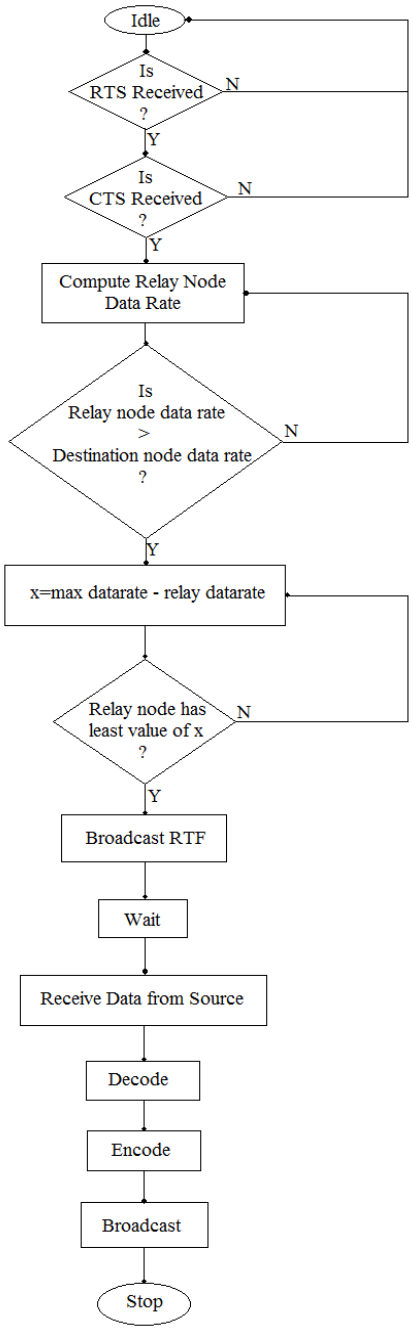

Fig. 2: Methodology at the Relay node.

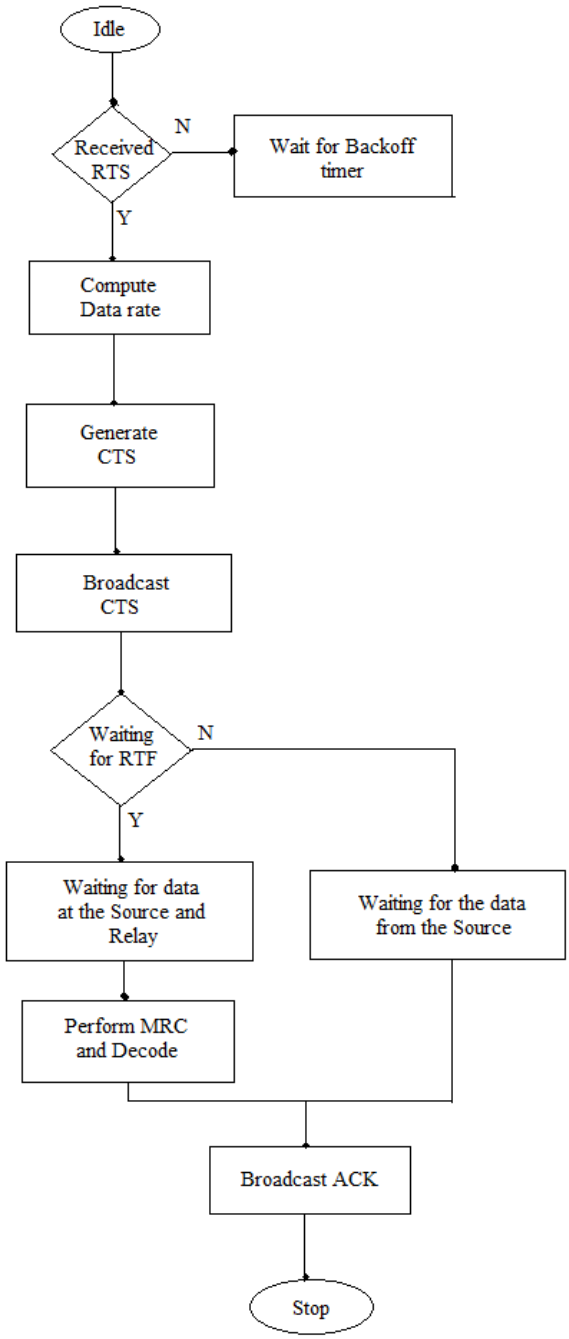

Fig. 3: Methodology to be followed at the Destination node.

encodes and broadcasts the data to the other nodes in the network.

Fig 3 specifies the methodology at the desired destination node. Initially destination node is assumed to be in idle state. If the RTS is obtained at the destination from the source, then it computes the data rate and broadcasts CTS .If it fails to receive RTS then it waits for the amount of time mentioned in the back off timer.

Once the CTS is broadcasted, it waits for the RTF from the relay node. Once the RTF is received it waits for the data from the source node in first time slot and from the relay node in the second time slot. If RTF is not received within a specified time duration, it will hold on until the data is obtained from source node only. On receiving the data, it performs Maximum Ratio Combiner (MRC) and decodes the data .Upon receiving the data the destination node will broadcast the acknowledgement in the network.

III. MATHEMATICAL MODEL

In a cooperative ad-hoc network there are many nodes which are close to the destination node that may have better channel capacity when compared to the source node while transmitting to the destination node. In order to select the right Relay node, the following mathematical model was developed.

Initially, the nodes in range with the destination will receive CTS and every node in that range compares their data rate with that of destination data rate, which is present in the modified CTS frame.

If Relay node data rate > Destination data rate then,

x= Maximum possible data rate - Relay node data rate

where maximum possible data rate supported by 802.11b is 11 Mbps.

If the relay node data rate is greater than destination data rate, then difference between the maximum possible data rate and data rate supported by the relay will be calculated. The relay with the least difference value will broadcast the RTF in the network. The smallest value of x will be set as the back off value in the timer. The relay node that backs off first with minimum back off timer value will be selected as the helper node and this node broadcasts the RTF in the network. Other neighbouring nodes which listen to the RTF will set their backoff value equal to the NAV specified in the RTF.

IV. MODIFICATIONS

A. *Modifications at MAC Layer*

According to the TCP/IP model there are five layers of which CSMA/CA protocol is used at the MAC Layer to facilitate wireless communication. In order to simulate this concept, few modifications were made to RTS and CTS frame formats. A new control frame format known as RTF is also developed to announce the relay that is selected to cooperate with the source in a distributed manner. The modified MAC frame is as shown in the fig 4.

- Subtype defines the values for the control frames such as RTS (1011), CTS(1100), ACK (1101) and RTF (1010).
- Duration of NAV: Network allocation vector is used for virtual carrier sensing and it also specifies the Roundtrip time (RTT) taken to occupy the channel. RTT is computed by considering the processing delay, Transmission delay and propagation delay.

B. *Modified RTS Frame*

It is broadcasted by the sender in the network before the actual data transmission begins. This frame format is as shown in fig 5. Two bytes are added between the destination MAC address and FCS to carry the location information of the source. Location information specifies the X-Y coordinates of the Source in the coordinate plane. The area of the coordinate plane used in this simulation is 250 x 250 m^2.

C. *Modified CTS Frame*

CTS (as shown in fig. 6) is broadcasted by the destination in response to RTS sent by the sender. Four bytes are added between the destination MAC Address and FCS of the CTS to carry the data rate supported between the source and the destination.

D. *Developed RTF Frame*

All the nodes in the network have received a copy of both RTS and CTS. Since RTS contains the location information of the source and every node in the network are also aware of their location information, all the nodes are capable of computing the data rate between themselves and the source. Data rate is computed considering the Euclidean distance from the source and the helping node. Nodes at different locations from the source provide different SNR, which in turn provide different data rates. Since CTS contains the data rate supported between the source and the destination, all nodes other than the destination can compare the data rate with that of the destination data rate. Using the mathematical model explained in section III, a node that is willing to cooperate will be employed as a helper node. The selected helper node will broadcast the RTF in the network. RTF frame format is shown in fig 7. Helping node Address specifies the MAC address of the relay node.

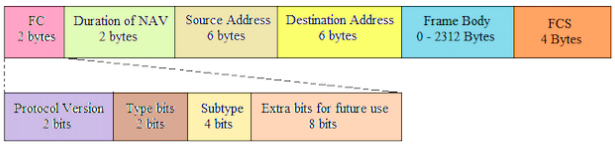

Fig.4: Modified MAC frame format.

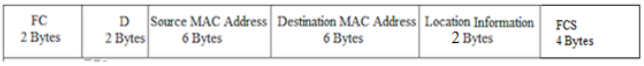

Fig. 5: Modified RTS frame format.

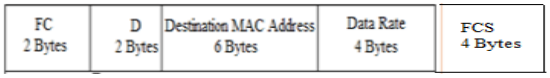

Fig. 6: Modified CTS Frame format.

Fig. 7: RTF Frame format.

V. RESULTS

An ad-hoc network is generated as shown in fig 8 using MATLAB software. These nodes are given fixed positions (or co-ordinates) in the X-Y plane in order to obtain accurate results. Twenty nodes are randomly placed in an area spacing of 250x250 m^2.

After deploying the nodes in the specified network, source node and destination node are selected (here source node is node 13 and destination is node 18) and the desired direction of data transmission is shown in fig 9.

Desired data information which is in random binary format, is generated depending on the number of bits entered that must be used for further transmission. 512 bytes of data bits generated will now be accepted at the application layer. 22 segments, each consisting of 512 bytes of payload are used for the simulation of this work.

Segmentation is performed at transport layer to convert entire stream of information into fixed sized segments and packets. After segmentation, segments are ready to be transmitted in the network. Once the channel is sensed to be free, RTS will be broadcasted from the MAC Layer of the source. CTS will be broadcasted in response to the received RTS from the Destination node. RTF is broadcasted from the selected Relay node as shown in fig 10.

Data information broadcasted by the physical layer of the source node is decoded and encoded again at the selected relay node. Encoded information is broadcasted by the relay node in

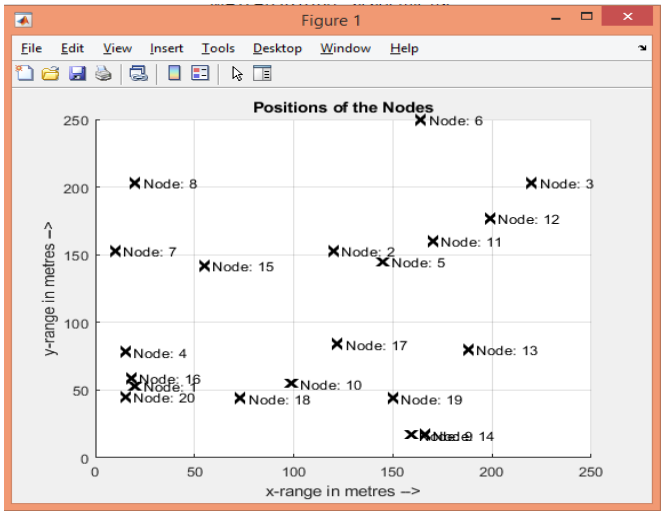

Fig. 8: Positions of nodes in the cooperative ad-hoc environment.

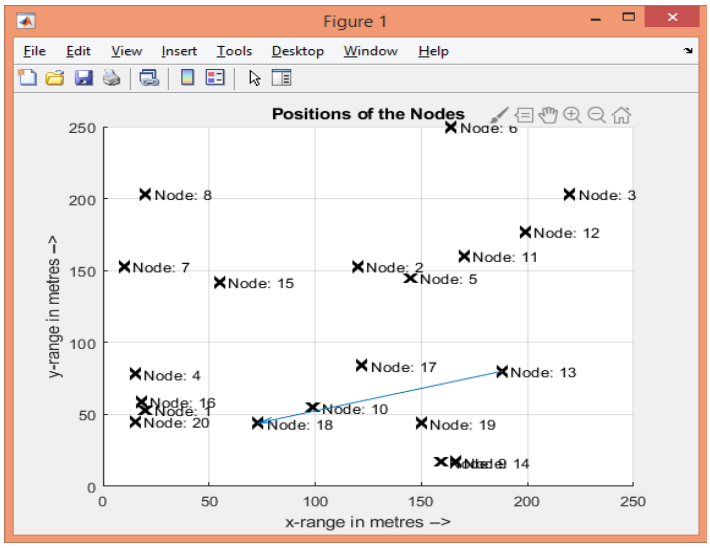

Fig. 9: Plot the direction of the desired transmission.

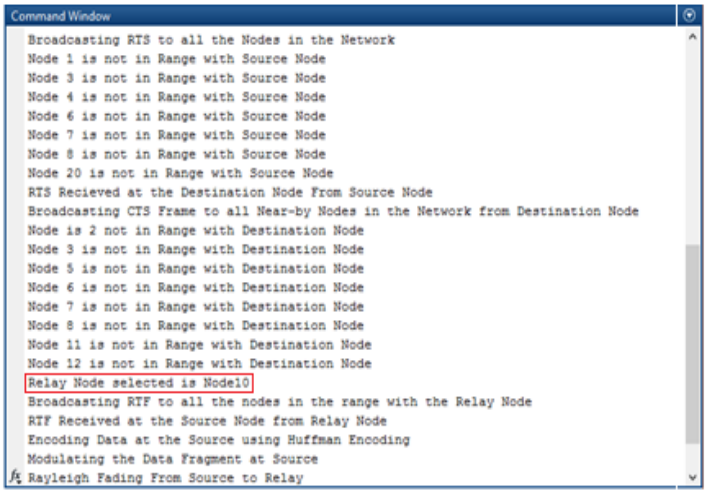

Fig. 10: Relay node selection

the network. This is illustrated in fig 10.

MRC is applied at the destination on the information received from source and the relay, resulting signal is demodulated and error free information bits are delivered to the MAC layer. Performance of the network simulated is evaluated in terms of Packet delivery ratio and Throughput.

VI. PERFORMANCE ANALYSIS

Table 1 shows the performance analysis of Cooperative ad-hoc networks in comparison with normal wireless Ad-hoc networks. The particulars are with respect to number of packets sent using data signal, number of packets dropped due to number of bits in error, packet delivery ratio and throughput in Kbps.

From the results of table 1, it is clear that the throughput and packet delivery ratio are improved in Cooperative Ad-hoc networks in comparison to Wireless Ad-hoc networks for data signals.

TABLE I. PERFORMANCE ANALYSIS OF RESULTS

Type of Network	No. of Packets sent	No. of Packets Lost	Packet Delivery Ratio	Through-put (Kbps)
Wireless Ad-hoc Network	22	13	0.409	$2.8943*10^4$
Cooperative Ad-hoc Network	22	7	0.681	$3.7757*10^4$

VII. CONCLUSION AND FUTURE SCOPE

Wireless Cooperative ad-hoc communication is beneficial in terms of high signal strength, secure network, throughput, packet delivery ratio and high spatial diversity-resistance to fading. The relay selection algorithm for transmission of data over Rayleigh faded channel with AWGN in cooperative ad-hoc network was simulated using MATLAB software. An RTF frame format along with the Distributed relay selection methodology for CC has been proposed for better throughput in the presence of overheads.

Ad-hoc networks are gaining attention amongst recent researches, as the existing mobile computing hardware and wireless networking is capable of supporting today's requirement. As a step towards improvement, an attempt can be made to increase the throughput by using channel coding techniques.

Abstract - Paper presents a newly modified power quality improved interleaved SEPIC power factor pre regulator with reduced ripples. Main objective is to obtain output voltage with improved efficiency and power factor with inductors directly coupled. Normally, power factor pre regulator with boost converter are used for regulating DC-link voltage for a range of fixed voltages , by using variable DC-link voltage the overall efficiency of the converters can be increased. Single ended primary inductor converter which are interleaved used for power factor pre regulation and PFP stage is the first stage of AC/DC converters .It is used for many applications such as inductive heating , wireless charging , and on board chargers for electric vehicles (PEVs). Here,the presence of coupled inductor reduces magnetic components . Hence new modified power factor pre regulator converter ,provides output voltage with high efficiency and power factor. Presence of coupled inductors decreases the voltage and current ripple. MATLAB simulation based results proved the effectiveness of the proposed system, compared with existing system.

Keywords- Power factor pre regulator (PFP),Single ended primary inductor converter (SEPIC),Coupled inductor, interleaved converter.

I. INTRODUCTION

The first stage of AC/DC converters will be a power factor pre regulator. The converters connected in grid require high power quality, less total harmonic distortion and large power factor. AC/DC converters are consisting of a PFP stage and a DC/DC stage, generally two stage AC/DC converters [1]. Due to soft switching, galvanic isolation, and high efficiency DC/DC converter is chosen as second stage of the converter. Nowadays interleaved SEPIC converters are used as the PFP stage. Power level can be made increased by using interleaved SEPIC converters. The advantage of SEPIC converter is the voltage at the voltage can be made lower or higher than the input voltage [2],[3].

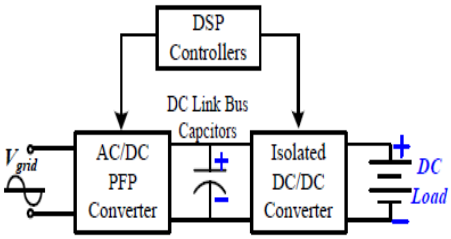

Fig 1. Structure of AC/DC converters

At first Boost type PFP were used. Main aim of PFP is to enhance the power quality also reduces harmonic distortion. This kind of converter is a bridge rectifier followed by Boost converter. But it is having a disadvantage such that by any chance the second converter doesn't get operated near the resonant frequency, then the overall efficiency may get reduced.[5].

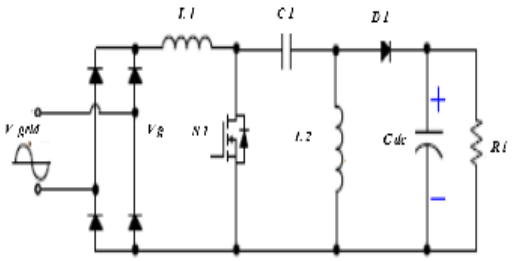

Fig 2. Traditional SEPIC PFP converter

Then a study conducted on the advantages of SEPIC converters as the PFP stage. It is having many advantages such as it reduces voltage ripples, voltage be made high or low than the voltage given to the input [6]. But it is not accepted widely because SEPIC converters cannot be used for high power applications, since the stress of voltage and current on the diodes and switches are higher.

Bridgeless SEPIC and Isolated SEPIC were also their but it is also not contributing much for the reduction of voltage and current stress. By paralleling two SEPIC converters directly, it can be made interleaved [4]. And by interleaving SEPIC converters power level can be increased. This can be designed with coupled inductors for reducing the current stresses and voltage stresses of all the switches and diodes in the circuit.

Here, in this paper an interleaved SEPIC AC toDC converter is designed. The input current is shared among two stages to cut back the present stresses of switches and diodes. Interleaved SEPIC converter having coupled inductors[7]. The presence of coupled inductors, magnetic components will be reduced in the circuit[11]. The new converter will provide output voltage,with improved power quality and high power factor[8][9][10].

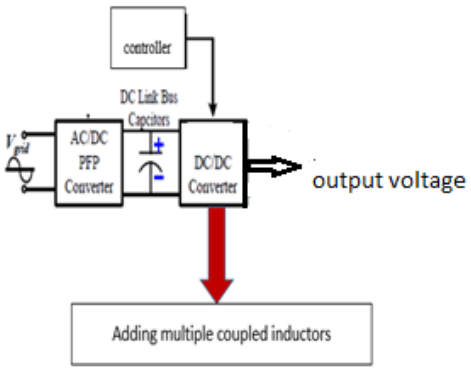

Fig 3. Block diagram of proposed converter

Wide range of DC link output voltage provided by SEPIC AC/DC converter. Large switching losses will be generated by CCM operation, soft switching will be provided by DCM operation. Zero voltage switching can be done for the MOSFET's to reduce the switching losses, and Zero current switching can be done for diodes. In order to reduce the number of magnetic components, the inductors corresponding to the two phases are directly coupled together.[12]

II. PROPOSED SYSTEM

A. CIRCUIT DESCRIPTION

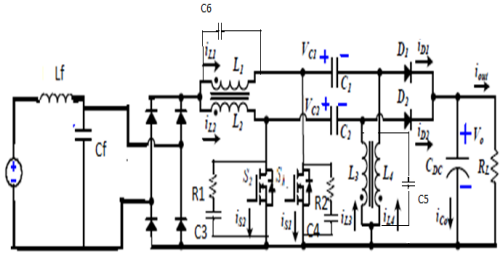

Fig 4. Circuit diagram of proposed converter

This paper proposes a newly interconnected SEPIC AC/DC converter. The input current get shared among two stages. The new interleaved SEPIC converter will provide output voltage, with improved power quality and high power factor and reduced ripples in its output voltage and hence power quality also improved.

ZVS can be realised for reducing switching losses of MOSFET and ZCS for reducing the reverse recovery losses of diodes.Presence of coupled inductors, reduces the number of magnetic components in the circuit and it significantly reduces the voltage ripple. The DC link voltages C_{DC} and the capacitors C_1, C_2, are high and its ripples at the voltage are negligible.[13]

B. MODES OF OPERATION

Mode 1

In this mode switch *S1* is on and switch *S2* is off. The diode D_1 off, and diode *D2* is on. The voltages across both inductors *L1*, *L4* are *Vg* and *L3*, *L2* are - *Vg*. Therefore, the inductor currents *iL1*, *iL4* increases and *Il3*, *Il2* decreases. The inductor current *iL2* decreases all the time and changes the flowing direction in this mode. The current through diode *D2*, *iD2*, keeps on decreasing. The variations of inductor currents, Δ*iL1* and Δ*iL2*, can be expressed as, where, *T* is the switching period, and *D'T* is the time interval between *t0* and *t1*.

$$M = \sqrt{L_{12} - L_{21}} \qquad (1)$$

$$K=\frac{M}{\sqrt{L_1 L_2}} \qquad (2)$$

$$\Delta iL1=\frac{V_g+KV_O}{(1-k^2)L_1} D'T \qquad (3)$$

$$\Delta iL2=\frac{V_O+KV_g}{(1-k^2)L_2} D'T \qquad (4)$$

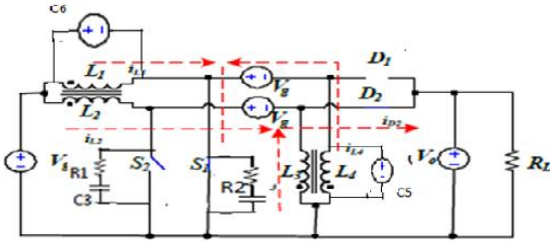

Fig 5. Equivalent circuit of Mode1

Mode 2

At *t1*, current through the diode *D2* is *iD2*..Sum of currents *iL2*,*iL3*, drops to zero. Due to ZCS the diode gets turned off. Currents *iL3* , *iL2* flows through a loop.

Variations of the inductor currents are the same due to the same voltage across the inductors. Average current *iL3* is larger than the average current *iL2*.*The* current of coupled inductor *L2* is constant. when the currents *iL3* and *iL2* drops to minimum, the current *iL3* is very much higher than *iL2* with *iL3* and *iL2* as positive and negative values respectively. Assuming the resistances of inductors and capacitors are small values and can be neglected, the loop current remains constant can be expressed as

$$i_{L3} = -i_{L2} = Constant \qquad (5)$$

Variation of inductor current ΔiL1, can be expressed as,

$$\Delta iL1=\frac{V_g}{L_1}(D - D')T \qquad (6)$$

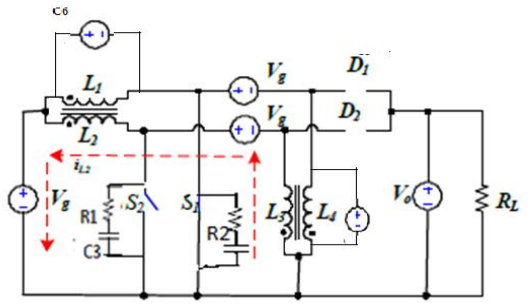

Fig 6. Equivalent circuit of Mode 2

Mode 3

Diodes *D2*, in off condition, while the diode *D1* turned on.Constant current flowing through the loop consisting of *L2* and *L3* inductors.The currents *iL1* and *iL4* decreases from maximum values.The sum of currents through the inductors flows through the diode *D1*. Voltages across inductors *L1* and *L4* are *−Vo*. The current through the inductor *iL1* decreases. It is expressed as,

$$\Delta iL1=\frac{V_O}{L_1}(0.5-D')T \qquad (7)$$

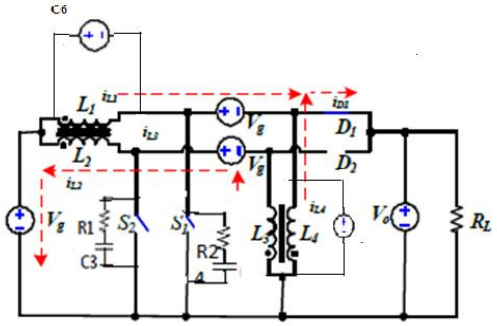

Fig 7. Equivalent circuit of Mode 3

III. DESIGN EQUATIONS

In order to design the proposed converter, certain equations are mandatory .

Equations for snubber design

$$R=\frac{Voltage\ Across\ the\ switch}{Input\ current\ Rating} \qquad (8)$$

$$C=\frac{1}{Voltage\ across\ the\ switch^2\ .\ Switching\ Frequency} \qquad (9)$$

$$P=\frac{V^2}{R} \qquad (10)$$

P is the power output.

$$D=\frac{V_{out}}{V_{out}+V_{in}} \qquad (11)$$

D is the duty cycle it is calculated for the inductor design

$$dt=\frac{1}{F_S\ .\ D} \qquad (12)$$

$$L=V.\ \frac{dt}{di} \qquad (13)$$

Output capacitor design

$$\Delta V_{cs}=\frac{I_{out}D_{max}}{C_sF_{sw}}=I_{out}\sqrt{\frac{V_{out}+V_D}{V_{in_min}}} \qquad (14)$$

Filter design

$$C_f=\frac{I_m}{\omega V_m}\tan\theta \qquad (15)$$

$$L_f=\frac{1}{4\pi^2 f_c^{\,2} c_f} \qquad (16)$$

IV. CONTROL SYSTEM

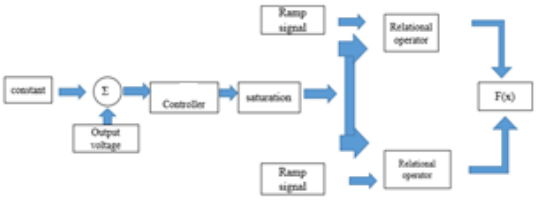

Fig 8. Block diagram of control system

Control system contains three sensors such as voltage and current at the input, and voltage at output. The repeating sequence or saw tooth carrier signals of switches *S1* and *S2* have 180^0 phase shift is used. I controller is implemented here. The error between output voltage and the reference voltage is fed to the voltage-loop. The generated error sum given to the fuzzy controller. In fuzzy controller we need to build fuzzy rules as per our requirement as shown in figure 12.Where as the fuzzy input and output as shown in figure 9,10,11 respectively.

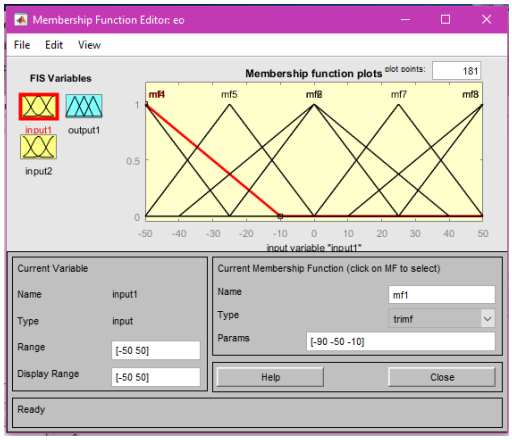

Fig 9.Fuzzy input 1

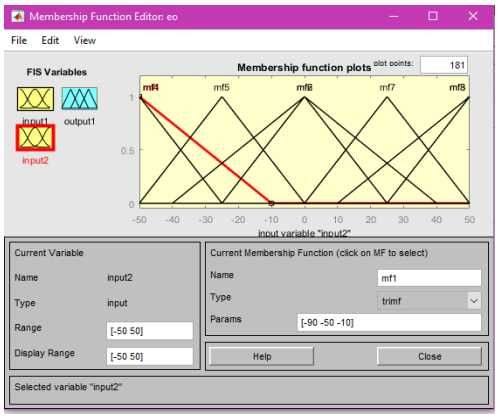

Fig 10. Fuzzy input 2

Fig11. Fuzzy output

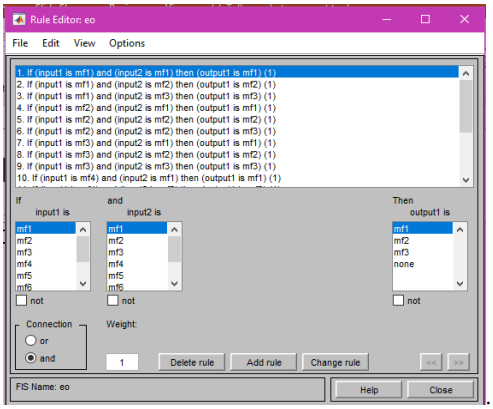

Fig12.Fuzzy rules

V. SIMULATION RESULTS

Simulations were done here for 14V as input voltage and 36 V as the output voltage. Inductance is set as .37mH for all the inductors. Input voltage is in phase with the input current. Power factor is 0.997.

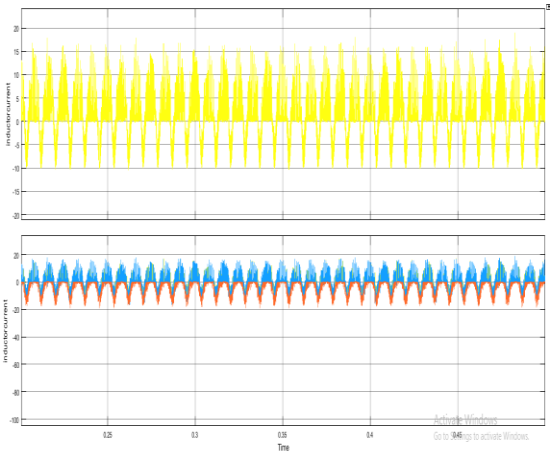

Fig 13. Inductor current

PARAMETER	VALUE
INPUT VOLAGE	14 V
OUTPUT VOLAGE00	36 V
INPUT INDUCTOR	.37mH
OUTPUT INDUCTOR	.37mH
SWITCHING FREQUENCY	30KHz

Table1 . simulation parameters

Figure 13 demonstrate the waveforms of inductor current. Waveforms of input voltage and output voltage are shown in figure 15 .The waveform of switching pulses as shown in figure 14.

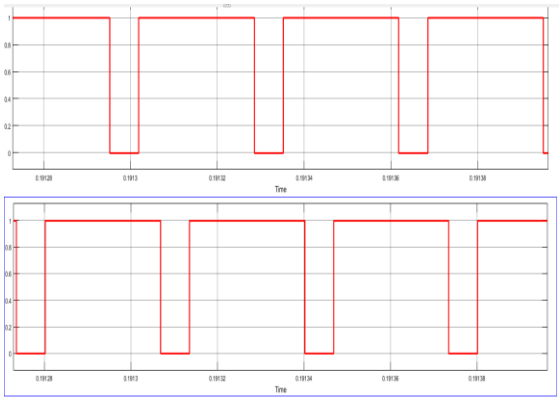

Fig 14. Switching pulses

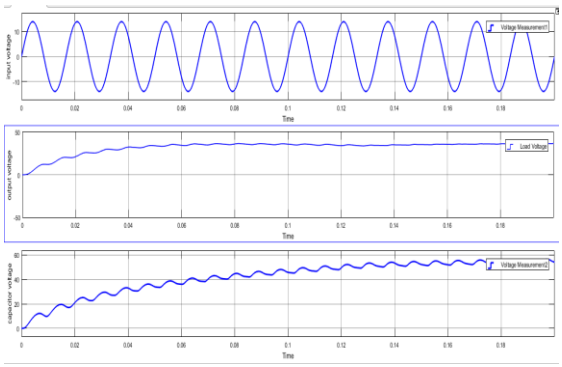

Fig 15. Input output and capacitor voltage

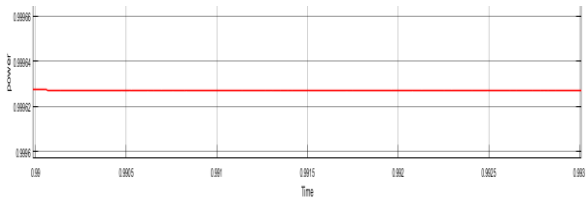

Fig 16. Power output

.

Converter can be used for a large range of input voltages as per our requirement.If the input voltage is 14 V, the output voltage can be boosted to 36V.Limits of output voltage can be varied with input voltage. The output voltage is regulated to 36V, and the output power is 13W with power factor measured as 0.997 and 96% efficiency.

VI. CONCLUSION

This paper proposed a modified power factor pre regulator converter with coupled inductors to provide output voltage with high efficiency and power factor for electric vehicles. Power level can be made increased by interleaving SEPIC converters. The maintenance of high efficiency is achieved . By coupling the inductors reduces the magnetic components can be decreased and decreases the ripples in voltage and current. MATLAB simulation based results proved the effectiveness of the proposed System, compared to the existing system.

***Abstract*— Auscultation is very important to physicians for accurate diagnosis of many heart diseases. Physicians need extensive training and experience in identifying and differentiating the main signs of cardiac diseases based on the heart sound that is being heard. It is essential to continuously monitor the heart activity and transmit the data to a remote centre for analysis. A modern cardiac monitoring system dependent on remote detecting to screen and investigate the cardiovascular condition is presented with the utilization of Internet of Things (IoT) which sends the data to the doctor. The system is low cost, easy and power efficient. The latest MQTT (Message Queuing Telemetry Transport) data protocol is used for data transmission. On the signal analysis part, Empirical Mode Decomposition method in conjunction with Hilbert-Huang Transform is used to realize preprocessing. Heart sound segmentation is done with efficient and accurate combined adaptive threshold method which forms a basis for feature extraction and classification to extract useful physiological parameters from heart sounds.**

Keywords— ***Auscultation, Combined adaptive threshold, Empirical Mode Decomposition, Hilbert-Huang Transform, Internet of Things, MQTT***

I. INTRODUCTION

Early and accurate detection of cardiac illnesses is important to limit deaths caused by cardiovascular diseases. To prevent serious health problems, diseases caused by abnormal heart valves and functions require appropriate detection. Cardiovascular diseases are the number one killer globally and is one of the leading causes of attack in the world. But the death rate depends on where you live. Cardiovascular diseases are the major challenge in worldwide.

Hypertension, high cholesterol and tobacco smoking are some of the risk factors that lead to cardiovascular diseases. The heart diseases can be categorized in to blood vessel diseases, arrhythmias and congenital heart defects [1]. Auscultation is one of the most used techniques for this purpose. Auscultation of the heart can provide clues to the diagnosis of many cardiac abnormalities [2]. It is the action of listening to sounds from the heart, lungs, or other organs typically with a stethoscope as a part of medical diagnosis. It is performed for the purposes of examining the circulatory and respiratory systems, as well as the gastrointestinal system. Auscultation of heart sound is dependent on personal opinion. It relies upon involvement, aptitudes and hearing capacity of the doctor [3].

Cardiovascular diseases (CVD) are the principle causes of death worldwide [4]. Cardiovascular Disease is a class of illnesses that include the heart or veins. Cardiac monitoring is very important and it leads to death if proper monitoring is not there. It is different from hemodynamic monitoring. Most of the cardiac diseases can be predicted by monitoring ECG with the help of electrodes placed on chest or limbs. Therefore, continuous monitoring of ECG is becoming more and more important in both home health care and hospital to prevent diseases related to heart and detect characteristic signs for patients with uncommon events [5].

Normally heart auscultation is done using stethoscope. Electronic stethoscopes are the ones which provide convenient result. The sensors used in electronic stethoscope can be microphone, piezoelectric, capacitive type etc [6]. The most widely used sensor material is piezoelectric. There are many electronic stethoscopes which reduce the ambient noise but the cost is high. Compared to electronic stethoscope digital stethoscopes are more accurate but the cost is very high which is not affordable. However, heart auscultation using stethoscope requires clinical expertise. It is critical to screen and dissect the cardiovascular condition which sends the data to expertise with the utilization of IoT. It is essential for the doctors to diagnose the diseases accurately by analysis of ECG signals. The noise in the ECG signal should be removed otherwise it will interfere the doctor's diagnosis. Many algorithms exist for the signal analysis of heart sound. For signal analysis, mainly three steps are there: preprocessing, feature extraction and classification. Heart sound signals recorded with electronic stethoscope are with external and internal noises. Noises can be due to motion, speech, digestion, respiration etc. Hence preprocessing is essential. Segmentation and classification are the two major challenges in the automated heart sound analysis.

The paper is structured as follows: Section II describes the details of previous works. Section III presents an introduction to functions of Heart and ECG. Section IV presents an overview of system design with the help of block diagrams. Section V describes the details including methodology. Section VI describes the details of experiment and results. Finally, conclusion is described in Section VII.

II. RELATED WORK

Nowadays Internet of Things or IoT is influencing our lifestyle. IoT is a giant network with connected devices. These devices gather and share data. IoT provides a common platform to dump the data. IoT is a combination of hardware and software technologies along with embedded devices which enables to provide facilities and services to anyone, anytime, anywhere using network. Most of the researchers had adopted Bluetooth technology, Zigbee or Radio Frequency Identification for monitoring patient's health and transmitting collected data to distance location. These methods are also meant for short distance communication. There are many cardiac auscultation devices that collect heart sound signals and transmit to a computer for further signal analysis.

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

Researchers had adopted many methods for the segmentation of heart sounds as part of signal analysis. Liang et al. recognized S1 and S2 utilizing the Shannon envelope [7]. Wang Xinpei et al. proposed a division technique dependent on Shannon entropy [8]. The segmentation results are not good when noise and interference occur with the above mentioned methods. Ting Li et al. proposed a segmentation method based on cyclostationary envelope [9]. Here segmentation results are more accurate but single threshold method [10] is adopted which had many shortcomings.

This research work presents an advanced heart observing framework dependent on remote detecting for human medicinal services. The system mainly consists of an acquisition module which includes heart sound sensor, a microcontroller board, a microprocessor board and signal analysis part. With the most recent innovation of Internet of Things, clients or specialists can get the prompt response of heart and yield medical intervention. The latest MQTT data protocol is used for transmitting data from one client to another client. This is the most efficient method and the overall system consumes low power and low cost. Signal investigation part incorporates preprocessing, division, highlight extraction and characterization of heart sound sign. EMD method is used to eliminate noises. The EMD method was first proposed by Huang et al. in 1998 [11]. Hilbert Huang Transform (HHT) together with double threshold was implemented for the preprocessing and feature extraction of the signals. This method is explained in detail in H. Ren et al. [12]. Later to improve accuracy, combined adaptive threshold method was adopted [13].

III. FUNCTIONS OF HEART AND ECG

The heart is the engine at the centre of the body's circulation system. The heart is really two pumps in one, working in a continuous cycle. The right side siphons blood to the lungs, while the left side gets blood again from the lungs, then sends it round the rest of the body. The heart pumps out about a cupful of blood about 70 times a minute, speeding up when necessary to meet body cells' increased demand [14]. There are two upper chambers, called the right and left atria, and two lower chambers, called the right and left ventricles. The blood flows in to the atria. The heart muscle is relaxed and blood enters the upper left and right heart chambers. The two atria contract and squeeze blood in to the chambers below them (ventricles). Lastly the ventricles contract and force blood either to the lungs or around the body. There are mainly four locations on the chest wall where these vibrations are more audible. They are Aortic area, Pulmonic area, Tricuspid area and Mitral area.

The heart sound includes four principle sections: the main heart sound (S1), the systolic interim, the second heart sound (S2) and the diastolic interim. At the point when a solid heart pulsates, it produces "lub" "dub" sound. The principal heart sound, "lub", is brought about by the conclusion of the mitral and tricuspid valves toward the start of ventricular systole. The second heart sound, "dub", is brought about by the conclusion of aortic valve and pulmonary valve toward the finish of ventricular systole. Murmurs are typically slosh sound that demonstrate reverse through the valves. S3 and S4 are a "ta" sound that shows ventricles that are either excessively frail or excessively hardened to adequately siphon blood. It can't close or open appropriately. The heart sound segments are shown in in Fig. 1 [15].

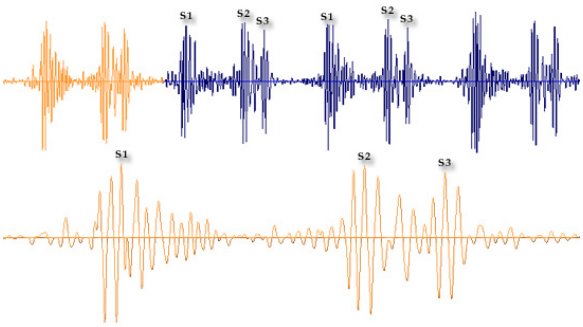

Fig. 1. Heart sound components

An electrocardiogram (ECG) is a tool which is used to visualize the electricity flowing to the heart. The typical electrocardiogram is made out of a P wave, a QRS complex and a T wave. Fig. 2 shows a typical ECG signal.

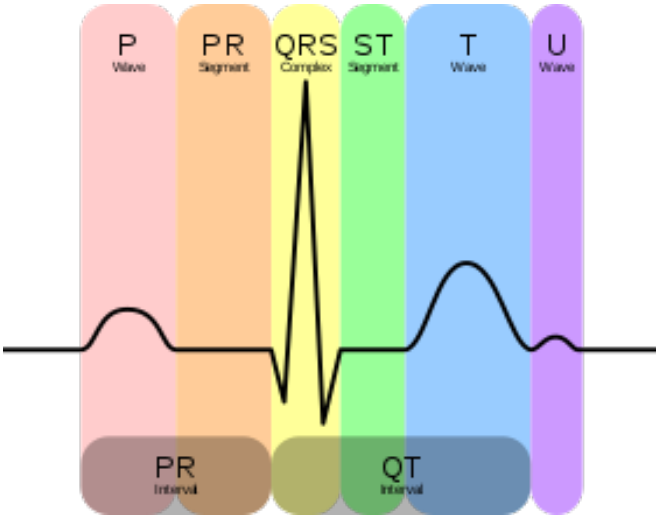

Fig. 2. A typical ECG signal

The P wave is suggestive of the atrial contraction. The first negative deflection is the Q wave, then R and the S wave. The QRS complex denotes the ventricular systole followed by the T wave. The T wave denotes the ventricular diastole. The PR segment is called the iso-electric line of the ECG which is also called the baseline. This is the baseline which compares the ST elevation and ST depression. The PR tell us the AV (Atrioventricular) conduction time. QRS complex is the graphical representation of electrical activity of heart when the ventricles are undergoing the process of depolarization. S1 and S2 corresponds to QRS complex and T wave respectively.

Continuous monitoring of ECG has become an important tool in diagnosing cardiac diseases. Modern ECG machines measure ECG signals in the bandpass of 0.05Hz to 100 or 150Hz. The abnormal sound mainly falls in the region 100-600Hz which can go up to 1000Hz. The heart sound signals together with noise are transmitted wirelessly to remote

centre so that the users or doctors at the other end can diagnose the heart sound signals after signal analysis.

IV. SYSTEM DESIGN

The complete cardiac monitoring system consists of heart sound sensor, the processing element and signal study part. The microcontroller and the microprocessor board together is called the processing unit. The output from the heart sound sensor is given to a microcontroller which digitizes the output value. The microprocessor transmits the information from microcontroller to server. From the server, data is transmitted to the remote client using MQTT data protocol. In the remote centre, signal analysis part is carried out in the PC which includes preprocessing stage (denoising and segmentation), feature extraction and classification of heart sound signals. Fig. 3. indicates the block diagram of complete cardiovascular observing framework.

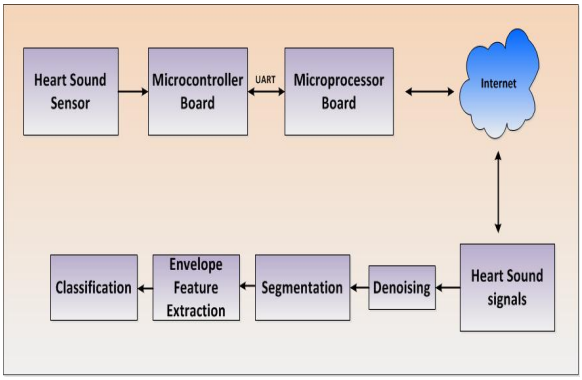

Fig. 3. Complete cardiac monitoring system

The heart rate sensor alongside the securing module measures electrical action of heart through the cathode pads placed on the skin. Here AD8232 is used as the sensor. It will be a little chip which measures the electrical action for heart. Furthermore, it is a single lead heart rate screen front end. If the distance from the AD8232 to the heart is shorter, then there will be less common-mode interference. The output of the board is analog value. The specifications of heart sound sensor are mentioned in Table 1. By connecting this board with Arduino, ECG graph is obtained through transforming IDE window. Heartbeats were recorded at 16-bit accuracy and stored as wav format. The function of Arduino (microcontroller board) is to convert the analog value to digital. Arduino Uno is a general purpose microcontroller board based on the device ATmega328P and has 14 digital input/output pins and 6 analog inputs. Arduino microcontroller have 32KB flash memory. The clock speed is 16MHz and draws less current. The Arduino board is communicated to Raspberry Pi via UART.

Raspberry Pi collects all information from Arduino and finally transmits to the server. Raspberry Pi is used as the microprocessor board. The Raspberry Pi is a credit card sized single board computer which is running a Debian based OS - Raspbian. The Raspberry Pi 3B+ uses a Broadcom BCM2837 SoC with a 1.4 GHz, 64-bit quad- core ARM Cortex-A53 processor, 1GB of SRAM, 2.4GHz and 5GHz integrated Wi-Fi, consuming ultra-low power of 800mA (4.0 W). When the microcontroller is turned on, it will initialize the serial port, for establishing communication with the Raspberry pi computer. It also initializes all necessary digital and analog input and output pins for the proper controlling. The microcontroller listens the serial port for any incoming commands from Raspberry Pi computer, which in turn listens commands from internet.

MQTT data protocol is used for transmitting the heart sound signal. The MQTT protocol is a light weight publish/subscribe informing protocol planned for M2M (machine to machine) telemetry in low bandwidth situations.

Table 1. Specifications of Heart Sound Sensor

Heart Sound Sensor AD8232	
Voltage	2V to 3.5V
Current	230µA
Output	Analog Value

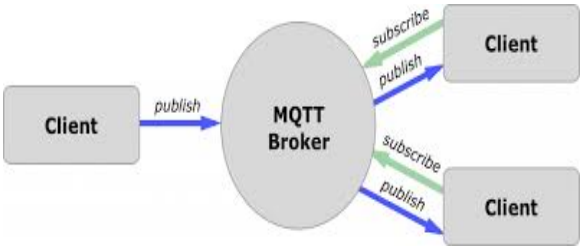

Fig. 4. MQTT protocol

It is useful for connections with remote locations. MQTT may be quick getting to be a standout amongst the fundamental conventions for IoT deployments. Fig. 4. shows how clients in the remote locations uses publish/subscribe messaging model with the application of MQTT server. MQTT is one of the widely used protocol in IoT applications. Its low power usage, less data packet and easy to implement make it ideal for machine to machine or Internet of Things world. It is based on a messaging technique. MQTT is based on clients and server. The server is called a broker and the clients are the connected devices. The MQTT protocol is implemented by using the Mosquitto which is an open source message broker.

The heart sound signals contain external and internal noises which interfere in the final diagnosis. Hence preprocessing is essential. So signal analysis part plays an important role in this. There are many Time-frequency distribution (TFD) methods adopted in signal processing. Some of them are approach based on mathematical model, method based on STFT (Short-time Fourier Transform), Wavelet Transform (WT) based TFD, generalized TFDs in the Cohen class (GTFD). These processing methods have some limitations [16]. So a suitable method should be implemented for heart sound signal analysis.

Hilbert-Huang Transform (HHT) is a time frequency method which is widely used. This is the most effective

method and many researchers have applied in the heart sound signal analysis [17]. There are predominantly two sections in Hilbert Huang Transform: Empirical Mode Decomposition (EMD) and Hilbert Transform. EMD is a time series technique, in which entangled informational indexes can be decayed in to a limited number of Intrinsic Mode Functions (IMFs). transform. For complicate data there should be more than one independent component at any given time. The decomposition should be adaptive in order to study data from nonstationary and nonlinear processes. The adaptive method will represent the characteristics of the signal better. Hilbert Transform offers meaningful Instantaneous Frequency for IMFs.

V. METHODOLOGY

Prior to division, the envelope of the heart sound sign must be separated. Hilbert Transform alone won't be adequate for extricating the envelope of heart sound sign. The Hilbert transformed amplitude oscillates too much. Hence before envelope construction, the signal should be decomposed. The envelope makes sense for each IMF. So Hilbert Huang Transform technique is implemented.

An IMF ought to fulfill the accompanying necessities: The quantity of most extreme and least focuses and the quantity of zero intersections should either be equivalent or their distinction must be one for the full informational collection, and the mean estimation of envelope for the nearby maxima and neighborhood minima ought to be zero.

The signal can be decomposed by applying EMD based on the following assumption [18], which is also depicted in the flowchart shown in Fig. 5.

1. Consider the signal x(t). Identify all the global maximum and global minimum points of x(t). At that point discover neighborhood most extreme and nearby least focuses with the goal that every one of the information are situated between the lower and upper envelope. Obtain the mean curve. Let it be m(t). Then we find the difference between x(t) and m(t) as:

$$x_1(t) - m_1(t) = c_1(t) \qquad (1)$$

where $x_1(t)$ is the original signal and $c_1(t)$ is the first IMF component.

2. $c_1(t)$ becomes the next original signal which is denoted as $x_2(t)$ and find the difference.

$$x_2(t) - m_2(t) = c_2(t) \qquad (2)$$

Here $c_2(t)$ is the next IMF component.

3. The above process is repeated and we define r = $c_k(t)$.

The methodology of extricating one IMF part is filtering. It is represented as

$$x\,(t) = \sum_{k=1}^{n} C_k + r_n \qquad (3)$$

C_k is one of the IMFs changing from C_1 to C_n and r_n is the residual signal.

The sifting procedure stops with a stoppage criteria S and SD. S is defined as the consecutive number of siftings. SD is represented as:

$$SD = \sum_{t=0}^{T} \frac{|h_{k-1}(t) + h_k(t)|^2}{{h_{k-1}}^2(t)} \qquad (4)$$

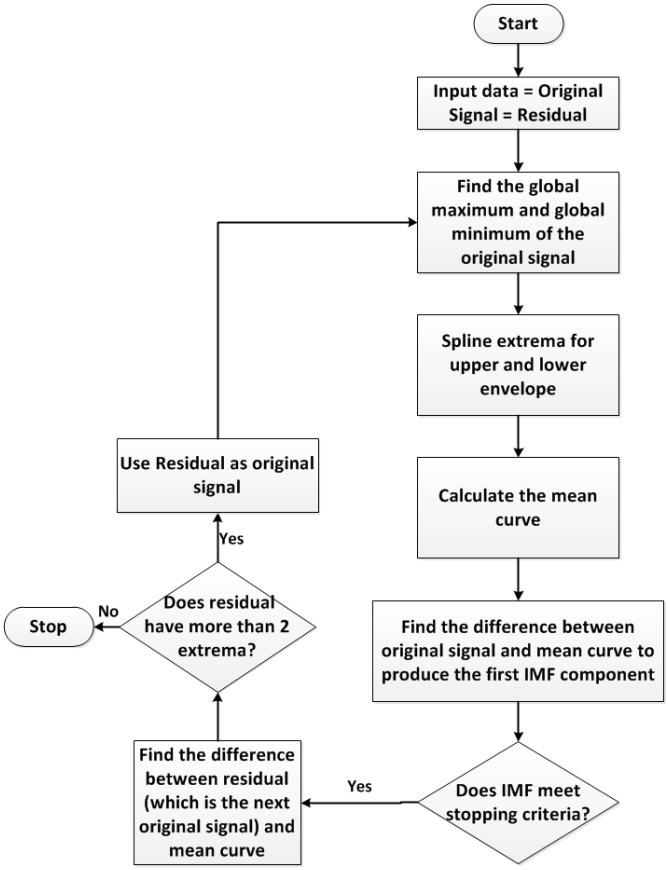

Fig. 5. Flowchart of EMD filtering process

The value of SD ranges from 0.2 to 0.3 [19].
The complex-valued function of heart sound can be expressed as:

$$X_k(t) = \mathrm{c}_k(t) + \mathrm{jH}[c_k(t)] \qquad (5)$$

All IMF enjoy good Hilbert transform:

$$c(t) = a(t)e^{i\theta(t)} \qquad (6)$$

In the Hilbert spectrum analysis, the original signal can be represented as:

$$x(t) = \mathrm{Re}\sum_{k=1}^{n} a_k(t)e^{j2\pi\int f_k(t)dt} \qquad (7)$$

where $a_k(t)$ is the instantaneous amplitude and is represented as:

$$a_k(t) = \sqrt{|c_k(t)|^2 + |H[c_k(t)]|^2} \qquad (8)$$

The most challenging task in the signal analysis part is the heart sound segmentation. The primary operation of segmentation is to detect the boundaries of S1 and S2 discover the begin and end focuses. Selection of threshold value is critical. The threshold may vary for individuals or depending on the cardiac disease. The threshold is mainly dependent on the time interval and the result will be largely influenced by noise peaks. There should a method where accuracy is higher. So we have chosen combined adaptive threshold method. The combined adaptive threshold method is a combination of three independent thresholds.

$$MFR = M + F + R$$

where M indicates versatile soak slant edge, F signifies versatile coordinating edge and R means versatile beat desire edges. The first threshold sets a slew rate value that has an ability to change to suit different conditions, a second one emerges when high recurrence happens and a third one determined to abstain from missing of low sufficiency beats.

VI. Experiment and Results

The information from 10 healthy subjects were gathered utilizing the proposed cardiovascular monitoring framework and this was a non-clinical examination. The test setup of the monitoring system is shown in Fig. 6.

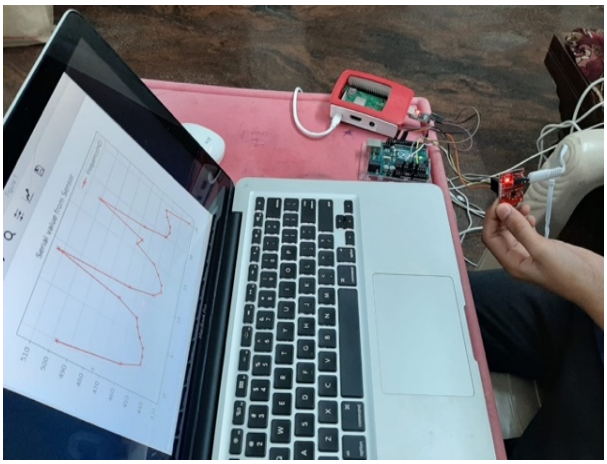

Fig. 6. Real time monitoring System

The data obtained from real time data acquisition is shown in Fig. 7. The data acquired through the processing unit is then transmitted to another client i.e., publish and subscribe of data through MQTT server is implemented here. This is shown in Fig. 8. Aside from this, both typical and irregular heart sound chronicles from the database Physionet/Computing in Cardiology (CinC) Challenge 2016 [20] are utilized to approve the exactness of categorization. The heart sound accounts last from a few seconds to up to more than one hundred seconds. The sum total of what chronicles have been resampled to 2,000 Hz and have been given as .wav group. 50 datasets from normal and 50 from abnormal are selected from the database. Further signal analysis is done in the PC.

The heart sound obtained from 10 healthy subjects was converted to .wav format and transmitted using the MQTT data protocol. These were plotted at the receiving end and found that all were normal beats. The accuracy of the system is 100%.

The decomposition results for the normal and abnormal heart sounds are presented in Fig. 9. The x-axis indicates the samples and y-axis indicates the amplitude in volts. Here the number of IMF shown is 2 with the residual value. All IMF components are the sum of spline functions. Natural cubic spline is used to maintain the smoothness.

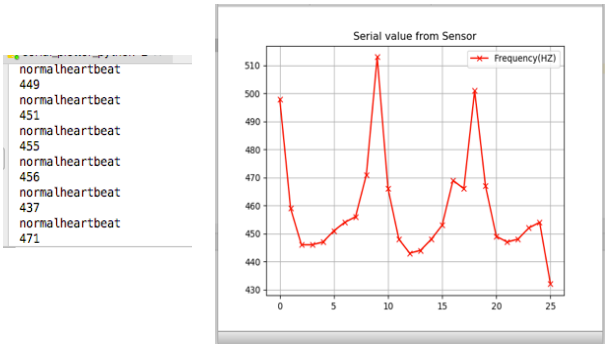

Fig. 7. Data obtained from the real time monitoring system

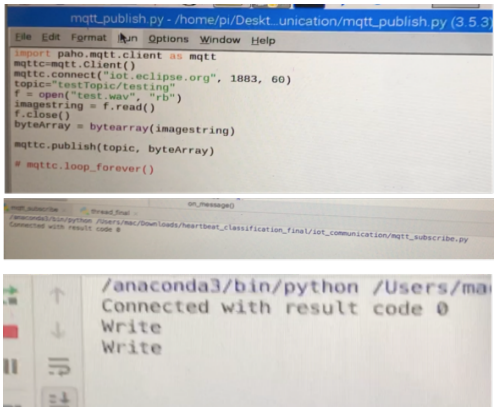

Fig. 8. Data transmission through MQTT server (MQTT publish and subscribe)

Fig. 10 and Fig. 11 shows the Hilbert spectrum for normal and abnormal heart sound respectively. The Hilbert spectrum shows that the normal heart sound frequencies are below 150Hz and that of abnormal are below 1000Hz.

The heart sound segmentation results are shown in Fig. 12. Complete algorithm is developed in Python programming language. The running time of the algorithm is less than 30seconds. The configuration of the computer used is 4 GB RAM, MacBook Pro macos Sierra, 2.5 GHz Intel Core i5.

Feature extraction has a significant role in categorization of heart sound signal. Feature extraction is the method of identifying distinguishing features of the signal. In this research work features are extracted from the time domain. Here Ta is considered as the time gap of first heart sound S1. Tb is considered as the time interval of second heart sound. Ta1 is the time gap from the start of first heart sound of one

cardiac cycle and start of first heart sound of next cardiac cycle. Ta2 is the time gap from the beginning of first heart sound S1 and last part of second heart sound S2 of the same cardiac cycle. These are considered as the highlights for heart sound characterization. So by calculating the appropriate time difference, the heart sounds are classified as normal and abnormal heart sound.

Out of 50 abnormal heart sounds, 48 were correctly identified as pathological. The heart sound sign investigation calculation assessed the typical heart sound exactness to be 100% and anomalous heart sound exactness as 96%.

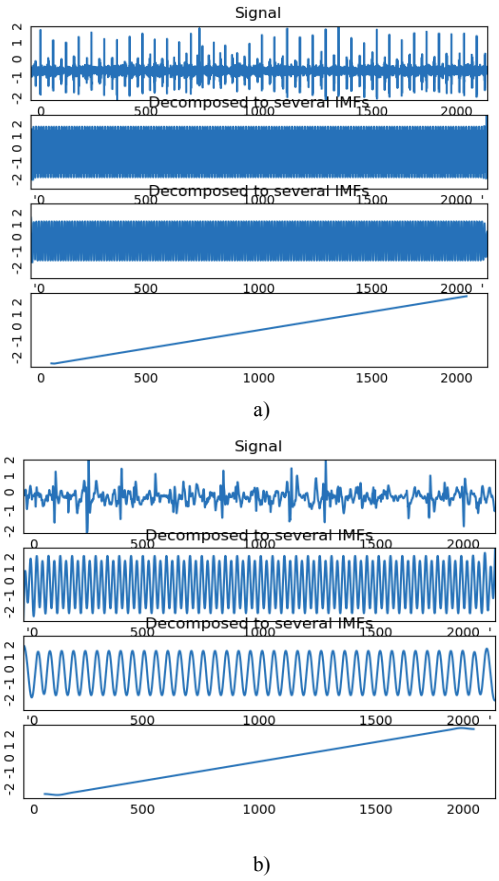

Fig. 9. Decomposition results (a) Normal heart sound (b) Abnormal heart sound

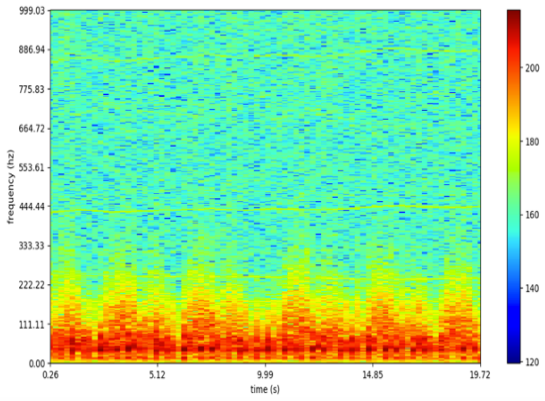

Fig. 10. Hilbert spectrum for normal heart sound

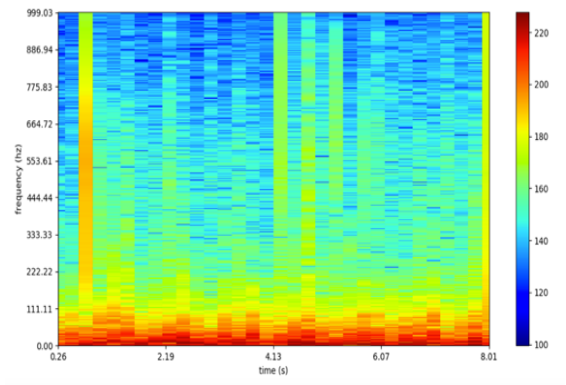

Fig. 11. Hilbert spectrum for abnormal heart sound

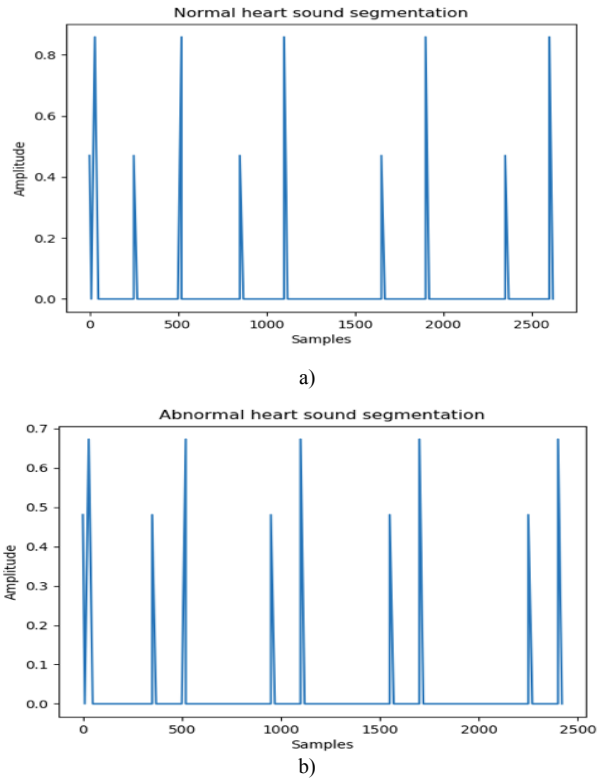

Fig. 12. Segmentation results (a) Normal Heart Sound (b) Abnormal Heart Sound

VII. CONCLUSION

A modern heart observing framework dependent on remote detecting for human medicinal services has been developed. The heart sound is acquired using a simple acquisition module and the processing part is implemented using low cost, low power hardware. The wireless technology is also simple to implement. The MQTT data protocol, which is the latest technology in IoT, is easy to configure and long distance transmission is possible. The signal analysis part was the challenging task. Efficient algorithm for the categorization of normal and abnormal heart sounds is developed using Python programming language, which is faster in execution. Accuracy of 96% is achieved for the abnormal heart sound. The future extent of the framework is to improve the heart sound acquisition module so that it can

be utilized for clinical investigation and furthermore separate the distinctive cardiovascular maladies.

ACKNOWLEDGMENT

The authors would like to thank the Principal and Head of the Department, Electronics and Communication, College of Engineering Trivandrum for providing the facility and support for completing this research work. Also thank the Head of the Department, Cardiology, Medical College, Trivandrum for their guidance.

***Abstract*— With the rapid advancement of mobile phones and low cost, fast internet access students/learners are using smart phones for learning purpose also. Mobile learning (m-learning) has been recognized as a competent method of seeking knowledge. As the quantity of users and lecture video contents is increasing, how to deploy m-learning becomes dubious because of limited memory space in mobile phones. The learning materials like ppt., docs, occupy less space but lecture videos consumes a lot of memory in a mobile device. Therefore there should be some measure where students can store as well as access lecture videos. Hadoop has been evolved as a promising technology to overcome the problems in m-learning. It provides reliable, customized environments for end-users. We present a new mobile application for a mobile learning system integrated with Hadoop, for storage and retrieval of lecture videos from mobile phone to the Hadoop Distributed File System (HDFS). Registered user of the application can perform the functions like upload video, search a video file and download a video file. We have calculated computational time to upload, search and download various size of video file (maximum size is 1.3 GB). The proposed application can be utilized where there is a high demand of exhaustive teaching and learning in higher education.**

Keywords*— Mobile learning, Hadoop, Hadoop Distributed File System (HDFS).

I. INTRODUCTION

With consistent development of internet technology and low cost of mobile phones users have started using it in learning purpose as well. This have increased the size of video data in mobile and due to the low storage power of mobile phones it is not possible to store each and every video in mobile phones. So there is a need of such solution which can provide user to store video data and can easily access or retrieve data when required latter on. One such solution which can resolve such problem is Hadoop, it has achieved remarkable acceptance due to its attributes like, low cost, easy accessibility, fault tolerant, distributed storage and processing , highly scalable [1].

Various researchers have used Hadoop in numerous applications like video Processing [2], query processing [3], video transcoding [4], post event investigation [5], video surveillance [6][7], traffic measurement[8] , event detection[9], face detection[10] and Content Based Image Retrieval [11]. Therefore this gives us motivation to develop a mobile application which can perform the following functions:

- User can send lecture video data from mobile to the Hadoop Distributed File System(HDFS)
- User can retrieve video data when required
- User can download video data easily

Storing video data into HDFS is a challenge as Hadoop was originally designed for text processing [1] so storing video files in HDFS is a challenge for the researchers. Remaining paper is structured as follows: section 2 consists of review of research which is carried out using Hadoop, section 3 discusses the proposed work and section 4 presents experiment and result, finally followed by the conclusion.

II. LITERATURE REVIEW

As data is growing continuously, so to efficiently store and process this consistently increasing data is a challenge. Hadoop which have evolved as a possible solution to this problem, is now been used in various applications which, engender enormous data. A lot of research has been performed by various researchers on how to use Hadoop best for storage and processing, either by changing the architecture of HDFS for increment in processing of mapreduce tasks or by designing efficient algorithms[5] to store data into HDFS, which can be retrieved easily. Apart from this many researchers have used Hadoop for video processing [12] task, video segmentation purpose [2], motion estimation in surveillance videos [13], multi-view object recognition [14].

A video monitoring system that can handle, the users' request of searching video, uploading video, downloading video and trans-coding video is presented in[6]. They also used FFMPEG to trans-code video. A Hadoop based recorder system is proposed in [15] which provides extensible video recording system, data backup, monitoring features and moreover they have used HDFS for storing data. Other video monitoring application proposed where Hadoop is used [16], for extracting metadata (its attributes are vehicle enter time, license plate recognition, type of vehicle) and correction of surveillance videos.

A framework for video playing and storage based on Hadoop is discussed in [17]. It supplies simultaneous access and playing streaming media in mobile phones. A Hadoop-based storage architecture for tremendous MP3 files is proposed in

[18]. Classification algorithm is used in pre-processing component to combine small files into sequence files. They validate that the effective indexing method is excellent quick fix to the issue of small files storage.

Among the huge amount of video data in internet the majority of files are copy of original videos, [19] have attempted to develop a real time video copy detection using Hadoop, they have designed two copy detection algorithms and then they have compared the performance of both the algorithms by implementing on Hadoop platform.

Various researchers have worked in the area of E-learning like reducing data size of e-learning videos [20], generating a time shrunk video by event detection [21], converting e-learning video which consists of power-point presentation into pdf format, enhancing lecture content [22][23] etc. The size on internet data comprising of images and video so [24] uses Hadoop for storage and processing of mass multi-media files for storage. Hadoop has been used for searching lecture videos, it provides list of lecture videos relevant to the user query [25]. But as far as e-learning mobile applications is concerned not many researchers have utilized Hadoop for storing and processing mobile data. So integration of mobile with Hadoop for storing and processing mobile video data is still a challenge.

III. Architecture of Mobile Application

Due to low cost internet and smart phones, students have started using mobile phones for accessing lecture (e-learning) videos, doc files etc for reading purpose, but due to its low memory size it is not possible to store each and every data in it. To resolve this issue we have proposed an android application integrated with Hadoop, where user can store data like e-learning videos. Data Stored can be accessed by other users when required. The components of our proposed application are as shown in fig. 1, it consists of mobile phone in which android application is installed and then the essential learning data i.e. video files is send to the server and third component is the Hadoop HDFS, where data resides and user can access data when required.

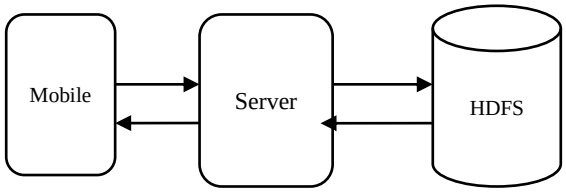

Fig.1 Components of mobile application

A. Mobile Application

We have developed a mobile application which connects with web server and further transfers data to the HDFS. The use case of mobile application user is shown in fig.2, firstly user has to login to perform any operation if user is the registered user then he is directed to the next page where he can perform following functions like upload video file, search a video, download a video. If the user selects an upload video file then again he is directed to the next page where user is asked to select the category like General Awareness, Computer Science, Electrical, Management etc. User selects the category and uploads video. If user selects searching video, then again he is asked to select the category of the video, user selects the category and finally the list of videos related to the category along with the download button is displayed. User clicks on download video option. Video is downloaded into the user mobile device.

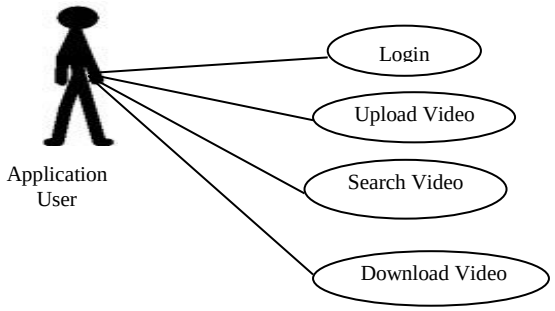

Fig.2 Use cases diagram of mobile application

B. Video Upload & Storage

Multi-media files like images which are usually small in size can be stored in Hadoop, by first converting images into sequential files and Hadoop Archive, CombineFileInputFormat[26], whereas video files are larger in size and some measure have to be done for storing. By default size of a data block is 64MB therefore storing video files becomes challenging as most of the video files are larger than the default size. If file is to saved then it is segmented [2][23] and then stored into various block. Video files is unstructured data so if any encoding scheme is applied to it then it can lead to correlation between video frames. If files are directly stored in HDFS then there is no purpose of using Hadoop for storage and processing. So it is very necessary to store files by first splitting them into various blocks.

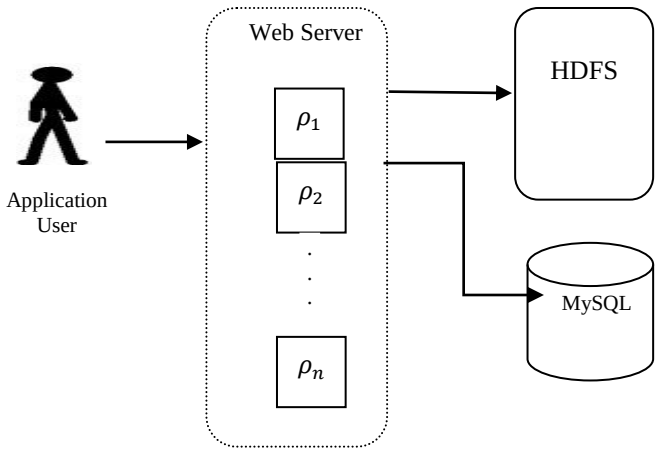

Fig.3 Video Storage Architecture of application

We have used FFMPEG [27] method for splitting video files into ρ segments. We have set size of every segment as ∅, where ∅ = 256MB as lecture videos will be of more than 1 GB, video storage architecture of our application is shown in fig. 3. When user needs to upload a video file, he selects video file, and the category video belongs to, then in the server side FFMPEG converts video file into various segment, and these segments are send to the HDFS, the information about the name of segment, category it belongs to and its HDFS location is stored in a MySQL database.

The segmented video files are stored in such a way that it is easier to access video files. Let's say name of video file is Fundamentals then the segmented video file is named as Fundamental ρ_1. Segmented video files are stored in various DataNode in HDFS, for every segmented file 2 more replica is stored in HDFS so that one of the DataNode fails then data and HDFS can work in spite of the failure. Moreover while uploading video user is asked to select the category of video i.e. which type or which category video file belongs to, this is done for easy accessibility of video files.

C Video Search & Video Retrieval

If the user wants to search any video then he clicks on search button, selects the category, list of videos related to the category along with a download button is displayed. User clicks on download button, with the help of FFMPEG segment video file are merged together and a video file is downloaded into the user mobile device. When user enters for the file name to be searched then *Map* divides the task to various *reducers*, *reducer* then finds the various segment of video files then again FFMPEG merges all the video files and provides the list of video files related to the category selected by the user, MapReduce architecture is shown in figure.4.

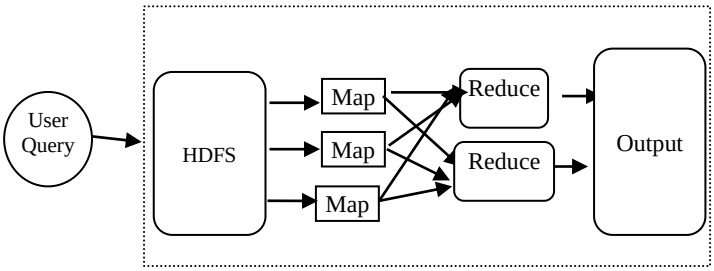

Fig.4 Video Search Architecture of application

IV. IMPLEMENTATION & RESULTS

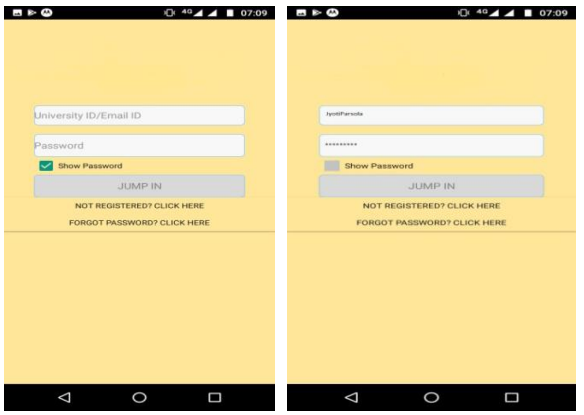
We have developed our mobile application in android studio version 3.3, the operating system we used for our work is Ubuntu.16.0.4, with 64 bit processor. We have used apache tomcat server which is an open source software implementation of the Java Servlet and JavaServer Pages technologies and eclipse with J2EE for server side programming, and the database used is MySQL. To test our application we have used Genymotion which provides emulator for testing android applications which works very much similar to the real device all the technologies and software used in our application is listed in table. 1. The prerequisite of our application is that both the application user and server should be in the same Wi-Fi range and second is whenever we have to use app, Hadoop have to be started using the shell command.

TABLE.1.TOOLS USED

S. No	Name of Tools	Version
1	Hadoop	2.9
2	Apache Tomcat Server	7.9
3	Eclipse with J2EE	3.7.1,SR1
4	Genymotion	2.10.0
5	MySQL	5.7.22
6	Android version	v8.0 Oreo

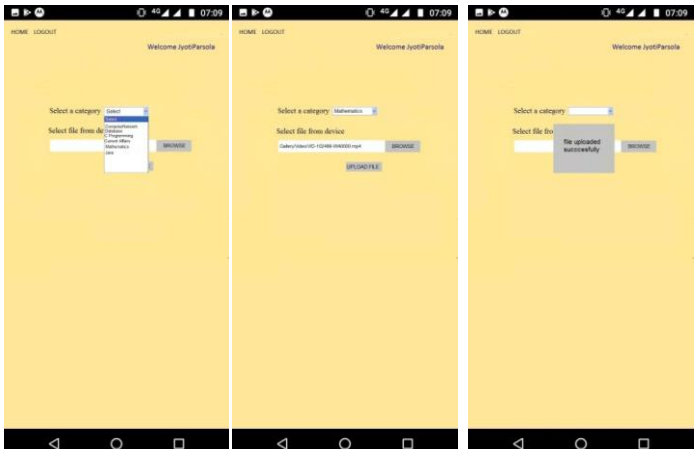
A. Video Upload

Working of our video upload module is shown with the screenshot fig.6. Initially when app launches it starts with the login page then user enters the credentials, if user is already registered then he is directed to the next page otherwise user have to register by filling the useful details like username, password, email id etc. Once user logs in, user can perform the following functions clicking on the buttons like upload video, search video, download video. User clicks on Upload Video button then he is asked to select category the particular video belong to, further with the help of browse button user can upload the desired video. A message is displayed that video is uploaded successfully.



(a) User Login (b) User entered credentials

(c) Task to perform (d) User selected upload button

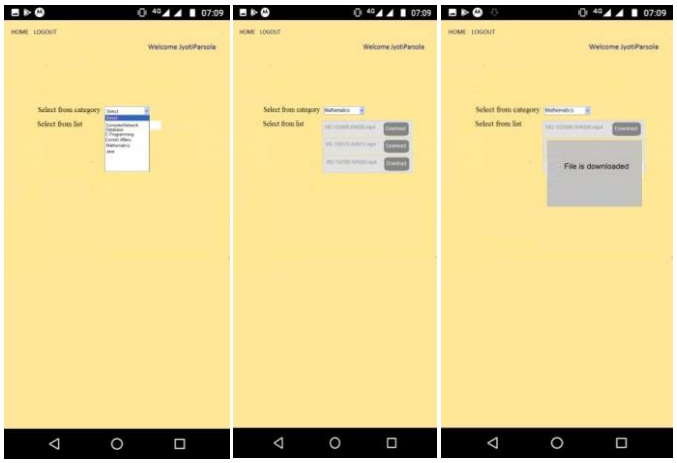


(e)User selected category (f)User has selected category and file from mobile device (g) File is uploaded successfully

Fig.6 Screenshots of our video uploading module of our mobile application

B. Video search and download file

If user wants to search a video in HDFS, user clicks on search video button, user is asked to select the category, once category is selected, the list of video related to the category is displayed along with the Download option and user is informed by message when video downloading is complete shown in fig 7, the same pages appears when user clicks on Download button in home page.



(a) User has to select query to search a video (b) List of video files is displayed (c) User downloaded the video file.

Fig.7 Screenshots of our video search and download module of our mobile application

TABLE. 1 TIME TAKEN FOR UPLOADING VIDEO

Data Size	Upload Time
538 MB	41 s
695 MB	52 s
762 MB	63s
793 MB	69s
853 MB	76s
1.32 GB	87s

Time taken by our application in uploading, searching and downloading video files of various sizes is shown in table.1, table. 2 and table. 3 respectively. Moreover we have reduced the search time of a video file by varying number of reducers. Figure 8 shows how search time changes by varying number of reducers, it is evident from our result that, small data size do not require much reducers but, for large data size in order to reduce search time number of reducers have to be increased. Uploading and downloading time is less as compared to time taken in searching videos. Searching can be reduced further by applying a *combiner* in between *map* and *reduce* task.

TABLE. 2 TIME TAKEN FOR SEARCHING VIDEO

Data Size	Search Time
538 MB	623s
695 MB	722s
762 MB	771s
793 MB	783s
853 MB	815s
1.32 GB	986s

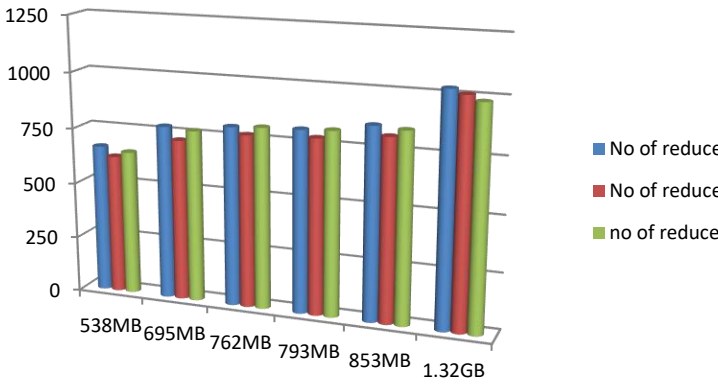


Fig.8 Search time by varying no of reducers

TABLE. 3 TIME TAKEN FOR DOWNLOADING VIDEO

Data Size	Search Time
538 MB	61s
695 MB	73s
762 MB	84s
793 MB	87s
853 MB	91s
1.32GB	128s

V. CONCLUSION & LIMITATION

With the easy access of internet technology and low cost of mobile phones students are using mobile phones for learning purpose by watching lecture videos in their smart phones. Due to less memory space it is not possible for user to store each and every video data in mobile phone, therefore to address this problem we have used Hadoop for storing lecture video. In

this paper we have successfully integrated Hadoop with mobile application, for storage and processing of mobile video data into HDFS. Through this application user can upload a video and store that video into HDFS, search a video and download the required video as well. We have been successfully able to upload and retrieve a maximum of 1.3 GB of video data. The limitation of our work is that the application user and server should be in the same Wi-Fi range, and Hadoop has to be initialized using shell command, with further enhancement in the application user can easily access videos as well as the Hadoop server can be automatically started. Moreover we can further reduce searching time by applying a *combiner* in between *map* and *reduce* task

***Abstract*— Service-Oriented Computing(SOC) rapidly gains importance in the industry to built complex web service applications. The web service plays a very important role in SOC. Service composition is the process of adding services to the existing one using functional attributes of multiple services rapidly and effectively. One of the critical issues in the composition is non-consideration of Quality of service (QoS) parameters which can lead to inaccurate and low performing composite service. Next to selection tasks in the composition process is to allocate resource to selected services in composite service is also crucial. Resource allocation in the composition is the process of allocating component service to selected candidate service for each and every candidate services in composite service. In the cloud environment, component service holds physical computational resource or infrastructural resource. This paper, present mapping of resource allocation problem in composition to 0/1 Multi-dimensional knapsack problem which is NP-hard computational problem. The work in the paper provides the solution to the resource allocation problem with the help of a dynamic programming strategy. The computational simulation was carried out and revealed that the dynamic programming strategy as not suitable for a large number of services considered during the allocation process. Further development of the solutions for such problems should be attempted by applying various heuristics and meta-heuristics approaches. However, after analysis of these approaches, the work suggests to study and apply meta-heuristics to address this type of problems for an optimal solution with the feasibility.**

Keywords— Quality of Service, Service Composition, Resource Allocation, NP-hard Problem, 0/1 Multidimensional Knapsack Problem.

I. INTRODUCTION

In Service-Oriented Computing (SOC), the Quality of Service (QoS) is important for most service-based complex applications. Service composition is the process of adding services using functional attributes of multiple services rapidly and effeectively[1, 2]. In resource allocation for composite web services, a critical problem that must be addressed is to achieve the QoS for composed applications. Overcoming this issue raises two problems. First is resources assignment to every abstract web services(tasks) in the composite web service. The resource allocation problem is critical because it occurred in various research domains out of one is a service-oriented architecture (SOA). An effective way to allocate resources in SOA affects the performance of the web-based system. The resource allocation problem is that a given composite service containing candidate services, each candidate service to be allocated to at least one of the services from a set of component services. Here component service holds a resource. Finding the allocation technique to these resources in order to finish all candidate services is challenging under some set of constraints while satisfying expected QoS. An allocation of very few resources on a cloud computing environment to complete tasks is known resource allocation problem[3].

The resource allocation problem exists in the IoT environment, allocation of tasks to reduce energy consumption devices in it. Due to the use of cloud computing as a platform in IoT applications. Here also the allocation of the resources from the cloud is a challenging issue to address[4]. Cloud computing [5] is an Internet-based computing model where resources and applications are delivered as web services over the Internet are provided on demand as public utilities. This pattern provides a way for the organization to create new composite web services or complex applications.

II. RELATED WORK

Many approaches to solving resource allocation problem have been proposed. Service-oriented computing has attracted huge attention over the past few decades. However, QoS parameters were less addressed as compared to other parameters like duration and storage of computational resources.

In [6] K. Gaia proposed Reinforcement Learning technique using Dynamic Programming to solve the resource allocation problem optimally for IoT content-centric services. They considered Energy, cost and response time parameters in the technique they used. But in this paper authors did not address the feasibility of optimal solution in a large scale environment.

Also, they did not analyses the time complexity of the proposed algorithms.

In [7] C. Tsai presented a solution to the IoT resource allocation problem. The search economics mechanism is used to solve this problem as it is a way to search for the solution of the complex optimization problem. This work considers communication cost whereas other QoS Parameters are missing. The time complexity of the proposed algorithm is $O(n^2.h.iter^{max})$ where n is the number of subsolutions of a complete solution and h the number of regions the solution space is divided.

V. Angelakis et al. [8] focus on IoT devices and network interfaces have heterogeneity in nature which need various services to allocate. Here a resource allocation problem target at getting the best solution. Spiting interface of device and allocation of services to the spat interfaces is called a Service to-interface assignment (SIA) problem. In this paper, they stated this problem is NP-complete problem.

In [9] M. Liu introduced Resource Allocation for non-orthogonal multiple access based Heterogeneous IoT. To solve this problem optimally a deep learning based algorithm is proposed. Energy efficiency was the parameter for the study. Time complexity analysis is not done of proposed algorithms and QoS parameters were missing while optimization of the method.

In [10] A. Singh proposed a resource allocation mechanism using buffering, scheduling and rate limiting. The authors confirms to SLA requirement meeting. The System parameters for study were the capacity and enforcement period where QoS consideration was missing. The work did not focus on the objective to present an optimized algorithm for the best solution to the resource allocation problem.

K. Lee et. al. [11] provided a generic representation of the allocation problem. It is based on the heuristic multi-attribute combinatorial exchange approach which is suitable for large scale environments and greedy optimization methods. The objective of this work is the conceptualization, implementation, and evaluation of proposed mechanism but not to an optimal solution to the allocation problem. The parameters considered for study are energy and cost whereas some important QoS are missing.

Q. Lu et. al. [12] presented quantifying and optimizing the fairness and efficiency of heterogeneous resources as a challenge of resource allocation problem in the cloud platform. A design of Fairness-Efficiency in allocation algorithm is presented. It is an iterative, dynamic-adaptive heuristic for solving the problem. The computation complexity of an algorithm is $O(n^2)$. Along with the solution to the problem the feasibility of solution is not analyzed.

J. Yao et. al. [13] we studied a robust multi-resource allocation problem with uncertainties in resource demands. The cost function is optimized which produces fairness and effiency in a robust manner in the cloud environment.

J. Li et. al. [14] proposed a multiclass resource allocation algorithm for services in IoT. Uplink resource allocation problem is explained. Comparison between different algorithms were presented with respect to delay distribution. Authors claim their algorithms give better performance than fixed allocation algorithms which satisfy the QoS requirements of users.

TABLE I. SUMMARY OF COMPARATIVE ANALYSIS OF THE RESOURCE ALLOCATION ALGORITHMS.

SN	Algorithm	Approach	Technique	Computational Complexity	Author
1	Dynamic Programming	Non-Heuristic	Reinforcement Learning	$O(n)$	K. Gaia et. al. (2018) [6]
2	Demand based	Non-Heuristic	Service-Interface Assignment	$O(n^2\ log(n))$	V. Angelakis et.al.(2016) [8]
3	Gradient method	Non-Heuristic	Dominant Shares	$O(n^2)$	J. Yao et.al. (2017)[13]
4	Multiclass Allocation	Non-Heuristic	Gateway Hierarchy	$O(n^2)$	J. Li et.al. (2016) [14]
5	Gradient method	Non-Heuristic	Deep Learning	$O(n^5)$	M. Liu et. al. (2018) [9]
6	Approximation	Non-Heuristic	Convex Segments	$O(n^2.log(n))$	P. Lai (2015) [15]
7	Greedy	Heuristic	Combinatorial Exchange	$O(2^n)$	K. Lee et. al. (2015) [11]
8	Gradient method	Heuristic	Dynamic Adaptive	$O(n^2)$	Q. Lu et.al. (2016) [12]
9	Dynamic local search	Meta-Heuristic	Search Economics	$O(n^2.h.I^{max})$	C. Tsai (2017) [7]
10	Generalized Ant Colony Optimizer	Meta-Heuristic	Hybrid (ant and global)	$O(m.n.log(n))$	A. Kumar (2018) [16]

A. Comparative analysis of existing approaches

Table I provides a summary of the comparative analysis of existing approaches for solving resource allocation problem. From the table, it has been found that the complexity of the algorithm proposed by K. Gai et. al.[6] is much better than the rest of the existing algorithms. The approaches provided with heuristic led to exponential time on the increasing number of resources. A gradient method with a non-heuristic approach is found computationally heavier than heuristic approaches. However, improvement in complexity was witnessed with metaheuristic approaches[16] with complexity as $O(m.n.log(n))$, where m is the size of initial populations and n is the number of iterations.

The synthesis of the literature revealed that dynamic programming strategy provide the solution in reasonable computational time so, this paper attempts a dynamic programming strategy for solving resource allocation problem. The major challenges can arrive in resources allocation problem are Optimality and Scalability. In case of increase in

scalability of solution space leads to optimality of solution searched in same solution space and vice versa.

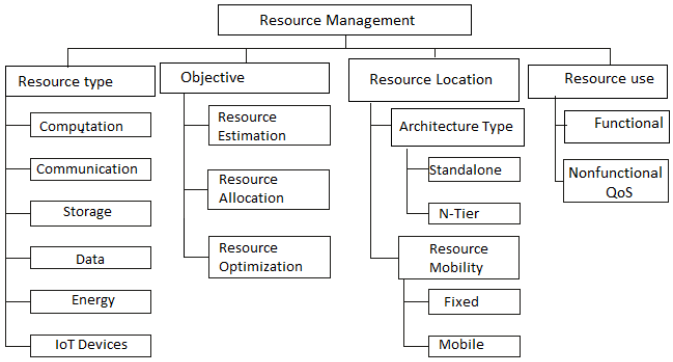

Fig. 1 Taxonomy of resource management

III. RESOURCE ALLOCATION PROBLEM

Fig. 1 illustrates the resource management taxonomy. It gives an overview of research in resource allocation area and presents four dimensions: resource type, an objective of resource management, resource location, and resource use. The first aspect is constructed by reviewing the current type of resources used. Our research focus is on the second aspect which is resource allocation. The resource location plays important role in describing the architecture and the last aspect is used in a survey as allocation criteria of the resource. This paper address resource allocation objective with non-functional QoS as resource use.

There may be many composite services for an activity. Each of the candidate services in a composite service needs to be allocated an instance of the component service. A single instance of a component service may be allocated to more than one candidate service task in the composite service task as long as it used at different time. This is stated as service allocated problem.

To find resource allocation plan which minimizes the aggregated response time of each composite service while satisfying cost constraint is called resource allocation cost constraint problem. The tasks mapping on distributed services is known NP-hard roblem[17,18], which divine computational complexity of resource allocation problem with cost constraint is NP-Hard.

Consider, CS={CS_1, CS_2, CS_3, ... CS_n}, set of composite services, n is total number of services. AS_i ={ $AS_{i,1}$, $AS_{i,2}$, $AS_{i,3}$,..... $AS_{i,m}$ }, set of abstract services, each i^{th} composite service consist of m number of abstract services.

C_i = { $C_{i,1}$, $C_{i,2}$, $C_{i,3}$,..... $C_{i,p}$}, set of p number of candidate service for each abstract service in cloud. $RT_{i,m}$ and $Cost_{i,m}$ response time and cost of candidate service $C_{i,m}$ in the cloud. Now allocation with cost constraint plan P={P_i|i=1,2,3....n}, such that aggregated response time $RT(P)$ is Minimal which is calculated using the following equation.

$$RT(P) = \sum_{i=0}^{m} (RT_i)$$

In above equation total number of candidate services and the constraint which is Cost(P) should not exceed.

A. 0/1 Multidimensional Knapsack Problem

The 0/1multidiamesional knapsack problem consists of an allotment of a specifed capacity items in a knapsack, in which each item has an associated profit and weight[19]. Applications like finance and telecommunication networks can be easily model using this problem[20]. A goal of this problem is to find a subset of items which will lead to the maximum total profit with fulfilling constraints imposed on it. Consider a set of candidate services (s = 1, 2, 3..., n) where n is number of candidate services in composite service and a set of resources (r = 1, 2, 3, ...,m) where m is a number of resources. Each candidate service has a cost associated with it from which maximum capacity is aggregated and resource has cost as well as its associated value of response time of service. Now the problem is an allocation of resources with a minimum response time of component service which holds resource for the given maximum aggregated capacity of candidate service. This can be mapped to 0/1 multidimensional knapsack problem[21].

IV. PROPOSED ALGORITHM

This paper presents an algorithm for resource allocation using a dynamic programming strategy as an *Alogorithm 1*. In this algorithm parameter *CompositeService(CS_n)* is set of candidate services which needs resource/s to execute. *AbstractServices(AS_m)* is set of abstarct services where each service is task in activity of m tasks. *ComponentServices (C_p)* is set of services which holds computational resources and gets allocated to candidate service. *Response Time of C_p (RT) is* response time of component service in other word it is response time of computational resource which is time (in microseconds) required to receive response from component/resource service against request from user/candidate service, *Cost of C_p (Cost)* is monitory cost of component service in terms of price which need to pay to service providers. *Services Allocation Plan (P)* is set of best plans of combination of component services with minimum response time satisfied by cost constraints in user requiremets.

The main idea of the algorithm is to allocate component service to serve the services with the highest resource cost and minimum response time. The algorithm confirms the aggregated response time will be minimized. The algorithm then steps forwards to allocate the services with lower resource shares and so on. The first two lines of the algorithm calculate the aggregated response time and total cost of the composite service. This is done by simple summing of the response time of all services in candidate service and summing of cost as well. Next step calculate aggregated response time of component service using V_n. Plan p with the best response time and cost will get the return.

Algorithm 1	*RESOURCE ALLOCATION ALGORITHM*
INPUT	*Composite Services(CS_n), Abstract Services (AS_m), Component Services (C_p), Response Time of C_p RT), and Cost of C_p (Cost)*
OUTPUT	*Services Allocation Plan (P) while all constratints satisfied*
STEPS	*Calculate aggregated response time of each composite service* *Calculate total cost of each composite service* *if total cost is Maximum then* *$V_n(RT) = Min\ \{V_{n-1}(RT),\ V_n(RT)\}$* *Allocate n^{th} component service with RT to respective Candidate Service in Composite Service.* *Return Plan P*

V. RESULTS AND DISCUSSIONS

The simulations were carried out with machine configuration is Intel Core i3 processor, 4GB RAM, 1TB HDD, Windows 7 64bits OS, and Java Platform(JDK1.7) for implementation. We focus on analyzing dynamic programming as well as a simple iterative method for the implementation of allocation of resources. In our implementation, 3000 component services were use for allocation to candidate services with cost and response time as QoS parameters. The results demonstrate the simulation of dynamic programming for 0/1 multidimensional knapsack version of resource allocation problem. We note down computation time in milliseconds for the number of services by keeping number candidate services constant to 10 in composite service. Fig. 2 shows the performance of dynamic and iterative solutions. From figure 2 it is observed that the brute force algorithm fails to allocate more than 2400 component services. The dynamic programming found to be better than brute force but still get stuck after 3000 services.

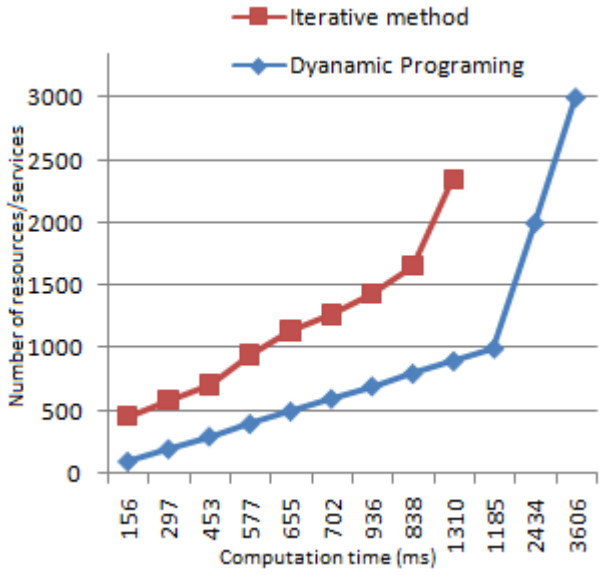

***Fig.**2 Computational time with a number of resources for allocation*

Though dynamic programming is better than brute force but computationally expensive with complexity as $O(n^2)$. From the computational experiments, it can be concluded that dynamic programming strategy fails for a large number of services so attempts for providing the solution with heuristics and metaheuristics technique.

VI. CONCLUSION

This paper presents the resource allocation problem in service composition modeled as 0/1 multidimensional knapsack problem. The stated problem is implemented with brute force and dynamic programing strategy. The computational results revealed that as number of services goes on increasing both the technique failed to allocate the resources. Hence it is concluded that heuristics and metaheuristics based technique should be developed for finding the solutions in reasonable computational time. The analysis results of our simulation show that implementation is good small scale composition. However, all constraints and dependencies are not taken into consideration in current work. The solution accuracy, optimality, and feasibility are not checked in our simulation work.

In future scope we will include the use of meta-heuristics for solving resource allocation problem in service composition with the constraints and dependencies for large scale services along with solution accuracy and feasibility.

***Abstract*:** In modern CMOS logic, due to scaling variety of fault occurs which causes reliability issue in circuits. Also in radiation environment, single event upset logic degrades the performance of CMOS IC's. Faults and single event effects becoming a major concern in scaled CMOS devices employed in circuits that have to be used at higher altitudes in space. In this paper, brief history of about the emergence and creation of errors in IC's , types of faults occurring in CMOS logic circuits and their fault tolerance and SEE's mitigation techniques have been discussed.

Keywords: CMOS, SEE, LET, Faults, Radiation effects, Mitigation.

I. INTRODUCTION

CMOS becomes the prevalent technology in past 30 years. CMOS circuits have been utilised at large scale for the construction of IC's which exercised in microprocessor, microcontroller and several other logic circuits. CMOS IC's also used for space application. Moore's Law plays a vital role in the advancement of CMOS circuits which summarised as the transistor density on chip twofold after every 18 months [1]. Speed and complexity of the microelectronic circuit had been boosted to 200-MHz and gate-per-circuit reached beyond million transistors in single chip due to technology scaling. Scaling of CMOS circuits worsen the electronic devices and leads to the establishment of faults in CMOS circuits [2].

Fault is an unsatisfactory behaviour of circuit which needs to be screen out. In CMOS circuits, faults were acknowledged and addressed infrequently in 80's [3]. CMOS being a prevailing technology is certainly focused on shrinking of devices which adds to its design complexity and making it more sensitive to small defects. Leakage current and short channel effects arise due to technology scaling and numerous faults appear in CMOS IC's. In space, radiation effects are principal concern and scaling of CMOS devices further escalate radiation effects in deep submicron dimensions device. Therefore, reliability of CMOS circuit can be enhanced by detecting and correcting the shortcomings and fault masking [4].

Therefore, fault tolerance plays a vital role in analog and digital circuits and it decides the performance of the device. Hence, it is important to work on the fault tolerance capability of the device as it is directly proportional to the reliable performance and it provides assuring successful operation. Fault tolerance system should be well efficient to handle all possible faults occurring in hardware or software components, due to power breakdown or any other possible disaster and still meet expected performance metrics. Owing to increased operating frequencies, the CMOS integrated circuits are more prone to be affected by faults like permanent and transient faults, SEE's and structural faults like interlayer and intra-layer[5].

Vital constituents of fault tolerance are error processing and fault treatment. Error processing features error removal, if there is probability of occurrence of malfunction whereas fault treatment includes elimination of faults before it set in motion. Fault tolerance can be accomplished by combining two fault masking and reconfiguration [6]. Fault tolerant techniques are categorized in static, dynamic and hybrid groups. The static tolerant techniques uses fault masking mechanism which is designed to achieve fault tolerance without requiring any action on the part of the system. The dynamic fault tolerance technique detects, locates and recovers the fault in an attempt to achieve fault tolerance. And hybrid fault tolerance techniques combine both static (passive) and dynamic (active) approaches [7-8].

The paper has been organised as follows: Firstly historical aspects are discussed in part II; In part III different CMOS faults have been discussed including structural faults, SEE's faults and several other faults. Part IV describes SET mitigation techniques and Fault tolerance techniques.

II. Historical Overview

Continuous downsizing of MOSFET technology and upsurge of chip size and area leads to complicated design of integrated circuits and speed and performance had been improved greatly. Operational frequency of MOSFET circuits has been escalated due to which probability of occurrence of faults had been increased. With the advancement and development in IC's design and

structure, faults and SEE's had been observed in MOSFET in late 80's [3].

In 1983, Diehl et al. explained about the digital single event transients and faults occurring in CMOS IC's [9].Faults at transistor level can jeopardize the functionality of CMOS devices and result in erroneous output [10]. Since various circuits were constructed using MOSFET technology, so it was important for analog and digital applications to tolerate various kinds of faults. Faults in CMOS circuits may arise at manufacturing stage. Because of faults occurrence, there has been a probability that transient may latched in a flip flop. Thus, faults and SEE's becoming principal concern in VLSI logic circuits [11].

A report submitted by Intel in 1984describes the dynamic fault imaging technique. This technique describes the voltage transients arising in IC's when it is operating dynamically. This was developed in order to mitigate faults arising due to manufacturing and designing of complex logic circuits[12].

Few years later, Kolasinski performed the experiment under heavy ion radiation and conveyed detailed contribution of SET (single event transients). They emphasis on two extents, LET of SEU particles and cross-section of upsets. It was observed that LET of SEU particles was between 6 and 15 MeV-cm^2/mg and it also witness that dynamic memories has more cross-section than static memories. SETs were observed in memory circuits and microprocessor [13].

New-berry *et al.* examined the transients at the output of devise such as logic drivers and receivers. They scrutinized that minimum LET required for SETs occurrence was 15 MeV-cm^2/mg and pulse width of SETs increases beyond 40ns as LET increase [14].

In 1990,s various papers have been published describing the issue of static and dynamic faults and also it explained that error increases with increase in operational frequencies. The analysis was performed for high speed devices based on Si ECL technologies and this was done at very high frequency i.e. 100Mbps. It concluded that these devices are sensitive for heavy ion interaction and proton irradiation for space applications [15-16]. At low frequencies error were observed in sequential logic circuits whereas at high frequency most of the defect noticed in combinational logic as error rate increases in direct proportion with frequency.

Later in 2000's study was done which describes SET's in digital circuits due to scale down to 150nm technology node. There were significant transients in deep submicron technology due to ion strike in tresstrial environment and the value of LET at which faults were observed in digital circuits was anticipated to be as low as 2 MeV-cm^2/mg [17].

Later it in 2010, it is also showed that reducing the source voltage of digital devices makes it more vulnerable to stuck at faults and SETs and the smaller node capacitances in CMOS circuits unable to protect the nodes from voltage variations. The circuit was designed which can tolerate SETs up to 15GHz of frequency. The amplitude and phase shift due to current and transient pulses injection presented mathematically as:

$$\Delta V = \frac{\Delta q}{C_{tot}} \ldots\ldots (1)$$

$$\emptyset_e = \frac{\Delta q}{q_{max}} \ldots\ldots (2)$$

[18].

Mukherjee *et.al.* Introduced a new defect tolerant technique using transistor redundancy where each transistor is replaced by three transistors. He showed that triple transistor redundancy technique is efficient in terms of area overhead at reasonably good reliability. Triple transistor logic is faster than Quadded transistor technique [19].

Later various error detecting and correcting techniques were proved to be resourceful for CMOS based memory circuit's whereas hardening techniques for combinational logic circuits.

III. Faults in CMOS Circuits

The objective of designing any electronic device using CMOS is to minimize chip area, low power consumption and high Fan-out while maintaining low noise power [20]. Fabrication of CMOS IC's involves various processing steps which may introduce a problem that in turn may introduce a fault. Faults in CMOS devices may occur at transistor level; gate level or system level. But at circuit level, fault can be categorised as follows:

A. Open and Short Faults

Open faults exists a missing link between two interconnects then generally these type of fault occur. They can occur due to missing drains or sources within same transistor or different transistor. On other hand, short faults occur when two or more interconnect lines get shorted. It includes shorting between power supply rails/ lines [21]. These are included in electrical fault models.

B. Stuck at Faults

In such faults, the output of CMOS is trapped at particular logic level; either zero or one. Stuck-at Faults is included at both chip as well as PCB level [19]. Fig 1 represents the stack at faults model, where value of a gate is stuck at 1.

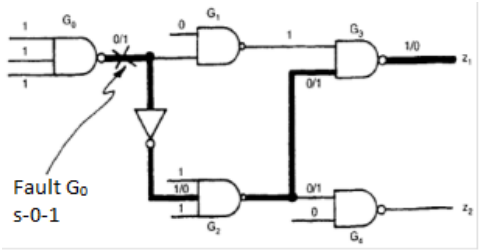

Fig 1 SFs detection [19]

C. Transition Fault

In case of transition fault, CMOS circuit failed to make transition from either 0 to 1 or vice-versa. When a CMOS circuit fails to make transition from 0 to 1 then is known as upward transition fault whereas when it fails to make transition from 1 to 0 then it is called as down transition fault [22]. Figure 2 represents the transition fault.

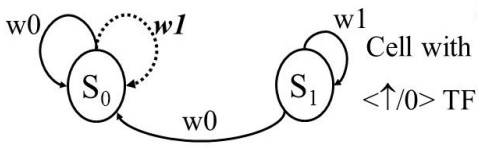

Fig 2 Up- transition faults[22]

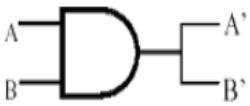
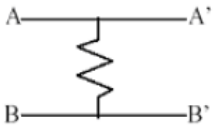
D. Bridging Fault

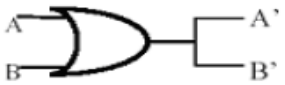
These faults are mainly related to reliability issues of circuit. Bridging faults are the connections formed between two or more wires and performing logical AND/OR between shorting wires. Bridge fault models are shown as follows in fig 3: [23].



(a) Wired –AND Model



(b) Low Resistance Model



(c) Wired-OR Model

Fig 3: Bridging Faults[23]

E. Single Event Effects

In space, various radiation sources exist that incorporates sun rays, solar winds and cosmic rays. Different particles such as neutrons, protons, electrons and heavy ions are acquainted in radiation environment. These particles when strikes the IC's may introduce error in circuits and these errors are termed as Single Event Effects (SEE). There are different types of single event effects occur in CMOS IC's [24].

In single event upset, when particle hits the IC's it may change the logic level of storage node. Single event transient effect leads to change of voltage in CMOS circuits. Single event transient becomes SEU when it changes the state of storage node. In CMOS, two parasitic BJT are formed which leads to the formation of thyristor like structure and when this thyristor like structure get turned ON due to particle strike then there is direct flow of current from power supply to ground. This triggering of thyristor like structure is termed as Single event Latch up. In Single event gate rupture (SEGR) effect, the gate of CMOS circuit is impaired due to particle strike at gate oxide insulation. Single event burnout happens in power CMOS circuits when drain current increases beyond limit [3],[25]. The energetic particle strike when hits the CMOS circuit, results in formation of charge cloud and it is shown in fig 4.

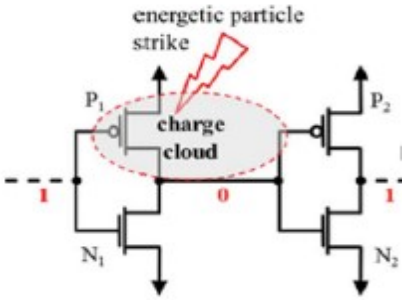


Fig 4 Particle strike CMOS inverter [3]

Therefore in CMOS circuits faults can occur at gate level, transistor level or at switch level. To mitigate the fault occurring in circuits a range of fault detection and correction mechanism are available that has been discussed further.

S.No	Faults	Effects
1.	Open and Short Faults	Produce the floating states at the output of the CMOS logic either at Pull-up network or at pull-down network
2.	Stuck at faults	Single logical connection is permanently stuck at a particular value and does not represents the correct at node
3.	Transition Faults	Spot defects and increases the delay of circuit
4.	Bridging Faults	Two nodes permanently get connect
5.	Single Event Effects	Changes the voltage of circuit because of striking of particle

IV. Fault Tolerance Mechanism and SEE Mitigation

Various fault tolerance and SEE mitigation techniques have been developed in order to prevent

failures in CMOS circuits and these could be implemented in programmable logic [26]. Changing the device structure physically helps to avoids faults and they are termed as fabrication process based techniques. These techniques involve epitaxial CMOS process and silicon-on-insulator process in order to eliminate radiation faults at satisfactory level. The fabrication process- based techniques are quite expensive and therefore, they are not preferred for low level production.

Design based techniques are widely used because they can be applicable to various design level in circuit and also termed as architectural techniques. These techniques include detection, mitigation and recovery techniques. Time redundancy and hardware redundancy techniques generally used for the detection of SEU's in combinational and sequential logic circuits [27]. Fig 5 represents the time redundancy technique.

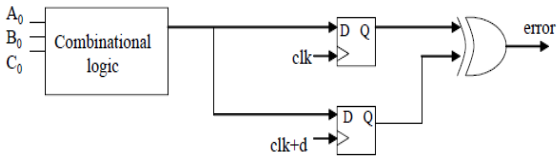

Fig. 5 Time Redundancy duplication scheme to detect SET [27]

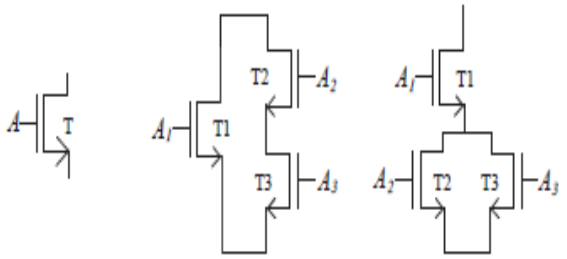
Hardware fault tolerance techniques use the concept of duplicity with comparison which could be used for CMOS IC's. The hardware tolerant techniques involve Triple modular Redundancy (TMR), N-Modular Redundancy (NMR), Triple Interwoven Redundancy (TIR), TT (Triple Transistor) Technique and QT (Quad Transistor) Technique [4].

In TMR technique, voter circuit is used which selects one circuit from three different circuit performing same operation but disadvantage associated with this technique is that it assumes voter circuit is fault free [8]. TIR is analogous to TMR technique in which replicated components are arranged randomly. Reliability of TIR technique is main issue [28].

The TT and Quad Technique rectify errors by toggling them from critical to subcritical states.TT technique was categorised as static redundancy technique. In this technique redundancy was added at transistor level and it is highly reliable and occupies less area as compare to other static redundancy techniques. TT is proficient in handling single faults in transistor [18]. QT uses four transistors to function for single transistor due to which error in single transistor can be tolerated. Double faults can also be tolerated using QT technique as long as they are not in parallel. Generally, TT technique is faster than the QT Technique and in addition to TT technique is appropriate because of its efficiency in terms of area and time [29-30]. TT configuration is shown in fig. 6



(a) Original Transistor (b) TT version1 of fig. a (c) TT version2 of fig. a

Fig. 6 TT configuration of single transistor [4]

Also, in case of hardware redundancy technique design can be modified logically. In this, we add the redundant bits using error detection and correction techniques which can identify faults and correct upsets.

Reconfiguration, partial reconfiguration and rerouting of bits or information using the programmable matrix in the circuit for detecting and correcting faults. Also detection with codes can be used for sequential or combinational circuits.

Hamming codes can be used for correcting the faults in circuits. It requires changes at circuit level by adding block like decoder blocks, storage cell and encoder. DICE cells can appropriately detect and correct the fault at transistor level [27].

SETs became main issue in CMOS devices in space application when size was reduced below 10μm and critical charge for originating a transient pulse was dropped below 1pC and LET is corresponding to 50 MeV-cm^2/mg. In order to mitigate SETs various techniques have been developed and they are categorised as: Temporal sampling and spatial sampling. Temporal sampling is widely used in deep submicron circuits that have to be employed at high altitudes in space. Generic temporal sampling is widely used form of sampling technique. It is shown in fig. 7:

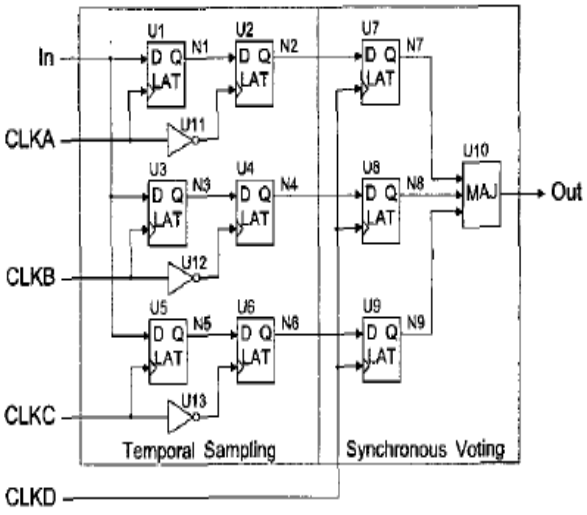


Fig. 7 Generic Temporal Sampling Latch [31]

In this, input data is sampled at different frequencies such that sampling frequency is higher that the single event upset pulse and voting circuitry picks the majority of sampled data [31]. In temporal sampling there exist the trade-off between size and speed.
Table 1 represents the mitigation technique and which fault is diminished by it.

Table 1: Mitigation Technique Summary

Sino.	Mitigation Technique	Fault Diminished
1.	Triple Modular Redundancy technique	Stuck- at fault
2.	Triple Interwoven redundancy technique	Stuck at fault
3.	Triple Transistor redundancy	Stuck at, transition and SET's Fault
4.	Quad Logic Redundancy Technique	Stuck at, Transition faults.

V. Conclusion

This paper discuss about the faults and how they are significant in high speed and complex digital CMOS IC's. Faults being the unsatisfactory behaviour of circuits need to be prevented. Various types of faults have been discussed and their effects on devices have been explained. These faults results in erroneous output and may damage the circuit permanently. Scaling of CMOS technology has increased the number of faults in circuit and also intensified the effects of SEE's. Increase in operational frequency and scale down of capacitance has enhanced the probability of fault and SEE occurrence in CMOS circuits. To mitigate these faults and SEE's various fault tolerance techniques have been discussed at gate level, transistor level and at circuit level. If in future, any kind of fault occur then we can rectify it by using current techniques or by doing advancement.

***Abstract*—In our country one of the main challenges facing the farming industry is the paucity of labour. The Farming industry is one of the major employment generators in our country, however the industry employs only seasonal labour resulting in many farm workers moving to cities for other stable occupations such as construction and hospitality. Thus in a country with human resource surplus, finding seasonal labour has become a challenge, and the available labour has become very expensive, resulting in many fields lying barren. Automation of the farming process is a reasonable solution to overcome this problem. An automated farm should be able to pseudo replace tasks which are worker intensive. These include sowing, weeding or disease detection, harvesting and lastly automated inventory. In this project a model is presented for fruit farms. A small farmer bot prototype is also developed. The prototype demonstrates the harvesting step, wherein it detects ripe fruits for plucking.**

Keywords—automated, harvester, apple, YOLO, bot

I. INTRODUCTION

The current farming sector is reliant on the manual based process of plucking and sorting of fruits for making them available for the customers. This is not consistent and is time consuming, thus affecting its efficiency. Nowadays the use of bots in our daily lifestyles such as robotic vacuum which cleans the house and abolishes the age old system of manual sweeping, and the use of chat bots in place of customer care leads to a great profit in the IT sector. A basic farming process includes planting, watering, weeding, harvesting and delivery which are manually done whereas an automated farming process is done with minimum human assistance. Automated farming can be done by using robots for performing the techniques in farming process such as planting the crops with robots, watering using smart drip irrigation system, spraying pesticides and weedicides by identifying the weeds and pests with the help of robots and so on. Taking the positives from this, the project aim at making a bot which will perform the tasks of harvesting and managing the inventory that a labour does on the farm with minimal cost. The proposed system is such that it is capable of automating the process of plucking with no man power and hence making it affordable in comparison to manual system and also maintaining an inventory of the count of the fruits in order to make it available to the customers. Introduction section gives an overview of the objective and the need for Smart Farming. Literature review section gives a brief explanation about the previously conducted research based on different automated techniques used for harvesting apple fruit. Methodology section includes a detailed description of the hardware incorporated in our system. Implementation and result section shows the explanation and analysis of the system. Conclusion section includes capabilities of the project and future work.

II. LITERATURE SURVEY

Different apple harvesting systems were studied to come up with a suitable system design. There are two ways in automated apple harvesting, one being bulk and the other being apple by apple. A mechanical apple harvester [1] is a mass harvester system that is designed for a narrow inclined trellis which requires uniform ripeness. There are two operators on the system which move the harvester towards each apple tree. They adjust the harvester to a tree and cover it with impactors. A shaker attachment then vibrates the tree causing the apples to detach from the tree and the apples fall on the impactors.

Another system engages in robotic bulk harvesting of apples [2]. Its main aim was to check the size and type of catching surface needed, and to use a surface to catch the fruit with no damage. It is a three wheeled harvester. A digital camera captures the images of the apples and the images were processed using a software. The Rapid Displacement Actuator (RDA), a hydraulic cylinder is guided to that position of apple by converting the image pixel coordinates into coordinates in space. Then the actuator is activated for fruit detachment and the apples are collected in the catching surface.

Autonomous Fruit Picking Machine (AFPM) [3] is a robotic apple harvester which uses apple by apple picking system. This system requires a proper fruit gripper. The AFPM is built on an agriculture tractor. The camera inside the fruit gripper will scan for ripe apple and will be then processed under uniform light conditions with the help of high frequency light source. The camera rotates in x and y axis and after the apple is aligned with the image centre and the object centre by using 6 DOF industrial robot then the silicon fruit gripper is in front of the apple. It then uses vacuum suction to detach the apple without damaging it.

A low cost fruit gripper [4] has been used for detachment of apple fruit. It is made of silicon with a camera fitted inside which is looks like a funnel. Its main aim was to detach the apple and enclose the camera. It checks the shape of the apple and encloses it firmly. Then it is activated by vacuum suction and detaches the fruit without damaging.

In this project the object detection approach used is You Only Look Once (YOLO). YOLO [5] is fast and an accurate object detector, thus making it useful for computer vision applications. It is based on regression i.e. instead of selecting parts of an image, it predicts classes and bounding boxes for the whole image in one run for the algorithm.

III. PROPOSED METHODOLOGY

The project aims at developing automated apple harvester bot and maintaining the count of apples in the inventory. "Fig. 1" shows the basic block diagram. The user will give the command from a smartphone to the bot and the bot will initiate its operation. The bot will be controlled by the processor i.e. raspberry pi 3. First the bot will move along the x axis. The camera will take continuous images. The algorithm used for object detection is YOLO and therefore if ripe apple is detected within the frame then the motor is driven by motor driver thereby adjusting the bot in line with the apple. After the bot is aligned in the centre of the apple then the arm in the z plane consisting of a cutter will move towards the apple and will stop until an active signal on the IR sensor is given which will successfully trigger the cutter to cut the apple from the tree. The count of the apple is taken and updated into the inventory mangement site of the user so that the customer can order the apples as per their requirement.

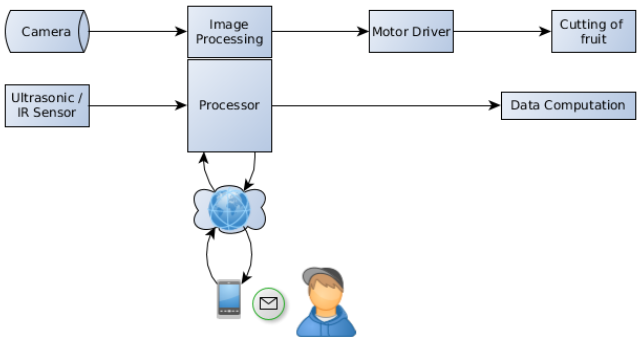

Fig. 1. Block Diagram

IV. HARDWARE USED

1. Motor Driver L293D

Fig. 2. L293D Motor Driver

L293D is a quadruple half H-bridge motor driver IC as shown in "Fig. 2". Motor driver acts as current amplifiers as they take low-current signal and provide a higher-current signal. This current signal is used to drive small DC-geared motors and bipolar stepper motors. It can drive current up to 600mA with a voltage range of 4.5 to 36 volts. The pulsed current per channel driver is 1.2 ampere and has thermal shutdown, back emf and internal ESD protection. L293D can drive two DC motors simultaneously, in both forward and reverse direction. The two motors can be controlled by logic pins 2 & 7 and 10 & 15. Input 00 or 11 stops the motor. Input 01 and 10 rotates the motor in clockwise and anticlockwise direction respectively while enable pins 1 and 9 must be high for motors to operate. When the enable pin goes high, the corresponding driver gets enabled. As a result, the outputs become active and driver drives their associated motors. Similarly, when the enable pin goes low, the associated driver is disabled, and corresponding motor is disabled.

2. DC Geared Motor

A DC geared Motor shown in "Fig. 3", has a gear mechanism connected to the motor. The speed of the motor is calculated in terms of rotations of the shaft per minute (RPM). The dc motor can be operated upto 12v and has 300 RPM. The gear mechanism helps in increasing the torque and therefore causes reduction in speed. The speed of the gear motor can be reduced to any desired speed by using different combination of gears. This hypothesis where gears reduce speed but increase the torque is termed as gear reduction.

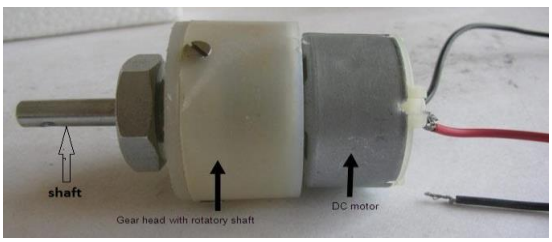

Fig. 3. DC Geared Motor

3. Raspberry Pi 3

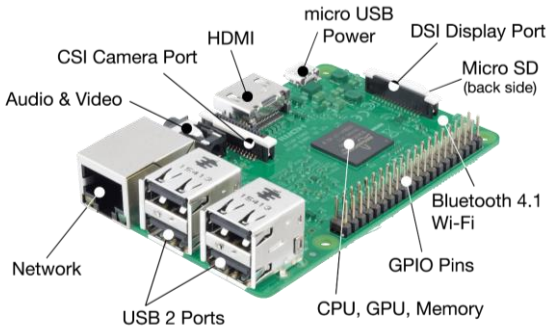

Fig. 4. Raspberry Pi 3

The quad-core Raspberry Pi 3 shown in "Fig. 4" is much more efficient than Raspberry Pi 2. It has a better performance than the other lower version of the pi. Unlike its predecessor, Pi 3 is competent of playing 1080p (Full HD) MP4 video at 60 fps at a rate of about 5400Kbps, and also supports wireless internet, with built-in Wi-Fi and Bluetooth. Raspberry Pi has a separate LCD display and camera port which eliminates the need of monitor and camera so one can connect them directly to the board and has PWM outputs for application use. Raspberry pi 3 uses Broadcom BCM2837 system on chip, ARM Cortex 4 core CPU, Broadcom Video Core 4 GPU, 1GB RAM, 2.4GHz wireless network, 4.1 Bluetooth and has 40-pin GPIO header, and HDMI, Ethernet, 3.5mm audio-video jack, 4 USB 2.0, Camera Serial Interface, Display Serial Interface ports.

4. IR Proximity Sensor

Infrared sensor is used to detect the presence of nearby objects without any physical contact. An IR sensor is shown in "Fig. 5". The IR sensor has builtin IR transmitter and receiver. IR transmitter is a type of LED which radiates infrared radiations. This radiation is invisible to human eye. IR receivers are called infrared sensors as they detect the radiation from an transmitter. IR receivers are typically photodiodes and phototransistors. IR transmitter emits radiation, and when it reaches the object some of the radiation reflects back to the IR receiver. The output of the sensor is shown based on the recepted intensity by the IR receiver. It is operated on 3 to 5 volts. Its detecting range is between 1cm to 30cm and the current consumption is about 23mA to 43mA. When an obstacle is detected its output goes low.

Fig. 5. IR Sensor

V. IMPLEMENTATION

The project uses Yolo V3 technique to implement the proposed idea as shown in "Fig 6". During the time of harvesting, the user will give the command from a smartphone to the bot and a code will be run. The flow chart of the program is shown in "Fig. 7". The bot will be

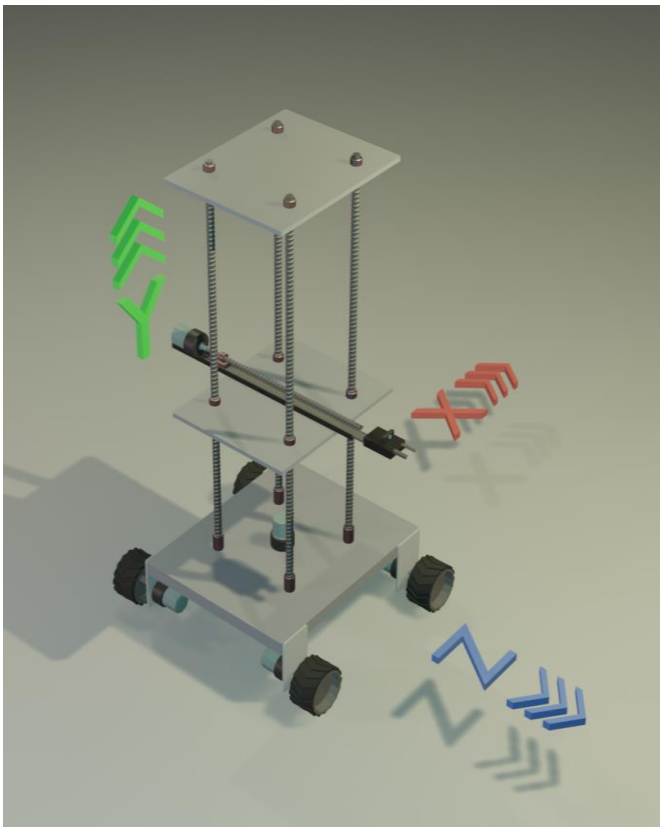

Fig. 6. Basic Model

controlled by the processor i.e. raspberry pi 3. The bot will move along the x axis. The camera will take continous images. The algorithm used for object detection is YOLO. YOLO start its process by dividing the image into SxS grid. For detecting the object, if the centre of an object falls into grid cell, that grid cell is responsible for detecting it. [6] Each grid cell predicts the bounding boxes and also the confidence percentage for those boxes. These confidence scores shows how much confident the model is for an object. It makes prediction across 3 different scales. [7] The detection layer is used to detect 3 different sizes, having strides 32, 16, 8. With an input of 416x416, detection is done on scale of 13x13, 26x26 and 52x52 and each grid cell predicts three bounding boxes. For image of size 416x416, YOLO estimates 10647 bounding boxes. And therefore if ripe apple is detected within the frame it will check if the image center and object center is the same, if not then the motor driver will drive the motors thereby adjusting the bot in x and y direction until the image center and object center is equal.

After the bot is aligned then the arm in the z plane consisting of a cutter will move towards the apple until a high signal on the IR sensor which will successfully trigger the cutter to cut the apple from the tree. Then the arm will move backwards to its initial position and this process will again be repeated. The count of the apple is taken and updated into the inventory of the user so that the customer can order the apples as per their requirement.

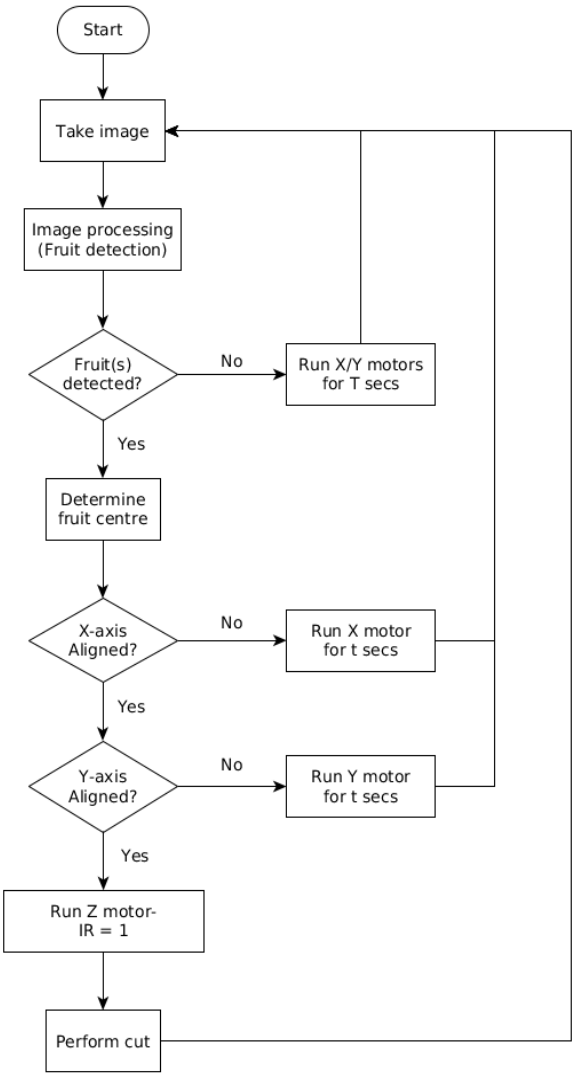

Fig. 7. Flow Chart

VI. RESULTS

The project is divided into three sections, first to detect the apple and move the bot in x axis, second to move to bot in y axis, and third to pluck the apple which is in the z direction and update the inventory. Therefore the results were seen of the project i.e. to detect the apple and aligns itself to the exact coordinates of X and Y. The bot then moved the arm in the z plane consisting of a cutter which on detection of the high signal on the proximity sensor had successfully cut the apple from the tree.

Testing of the program to detect the apple. “Fig. 8.a” and “Fig. 8.b” shows the images taken by the camera and apple has been detected respectively. First, the detection and moving the bot in x direction using only apple was done. Then the detection using two different fruits was tested as shown in “Fig. 9” i.e. for apple and orange to check if the bot will take real time images and classify the objects as apple and orange. The bot was programmed to move towards the apple. So as shown in “Fig. 10”, the bot detects both the fruits but starts moving towards the apple. Therefore after moving and aligning with the object and image centre, the bot stops.

Fig. 11. Completed Bot

Fig. 12. Bot alinged in X & Y plane

Fig. 13. Cutting Arm moving in Z plane

Fig. 14. Cutting mechanism

VII. CONCLUSION

The bot was trained to pluck an apple from an artificial tree under normal conditions without the obstruction of leaves and the deam light factor.

VIII. FUTURE SCOPE

The two factors listed in the conclusion that is the obstruction of leaves and the deam light factor can be taken into account for any future research in this domain.

IX. ACKNOWLEDGEMENT

The authors gratefully acknowledge the contributions of our guide Professor Flavia Leitao, co-guide Professor Vidhya D.S. and Sir Joseph Dias for their assistance, suggestions and unconditional support given to us in our project work.

Abstract—**Cloud Computing (CC) is a very trendy topic in the research field. Cloud computing has integrated distributing computing, web services, internet, software, and virtualization together. Most of the companies are using cloud computing on large scale. Cloud Computing (CC) services are demanding in the market. Cloud computing has been growing very fast since last few years. Over the past few years, cloud computing has the most powerful technology. A researcher has also shown his interest in cloud computing in past few years. In load balancing, there must be using so many algorithms in one at a time. We have also discussed about response time, turnaround time, and throughput. We have comprehensively analyzed and compared results of the above mentioned LBA. In CC, role of virtual machine is to utilize processor speed, which is discussed in this paper. Cloud Computing models, VM allocation, role of load balancing, simulation, cloudsim have also been explored in this paper.**

Keywords— Cloud computing (CC), Virtual Machine, Load balancing algorithm (LBA), Data Center Controller (DCC).

I. INTRODUCTION

CC could be understood as the delivery service of computing. A cloud must be an environment in which we have around some online services like storage space online compiler, online gaming and so on. Cloud computing provides various resources which can be used online [1]. A cloud can offer some services which should be payable and to be free. Cloud computing is undergoing major changes to allow multifaceted enhancements with each passing day. Nowadays so many companies make use of cloud computing technology like Google, Apple, Amazon, Microsoft, and so on. In a cloud, various data center are located at various locations. A user has been requested to the data center regarding its services [2]. A data center accepts the request of the user and provides its service. A cloud facilitates an online platform like data storage space, online compiler, online video gaming, online music player and so on. This service is provided only on a rented basis. A user can pay for all these services.

Cloud deployment model can be categorized into three types:

a. Public: In a public cloud, service should be public in a public cloud. A public cloud should be a standard Model. In public cloud, Mostly services should be free for a user.

b. *Private*: Private cloud is a service offered to a selected user instead of a public cloud. It provides high-level security and also has some additional feature. All services should be paid in the public cloud.

c. *Hybrid*: A partial mixture of public and private cloud made up of hybrid cloud. It provides more flexibility to enhance IT infrastructure. It provides more data deployed options.

Cloud computing [3] has new emerging technology. Nowadays cloud computing is on the trending list to the company perspective. A cloud computing service can be categorized into four qualities: IAAS, PAAS, and SAAS etc. A service should be offered in the form of layers one by one in cloud computing. It should be performed like a stack. They will accomplish its business goal very easily. There is:

a. Infrastructure as a service (IAAS): It is an infrastructure for instant computing. It should do outsourcing and support to manage an enterprise [1]. It also provides the software. IAAS (Infrastructure as a service) is also known as HAAS (Hardware as a service). It should be a very high-level API.

b. *Platform as a service (PAAS*): It is an architecture of cloud computing and it also just a third party software. It should provide hardware and software as per the user needed. A PAAS provides hardware and software in the platform. A supplier to provides a toolkit and standard parameter has been applying for development and channel for a purchasing purpose.

c. Software as a Service (SAAS): It provides a host a software application over the internet. It is a being third party. The software must always be available for the user in the platform.

CC is a modern technology. Now a days so many companies showing their interest in this emerging technology [4]. A researcher has also showing his interest

in cloud computing. Fig1 shows a cloud computing environment.

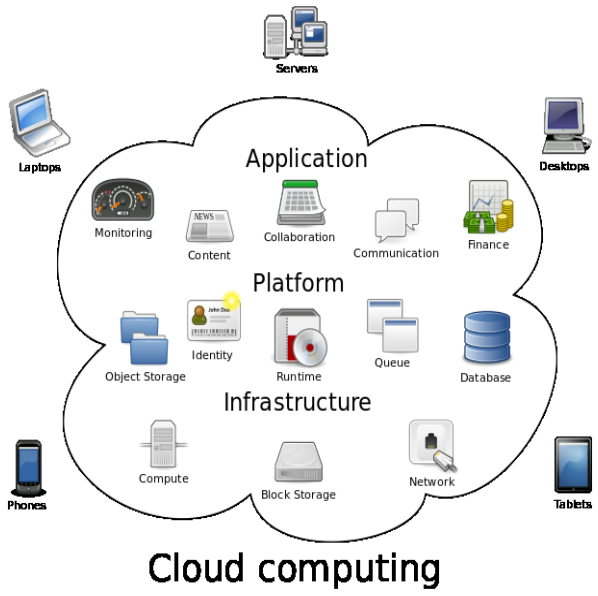

Figure 1: Cloud Computing Environment [Source: Google].

II. LOAD BALANCING

LB could be termed as a process in cloud computing which enhances the accomplishment of CC. It should distribute the load assignment among the nodes in a uniform manner [5]. Load balancing is a model in which we use certain algorithms to fulfill our task. Load balancing works as a part of cloud computing. With the help of load balancer, we are enabled to distribute the load in a uniform manner. In a load balancer, we have to specially take care about load balancing algorithm. An algorithm must have good response time, less turn-around time and good performance [6]. A load balancer is a specific part of CC which enhances the quality of CC. The main motivation for the load balancing algorithm is:

- Good response time.
- Less turn-around time.
- Full utilization of resources.
- No fault tolerance system.
- Improve of efficiency and performance.
- To improve resource utilization.
- Stability maintenance of the system.

Therefore, in a cloud computing environment, we can also try to avoid overloading at a specific node. We have thus categorized the load balance algorithm into two types:

a. *Static*: A static algorithm is basically made for a stable environment like a homogenous system. In the static algorithm, we should have prior knowledge about the system resources, so the load change judgment does not depend on the current system status. That algorithm has a decent mixture in the system that is why it should have low variation in load.

b. *Dynamic*: A dynamic algorithm can be modified effectively in both the homogeneous and heterogeneous environments. Dynamic load balancing may utilize the current state of the system and it ought to be helpful in managing the systemof the load [5].

A static algorithm has been found to be much faster than a dynamic algorithm. But dynamic algorithm has been designed only for the heterogeneous request. If we compare both the algorithms, the static algorithm has less overhead. The main objective in the load balancing algorithm is- to enhance request allocation to VM on the basis of the algorithm. There must be an agreement termed as service level agreement (SLA), existing between the developer and the user. It should generate proper implementation of the algorithm in a successful manner. Fig 2 shows a load balancing process.

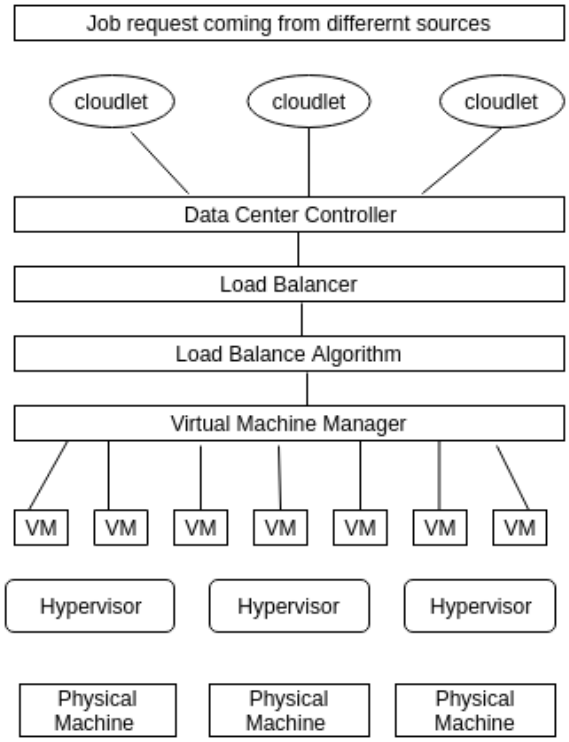

Figure 2: Load Balancing Process.

The algorithm-1 has been shown to balance the load in VM of cloud computing as follows:

```
Algorithm-1
    Begin
      Connect_to_resource()
      L1
      If (resource found)
        Begin
          Calculate connection_string()
          Select fuzzy_connection()
          Return resource to requester
      End
      Else
        Begin
          If (Anymore resource available)
            Choose_next_resource()
```

```
            Go to L1
          Else
            Exit
        End
End
```

Firstly that proposed algorithm has been requested resources for a connection request and then test for obtainable for resources [6]. It measures the connection request and if the resource found. Then choose the connection that is used in the virtual machine to connect the resource as per processor speed and load. Here this graph has been plot energy consumption according to the number of the task and its algorithm. Fig3 shows a graph plotting of various algorithms.

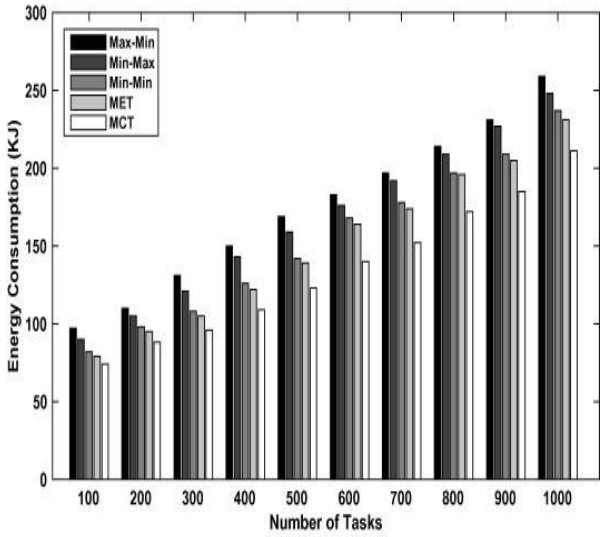

Figure 3: Graph Plotting of various algorithm.

Fig 4 shows plot between before load balancing and after load balancing.

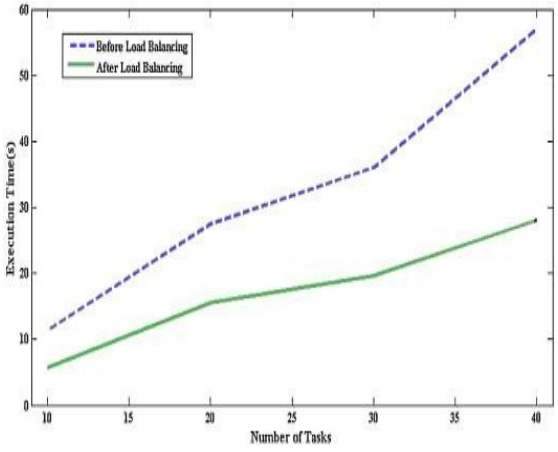

Figure.4 : Before Load Balancing and After Laod Balancing

III. MODELING THE VM ALLOCATION

A virtual machine is an additional layer of an operating system. A virtualization concept in cloud computing is tremendous. It works as an application layer which has only work like hosting, management and execution [7]. Therefore, virtualization has a main key in cloud computing [8]. In order to make proper utilization of available physical resources virtualizations is the best option. In virtualization, various physical machines are integrated assigned to an application dynamically. While using virtualization, several OSs and several applications can run simultaneously on a single server. It rises up the flexibility and utilization of hardware. The basic purpose of virtualization to creates a pragmatic interface. The virtualization environment having some component which we discuss below:

a. *Guest*: It shows as a component in a system. It should communicate with a virtualization layer or even with the host.

b. *Host*: It symbolizes the original environment. This is the palace where guest to be managed.

c. Virtualization: Virtualization allows to us, we will create the same or different environment. Guest operates in virtualization layer. It focuses primarily on computing, storage, and virtualization of the network.

IV. SIMULATION

A simulation is an estimated rendition of a process or system's operation [9]. In the process of simulation, we have required a model which should be developed. That model should be predetermined overview of a subject. It also represents its key features, such as its behavior, functions and abstract or physical properties. Today's simulation tools for CC are: gridsim, simjava, and cloudsim.

V. CLOUDSIM

CloudSim is simulator which helps to create model and simulation of cloud infrastructure [12]. It should create a virtual environment and then we have done some operation in cloudsim. Basically, it was designed for cloud computing and distributing. It should not being a software [10]. It should be a java package. That package we have imported in IDE. Cloudsim was written in java. Cloudsim does not have itself user interface.

VI. CONTEMPORARY VM LOAD BALANCERS

A load balancing algorithms basically allocates the work dynamically. A virtual machine allows the concept of OS and application to run over the hardware. Cloud model make connection request to internal hardware via data center elements. A data center should take care of all service requests and that requests placed in sandbox (processing element) within VM [15]. After that all requests are allocated to the data center host component. A data center object takes care of all the managing activity such as virtual machine creation, virtual machine destruction and routing request of the user request. A virtual machine load balancer controlled by DCC. A DCC creates the table of user's requests which VM allocate for processing. There are various contemporary VM load balancer algorithm which are given below:

a. *Round Robin Load Balancer*: A data center controller contains a list of all VM. A data center controller is being responsible for assigning a request to each VM. If a VM is allocated to a request then it will go the end of the queue. In a Round Robin Load Balancer (RRLB) has a good concept which name is Weighted Round Robin Allocation. In a Weighted Round Robin Allocation, a weight is associated with every VM. If any VM can handle the higher load then its weight is incremented and that VM have treated as more powerful than other VMs [18]. Next time when more than one new request arrives then we will assign that requested to that high weighted VM [19]. It is having a major issue that it doesn't capable of handling the advance load balancing requirements such as execution time for every requests.

b. Throttle Load Balancer (TLB): A Throttle Load Balancer makes a table regarding the state of every individual request of VMs. On this table, TLB keeps the record regarding VMs such that which VM is allocated to a particular request and which one is ideal. If any request has arrived then TLB generate an ID of the ideal VM. That ID send to a data center controller [7]. A data center controller assigns a VM to that request.

c. *Active Monitoring Load Balancer*: The active monitoring load balancer keep the information regards VM and it also keeps that which request assign to a particular VM. When a new request has arrived, it allocated to a new VM arrives. It recognizes the least loaded VM. If there are more than one request comes then it simply follows the FCFS. Active Monitoring Load Balancer sends VM ID to the data center controller. A data center controller recognizes that VM Id and make a request to that VM which is given by active monitoring load balancer. A data center controller will tells about new allocation to Active Monitoring Load Balancer (AMLB). It performs a new allocation and send to the cloudlet.

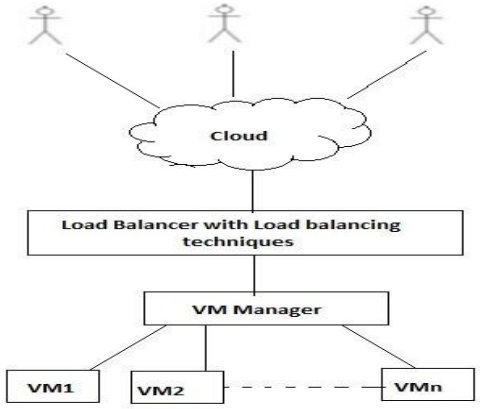

Figure 5: Contemporary VM Load Balancer [Source: Google].

VII. CONCLUSION

L.B [4] is handling a major issue in CC [21]. It allocates the workload dynamically to the server. It also maintains user satisfaction. It makes highly supervised resource utilization [16]. In load balancing, there is two major issues i.e. cost effective and time effective. Cost and time have a major key challenge in the software industry. Both of the parameters enhanced utilization and effectiveness in software industry. In this paper, we have discussed so many algorithms that algorithms are totally dependent on time and cost. Load balancing model and architecture plays an important role in software. Load balancing algorithms make better utilization of processing resources. An ideal load balancing algorithm should have these qualities like maximize throughput and better response time. This is the main aspect of this paper. In load balancing, we can try to use a dynamic algorithm.

***Abstract*—Increase in the number of vehicles on road necessitates the use of automated systems for driver assistance. These systems form important components of self-driving vehicles also. Traffic Sign Recognition system is such an automated system which provides contextual awareness for the self-driving vehicle. CNN based methods like Faster R-CNN for object detection provide human level accuracy and real time performance and are proven successful in Traffic Sign Recognition systems [1]. Single stage detection systems such as YOLO [2] and SSD [3], despite offering state-of-the-art real-time detection speed, are not preferred for traffic sign detection problem due to its reduced accuracy and small object detection issues. RetinaNet has shown promising results with respect to accuracy and speed required for object detection problems. It uses Focal Loss [4] and Feature Pyramid Network (FPN) [5] for tackling the low accuracy and small object detection problems. In this paper, an approach for traffic sign recognition system for self-driving cars based on RetinaNet is presented with comparative analysis of its performance with Faster R-CNN based sign detector [1] and YOLOv3 [9] based detector. RetinaNet forms the traffic sign detection network and a CNN-based classifier forms the traffic sign class recognizer. The network training and evaluation are done using the German Traffic Sign Detection Benchmark (GTSDB) [6] dataset and the classifier performance is verified using German Traffic Sign Recognition Benchmark (GTSRB) [7] dataset.**

Keywords— Traffic sign detection, CNN, RetinaNet, Faster R-CNN, YOLO

I. INTRODUCTION

Systems for assisting the drivers to avoid accidents are becoming more and more important as the number of vehicles on road is on an exponential increase. Advanced Driver Assistance Systems (ADAS) are being effectively used in automobiles for providing lane keep assistance, forward collision warning, pedestrian warning, driver drowsiness detection, traffic sign assist system etc. These form essential systems in autonomous cars for contextual awareness and road attribute mapping in order to control the vehicle motion trajectory. Traffic Sign Recognition (TSR) is the core component of traffic sign assist system for providing timely instructions and warnings to the drivers regarding traffic restrictions and information. In self driving cars, the inputs from traffic sign recognition system are used to make suitable decisions by the car, for example, to reduce speed or prepare for a detour etc.

Traffic sign recognition involves traffic sign detection and classification. Several studies have been conducted to address the traffic sign recognition problem. Even though some of the existing approaches have demonstrated good results on various benchmark datasets, most do not work very well in adverse conditions like motion blur, poor illumination, rainy or foggy weather, small sized signs etc. Recent studies use deep learning techniques, especially Convolutional Neural Networks (CNNs) for solving the traffic sign detection and classification problems. Majority of such studies use the German Traffic sign Detection Benchmark (GTSDB) [6] and German Traffic Sign Recognition Benchmark (GTSRB) [7] datasets for training and evaluation of their detection and classification networks. Improvements are made in the general CNN based object detection networks for traffic sign detection. A modified version of Faster-RCNN, a two-stage object detection network comprising of Region Proposal Network, bounding box regressor and classifier networks, has shown good accuracy and speed and it is found to be promising for real world problems like self-driving cars. Single stage detectors like YOLO [2] offer real time speed in detection, however these suffer from foreground-background class imbalance problems and does not provide the required detection accuracy. Also, these detectors are not efficient in detecting small objects, which is critical for traffic sign recognition. The recent improvements made as part of YOLOv2 [8] and YOLOv3 [9] have tackled the problems to some extent.

In this paper, RetinaNet object detection network, which is based on feature pyramid network and focal loss, is tuned and used for the traffic sign detection purpose. Very good detection result on the GTSDB database is observed using this approach. The CNN based traffic sign classifier proposed by Li and Wang [1] is used for classification of the traffic signs.

The rest of the paper is organized as follows. Section II covers the related work, Section III describes the technical approach, Section IV details the experiments done, Section V covers the performance evaluation and Section VI draws the conclusion of the work.

II. RELATED WORK

A. Traffic Sign Recognition

Extensive research is being done by the computer vision and machine learning communities to address the problem of automatic traffic sign detection and recognition in the past decade. Issues such as non-uniform scene illumination, blurring due to motion of vehicle-mounted camera with respect to traffic signs, traffic sign occlusion due to other vehicles, trees etc. make the traffic sign recognition task very challenging. Traffic sign detection based on extracting sign proposals and classifying based on a color probability model and Histogram of Oriented Gradients (HOG) is proposed by

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©2019 IEEE

Y Yang et.al [10]. However manual features such as HOG fails due to the challenges mentioned above. Recently, several object detection problems are being better addressed using Convolutional Neural Networks (CNNs). Computer vision research for intelligent transportation systems are also following the trends and many such work are finding practical use in advanced driver assistance applications as well as in autonomous driving vehicles. In line with that, several researchers have attempted to solve the problem of traffic sign recognition using CNN based object detection frameworks.

Y Zhu et al [11] proposed a method based on deep learning components for traffic sign recognition. It consisted of a Fully Convolutional Network (FCN) for proposal generation and a CNN for classifying signs. Later Zhu et al [12] proposed a traffic sign recognition system using an end-to-end multi-class CNN for simultaneous traffic sign detection and classification. They have also created a new dataset called Tsinghua-Tencent 100K dataset for performance analysis. They also proposed a single class detection network for the traffic sign detection and using a separate classifier for classifying the detected traffic signs.

The performance of Fast-RCNN [13] for traffic sign recognition is studied by Zhu et al [12]. Peng et al. [14] analysed Faster R-CNN for traffic sign detection, even though this approach was promising as compared to the previous studies, consistent accuracy and detection speed could not be achieved. Another real time traffic sign recognizer based on Faster R-CNN [15] following the Mobilenet [16] structure proposed recently by Li and Wang [1] could show the real-time performance and accuracy required for applications such as self-driving car, based on their evaluation using GTSDB dataset. In this approach they have also proposed a classifier network using asymmetric kernels for classifying the signs into 43 classes.

B. *Traffic Sign Classification*

CNN based classifiers trained with GTSRB dataset could achieve high classification accuracy in classifying traffic signs. The classifier based on Multi Column Deep Neural Network (MCDNN) proposed by Ciregan et al. [17] and Multi-scale CNN by Sermanet et al [18] could achieve accuracies of 99.17% and 99.65% respectively. These networks however are large and have to learn a huge number of parameters. Another approach by T L Yuan [19] using Spatial Transformer Networks (STN) could achieve an accuracy of 99.59%. Classifier network based on CNN using asymmetric kernels proposed by Li and Wang [1] reported an accuracy of 99.66% when evaluated with GTSRB dataset. Their FRCNN based detector and CNN based classifier combination has proved superior to the state-of-the-art traffic sign recognizers. The CNN based classifier employing asymmetric kernel proposed in [1] is used as the classifier in the proposed traffic sign recognition pipeline.

III. APPROACH

In this section, our approach for traffic sign recognition based on RetinaNet is presented. The traffic sign recognition pipeline, which is illustrated in Figure 1 consists of the RetinaNet based detector, the bounding box pre-processor and the CNN based classifier. The detector trained using GTSDB dataset, detects and localizes the candidate traffic signs. Bounding box pre-processor pre-processes the localized traffic signs for classification. It enlarges the bounding boxes, crops and resizes the boxes containing candidate traffic signs and fed to the classifier. The CNN based classifier classifies the candidate traffic sign as belonging to one of the 43 traffic sign classes.

A. *RetinaNet based Traffic Sign Detection*

RetinaNet is used as the traffic sign detector. RetinaNet is a composite network consisting of the following.

- Feature Pyramid Network (FPN) [5], which forms the backbone network
- A subnetwork for object classification
- A subnetwork for bounding box regression

RetinaNet structure is illustrated in Figure 2.

1) Feature Pyramid Network (FPN): The RetinaNet based traffic sign detector uses FPN as the backbone network and is built on top of ResNet-50 [20] deep feature extractor. FPN is a fully convolutional network, which takes traffic scene image of an arbitrary size and outputs feature maps at multiple scales resulting in a feature pyramid, a semantically strong multi-scale feature representation. This multi-scale feature representation enables the detector to detect candidate traffic signs of varying sizes present in the traffic scene. The feature pyramid network consists of bottom-up and top-down pathways. A feature hierarchy comprises of feature maps of different scales is generated by the bottom-up pathway. The top-down pathway with lateral connections, up-samples the feature map from the higher pyramid level, to generate semantically strong, but spatially coarse feature maps of different spatial sizes. Using lateral connections, the feature maps of same spatial sizes from both pathways are merged, resulting in feature maps of different scales, which are semantically strong with accurately localized activations.

2) Classification Subnet: The object classification subnetwork comprises of fully convolutional networks attached to each feature map level of the feature pyramid. Each subnetwork consists of four convolutional layers of filter size 3×3 with 256 filters with ReLU activations followed by another 3×3 convolutional layer with $C \times A$ filters with sigmoid activation, where C is the number of classes and A is the number of anchor boxes. The output

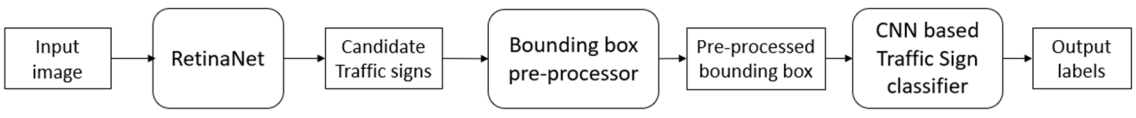

Figure 1. RetinaNet based traffic sign detection pipeline

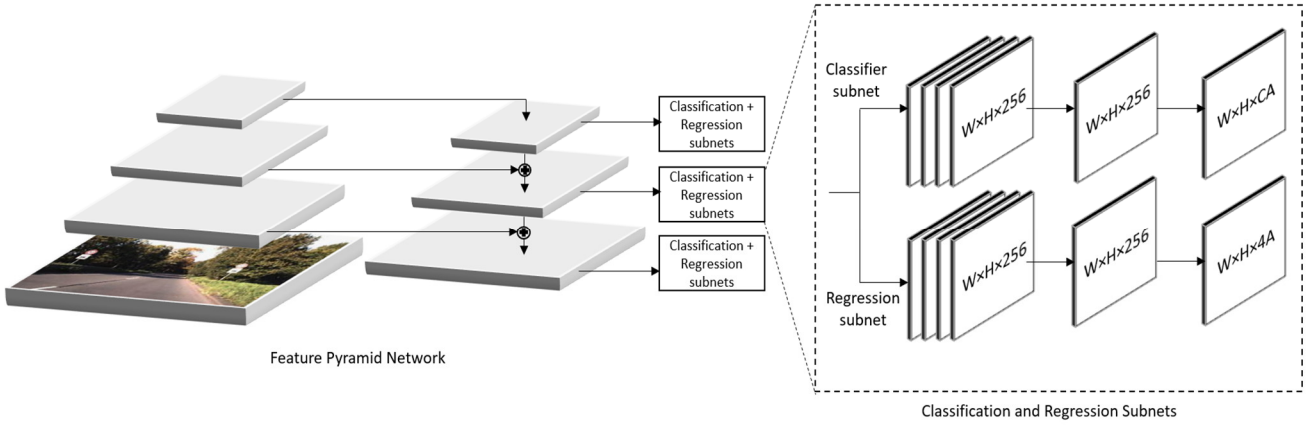

Figure 2. RetinaNet detector architecture

shape would be (*W, H, CA*), where *H* and *W* are proportional to the height and width of the input feature map level respectively.

3) Regression Subnet: The bounding box regression subnet is also attached to each feature map level of the feature pyramid. The subnetwork structure is similar to that of the classification network, the only difference is in the filter count of the last convolutional layer, which is *4A* in this case with 4 bounding box coordinates per anchor box. The output shape would be (*W, H, 4A*) in this case.

4) Loss Functions: RetinaNet uses a multi-task loss that contains two terms – localization loss and classification loss.

$$L = \lambda L_{loc} + L_{cls} \quad (1)$$

Here L_{loc} is the localization loss and L_{cls} is the classification loss. λ is a balancing factor, which balances the two task losses.

In single stage detectors, due to foreground-background class imbalance, the training process is dominated by easily classifiable background examples, which results in less accurate detection performance. RetinaNet resolves the class imbalance problem by using a variant of Focal Loss proposed by Yi Lin et al [4] as the classification loss. For each anchor, the classification loss is defined as:

$$L_{cls} = -\sum_{i=1}^{C} \{\alpha_i y_i (1 - p_i)^{\gamma} \log(p_i) + (1 - \alpha_i)(1 - y_i) p_i^{\gamma} \log(1 - p_i)\} \quad (2)$$

where C denotes the number of classes; $y_i = 1$, if ground trth belongs to i^{th} class and 0 otherwise; p_i is the predicted score for the i^{th} class; γ is the focusing parameter, whose value can range from 0 to +∞; α_i is the weighting factor for the i^{th} class and can range from 0 to 1. Here, the categorical cross entropy loss function is modified by adding the term $(1 - p_i)^{\gamma}$ called the modulating factor which down-weights easy examples and thus focusing training on hard negative examples. For a misclassified example with small p_i value, the modulating factor is close to 1 and hence the loss is not affected, whereas when p_i is close to 1, i.e., for a well-classified example, the modulating factor becomes 0 and the loss is down-weighted. α_i and γ are hyper-parameters, which can be tuned. The effect of the modulating factor is increased with increase in γ. If α_i = 1 and γ = 0, the focal loss becomes equivalent to the categorical cross entropy loss. Smooth L1 loss function [13] is used as the localization loss.

B. Bounding Box Pre-processor

Bounding Box Pre-processor stage extracts and prepares the detected candidate traffic sign boxes for classification. The center of the regressed bounding box is determined and the box is enlarged by 25% to compensate for any regression errors to make sure the traffic sign is completely enclosed in the region. The enlarged boxes are cropped and resized to 48 × 48 size and fed to the classifier network for recognition of the traffic sign class.

C. Traffic Sign Classifier

A fast and accurate traffic sign classifier network architecture proposed in [1] is used here.

In this architecture, an $n \times n$ convolution is replaced by an $n \times 1$ convolution followed by a $1 \times n$ convolution, which reduces both the number of convolution operations and the network parameters. This leads to computational cost reduction and increased speed.

The classifier network structure is in Table I. Batch Normalization and ReLU layers follows all layers other than the final dense layer. The sixth layer forms an inception module where kernels of different sizes are used to extract information from feature map output of the previous layer. The output feature maps from the inception layer are concatenated to combine the feature maps. Dropout layers are also used to regularize the activations of the final stages. To recognize the 43 traffic sign classes, fully-connected layer of an output size of 43 with Softmax activation is used as the last layer.

IV. EXPERIMENTS

The RetinaNet based traffic sign detector and CNN based classifier are implemented using Keras with TensorFlow backend. The detector and classifier are trained and evaluated on the GTSDB and GTSRB datasets respectively. Google Colaboratory environment with Nvidia Tesla T4 GPU having 16GB GPU memory was used for training the detector. The evaluation of the detector, as well as the training and evaluation of the classifier are done on a computer with an Nvidia GTX 1060 GPU having 6GB GPU memory.

Figure 3. Traffic scene image samples from GTSDB dataset [6]. These show different driving scenarios and lighting conditions.

TABLE I. TRAFFIC SIGN CLASSIFIER ARCHITECTURE [1]

Layer	Type		Filter Size/ Parameter	Filters/ Stride	Output shape

A. Datasets

The GTSDB and GTSRB datasets are very popular datasets for training and evaluating models for traffic sign detection and recognition respectively.

The GTSDB dataset is generated from video sequences recorded near Bochum, Germany. It consists of images from urban, rural and highway scenarios under different weather and lighting conditions making it pretty representative and challenging. The total dataset consists of 900 images of 1360 × 800 pixels in raw PPM format, which are divided into 600 training images and 300 test images. The training images contain 846 traffic signs and test images contain 360 traffic signs. The traffic sign sizes in the images vary between 16 and 128 pixels.

Representative sample images from GTSDB dataset is shown in Figure 3. It shows traffic scenes from urban, rural and highway driving scenarios in different sizes as well as under different lighting and weather conditions. It can be seen that due to harsh background lighting, traffic sign is barely visible in one of the images. Also, in the highway scene, it can be seen that the traffic sign images are small in size. Being a dataset having images of such diverse conditions, the GTSDB dataset is used to train and evaluate the RetinaNet based detector.

The GTSRB dataset consists of more than 50000 traffic sign images of 43 classes with sizes varying between 15 × 15 pixels and 222 × 193 pixels. Sample images of different traffic sign classes is shown in Figure 4. The classifier is trained using 39209 training images and evaluated on 12630 test images from GTSRB dataset.

B. Evaluation criteria

Intersection over Union (IoU) between the ground truth box and the predicted bounding box > 0.5 is considered as a positive proposal. Mean average precision (mAP) is used for evaluating the detector performance. Speed of detection per image, measured in milliseconds (or number of frames per second) is also used for evaluating the detector. These performance measures are used for comparing the performance of the proposed detector with Faster R-CNN and

YOLOv3 based detectors. Accuracy is used as the measure for evaluating the classifier performance. Confusion matrix-based evaluation for analyzing the accuracy of the classifier across various traffic sign classes is also used.

C. *Detector training*

Detector training was done on GTSDB dataset with 600 training images. Resnet50 model pretrained on COCO dataset was loaded as the backbone model for the RetinaNet. The regression subnets and classifier subnets are trained for 64 epochs with 500 steps/epoch, using minibatch training with a batch size of 4. The Adam algorithm [21] was used as the loss function optimizer with an initial learning rate of 1e-5 with learning rate reduction by a factor of 0.1 if learning plateaus. For focal loss, a weighting factor of $\alpha = 0.25$ and focusing parameter $\gamma = 2$ is used. $\lambda = 1$ is used as the balancing factor for the multi task loss. After 64 epochs of training, the classification loss has reduced to 0.0066 and regression loss to 0.196.

D. *Classifier training*

Classifier was trained on GTSRB dataset with 39209 training images. Minibatch training with batch size of 16 was done. Adam optimizer was used with an initial learning rate of 0.001 and learning rate decay of 1e-6 per mini batch. The classifier was trained for 50 epochs initially without any data augmentation and further for an additional 200 epochs with data augmentation, as proposed in [1], using various image transformations like shifting, shearing, scaling and rotation.

V. EVALUATION

A. *Detector Performance*

The RetinaNet based traffic sign detector was evaluated using the GTSDB test set consisting of 300 images. Mean Average Precision (mAP) is used as the performance measure for the detector. The proposed detector could achieve a state-of-the-art detection performance of 96.7% on the GTSDB test set. mAP of 97.1% is observed when verified with the training

Figure 5. Sample images of 43 traffic sign classes from GTSRB dataset [7]

Figure 5. (a) Traffic sign detection results. (b) Traffic signs labelled with classification results

set images. It took an average of 197ms for processing an image, i.e., an average frame processing rate of approximately 5 frames/sec (fps) could be achieved. Examples of detection results are shown in Figure 5 (a).

The detector performance is compared with traffic sign detector implementations using Faster R-CNN [1] and YOLOv3 [9] evaluated using the GTSDB test set. The proposed RetinaNet based detector outperforms both the detectors in terms of accuracy. However, YOLOv3 could achieve a higher frame rate performance of 9.87 fps with a mAP of 92.2%.

A comparison of the detector performances evaluated on Intel i7 based PC with Nvidia GTX 1060 GPU is in Table II.

TABLE II. TRAFFIC SIGN DETECTOR COMPARISON

Detector	mAP	Time per image	Frame Rate
Faster R-CNN [1]	84.5%	261ms	3.82 fps
YOLOv3 [9]	92.2%	101ms	9.87fps
RetinaNet (proposed)	**96.7%**	197ms	5.07fps

B. *Classifier Performance*

The CNN based custom traffic sign classifier was evaluated using the GTSRB test set consisting of 12630 images. Model trained without data augmentation could achieve an accuracy of 96.46%. With data augmentation, accuracy has improved to 99.6% as reported in [1]. Figure 6 shows the confusion matrix of the classification results from the model trained with data augmentation, where the per class accuracy of the classification results can be seen. It can be seen that most of the classes could be classified with 100% accuracy. A minimum accuracy of 97% is observed for one of the classes.

A complete traffic sign recognition pipeline using RetinaNet based detector, bounding box processor and CNN based classifier has been setup by integrating the components. The final result images with labels generated by the classifier on bounding boxes from the detector are shown in Figure 5(b).

VI. CONCLUSION

In this paper, a traffic sign recognition system based on RetinaNet detector and a custom CNN based classifier is proposed. The detection performance, with traffic-sign being considered as single class, is found to be superior to all previous detectors, based on the detection accuracy, with a reasonably high frame rate. The proposed detector has been proved to be able to detect almost all categories of traffic signs and could regress accurate bounding boxes for the detected signs. The CNN based traffic sign classifier is simple in architecture with very high accuracy. The RetinaNet based detector and CNN based classifier completes the traffic sign recognition pipeline.

The fine-tuning and evaluation of the proposed detection network on other benchmark datasets such as Tsinghua-Tencent 100K can be taken up in future, which could make

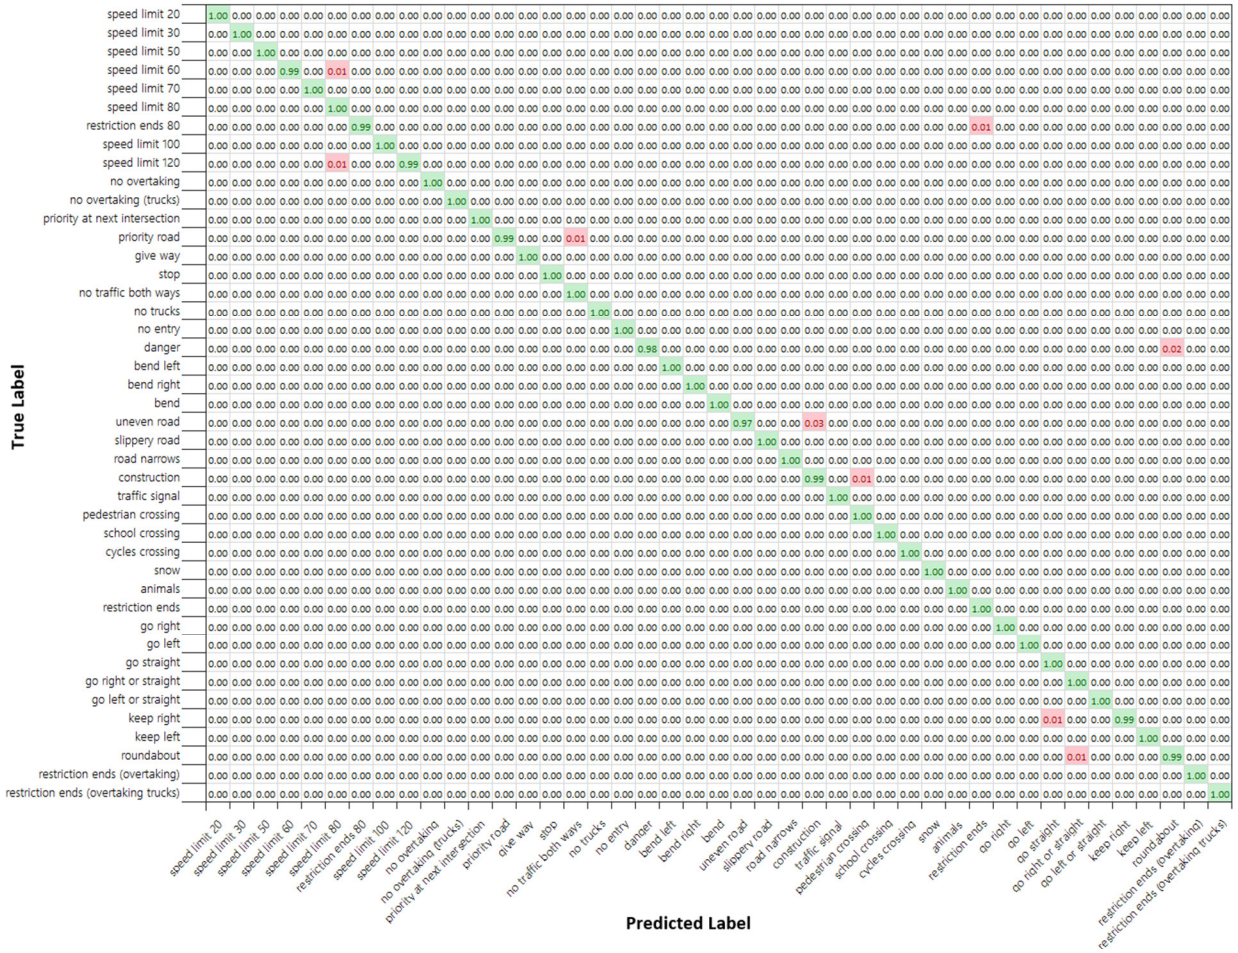

Figure 6. Traffic Sign Classifier Confusion Matrix

the recognition system more robust. Also, there is a possibility of enhancing the datasets with newly added traffic signs, so that the model can be made current with the existing transportation infrastructure in various countries. End-to-end traffic sign recognition pipeline using the proposed detector is another aspect which can be explored further. Based on some of the initial evaluations, it is observed that RetinaNet detector's performance is promising for end-to-end traffic sign recognition. Experiments with fine tuning the network parameters to bring the performance of end-to-end recognition comparable to the detector-classifier combined approach can be taken up in future.

***Abstract*— This paper presents direct torque control scheme for an asymmetric multilevel inverter fed induction motor drive for fuel cell based electrical vehicles. The controlling principle is based on Direct torque control (DTC) method. The torque and flux estimator takes input as measured voltage, current and stator resistance. The estimator further calculates the error in flux and torque. The SPWM generates such switching signals which reduce error. The asymmetric multilevel inverter provides almost sinusoidal voltage with less total harmonics distortion (THD) and less switching devices resulting in lesser switching losses. In addition, torque ripple is minimized because of small dv/dt, since each power cell of multilevel inverter operates at switching rate which is very high so we obtain an efficient torque and flux controller. A comparative analysis of two level and multilevel inverter is also done in respect of transient responses and torque ripple. To authenticate the accomplishment of DTC for an asymmetric multilevel induction motor drive for fuel cell electrical vehicles, Simulations are executed in MATLAB/Simulink. The results vindicate advantages of asymmetrical multilevel induction motor drive DTC control for electrical vehicles.**

Keywords—Total harmonic distortion(THD), Direct torque control (DTC), Sinusoidal pulse width modulation (SPWM), Electrical Vehicle (EV) cascaded h-bridge (CHB)

I. INTRODUCTION

Due to extensive use of fossil fuels vehicles, the environmental condition is becoming deteriorating day by day. Co_2 production by these vehicles is increasing at alarming rate, which cause various environmental issues like greenhouse effect and many more. Fossil fuels are limited in nature and if we keep using them at the present rate then the day will be near when we are devoid of them [1]. These all environmental apprehensions have forced to limit the conventional vehicles. Fuel cell based electrical vehicles are one of the most prominent solutions to overcome the challenges caused by conventional vehicles. Due to low weight, small size and low temperature operation, fuel cell is famous in electrical vehicle application. Fuel cell is having high energy density but low dynamic response. Therefore another fast charging storage is required to improve dynamic response of fuel cell. Efficiency and dynamic response of fuel cell can be enhanced by the use of ultra-capacitor [2].

Today induction motors are very famous in variable speed drive. DTC is one of the emerged solutions for better dynamic accomplishment of these machines. DTC method combined with PWM and space vector modulation (SVM) reduces ripple in torque and also maintain the switching frequency of inverter constant [10]. While DTC scheme having no modulator and linear torque controllers which gives significance upswing along with high dynamic performance[3-5]. Additionally, multilevel inverters have emerged as most promising elucidation for high power implementation. Because of output sinusoidal voltage, harmonics spectrum is better and limits the stress on motor insulation windings. It gives the solution over low levels of output voltage and requirement of an expensive and large filter [6].

In this paper, Direct torque control (DTC) enables the natural consolidation of multilevel inverter with induction motor drives. In this model, an asymmetric H-bridge multilevel inverter of seven levels is used [9]. It reduces torque ripple and improve transient responses compared to two level inverter. Simulation results confirm the improvement and advantage of proposed method [7].

This paper has organized in the following sequence. Section II consist a brief discussion about asymmetric CHB inverter. Section III includes DTC scheme for induction motor drive. In section IV results have been discussed for two level and multilevel both. And finally section V concludes the outcomes of the presented work and also discussed about future scope of this work.

II. ASYMMETRIC CHB INVERTER

The asymmetric seven level cascaded h-bridge inverter power circuits exhibited in figure.1. It has three legs each contains two cell fed by independent unequal DC sources. Here DC voltage is obtained by fuel cell.

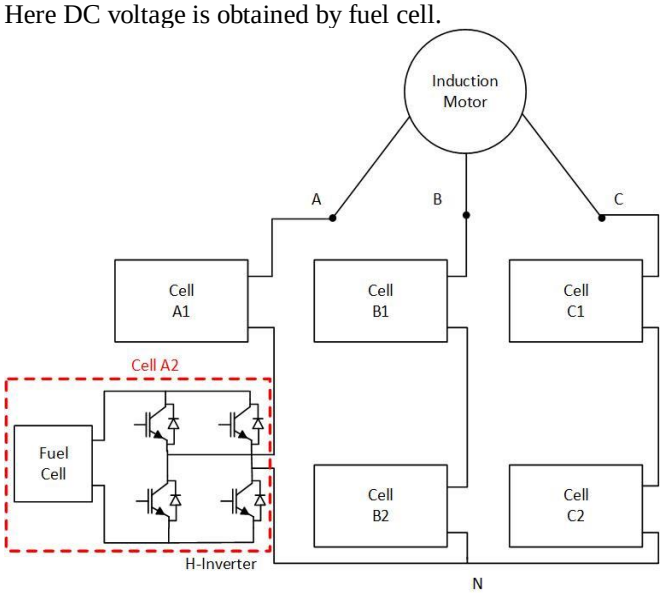

Fig. 1. Presented asymmetrical multilevel inverter

The foremost benefit of an asymmetric multilevel inverter is that with same number of semiconductors switches, it give more number of levels and hence switching losses reduces with a significant factor [8]. If we feed partial voltages of V/(M-1), the all possible redundancies is equal to (3^a -2a -1). If 'a' number of cells are connected to each leg of inverter then the 3^a switching configurations are there [10]. Output voltage of multilevel inverter relies on partial voltage fed to each cell. The feasible switching states can be also minimized if each cell is fed by unequal dc voltage. This result in reduction of cost, volume and switching losses and the conversion efficiency becomes very high.

Particular cell j can give three different voltage levels ($+E_j$, 0, $-E_j$). The asymmetry we can attain from dc voltage is scaled in power of two or three, gives seven or nine distinct levels of output voltage. Seven levels of output can be obtained by two cells, while three cells are required to generate the same seven levels of output with symmetrical multilevel of inverter.

III. INDUCTION MOTOR DTC SCHEME

Direct torque control is an alternate scheme to flux-oriented control(FOC). DTC scheme is generally based on refinement of stator voltage on the basis of torque and flux error. DTC method has advantage that stator flux and current waveforms are almost sinusoidal. The motor parameters won't affect the DTC scheme except the stator resistance. DTC provides superior torque control in transient and also in steady state [12].

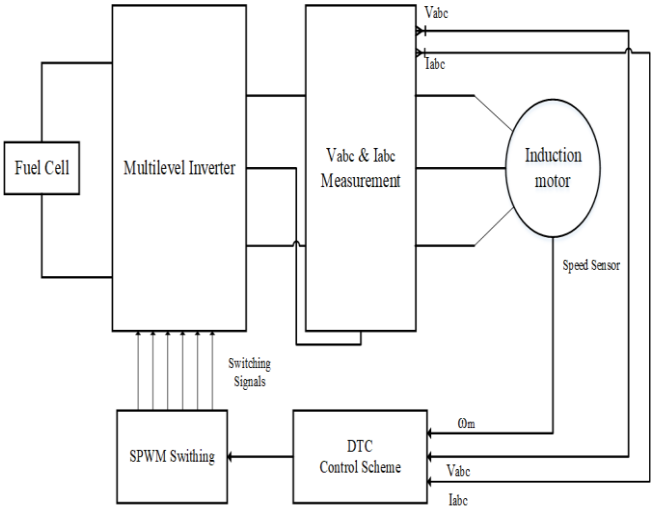

Fig. 2. Block diagram of multilevel DTC induction motor drive

The concerned multilevel drive system is displayed in fig 2 for study point of view. The system consists of multilevel inverter fed by fuel cell (V_{dc}) to drive the induction motor. V_{abc}, I_{abc} and speed are sensed by sensing devices. DTC block used to govern torque and speed of induction motor and with the help of carrier base sinusoidal PWM scheme it generates switching signal for multilevel inverter[11].

A. Modulation strategy

In this paper, the phase shifted multicarrier PWM scheme is accomplished for generating switching signal for multilevel inverter. Usually for P voltage level inverter , (P-1) carriers are needed. In this scheme all carriers have equal frequency and amplitude while two neighbouring carrier signals have some phase shift, given by

$$\Phi = 360/(p-1)$$

The modulating wave is generally a sinusoidal signal having alterable frequency and amplitude. The switching pulse are produced by comparing both modulating and carrier signal. Output wave of each cell is identical except having some phase difference due phase shifted carrier signal.

B. Induction motor modelling

$$\frac{d\Psi_s}{dt} = -\frac{1}{T_s\sigma}\Psi_s + \frac{L_m}{L_r T_s \sigma}\Psi_r + U_s \quad \ldots\ldots. 1$$

$$\frac{d\Psi_r}{dt} = \frac{L_m}{L_r T_s \sigma}\Psi_s - \left(\frac{1}{T_s\sigma} - j\omega_r\right)\Psi_r \ldots\ldots 2$$

Where,

Ψ_s	stator flux
Ψ_r	rotar flux
u_s	stator voltage
L_s	stator total inductances
L_r	rotor total inductances
L_m	magnetizing inductances
R_s	stator resistance of IM
R_r	rotor resistance of IM
ω_r	rotor speed of IM

$\sigma = 1-L_m^2/L_sL_r$, $T = L_s/R_s$, $T_r = L_r/R_r$,

Torque is expressed as

$$T_e = \frac{1.5PL_m}{L_{\sigma_*}^2}\left(\Psi_{s\beta}\Psi_{r\alpha} - \Psi_{s\alpha}\Psi_{r\beta}\right) \quad \ldots\ldots 3$$

Where, P denotes pole pairs and $L_{\sigma_*}^2 = L_sL_r\sigma$

C. Design of Direct torque control scheme

The presented DTC scheme displayed in figure 3, consists three major Parts: torque and flux estimator, PWM gating pulse originator and PI controller.

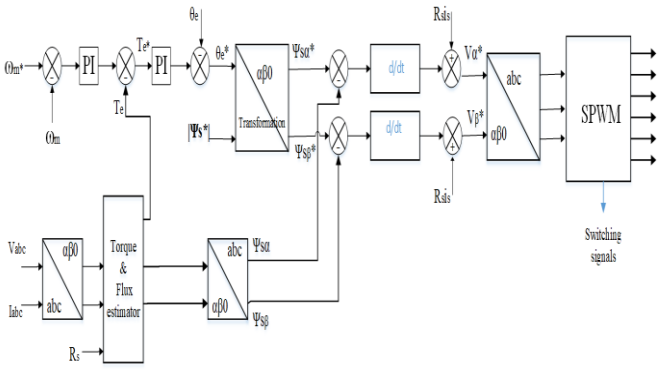

Fig. 3. Presented DTC scheme for multilevel IM drive

The computed voltage, current and stator resistance is given for torque and flux estimation, Evaluated value by torque and flux estimator block are further practiced to determine errors. Speed error is deliberated by comparing

constant speed(ω_{r*}) and computed rotor speed (ω_r) and fed to PI controller which gives reference torque (T_{e*}). PI torque regulator gives reference angle (θ_{e^*}) and after comparing them, we get angle error (θ_{e^*}- θ_e) which further given to transformation block.

The constant stator flux (Ψs^*) is same as rated stator flux ($\Psi s_{_rated}$) when speed is less the base speed (ω_{br}) and when speed is more than base speed it proportionally reduces. The switching block get three sinusoidal signal which generate the gating pulse for inverter.

$$\Psi_s^* = \Psi_{s_rated} \; for \; \omega_r < \omega_{br} \; \ldots\ldots\ldots\ldots\ldots 4$$

$$\Psi_s^* = \Psi_{s_rated} \left(\frac{\omega_{br}}{\omega_r}\right) \text{ for } \omega_r > \omega_{br} \; \ldots\ldots 5$$

The stator flux components are calculated with the help of direct and quadrature axes values of voltage, current and resistance (R_s).

$$\psi_{\alpha s} = \int \left(v_{\alpha ss} - i_{\alpha ss} R_s\right) dt + \psi_{\alpha so} \; \ldots\ldots\ldots\ldots 6$$

$$\psi_{\beta s} = \int \left(v_{\beta ss} - i_{\beta ss} R_s\right) dt + \psi_{\beta so} \; \ldots\ldots\ldots\ldots 7$$

Total stator flux (Ψ_s) is given as

$$\psi_{\alpha s} = \sqrt{\psi_{\alpha s}^{\,2} + \psi_{\beta s}^{\,2}} \; \ldots\ldots\ldots\ldots\ldots\ldots 8$$

The developed torque is enumerated by help of direct and quadrature axis flux and current components.

$$T_e = \left(\frac{3}{2}\right)\left(\frac{P}{2}\right)\left(\psi_{\alpha s} i_{\beta ss} - \psi_{\beta s} i_{\alpha ss}\right) \ldots\ldots 9$$

Where

$v_{\alpha ss}, i_{\alpha ss}, \psi_{\alpha s}$ Direct axis stator voltage, current and flux respectively

$v_{\beta ss}, i_{\beta ss}, \psi_{\beta s}$ Quadrature axis stator voltage, current and flux respectively

V_{abc}, $v_{\alpha ss}$ and $v_{\beta ss}$ is computed using Clarke transformation

$$v_{\alpha ss} = \left(\frac{1}{3}\right)\left(2v_a - v_b - v_c\right) = v_a \; \ldots\ldots 10$$

$$v_{\beta ss} = \left(\frac{1}{3}\right)\left(\sqrt{3}v_b - \sqrt{3}v_c\right) \; \ldots\ldots\ldots 11$$

In Fig.4 scheme for computation of flux and torque is presented. With the help of equation given in 6 and 7 flux can be estimated and by equation 9 torque is estimated.

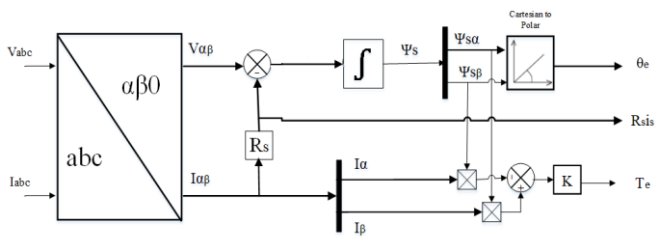

Fig.4. Flux and torque estimation block diagram

IV. SIMULATION RESULTS

For the authentication of presented control scheme for multilevel induction motor drive, simulation of asymmetrical multilevel inverter IM drive and two level inverter fed IM drive are performed using MATLAB. The IM parameters used in MATLAB simulation is presented in TABLE 1.

TABLE 1 : Induction motor parameters

Parameter	Value
Power Rating	4 KW
R_s	1.404 Ω
R_r	1.396 Ω
L_s	0.00598 H
L_s	0.00589 H
L_m	0.1730 H
Inertia(J)	0.0132 Kg.m^2
No of poles	2
Speed (Rated)	1430 rpm
Line voltage	400 V
Rated Frequency	50 Hz

A. *Results of two level Inverter*

Output voltage of two level converter which is fed to IM is displayed in Fig. 5 . The output voltage waveform clearly explains poor dynamic response of induction motor drive as it required notable time to settle at final value.

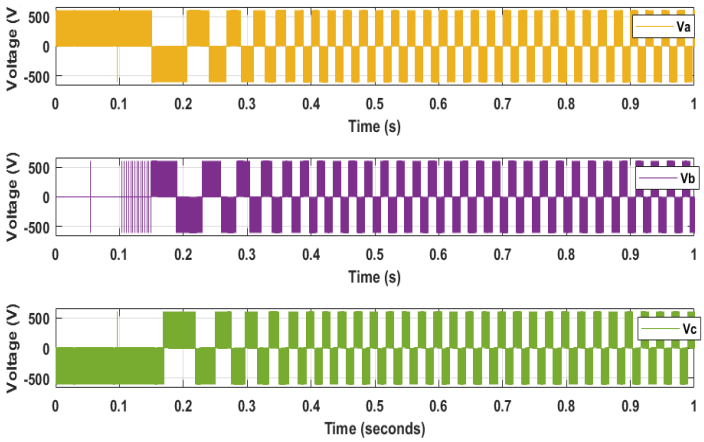

Fig.5 stator voltage in case of two level inverter

In Fig. 6 input current of induction motor is shown. The nature of this current is sinusoidal due to stator winding inductance which acts as filter. The values of current are varying in accordance to the torque.

In Fig.7 stator flux in α and β axis are shown. Both the signals are 90 degree apart from each other sinusoidal in nature. Stator flux is kept invariant in spite of variation in torque and speed.

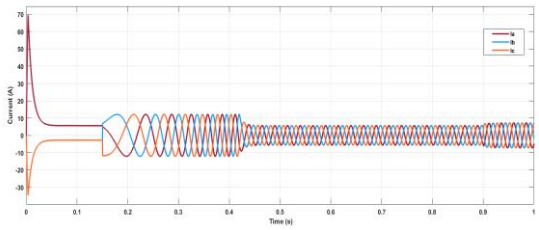

Figure 6 Stator phase current in case of two level inverter

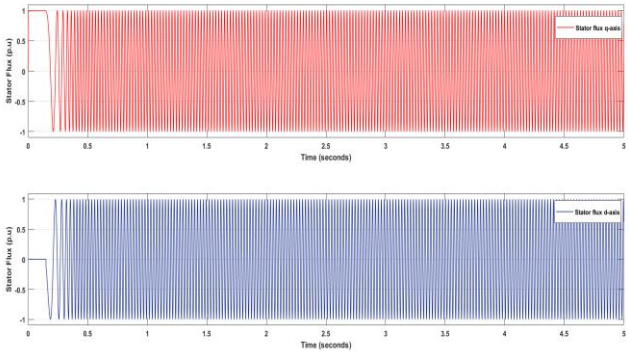

Figure 7 stator flux in α and β axis in case of two level inverter

In Fig. 8 actual and reference speed of induction motor are shown. The reference speed is tracked by actual speed as clearly shown in figure. But the time required by actual speed is 0.4 sec to track the reference speed which indicates poor dynamic response of drive with two level inverter.

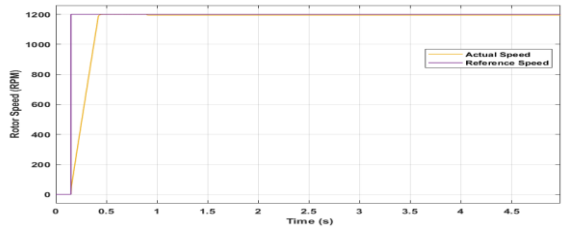

Fig. 8 Reference and actual speed in case of two level inverter

Like speed, actual and reference torque are displayed in figure. 9. Reference torque is tracked by actual torque still dynamic response is worse because actual torque takes approximately 0.8 sec to track the reference torque. In addition to this, transient response also need to be improved as it's value rises to 30 during starting in case of two level inverter.

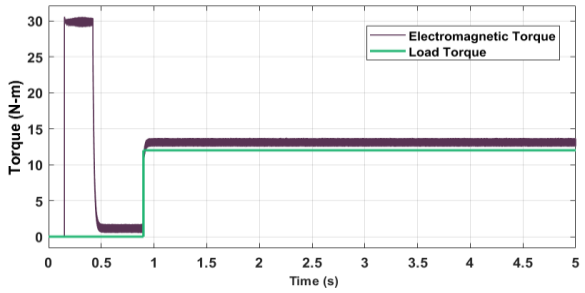

Figure 9 Reference and actual torque in case of two level inverter

B. Results of multilevel inverter

In fig. 10 phase A multilevel inverter voltage signal is shown. Dynamic response compared to two level inverter is much better also total harmonics distortion is less.

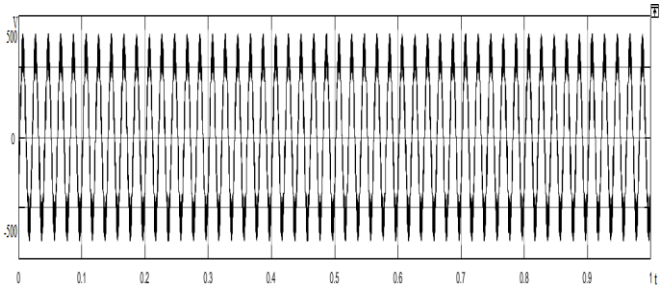

Figure 10 stator phase voltage of multilevel inverter

Likely, stator current is displayed in fig.11 which clearly indicates better dynamic response and current transient as compared to two level inverter . It needs very few time to settle at a final value.

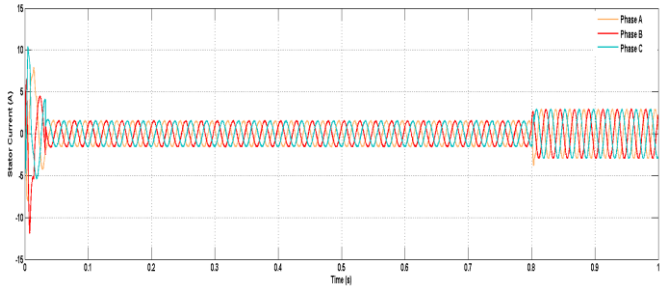

Figure 11 Stator current in case of multilevel inverter

The d and q-axis stator flux are displayed in fig. 12 which is constant everywhere similar to the two level inverter.

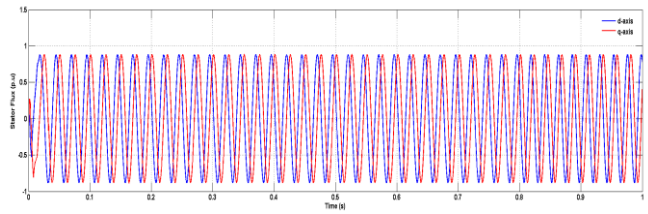

Fig. 12 Stator d and q- axis flux in case of multilevel inverer

In fig.13 actual and reference speeds are shown. We can clearly observe from the figure that it has better dynamic response of IM drive as compared to two level inverter. In case of multilevel inverter actual speed takes 0.2 sec to track the reference speed, While in case of two level inverter, it takes only 0.4 sec.

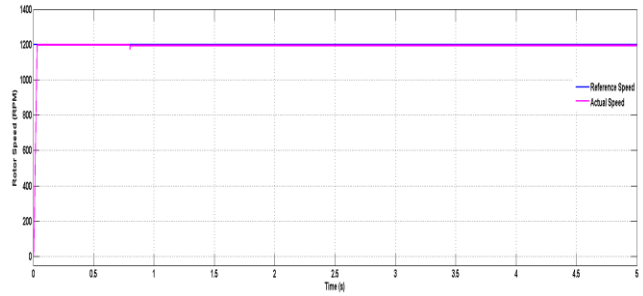

Fig. 13 Reference and actual speed in case of multilevel inverter

Like wise, The reference torque and actual torque is displayed in fig 14. It can be seen from figure that both transient and dynamic resposnse are improved in case of multilevel inverter.

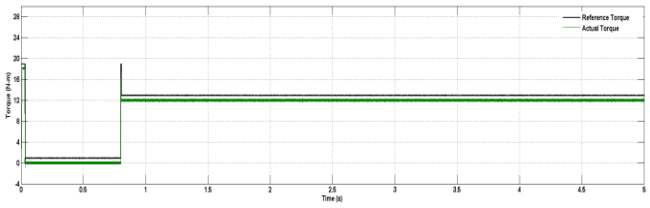

Fig. 14 Actual and reference torque in case of multilevel inverter

VI. CONCLUSION

This paper elucidates performance of asymmetrical multilevel inverter fed induction motor drive with DTC control scheme, which is very popular for electric vehicles. The multilevel inverter drive provides a DTC consolidation for high power application. The major accomplishment of the presented control scheme are minimization in torque ripple, better dynamic response, sinusoidal output voltage having very low THD and lower switching losses in compared of two level inverter. The simulation results validate the better performance of multilevel inverter drive over two level inverter drive. The results also infer that there is yet a chance of further refinement in the presented scheme in terms of new switching techniques and new multilevel topology with reduced number of switches.

Abstract:

This paper presents a surveillance system that is capable of transmitting its geo location and the information from real time images to a central unit in no network zone. The system is further configured for using image processing and machine learning algorithms to deduce any suspicious object from the captured image. Thereby, the system is helpful in identifying threats in all kind of weather conditions on land and in oceans. The system is very efficient, cost effective and is simple in design. Once the threat is identified, the system transmits the information to the central unit through the LoRa by using certain communication protocols. Compared to existing devices, this system has the potential to reduce causalities by enhancing navigational and observational features in the surveillance sector.

Keywords:

Image Enhancement; Object Identification; LoRa; LoraWAN; Geolocation; RSSI.

I. INTRODUCTION

Surveillance, a process of monitoring an area, a situation or a person. Borderline areas and restricted territories surveillance are important for any country's safety. In some cases, human forces are deployed to achieve surveillance by constantly monitoring for changes. But the human surveillance is not always a feasible option in cases when the areas to be monitored are risky and inaccessible. There are also the added risks of losing personnel in the event of getting caught by the enemy or any other possible events. With present inventions in modern technology over the years, it is possible to remotely monitor areas of importance by using robots in place of humans. Till date, many remote surveillance robotic systems are available in the market for this purpose. Recently designed robotic systems mostly comprise different types of localization aids such as a GPS system or internal compass, and communication means to exchange information and instructions with a remote-control station.

However, the remote surveillance systems available in recent times highly depend on the availability of communication networks. In case of unavailability of communication network these systems are bound to stop functioning. The communication networks often get affected due to weather conditions or due to destruction of communication channels in war zones. Thus, surveillance becomes difficult in war zones. Hence, a system and method for remote surveillance in no network zones has to be developed. Also, a need to develop a system for remote surveillance that is capable of transmitting geo location and information from real time images to a central unit in no network zone. A system and method of remote surveillance in no network zone could lead to greater advances in surveillance sector by providing: (a) a system to provide a surveillance system that uses image processing and machine learning algorithms to deduce any suspicious object (b) a system that does not rely on Global Positioning System(GPS) but rather relies on the local positing system (c) a system to provide a surveillance system capable of collecting real time images and geo location in no network zones for identifying potential threats (d) a system to provide a remote surveillance system capable of working in all kind of weather conditions on land and in oceans while being more efficient, cost effective and is simple to design.

II. SYSTEM MODEL DESIGN

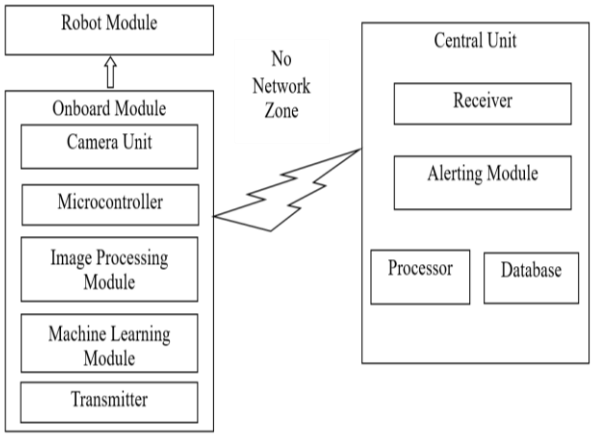

Fig 1: System model

This section briefs on the various components associated with the model. The components were decided mainly focusing the efficiency, the cost effectiveness and power consumption levels. The system has basically two main units as shown in the Fig 1: (a) Robot Module present at the no network zone and (b) the central unit at communicable area.

Robot Module:

The robot module has various onboard components. The robot has been built in a way that it has the dynamic capability to cover any kind of terrain. The chassis is made up of light fiber material, embedded with motor shield for driving the motors, Raspberry Pi as the major microcontroller. Additionally, a camera is deployed for taking the images of the surrounding. The captured image is further processed to extract information using the image processing and machine learning algorithms. The reliable extracted data is then sent over to the central unit via the LoRa module SX1278 (works at a frequency of 433Mhz) which is controlled by the Arduino as a microcontroller.

Central Unit:

The central unit comprises of LoRa module SX1278 which receives the data from the robot module through LORAWAN protocol. Then the received data is further processed with the help of Arduino as a microcontroller. Received information is then processed and classified as the suspicious or non-suspicious object.

III. STATE OF THE ART

The sections followed describes the various state of the art regarding the individual components that are being utilized. Firstly, the image processing algorithms are applied on the captured image for qualitative improvement of the images, that is further processed by implementing machine learning algorithms to identify the elements present in the image. Furthermore, the transmission of information done in no network area with LoRa as a transceiver is discussed. Lastly, the section ends with the integration of individual platforms as a whole.

A. Image Processing:

Due to the limitations of cameras or the presence of non-ideal situation degrade the quality of images. Even different camera devices do not correctly capture the luminance. The contrast, brightness and sharpness of an image are the most important factors which affects its quality. An image which has low contrast and brightness, is associated with dynamic range. The pixels of image can be classified in shadow and highlight. To enhance the images with low brightness, contrast and sharpness we are using conventional algorithms like gamma correction, histogram equalization and unsharp masking to produce the expected results.

Each pixel has some brightness level called luminance [3]. The value of luminance lies between 0 to 1 where 0 means completely dark and 1 means complete bright. So, to correct the luminance we are using gamma correction. Histogram equalization is such a widely used algorithm. Histogram Equalization preserves the brightness and improve the contrast of the image. In our work our main aim is to improve the overall quality of the image so it will easy of the machine to identify the objects in the image.

This section provides a complete description of the proposed method. Figure below shows stepwise flowchart of the proposed method. The proposed method is initiated by calculating the Gamma correction of the image then the conversion of RGB image to YUV image and then the implementation of histogram equalization. In last convert the YUV back to RGB image.[6]

In the gamma correction the gamma is represented by Greek letter which can be described as the relationship between input and output image. The output is proportional to the input raised to the power of gamma.

$$I' = 255 \times \left(\frac{I}{255}\right)^{\frac{1}{y}}$$

Histogram equalization is one the most commonly used contrast enhancement algorithm. It is simple and effective technique. In the equation X = {X(i, j)} denotes an image composed of L discrete gray levels. X(i, j) represents the intensity of the image at (i, j).

$$p(X^k) = \frac{n^k}{n}$$

For k = 0, 1, 2, 3, ……L-1.

Unsharp Masking is most widely used method for image sharpening. This method is simple and work well in many applications also. This algorithm usually decomposes the original image into low frequency component and then process two components [3].

B. Machine Learning:

a) Detection process:

This system comprises of the methodology which is a new approach to the object detection. We are using the YOLO object detection.[8] Previously the object detection required classifiers to perform the detection for them.[12] But this methodology frames the object detection as regression. A single neural network estimates both the probabilities and the bounding boxes from the entire image in one evaluation. Hence improving the performance of the detection. It can process around 45 frames per second. It outperforms various other forms of detection mechanisms present.

The system divides the image into S*S grid. The center of the object which gets in the grid cell is responsible for that object. Each of the grid cell predicts the bounding boxes denoted by B. Also, the scores for these boxes is denoted by the confidence C.

Formally the confidence is defined as

$$\Pr(\text{Object}) * \text{IOU}_{\text{pred}}^{\text{truth}}$$

If no object is present then the confidence is given as zero. Each of the bounding boxes consists a total of 5 predictions: confidence, h, x, y, w. The (x, y) coordinates tell the center of the boxes relative to the grid cell present. The height and width are also then predicted as relative to the entire image.

Confidence prediction shows the IOU between the predicted boxes and any ground truth box present. Here, each grid cell also predicts C conditional class probabilities i.e.

$$\Pr(\text{Classi}|\text{Object})$$

These probabilities are dependent on the grid cell that contains the object. It can only predict one set of class probabilities per grid cell present. It is regardless of the number of boxes B present there. Then multiply the conditional class probabilities and the individual box confidence predictions, which gives the specific confidence scores for each class.[8]

$$\Pr(\text{Classi}|\text{Object}) * \Pr(\text{Object}) * \text{IOU}_{\text{pred}}^{\text{truth}} = \Pr(\text{Classi}) * \text{IOU}_{\text{pred}}^{\text{truth}}$$

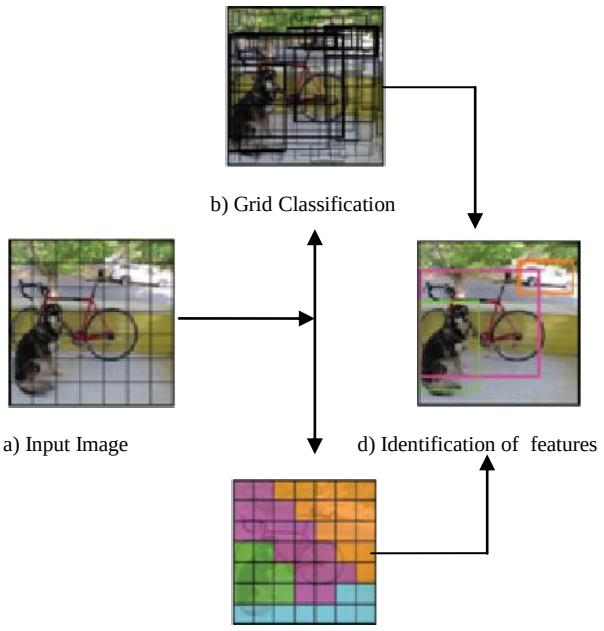

Fig.2. Working structure of Machine Learning

{Image taken from [7]}

Here the problem is taken as a regression. The image is divided into an even grid while simultaneously predicting the various bounding boxes, their confidences and class probabilities. Then these are encoded as a S * S * (B * 5 + C) tensor.

The image has S=7, B=3 and C=20. So, our final prediction is 7*7*35 tensor.

b) Training:

We train our convolutional neural network with the help of the data set of MobileNetSSD [16]. The OpenCV is being used because of its compatibility for multiple platforms and with higher speed and low computational power. We have trained 90 objects for this model.

Once the image is obtained, it is fed to the neural network [7]. But for feeding it to the neural network it has to ben converted into a tensor. A tensor can be described as the pre processed image that serves as the input. The image is converted into 300x300 size for training and the colors are swapped from BGR to RGB. As the OpenCV reads in BGR while RGB is used for training.

Each detection gives us the class probabilities or the confidence (ranges from 0 to 1). The higher confidence objects are selected and the others are discarded. Then based upon the bounding boxes recognized a rectangle is drawn across the objects identified. The class id, confidence and class name are used for drawing the bounding boxes (Figure 2). Further, text is added based upon the image size upon scaling it. So, in this way this method allows us to recognize and get a desired box across our detected objects.

C. LoraWAN for Localization

LoraWAN module SX1278 works at a frequency of 433 MHz band plays a crucial role in this work. This module is considered with the motivation of implementing a system which consumes low power for localization and transmission of data. LoraWAN modules consume 2.8mA of power in steady state and 38.9mA and 14.2mA for transmitting and receiving the data respectively. With these interesting features, the geographical localization becomes a strong application which can be achieved by applying triangulation algorithm with the RSSI values on the gateways from received packages.

a) System Design

The complete system comprises of three blocks: client, 3 gateways, server and a third-party application. The client transmits the packages using LoraWAN protocol and the gateway receives the packages which are

further forwarded to the server using LoraWAN protocol, together with the RSSI signal strength. After the server receives the data, server processes the received data and transmits the messages to the application by using Message Queue Telemetry Transport (MQTT) client. The algorithm for estimating the geographical location is then applied by processing the received information.

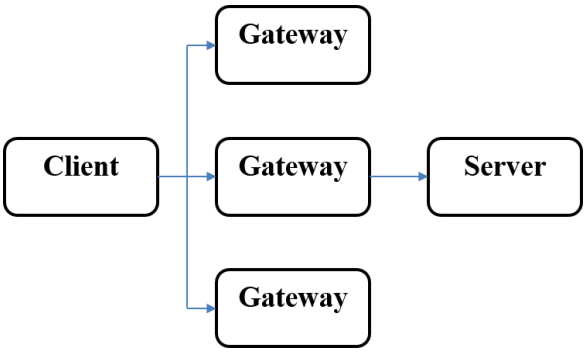

Fig.3. Experimental Setup

- *Client*

The client transmits the data acquired from the machine learning algorithm through a LoraWAN module. The data comprises of the object identification information which is received using the machine learning algorithms and sends it to the server via gateways. The client comprises of a dynamic autonomous robot with the accessories of a camera, 4 motors and a motor driver and a raspberry pi 3B+ module which plays a role of a microcontroller. The camera is used to capture the image which is processed without distortion and keeping the naturalness of the image by using the several image processing algorithms and then the identification of the object is done by using FCNN algorithm, the data is then compressed according to the limitation of the LoraWAN module, which can transmit a limited data. The overall process takes 90 seconds for processing and transmitting the data.

- *Gateways*

The important function of the three gateways is to route the received data from the client to the server via LoraWAN protocol. To estimate the location of the device, the Received Signal Strength Indication (RSSI) value is used to estimate two phases: Distance estimation and Position estimation. The distance is estimated with received RSSI strength value from the client which is considered as an unknown target, the known position of the gateways gives the coordinates of the gateways which receives the signal. By applying the log Normal Shadowing model's algorithm, the estimation of distance (d) is done. The formula for estimation:

$$RSSI(d) = -10n\log(d) - C$$

n= Path loss exponent, C= environmental constant

The estimation of distance d1, d2, d3 from the three gateways respectively is used further to estimate the accurate location of the target.

- *Server*

Server acts as a central unit of the system where the data together with the information of the RSSI value and the estimated distance from each gateway is received via LoraWAN protocol. The estimated distance is used to calculate the accurate position of the target by applying trilateration algorithm.

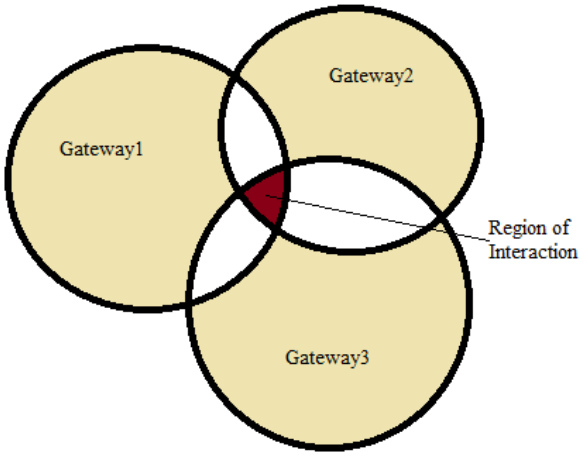

Fig.4. Trilateration Technique

The coordinates of the gateways (x1,y1), (x2,y2), (x3,y3) and the estimated distances d1, d2, d3 from each coordinates of the gateways respectively is used to estimate the unknown coordinates (x,y) by using the least mean square approximation. This is implemented by using the formula:

$$Min\|AX-B\|^2$$

X is a best solution

The circle with the distances d1, d2, d3 as the radius is drawn and the intersection of the three circular boundaries gives the coordinates of the target client.

IV. IMPLEMENTATION AND EVALUATION

This section describes how the entire operation takes place. The system comprises a robot(client) that is deployed in an area. The motion of robot is controlled

by the motor. The onboard module comprises an Arduino board and a raspberry pi board. The image processing [4] and machine learning [8] algorithms are processed in the raspberry pi. Further the raspberry pi is connected with a camera module for taking the input images of the surrounding areas. The Arduino board communicates with the raspberry pi with the help of the serial bridge between them. Also, the LoRa SX1278 module is connected with the Arduino. All the information processed by the raspberry pi is sent to the Arduino board which further sends the only required data with the help of LoRa SX1278 module. Thus, these are the modules present on the client.

The client and the server communicate is achieved using wireless radio frequencies. OpenCV is used to capture the images through the connected WebCam. It is then processed accordingly to feed to the neural network. The neural network is based on the dataset called MobileNetSSD. On detecting the provided set of pre-mentioned targets, the object is detected and its accuracy is sent to Arduino through the Serial interface connected through the USB. The Arduino uses a library called RadioHead which is provided by AirSpayce. It is used to initialize and communicate with the LoRa module. Arduino collects the data sent by Raspberry PI on the serial interface and broadcasts it using LoRa on the specified frequency (433.00 MHz). Then the gateways collect the information being broadcasted and is then combined at the server. The server is designed to show us a real time location of the client along with the detected threats.

When the experiment was conducted under the guidance of the professor the results obtained were cross referenced with the outdoor measurements and locations respectively. The errors noted were minimal. Thus, we were able to locate the object with an error of about 10 meters.

V. EXPERIMENTAL RESULTS

The results at the server side obtained were basically the distance, signal strength and thereby geo locations. Also, the system notified the user if a threat was detected. The following section will show these various components individually.

A. The image enhancement

The image below shows the image prior and after the application of image processing algorithms.

a) Test Image b) Gamma Correction c) After HE & UM

Fig.5. Results for Image Enhancement

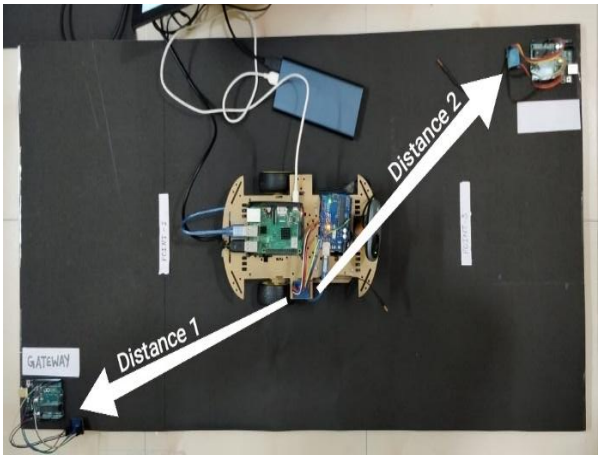

Fig.8. System Setup

VI. CONCLUSION

We here introduce a unified model, for detection of threats in a no network zone. Our model is simple to construct and can be easily used. It also is cost effective and power requirements are minimal. The implementation and evaluation part show that this technology has a lot of applications in the context of surveillance and poor network zones. Furthermore, the system can be improved in future and designed to work in designated areas.

***Abstract*—Brain tumor at beginning period is exceptionally troublesome errand for specialists to distinguish. X-ray images are increasingly inclined to commotion and other ecological impedance. So it winds up hard for specialists to distinguish tumor and their causes. So here we concoct the system, where system will identify brain tumor from images. Here we convert image into gray scale image. We apply channel to image to expel commotion and other ecological obstruction from image. Client needs to choose the image. System will process the image by applying image preparing steps. We connected k-means++ bunching based Division to identify tumor from brain image. Yet, edges of the image are not sharp in beginning period of mind tumor. So we apply image division on image to distinguish edges of the images. In this technique we connected image division to recognize tumor. Here we proposed image division process and many image separating strategies for precision. This system is executed in tangle lab. Tumor is undesirable development of unfortunate cell which increment intracranial weight inside skull. Restorative image preparing is the most testing and imaginative field uniquely X-ray imaging modalities. The system exhibited includes pre-handling, division, highlight extraction, identification of tumor and its grouping from X-ray examined brain images. Attractive Reverberation Imaging (X-ray) is a non-obtrusive imaging modalities which is most appropriate for the location of brain tumor. In this work, Multi Bolster Vector Machines (m-SVMs) has been proposed and connected to brain examined image cuts arrangement utilizing highlights got from slices**.

Keywords—Brain tumor x-ray, k-means++, m-SVMs etc.

1. INTRODUCTION

National Brain Tumor Foundation (NBTF)[1] in the US, around 13 thousand individuals cease to exist of 29 thousand individuals in the U.S. who are determined to have essential mind tumors every year. In light of the estimation of World Wellbeing Association (WHO), mind tumor is viewed as a standout amongst the most well-known cerebrum maladies, so its analysis at beginning time and convenient treatment can help a great many influenced people every year on the planet to expand the odds of survival. In addition, according to review of WHO, numerous instances of death are accounted for overall in light of threatening or destructive tumor.[2-3]

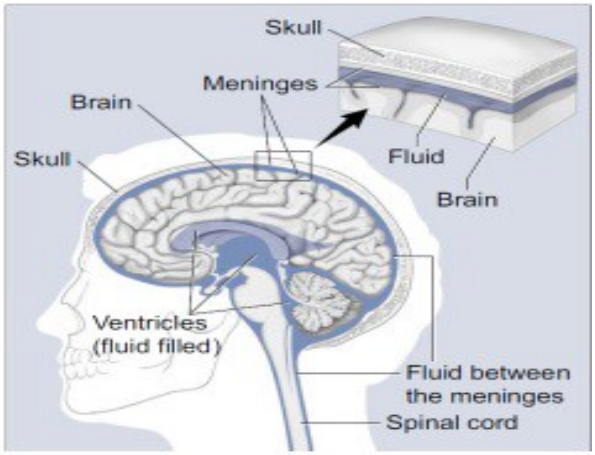

Figure 1: structure of Brain [10]

A. Features of Tumor

In general, the tumor is portrayed as tissue bunch formed as a result of the gathering of unpredictable cells in the body. Routinely, at a fitting time, the old cells are being displaced by new ones. Due to the happening to a destructive tumor(s), this cycle is disturbed. The tumor cells grow exponentially and don't kick the bucket, not under any condition like sound cells. Two sorts of brain tumors are an essential tumor and optional or metastatic tumor [6]. Commonly, the essential brain tumor begins in the brain and will in general stay amid its development residency. While, the auxiliary brain tumor starts elsewhere as disease in the body, later spreads to the brain region.

TABLE I. FEATURES OF TUMOR

Benign Tumor	**Malignant Tumor**
Distinct borders	Invasive borders
Slow Growth	Rapid Growth
Rarely spreads	Often spreads
Less harm	Life- threatening

Generally, Attractive Reverberation Imaging (X-ray) and Registered Tomography (CT) methods are used to dismember the tissues and furthermore tumors appear in the brain. Propelled

picture planning techniques expect a crucial part in the restorative field to look at the medicinal reports. Further, AI Innovation has viably handled different issues in the medicinal history. A part of the systems to recognize and discover the proximity of tumor in the X-ray brain pictures are according to the accompanying: (1) Edge based detection technique, (2) Shape-based detection strategy, (3) Feature-based

Brain tumor recognition is a significant issue in imaging science. By and large, the seriousness of illness is chosen by the size and kind of tumor. A significant advance in examination of mind X-ray check picture is to extricate the limit and locale of tumor. To take care of the issue, the proposed work depicts the system for identification, division and highlight extraction of cerebrum tumor part utilizing MATLAB programming. This product based methodology intends to present a calculation for identifying and fragmenting the cerebrum tumor from ordinary mind utilizing fundamental picture preparing tasks (de-noising picture, sifting), division pursued by highlight extraction.

II. RELATED WORK

Mukambika P. S., Uma Rani K. (2017) Proposed Approach in which Picture is prepared through: Pre-handling, Division, Highlight extraction Order stages. In preprocessing, Morphology procedure utilizing twofold thresholding is connected to expel the skull out of the X-ray cerebrum images.[11]**Astina Minz et.al (2017)** In restorative analytic application, early disfigurement disclosure is a urgent assignment as it gives fundamental comprehension into examination. Medicinal imaging framework is as of now creating field in designing. Attractive Reverberation imaging (X-ray) is one those reliable imaging systems on which restorative symptomatic relies upon. [12]Manual examination of those pictures is a redundant action as the proportion of data and moment focal points are hard to see by the human. **G Rajesh Chandraet al. (2016)** Detection of mind tumor is very normal setback in current circumstance of human services society. Picture division is utilized to isolate the sporadic tumor segment in cerebrum.[13] Mind tumor is an unpredictable mass of tissue in which cells grow besides, copy uncontrollably, clearly unregulated by instruments that control cells.

III. PROPOSED WORK

K-means k-implies grouping is a strategy for vector quantization, initially from sign preparing that is well known for bunch examination in information mining. k-implies bunching plans to segment perceptions into k groups in which every perception has a place with the bunch with the closest mean, filling in as a model of the group. This outcomes in an apportioning of the information space into Voronoi cells. The issue is computationally troublesome (NP-hard); in any case, productive heuristic calculations meet rapidly to a neighborhood ideal. These are normally like the desire amplification calculation for blends of Gaussian appropriations through an iterative refinement approach utilized by both k-implies and Gaussian blend demonstrating.

The two of them use group focuses to demonstrate the information; nonetheless, k-implies bunching will in general discover bunches of tantamount spatial degree, while the desire augmentation system enables bunches to have distinctive shapes the k-implies strategy is a broadly utilized grouping procedure that looks to limit the normal squared separation between focuses in a similar bunch. In spite of the fact that it offers no exactness ensures, its straightforwardness and speed are engaging practically speaking. By expanding k-implies with a basic, randomized seeding system, we acquire a calculation that is O (log k) - aggressive with the ideal bunching. Analyses demonstrate our increase improves both the speed and the precision of k-implies, frequently significantly.

K-Means calculation is an unsupervised bunching calculation that characterizes the information focuses into numerous classes dependent on their characteristic separation from one another. The calculation accept that the information highlights structure a vector space and endeavors to discover normal grouping in them. The focuses are bunched around centroids μI

$$V = \sum_{i=1}^{k} \sum_{x_j \in S_i} (x_j - \mu_i)^2$$

∀I = 1 . . . k which are obtained by minimizing the objective.

The k-implies bunching issue is one of the most established and most significant inquiries in all of computational geometry. Given a number k and a lot of n information focuses in R.

The proposed work performs handling of X-ray cerebrum pictures for location and grouping of tumor and non-tumor pictures by utilizing a classifier. The picture preparing strategies like histogram evening out, picture upgrade, picture division and afterward removing the highlights for discovery of tumor have been utilized. Removed highlights are put away in the learning base. A proper classifier is created to perceive the cerebrum tumors by choosing different highlights.

Attractive Reverberation Imaging (X-ray) is a non-obtrusive imaging modalities which is most appropriate for the discovery of mind tumor. An easy to understand condition has been made by utilizing GUI in MATLAB bringing about a mechanized cerebrum tumor identification framework for X-ray examined pictures. By utilizing the GUI device, the doctor and different specialists are encouraged in recognizing the tumor and its geometrical component extraction. Multi-SVM has used to group the different sorts of tumors like Gliomas, Metastasis, and Astrocytoma and so forth. In this work, Multi Bolster Vector Machines (m-SVMs) has been proposed and connected to cerebrum filtered picture cuts characterization utilizing highlights got from cuts. This work helps in acknowledgment of tumor which thusly spares the valuable time of restorative demonstrative to analyze the tumor naturally in limited capacity to focus time.

K-means++ reliably beaded k-implies, both by accomplishing a lower potential esteem, at times by a few requests of size, and furthermore by finishing quicker. With the manufactured precedents, the k-implies technique does not perform well, in light of the fact that the arbitrary seeding will definitely combine groups, and the calculation will never have the option to part them separated. The cautious seeding technique for k-means++ stays away from this issue by and large, and it quite often achieves the ideal outcomes on the manufactured datasets. The contrast between k-means and k-means++ on this present reality datasets is likewise very generous. On the Cloud dataset, k-means++ ends twice as quick while accomplishing potential capacity esteems about 20% better. The presentation gain is considerably progressively exceptional on the bigger Interruption dataset, where the potential esteem gotten by k-means++ is better by elements of 10 to 1000, and is likewise acquired up to 70%

quicker. The system is designed to be user friendly by using MATLAB GUI tool based on following steps.

Preprocessing: wiener filter
Segmentation: K-means ++ clustering based Segmentation
Feature Extraction: GLCM Based Feature Extract
Classification: Support Vector Machine (SVM)

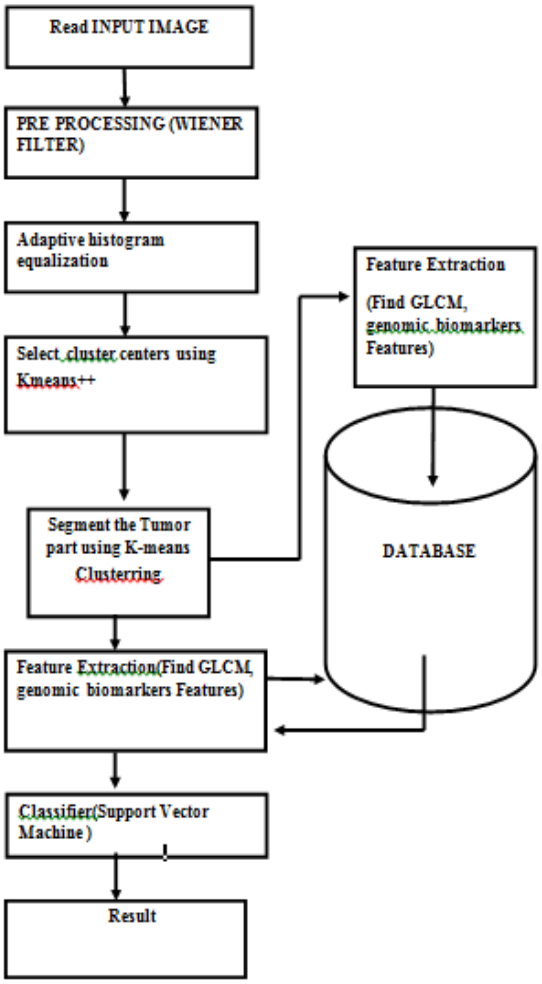

Figure 2: Block diagram

Step 1: Read Input Image
Step 2: Gray Scale conversion
Stage 3: Preprocessing-Evacuate commotions utilizing Wiener channel
Stage 4: Image Upgrade utilizing Versatile Adaptive Histogram Equalization
Stage 5: Pick one focus consistently from among the information focuses.
Stage 6: For every datum point x, figure D(x), the separation among x and the closest focus that has just been picked
Stage 7: Pick one new information point indiscriminately as another inside, utilizing a weighted likelihood dissemination where a point x is picked with likelihood relative to D(x) 2
Stage 8: Rehash Stages 5 and 6 until k focuses have been picked.
Step 9: Now that the underlying focuses have been picked, continue utilizing standard K-mean grouping.
Stage 10: Allot each article to the gathering that has the nearest centroid.
Stage 11: Recalculate the places of the centroids.
Stage 12: If the places of the centroids didn't change go to the following stage, else go to Stage 10.
Stage 13: Concentrate the GLCM highlights and genomic biomarkers from Grouped District.
Stage 14: SVM train
Stage 15: SVM classify

IV. RESULTS

The following samples are taken from the hospital are the tumorous image. So we are applying our proposed work on them in order to test. some statically features of samples are shown graphically also.

SAMPLE 1: This sample had been taken from erode hospital various steps of our proposed work has been compared.

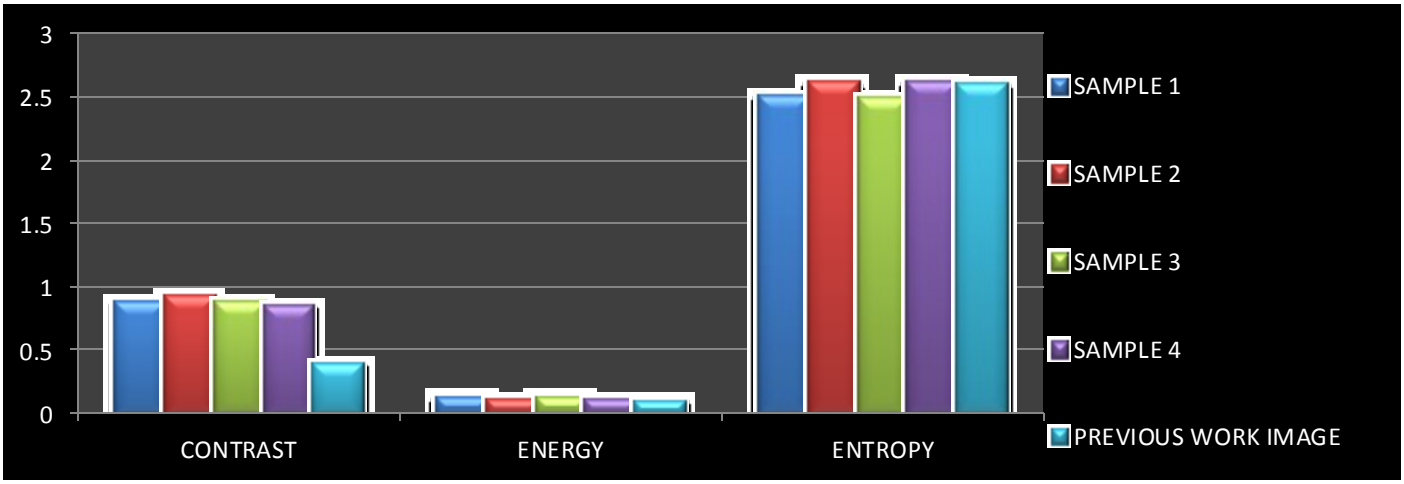
ENERGY	0.141	0.1215	0.141	0.1233	0.11
ENTROPY	2.5148	2.624	2.51	2.633	2.61

The graphically representation is about the statistical features of various samples taken above and thus compared with the previous work as shown



V. CONCLUSION

MR image segmentation is a critical yet unavoidably inconvenient issue in helpful image dealing with. At the point when all is said in done, it can't be fathomed using immediate, standard image dealing with techniques. As a result of the characteristics of MR images, improvement of automated estimations is trying. There is an enormous between patient assortment of sign powers for one same tissue type in light of midway volume sway, regular tumult and wide extent of imaging parameters, which impact the tissue powers. We have proposed a beneficial portrayal structure subject to thickness based batching approach to manage recognize the brain tumor. The MATLAB multiplication is carried on different personality images and tumor is recognized using K-means++ procedure for image division and perfect overall thresholding. The cerebrum tumor acknowledgment is an unprecedented help for the specialists and a guide for the restorative imaging and adventures managing the age of CT Range and X-beam imaging.

In future this program should be possible further developed so tumor can be arranged by its sort. Additionally tumor development can be broke down by plotting chart which can be gotten by examining consecutive images of tumor influenced understanding.

Abstract—Flood is a cataclysmic event that occurs far and wide causes the extraordinary misfortunes. The floods additionally compromise the human life and the economy of the included nation likewise gets influenced. Neural Networks are generally connected in flood gauging and got great outcomes. The main objective of the project is to predict the flood situation and intimate about it to the people. The importance of predicting the flood is widely increased. The human life can get damaged due to floods; it can prevent loss to economy and human if it is predicted earlier. For prediction there are various methods but the most commonly used method is Neural Networks. This paper develops deep learning approach by combining Convolutional Neural Network (CNN) and Modified Particle Swarm Optimization (MPSO) for the prediction that the area is flooded or not. CNN extracts the attributes cataclysm in all respects productively. CNN is vigorous to shadow. CNN can get the attributes of calamity palatably and it additionally overpowers the misdetection or miscount by administrators, which further influence the handiness of fiasco help. MPSO is applied as optimizer to search for the optimal parameter values for the CNN training process.

Keywords— Convolutional Neural Network; Modified Particle Swarm Optimizer; prediction; disaster; flood; deep learning;

I. INTRODUCTION

Disaster disclosure has been a standout amongst the most unique research zones today since sparing human lives is our earnestness once a catastrophe occurred. It is essential in the administration of fast answer exercises after a hazardous catastrophe, for example, floods. A disaster is an abrupt, disastrous occasion that truly disturbs the working of a network or society and causes human, material, and monetary or natural misfortunes that surpass the network's or society's capacity to adapt utilizing its own assets. [18] Though often caused by nature, disasters can have human origins as well. There can be various types of disaster occur which are categorized as geological disasters, hydrological disasters, meteorological disasters, and wildfires. Among which floods, earthquakes, landslides occur thoroughly.

Predicting flood is the complex process. The flood is predicted at early stage so that the loss to the society can be prevented. Predicting the flood can minimize the risk to human and economical losses. As predicting the flood can intimate the people nearby the flood prone area due which the people are able to relocate to the safer place and prevent the damage [18]. By predicting the flood at earlier stage can cause the preventive and curative measures to be taken by the government.

Flood is a typical cataclysmic event that influencing a quantities of nations around the globe [18]. In spite of it is normal, yet flood can at present be really shocking to a limited extent where it starts to make huge pulverization open offices, private house or even most noticeably awful, passing [1].This influence massively toward to the financial matters structure of the nation that must face this disaster uncommonly for poor people and creating one [1]. To overcome the above issues early prediction systems are

designed using different techniques to provide message to the people before the flood occurs in the area.

Deep Learning is a part of machine learning methods. Machine learning is a technique in computer science which allows data to drive and guide the execution of algorithm [10]. Using a training dataset, the algorithm develops a model which is used to compare against the expected output [10]. An algorithm that uses deep learning goes through much the same process. Each hierarchy applies a transformation on the training input and forms it as a model [10]. This process is repeated until output has reached and an acceptable level of accuracy [10]. Learning can be supervised, unsupervised and semi-supervised. Deep Learning incorporates numerous systems, for example, CNN (Convolutional Neural Network), RNN (Recurrent Neural Network), Recursive Neural Network. These systems are essentially calculations.

Various productions on flood forecast utilizing Artificial Neural Network (ANN) methods have been accounted for [4]. It has been proposed, in light of the fact that it has the incredible ability to display nonlinear and complex frameworks without clear physical clarification [3]. Presently a the very first moment's of the most notable practices in deep learning, CNN is making location showing signs of improvement result in a cataclysm, for example, a flood, earthquake, and landslide. The system is intended to guess the flood on the basis of present image of a specific flood prone area, on the basis of the image the system will guess whether the area is in risk and essential to be relocate or not. The accuracy of the developed model is high due the use of Convolutional Neural Network and Modified Particle swarm optimization. The early prediction leads to save lot of lives and prevent more damage due to flood. The modified particle swarm optimization (MPSO) technique is applied as a parameter searching process for the CNN.

II. RELATED WORK

A. Literature Review

In [13] the writers proposed Bare-Bones multi objective particle swarm optimization (BBMOPSO) algorithm calculation for condition/financial dispatch issues. This paper is having three highlights. The molecule notifying procedure does not require tweaking control parameters. The transmutation administrator is to amplify the pursuit capacity and to maintain a strategic distance from the untimely combination issue. The molecule decent variety is to refresh the all inclusive molecule leaders. From the outcomes, BB-MOPSO calculation is making amazing count of genuine Pareto front and it is reasonable to settle a wide range of multi target advancement issues. BB-MOPSO calculation is giving preferable outcomes over different calculations like multi-objective particle swarm optimization with sigma method (SMOPSO), multi-objective particle swarm optimization method (CMOPSO) and time variant multi-objective particle swarm optimization (TVMOPSO) as far as combination execution. BBMOPSO calculation is superior to CMOPSO and TVMOPSO calculations in the appropriation of arrangements on the acquired Pareto front. BB-MOPSO is accomplishing littlest standard deviation esteem.

In [11] the writers proposed Modified Particle Swarm Optimization algorithm (MPSO) for to take care of building basic streamlining issues. By improving the versatile wellness work we balance the target capacity esteem and imperative infringement particles. The algorithm utilizes the versatile inertial load to adjust abuse. They got outcomes are contrasted and right now accessible advancement calculation which demonstrates that the MPSO calculation is superior to others as far as precision.

III. METHODOLOGY

The Figure 1 shows the proposed system for disaster prediction using deep neural network. Convolutional neural system preparing for stream water flood forecast by utilizing PYTHON.

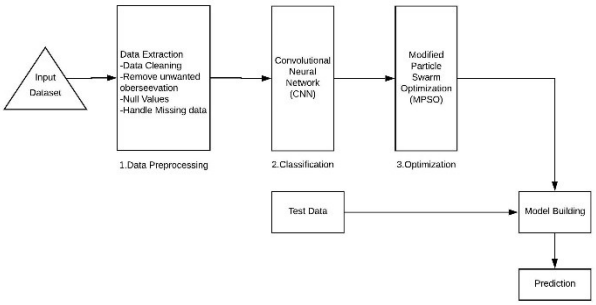

Figure1. Proposed System

B. Data Collection and Used

The prediction done at this paper is to predict the flood in the image. The prediction can be done in three conditions such as flood will occur, flood had been occurred and flood has been occurred. The samples utilized in model improvement were separated into two sets to be specific: training and testing sets. The model was first acquired utilizing training sets. The new testing samples were then nourished to the framework to validate the performance of the system. The data is in the form of images. We obtain images from the Google as input images. Training samples contains 137 images and testing samples contains 500 images.

C. Prediction Model

In this section we are describing our CNN-MPSO model. The model works in three phases such as data preprocessing, MPSO process and CNN training. In first phase the extracted data is pre-processed by performing some operation such as cleaning, removing unwanted observations, removing null values and handling missing values.

In the next phase the particle swarm optimization algorithm is applied to the output of the first phase which optimizes the data so the time taken by the CNN is reduced.

In the last phase the CNN is applied on the optimized data and the output is taken and prediction is performed on the output. The accuracy of the CNN-MPSO model is more than the CNN model.

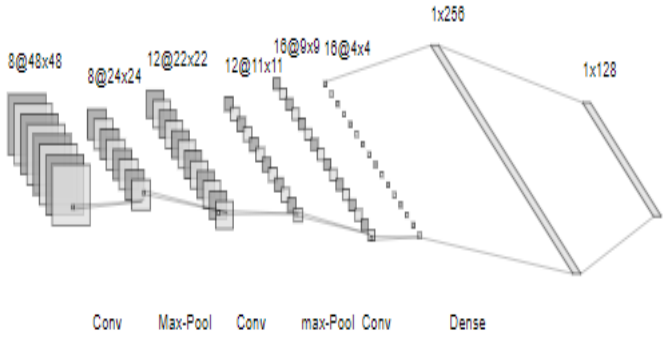

Figure 2. CNN Model

D. Convolutional Neural Network

CNN is a succession of layers, and each layer of CNN changes one volume of actuations to another through differentiable capacity [6]. CNN has concealed layers of 3 essential types, for example, convolution layer, pooling layer, and dense layer which is likewise called as fully-connected layer; the neurons are organized in 3 measurements (width, tallness, profundity).

A Convolution layer is additionally called as conv layer we have utilized keras capacity to execute this model. It is a structure square of a convolution network that does the vast majority of the computational hard work. Convolution layers perform feature extraction on the picture by applying different filters on it. In our model we have utilized 3 convolution layers with 3*3 filters.

It isn't unexpected to occasionally embed a Pooling layer in the middle of progressive conv layers. Pooling Layer capacity is to diminish the spatial size of the portrayal to lessen the measure of parameters and thus to command over fitting. This layer works on each profundity cut utilizing the max operation.

A Dense Layer plays out the characterization on the features which are extricated from the convolution layer and further down inspected by the pooling layer. In this layer every neuron is associated with the previous layer neurons.

In fully connected layer, every neuron is associated with the each neuron of other layer. This layer is like the conv layer just contrast is that the neuron in the conv layer is just associated with the nearby area.

Figure 2 demonstrates the proposed CNN model with the five concealed layers.

E. Modified Particle Swarm Optimization

MPSO algorithm an assessment strategy used to improve the arrangement by advancing the issue. It improves the issue by utilizing particles as an applicant arrangement so these particles fly over a hunt space as per counts to change the area and speed of individual particles, this vacillation of positions is affected by close to home best area and guided toward worldwide best position which is best area in all inquiry space found and affirmed by different particles [8]. The algorithm utilizes the chaotic mapping to produce the underlying population, which guarantees the decent variety of the underlying population and establishes the framework for the worldwide pursuit capacity of the calculation, utilizing instructing component to expand the extent of doable arrangements in the population [11].

The particles of swarm cooperate to accomplish best spot as per the mutual data in the middle of them. Whenever, every particle of swarm can have a local best position (pbest) which is the littlest achieved cost in the cycles [8]. The best position came to in the swarm which known as the global best position (gbest) which is valuable to control the particles toward the global optimum.

The equation (1) is to compute the velocity of the PSO and the equation (2) used to compute the position of the particle.

$$V_{p+1=Vp} + c_1 r_1 (pbest - x_p) + c_2 r_2 (gbest - x_p) \quad (1)$$

$$X_{p+1} = X_p + V_{p+1} \quad (2)$$

Where c1 and c2 are steady qualities and r1 and r2 are arbitrary numbers.

Following are the essential strides of the MPSO calculation:

Step 1.Initialization of fundamental parameters and population. D is the component of capacity, N is the quantity of molecule, T is the most extreme emphasis and set t=0.Initial position xi=(xil,… … ,xiD)is determined by equations (3) and (4).

$$Z_i^{k+1} = \mu Z_i^k (1 - Z_i^k) \quad (3)$$

$$x_{ij} = a_i + (b_i - a_i).z_{ij} \quad (4)$$

Step 2. According to (5) ~ (7), give rise to a new population, that is $(x'_1, x'_2, \ldots x'_N)$. If $f(x'_i) < f(x_i)$, particle x'_i can be replaced with particle x_i. If $f(x'_i) >= f(x_i)$, particle x_i is retained.

$$x'_i(t) = \begin{cases} x_i(t) + r_3\left(gbest - \beta x_{mean}(t)\right), if \ \ r_f < 0.1 \\ x_i(t) + \overline{x_i}(t), \qquad otherwise \end{cases} \quad (5)$$

$$\overline{x_i}(t) = \begin{cases} rand_i\left(x_m(t) - x_i(t)\right), fit(x_m) < fit(x_n) \\ rand_i\left(x_n(t) - x_i(t)\right), fit(x_m) > fit(x_n) \end{cases} \quad (6)$$

$$\beta = round\left(1 + \frac{fit(x_i) - min(fit)}{max(fit) - min(fit)}\right) \quad (7)$$

Step 3. Learning factors c_1, c_2 and inertia weight w is calculated by equations (8) ~ (10).

$$c_1 = (c_{1e} - c_{1s}) \sin(\frac{\pi}{2}\frac{t}{T}) + c_{1s} \quad (8)$$

$$c_2 = (c_{2s} - c_{2e}) \sin(\frac{\pi}{2}\frac{t}{T}) + c_{2e} \quad (9)$$

$$w = w_{max} - (w_{max} - w_{min}) \sin(\frac{\pi}{2}\frac{t}{T}) \quad (10)$$

Step 4. Equations (1) and (2) are used to change the velocity and place of the particle.

Step 5. Change the individual extremum and global extremum of the particle and readjust the particle according to algorithm 1, t=t+1

Step 6. If t > T, algorithm stop. Otherwise, go to Step 2.

MPSO is the advance algorithm of the PSO. MPSO takes the shortest time to process as compare to PSO. The convergence rate of the MPSO is faster than the PSO. Adam is slower than the PSO.

IV. RESULTS AND DISCUSSION

Figure 5 shows the test accuracy of the model at number of epoch. When the epoch is >2 then the accuracy is linear to the epoch. The model takes 137 images at the time of training phase and 500 at the time of testing phase.

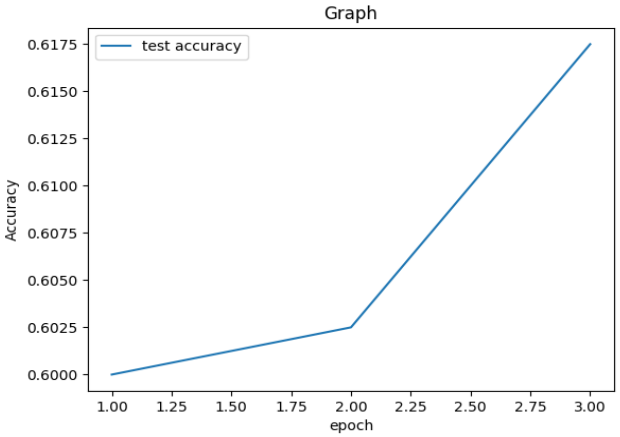

Figure 3. Variation in accuracy with the amount of epoch in the model.

The figure 4 is in view the accuracy at the time of both the phases. The training phase accuracy is 96.88 %. The testing phase accuracy is 64.25 %. The accuracy may vary when the epoch are changed.

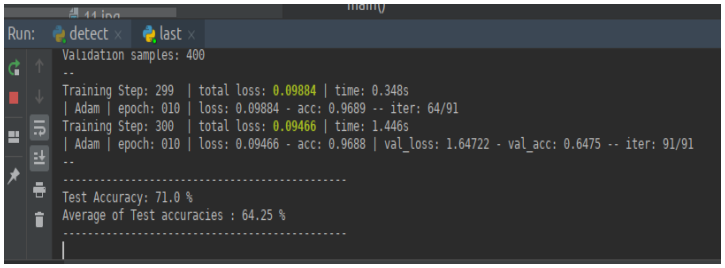

Figure 4. The average accuracy of the prediction model.

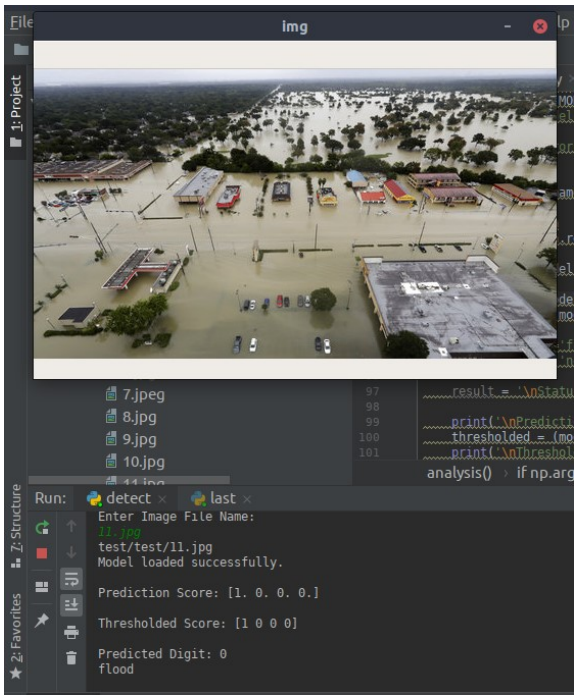

Figure 5. the image is predicted as flood.

The final output is predicted as shown in the figure 5 and figure 6. The images are classified using binary classification i.e. 0 and 1. If the predicted output is 0 means flood and if it is 1 then non-flood.

Change in the number of epoch can affect the accuracy of the model. The image pattern and their types will affect the models accuracy. Different types of pattern and plenty of patches will give a perfect output as compared to bounded ones.

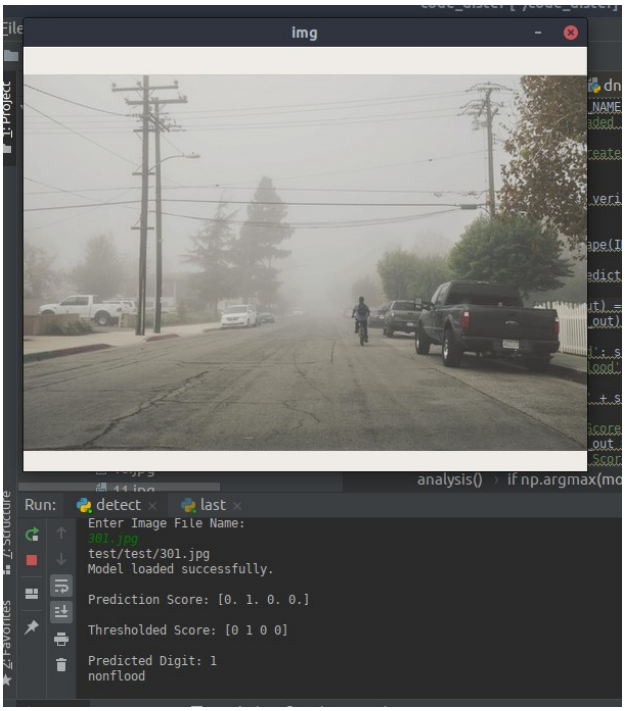

Figure 6. the image is predicted as non flood.

The dataset created by us is tested on Support Vector Machine, K Nearest Neighbors are Traditional Ml algorithm. It is found that results obtained from our proposed system is better than existing system.

Algorithm	Precision	Recall	F1 Score
SVM	0.7317	0.5882	0.6521
KNN	0.5052	0.3773	0.6620
CNN	0.6550	0.7428	0.6552
Proposed System	**0.75**	**0.75**	**0.8**

V. CONCLUSION AND FUTURE WORK

The proposed prediction model using neural network structure is able to predict the flood from the images. In this proposed system, the model applies the CNN on the image and extracts all the features from it. The model also applies MPSO to get the optimized parameters. As per the result we get, it come to know that the proposed model provide relatively high accuracy for flood prediction. The research method which we have suggested in this paper has capability to get executed as a prediction system.

Abstract*— In today's smart revolutionary era, Intelligent Transportation System (ITS) is a buzzword that plays a vital role. Vehicular ad-hoc network (VANET) techniques help ITS for improving efficiency as well as road safety services to vehicles and drivers. The vehicle acts as a node in the special ad-hoc network. Communication in the VANET is accomplished through IEEE802.11p i.e. Dedicated Short Range Communication (DSRC) and Wireless Access Vehicular Environment (WAVE). The ways of communication in the VANET are within vehicles (V2V) and vehicle-to-road (V2R). Routing is a foremost issue in the VANET environment due to the dynamic variation of topology, the restricted movement pattern of the vehicle, unstable links and complex city environments. Implementation of the VANET environment is a difficult task in a real environment. The objective of the paper is to simulate topological routing protocols to evaluate QoS. The simulation uses ManhattanGrid mobility to reflect the realistic vehicular environment. The simulation is conducted in various test environments with the variation in the vehicular density and speed of the vehicle. The influence of both factors on the QoS parameter is evaluated with Packet Delivery Ratio, Throughput, Avg. E2ED and Normalized Routing Overhead. AODV produces better PDR, Throughput and less NRL. OLSR produces less Avg. E2ED with respect to other protocols.

Keywords*— VANET, topological routing protocols, ManhattanGrid, QoS.

I. INTRODUCTION

A. Overview of Vehicular Ad-hoc Network (VANET)

The Indian government started taking initiative towards smart cities recently. An intelligent transportation system is a key component related to the smart city. In addition, a huge investment in the vehicle manufacturers seeks to deploy networks of automotive networks in real time. For example, due to the applicable rules, all new cars in the US will be connected by the end of 2020. The main goal of ITS is to make effective transportation, improve the environmental condition, protection, durability and efficacy of the transport system [3]. It performs information processing, communication, and use of a sensor in vehicles such as cars, trucks, trains and aircraft. In India, tremendous growth is recorded in registered vehicles from about 0.3 million in 1951 to 230 million in 2016 [24]. Urban areas in India are not able to cope up with vehicle growth. Thus, traffic management has a key challenge in many cities that must be paid more attention. According to the survey of World Health Organization (WHO); in India, there is one death every four minutes because of a road accident and in addition to the significant impacts and consequences for the environment [3].

The goal of the VANET is to improve safety of the drivers on the street and provide commercial services. It also disseminates accurate information to vehicle drivers and transport authorities in time [1] [2]. The VANET can help in spontaneous data exchange between various vehicles. Thus, VANET provides a way to connect people on the road. The question is how to achieve this? The solution is to exchange traffic information through the wireless ad-hoc network without infrastructure or through the support of VANET. The vehicular network is the subclass of MANET which achieves communication in vehicular areas by an exchange of messages among vehicles comprising the roadside wireless sensors. This allows information to be communicated to guarantee driver security [4].

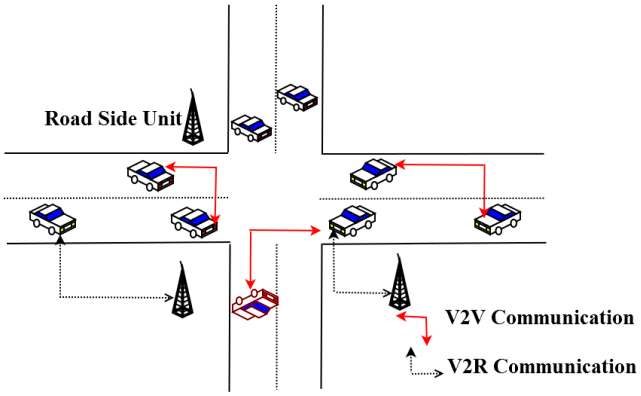

Fig. 1. Vehicular ad-hoc Network Scenario

Communication between the vehicular nodes is very important. Two types of communication that have typically considered in the VANET. One is known as the inter-vehicle communication and the other one is between the vehicle and roadside infrastructure communication. VANET provides communication using hop by hop and multi-hop manner. Components in the VANETs transmit packets in multi-hop mode such as vehicles and road-side units (RSUs). Due to less transmission range, communication is achieved by multi-hop communication amongst intermediate nodes. The vehicle comprises the On-Board Unit (OBUs) that allows short-range wireless V2V communication or V2R communication along with location service like GPS. On the roads, a road-side unit (RSU) is the unit of infrastructure communication. Various OBU and RSU communicate with each other [1] [2]. Fig.1 illustrates the working of VANET.

Thus, VANET is a dynamic network of vehicles without fixed infrastructure like a base station. Vehicles follow the disciplined way for the movement due to its velocity and acceleration. Deployment of VANET is highly expensive as compared to MANET. In terms of mobility; the MANET is having low mobility whereas, VANET is having high mobility being faster vehicles. MANET operates in the 2.4 GHz frequency range whereas, VANET in the 5.9 GHz. The communication range of MANET is up to 250 meters whereas; in VANET it is around 1000 meters. MANET supports infrastructure less operation whereas operations in the VANET supports infrastructure oriented and without infrastructure.

B. Communication Standards in VANET

Vehicles communicate directly with DSRC IEEE 802.11p as well as IEEE 802.16. DSRC is the standard developed by the US and the Federal Communication

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

Commission. It allocates a 75MHz spectrum at 5.9GHz for DSRC communication in an approximate range of 1000m. It is used for collision avoidance. Out of seven channels, all channels have a width of 100 MHz. The control channel is dedicated to safe and secure communications. At the end of the spectrum, two channels have reserved for the acute safety of life and high public safety. All other channels are Service Channels (SCHs) [5]. VANET needs rapid bandwidth and interaction because of regular changes in topology and excellent mobility. The American Society for Testing and Materials (ASTM) 2313 working group renamed IEEE 802.11 as a Wireless Access Vehicular Environment (WAVE) [5]. WAVE contains rules for safety, health and the environment.

The Main focus of the paper is:

1. To use ManhattanGrid mobility model to create scenarios for the vehicular density and the speed of the vehicle.
2. To learn and simulate topological routing protocols in VANET.
3. To evaluate the effect of density and speed of the vehicle on the performance measure in terms of quantitative QoS parameters.

It is possible to determine the problems associated with a vehicular node in the simulation environment.

The organization of the paper is as follows: Section II presents related work discussing the basics of routing in the VANET with its protocols. Section III illustrates the QoS evaluation of routing protocols using simulation. Section IV describes an experimental setup for the simulation and section V highlights the conclusion.

II. Related Work

Routing is an intelligent decision process that determines the best appropriate path from the originating node and the target node. Routing in the VANET has various issues like Quality of Service management for several services, network management and road traffic management.

High mobility of the node causes rapid variation in topology, deviation in the velocity and density of the vehicles on the road. The sparse distribution of vehicles in geographical regions degrades network performance. The volatility of the route affects Throughput, with a higher transmission delay and increases in the routing overhead. The VANET area includes buildings, tracks and stringent roads in which vehicles move in a specific direction.

Previously many authors touch the issue of routing protocols evaluation with QoS. These are classified based on the topological routing protocol, transmission strategies and position-oriented routing protocols. The nature of topological routing protocols is proactive and reactive. Table I describes comparative literature of the topological routing with protocol, mobility, nodes, speed, QoS parameters, Time of Simulation (ToS) and tools used.

AODV is a reactive routing protocol. It is always in search of the route in between the source and the sink. It adopts the path discovery procedure with the RREQ, RREP and RERR messages. These messages are exchanged between source and sink. AODV provides unicast multicast and broadcast communication ability. It reduces routing overhead but produces more delay [13] [20].

An enhanced version of AODV routing protocol with the multipath approach is known as AOMDV. In AOMDV, unicast communication is achieved. It is used to compute loop-free and disjoint paths. It produces less routing load while doing the route discovery [14] [21].

OLSR is a pure link state and a proactive routing protocol. The use of Topology Control (TC) and Hello messages determines and disseminates link state information throughout the network. It avoids excessive transmission of Link State Packets (LSP). The main feature of OLSR is the selection of Multi-Point Relay (MPR). One-hop neighbor selects MPR and retransmits all broadcast messages received by it. A multipoint selector is going to select the MPR node, having permission to retransmit the packet. A routing table has preserved in the OLSR [15] [18].

ZRP addresses the routing by acquiring the best properties from both proactive and reactive protocols. Each node has an individual zone. The zone has overlapped with the adjacent nodes. The zone is assigned a radius represented by r. The zone comprises the nodes in its area of radius r. The ZRP consists of peripheral and interior nodes. The node having the minimum distance equal to r with the central node is termed as the peripheral node. The interior nodes are the nodes inside the zone and having distance less than r. It includes a routing component such as IARP and IERP. IARP is a local proactive component comprises routing information related to the nodes within the zone. IERP is a global reactive component that provides services such as improved route discovery and route maintenance. Support for bordercasting is the uniqueness of the ZRP. The bordercasting utilizes the information about the topology provided by the IARP. ZRP also make use of NDP at the MAC layer to locate the new nodes as well as link failures [22] [23].

III. Quality Of Service

Quality of Service (QoS) states the network's ability to offer the best service for the specific network traffic by several technologies. It represents the collective outcome of service performance that determines the degree of satisfaction of a user of the service. Each layer in the network is having separate parameters. E.g. delay is used in the

network layer of the OSI model. Working with QoS is one of the most difficult tasks in the VANET because of less accurate QoS, an inappropriate method to estimate QoS and improper selection of route [11].

QoS evaluation plays a major role in various applications of VANET. For instance, an emergency warning application warning is useful only if it hits an appropriate time. If the warning gets delayed then no use of such applications. The VANET uses several quantitative indicators to evaluate QoS.

A. Avg E2ED

Avg E2ED represents the average time for data packets to achieve the goal. It represents the difference between packets arrival time at the destination vehicle and packet transmission time at the source vehicle. It includes MAC layer retransmission time of packets, delay in propagation and the time required for buffering and queuing time.

$$Avg.E2ED = E2ED + \frac{(Et - St)}{count} * 100 \qquad (1)$$

Where, E2ED, St, Et stands for an end to end delay, capture start time on the occurrence of the event and Time at which the packet is completely received.

B. PDR

PDR is the ratio among the number of data packets that arrive at the target vehicle and the number of data packets sent from the source vehicle.

$$PDR = \frac{Tx}{Rx} * 100 \qquad (2)$$

Where PDR stands for Packet Delivery Ratio, Tx represents obtained packets by the target node and Rx indicates generated packets by the source node.

C. NRL

It is the ratio of generated routing packets by delivered data packets.

$$NRL = \frac{Rp}{Dp} \qquad (3)$$

Where, NRL, Rp and Dp represents Normalized Routing Load, sent routing packets and sent data packets respectively.

D. Throughput

It is the total number of successfully received bits by vehicles.

$$Throughput = \frac{Rs}{Et - St} * \left(\frac{8}{1000}\right) \qquad (4)$$

Where Rs, Et and St stands for the size of received packets, end time of the simulation and start time of the simulation.

IV. Experimental Setup

A. Simulation Environment

The simulation is performed on topological routing protocols such as AODV, AOMDV, OLSR and ZRP routing protocols. The objective of the simulation is to analyze quantitative QoS factors such as PDR, NRL, Avg. E2ED and Throughput. It uses network simulator i.e. NS-2.35. The simulation is performed on UBUNTU 14.04 machine comprising a RAM of 8GB with Intel core i-5, 3.2 GHz. processor.

The Manhattangrid mobility model is used for the generation of scenarios. The VANET requires a restricted movement pattern hence the use of the ManhattanGrid model is suitable for such mobility pattern. The ManhattanGrid mobility model is suitable for urban mobility. It uses a grid road topology. It helps the vehicle driver for the selection of a correct path. It works optimally where the roads are in a proper manner. The nodes traverse in the horizontal or vertical direction on the urban map. It hires a probabilistic approach in the selection of node movements. The vehicle selects to keep moving in the same direction at the intersection. The vehicles move straight, left and right with a probability of 0.5 and 0.25 respectively. It is not a good choice for highway scenarios. Even though it offers nodes to change the direction, it levies geographical limitations on node mobility [12] [16] [17].

TABLE II. Simulation Environment

Parameter	Simulation value
Mobility model	Manhattan Grid [19]
Simulation time	600s
Wireless transmission range	250m
Antenna	Omni-directional
Propagation model	Two Ray Ground
MAC protocol	IEEE 802.11p
Simulation area	1100m*1100m
Interface Queue Type	Droptail, priority queue
Number of vehicles	20-70
The speed of the vehicles	Ranging from 8m/s-24m/s
Routing protocols	AODV, AOMDV, OLSR & ZRP
Type of data traffic model	CBR with UDP 10 connections
Data Packet	512 byte
Control Packet	64 byte

Each scenario comprises 50 nodes dispersed in the area having dimension 1100*1100. The 4*4 grid pattern is used in the simulation area. The transmission range used by each node is 250m inside a simulation environment. The node is having 10s pause time. The time of the simulation is 600s. Node density is in the range of 20 -70 by assuming that within 600s approximately 20 to 70 vehicles traveled on the road. The simulation parameters are listed in the Table-II.

The type of traffic used is Constant Bit Rate (CBR) with User Datagram Protocol (UDP). It allows creating traffic at a stable rate by transmitting packets of the same size. It delivers background traffic which matches statistical characteristics of several network applications. In addition, many applications need probable reply times and constant availability of constant bandwidth [10].

B. Observations and discussions

The simulation is conducted to evaluate QoS of the routing protocols in the VANET under various conditions such as according to vehicular density and vehicular speed.

Vehicular Density- The scenarios for the various vehicular densities such as 20, 30, 40, 50, 60 and 70 are used for the simulation. For each density 5 mobility scenarios are generated. The results for the performance measures such as PDR, NRL, Avg.E2ED and Throughput are evaluated. The average of each result is considered and the observation has been made accordingly.

As observed in Fig. 2, PDR is increased across the number of vehicles. For the 20 vehicles, AODV attains 0.49, 1.64 and 1.71 % better PDR as compared to AOMDV, OLSR and ZRP. For the 70 vehicles, AODV attains 3.53, 4.16 and 24.30% better PDR. With the increase in the vehicular nodes, the packet drop ratio decreased.

Related to NRL, AOMDV observed NRL reduction with the increase in the vehicular nodes. In all other protocols, increase in the NRL is witnessed with the increase in the density of the vehicles. Overall AODV produce less NRL as compared to other protocols under study. AODV attains 3.58, 0.96 and 3.89% less NRL for 20 vehicles. In the case of 70 vehicles, AOMDV gets 0.48, 2.38 and 10.68% less NRL compared to the selected protocols.Fig.3 represents NRL performance.

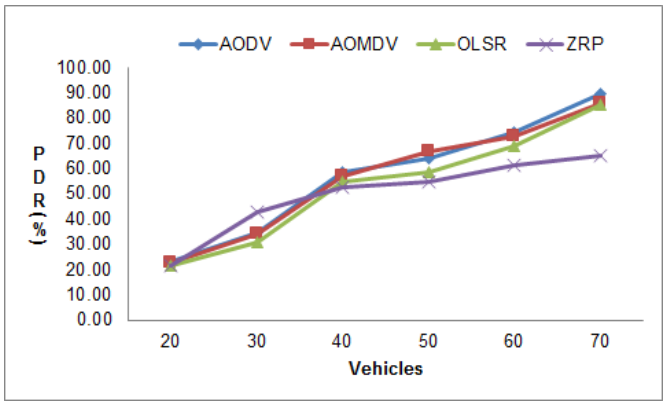

Fig. 2. Measurement of PDR by varying vehicular densities

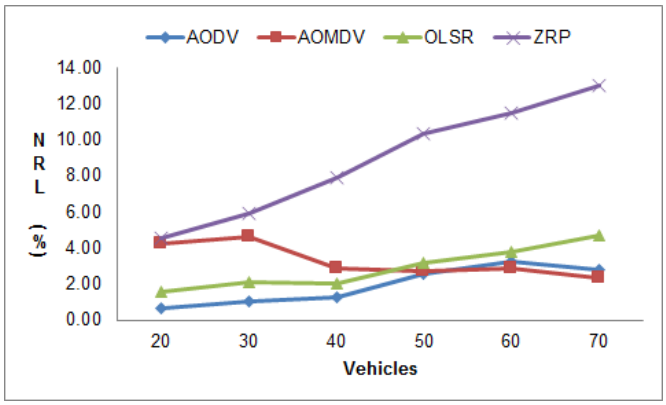

Fig.3. Measurement of NRL by varying vehicular densities

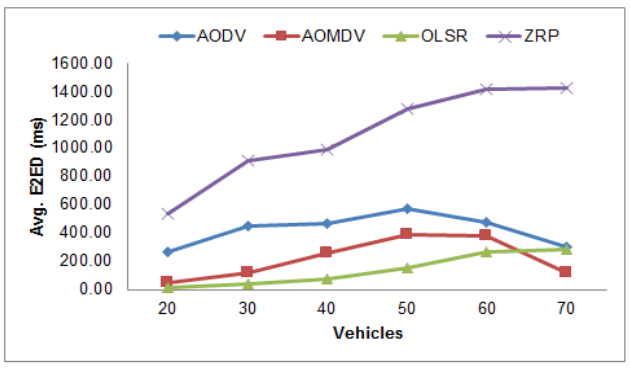

Fig. 4. Measurement of Avg.E2ED by varying vehicular densities

Related to Avg.E2ED, Overall OLSR protocol produces less Avg.E2ED. For the scenario of 20 vehicles, OLSR produces 250.15, 35.48 and 519.31ms less Avg. E2ED as compared to AODV, AOMDV and ZRP. For the case of 60 vehicles, OLSR produces 209.26, 112.34 and 1148.96ms less Avg.E2ED as compared to selected protocols. Fig. 4 shows the behavior of the Avg.E2ED.

AODV produces better Throughput as compared to other protocols. Throughput increases linearly with vehicular nodes for all protocols as shown in Fig.5. In the case of 20 vehicles, AODV produces 0.94, 3.23 and 3.1kbps better throughput with respect to AOMDV, OLSR and ZRP. In the case of 70 vehicles, AODV achieves 7.05, 8.23 and 45.39 kbps better throughput respectively. Table III represents results for the selected protocols of various performance measures.

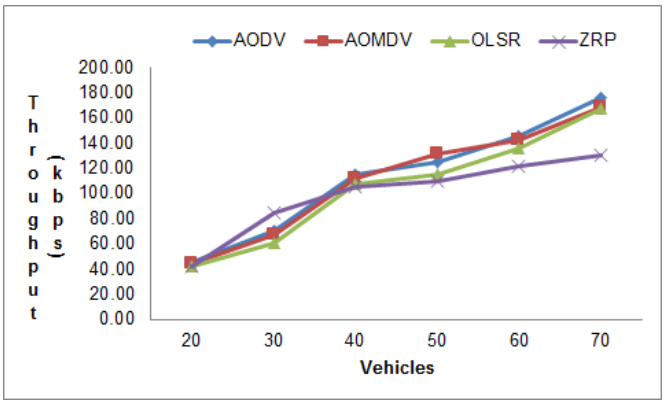

Fig. 5. Measurement of Throughput by varying vehicular densities

Vehicular Speed- The scenarios are generated for the various vehicular speed such as 8, 10, 12,14,16,18,20,22,24 m/s. The results for the various performance measures are evaluated and accordingly, the observation and analysis has been done. Fig. 6. illustrates the behavior of PDR with respect to the varying vehicular speed for the selected protocols. In the case of 8m/s speed, AODV produces 1.04, 4.3 and 6.11% better PDR as compared to the selected protocols. In the case of 24m/s, AODV achieves 4.7, 7.56 and 17.43% better PDR. Thus, PDR for low speed is better but as the speed is increased, a small variation is observed and again when the speed is above 16m/s, an increase in the PDR is observed. The reactive protocols due to their on-demand behavior and quick convergence feature are more appropriate for VANET. Repair of local links in route maintenance provides greater convergence to AODV. Due to the use of route reply, AODV performs better.

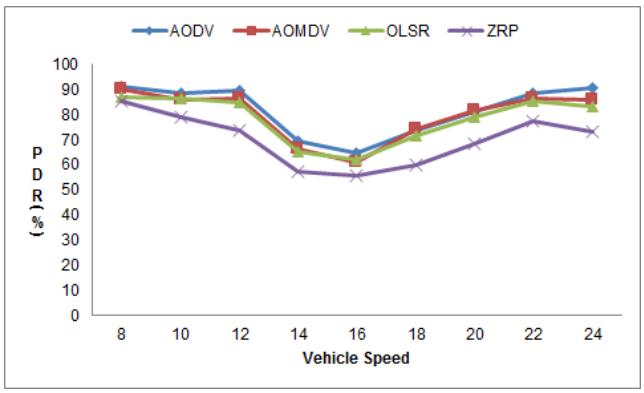

Fig. 6. Measurement of PDR by varying vehicular speeds

Initial development of reactive protocols reduces the routing overheads. AODV generates 0.83, 1.6 and 5.42% as well as 0.4, 0.9 and 6.56% less overhead for the speed of 8m/s and 24m/s vehicles respectively. ZRP generates extra overhead as compared to protocols under study. The RREQ packets control the load of the network in AODV. In ZRP because of mobility, lots of routes are damaged that causes a packet drop. As there is an increase in the vehicles, route search becomes complicated and a large overhead is introduced due to the communication between IARP and IERP. Fig7. illustrates NRL measurements with variation in the vehicular speeds.

TABLE III.SIMULATION RESULTS FOR PERFORMANCE MEASURES FOR VARIOUS VEHICULAR DENSITY (20-70)

Vehicles	PDR (%)				NRL (%)				E2ED(ms)				Throughput (kbps)			
	A	*B*	*C*	*D*	*A*	*B*	*C*	*D*	*A*	*B*	*C*	*D*	*A*	*B*	*C*	*D*

30	34.74	34.06	31.05	42.56	1.04	4.60	2.08	5.94	445.93	117.6	35.73	910.41	70.13	66.78	60.90	84.90
40	58.63	56.95	54.62	52.62	1.30	2.84	2.01	7.86	464.78	258.7	76.60	989.45	114.8	111.2	107.3	105.18
50	63.84	66.94	58.73	54.7	2.57	2.72	3.15	10.33	574.48	389.4	154	1276	125.3	131.3	115.2	109.54
60	74.15	72.62	69.12	61.07	3.25	2.86	3.75	11.50	476.45	379.5	267.2	1416.1	145.4	142.5	135.5	121.99
70	89.55	86.02	85.38	65.25	2.78	2.30	4.68	12.98	297.68	116.8	280.5	1424.3	175.9	168.8	167.6	130.48

Notations- A: AODV, B: AOMDV, C: OLSR and D: ZRP

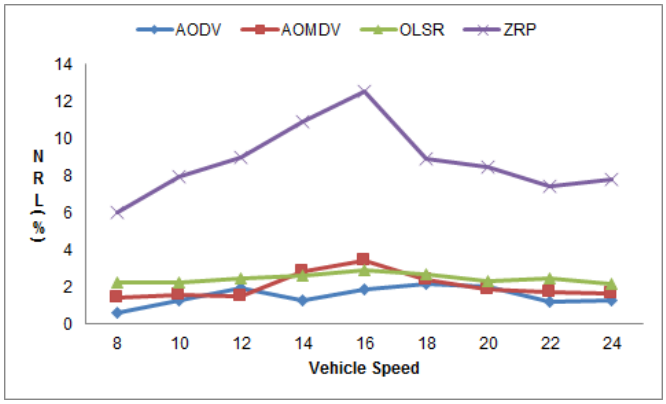

Fig.7. Measurement of NRL by varying vehicular speeds

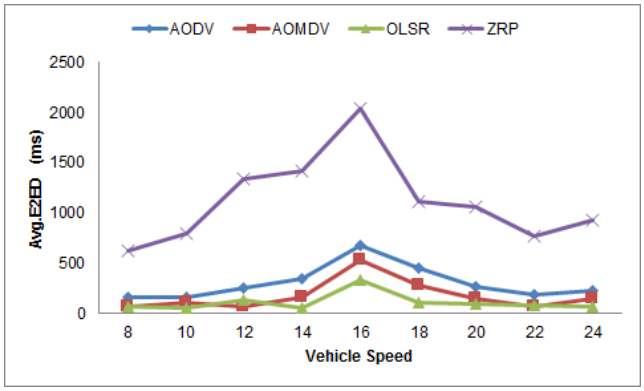

Fig. 8. Measurement of Avg.E2ED by varying vehicular speeds

Precalculating routes reduce the delay in proactive routing protocols. OLSR attains 109.59, 50.88 and 743.15ms as well as 149.25, 75.56 and 852.95ms less Avg. E2ED respectively for the speed of 10 and 16m/s vehicles for the protocols under study. Thus, Avg.E2ED of OLSR is lower in VANET. Repair of local links sometimes increases routing latencies in AODV. In OLSR, it is necessary to look in the routing table while doing a route search. But AODV initializes route search when there is an existence of the valid route. Therefore, a simple search of tables takes less time than flooding a network, which improves the performance of the OLSR protocol in a network sensitive to delay. ZRP produces more Avg.E2ED because the route discovery requires extra time. ZRP produces more control packets since it is composed of protocols i.e. IERP and IARP. IERP initialized by the source vehicle if a destination node is not reachable in the routing zone. Within a local zone, IARP facilitates the maintenance of the routing tables of a node. The interaction between IARP and IERP causes unnecessary traffic on the network that generates a delay in the acquisition of the route. Fig.8. shows Avg.E2ED with variation in the vehicular speeds.

For the smaller speed of the vehicular node, the Throughput generated is more. As the speed of the vehicle increases, the decrease in the Throughput is observed for all protocols. Upto a certain threshold of the speed 16 m/s Throughput decreases in all protocols. Afterward, an increase in Throughput is observed. AODV produces 4.88, 4.69 and 16.03kbps as well as 7.7, 9.31 and 27.41kbps better Throughput for the vehicles with speed of 10m/s and 24m/s compared to the selected protocols. Fig.9. shows Throughput for vehicles with varying vehicular speeds.

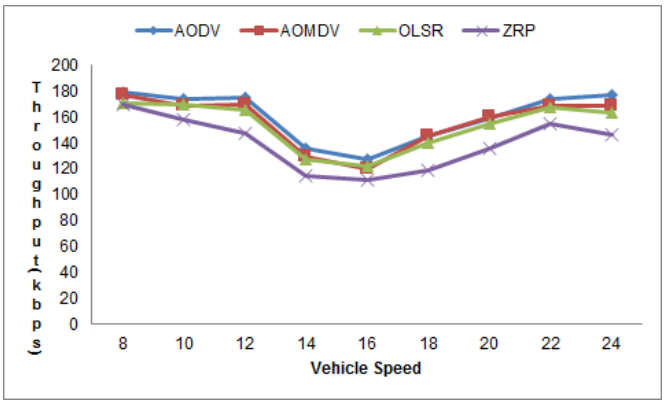

Fig.9. Measurement of Throughput by varying vehicular speed

Table IV represents simulation results for performance measures of various vehicular speeds.

V. CONCLUSION

The vehicular ad-hoc network achieves V2V and V2R communication with the help of IEEE802.11p. Importance of a ManhattanGrid mobility model along with its applicability in the VANET is studied. The simulations are conducted on topological category protocols under various test environments such as density and speed of the vehicle. The QoS affects communication in the VANET. The paper elaborates probable causes towards QoS efficiency along with their parameters with the significance. The influence of density and speed on the QoS parameter is assessed in the VANET environment. The results indicate that AODV, a reactive approach performs better in terms of PDR, Throughput and NRL except some cases in the density environment. AOMDV observed less routing load in case of 60 and 70 vehicles. OLSR produces less Avg.E2ED in all test environments. ZRP achieves moderate results for all parameters except NRL and Avg.E2ED. Overall AODV outperforms all other protocols. Topological routing protocols are less suitable for delay-sensitive networks. In future, a routing protocol will be developed which can cope with the delay sensitive network and intersection oriented environment.

***Abstract*—The Internet of Things (IoT) is rapidly becoming a part of our regular activities and environment. According to Cisco by 2030, it is expected that 500 billion devices will be connected on the IoT. Every passing day we see new devices and sensors coming in the market, which use different protocols to connect to the network. With this expected growth of the Internet of Things and the emergence of Fog and Cloud Computing, there is a need for a standard protocol suite to handle different aspects of standardization and cloud protocols in the IoT environment that is not covered by currently existing Three, four, and five layered IoT models.**
We propose a T2C architecture that provides the most prominent standard protocols into nine layers and show why this extension is essential. The proposed T2C architecture fulfills the prescribed activities for smart sensors and fog networking in the backbone. Which brings significant benefits, scalability, and low-power consumption in the IoT architecture. It emphasizes on how IoT device classification can be mapped to our proposed nine layered T2C Architecture.

Keywords: Internet of Things, IoT Protocols, IoT layers, Things-to-Cloud (T2C)

I. Introduction

Things-to-Cloud (T2C) is a bridge between the Internet of Things, Fog Computing, and Cloud Computing. We are putting together IoT and Cloud premises, and calling it as Things-to-Cloud (T2C). Internet of Things (IoT) is a system of interconnected electromagnetic tracking devices, computing devices, and smart digital devices. These devices are capable of transferring the data to the cloud via fog computing. The IEEE has defined an IoT architecture, domains of IoT, the definition of IoT, and identification of public IoT domains. O. Logvinov et al., [1] introduced three-tiered architecture with Sensing layer, Networking & Data Communication layer, and Application layer.

Several attempts were made in the past to provide a layered architecture for IoT based on operations they perform. In the last two-three years, the gap between IoT and Cloud has been bridged due to the introduction of a Fog Computing, which communicates with both these components. IoT-Devices are becoming more powerful and capable of performing various tasks. Due to this advancement, there is a need for re-look-up the five-layered architecture [2]. In this paper, we have proposed nine layered T2C architecture to connect sensor enable IoT-Devices to the Cloud and also explained the required layers for each type of IoT-Devices.

Based on operations performed in each layer, we classified the common standard protocols to handle this operation. The nine layers are IoT-Devices layer, Connectivity layers, Link Protocol layers, Transport & Network layers, Session & Communication layers, Data Aggregation & Processing layers, Data Storage & Retrieval layer, Business Model layer, and Business Application (Apps) layer. At every layer, we have suggested different protocols to be used. Also, we briefly reviewed Things-to-Cloud (T2C) management protocol standards and the current state of security concerns related to specific protocols. We also presented a brief comparison between various IoT protocols and how to choose among these protocols.

The rest of the paper is organized as follows: Section II presents different IoT Architectures available in the literature and present four IoT architecture, in Section III we present the proposed Things-to-Cloud (T2C) which is a protocol based nine layered architecture, in Section IV we discuss IoT Security & Privacy trust framework, and Section V we gave a summary of lessons and future scope of IoT.

II. IoT Architectures

The IoT architecture introduced for smart service domains has to reach the main demands of having Intelligence, Scalability, Interoperability, Think of Security Rights, Challenges in Securing, Managing, and Optimizing. Several IoT architectures are proposed in the literature, but they do not adhere to common architecture design. IoT Basic Model is essentially the architecture which allows us to gather data from various sources, where data has never been traditionally looked at with Three-layer IoT Architecture expressing of the Application Layer, Network Layer, and Perception Layer has been presented in Figure 1 (a) [3] [4]. In the recent survey, another architecture has been considered that add more abstraction to the IoT model [2] [3] [4].

Also, three-layer architecture has been extended to Middle-Ware based architecture and address a different type of communication medium Figure 1 (b). It has been extended to SOA based architecture while having a layer like "Service Composition" to run on resource-constrained devices in Figure 1 (c). The Five-layers architecture is quite similar to the three layers architecture. R. Khan et al., [5] extended the three layers architecture to five layers in Figure 1 (d), that helps to visualize a clear view of IoT architecture with Objects Layer, Object

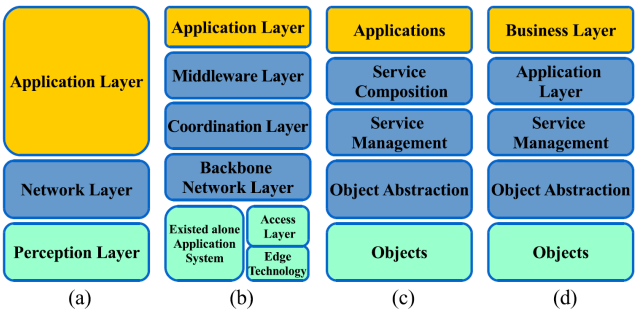

Figure 1: layers Wise IoT Architecture. (a) 3-Layer [4]. (b) Middle-Ware based. (c) SOA based. (d) 5-layer [2].

Abstraction Layer, Service Management Layer, Application Layer, and Business Layer for the easier operation for the IoT ecosystem.

The main limitations for these IoT architectures, the three-layer architecture does not cover all underlying technologies that transfer data to an IoT platform. The SOA-based architecture takes a big fraction of time and energy of the device to communicate with other devices and integrate the required services. The five-layer model is a rather complex model and has very large computational requirements and thus it requires very powerful devices for it's hosting. These models do not cover all standards in the real IoT environment. For example, "Object Abstraction Layer and Service Management Layer" does not cover all Cloud Protocols, neither does it integrate the required services.

III. Protocol Based Nine Layered Architecture for Things-to-Cloud (T2C)

T2C Architecture provides an overview of all the protocols that would be helpful for the performances of the IoT Services. In Figure 2, we present a layered diagram of the important standard protocols and technologies. In the T2C Architecture we extended Object Abstraction Layer to Connectivity Layer, Link Protocol Layer, and Transport & Network Layer. The Service Management Layer has been extended into three different layers; Session & Communication layer, Data Aggregation & Processing layer, and Data Storage & Retrieval layer.

We added Business Model layer to reach Business Application layer with the help of open framework. This extension is brought with intention to reduce the maintenance cost, better services & support, smoother logistics, improved experience, and enhanced security with the low-power. The T2C protocol based architecture defines a protocol based networking architecture to implement protocols in nine layers. Different groups (W3C, IETF, IEEE, EPCglobal, ETSI) are the protocols provided in support of IoT ecosystem. The T2C protocol based nine layered architecture provides the most prominent Standard protocols into nine broad categories.

IoT-Devices Classification and Mapping With T2C Layers: The IoT-Device layer is classified in five parts: Home Automation Based IoT-Devices, Industrial Based IoT-Devices, Health Care Based IoT-Devices, Development Board IoT-Devices, and Virtual Reality & Miscellaneous IoT-Devices. The detailed classification of IoT-Devices can be seen in Figure 3. These devices connect to Link Protocol Layer and receive the data feed over the Transport & Network layer using 2G, 3G, 4G, 5G network technologies. This will not interfere with Transport & Network layer protocols for messages by-passing in the Session & Communication layer. The Session & Communication Layer sends the data feeds to the Aggregation & Retrieval layer to provide low-latency platform for managing real-time, unified, and high-throughput data feeds. For storage purposes, the Aggregation layer sends the data feeds to the Data Storage & Retrieval layer and pop the data feeds with the help of an open framework to the Business Model layer.

However, not all of these nine layers have to be aggregated together to deliver an IoT-Device. Moreover, based on the inherent nature of IoT-Devices, some layers may not be required in them. We provide a mapping for IoT-Devices classification with T2C Layers in Table I.

A. IoT-Device Layer

1) Home Automation Based IoT-Devices: These little devices that consist of the perfect combination of the various sensors to prepare our home intelligent and protected i.e. HD Camera, High Quality Microphone, Smart Temperature, Night-Vision, Motion Detection, Smart Thermostats, Smart Lights, Smart skybell, Intelligently Tracking, Teleportation, 360 degree IR blaster, UV, Humidity, Noise detector, Vibration, Monitor Indoor Air, Outdoor Weather, Energy Consumption, and many more.

These devices intelligently analyze sensor data and send us alerts in case of unusual activity. We empower them to take action when we are traveling.

2) Industrial Based IoT-Devices: Industrial-IoT (IIOT) devices are smart assets providing many benefits, including improvements to Productivity Monitoring, Operational Efficiency Safety, Control Liability Performance, and Diagnostics Regulatory. IIoT eliminates workers from many organizations and industries, allowing IoT-Devices to act autonomously decreasing risks associated with worker injury or human error system failures.

3) Health Care Based IoT-Devices: In the health care industry, it is very difficult to collect samples, patient information, and diagnosing in real-time. The Health Care Based IoT-Devices help in monitoring and keeping track of patients health continuously and are responsible for performing certain actions when the critical condition is triggered. It is expected that by 2025, 80% of all health-care organizations will have implemented IoT technology. Some companies have also designed other health-related IoT products like Thermometers, Fitness Sensors, Baby Monitors, and more.

4) Development Board IoT-Devices: Development Board IoT-Devices have a sensor embedded at the IoT Development Board. In development boards, we realize how a sensible,

Table I: IoT-Devices and Required Layers

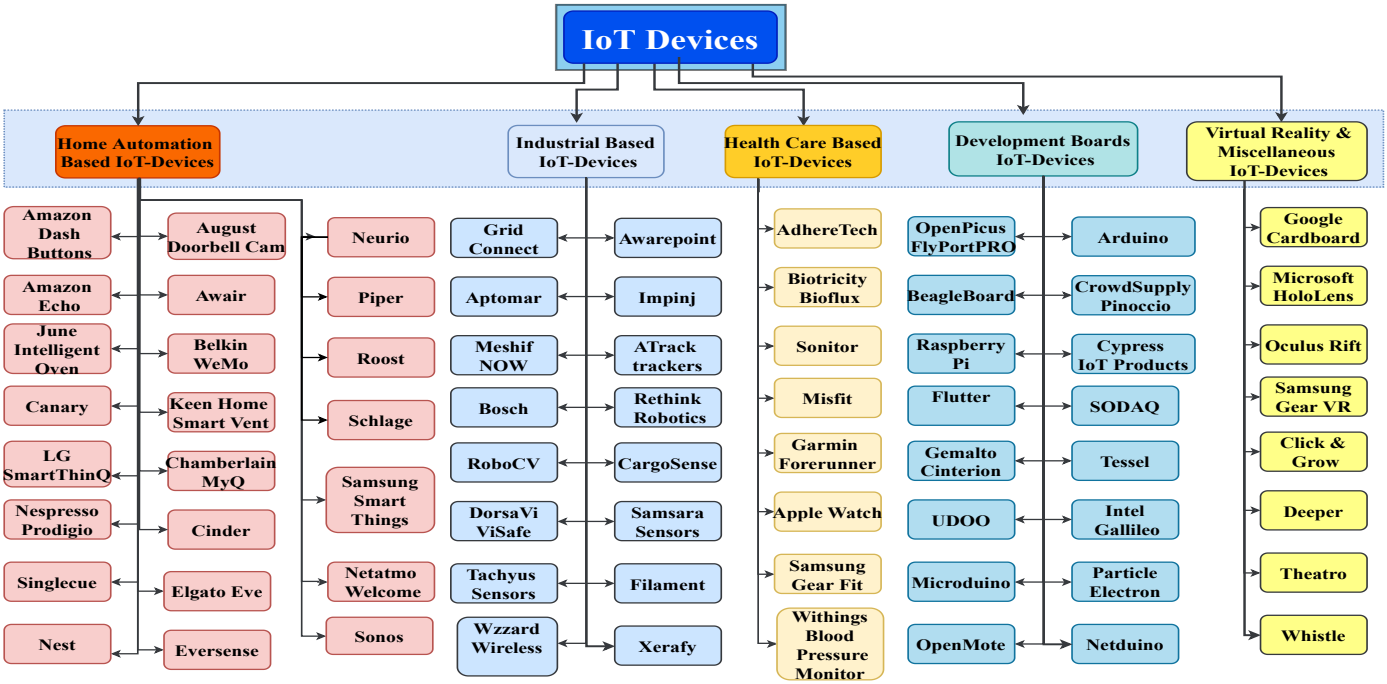

Figure 3: IoT-Devices Classification

smart device acquires, processes, and communicates information to the cloud platform. IoT software and hardware work together to build the IoT Technology stack. In the Development Boards market, there are more than 100+ Single Board Computer (SBC) / Boards available like *Arduino, BeagleBone, Intel, Raspberry Pi families,* etc.

5) Virtual Reality & Miscellaneous IoT-Devices: IoT is also used for the low-Frequency approach to Augmented Reality (AR) / Virtual Reality (VR). There are so many devices designed primarily for enterprise use, *Google Cardboard* for nostalgic toy lovers, *Microsoft HoloLens* augmented reality smart device which can assist with training, design work, communication, and more.

B. Connectivity Layer

While developing any IoT solution big question which arises is how to connect to the above layer? There are so many connectivity protocols available in the literature. We will discuss the most popular connectivity protocols and suggest how to choose the most suitable protocols for an IoT solution. The Connectivity layer protocols provide connectivity to models and interfaces to the set of sensors. We will further continue into detailed features regarding the pros and cons of each of them:

1) OBD-2: Connected Car - The future of automobile, IoT-OBD (On-Board Diagnostics) device is the best car tracking and diagnostic devices for someone who wants to track a car's location, experience travel rates, identify the problem of a check-engine light, and automatically get emergency help after an accident.

2) Ethernet: It is external communication in a local area network. It controls the transmission of the information and avoids simultaneous transmission by various IoT-Devices.

3) RS-485: It is an Industrial protocol. This kit consists of the features of the WiFi connectivity, which establish the real-time overall achievement, authenticity, and accuracy for T2C while transferring information between the application and the fundamental layer.

4) RS-232: It is an Industrial protocol. This kit includes the features of the LoRaWAN connectivity plus the benefits of having an RS-232 connection to be integrated with industrial devices.

5) SDIO: SDIO is an evaluation board. It supports 802.11 series protocols and low-cost IoT USB interface.

6) Wireless: In the IoT, there are a series of factors, all working in tandem to transmit the system records in real time. There are many purposes that fall below the IoT umbrella.

7) SPI: SPI device, gadgets communicate in full duplex mode using a master-slave structure with a single grasp. It's faster than asynchronous serial.

8) RJ-45: RJ-45 is a dual-port connector including with smart sensors, operator terminals, remote input/output, gateways, and transmitters. It supports industrial protocol stacks.

9) UWB: Ultrawideband technology could be an undiscovered option for some IoT applications. A UWB was affiliated to a DCU (data collecting unit), and they send their IoT sensor data to the server, wirelessly [6].

10) IrDA: The Infrared Data Association (IrDA) offers requirement for an entire set of protocols for Wi-Fi infrared communications, and the name "IrDA" also mention that set of protocols.

11) PLC: PLC is a Power Line Communication. For the IoT sensor network SmartGrid, C Chaauvenent et al., [7] proposed G3-PLC (Narrowband Powerline Communication) standard. PLC-IoT Application approves agencies of all sizes to upgrade and enhance their legacy systems for the future.

12) LonWorks: LonWorks is a conversation protocol in the Local operating network (Lon), so it is called LonWorks and open protocol technology. It is a networking platform and individually built address that caters the needs for applications.

13) KNX: KNX is a communication protocol developed for home and building automation. KNX-IoT is state of the art technology. It also supports diverse interactions between KNX and 3rd party equipment driven by relevant use cases from various categories.

14) GPIO: A GPIO (General Purpose Input/Output) port controls both incoming and outgoing signals. It is a standard interface for electronic devices and connects to microcontrollers. It can be used with System-on-Chip (SoC) Modules, Sensors, Displays, and Diodes. It supports Windows and Linux Operating Systems.

15) I2C: Inter-Integrated Circuit (I2C), I2C is a serial and synchronous communication protocol, so they enable apps to speak with Inter-Integrated Circuit devices. In I2C devices EEPROMs, real-time clocks, processors, sensors are used as a control interface. I2C devices have respective data interface (Video Decoders, Digital TV Tuners, Audio processors).

16) USB: USB stands for Universal Serial Bus. Its send and receives a data feed along with clock pules. It is very fast compared with USART and USB. USB have three generations i.e USB1.0, USB2.0, USB 3.0. The USB cable is the only medium that connects Arduino and Computer.

17) PWM: Use Pulse-Width Modulation (PWM) signals for motor control. PWM controls analog circuits with digital outputs. PWM required less heat dissipation, greater efficiency, and higher power output.

18) DSI: Digital Serial Interface (DSI) capabilities allow signals communication (high-speed serial interface) between machines and sensors. Machines to be captured and analyzed the data feeds. DSI could help us to connect machines, devices, things, and sensors in various environment. DSI research & development helps to our Military to reduce the expense of display controllers.

19) UART: Universal Asynchronous Receiver/Transmitter (UART), It's not a communication protocol like I2C, SPI, and more, but it's a stand-alone IC. The main purpose is to transmit, broadcast, and receive serial data.

20) USART: It is a Universal Synchronous & Asynchronous Data Transmitter & Receiver. USART push and pop a block of data with classes pulses. It is a duplex communication. It is fast compared with UART.

21) CAN: Controller Area Network (CAN) is a CSMA-CD/ASM protocol. CAN is an interface for Telit cellular module, as well as a positioning component for the Global Navigation.

22) McASP: Connected McASP is simple to establish a sensor available to work on your existing device, machinery. You need to install the gateway on the devices or machines which we want to track and start monitoring them remotely.

C. Link Protocol Layer

In the IoT ecosystem, connected with millions of devices in the system. We securely transfer the information and data feeds in the Transport & Network layer. Almost all IoT-Devices need some wireless or wired connectivity interface that gives them the ability to collect information from IoT-Devices and transmit the information in The Transport & Network layer with different standard link protocols. These protocols make use of radio waves to transmit the collected information across a network. Link Protocol layer works as a two-way traffic, data or information received from the IoT-Devices will also pass through the IoT Gateway. We shall briefly explain different protocols standards.

1) Bluetooth/BLE: Bluetooth/BLE designed for connecting devices to the internet with low energy consumption. It is an ultra-low power connected devices in short range. Matti et al., [8] investigate Ipv6-based connection over BLE. It is appropriate for future IoT scenarios.

2) Wi-Fi: Any of several standards for short-range wireless data feed transmission. Wi-Fi is a wireless fidelity technology. It is a real-time high-speed less communication protocol [9] for cyber-physical control applications.

3) RFID: RFID tags or smart labels for radio-frequency identification, RFID tags are the small wireless accessory that helps identify people, things, and objects [10]. RFID is a built-in part of our life, which increases convenience and productivity.

4) LTE: LTE is a high-speed wireless communication based on EDGE/GSM and HSPA/UMTS. LTE will pass large packets of data and streamline the IoT Service. It reduces the latency of information delivery.

5) GSM: It is established on eGPRS and construct as a high capacity, long range, low power cellular gadget for IoT applications.

6) DECT/ULE: DECT (Digital Enhanced Cordless Telecommunications) and ULE (Ultra Low Energy) is an ordinary European widespread for cordless phones. They have specific a low-power air interface technological know-how that can be used for IoT applications.

7) G.9959: G.9959 performed at low cost, low bandwidth, and half-duplex reliable wireless communication. It is planned for real-time functions and required the authenticity for low strength consumption [11].

8) IEEE 802.11 series: 802.11 series a/b/g/n/ac/..etc, also known as Wi-Fi for between two wireless clients. It includes a limited range of being connected technology containing wireless LANs (WLANs). IEEE 802.11 wireless communication medium access standard. The basic of 802.11 series MAC layer features include; simultaneous occurrence Frame, Null Data Packet, Short Mac Frame, Efficient Bidirectional Packet Exchange, and Increase Sleep Time.

9) Zigbee: It is high-level intelligence communication protocols based on the IEEE 802.15.4. We can develop personal area networks, helps to a medical device for data collection, and home automation with low-power. ZigBee Pro offers greater aspects such as security the use of the balanced symmetric-key exchange, scalable the usage of random address assignment, and better overall performance the use of environment-friendly many-to-one routing mechanisms.

10) CDMA: C-Code D-Division M-Multiple A-Access P-Protocol (CDMA), It used 2G and 3G wireless communications. The CDMA-based protocol can support IoT traffic in upcoming 5G-MNA (Mobile Network Architecture).

11) Ethernet IEEE 802.3: Ethernet 802.3 is a physical communication in a LAN. Its wired connectivity & networking for computer and data applications.

12) IEEE 802.15 / 802.16: IEEE 802.15 is based on direct sequence spread spectrum, DSSS techniques. IEEE 802.16 is a Wireless Communications Standards (WCS) for metropolitan area networks (MANs).

13) WiMax: Worldwide Interoperability for Microwave Access (WiMax), produce 4G and 5G of wireless Internet. WiMax has average bandwidth in the local LAN connection and offers wireless broadband.

14) CSMA/TDMA/FDMA/CDMA: There are some methods for Signal. Different users share a common channel using F-Frequency D-Division M-Multiple A-Access (FDMA), T-Time D-Division M-Multiple A-Access (TDMA), C-Carrier S-Sense M-Multiple A-Access (CSMA) or C-Code D-Division M-Multiple A-Access (CDMA). These are secure and authentic MAC protocol. They have advance Encryption-Algorithms to encrypt the messages and calculate the coherence and cohesion.

15) LTE-A: L-Long T-Term E-Evolution Advanced (LTE-Advance) is a standard to construct Machine-to-Machine (M2M) communication and IoT-Devices networks. LTE-A is a flexible, scalable, and low-cost protocol related to other cellular protocols [12]. LTE-Advance is a new evolution to help band-aid to increases data speeds, faster, performance, greater stability in the future.

16) DigiMesh: It is the high-latency for information transfer, as the network-dictates in the time-frames for data. They increase network range, and every device performs like a router [13].

17) NFC: Near Field Conversation (NFC) is a set of communication protocols that authorize to electronic devices. It is a flexible system such as a smart-phone and set up authorize communication by bringing them inside four cm of every other [14]. NFC at a receiver apparatus and radio transmitter. The best example is Beacons that come with a built-in NFC tag, and ANT+ provides such strengthens.

18) WirelessHART : It is a wireless sensor networking science primarily based on the H-Highway A-Addressable R-Remote T-Transducer (HART) Protocol. It is advanced developed as an inter-operable wi-fi standard and multi-vendor. WirelessHART was characterized by the necessities of development field system networks. WirelessHART, the first worldwide industrial wi-fi general (IEC 62591), is built on the pinnacle of the IEEE 802.15.4 widespread [15].

19) Z-WAVE: A Z-Wave network consists of IoT units, and a foremost controller additionally acknowledged as a smart domestic hub. Z-Wave is one of the oldest and most commercially profitable IoT protocol, while Thread is one of the most current protocols [16]. Z-Wave protocol used for home appliances to monitoring and control.

20) DASH7: This protocol is a wireless verbal exchange protocol for pushing RFID that operates in universally accessible I-Industrial S-Scientific M-Medical (ISM) smart band, and it is suitable for all T2C requirements [17].

21) HomePlug: It is designed for consistently and especially for Home-Automation and Smart-Grid applications. It is specially constructed to scale down the value and energy utilization of smart HomePlug-AV while maintaining its coverage, interoperability, and reliability.

22) Weightless: Weightless is another Wi-Fi WAN, designed with the aid of the Weightless Special Interest Group (SIG). There are two units of standards, like Weightless-N and Weightless-W. There is the first developed aid with low cost and low energy machine-to-machine conversation with the time division multiple access[18].

23) 6LoRaWAN: It is a recently bobbing up wireless technology constructed for low-power WAN networks with bi-directional communication, low cost, security, and mobility for IoT purposes [19].

24) MiWi: In the MiWi development, there are some different protocols like Miwi protocol, Miwi Mesh, and Miwi P2P. These protocols are used for short range area.

25) ANT+: ANT+ provides such strengthens and features goal for the IoT. It manages the ANT network and defines how to transmit information across the system in a consistent way. ANT+ is an enabled sensor to help health care services.

26) EnOcean: EnOcean is an energy harvesting and energetically exploitation of mechanical motion and other potentials from the IoT Ecosystem, such as temperature difference and indoor lights for building automation and home.

D. Transport and Network:

The Transport & Network layer is responsible for assigning some address and routing of data feeds. At this layer, the data packets are delivered from the Link Protocol layer to the destinations by using the IP address. These layers communicate data to The Session & Communication layer. There are some mechanisms of Network layer encapsulation protocols (IPv4, IPv6 over BLE, IPv6 over G.9959, 6LoWPAN, 6TiSCH, 6Lo, TCIP/UDP, IP, SLIP). IP version 4 (IPv4) is the network layer protocol. IPv4 has five classes, i.e., Class-A IPv4, Class-B IPv4, Class-C IPv4, Class-D IPv4, and Class-E IPv4. Commonly we used Class-A, Class-B, and Class-C. The Class-D and Class-E fixed for multi-casting and some experimental purposes. IPv4 has limited address space (approximately 4.3 billion devices), so we need more address space because there will be more than 50 billion IoT-Devices alone by the year 2025. IPv6 have 128-bit address space (approximately 320

billion devices). In IPv6, there are three types of addresses in standard, i.e., Uni-Cast Address, Multi-Cast Address, Any-Cast Address [20].

6LoWPAN, 6-IPv6 L-Low P-Power W-Wireless P-Personal A-Area N-Network (6LoWPAN) [21] developed for IoT-Devices in a WSN. It is a modified version of IPv6. 6TiSCH, allows IPv6 addresses to pass by T-Time S-Slotted C-Channel H-Hopping (TSCH) mode. Resource-Constrained Nodes (6Lo) is IPv6 protocol for data-links that were left excluded by 6TiSCH and 6LoWPAN. These protocols reduce communication by the following three optimizations, i.e., Header Compression, Fragmentation, and Link Forwarding. The consequence of imparting these protocol standards is to spotlight the main challenge of between particular specific MAC requirements and the variety of protocols. So, the IPv6 and the standard protocol stacks based on the future growths of IoT-Devices. It has sufficient address space for IoT ecosystem while using IPv6.

These are some Routing Protocols (RPL, CORPL, CARPL) presented in IoT. RPL is a measure vector protocol created by IETF in 2012. RPL: IPv6-Routing-Protocol for Lossy Networks and Low-Power. It calculated the de-facto-routing-protocol for IoT. C-Cognitive RPL (CORPL) is an aberrant addition of RPL protocols that are designed for cognitive networks and appropriates the opportunistic sending to deliver packets at each Hop (networking). CA-Channel-Aware R-Routing P-Protocol (CARP) is the only distributed Hop (networking) based routing protocol that is produced for IoT-Devices based network applications. CARP is used for under the water's surface and submarine communication and send the information mostly.

E. Session & Communication Layer

In the Session & Communication layer, we communicate (Request/response, Publisher/subscriber) between Server-2-Server (S2S), Device-2-Device (D2D), Device-2-Server (D2S), and Server-2-Device (S2D). These protocols are very light-weight to publish and receive messages. These protocol designed for constrained IoT-Devices with low-bandwidth.

Things-to-Cloud (T2C) has many standard communication protocols which are briefly highlighted in this section. Those protocols are application structured based and software application specific. For example, if a software application has been constructed with XML, it receives a piece of code in its headers, XMPP may be the considerable option to appoint in the middle of session layer protocols. At the same time, if the application is energy sensitive, then we need to select MQTT. It would be predictable, trustworthy option. However, that appears with the other additional implementation. If the request application needs REST serviceability as it will be HTTP based, then CoAP would be the genuine, authentic alternative if not the single one. The list of alternatives are: CoAP, XMPP, HTTP, Telnet, MQTT, SMQTT, DDS, AMQP, FTP, SSH, EBHTTP, LTP, SNMP, DNS, NTP, IPfix, DLMS, DNP, MODBUS, COSEM, etc.

1) CoAP: The Constrained Application Protocol (CoAP) used with constrained (i.e., lossy, low-power) networks and constrained node. CoAP is the most promising protocol for smart IoT-Devices and M2M applications. CoAP is prescribed in IETF RFC 7252.

2) XMPP: XMPP is a lightweight Publish or Subscribe resource-based constrained IoT-Devices [22]. X-eXtensible M-Messaging & P-Presence P-Protocol (XMPP) reduce interoperability between different networks.

3) HTTP: HTTP is applied for data transfer on the internet, and it is mostly used for IoT-Devices that lack to publish a lot of data feeds.

4) Telnet: Telnet is a Client/Server protocol used in the local area network. It is based on a trust-able connection-oriented transport.

5) MQTT: MQTT is broadly used in T2C Architecture due to the low power consumption. It stands for M-Message, Q-Queuing, T-Telemetry, T-Transport. MQTT is an M2M/IoT connectivity protocol. It is a dial-up connection with home automation, health-care providers, Industrial application, and small device scenarios. It is very small in size, does efficient distribution of information, minimized data packets, and has low power usage to one or many receivers.

6) SMQTT: M Singh et al.,[23] proposed secure SMQTT protocol for IoT. SMQTT is an extension of MQTT and used in lightweight attribute-based encryption.

7) DDS: D-Data, D-Distribution, D-Service (DDS) developed M@M communication by Object Management Group. DDs is low footstep of our devices to cloud.

8) AMQP: A-Advanced M-Message Q-Queuing P-Protocol (AMQP), this is an open source protocol for asynchronous messaging. AMQP gives better performance compared to other protocols [24].

9) FTP: F-File T-Transfer P-Protocol (FTP) is a protocol for exchanging files between a client and a server in the network.

10) SSH: SSH works in the between client and server model. SSH uses public key cryptography.

11) EBHTTP/LTP: E-Embedded B-Binary HTTP (EB-HTTP) and L-Lean T-Transport P-Protocol (LTP) are light-weight protocols. That protocol works on low data rate, low computation complexity, and low energy consumption [25].

12) SNMP: S-Simple N-Network M-Management P-protocol (SNMP) is the most long-range protocol. It supports conventional network equipment like IoT-Devices, scanners, printers, etc.

13) IPfix: I-Internet P-Protocol F-Flow I-Information E-Export (IPFIX), it consists of a unidirectional protocol for export and format the data.

14) DNS: D-Domain N-Name S-Service (DNS), it resolves the host Internet Protocol-Addresses (IP-A) rendering IoT services. There are some Service Discovery protocols, i.e., m-Multicast D-Domain N-Name S-System (mDNS), DNS S-Service D-Discovery (DNS-SD), U-Universal P-Plug n-and P-Play (UPnP), DNS N-Name A-Autoconfiguration (DNSNA),

S-Simple D-Discovery S-Service P-Protocol (SDSP), DNS SEC-Security DNSSEC [26].

15) NTP: N-Network T-Time P-Protocol (NTP), NTP exchange of time-stamped messages in long-range. NTP-client implements a time-request exchange with IoT-Devices and data packet exchange protocol, called Synchronization Protocol for IoT (SPoT) [27].

16) DLMS: D-Device L-Language M-Message S-Specification (DLMS) or D-Distribution L-Line M-Message S-Specification (DLMS) is an advance Utility IoT protocol. DLMS is used for network connectivity that helps smart metering, thermal energy, water, and gas.

17) COSEM: CO-Companion S-Specification for E-Energy M-Metering (COSEM), COSEM is an interface that is used in the communicating of energy-related equipment.

18) DNP: D-Distributed N-Network P-Protocol (DNP). It is a set of communication protocols that communicate with a master station and IEDs of RTUs.

19) MODBUS: Modbus has allowed thousands and thousands of automation units to talk with each other. The embedded operating system start the communication between the stations, and they talk with another device in cyclic repetition in the Modbus Communication Protocol.

F. Data Aggregation & Processing Layer

When IoT-Devices send data feeds, huge data, we require an endpoint to act something with the enormous data. It is a partitioned, distributed, and replicated log service or messaging system. *Storm* help to process in the real-time environment. *Kafka* getting the data feeds and sending at other destination at large scale. Kafka generates IoT data events and gives a continuous stream of data to sources [28]. Other alternate solutions are Scribe, RabbitMQ, Flume, Storm, Luxun, Flint, JMS, ActiveMQ, Qpid, Kestrel, Scribe, Hedwig, Batch Jobs. They help to monitor the traffic of the data in The Data Aggregation & Processing layer.

G. Data Storage & Retrieval Layer

This layer handles the data passes between IoT-Devices and the Business Model layer. In the recent past, a lot of attention has been migrated from computing to data, which can we saw in the form of several data processing software products in the market. From SQL to NoSQL, a normal relational database to Big Data all are used to provide backend solution. Hadoop, HBase, Apache Cassandra, MongoDB, Reds, CouchDB, Neo4j, Couchbase, Riak, MarkLogic, DynamoDB, Spark, Google AppEngine dominate the field. They provide Data-Partitioning, Data-ingest, Data-quality, Data-Governance, Data-Cleansing & Processing, Predictive Capabilities & Normalization in a Distributed Database System (DDS).
This layer is responsible for providing fast services on high-performance distributed databases, highly-scalable, and reconfigurable servers to handle huge amounts of data sets. This allows the user to do reliable, scalable, distributed computing, and cost-effective solutions.

H. Business Model Layer

The basic Business model depends on Cloud Services such as Data as a service, Process as a service, and Product as a service. In a new era industry and people transform their business models and adopt a new business model for social change with the presence of IoT Ecosystem. This business model provides the business value, business purpose, business methods, and business processes by using Integrated Cloud Model, On-demand Model, Hybrid Model, Platform Independent, Ubiquitous, Cross-domain Application, Standardization, Server-less Model, and Open Framework Model, etc.

I. Business Application (Apps) Layer

Business Application (Apps) layer is divided into three parts, i.e., Device Management, Business Processes, and Analytic & Automation. The function of the Device Management Component is device registration, device provisioning, firmware management, product & asset structure with security, and remote access. The Business Processes Component, on the other hand, is responsible for the transformation of services between the IoT-Devices, Marketing for IoT-Devices, and analyzing the impact of IoT-Device-manufacturing on the market. Finally, in the Analytics & Automation Component provide tools for processing data coming from IoT-Devices. It also has a component for data visualization, data mining, and intelligent data gathering services. A Machine learning library can also be incorporated.
With this proposed approach a new nine layered architecture which we call it Things-to-Cloud (T2C) is introduced in which the data can travel from sensor to the cloud and come back to the user with a lot of value added into. It is evident that all layers are not required every time.

IV. IoT Security & Privacy Trust Framework

O-Online T-Trust A-Alliance (OTA) is an Internet Society Initiative [29]. OTA has released two trust framework for IoT i.e "IoT Security & Privacy Trust Framework v2.0 [29]" and "IoT Security & Privacy Trust Framework v2.5 [29]". This framework includes a set of essential principles required to help secure smart IoT-Devices and their data feeds. This framework is divided into four areas, i.e., User Access & Credentials, Security Principles, Notifications & Related Best Practices, and Privacy Disclosures & Transparency. This particular framework can be incorporated in the proposed layer assuming that all the communication between layers are secure in nature.

V. Conclusions

We have proposed a nine layered protocols based T2C architecture. In the protocol environment architecture, we discussed different protocols. These protocols have been developed by W3C, IETF, EPCglobal, ITU, IEEE standards and products are developed by different companies using these standards. An attempt has been made to decentralize the functionality into layers and clearly dividing the role, protocol, and software stacks that can be used to realize a real world scenario.

Any application development of T2C can be designed and implemented using these proposed layers. The purpose of this paper is to provide an insight understanding of this whole ecosystem and the mapping of IoT-Devices with the respective T2C layers. It is a foundation for IoT practitioners and researchers to understand standard protocol classification and to gain an insight into the IoT protocols and standards to understand overall T2C architecture.

***Abstract*--An extravagant receptiveness to healthcare commercial enterprises is the redistributing of health files to cloud. Howbeit, the exceeding deportments of the cloud system are armament and privacy of sensitive erudition. By the applicability of attribute based encryption dispositions in specification to access control many solutions have been envisaged in order to assuage those challenges. To phase out and also to procure ascendable and decisive secure solution, a distinct key criterion has been milked as multi-signer digital signature paradigms have been made the most of as multi-signer digital signature confrontations. It is entrenched to mollify the measurable attacks. In this paper, a strategic and distinct signature scheme designated as key aggregation scheme which concedes users to decrypt conglomerate classes of file using single key that can be communed betwixt the users in demoniacally fabricated group. The consorted model encompasses aggregate key generation for accessing the files systemized in a pecking order, hashing of key to upturn the security of keys, ring signature has been inculcated to dynamically fabricated group for data admittance using cryptographic proposals. The reserved files will be in the encrypted form which the user can have ingress to capacitate the hoarded files.**

Keywords-- key aggregation, ring signature, Encryption, Health Records, Data preserving, aggregate key.

I. INTRODUCTION:

The up to date onset of cloud Computing has tuned up the confinements of data outsourcing. Cloud-based electronic health records permit medical documents returned and traded amidst medical institutions therefore becoming an imperative model for intensification of productivity and is conventional to contribute improvements in disparate medical services in the offing [1]. Conceivably it springs up with an over-and-above safekeeping threats on incaldenment of millions of users which erects as the foremost impediment surrounded by data owners.

Consequently patients may occurrence disclosure of secretive data that they do not aspire to unveil. For this reason making sure of the security and seclusion on the cloud is a non trifling task. The long-established way to make certain the data is to be dependable on the server to insist on the admission and accession control after substantiation which means any unpredicted dispensation intensification which will supplement depiction on all data [2]. Attribute based encryption has been availed to administer security and ingress control on one and the other attacks to the outsourced data as it became well-liked on harmonization. In Attribute-Based encryption type of impenetrable ingression control where attributes of the users are pre-owned to cobble up access policies and the proprietor of data who ascribes indications are conceded to initiate data in the entity [3].The cryptographic virtuosities are once more deceitful face down to key administration contentions aforesaid key escrow problem, computation power, key denunciation, lampooning, eavesdropping and accelerated attacks. In regulation to chaperon the seclusion of patients, many advents have been contemplated to give accession control to patient documents while providing services related to physical conditions [4]. The extanting data partaking strategy on the cloud is extensible and conducive, if data proprietors can emisorily access rights to their files efficiently to myriad users, who can then access the data unswervingly from the cloud servers. In further cases data owners have a preference to accumulate rift sets of file in cloud and entrust that detachment of file to unusual users with mottled access policies. To accomplish this, data owner has to endow with each user with decryption privileges to unambiguous class of data. This leads to supplementary face ups to and it becomes in competent in large scale appliances. In this paper, the key aggregate format has been sculpted in order to put up a signature for the dynamically establishing group by the data owner and generated signature is again secured using hashing procedure. In adding

together, Constant size aggregate key coalesce the decryption rights of numerous classes of data and uses the public key cryptosystem [5] alongside ring signature to carve up the key to the target deposit of user. Moreover single decryption is conceded out in the midst of the set of user in the intention group in accordance to diminish the multiplication cost, decryption time and memory exploitation through assimilation of substitute attendant to pile up the decrypted data.

II. LITERATURE SURVEY:

Techniques that are relayed on security concerns in cloud have been shared by most of the reviews related to this paper. The recitals which execute pertinent to the projected procedure have been portrayed underneath.

A. Multi Authority Attribute Based Encryption

Control Mechanism with user-centric ingression is a collection of machinery for data admittance to healthiness files accumulate in semi-trusted attendant. To accomplish well-accorded and scalable data admittance have power over files based upon health status, attribute based encryption (ABE) techniques is influenced to encrypt healthiness of apiece patients' file predestined on the insightful attributes [6].The sheltered data outsourcing is paying attention on the manifold data possessor circumstances as to partition the users in the make safe health file coordination into numerous defense domains that significantly lessen the key administration involvedness for owners and users. An elevated degree of unwearied privacy is sure fire concurrently by taking advantage of Attribute based encryption using multi authority.

B. Cipher Text Policy Based Attribute Based Encryption

It tenacities seclusion issue and it makes use of attribute set as confidential key and admittance policies is entrenched into the cipher text for concealed. The key production algorithm takes user's unrestricted as well as secretive attributes to manufacture the undisclosed key for the user. Each cipher text is completed up of access policy. The user can set access policy which consents to set of users to decrypt data. CP-ABE proposals brings into play user's attributes as the reciprocative set for creating new access policy and comparable for creating the private key using a set of user attributes [7]. Nonetheless direct accomplishment of the CP-ABE undergoes two concerns such as access policies are in clear text form and divulge insightful health-related in turn in the encrypted health records (SHRs) and it habitually prop ups small attribute set, which places an detrimental constraints on realistic consumption of CP-ABE because the dimension of its unrestricted parameters grows linearly with the size of the attribute set.

C. Attribute based Encryption by the use of file hierarchy

Cipher text or Key policy Attribute based Encryption has been regarded as to decipher the data allotment disputes in the cloud. It is mulled over as multi layered ingress composition which is incorporated into tree like access structure on lengthening cyclic and acyclic sculpt to engender tree hierarchy of symmetric keys[8]. The admission composition is used to encrypt the hierarchical files with characteristics which exclusively accumulate cipher text production time and data storage time. The cipher text components interrelated to the attributes will be allocated by the files. The massive enlargement in size of the key is the most important negative aspect in this encryption.

III. PROPOSED SYSTEM:

A new theme is being discussed in this section called key aggregate to the secure statuses of data ingression and key distribution among myriad users. The storage bytes have been reduced by the use of this aggregate key scheme.

A. Groundwork

The plot is catalogued into two sections. Hashing model by the data possessor is generated by the use of ring signature scheme and succeeding focuses on production of aggregate key for set of classes in the case. The generated key is at last shared amongst the data users in the set.

B. Data holder

Data proprietor enraptures the file with requirement of class to file detachment and encrypt the partitions for data admission among the data consumers. It is widespread group signature employed to form vibrant contour group towards access of the data files by the holder.

C. Trusted Authority

Trusted Authority is responsible for generating key pairs for data owner and the users.

D. Data User

Data user is consented to access the files of the data possessor which is encrypted with creation of access keys like ring signature and aggregate key. Data owner execute the decryption operation with aggregate key

E. Bilinear Pairing

A coupling is a bilinear map definite over groups. Let's regard as G1 and G2 as subordinate groups of the equivalent prime categorize q. G_T is

passed on as multiplicative group of order q. P and Q are a point which emerges up the G1 and G2.

Bilinear Map is reflected as G1 * G2→ G_T after gratifying the subsequent assets like

Non Degeneracy : If P and Q be the generators for G1 and G2 respectively where neither group only contains the point at infinity

3.1. Threshold model on Aggregate Key generation:

The major beneficiary fact in this proposed system is the lessen in exploitation and increase in its efficiency and decline in storage bytes[9]. The foremost process includes the key generation which is denoted as in figure 3.1. in turn sends it to the data holder as soon as the user‘s schemes are accumulated in the cloud storage. By the formulation of aggregate key through key aggregation, the data holder then passes the data to the encrypted file transmission.

A. Key generation

A data owner disposed to carve up the file registers to obtain her individual public and private key pairs. The data owner is conscientious for classifying each of data file into specific classes. It causes the public key TK and master secret key MSK for data holder.

B. Encrypt

The Classes of file is encrypted by the use of AES encryption procedure and accumulated in the cloud. It attains public key restriction PK, data class d and plain text data T, harvests the cipher text C.

$C= (C0, C1, C2) = (K,(T_m1+K_i), m .e(T_n, K_n)$.

C. Decrypt

When farming out the decryption rights to an unambiguous detachment of message classes, the data owner uses the Extract maneuver to engender an aggregate decryption key that is distinctive to that rift [10]. It acquires Master secret key MSK and data classes’ d. Calculate aggregate key T_K all encrypted messages belonging to this subset of classes.

The cryptographic virtuosities are once more deceitful face down to key administration contentions aforesaid key escrow problem, computation power, key denunciation, and lampooning, eavesdropping and accelerated attacks.

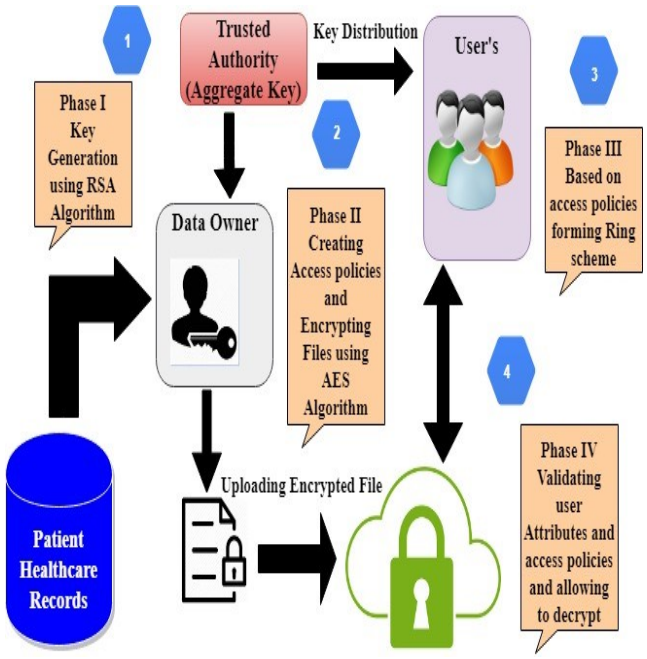

Fig.3.1 Proposed data sharing using Aggregate Key

D. Set Up:

It is used to set up the public parameters param by obtaining the number of data class’s d and security parameter p.

3.2. Aggregate key

Based on bilinear pairing, it is recognized as the most effective one in the cryptographic analysis of aggregation. Especially of Composite order and demonstrated to be sheltered under the postulation that the subgroup pronouncement problem and computational Diffie Hellman predicament are unbreakable [11]. It is carried out on the file surface. Each file fit in to the group is encrypted using the key. AES algorithm is used for the encryption. The key of the dissimilar file utilized for the encryption is combined with tokenize symbol to produce the aggregate key. The aggregate key is produced from encryption of combined key using ring signature [12]. The aggregate key will be mottled on accumulation of file and deletion of files to the group. By the formulation of aggregate key through key aggregation, the data holder then passes the data to the encrypted file transmission

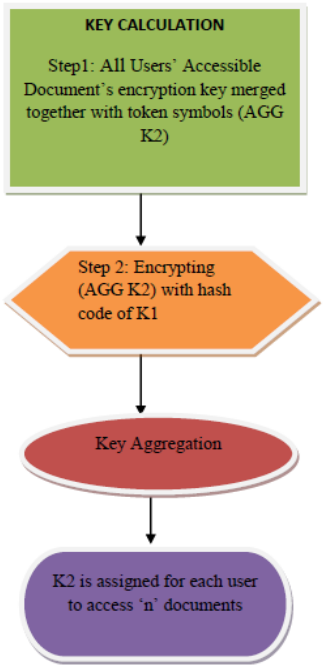

Fig.3.2 Aggregate key calculation

The above figure 3.2. Descripts the accession of users' documents with encryption key concatenated with token symbols (AGGK2). The symbols are ten encrypted with hash code k1 through aggregate key by key aggregation process which is then assigned for each user to access documents.

A. ALGORITHM

Below shows the procedure of Key aggregation using RSA algorithm

STEP I: Generating public key/private key
STEP II: Compute the RSA modulus 'n'
STEP III: Selecting two large primes at random: P, Q
STEP IV: Computing their systemmodulus n=p.q
STEP V: Note ø (n) = (p-1) (q-1)
STEP VI: Consider K secure parameter and outputs the public signing key K_{sig} and Private signing Key V_{sig}

B. Description of Algorithm

The primary process in aggregate method is that the user has to engender either the public key or the private key by choosing the random variables P AND Q followed by the process of enumerating the RSA modulus declared by 'n'. The procedure of termination includes the system computation n=p.q modulus. An authoritative data user can make use of this aggregate key to decrypt any message fitting in to any class. It gets hold of the cipher Text C, data class d and aggregate key AG to generate the decrypted message.

C. Cipher Text Storage Calculation

Step 1: Calculate number of users (Ui).

Step 2: Calculate number of files size decrypted by the user (Fi).

Step 3: Formulate $N = Ui * F_i$

The decryption progression moniterates the ordinary text of the requested file and it will be located in the proxy server in order to set aside the decryption time of further users in the group by abolishing the decryption process for the intact group members. In addition, all process is time embossed for revocation of the group.

IV. EXPERIMENTS

In this segment, we scrutinize the security of the proposed model adjacent to the an assortment of data size is been computed and illustrated in terms of concert charts and tables for cipher text storage Reduction

A. Experimental Set up

The experimental results are obtained with an Intel Core I3 processor with 2620 Processors (2.0 GHz) and 4 GB RAM and 500 GB Hard disk using Dot net programming. The database server and file server has been established in the file system which acts as Cloud infrastructure. The different file sizes are used for computation of the efficiency of the model. Proxy server has been established using virtualization process as Virtual machine.

B. Performance Analysis

The reliability of the system is defined in terms of utilization of proxy server technology in data sharing systems to reduce the storage bytes of the group members. It will greatly facilitate data owner delegating the access rights to other members.

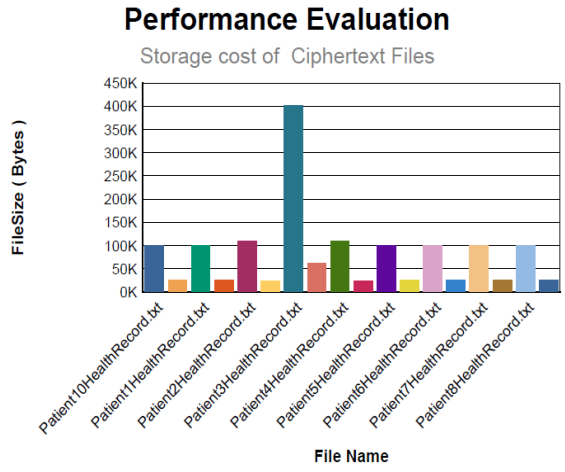

Fig. 4.1. Performance Evaluation of Filesize in storage cost of ciphertext Files.

The statistical figure 4.1 depicts the patients' health records with respect to file sizes in varying storage costs of ciphertext files.

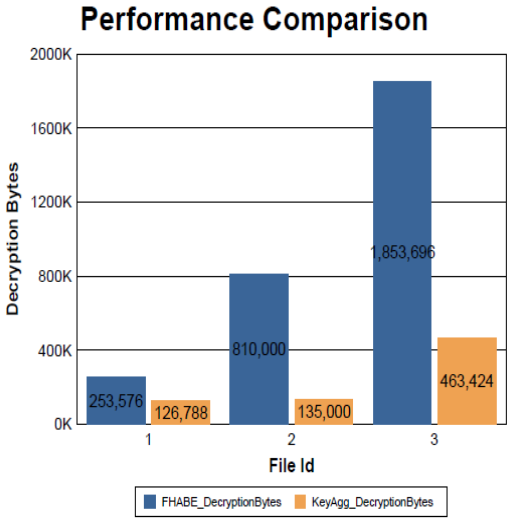

Fig.4.2 Performance comparison of the cipher Text Storage Bytes reduction on the proposed model and existing model to various File sizes

The figure 4.2 and table 1 describes and summarizes the performance of the proposed model and existing models to various files. Arrival of new users and revocation of existing user will lead to changes in key access rights due to expected to change occurs dynamically. User revocation is also achieved without any additional cost. The collusion resistance property ensures that the knowledge of prior aggregate keys does not compromise the knowledge of these new file.

Table 1: Performance Evaluation of the Cipher Text Storage Bytes

Technique	Storage Bytes for File ID 1	Storage Bytes for File ID 2	Storage Bytes for File ID 3
Key Aggregation	126,788	135,000	463,424
File Hierarchy Attribute based Encryption	253,576	810,000	1,853,696

In preference if the data owner desires to adapt an existing document, she could use a dissimilar index for it to make sure that a retracted user cannot ingress it in the outlook.

V. CONCLUSION

In this paper, we have devised and employed the key aggregation application to engender the protected and scalable data allotment model on the multi capability environment. The proposed model explains the effectual of the system on an assortment of phases like key generation, encryption and decryption to an assortment of file sizes and various group member formations. Aggregate key convention has been explained in detail on allocation multi classes of file diverse to set of users. This model has been found to be well-organized among arbitrary number of data classes. The experimental analysis has established Reduction of the storage and decryption time. It has been demonstrated that model is high conspiracy resistant against multiple users. As a future work, competent entree on stipulate data access under emergency circumstances can be enabling under break glass admittance observable fact.

Abstract:
Software defined Networking addresses the growth of traffic with static architectures. SDN is a standard which separates the network structures. Quality of Service is used with network traffic to transfer high bandwidth and multimedia information. Fractional Order Darwinian optimization(FODPSO) is used with Particle Swarm Optimization algorithm to enhance the detection accuracy. Comparison with Classification algorithms are used to achieve better performance.

Keywords: SDN, Anomaly detection, Fractional order Darwinian Particle Swarm Optimization.

I. INTRODUCTION

Quality of Service (QoS) is used for allocating the network resources [11] based on the requirements. These services have requirements like throughput, inaccuracy and idleness. Creating a replica by addressing all these requirements is complicated. Intserv and Diffserv are two methods to solve end-to –end connections and scalability. QoS is important for communication network and applications. This is specified in the form of interruption for the navigation of information. Therefore FODPSO [15] is used for accuracy detection. Reinforcement of QoS networking leads to higher cost and effort.

Data plane includes switches to handle network traffic. The information about the networks is gathered by a central organizer. A set of QoS parameters include throughput, end-to end delay [13] and error rates for better performance. The goal of the study is to provide greater QoS performance using Particle Swarm Optimization (PSO) based Delay constrained Least Cost algorithm. PSO is a collective behavior of a system which is used to interact with their location to provide efficient [9] data.

A flock of birds is searching for food without any knowledge of food. So the best criterion is to follow the bird which is near to food. The birds can identify the location using these criteria's: i) birds fly in similar path ii) revisit to path of maximum attention iii) progress through the nearest [10] target. The candidate solution moves towards the target to identify the destination. The confined best, large-scale best and neighborhood solution is calculated. Then the greatest solution is rationalized through entire swarm. This structure of the paper is illustrated as: the prose of the algorithm is explained in sec 2. The illustration of methodologies of PSO based FODPSO is specified in sec 3. Optimization techniques are concluded in sec 4.

II. LITERATURE SURVEY

In 2016, Benuwa.B describes about the swarm behavior and its properties for adapting different environments. An intelligence [1] algorithm is used with an optimization technique.

In 2012, Michael proposed Darwinian algorithm to improve its fitness function. This local optimum has been increased with natural selection.

In 2012, Xu.Y, this approach is used to reduce the interruption constraint direction-finding [12] troubles. Search and relinking optimization method is used scatter search and path.

In 2014, Guck et al proposed an approach for real-time QoS performance. Greedy algorithm [13] and a Mixed Integer Program is used to fix queue allocation. Delay Constrained Least Cost algorithm is used to calculate the minimum cost end-to- end delay.

III. METHODOLOGY

This methodology is used for reducing constant and isolated optimum paths. Particles represent source and location of an element indicates destination. This is swarm intelligence. The communal behavior of the individuals interacting with their surroundings is called as Swarm Intelligence. This optimization technique is used to improve the detection accuracy. This technique is processed with swarm of birds.

A. Particle Swarm Optimization

This is a technique which is called after behavior its birds flocking. A group is started with

random elements. The updation is done by searching optimum solutions. The group of variable gets closer to the member near to the target environment. This algorithm keeps track of three variables such as target value, global value and stop value. The bird has a position and velocity at any time. Position is changed by adjusting the velocity.

Velocity is changed based on the experience and the feedback from the neighbor. Each particle considered with two best values. One is the fitness value called as the pbest. Later one is achieved from any particle with the group called as globbest. The particle gets updated when the best values are established with its velocity and positions. To represent the position of the swarm every element travels through the swarm as:

$$v_{t+1} = \omega v_t + c_1 * \text{rand}(p_i - a_i(t)) + c_2 * \text{rand}(g_i - a_i(t)) + c_3 * \text{rand}(n_i - a_i(t)) \quad (1)$$

$$a_{t+1} = a_i(t) + v(t+1) \quad (2)$$

In above equations, ω denotes the inertia weights and c1, c2, c3 are learning factors denoted as constant values. While determining the velocity p_i denotes the pbest, g_i as global best and n_i as neighborhood best. The parameter rand is random vectors with numbers between 0 and 1.

Initially the element is assigned as null and the position is assigned at random among the borders of its population (Alg 1). Population size is used to optimize the solutions within time limit. Stop criterion is already distinct with the amount of executions.

Alg. Particle Swarm Optimization

Init element (Init a_t^n, v_t^n, $a_t^{\sim n}$, $n_t^{\sim n}$, $g_t^{\sim n}$)
SLoop:
through all elements
find the accuracy of individual element
revise $a_t^{\sim n}$, $n_t^{\sim n}$, $g_t^{\sim n}$
revise v_{t+1}^n, a_{t+1}^n
stop
till stop criterion

The information is called as the individuals decision made for success. Knowledge is termed as the performance of the other neighbor individuals. The virtual value of this factor will differ as of each other decisions. So random weights is applied and its velocity can be considered as

$v_i(t) = v_i(t-1) + \varphi_1.r_1.$ ($s_i^{\sim}$ - $a_i^{\sim}$(t+1)) + $\varphi_2.r_2.$ ($s_g^{\sim}$ - $a_i^{\sim}$(t+1))

where φ_1 and φ_2 are positive numbers and r_1, r_2 are random numbers. The velocity has three components. First, intertia is considered to direct the particle in the same direction. Second, the preeminent location of the element p_i its fitness value is called as pbest, which is scaled by $\varphi_1.r_1$. Third, velocity updation of the best particle g_i found as gbest. This is scaled by $\varphi_2.r_2$. This method can be implemented for this particle swarm optimization technique as:

Step 1: Initially this particle is assigned with arbitrary positions in the group for individual element.

Step 2: Fitness purpose is evaluated for each element.

Step 3: Each individual particle is compared with its fitness value pbest. If it achieves maximum value than pbest then consider this value as present element location a_i as p_i

Step 4: Evaluate the elements maximum fitness value. Fitness function is calculated as globbest and location as g_i.

Step 5: Velocity and position of all the particle is updated by using step 1 & 2.

Step 6: Continue steps 2-5 till stop criterion is acheived.

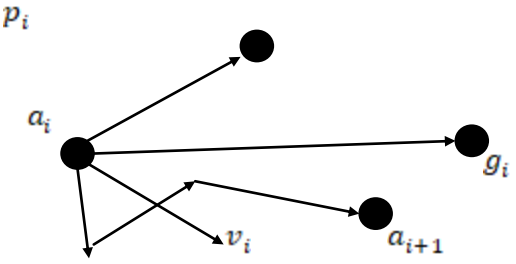

Fig 1. Particle swarm algorithm

Particle swarm algorithm is shown in fig 1. Various criteria's has to consider while implementing the particle swarm algorithm to avoid the sudden increase of the particles. This includes reducing the greatest velocity [6-7], select increase of [8] constants, construction factor or the inertia issue.

Proposed algorithm FODPSO is used to enhance the fitness function. This is composed of particles as a group. This group is managed with a natural selection mechanism. Generally, search to local optima in that area is discarded and new search is started. In order to analyze the state of the group all the particles is executed. So that local position for each group can be rationalized. Finally if it fails, particles are removed. The discarded swarms prematurely move towards non optimal solutions. This algorithm is compared with the clustering algorithms to evaluate detection accuracy. The following procedure can be used for evaluating fractional order Darwinian swarm optimization:

Step 1: Initialize the parameters

Step 2: Update each particles fitness function and best optima
Step 3: Execute all the particles. If swarm obtains best position, extend life of the swarm
Step 4: If Swarm has not improved, delete swarm.
Step 5: End the process

In FODPSO, few attributes has to be considered for efficient best fitness function: population of swarm, min and max of swarm population, initial number of swarms, threshold. Fitness evaluation of best particle is considered.

Feature Subset selection

Subset feature FS={FS| a=1,….,n}
find a subset FS_a, with x < y
max an function F(FS)
$FS_a=\{fn_{a1},fn_{a2},\ldots\ldots fn_{ax}\}$ = arg max= F{ FS| a=1,….,n}

Feature subset selection is described in the above algorithm. FS is initialized with all the particles. Then evaluate the maximum number of swarms in the subset.

B. Experimental Result

Evaluation is done with MATLAB R2017b. The KDDCup99 dataset is used with records. DoS, R2L, U2R are the attacks used for information gathering. Labelled records consist of 25 features as depicted in Table 1. The category name is indicated using target. Decision Tree, Random Forest, Support Vector Machine, AdaBoost classifiers are used for feature selection. Proposed algorithm is compared with feature selection in terms of classification accuracy. This algorithm is compared with Kmeans, MeanShift, Birch. These algorithms are compared in terms of Runtime, Score, Completeness, Degree, Accuracy. Experiments are executed several times under these metrics. FODPSO achieves greater accuracy and runtime compared to other clustering algorithms. Different ranges of clustering algorithms are specified in table 2. This algorithm achieves higher detection accuracy when compared to other cluster algorithms.

FODPSO	1.69	2.10	0.781	0.853	91.24

Through this analysis, FODPSO achieves highest accuracy with all the influential features. Graphical analysis of feature selection algorithms is represented in fig 2.

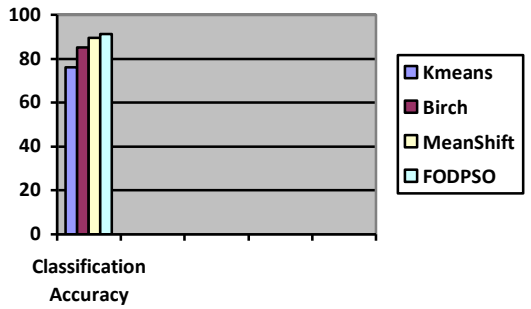

fig 2. Classification accuracy

IV. CONCLUSION

SDN controller estimates the multicast tree based on the network status with delay constraint. This particle algorithm calculates the velocity and position of the element by using fitness function. PSO based FODPSO technique is used to enhance the detection accuracy. Estimation of minimum cost reduces the packet loss. For future work this can be extended for solving multi constrained algorithm for large scale networks.

***Abstract* — Due to rapid advancement in the digital display, communication and storage devices with effective techniques are needed to organize, index, retrieve and annotate a large image database. Image segmentation finds application in various areas of image processing and computer vision. Inferring of low level features from the given image is a challenging task in unstructured regions. Most of the annotation and retrieval algorithms fail to consider region semantics. This paper proposes convolutional neural network (CNN) based image segmentation for image annotation application. The proposed CNN includes pixel based prediction of the regions that are applied to obtain low level image features. The algorithm uses image region information based on the precise color distribution within the image. Experimental results demonstrate better results of image segmentation using CNN.**

Keywords — image Segmentation, Convolutional Neural Network(CNN), Automatic Image Annotation.

I. INTRODUCTION

With the advancement of digital capturing technologies, storage devices and communication network, the number of digital images have increased rapidly. Hence, it is necessary to have effective technique for organizing, indexing and searching of these images. Concept-based and content-based image retrieval are two major categories to address problems related to emerging opportunities [1]. However in CBIR system, one of the most significant issues is a semantic gap. Semantic gap is the dissimilarities between the image features extraction interpretation and image features content interpretation by Human Visual System(HVS) . Therefore from last few years, more research is focused on important part of concept-based retrieval i.e. automatic image annotation. The purpose behind the automatic image annotation (AIA) is to allocate textual labels to the image that clearly describes content or objects in the image. Many researchers have developed various methods and frameworks for AIA but more research is carried out on complete image annotation rather than considering the semantics of the regions. Region based image annotation methods have achieved more accurate semantic information than global based image annotation [2]. It focuses on each independent region of an image, making the visual features more accurate in order to present a particular semantic concept. Therefore, image region needs to be analyzed and labeled for attaining accurate image annotation. Image segmentation is used to detect boundaries and objects in images. If the underlying segmentation is inaccurate then image annotation will not provide better results [3]. The good image segmentation aims at segmenting the image correctly and labeling each segment with the respective semantic class. Since image segmentation is a foundation of region annotation, effective image segmentation is needed for an accurate region based image annotation. AIA methods can roughly be classified into five categories[4][5]: (i) Nearest neighbor models, (ii) Generative models, (iii) Discriminative models, (iv) Tag completion-based AIA models and v) Deep learning based models. Nearest neighbor models assume that the images that have similar features may have a high probability of similar labels. Various models used are Joint Equal Contribution (JEC) [6] and Tag Propagation (TagProp) [7]. Generative models emphasis on inferring the correlations between image features and semantic concepts. It finds the probability of a label by computing joint probability of image features and labels from training samples. Some of the generative models are Cross-Media Relevance Model [8], Multiple Bernoulli Relevance Model [9], Latent Dirichlet Allocation [10]. Discriminative models consider AIA as a classification problem where, each label/keyword is treated as a class. Researchers have designed these models for class predictions such as SML [11], SVM [12]. Tag completion-based AIA methods predict and automatically fill the missing labels for any given image ant at the same time correct noisy tags. It consist of various models such as Subspace Clustering and Matrix Completion model [13], TMC model[14]. Deep learning based models enable to solve AIA task using feature representation based on deep learning. For image annotation, CNN is used for robust features generation. Several models are used for this, such as CNN-RNN framework used in the RIA model [15] for image annotation, Deep Multiple Instance Learning (DMIL) model [16]. The AIA framework is basically consisting of steps such as image segmentation, feature extraction and classification. Image segmentation is one of the essential modules in AIA. Images containing natural scenes has unstructured regions that require computationally complex analysis for segmentation. Several segmentation algorithms proposed in the literature use various image elements such as colors, textures, shape and object compositions [17]–[18]. The image segmentation aims at segmenting the image correctly since it is a foundation of the region annotation. Many image segmentation algorithms,

such as JSEG [17] and NCUT [18] have been designed and are commonly used in image annotation. However, it is ineffective in segmenting region bearing similar color distribution. Texture, color and shape are the important features within the image. These features play an important role in the effective segmentation of the objects or regions. Colors are observed by the human eye and are the fundamental feature that differentiates among the objects. Therefore color enhanced segmentation algorithm using CNN is proposed. The algorithm attempts to differentiate objects bearing similar color through separately processing each R, G and B color space effectively assisted by edge detection.

Convolutional based networks are the popular architectures for Image segmentation. Long et al. [19] developed fully convolutional networks that are pre-trained on ImageNet[20] with each pixel classification. For semantic segmentation, contextual hierarchical model is developed by Seyedhosseini et al. [21] for learning contextual information in a hierarchical framework.

The main contribution of this paper is the CNN for image segmentation for the application of image annotation. The algorithm uses image region information based on precise color distribution within the image. The paper is organized as follows. Section II outlines the proposed methodology. Section III demonstrates the experimental result obtained after training and classifications of images. Conclusion and future scope is illustrated in section IV.

II. Colour Enhanced Segmentation Algorithm using CNN

CNN is made up of one or more convolution layers with pooling layer and one or more fully connected layers followed. The CNN architecture is designed in such a way that it takes advantage of two dimensional input image structures. This is achieved through local connections and associated weights followed by pooling (average or max pooling) resulting in translation- invariant features. With the same number of hidden units, a fully connected network needs more parameters than CNN. Therefore, it is easier to train CNN than a fully connected network [20].

The paper proposes a framework for supervised image segmentation based on candidate regions. The framework of the paper consists of two phases of learning and testing. Fig. 1 demonstrates the CNN architecture employed in this algorithm.

A. Convolutional Layer

In the proposed algorithm, each layer of image data is a three-dimensional array of size p x q x r where, p and q are spatial coordinates of the image pixels and r is the feature or channel or color dimension. Predicting each pixel's class independently of its neighbors results in better region / class predictions accuracy. Mostly it is observed that objects have smooth boundaries and well defined shapes, different from the background that tends to be shapeless regions. Convolutional layer initially starts with the smoothing operations to predict a standard pixel with a kernel size of 5x5. The smoothing improves algorithm by forcing each pixel with low probability of being part of an object and improves performance accuracy. The weights of the kernel are initialized to one by twenty five which is updated in the learning / training process so as to predict object through image pixels as given in equation (1). The convolution operation is represented using equation (2) that is applied on each color space (RGB) separately.

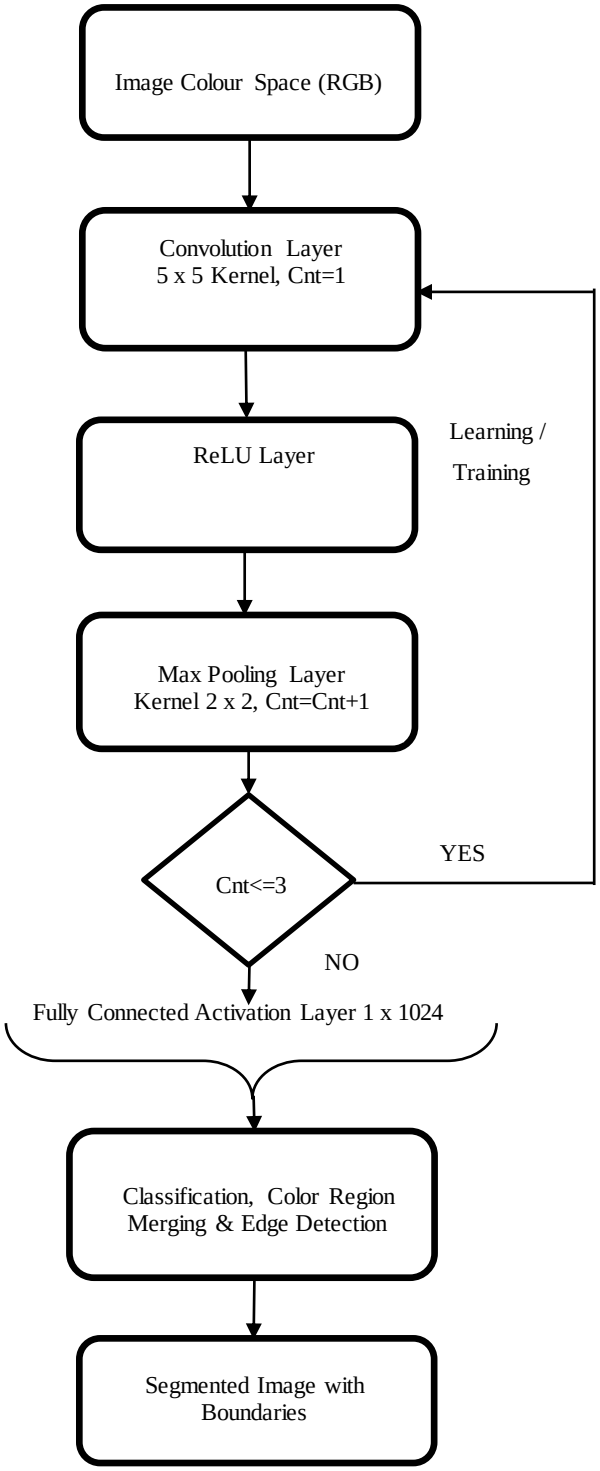

Fig. 1. CNN architecture for image segmentation.

$$w_{ij} = \frac{1}{25}\ for\ i,j = 1\ to\ 5 \quad (1)$$

$$I_c(x,y) = \sum_{x=1}^{p}\sum_{y=1}^{q}\sum_{i=-2}^{2}\sum_{j=-2}^{2} I(x+i,y+j) * w_{ij} \quad (2)$$

Where,

w_{ij} are the initial weights of the kernel that are updated during training process.

$I_c(x,y)$ Output of convolutional layer

B. Rectified Linear Units (ReLU) Layer

There are many activation functions available for neural network models. Deep learning models mostly use ReLU as an activation function due to the reduced probability of vanishing gradient. For every positive value of x, it returns the same value (x), but if it receives a zero or negative value of x, zero is returned[19]. Therefore, mathematically ReLU can be represented using equation (3).

$$f(x) = f(0,x) \quad (3)$$

C. Max Pooling Layer

The accumulation should lead the network towards correct pixel level assignments for each region within the image, so that segmentation task can be performed properly.

An evident accumulation task is to take the average of all pixel positions under consideration. In Max pooling layer, the kernel size is selected at 2 x 2 that provides accumulation of 4 pixels values. It increases the score of the pixels that further helps in classification. The operation performed in max pooling can be represented using equation (4). The advantage of this accumulation is that in the training procedure, pixels with similar scores have a similar weight, while maintaining the goal of predicting similar pixels / regions.

$$I_{mc}(x,y) = \sum_{x=1}^{m}\sum_{y=1}^{n}\sum_{i=1}^{2}\sum_{j=1}^{2} \frac{I_c(x+i,y+j)}{4} \quad (4)$$

D. Implementation Details

The variation image sizes are standardized using image resize at 284x284x3. The three stage convolutional neural networks are illustrated in fig. 1. The input given to network is of the size 284x284x3. Three filters of size 5×5 are used in first convolutional stage. The activations size is 280*280, as no padding is used. These are normalized in the neighboring feature map. With a stride of one, no overlapping spatial pooling is applied in 2x2 local regions

The second and third stages are similar to the first, except that the size of the input data is 140x140 and 68x68 respectively, whereas number of filters remains to 3. The entire network is trained by back propagation using the soft-max function to normalize the logistic regression loss against the predicted scores. The biases are initialized as constant one in the first convolutional layer, as well as the remaining fully connected layers. After each mini-batch of the size 50 images, the network updates all weights. The training starts with a learning rate greater than 0.05 (5%), and reduces it to 0.01 (1%) when the performance of the evaluation set no longer improves. The algorithm separately processes the R, G and B, color spaces through CNN. Thus each object is marked / identified in every color space and effectively backed with edge detection. Finally the result of R, G and B color space are merged that effectively segments the objects.

III. Experimental results

The data set used in this experiment is obtained from the Corel-10k database for segmentation purposes [22]. This dataset contains 10,000 images and 100 categories. The training set contains 10k images. The task is to segment the image into its various regions that include foreground, objects, and background. The images have different sources such as natural scenes, objects such as person, gun, ships, toys, balloon etc. and also images with multiple objects are selected. The images from database are selected randomly to train the proposed CNN. Test image that is excluded in the training is taken from the same dataset in order to validate the algorithm. The experiments are conducted using computer with i7 processor speed 2.8 GHz and 8GB RAM and MATLAB version 9.6 software is employed for implementation of proposed CNN. The step-by-step result obtained after the training and the classification of the balloon image is shown in Fig. 2

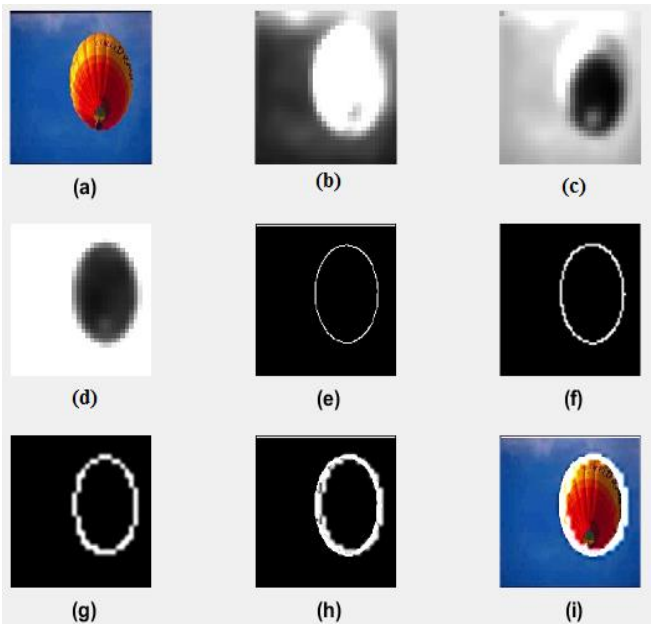

Fig. 2 (a) Original image, (b) The first channel output of CNN, (c) The second channel output of CNN,(d) The third channel output of CNN ,(e)-(g) Result of Edge detection using canny after each layer, (h) Result of color region merging, (i) Segmented image.

Segmented results are illustrated in Fig. 3 after training and classification. In the learning phase, images are applied to the CNN sequentially which updates the weights of the filter in each layer. It is proposed to start with a learning rate greater than 0.05 (5%), and reduces it to 0.01 (1%) when the performance of the evaluation set no longer improves. These updated weights are applied in testing phase that performs segmentation. The results clearly indicate that the proposed image segmentation algorithm using CNN segments regions within the images. It clearly segments foreground, objects and background in the images. The algorithm has been further improved therefore it predicts the map of an image back to its original size without any post-processing. Finally results are obtained in multiple separated region of an image. The metrics commonly used for evaluating image segmentation are variations in pixel accuracy.Let b_{ij} be the number of pixels of class i predicted belonging to class j and let c_i be the total number of pixels of class i. The pixel accuracy (pa) is given by equation (5) and tabulated in table I & II for images containing single and multiple objects respectively.

$$pa = \frac{\sum_i b_{ij}}{\sum_i c_i} * 100 \quad (5)$$

The obtained experimental results are compared with early hierarchical contexts learned by CNN [23] and image segmentation based on CNN and conditional random field [24] depicted in table III & IV respectively. Technique in [23] is applied for single object segmentation whereas technique in [24] is applied for multiple objects.

It is clearly observed that the proposed technique is suitable for multiple and single image segmentation application. Careful observation of the resultant images shows that proposed algorithm effectively segments the objects based color space. Each object consists of some uniform pattern of color which is made from combination of R, G and B color space. Processing each color space separately evaluates each object with uniform distribution followed with edge detection. Finally, merging of each color space with edges enhances the major boundaries of the object whereas suppresses the minor regions within the image.

Fig. 3(c) and 3(d) illustrate some minor boundaries within the object and highlights the major boundaries.

IV. CONCLUSION

This paper focuses on CNN based image segmentation for image annotation application. The proposed CNN includes a prediction of the region using image pixels that are applied to obtain low level image features. The algorithm uses image region information based on precise color distribution within the image. Experimental results demonstrate better image segmentation using CNN. Pixel accuracy is calculated to measure the performance of the algorithm to predict and segment foreground, background and objects in the image. Mean filter at the convolution layer and accumulation at the max pooling layer effectively improve the accuracy of the segmentation algorithm. To smoothen the boundaries or ensure consistent segmentation, more sophisticated post processing can be applied. Further, the algorithm can be improved to region based segmentation for semantic segmentation and automatic image annotation applications.

***Abstract*—As power flow controllers and voltage compensators, flexible alternating current transmission systems (FACTS) have become popular in transmission systems. The system's power transfer capability increases while the usage of these power electronic devices improves the controllability. The Static Synchronous Series Compensator (SSSC) is a very useful FACTS device that can inject voltage with the line in series. This injected voltage can be described as an inductive or capacitive reaction connected in series to the transmission line that provides control over voltage compensation. This reaction has serious effects on the operation of remote protection systems running along the transmission line as they operate on the line's net impedance basis. Due to the presence of SSSC, this change in system dynamics causes problems of under-reaching or over-reaching and may cause maloperation of the protection scheme. The purpose of this paper is to study the effect of series compensation on distance relaying caused by using SSSC in a fault-condition transmission line. The influence on the distance relay characteristic of mho is studied using MATLAB / Simulink and the results are validated by experiments on a transmission line hardware prototype. A double circuit doubly fed transmission line is considered for this study.**

Keywords: **FACTS, distance relay, SSSC, MATLAB/Simulink, double circuit doubly fed transmission line, fault**

I. Introduction

Introduction of FACTS devices has revolutionized the concept of power flow in transmission lines over last decade. Active and reactive power flow control, control over bus voltages, fast and reliable operation are few of its many advantages [1]. With consumer demand steadily increasing, it was necessary to increase the transmission line's power transfer capacity. FACTS devices made it possible to improve the line's power transfer capability by controlling factors that govern it such as the impedance of the transmission line and the angle of the phase between the voltage sources at both ends of the transmission line. By controlling these factors, transient stability of the line improves such that its power carrying capability improves for same thermal limit.

Of all the FACTS devices, SSSC, which is a series compensating device is very popular and is of particular interest to many researchers owing to its usefulness under any type of loads [2]-[13]. It is a series compensating device used to control the flow of power in transmission lines and improve the damping of power oscillation on power grids. A voltage is injected by SSSC in series with the connecting transmission line and it also acts like a active harmonic filter.

However, a drastic change in current and voltage values is observed due to introduction of SSSC in transmission lines as against their usual values. Distance relay which is most popular method used to protect transmission lines works on the principle of impedance characteristics of the line experiences maloperation in the form of under reaching or over reaching the fault point due to this. Various studies are conducted in this area to investigate influence of SSSC on performance of distance relay [14]-[18].

Hardware demonstration of the concept is not covered in most of the literature presented on this topic. This paper aims to provide experimental results along with simulated results to analyze the effect of SSSC on transmission line protection system and Mho characteristics of the impedance relay on a doubly fed double circuit transmission line. The paper is organized as follows: Section I introduction is immediately followed by Mathematical modelling and operation of SSSC in Section II. Section III discusses the simulated results obtained by simulations using MATLAB/Simulink while Section IV validates the same on a hardware prototype of transmission line. Section V concludes the paper.

II. Mathematical Modelling and Operation of SSSC

SSSC is a series compensated FACTS device and was initially developed in 1989 [3]-[10]. It uses a VSC (Voltage Source Converter) as a VAR compensator that is connected through a transformer in series with the transmission line. It is composed of a VSC, transformer and an energy source. Basic configuration of SSSC connected to the transmission line is shown in Fig. 1.

In capacitive or inductive mode, SSSC can vary the reactance of the transmission line and is thus able to control the active and reactive power flow in the line very effectively. It is capable of maintaining highly effective X / R irrespective of the degree of series compensation. Moreover, a small supply is enough if the operation is only limited for reactive power compensation. With the voltage developed across the line, it

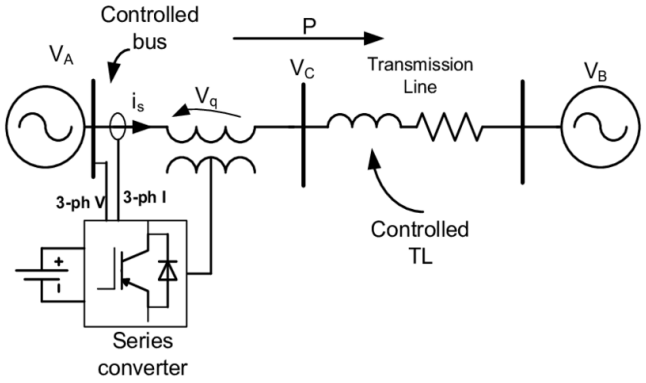

Fig. 1. Basic Configuration of SSSC

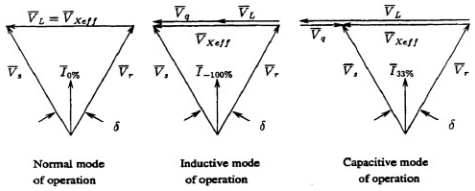

Fig. 2. Phasor diagram showing modes of operation of SSSC

can inject voltage that is of the same magnitude but opposite in phase angle.

Operation of SSSC can be classified into two modes, namely constant mode of reactance and constant mode of quadrature voltage and are represented by phasor diagram as shown in Fig. 2. SSSC voltage is a function of the current flowing through the transmission line in constant reactance mode while it doesnt depend on line current in constant quadrature voltage mode. If an energy storage system is present in the operation of SSSC, an impedance compensation controller acts as a transmission line resistance compensator whereas when energy storage system is absent, it compensates the reactance of the transmission line.

Series capacitor connected in the line counteracts its reactance, thus impedance of the transmission line is reduced. From the phasor diagram, it is seen that the injected voltage acts opposite in polarity to the voltage across series line reactance at a given line current and is given by (1).

$$\mathrm{Vq} = -\mathrm{jkXI} \tag{1}$$

$$\mathrm{k} = \mathrm{X_{SSSC}}/\mathrm{X} \tag{2}$$

Where, V_q is infused voltage, I is line current, X_{SSSC} is SSSC reactance, X is the line reactance and k is the degree of series compensation and j=$\sqrt{-1}$.

Voltage injected by SSSC depends on the flow of power through the line. Active power (P) and reactive power (Q) in the line using sending and receiving end voltages (V_s and V_r) and line reactance (X_L) can be expressed as:

$$\mathrm{P} = \frac{\mathrm{V_s V_r sin}(\delta_\mathrm{s} - \delta_\mathrm{r})}{\mathrm{X_L}} \tag{3}$$

$$= \frac{\mathrm{V^2 sin}(\delta)}{\mathrm{X_L}} \tag{4}$$

$$\mathrm{Q} = \frac{\mathrm{V_s V_r}[1 - \cos(\delta_\mathrm{s} - \delta_\mathrm{r})]}{\mathrm{X_L}} \tag{5}$$

$$= \frac{\mathrm{V^2}(1 - \cos\delta)}{\mathrm{X_L}} \tag{6}$$

$$\delta = (\delta_\mathrm{s} - \delta_\mathrm{r}) \tag{7}$$

$$\mathrm{V_s} = \mathrm{V_r} = \mathrm{V} \tag{8}$$

$$\mathrm{P_q} = \frac{\mathrm{V^2}}{\mathrm{X_{eff}}}\sin\delta \tag{9}$$

$$\mathrm{Q_q} = \frac{\mathrm{V^2}}{\mathrm{X_{eff}}}[1 - \cos\delta] \tag{10}$$

Where,
δ_s is sending end voltage angle,
δ_r is Voltage angle at receiving end,
P_q is Bus 2 active power,
Q_q is Bus 2 rqqeactive power,
X_{eff} is sending and receiving end total effective line reactance.

III. MATLAB Simulation Results and Discussion

A 400 kV, 300km transmission line was used to analyze the performance of the distance relay with and without SSSC connected in series with the transmission line at the mid-point. Fig. 3 represent the model developed using MATLAB/Simulink for calculation of a single phase to ground in double fed transmission line.

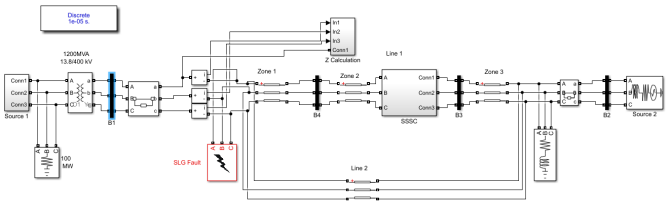

Fig. 3. Modelling Of Double Fed Transmission Line

Figs. 4-6 represent the mho relay characteristics for the fault generated at various locations of the transmission line without SSSC system. Convention uncompensated distance relay was used for this simulation. Typical calculations for finding impedance based on magnitude and phase angle were used.

Figs. 7-9 represent the MHO relay characteristics for the fault generated at various locations of the transmission line with SSSC compensation system.

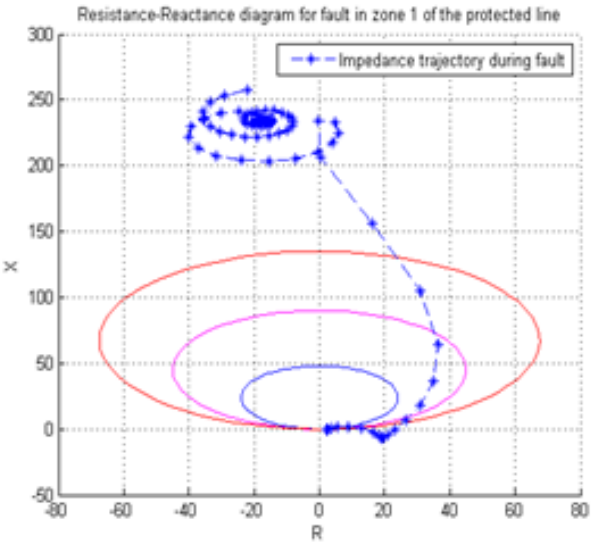

Fig. 4. R-jX plot for the fault in zone 1 without SSSC

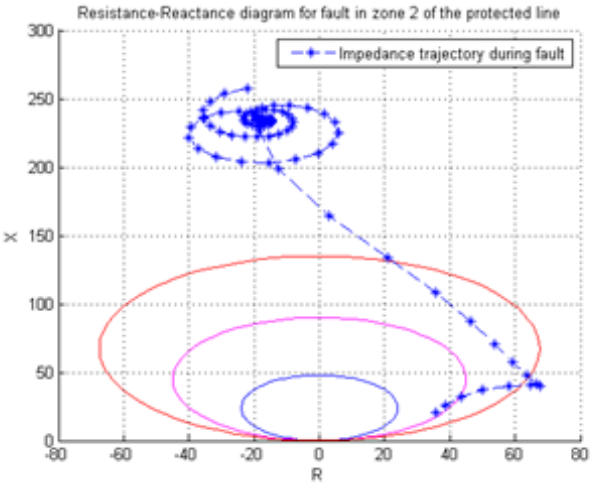

Fig. 5. R-jX plot for the fault in zone 2 without SSSC

An algorithm is used to plot the impedance values of the simulation in a way to represent the impedance characteristics of the line. It can be seen from the figures that mho characteristic under reaches in the presence SSSC connected in zone 2 for fault in zone 3. Similar observations were found for other types of faults as well.

IV. Hardware Experimentation

A hardware prototype of transmission line with distance relaying scheme was designed and constructed with SSSC for validation of the simulation result. A 230V double circuit doubly fed single phase equivalent circuit of transmission line of 300km was design with parameters as shown in Table I. A pair of inductance and resistance is used to represent 100 km section of the line.

Capacitance of the line was neglected as the line was

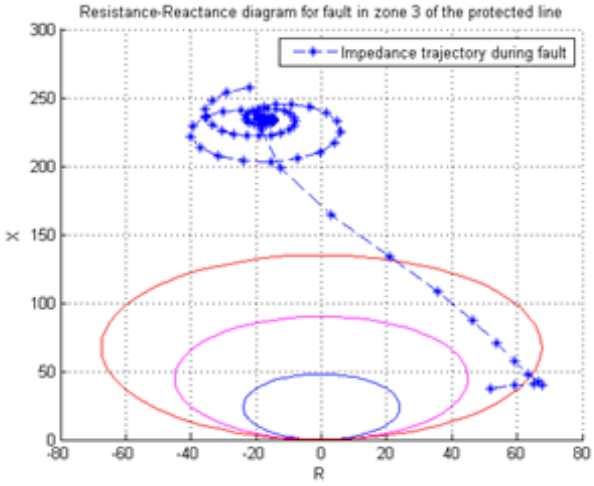

Fig. 6. R-jX plot for the fault in zone 3 without SSSC

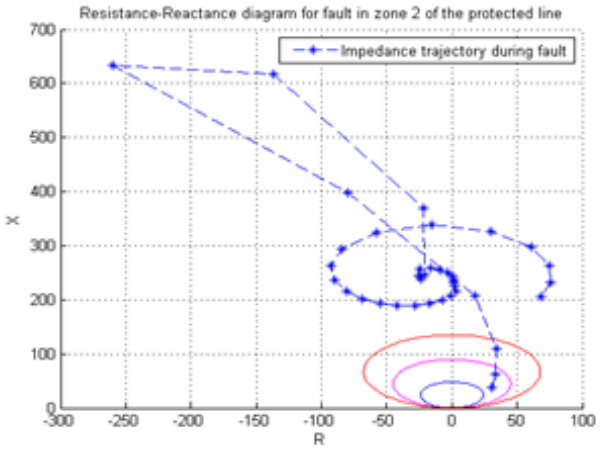

Fig. 8. R-jX plot for the fault in zone 2 with SSSC

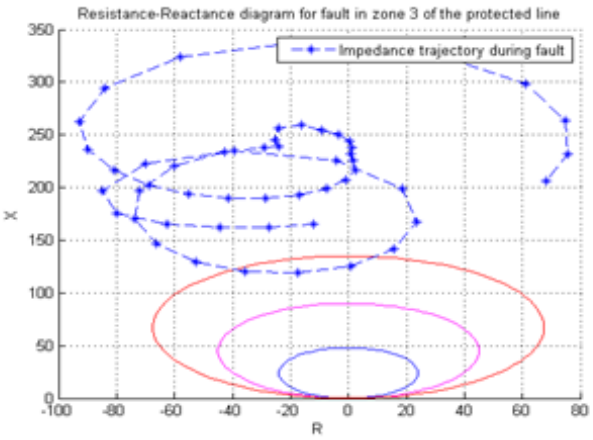

Fig. 9. R-jX plot for the fault in zone 3 with SSSC

TABLE I
PARAMETERS USED FOR HARDWARE PROTOTYPE

Parameter	Value
R1, R2, R3 Line Resistances	4.7 ohms, 10W
L1, L2, L3 Line Inductances	0.1mH, 5A
Voltage	230V, 50 Hz
Line Rating	5A
DC Capacitor for SSSC	1000μF, 63V
Coupling Transformer	230V/24V, 5A

considered to be moderately loads and due to experiments during fault conditions. 100W lamps were used as loads while 200W lamps were used to recreate line to ground fault at various locations of the line. Voltage and current sensors were used for measurement of line parameters. A single phase VSC was connected in series with help of circuit breakers and a step-down coupling transformer. The algorithm for distance relay and for operation of SSSC was implemented using user friendly Arduino Uno platform. Both inductive and capacitive modes of operation were tested on the prototype hardware. The prototype is shown in Fig. 10 and one of its operating modes is shown in Fig. 11.

The distance relays detects the zones of fault location accurately during normal operation. During presence of SSSC, it works effectively to determine fault in zone 1. However, it cannot distinguish between fault in zone 1 and zone 2 as it displays fault in zone 1 for both zones. Thus it under reaches for fault in zone 2. It cannot detect fault in case of fault in zone three as impedance measured is lesser that the relay setting for the same. Phenomenon of over reaching was observed in the case.

V. CONCLUSION

Behaviour of distance protection scheme for transmission under the influence of SSSC during single line to ground fault was discussed in this paper. It was observed that the distance relaying maloperates due to unpredictable change in impedance value in presence of SSSC and thus the distance

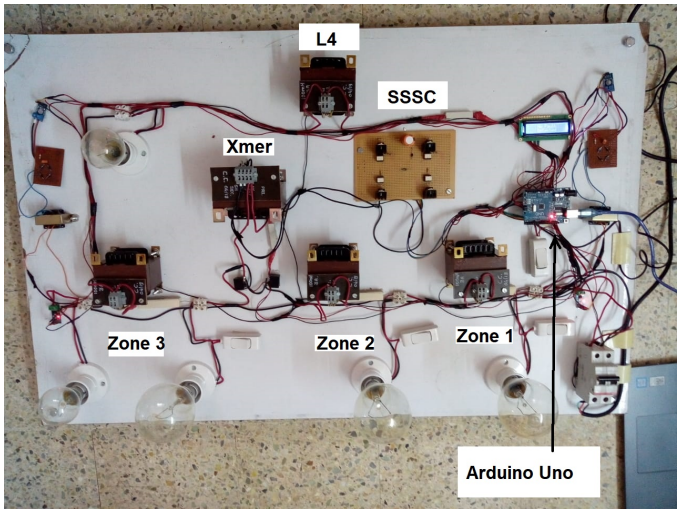

Fig. 10. Hardware Prototype of transmission line with distance relay and SSSC

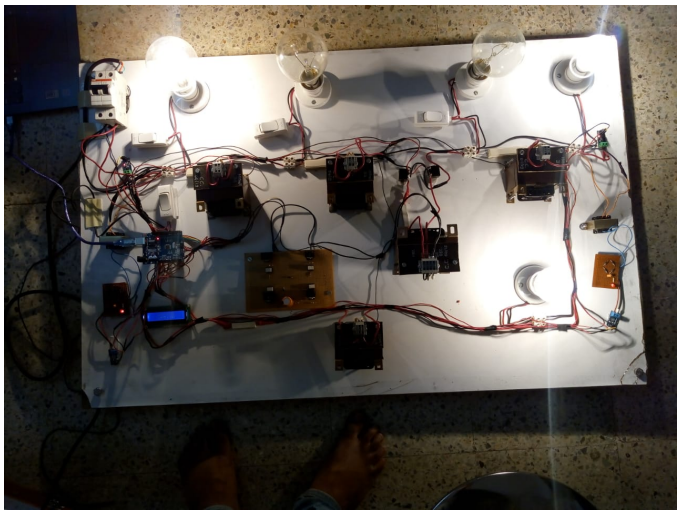

Fig. 11. Hardware Prototype during operation: Fault in zone 1

protection system fails. Both simulated results and experimental results validate these outcomes.

Faults occurring at various locations in the line are studied and its effect is analyzed in this paper. It was found that when SSSC is connected between zone 2 and zone 3 of the transmission line, distance relaying gets affected for these zones while only zone 1 operates ass expected. It can be concluded from the observations that distance relay under reaches for zone 2 if the fault occurs before connection with SSSC while it over reaches for zone 3.

It is very much essential to mitigate the problem of maloperation of distance relay under the presence of SSSC for stable and reliably operation of power system. Various algorithms can be developed for compensation of this error in measurement of distance relay. Recent advancements in Artificial Intelligence, Fuzzy Logic and Artificial neural network can be employed for this task and is a future scope for this research.

***Abstract*— The Silicon MOSFET scaling is constrained; because of this CNTFET is observed to be a standout amongst the most encouraging choices. The principle distinction between CNTFETs and MOSFETs is that, the channel in CNTFET is designed by using Carbon Nano Tubes rather than Silicon. This empowers a higher drive current density because of the immense amount of current carrier mobility contrasted with the bulk silicon. Such transistors are being seriously considered for applications in the emerging field of Nanotechnology. A CNTFET can utilize a single CNT or an array of CNTs as the channel material. In this paper, n-type CNTFET and p-type CNTFET will be modeled in Cadence Virtuoso Analog Designing environment and I-V characteristics will be plotted. An inverter will also be designed using the modeled CNTFETs. dc analysis and transient analysis will be done for the designed inverter.**

Keywords*— *CNTFET, device modeling, inverter, circuit designing, dc analysis, transient analysis

I. INTRODUCTION

The gate length of the MOSFETs has been enrolled in the deep sub-micron region because of the 0.35 micrometer node technology. Since 2006, the 65 nm technology has become very common and 45 nm technologies have surfaced in the year 2007. As CMOS enters into nanoscale with respect to size, various device characteristics which are not ideal make the I-V characteristics to extensively differ from that of the MOSFETs, which makes it hard to improve device performance furthermore by downsizing the size of the gate length. In today's technology, one can notice a brilliant advancement and development in electronics which has the device size in the order of nanometers. Few complicated electronic circuits were designed by using leading edge silicon technology. Carbon nanotubes are one of these latest materials because of the rare electronic and mechanical effects. The three logical points why CNTFETs are (1) the theory of operation and the design of the device is very comparable to CMOS devices, (2) the fabrication process of CMOS also can be repeated, (3) CNTFET's current carrying capability has been the best till now.

As CMOS enters into nanoscale with respect to size of the device, various non-ideal characteristics of the device make the I-V characteristics to extensively vary from that of the MOSFETs [1]. The S/D series resistance is a crucial element in the overall device structure. Devices which are fabricated without using silicon such as the CNTFETs work with distinct physics of the device with ballistic conduction in the channel. Also, they work with Schottky barrier contacts at the source terminal and drain terminal. So as to legitimately benchmark future nanoscale Silicon FETs and CNFETs, it is important to build a benchmarking metric that assess the shape of the I-V characteristics with the device that is working in a circuit domain [2]. The major critics are: The absence of a thin equivalent gate oxide, the inclusion of the parasitic capacitance is becoming larger, the growing addition of the S/D resistance to the total resistance of the device [3].

The paper has been divided into five parts. First part gives a detailed explanation about lattice of graphene and computation of circumference and diameter of carbon nanotube. And it also explains how carbon nanotube can be displayed as a sheet of graphene. The second part gives a brief discussion on how carbon nanotubes can be classified based on the chiral number and the operation system. The third part explains the prerequisites for a decent device model and the important parameters that are responsible for deviations and defects brought about by the present CNT manufacturing process. The fourth part gives a detailed explanation about Virtual-Source CNTFET model, user-defined input parameters and hierarchical structure of CNTFET. The fifth part explains the results that are obtained from the model and their interpretations. And it also gives a conclusion of our findings.

II. LITERATURE SURVEY

Carbon atom has an electron configuration of $1s^2 2s^2 2p^2$ in its ground state. sp^2 hybridization develops through covalent bonding. A carbon atom in graphene gathers in a solitary sheet hexagonal lattice. The distance between two adjacent carbon atoms within the hexagonal lattice (d) is 1.44 Å, and the angle between C-C bonds is 120°. The lattice constant (a) is given by $\sqrt{3}\ d$ = 2.49 Å. The inner spacing between the multiple sheets in graphene is approximately 3.35 Å. The frail electrostatic energy between the sheets makes it potential to expect the electrical properties of the graphite sheets are autonomous to each other.

A single-walled carbon nanotube (SWCNT) can be displayed as a sheet of graphite which is folded up and combined along a wrapping vector:

$$C_h = n_1.\bar{a}_1 + n_2.\bar{a}_2 \quad (1)$$

where [$\bar{a}_1$, $\bar{a}_2$] are lattice unit vectors as shown by Figure 1, and the indices (n_1, n_2) are positive integers that determine the chirality of the tube [4]. The length of C_h is therefore the circumference of CNT and it can be computed by the following formula:

$$C_h = a\sqrt{(n_1^2 + n_2^2 + n_1 n_2)} \quad (2)$$

Single-walled CNTs are characterized into three groups depending on the chiral number (n1, n2): (1) armchair, it is in which n1 and n2 are equal, (2) zigzag, it is in which either n1=0 or n2=0, (3) chiral which is said to have different indices.

The CNT diameter is given by the equation $D_{CNT} = C_h/\pi$ [5]. The usual CNT diameters are around a few nanometers. The small diameter of CNTs leads to the wave vector's quantization in the circumferential direction. The electrons in CNT are limited to the atomic plane of graphene. Graphene is an allotrope of carbon which has single layer of carbon atoms organized in lattices which are in the shape of hexagons [6]. The movement of the electrons in the nanotubes is limited due to the quasi 1D structure. Electrons may just move openly along the direction of the tube axis. Therefore, all the wide point scatterings are restricted. Because of electron phonon collaborations only forward and back scattering are feasible for the carriers in nanotubes. The overwhelming transporter transport and conduction trademark makes for nanoelectronics applications CNTs are wanted due to their superior carrier transport and conduction properties for example interconnect and nanoscale devices.

The CNTFET operation principle is similar of conventional Si appliances. In the device that has three terminals, the source and drain contacts are being bridged by the semiconducting nanotubes acting as a conducting channel in the device. Through the gate the appliance is electrostatically switched on or off. Compared to the 3D devices such as bulk Complementary MOS and 2-Dimensional devices, better gate electrostatic control over the channel area is offered by the 1D quasi device structures. CNTFET can be divided as either MOSFET-like FET or Schottky Barrier (SB) controlled FET (SB-CNTFET) depending on the operation system. In consideration of both the usefulness of manufacturing and exceptional working of MOSFET-like CNTFET when contrasted with SB-CNFET, we will concentrate on MOSFET-like CNTFETs.

To assess the appliance execution just along with the work reliance on structure characteristics, the prerequisites for a decent device model include: (1) Decent expandability, (2) At least partially physics based, (3) Large signal and small signal analysis with reasonable accuracy, (4) Tolerable run time. To assess CNTFET device execution with improved precision, a CNTFET device display with an increasingly total circuit-appropriate structure and furthermore fusing the common device non-conceptions is required. A decent harmony among the run-time simulation and precision is wanted. The macro level circuit isn't just constrained by the execution of a single device, yet in addition restricted by the device variation in performance which is vital for nm devices. There are various device conditions deviations and defects brought about by the present CNT manufacturing process: (1) CNT width and chirality control, (2) Adulterating limit control, (3) The likelihood of a CNT to be metallic, (4) Focused-CNT-development. At long last, with the goal for CNTFET to form into a competitive technology, it ought to have great adaptability, for example the advantage in the working of CNTFET over MOSFET is relied upon to enhance (or if nothing else keep up the equivalent) as the technology progresses. And CNTFET is also used to examine the antimicrobial activity of Chitosan-CNT hydrogels [7].

III. Proposed Methodology

The Virtual-Source CNTFET is a semi-empirical model [8] that illustrates the current-voltage (I - V) and capacitance-voltage (C – V) characteristics in a MOSFET having short channel with CNTs as the channel material. The model describes about the dimensional scaling properties and it also includes parasitic resistance (CNT-metal contact resistance and doped extension resistance), parasitic capacitance (metal-to-metal coupling capacitance and metal-CNT fringe capacitance) and tunneling leakage currents (Direct source-to-drain tunneling and gate-to-drain junction band-to-band tunneling). The VS model has only few physical parameters like VS carrier velocity and carrier mobility that can be extracted from experimental I-V/C-V data. In this paper, the equations of the VS model will be used without detailed explanation. Inputs to the VS-CNTFET consist of CNTFET dimensions and CNT diameter. Empirical parameters in this model were extracted from either experimental data or numerical simulations based on the NEGF formalism to ensure the validity. Some equations are empirical but not completely physical. Calibration of the model is performed at room temperature that is 25° C. For temperatures other than 25° C, correctness of the empirical parameter is not guaranteed. This model is only applicable to MOSFET-like CNTFETs but not applicable to Schottky-barrier type CNTFETs. The CNTs are assumed to be all semiconducting [9] [10] [11]. Fig. 1. shows a representation of a CNTFET, whose conduction behavior is similar to a common MOSFET.

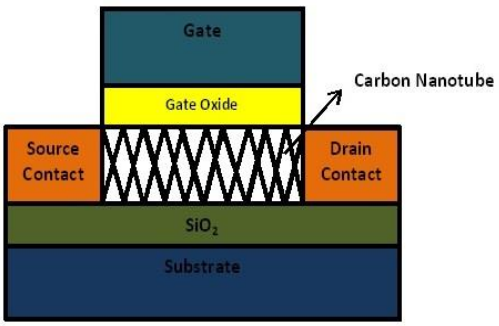

Fig. 1. Representation of CNTFET

Inputs to the VS-CNTFET are design-related parameters such as the gate length (L_g),contact length (L_c), CNT diameters (d), and gate oxide thickness (t_{ox}). The column "suggested scope" shows the range of the input that has been tested. Any

values outside the suggested scope may lead to unexpected results, though the model may still generate outputs as long as the given inputs are valid. The User-defined input parameters are given in Table I.

TABLE I. USER-DEFINED INPUT PARAMETERS

Name	Suggested Scope	Description
Type	-1 or 1	Type of transistor 1: nFET; -1 : pFET
s	[2.5e-9:inf)	Spacing between the CNTs (centre-to-centre) [m]
W	[s:inf)	Transistor width [m]
Lg	[5e-9:100e-9]	Physical gate length [m]
Lc	[1e-9:inf)	Contact length [m]
Lext	(0:inf)	Source/Drain extension length [m]
d	[1e-9:2e-9]	CNT diameter [m]
tox	[1e-9:10e-9]	Gate oxide thickness [m]
kox	[4:25]	Gate oxide dielectric constant
kcnt	1	CNT dielectric constant
ksub	[1:kox]	Substrate dielectric constant
kspa	[1:16)	Source/Drain spacer dielectric constant
Hg	[0:inf)	Gate height [m]
Efsd	[-0.1:0.5]	Fermi level to the band edge [eV] at the source/drain
Vfb	[-1:1]	Flat band voltage [V]
Geomod	1	Device geometry (cylindrical gate-all-around)
Rcmod	0	Contact mode (User-defined value Rs0)
Rs0	[0:inf)	User-defined series resistance (Ω)
SDTmod	1	Source-to-drain tunneling mode (SDT with inter-band tunneling)
BTBTmod	1	Band-to-band tunneling mode (on)
Temp	25	Temperature (°C)

Primarily the given inputs consist of structural and physical parameters. The structural parameters consist of W, L_g, L_{pitch}, L_c, d_{CNT}, N_{CNT} and various other parameters. The physical parameters consist of contact resistance, carrier mean path and various other parameters. By having both the structural and physical parameters as inputs, we will now move on to the next stage, which is called as "First Level" where we are supposed to determine the values of Mobility, Parasitic Resistances and capacitances.

In second level of hierarchical structure, there are two sub-levels where one is derived from the values of first level and the other is derived from the initial conditions (i.e. structural and physical parameters). The second level yields two outputs. One of them is Virtual Source Current and the other on is Tunneling Leakage Current. Tunneling Leakage Current is defined as the sum of Direct Source-to-drain Tunneling Current and band-to-band Tunneling Current [12]. Thus the current at drain terminal can be obtained by:

$$I_D = I_{VS} + I_{TUNNEL} \quad (3)$$

The entire functionality of this structure of CNTFET model is represented in Fig. 2.

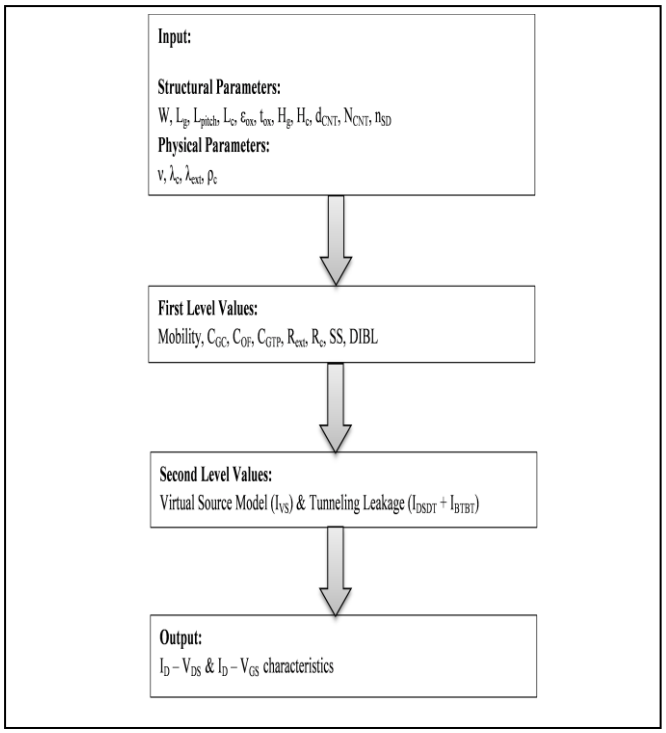

Fig.2. Hierarchical structure of CNTFET model

IV. RESULTS

Fig. 2 displays the graph between drain current and voltage between gate and source for n-type CNTFET. Fig. 3 displays the graph between drain current and voltage between drain and source for n-type CNTFET. Fig. 4 displays the graph between drain current and voltage between gate and source for p-type CNTFET. Fig. 5 displays the graph between drain current and voltage between drain and source for p-type CNTFET. Fig. 2 and Fig. 3 are the graphs obtained from the output of the Virtual-Source n-type CNTFET. Fig. 4 and Fig. 5 are the graphs obtained from the output of the Virtual-Source p-type CNTFET.

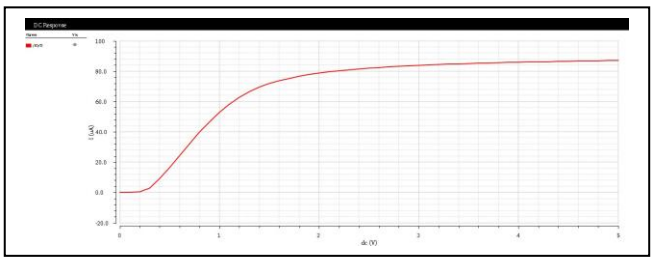

Fig. 2. $I_d - V_{gs}$ graph for n-type CNTFET

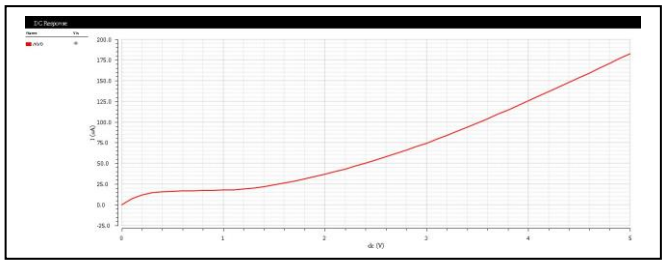

Fig. 3. $I_d - V_{ds}$ graph for n-type CNTFET

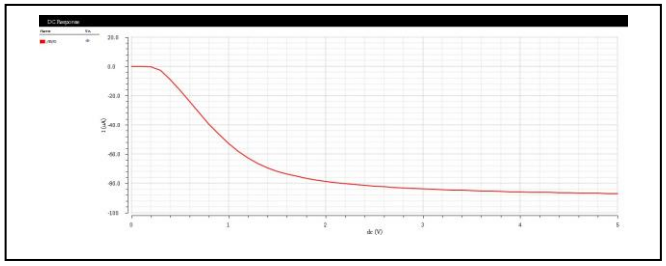

Fig. 4. $I_d - V_{gs}$ graph for p-type CNTFET

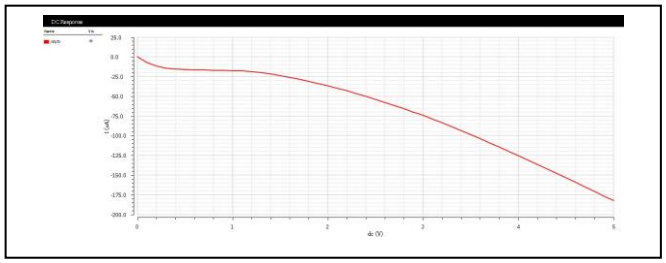

Fig. 5. $I_d - V_{ds}$ graph for p-type CNTFET

Let Vin be the input voltage, Vout be the output voltage and Vdd be the voltage supplied to the inverter. Fig. 6 displays the Voltage Transfer Characteristics (VTC) of an Inverter. When input is low (Vin = 0 V), p-type CNTFET gets switched ON and n-type CNTFET gets switched OFF. Thus, p-type CNTFET pulls Vout to Vdd and hence maximum output voltage occurs. When input is high (Vin = Vdd), p-type CNTFET gets switched OFF and n-type CNTFET gets switched ON. Thus, n-type CNTFET pulls Vout to ground and hence minimum output voltage occurs. The difference between maximum output voltage and minimum output voltage is maximum swing of output signal and this is also known as Logic Swing. Since minimum output voltage is O V and maximum output voltage is Vdd, the logic swing is equal to Vdd. The region between minimum output voltage and maximum output voltage is called Transition Region. Maximum current will flow at Vin = Vout that is at the mid-point of transition region. This is the dc analysis of the designed inverter.

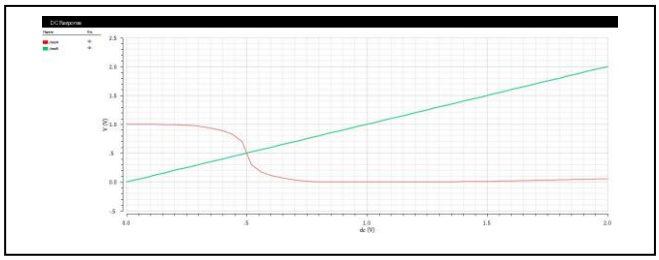

Fig. 6. dc analysis of the inverter circuit

Fig. 7 displays the transient response of an Inverter. When the input voltage is low (Vin = 0 V), output voltage is high (Vout = Vdd). When the input voltage is high (Vin = Vdd), output voltage is low (Vout = 0 V).

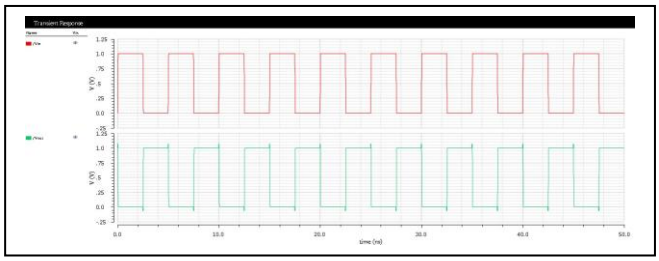

Fig. 7. transient response of the inverter circuit

V. CONCLUSION

In this paper, a semi-empirical model called Virtual-Source CNTFET was proposed that illustrates the current-voltage characteristics in a MOSFET having short channel with CNTs as the channel material. The proposed model describes about the dimensional scaling properties and it also includes parasitic resistance, parasitic capacitance and tunneling leakage currents. In late future, manufacturing a solitary integrated circuit where transistors reaching out in three dimensions is called 3-Dimensional Very large Scale Integration innovation, which will be the prospective of IC manufacturing field rising the stature: from small to miniature. CNTFET could be a fitting device for its miniature size and restrictive ballistic, heat dissemination and low resistive properties. Because of high dielectric material, movement of charges accelerates higher whereas channel measurement diminishes thoroughly. The unique characteristic of channel measurement prompts ballistic transport because of high channel density, showing CNTFET as more reasonable in nanoelectronic devices. What's more, devices that can store the data can be produced by utilizing CNTFET for its high value of current will open another time in nano-computational field. This must be referenced that fabricating the CNTFET is very expensive and it has unwavering quality because of development of misorganised CNTs in development process and expanding leakage power in metallic CNT. Considering all of these, CNTFET is one of the most reliable and assuring competitors and its amazing performance opens a door of new innovations in the field of nanotechnology.

***Abstract*- Now-a-days demand forecasting is used in many countries for military applications such as spare parts of aircraft and for improving budget efficiency. In supply chain management demand forecasting is a major issue. Currently, time series technique is used to demand forecast but this technique resulted in lack of accuracy and improvement in accuracy is needed .So this paper focused on comparing the features which leads to improvement in the accuracy and propose a system for demand forecasting of spare parts of anti-aircraft missiles, which are based on machine learning and neural networks such that equipment's are properly utilized and alongwith that budget is also maintained. We have compared the existing features with the new features added and applied algorithms and looked upon at the accuracy. Experimental results proves that the new features added gave higher accuracy. Here, we also present an end-to-end boosting system called XGBoost and Multi-layer Perceptron. These new techniques were compared with traditional Machine Learning techniques. This experiment is conducted on the Vietnam War dataset.**

Keywords- Demand Forecasting; Spare Parts; Military; Missiles; Aircraft; MLP;XGBoost..

I. INTRODUCTION

The retail inventory management system has grown significantly over the last two decades with its emergence in the intelligent system for forecasting. Predicting any spare part for its future use itself is a very challenging task.This ultimately affects business reputation and also much loss of time.if a company does not have proper facts and figures regarding the stock required ,time maintenance operation will get affected. This hampers the growth of a company, loss of reputation, may endanger the customer's productivity if there is any sort of delay. Over loading of stock in inventory buffer is a costly job if there are large number of items or if any part is expensive.Effective spare part inventory management is thus a chief but challenging task because it is an issue of time versus availability of the desired service in minimum amount of time. Efficient spare parts management is essential for companies that are increasingly providing services. In most automotive spare parts industry, it is important to conduct sales/demand forecasting and reduce logistics costs due to extras and opportunity costs due to product shortages. To meet these demands, it is necessary to purchase spare parts in order to reduce the cost per inventory, while the demand is being met or an administrative decision is being made.

Machine learning and a data-driven approach are becoming very important in many areas. The scalable learning system uses models and learns models of interest from large data sets. In this paper, we describe MLP AND XGBoost, machine learning technique for the tree boosting. The proposed techniques are supportive of spare parts management in the simplest way that they can be implemented to achieve more accurate results in spare inventory management. The analysis helps to determine how to manage a particular group of parts that represent similar features. The demand for spare originated from maintenance activities and use of this part (known as active installation bases) in combination with component failure behavior and maintenance plans. This forecast is used to manage inventory using the inventory-based policy. The Croston' technique offers precise estimation of the mean level of demand if there is any demand. In this, they compare Croston's and smoothing technique with the bootstrap basis on the uniformity of observed LTD percentiles. This bootstrap technique is more accurate forecasting technique [4].

In this paper, literature review is covered under section II, the proposed approach modules description, Mathematical Modeling, Algorithm and Experimental setup in section III .and at finally concluded in section IV.

II. LITERATURE REVIEW

This chapter focus on the use of machine learning approach in time series forecasting and they consider the three aspects: supervised learning tasks such as validation problems of the single-step predictions, which forecasting approach to use when moving from single step to multi-step prediction and how local learning techniques such as radial basis functions network,k -nearest neighbours method ,etc. deal with data that fluctuates over time.

In this [2], they present the role of supervised machine learning practices in dealing with the forecasting problems. Especially, the role of the local learning approximation is emphasized to cope with important problems in prediction such as error accumulation, nonlinearity, and non-stationary. Constructing an effective predictor is between observations of past and short-term future values, forming historical data, as well as the appropriate strategy for long term vision data. In this [3], they present comparison performance of the different machine learning practices such as NAR, LSTM, ANN and SVM in terms of stepped ahead forecasting error variance and error. The LSTM network gives a slightly worse prediction accuracy with respect to other algorithms. The NAR gives the best accuracy for the short prediction and SVM gives the guaranteed best accuracy. This technique allows performing the forecast processes and training in a parallel manner. They implement efficient training framework and parallel by using power demand traces from the real deployments. Machine learning approach gives less prediction errors in the variance and mean with respect to the ARMA was proved using trial results.In this [4], paper they proposed a bootstrapping system to forecasting delivery of a summation of intermittent demands over the fixed lead time. They combine the values from each of the many inventory items into one and evaluated the accuracy of the overall lead-time demand forecast across all items. The Croston' techniques offer precise estimations of the mean level of demand at moments in case there is a demand. In this, they compare Croston's and smoothing technique with the bootstrap based on the uniformity of observed LTD (Lead Time Demand). This bootstrap technique is more accurate forecasting technique. Hemeimat Raghad, Qatawneh Lina, and Masoud Shadi [5], they proposed a comparison between the five forecasting techniques based on MSE (Mean Squared Error), MAD (Mean Absolute Deviation) and ME (Mean Error) and experimental results showed that the performance for all these techniques. This technique tested on the local paper mill company. Experimental results show that this technique of tracking signal techniques helps companies to better select the ideal forecasting method and minimize forecast errors.

In this paper [6],following types of probabilistic estimation methods are used, threshold-based and percentile-based. The percentile-based rating calculates the frequency of the reference discharge falling below the ensemble percentile. If the combined extent is precise, these frequencies should be consistent with the non-excess percentile probability. The excess probability of great expulsion threshold is overestimated in the prediction, and this overestimation increases with increasing probability level. The contribution to these inaccuracies is similar in the case of spread underestimation but slightly larger in the case of overestimated excess probability.The main objectives of the study are to find out the opportunities and challenges of spare parts management in the durable goods industry through a case-based study conducted by 10 manufacturing companies. Improving capacity helps to better understand current management approaches and methods and its deficiencies, finding the most suitable (though simplistic) improvements, the IT and performance supply chain perspective, and the adoption of integration practices with customers and suppliers, as the last step, will finally come. This visibility also helps to reduce the spare parts management process (each dealer can reduce the stock level of these codes) and the effectiveness (the wait for the end user) [7].Most companies in the automotive spare parts business, it is important to conduct sales/demand forecasting and reduce logistics costs due to surpluses and opportunity costs due to product shortages. To meet these demands, it is necessary to purchase spare parts in order to reduce the cost per inventory, while the demand is being met or an administrative decision is being made. This analysis will be complicated in countries such as Mexico, where fewer companies maintain a good record of their activities, products, and procedures, making it possible at certain moments within the practice. The resulting model of each part is presented first, in order to analyze the results later in the sample and post-sample period[8]. Predicting the demand for spare parts with high accuracy consists of a variety of factors, so a simple predictive model cannot be expected. These include part shipping data, how many products are under operation, and the time since that product was released. In this [9], they proposed a solution on spare parts demand forecasting .It NEC's big data analysis technique called the "Heterogeneous Mixture Learning Analysis Technology".NEC fielding is one of the maintenance businesses based on Know-How and performance of these activities, and appropriate parts management services subcontracted by customers such as manufacturers include endorsements based on demand estimates and cost reduction measures with greater accuracy and high added value. In this paper [10], the demand spare parts are characterized by volatility and fluctuation. It is affected by probabilistic factors, such as the wear behavior, the intensity of the product use, the rate of failure and the type of maintenance. For achieving the competitive advantage of company spare parts strategy aligns with the specific situation of the company. The proposed techniques are supportive for spare parts management is the simplest way that can be implemented to achieve more accurate results in spare inventory management. The analysis helps to determine how to manage a particular group of parts that represent similar features. This decision is how many pieces of stock you have to keep.In this paper [11], they present technology for installed base forecasting of end-of-life spare part demand and formulates research hypotheses on which of four installed base types performs best under which conditions. This technology is illustrated by a case study of

spare parts for six products from appliance manufacturers. The research hypothesis is sustained in the most of cases, and the predictions obtained from the installed base are substantially superior to the simple black-box predictions. The final production decision that supported the past sales stand is a spare part to meet the consumption demand in the future.

III.FORMULATION OF PROPOSED MODEL

A. Proposed System Overview

Spare parts database is considered for forecasting which has features such as unit name, unit NSN, operation date, unit of issue, unit exhausted, consumption number, worker number, worker name, etc. Clusters are formed according to the features extracted. Data mining techniques such as SVM, Random Forest, Linear Regression , MLP and XGBoost are applied on the existing dataset[1] and are compared with the new dataset (Table II) with additional features like unit of issue, unit exhausted ,unit remaining, per unit cost, country budget, total cost of unit, units needed to order. Both these datasets are compared to find out if the additional features give any different prediction in terms of accuracy. When these were compared ,the dataset with additional feature gave higher accuracy .

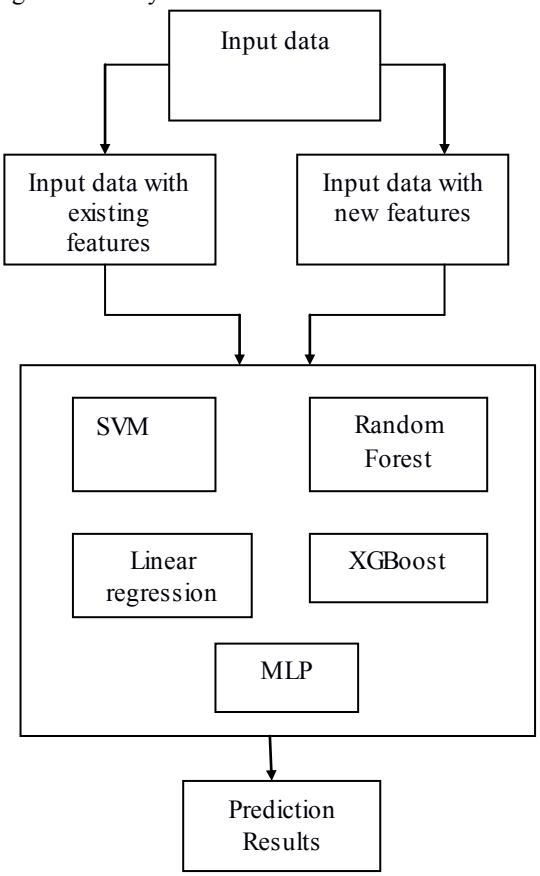

Fig 1 : Proposed System Architecture

- Read input Data:

In this module, it read spare parts data from existing data as well as new data. This data set contains the structured data of anti-aircraft missile.

- Data Mining:

Data mining is the processes which can identify knowledge by modeling, exploring, and analyzing the beneficial information and associations in large-scale data by using classifiers.

- Prediction Results:

Finally, it will predict accurate demand forecast of spare part of aircraft and missiles using XGBoost algorithm.

B. Algorithm

1) XGBoost:

XGBoost is the Extreme Gradient Boosting technique which helps in regularization by avoiding overfitting.It computes optimized results in less amount of time by using less computational resources.

- **Algorithm : XGBoost Model**

i. An initial model F0 is defined to predict the target variable Y. This model will be associated with a residual (Y – F0)

ii. A new model h1 is fit to the residuals from the previous step.

iii. Now, F0 and h1 are combined to give F1, the boosted version of F0. The mean squared error from F1 will be lower than that from F0:

$$F_1(x) < -F_0(x) + h_1(x)$$

iv. To improve the performance of F1, we could model after the residuals of F1 and create a new model F2:

$$F_2(x) < -F_1(x) + h_2(x)$$

v. This can be done for 'm' iterations, until residuals have been minimized as much as possible:

$$F_m(x) < -F_{m-1}(x) + h_m(x)$$

C. Mathematical Model:

S = {I, O, P};
I = Input;
O = Output;
P = Process;

- Process P1

P1 = {I};

- Process 2
  P2 = {P1};
- Process P3
  Perform logistic regression in term of
  $P(T = 1|B) = \Lambda(B^t B)$
  $Where;$
  $T \rightarrow Binary\ random\ variable\ T = m + 1$
  $B \rightarrow Random\ Prediction\ Variable$
  $B = (B_0, B_1, \ldots\ldots\ldots B_m)$
- Process P4
  Perform XGBoost
  $F_m(x) = F_{m-1}(x) + \gamma_m h_m(x)$
  Where,
  $F_m \rightarrow Multiplications\ Factors$
  $h_m \rightarrow Mean\ residual$

- Process P5
  Perform MLP
  $w = w_{old} + \eta\ dx$
  $$O_j = f\left(\sum_i w_{i,j}.x_i\right)$$
  $$y_k = f\left(\sum_i w_{i,j}.O_j\right)$$
  Where;
  $Y_k \rightarrow Output\ layer$
  $O_j \rightarrow hidden\ layer$
  $X_i \rightarrow Input\ layer$

- Process P6
  Perform XGBoost
  $$\frac{\partial\left(y, f^{(m-1)}(x) + f_m(x)\right)}{\partial f_m(x)}$$
  for each x in the dataset.

D. Dataset

We applied various Machine Learning algorithms on Vietnam War Bombing Operations dataset along with some features from [1].In total, we used over 10,000 missiles data. More fields were available ,since these were not relevant for the statistical analysis those were ignored. The features included here are : Aircraft name, aircraft spare parts, aircraft type,unit NSN,Unit series number,Operation date,Spare parts NSN, QPA (Quantity per Assembly Unit),Unit of issue, Unit exhausted, Unit remaining, Country flying mission, Acquisition year, Maintenance year, Procurement Lead Time, Order Shipping Time,etc. This helps to decide when to order,re-order or no order of spare parts.Table 1 describes about the dataset and the features used for forecasting.

IV. RESULTS AND DISCUSSION

A. Experimental Setup

Hardware and software of proposed system given below:

- Software Technology:
  1. Technology: Core Python
  2. Tools: Jet- JetBrains, PyCharm
  3. Operating System: Windows 7
- Hardware Technology
  1. Processor: 1.0 GHz
  2. RAM: 1 GB
  3. Hard Disk: 730 GB

B. Expected Result

Machine learning and Neural Network approach was applied on 10000 observations. The features used in predictive modeling influence the results. The better the features that you prepare and choose, the better the results you will achieve. The main aim of this research is to compare the features which proved to be more useful in predicting the spare parts in minimum amount of time with higher accuracy. In general, Machine learning algorithm learns from its sample data. Feature selection selects only the useful subset of data. This means removing irrelevant data. Experimental results (Table I) show that the added new features such as Unit remaining, Per unit cost of spare part, country budget, total cost of a unit, units needed to order proved to contribute to higher accuracy but it leads to over fitting of data. Here we are trying to improve spare parts utilization rate by maintaining the budget .So including such features obviously helps for better performance. Table I shows the accuracy comparison between existing system and the proposed system. As we can observe from Table I, XGBoost and MLP gives the highest accuracy both in existing system and new proposed model meaning that our model is accurate for most of the times.To evaluate the model we need to understand how good the predictions are[14]. For this we need to understand these basic terminologies:

Accuracy - Accuracy is the most intuitive performance measure and it is simply a ratio of correctly predicted observation to the total observations.[14]

Precision - Precision is the ratio of correctly predicted positive observations to the total predicted positive observations.[14]

Recall (Sensitivity) - Recall is the ratio of correctly predicted positive observations to the all observations in actual class – yes.[14]

F1 score - F1 Score is the weighted average of Precision and Recall. [14]

Table I: Comparison of accuracy for Existing Features and New Features

Algorithms	Accuracy with existing features	Accuracy with new features
SVM	76	93
Random Forest	85	93
Logistic Regression	79	90
Decision Tree	83	90
MLP	93	97
XGBoost	87	98

Table I shows the accuracy comparison between existing system and the proposed sytem with newly added features. Differences in accuracy with existing and new dataset can be contributed to the relevant features and the algorithms applied. SVM, Random Forest, Logistic Regression, Decision Tree have some drawbacks which gives lesser accuracy.For example, a small change in dataset leads to very high changes in model.If the features are correlated it does not reduce variance. Also, Random Forests is not preferred due to its complexity.They are much harder and time-consuming than other algorithms. Gradient boosted decision trees are among the best off-the-shelf supervised learning methods available. Achieving excellent accuracy with only modest memory and runtime requirements to perform prediction, once the model has been trained. Like other decision tree based learning methods, there is no need to apply feature scaling for the algorithm to do well. These are some of the reasons that XGBoost and MLP performed exceptionally well.

The increased accuracy can be contributed to the concept of Economic Order Quantity.Whenever the concept of inventory management comes two factors need to be considered-i) demand to be fullfilled immediately ii) demand to be fullfilled in minimum time in provided budget.So keeping in mind these two factors we contributed this in our novel system.

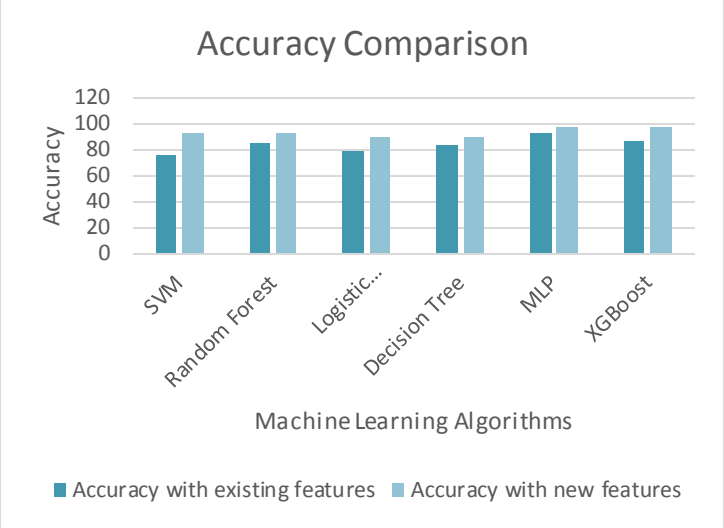

Fig 3: Model accuracy for ML classifiers

IV. CONCLUSION AND FUTURE SCOPE

Developing a precise forecasting model for requesting of spare parts enables the inventory to take necessary actions i.e it can prevent stoppage of spare parts production.Since many decades time series forecasting has been a popular method. But by taking into consideration the drawbacks of each of these methods we continued our research on developing such a model which will improve its accuracy. In this work, we put forward a new prototype for demand forecasting of spare parts of anti-aircraft missiles using Machine Learning approaches and Neural Networks. We compared our new model with that of the existing one which did not take into consideration the country's budget.So we included the concept of Economic Order Quantity (EOQ) which suggested to order optimal number of product units to order.It also helps to re order products in case there is a need to plaace some more orders.The results suggested the dominance of XGBoost and MLP over other classifiers.

Additionally,the analysis on performance results by adding new relevant features improved the accuracy of SVM by 17%,Random Forest by 8%,Logistic Regression by 11%,Decision Tree by 7%,MLP by 4% ,XGBoost by 11%.Thus,it proves that XGBoost proved to be a likely classifer for coorect estimation.

Finally, here we have considered only structured data.Further if unstructured data is considered some new method need to be applied for its prediction. We can also consider geographical conditions in further work.

***Abstract* - Automated brain tumor identification and classification is still an open problem for research in the medical image processing domain. Brain tumor is a bunch of unwanted cells that develop in the brain. This growth of a tumor takes up space within skull and affects the normal functioning of brain. Automated segmentation and detection of brain tumors are important in MRI scan analysis as it provides information about neural architecture of brain and also about abnormal tissues that are extremely necessary to identify appropriate surgical plan. Automating this process is a challenging task as tumor tissues show high diversity in appearance with different patients and also in many cases they tend to appear very similar to the normal tissues. Effective extraction of features that represent the tumor in brain image is the key for better classification. In this paper, we propose a hybrid feature extraction process. In this process, we combine the local and global features of the brain MRI using first by Discrete Wavelet Transformation and then using texture based statistical features by computing Gray Level Co-occurrence Matrix. The extracted combined features are modeled by Support Vector Machine with different kernel functions like Linear, quadratic and RBF for classification of brain tumors in to benign or malignant class.**

Keywords— Brain Tumor, MRI, Segmentation, DWT, GLCM, SVM, RBF

I. INTRODUCTION

Brain tumor is an unwanted collection of cancerous cells that develop in the brain beyond the natural cell cycle. These tumors may be benevolent, usually termed as benign, or malevolent, referred to as malignant. The benign tumors contain non-active cancer cells and many a times have uniform structures where as malignant tumors contain active cancer cells that may stretch to other body parts. Also, the malignant tumors mostly have non-uniform structures. Magnetic Resonance imaging is a non radio-active imaging technique used for study of internal organs to envisage high resolution images of the internal body parts, their structure and functions. With MRI doctors can visualize both surface and deep structures with a high degree of anatomical details and they can detect the occurrence of minute changes in these structures. Early and accurate detection of tumors increases the chances of better planning of treatment and hence better chances of survival of the patient. Automating this process is a challenge as tumors tend to develop in diverse shape, size and position and in some cases they exhibit appearance similar to the normal tissues.

Medical Image Analysis involves processing of image at various stages. First, the **Pre-processing** is done to enhance the image quality where we remove the noise components, boost the image intensity and prepare the image for further processing [2]. In **Segmentation** stage the specific region of interest in the image is identified through one or combination of many intelligent methods [3] to obtain determinant characteristics of tumors from medical images. Following are some of the applications of image segmentation: to locate tumors, to measure tissue volumes, image simplification, classification and recognition of region of interest. **Feature selection** is the general term to represent the methods used for constructing the combination of variables that describe the data effectively [4]. It is the technique of obtaining a subset of highly relevant variables by eliminating irrelevant and redundant variables to build appropriate learning models. Accurate tumor classification is possible with more accurate feature selection techniques. **Classification** is a phase of analysis where we compute the numerical properties of given image features so that the image can be placed into one of the many categories. Classification is achieved by employing two processing phases: first, the training phase and then, the testing phase. In training phase, unique descriptions of each category of classification are obtained using the labeled training samples. In testing phase using an appropriate feature space boundary we classify the unique descriptions of the test image [5].

In this paper we propose an automated method for tumor classification with two class labels namely benign and malignant. We propose a hybrid feature extraction method to get the better representation of image samples by combining local and global wavelet coefficients obtained from DWT and texture based statistical features obtained by computing GLCM. This approach is motivated by the fact that both the local and global features are experimentally found to be uncorrelated and hence upon combining can give enhanced statistical details. This paper is organized into 5 sections. In section II we have summarized related works by various researchers in the field of brain image tumor classification. Section III gives the details of proposed work. The outcomes of the proposed work and evaluation with other benchmarks are discussed in Section IV. Section V has concluding remarks and discusses future enhancement options for this work.

II. Related Work

Many articles have been published by the researchers in the recent years on methods for classification of tumors from MRI images.

Ayush Arora et al [6] suggested a method where the image was segmented using the popular segmentation techniques like thresholding followed by morphological operations. The features ware extracted from the segmented image using DWT. Using principal component analysis the high dimensional features features were reduced to computationally convenient lower dimension without losing much of the classification information. Then, k-NN classification was used to decide if the tumor is benevolent or malevolent.

A scheme for brain tumor identification and further classification from MRI images by probabilistic neural network is suggested by Shree and Kumar [4]. They have used DWT to decompose the images into horizontal, vertical and diagonal components followed by textural image features extraction by computing GLCM. PNN classifier was used for the categorization of tumors.

Another approach for brain tumor classification is suggested by Rathi and Palani [3]. They have extracted shape, intensity and texture features from the normalized images. Prominent features were selected using LDA. SVM was used to classify the tumors.

Adhi Lakshmi et al [7] suggested techniques for tumor analysis. In this method image pre-processing was done with Distribution based Adaptive Mean Filtering and Adaptive Threshold based Edge Detection. Segmentation was achieved by using connected component analysis with Cellular Automata and Multi-angle Cellular Automata. The most representing features were obtained using a method called Dynamic Angle Projection Pattern. Those features optimized with Cockoo Search Optimization and such selected features were passed to SVM with Pointing Kernel Classifier.

A comparative analysis of various feature extraction algorithms is published by El-Gayer et al [8]. They have compared the performances of FAST, SIFT, PCA-SIFT, F-SIFT and SURF algorithms with respect to scaling, rotation, illumination change and other transformations.

Image processing techniques for brain tumor analysis is published by Hemanth and Anitha [2] where they have conducted a survey of many techniques for pre-processing, feature extraction, classification. They have proposed a method where pre-processing was done with connected component analysis. Eight textural features namely Correlation, Contrast, Entropy, Variance, Angular Second Moment (A measure of Uniformity), Skewness (A measure of symmetry), Inverse Difference Moment (A measure of homogeneity) and Kurtosis (A Measure of data distribution) are extracted and these features were used for classification.

Stationary Wavelet Transformation (SWT) which has superior wavelet coefficients as compared to DWT in terms of translation invariant property is proposed by Zhang et al [9]. Those features were reduced with PCA and Fisher Discriminant Analysis (FDA) was used to categorize brain into benevolent or malevolent.

Daljit Singh and Kamaljeet Kaur [5] have observed that GLCM features and classified using SVM with any of the RBF, Linear and Quadratic kernel functions will also yield better classification. They have compared GLCM with PCA for feature extraction.

GLCM features were extracted from the fuzzy clustering based segmented images is proposed by B. Thamaraichelvi and G. Yamuna [10]. Entropy, Correlation, Energy, Contrast, Mean, Standard Deviation and variance features were extracted. SVM with RBF kernel was used to classify brain tumors with an accuracy of 98%.

Using deep learning methods a survey on segmentation of MRI-based brain tumors is published by Işın et al [11]. They have effectively highlighted the challenges in manual, semi-automatic and fully automatic segmentation methods.

III. Proposed Methodology

From the literature Survey we conclude that accurate brain diagnosis can be done by developing more effective and accurate techniques in feature extraction and classification. Literature survey motivated us to look into methods for extracting more meaningful features from the MR Images. In this work, we propose a method for extracting the features as shown in figure 1. First, the image samples are prepared for segmentation. This pre-processing and segmentation stages are described in sections A and B respectively. We extract the local features from the segmented image and global features from the fused images. The details are discussed in sections C, D and E. We were motivated to use a hybrid of local and global features of the image, after closely examining the local and global image features. We found that both the features are not correlated. Hence we hypothesize that use of hybrid features can give better description of the area of interest. These feature vectors obtained from DWT were reduced using PCA and further by computing GLCM, 13 statistical features were computed from them namely, Energy, Contrast, Mean, Correlation, Standard Deviation, Homogeneity, RMS, Entropy, Skewness, Inverse Difference Movement (IDM), Variance, Kurtosis and Smoothness. Using these statistical features the SVM classifier was modeled. The classifier efficiency was tested and compared with Linear, quadratic and RBF kernels functions.

A. Preprocessing

Brain MRI Image data set is obtained from the online repository of IMAGE & DATA ARCHIVE (IDA), University of Southern California [1]. The dataset contains RGB MRI FLAIR image slices with matrix size of 256 x 256, all with axial perspective. Results of various pre-processing stages are shown in figure 2. The images are first converted to gray scale and then enhanced by median filter (Figure 2a).

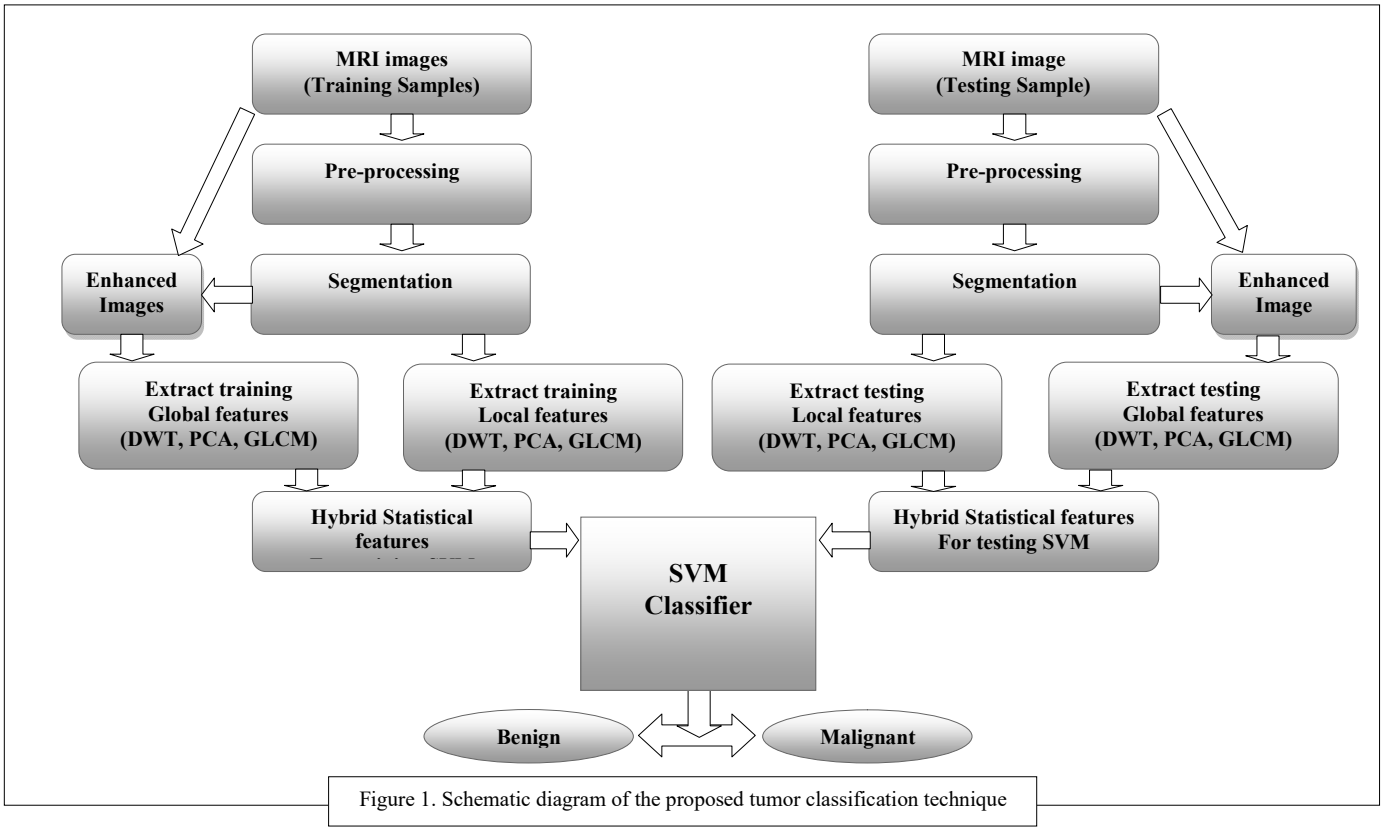

Figure 1. Schematic diagram of the proposed tumor classification technique

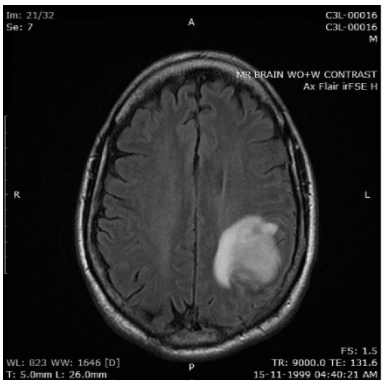

Figure 2 a) Color to Gray Conversion and Enhancement with median filter

2b) Dynamic Thresholding

2c) After flood Fill

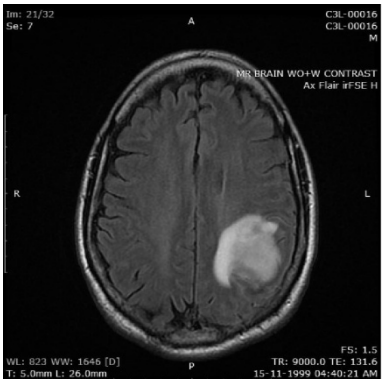

Figure 3a) Original Image

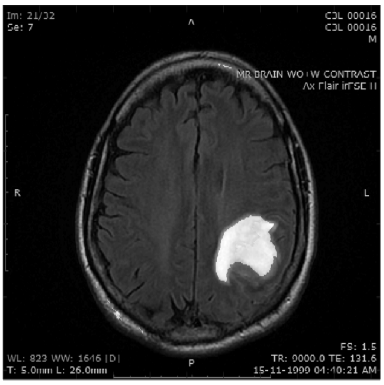
3b) Segmented Image



3c) Masked Image

B. Segmentation

The emphasis was on the removal of skull tissues and text in the MRI. Image was segmented using a Dynamic thresholding technique (Figure 2b) along with suitable morphological operations to filter out those undesired pixels (Figure 2c). Filling and Erosion are the two main morphological operations that are performed on binarized image to highlight the area of interest and generate the mask as shown in figure 3b. The original image is fused with the segmented image to get the masked image as shown in Figure 3c.

C. Discrete Wavelet Transformation

MRI image is decomposed using discrete wavelet transform with four sub regions. These regions are called approximate component region and three high-frequency regions, namely horizontal component, vertical component, and diagonal component. Theoretically the approximate component region is obtained by using two successive low-pass filters. The horizontal component is obtained by a pair of high-pass and low-pass filter. The vertical component is filtered using a pair of low-pass and high-pass filter. The diagonal component is created by two successive high-pass filters.

Subsequent levels of decomposition follow the same procedure by decomposing the approximate component sub image of the previous level. 2D discrete wavelet transform was applied with the three-level wavelet decomposition. Here it is important to determine the most suitable decomposition level. With the increase in number of levels more detailed information will emerge. At the same time this will affect the classification model stability and hence reduce the computing efficiency. By trial and error method we have found that at third level all but particularly the diagonal component information is maximized and hence we have taken three levels of Haar wavelet decomposition. 30 MRI images are used to extract the features as training samples with 10 of them belonging to benign class and 20 belonging to malignant class. The masked images (as shown in Figure 3c) are used to compute DWT coefficient vectors of all the four components.

30 MRI images are used to extract the features as training samples with 10 of them belonging to benign class and 20 belonging to malignant class. The masked images (as shown in Figure 3c) are used to compute DWT coefficient vectors of all the four components.

These global features are the input for PCA for further feature reduction. Output of such an image sample is shown in figure 4a. The segmented images (shown in Figure 3b) are used to compute DWT coefficient vectors which are the local features. DWT coefficients of segmented image sample are shown in figure 4b.

D. PCA and GLCM

For feature dimensionality reduction PCA is one of the most commonly used technique. PCA technique preserves the variance of the given input data and finds the linear lower-dimensional closest representation of that data by using orthogonal transformations. It transforms a large set of correlated points into set of principal components.

This reduced feature set of all the components are used to compute GLCM. GLCM is a statistical procedure to tabulate how often different combinations of pixel intensity levels co-occur in an image. Every element in the i^{th} row and j^{th} column of the GLCM is an indicator of how many times a pixel with a specific intensity i occurs in relation with other pixel with

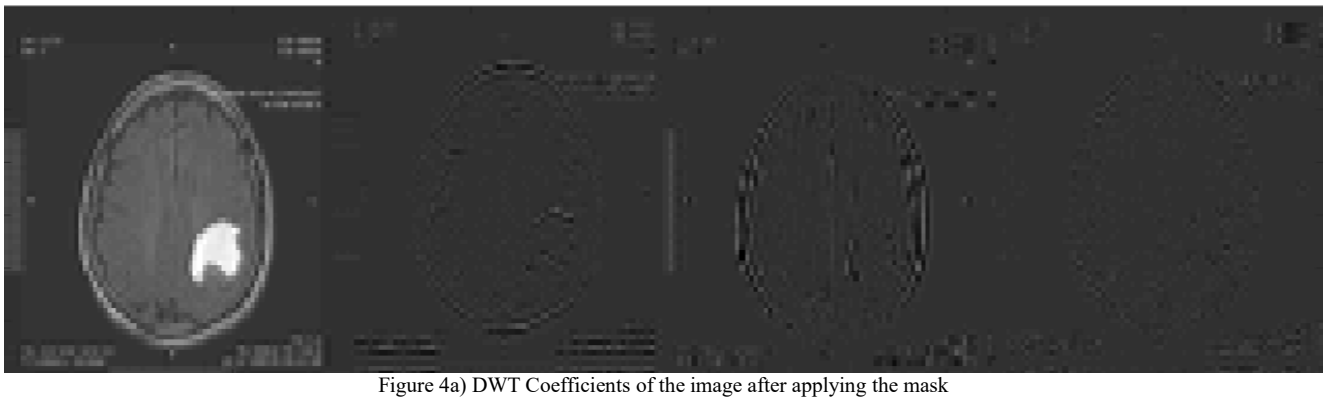


Figure 4a) DWT Coefficients of the image after applying the mask

Figure 4b) DWT Coefficients of the segmented Image

intensity *j*. Two GLCMs are computed, one for local DWT coefficients and the other one for global DWT coefficients.

E. Statistical features

13 statistical features [12] namely Inverse Difference Movement, Skewness, Kurtosis, Smoothness, Variance, RMS, Entropy, Standard Deviation, Mean, Homogeneity, Energy, Correlation and Contrast are computed from both local and global GLCM. A set of 26 features extracted using DWT followed by PCA and GLCM from the sample image is as shown in the following table.

Features	Segmented Image	Fused Image
Contrast	36.54664	98.03584
Correlation	0.84167	0.85767
Energy	0.90735	0.12737
Homogeneity	0.96503	0.60031
Mean	3.87178	31.37863
Standard Deviation	61.48974	108.52944
Entropy	0.39561	2.44954
Root Mean Square level (RMS)	15.74675	62.69145
Variance	3400.14272	6370.37139
Smoothness	0.99998	0.99999
Kurtosis	259.18122	41.06553
Skewness	15.59871	5.03187
Inverse Difference Movement (IDM)	19132.42966	47963.94913

F. Support Vector Machine

SVM is basically a two class linear classifier model built upon numerical learning theory. The idea behind SVM is to build a decision boundary such that the margin of separation between support vectors of both the classes (positive and negative) is maximized. This decision boundary is a hyperplane in high dimensional feature space. This can be represented by $\boldsymbol{w}\ \mathbf{x} + \mathbf{b} = \mathbf{0}$ where w is the weight vector normal to the hyperplane and b is the bias. The training data can be described by

$(\boldsymbol{w_i}\ \mathbf{x} + \mathbf{b}) \geq \mathbf{1}$ for all y_i = Positive Class and

$(\boldsymbol{w_i}\ \mathbf{x} + \mathbf{b}) \leq \mathbf{1}$ for all y_i = Negative Class

Support vectors are basically the planes as shown in figure 5 where: $(\boldsymbol{w_i}\ \mathbf{x} + \mathbf{b}) = +\mathbf{1}$ for hyperplane 1

and $(\boldsymbol{w_i}\ \mathbf{x} + \mathbf{b}) = -\mathbf{1}$ for hyperplane 2

During learning the hyperplane the placement of hyperplane is determined by all training samples with an object of maximizing the distance between hyperplane 1 and hyperplane 2. All samples that are at the distance of the margin are called support vectors. When a new sample is used with unknown class label the value of $(\boldsymbol{w}\ \mathbf{x} + \mathbf{b})$ decides the class of the test sample. Usually along with many other parameters a tuning parameter C is used to define the amount of allowed violation of the margin. Larger the value of C more relaxation is allowed for the model to fit the data.

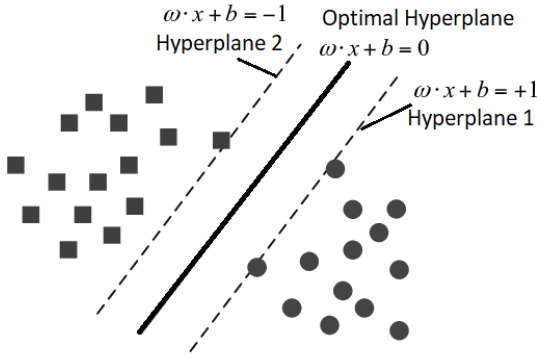

Figure 5. Hyperplanes and Support vectors in SVM

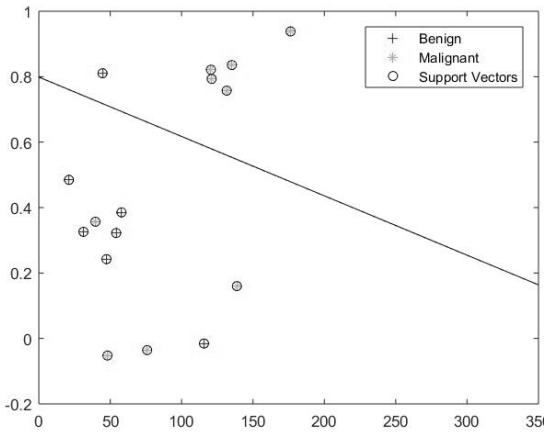

Figure 6a) Trained SVM with Linear Decision Boundary

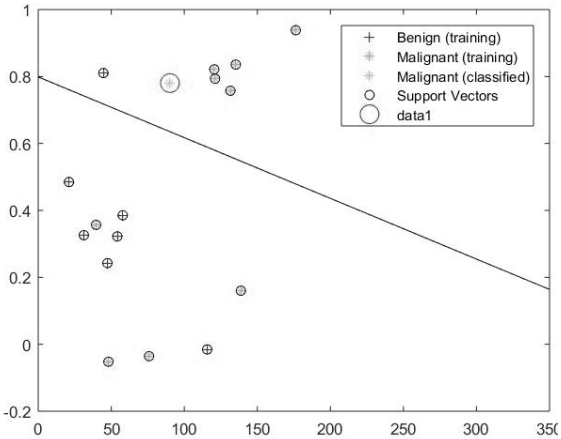

6b) Result of testing new test image where SVM has classified the test sample correctly as Malignant

In this paper we have used linear Support vector where the decision boundary is linear. The SVM training scatter map is shown in Figure 6a with a linear decision boundary. A test sample is being tested in Figure 5b. The test sample as shown in 6b above the linear boundary with bigger circle is classified correctly as malignant.

IV. Result Analysis

Along with the above linear decision boundary model we have also modeled SVM with RBF and Quadratic kernel function to map linear data to nonlinear feature space and the decision boundaries will then be nonlinear. The kernel functions are used to project the data on to the higher dimensional feature space and at this space the data points become linearly separable. The proposed method is yielding acceptable results with linear, RBF and polynomial kernel functions. Polynomial kernel with degrees 2, 3, and 4 are used and best result was found with degree 2 as shown in the below result table.

The performance measure, Accuracy is computed as the probability of correctly classifying the samples. We compute accuracy as:

$$\text{Accurcy} = \frac{TP + TN}{TP + TN + FP + FN}$$

Where TP is True Positive, the number of correctly classified benign tumors; TN is True Negative, the number of correctly classified malignant tumors; FP is False Positive, the number of incorrectly classified benign tumors and FN is False Negative, the number of incorrectly classified malignant tumors. The experimental results are tabulated as follows:

Kernel Function	Feature extraction Method	Accuracy (Rounded)
Linear	GLCM	92%
	DWT	68%
	Proposed Method	**94%**
Quadratic	GLCM	62%
	DWT	73%
	Proposed Method	**89%**
RBF	GLCM	86%
	DWT	93%
	Proposed Method	**95%**
Polinomial	GLCM	92%
	DWT	68%
	Proposed Method	**94%**

V. Conclusion

In this paper we have shown implementation of our proposed method, a hybrid of local and global feature selection with statistical features extracted from the Brain MR Images. They were reduced using PCA and GLCM was computed. Those local and global features were combined to form a set of 26 features are used to train the SVM model. After successful implementation of this model we have tested the model with test image samples and found that this method is having a maximum accuracy of 95% as listed above. There may be many possibilities to improvise this method in future. Different feature selection techniques may also be employed to obtain the hybrid feature set and investigate for even better accuracy over larger datasets. This method can also be employed in analysis of other disease MRI for the purpose of diagnosis.

Acknowledgment

I wish to pay my sincere gratitude to Dr. Narasimha Kaulgod, Professor, Department of E & C, NIE, Mysuru, who has reviewed and suggested modifications. I also thank Dr. A. D. Kulakarni, Professor (Rtd), Department of E & E, NIE, Mysuru, for his continuous motivation.

***Abstract*—Session Initiation Protocol (SIP) is widely used in Voice-over-IP (VoIP) communication to initiate communication between user and server. SIP authentication mechanism was found insecure against various attacks because of its inherent open text architecture. We analyzed different models for SIP authentication and noted their vulnerability against various attacks. Major identified weakness was lack of mutual authentication in various schemes. In this paper, we provide a new authentication model for SIP communication for secure communication establishment. We use AVISPA tool for formal security evaluation of our model. We then prove how our model can resist against various known attacks and provide mutual authentication. Our model is relatively more efficient as we use symmetric key cryptography with ECC instead of asymmetric key cryptography.**

Keywords: VoIP, SIP, AVISPA, mutual authentication, user anonymity, security.

I. INTRODUCTION

We rely mostly on internet and wireless technologies to accomplish various tasks in our daily life. Different architectures, models and applications are developed which are based on these technologies that require a secure user authentication mechanism to validate identity of user and server. As a result multiple authentication schemes were proposed [1], [2], [3], [4], [5], [6], [7] . SIP is a widely used protocol for internet services which is used for authentication [8], [9], [10]. The Internet Engineering Task Force (IETF) designed SIP in 1996. Main role of SIP is to establish, modify and terminate communication between two or more communicating parties. SIP is essential for most of VoIP communications. But SIP was found vulnerable and could easily be hacked [11] .

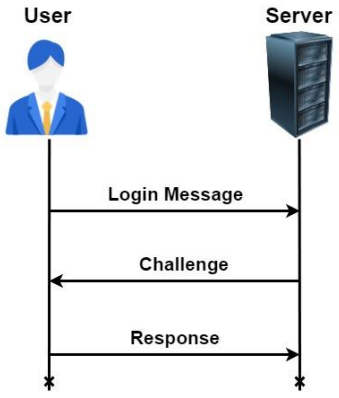

Fig. 1. General Flow of Data in Challenge Response Mechanism in SIP.

In SIP, most commonly used mechanism for login and authentication is challenge response mechanism. In this mechanism, user sends a login message to server which comprises of user specific login data and some dynamically generated parameters. Server verifies user identity on the received login data and generates a server verification token based on dynamic parameters received from user. Server then sends server verification token and some dynamically generated server specific data to user as challenge message. User verifies identity of server through parameters generated at user end. After successful server verification, a user token is generated based on the dynamic data received from server. This token is sent as response message to the server. Server does final verification of user based on user token. A dynamic session key is generated based on the dynamic parameters exchanged in these messages. Figure 1 shows the general flow of data in SIP architecture.

One of the major role of SIP is to provide a secure authentication mechanism. When SIP is implemented, it should ensure to the system that a valid user is accessing its services and to the user that he is connected to a valid system. There are few globally known parameters about the system which varies depending on the implementation. Some knowledge is kept secret by both user and the system. User uses his secret knowledge and public parameters to send a loginrequest to server. Server verifies identity through secret parameters and sends appropriate reply message. Thus client verifies his connection to appropriate server from the received reply message. [12], [13], [14].

Another major aspect in terms of authentication is mutual authentication. Server must ensure that legitimate user is provided access and not an attacker. User must ensure that he is connected to legitimate server and not some malicious spoofed server created by attacker. Multifactor authentication provides advantage over traditional single factor authentication. Amongst Knowledge, Ownership and Inheritance factors of authentication, it is essential to use at least 2 factors for authentication. Knowledge factor can easily be included by including PIN or password for authentication. Ownership factor can be included through devices like smart cards, smart wearable devices or software tokens stored in mobile devices. Inheritance factor is relatively tough to include is system due to nature of biometrics which are used as authenticator. Biometric data is generally tough to replace if leaked from the system. The biometric template of user can

be captured by the attacker if there is vulnerability present in the reader. Biometric data cannot be replaced by user unlike ownership or knowledge factor. Thus it is considered better if only ownership and knowledge factor is used for authentication.

Many SIP schemes used verification table containing user passwords at server for authentication. This made system vulnerable to various attacks like insider attack, password guessing attack, stolen verifier attack, server spoofing attack, etc. Reduced efficiency and lack of scalability is another issue with this approach. To address this problem, new schemes were developed where remote server could authenticate user without verification tables [11], [14] . This new approach also allowed early detection of wrong credentials from user.

Rest of this paper is divided as follows: Section 2 provides literature review for different SIP authentication schemes. In Section 3, proposed model is explained in detail. We evaluate security and functionalities of our proposed model in Section 4. We conclude our paper in Section 5 and provide scope for future work.

II. Literature Review

Several schemes were proposed on SIP to provide secure and reliable authentication [8], [9], [10], [11], [13], [14], [15], [16]. Many of these schemes were vulnerable to many attacks like insider attack, stolen verifier attack, spoofing attacks, etc. Some lacked important functionalities like mutual authentication, secure and dynamic session key generation, or multifactor authentication. Some schemes contained elements like verification tables or global clocks which made them vulnerable.

Yeh et al. [17] proposed an authentication scheme using ECC and smart cards. They provided early wrong password detection by providing offline password verification, Mutual authentication was provided by using a challenge response mechanism. They stated their scheme was resistant to password guessing attacks. However, Farash et al. [18] proved that Yeh et al.'s scheme was vulnerable to offline password guessing attack, user impersonation attack and server impersonation attack.

Farash et al. [18] proposed authentication scheme to overcome weakness in Yeh et al.'s scheme. They stated their scheme could provide security properties like user anonymity, untraceability and offline password changing phase. Alamr et al. [19] proved that Farash et al.'s scheme could not provide user anonymity and confidentiality. Offline password changing phase also made their scheme vulnerable to offline password guessing attack and brute force attack.

Farash et al. [20] stated that their scheme can withstand well known attacks. Kumari et al. [21] showed that Farash et al.'s scheme was vulnerable to user impersonation attack, session specific information leakage attack and password guessing attack. Also there was lack of user anonymity.

Major identified issues in literature review are vulnerability to password guessing attack, user and server impersonation attack, brute force attack and session specific information leak- age attack. Key functionalities which were missing includes mutual authentication and user anonymity.

III. Proposed Model

The proposed model consists of four different phases, i.e. Setup Phase, Registration Phase, Login and Authentication Phase and Password Change Phase. Figure 2 illustrates the workflow of system. We have provided a mechanism for offline password verification to detect invalid password at an early stage. Our proposed model performs multiple checks to verify identity of user and server. A secure session key is dynamically generated based on generated random data. In this section, we see elliptic curve cryptography followed by phases of our system.

A. Elliptic Curve Cryptography (ECC)

Miller [22] and Koblitz [23] were first to explore application of ECC in cryptography. This turned out to be more secure when compared with traditional public key cryptography [24]. Same level of security is provided in ECC but total number of parameters included is reduced. For ECC based cryptography, operations are carried out which completely depends on single equation which is as follows:

$$E_q(i, j): y^2 = (x^3 + ix + j) \bmod q$$

where q is a very large prime number. Size of q is greater than 160 bits and i and j belongs to integers. (x, y) are points that satisfies $94i^3 + 27j^2) \bmod q \neq 0$. Value of integers i and j defines the elliptic curve. Identity element is considered as point at infinity O. Multiplication in ECC is scalar and is considered as repeated addition. So if P is considered as a point over equation $E_q(i,j)$ and v is integer to be multiplied then vP= P + P + P+ P +…P (v times).Computational problems with respect to ECC are as follows:

1. Elliptic Curve Discrete Logarithm Problem (ECDLP)
   ECDLP states that if 2 points R and S are given on an elliptic curve $E_q(i,j)$, then it is computationally hard to find another integer k such that R=kS in polynomial time.

B. Setup Phase

Server generates system parameters in this phase as follows:

- Large prime number: n
- Elliptic curve: $E_p(a, b)$
- Server's private key: $q_s \in Z_n^*$
- Secure one way hash functions: $h_p(.)$, $h_s(.)$ such that $h:\{0,1\}^* \rightarrow \{0,1\}^l$
  where l is the security parameter
- Symmetric encryption/ decryption functions $E_K()/D_K()$ where K is secret key

Server is initialized once all the parameters are set.

C. Registration Phase

Whenever a user wants to register, user and server cooperates to perform following steps via a secure channel. The steps which are performed are as follows:

1) User selects and enters his username as Un and password as Pu. A number M is generate dynamically

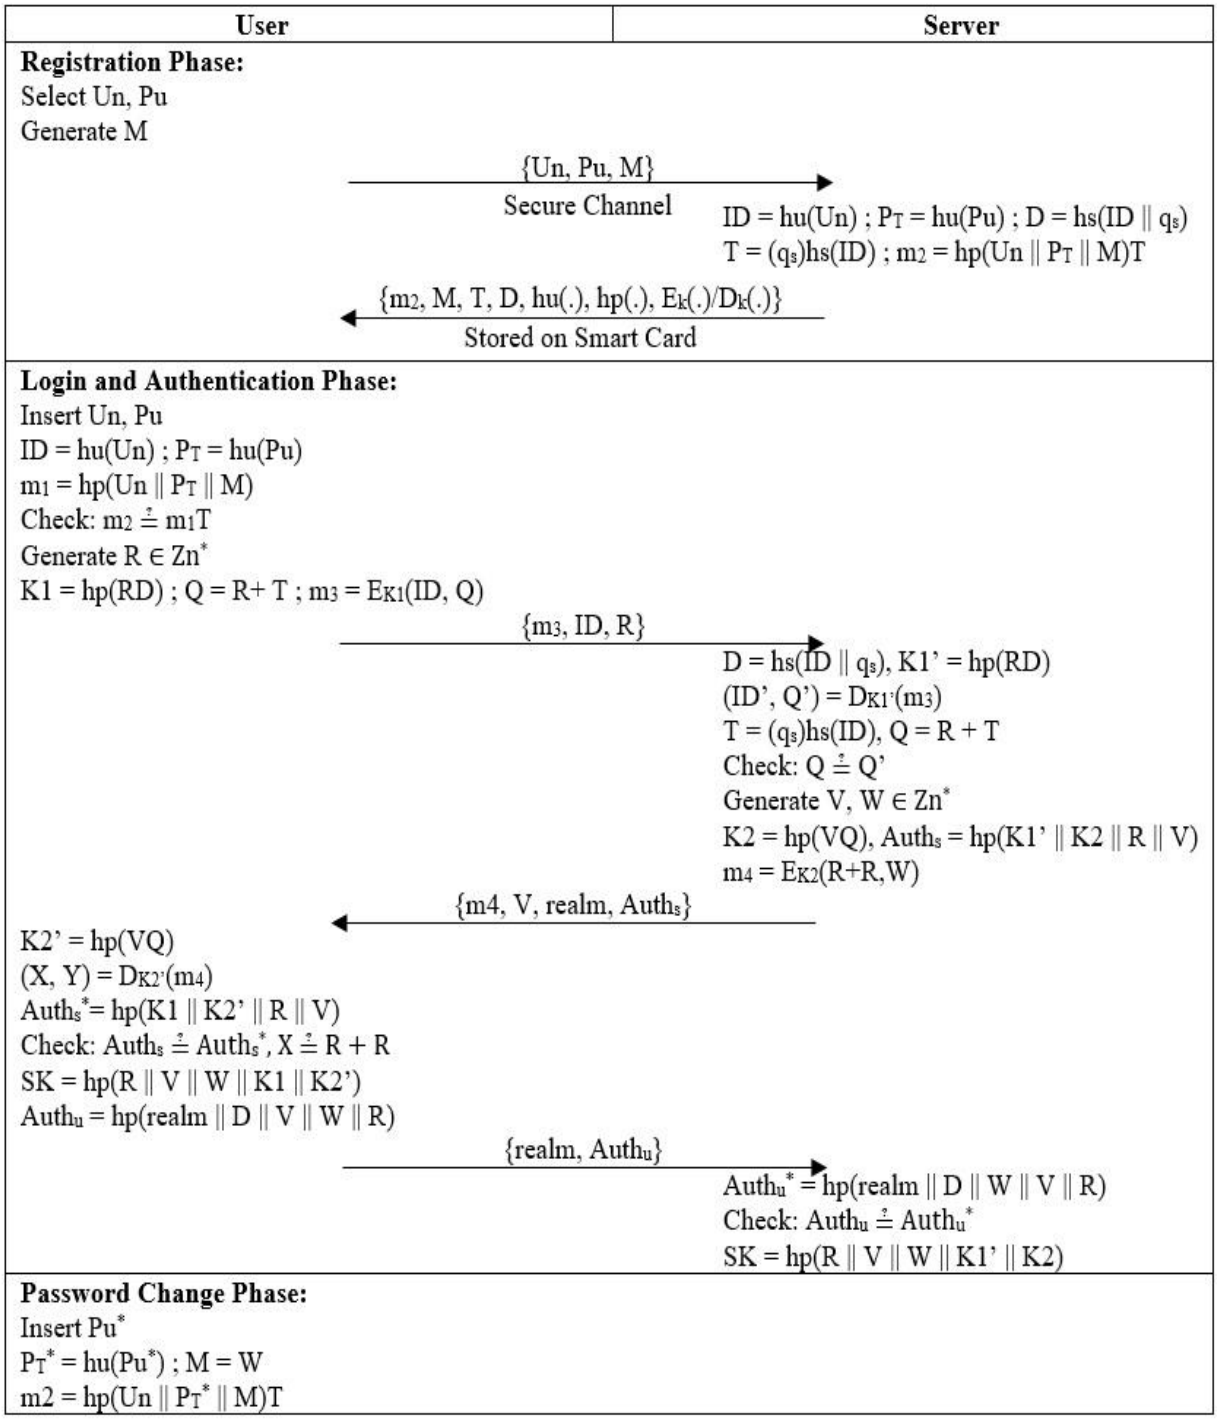

Fig. 2. Data flow in proposed model.

such that $M \in Z_n^*$. All these 3 parameters are then sent to server.

2) Server generates a unique hash function $h_u(.)$ dynamically which is user specific. Then ID is generated as $ID=h_u(Un)$ and P_T as $P_T = h_u(Pu)$. T is generated as $T=q_s(h_s(ID))$ and D as $D=h_s(ID||q_s)$. Secure user authentication parameter (m_2) is generated as $m_2=(h_p(Un||P_T||M))T$.
3) Parameters $\{m_2, M, T, D, h_u(.), h_p(.), E_K(.)/D_K(.)\}$ are stored on smart card. Smart card is sent to the user via a secure channel.

D. Login and Authentication Phase

Whenever user wants to get services of the system, he first passes through this phase to verify identity of system and authenticate himself. Steps followed in this phase are as follows:

1) User enters Un and Pu in the system after entering smart card into the reader.
2) ID is computed as $h_u(Un)$ and P_T as $h_u(Pu)$. Message m_1 is computed as $h_p(Un||P_T||M)$. If value of m_1T equals m2, then user is successfully authenticated, otherwise invalid credentials message is displayed.

3) R is generated dynamically after successful authentication as R Z_n^*. Key K1 is computed as $K1=h_p(RD)$. Q is computed as Q = R+T. Message m_3 is generated by encrypting (ID,Q) with the Key K1. {m_3, ID, R} are sent to the server as login request to the server.
4) After receiving login message, server first computes D as $D=h_s(ID \| q_s)$ followed by key K1' as $K1'=h_p(RD)$. m_3 is decrypted with Key K1' and parameters ID' and Q' are obtained. T is computed as $T=(q_s)h_s(ID)$ and Q as Q=R+T. If Q equals Q', then the identity of user is verified successfully, otherwise the connection is terminated. V and W are generated dynamically after successful authentication as $V, W \in Z_n^*$. K2 is computed as $K2=h_p(VQ)$. Server authentication message $Auth_s$ is computed as $Auth_s=h_p(K1'||K2||R||V)$. m_4 is generated by encrypting (R+R, W) with key K2. {m_4,V,realm,$Auth_s$} is sent as challenge to the user.
5) Key K2' is generated as $h_p(VQ)$. m_4 is decrypted with key K2' to obtain parameters X and Y. $Auth_s^*$ is computed as $Auth_s*=h_p(K1||K2'||R||V)$. Server authentication is successful if $Auth_s$ equals $Auth_s^*$ and X equals R+R. Session key SK is generated as $SK=h_p(R||V||W||K1||K2')$. User authentication message $Auth_u$ is generated as $Auth_u=h_p(realm||D||V||W||R)$.{realm,$Auth_u$} is sent as response to the server.
6) Server generates user authentication message $Auth_u^*$ as $Auth_u^*=h_p(realm||D||W||V||R)$. Final user verification is successful if value of $Auth_u^*$ equals $Auth_u$. After successful authentication, session key is generated as $SK=h_p(R||V||W||K1'||K2)$.

Now server and user communicates securely through the newly generated session key SK.

E. Password Change Phase

This phase is executed when user wants to change his pass- word. In order to change password, entire login and authentication phase is executed first to establish a secure channel with server. Steps performed after generation of SK are as follows:

1) User enters new password P_u^* in the system. P_T^* is computed as $P_T^*=h_u(Pu^*)$. M is modified as M=W.
2) m_2 is then computed as $m_2=h_p(Un||P_T*||M)T$ and the modified value is stored on smart card.

IV. Result Analysis

In this section, we provide security analysis of the proposed model. Then the security of proposed protocol is compared with various proposed schemes. The security provisioning has also been elaborated in this section keeping in contention the aspects that enhance the strength of the system. The key security aspects of the proposed model are mutual authentication ensuring proper identity checks for user and system, user anonymity to prevent access from privileged insider to identify user along with dynamic and secure session key generation for perfect forward secrecy. All these provisions ensure that modularity of the system is maintained to the maximum extent possible. The given system carries forward all the security provisions of symmetric key cryptography as core concepts.

A. Formal Security Evaluation using AVISPA tool

We use Automated Validation of Internet Security Protocols and Applications (AVISPA) tool [25] for formal security evaluation of our proposed scheme. There are different back-ends available to verify security of proposed schemes. We have used On-the-fly Model Checker (OFMC) back-end to evaluate security of our scheme. Figure 3 shows simulation results of our proposed scheme.

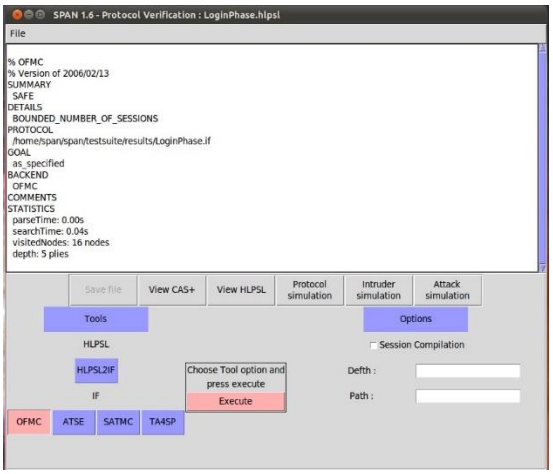

Fig. 3. Simulation result under OFMC model of AVISPA

B. Informal Security Analysis of proposed model

1) Mutual Authentication: In our model, we perform user authentication at server without message freshness in step 3 when we compare Q with Q'. After this preliminary verification, Server is authenticated by user in step 4 when $Auth_s$ is compared with $Auth_s^*$. After successful server authentication, user generates user authentication message as $Auth_u$. Server authenticates user in step 5 when $Auth_u$ is compared with $Auth_u^*$. Thus we provide mutual authentication in our system when we compare $Auth_s$ with $Auth_s^*$ and $Auth_u$ with $Auth_u^*$.

2) Dynamic and Secure Session Key Generation: In our model, we generate session key based on 5 different parameters, (R, V, W, K1 and K2). K1 and K2 are securely generated keys at user and server end respectively, R and V are dynamically generated random values which are transmitted openly between user and server and W is dynamically generated random value at server which is passed securely to user.

Values of W, K1 and K2 is either transferred directly through secure channel or indirectly generated securely by hiding partial information in transferred messages. As a result, it becomes computationally impossible for attacker to guess all 3 secure values correctly. Thus our model supports secure session key generation. Also, as all 5 parameters are random and dynamically generated, our model supports dynamic

session key generation.

3) User Anonymity: In our model, username is accepted from user as Un. This value is then passed from a secure hash function $h_u(.)$ to get a dynamically generated user specific random identity ID. It is impossible to obtain original input value from the hash function. Also, it is impossible for attacker to read contents of message m_3 transferred in step 3 without getting security parameter D. Thus our model supports user anonymity.

4) Resistance against Password Guessing Attack: In our model, we accept 2 different parameters Un and Pu from user to generate user identity ID and password P_T. Neither Pu nor P_T is stored directly on card. ID is transferred through insecure channel to server. But it is impossible to generate Un from ID even if $h_u(.)$ is known to attacker. Thus our model provides resistance against password guessing attack.

5) Resistance against Server Impersonation Attack: In our model, key K1 is generated at user end from a secret parameter D, which was generated by server in registration phase. Q is sent in an encrypted form to server in m_3. Key K2 can only be generated with the knowledge of this Q. Message m4 cannot be sent without K2. As a result, our model provides resistance against server impersonation attack.

6) Resistance against User Impersonation Attack: In our model, user sends message m3 to the server. This message is generated only with the knowledge of security parameter D which is stored on card by server in registration phase. If message is replayed, attacker still cannot generate $Auth_u$ as it contains knowledge of D as well as dynamically generated parameter V and W. Thus our model provides resistance to user impersonation attack.

7) Resistance against Brute Force Attack: In our model, we accept 2 parameters Un and Pu from the user to verify identity of user. None of these parameters are stored directly on the system. It is essential to provide correct Un and Pu in order to login successfully. As it is computationally infeasible to brute force 2 different parameters in polynomial time, our model provides resistance to brute force attack.

8) Resistance against Replay Attack: In our model, values R, V and W are dynamically generated at user and server end. These values are to be included as a reply message to the received message. As attacker cannot modify the messages to add these values, our model provides resistance to replay attack.

9) Resistance against Relay Attack: In our model, session key is generated securely. The parameters which are generated are not transferred directly over insecure channel. Two-factor authentication is also included which gives resistance against relay attacks [26]. Thus our model provides resistance to relay attack.

10) Resistance against Man-in-the-Middle Attack (MITM): In our model, we generate a secure session key in login and authentication phase. This session key is used to transfer data securely through symmetric encryption schemes. Cryptographic techniques are strong security mechanisms to resist MITM attack [26]. Thus by including encryption, we provide resistance against MITM attack.

C. Comparative Security Analysis

We compare security of our proposed model with different schemes from Section 2 to evaluate security of our model relatively in Table 1. Attacks and properties which are considered for security evaluation include password guessing attack, server and user impersonation attacks, brute force attack, relay attack, replay attack, MITM attack and property like user anonymity. Attacks and functionalities which were common for all the schemes are not included in the table.

TABLE I
RELATIVE SECURITY ANALYSIS

Attack Types	Yeh et al. [17]	Farash et al. [18]	Our Model
Password Guessing Attack	Insecure	Insecure	Secure
Server Impersonation Attack	Insecure	Secure	Secure
User Impersonation Attack	Insecure	Secure	Secure
Brute Force Attack	Secure	Insecure	Secure
Relay Attack	Secure	Insecure	Secure
MITM Attack	Insecure	Secure	Secure
User Anonymity	Absent	Absent	Present

V. CONCLUSION AND FUTURE SCOPE

SIP is key component in every VoIP communication. It is responsible for ensuring proper and secure connection establishment between the communicating parties. However there is an inherent vulnerability in authentication phase of SIP due to its open text nature.

In this Paper, a secure authentication model for SIP is proposed. Key functionalities like mutual authentication and user anonymity along with secure and dynamic session key generation mechanism are provided in the proposed model. Lastly informal security analysis is done against various attacks and relative analysis is provided.

Future work can be done to provide security in multiserver environment. Three factor authentication can also be provided for critical applications where smart cards have higher processing power and added functionalities.

Fully Connected Convolutional Network with Laplacian Filter For Salt Segmentation In Seismic Images

Jasdeep Singh, Tarandeep Singh and Munish Rattan GNDEC, Ludhiana,Punjab,India
jimmy50singh@gmail.com

***Abstract*— Nowadays Convolutional neural networks (CNN) has become very popular, since they are able to surpass human efficiency in image classification task on ImageNet dataset. CNN are able extract features from images. These features has given state of the art accuracy as compare to the hand engineered features. Large deposits of salt normally contain large accumulations of oil and gas. But to pinpoint their accurate location in seismic images require human expertise. As the number of data is increasing now days, it becomes impractical to use human for this task. In this paper, for this task a CNN model based on U-NET architecture, a fully convolutional neural network with Laplacian filter is presented. It has been observed that the preprocessing with Laplacian filter lead to better results.**

***Index Terms*— Convolutional neural network, Salt segmentation, U-NET, Image segmentation, deep neural network, seismic images, Laplacian filter**

I. INTRODUCTION

In sedimentary rocks a dome- shaped structure is formed by evaporation of a large mass of salt. It is known as salt dome. Salt domes have trapped oil and gas reservoirs. Compared with the surrounding strata, salt domes often exhibit chaotic reflections in the form of a distinct texture. Therefore, salt dome interpretation can be formed as a structure segmentation problem. However, the boundaries of salt domes are not easily identified in most geologic scenarios. As the underlying physics with noisy and low-resolution data make it difficult.

Recently Deep neural network methods have been successful in solving problems which require feature extraction[1] .They provide the state of the art results as compare to hand crafted features. In this accuracy can be increased as the amount of the data increases. A subtype of of deep neural network is Convolutional Neural Networks (CNNs). In the field of image analysis it is pushing the state of the art.

LeCun et al. in 1990 [12] and later improved it in 1998 [10] proposed LeNet.It is a Convolutional Neural Network based model. It is used for Handwritten Digit Recognition.It has many applications such as in reading zip codes, digits, etc. But at that time there was a lack of high computing machines which prevented the use of CNN.

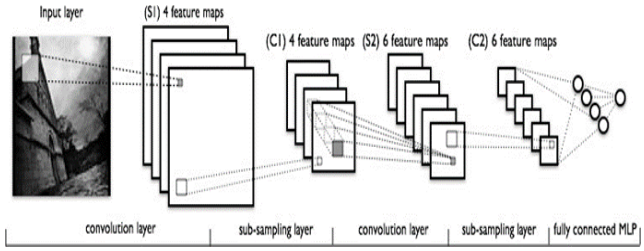

Figure 1: A simple CNN flow diagram [2]

AlexNet architecture was developed by Krizhevsky et al. [3]. It is one of the few works that popularize the Convolutional Neural Networks in the area of image analysis. Its network architecture is similar to LeNet. But AlexNet has larger and deeper architecture with more parameters. In ILSVRC-2012 competition, AlexNet was able to achieve the top-1 and top-5 error rates.

Zeiler M et al. utilize a multilayered Deconvolutional Network (DeConvNet) to see activities within the network[4].It helps in visualizing how the features of the network during the training evolve. They also used it, to troubleshoot the network in case of any issues. They were able to analyze the architecture of AlexNet and did some changing in the network such as decreasing the filter size and stride in the first layer and increase the size of the middle convolutional layers. This new network, which is the improvement of AlexNet,was able to win ILSVRC 2013.

Simonyan et al [11] have done an analysis of network architecture by keeping all the parameters fixed except the depth factor. This could lead to a large number of parameters. But by using small 3x3 convolution filters, they were able to efficiently controll this problem. This result in a development of a new and accurate ConvNet architecture known as VGGNet. It came second in the ILSVRC 2014 contest.

Szegedy et al.[5] introduced a new architecture known as Inception (v1).They were able to win the ILSVRC 2014 competition using it. It utilizes more computing resources than the AlexNet . GoogLeNet is a network, which has a less parameter as compare to AlexNet with twenty-two layers of Inception module. Later, many changes have been done in Inception-v1, which lead to increase in performance. Such as

the introduction of batch normalization by Ioffe et al. [6] which led to Inception-v2. More improvements were done in this version and the architecture was later known as Inception-v3 [7].

Kaiming et. al. proposed a novel CNN architecture known as ResNet. They used residual connection to learn residual function with respect to the input. They propose that it will be easier to learn identity function then compare to unreferenced functions [9].This make it easier to optimize deeper network. It results in increasing the overall performance and accuracy. One of its drawback is that it also increase the number of overall parameters to optimize. Hence make the network much more expansive in terms of resource utilization.But without affecting the performance , overall parameters can be decreased by removing the first Fully-Connected layer .Since this layer contains most of the parameters.

Szegedy et al [8], later in 2015 show that by using residual connection with inception module, model can learn faster. It makes the network more efficient. They were able to win 2015 ILSVRC challenge using this architecture.

Recently, Ross et al [13] review popular facies classification methods based on machine learning algorithms. Huang et al. [14] show that for identifying geologic faults in 3D seismic volumes CNN provides much better results than the methods like support vector machines(SVMs) and logistic regression. Their experiments show much bettrer accuracy in a variety of seismic processing and interpretation tasks. Araya-Polo et al. [15] use pre stack seismic data, without processing the data to seismic image, to identify faults.

Wu et al [16] train a CNN to perform pixel-by-pixel salt body classification. Previous researchers [17][18] discuss salt boundary extraction as a global image segmentation problem. Considering it as an image segmentation problem, it faces problems due to some drawback of deep learning approaches, which only depend on network made for object categorization for pixel wise labelling [19]. It is necessary to have a mechanism such that the deep layer feature are mapped to the same dimension of the input images. Such approaches lead to ad hoc methods to upsample features, e.g. by element replication.

An alternative network architecture, inspired by U-Net [20], that overcomes the problem by mapping the encoder outputs to the final classification labels of image dimension is adopted in this paper. This architecture is include a stack of encoders and their corresponding stack of decoders. Their final output is give to a sigmoid classification layer. Both encoder and decoder are fully convolutional layers. It has dual input channel, one has seismic image as a input and has the Laplacian of the image. The Laplacian operator computes the second derivative of an image and the resultant image highlight regions of rapid intensity changes. Therefore it is often used for edge detection[21][22]. The Laplacian operator for an Image is defined as shown in equations (1), (2) and (3)

$$\Delta^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} \quad (1)$$

For X-direction,

$$\frac{\partial^2 f}{\partial x^2} = f(x+1,y) + f(x-1,y) - 2f(x,y) \quad (2)$$

For Y-direction,

$$\frac{\partial^2 f}{\partial y^2} = f(x,y+1) + f(x,y-1) - 2f(x,y) \quad (3)$$

Single input channel model which takes only seismic image as an input. The results of both the models are compared. It has been observed that the dual input channel model has outperform the single input channel model.

II. Model Architecture

Firstly, the salt body classification as a semantic image segmentation problem with two classes has been constructed. The algorithm assigns a salt label to each image pixel based on the shape of the seismic image. The frame work of the proposed method is a convolutional encoder decoder network. It is inspired from U-Net[20],an architecture applied to biomedical image segmentation. This encoder-decoder architecture is trained end-to-end such that it jointly optimize all the model parameters of the network. Proposed network architectures for dual input channel is illustrated in figure 2.

First proposed model contain dual input channel with both Laplacian of a seismic image and seismic image as an input where as the second contain only seismic image as input. The rest of the architecture is same in both cases. The Laplacian operator helps in highlighting of the sharp intensity changes in the image which helps in better performance of the model.

The decoder network contains a stack of decoders corresponding to each encoder. It is one of the key components of the proposed network. Each encoder contains a filter bank. By using it for performing a convolutional operation, a set of feature maps is produced.

Element-wise rectified-linear unit ($\sigma(x) = \max\{0,x\}$) is applied as non-linear activation. Following that, max-pooling operation is performed such that the resulting output is sub-sampled by a factor of 2. In the input image dve to max-pooling, over small spatial shifts translation invariance is achieved. The appropriate decoder in the decoder network up samples its input feature maps by resizing-interpolation. This results in a sparse feature maps which are further convolved with a trainable decoder filter bank and produce a dense feature maps. The high dimensional feature representation at the output is fed to a trainable sigmoid function. The output of the classifier is a single channel image of classification probabilities.

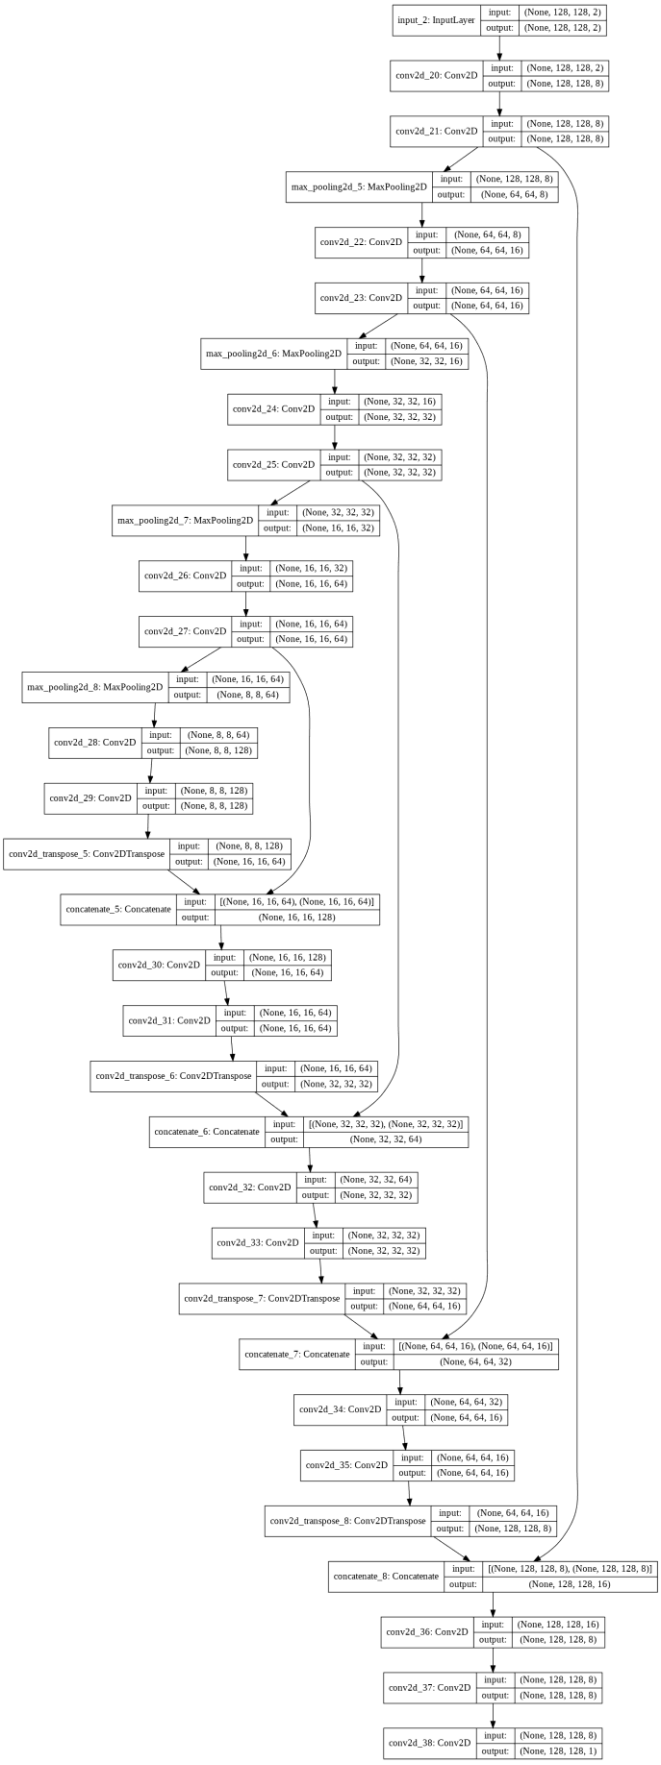

Figure2: Proposed model architecture.Model has dual input channel. Model architecture is inspired from U-net.

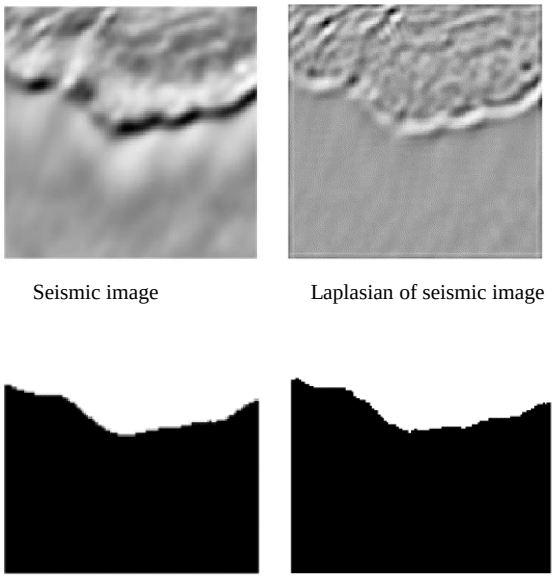
III. TRAINING

Dataset is proved by TGS , as they hosted Kaggle Competition of salt segmentation from seismic images [25]. Input seismic images are of 101 × 101 dimension images. They have binary mask of salt deposition. Their is total of 4000 images of train dataset which are divided into training set and validation set. First 3,400 images is used for training and last 600 images is used for validation set.



Seismic image | Laplasian of seismic image

Mask | Predicted mask

Figure 3:From left to right first image is a seismic image from validation set and its Laplacian is shown next as the second image. Third image is the output mask of an image which it never seen before while training and its predicted value is shown at last as fourth image.

He et al. [23] propose a technique for weight initializing and it is used for parameters initializing in the proposed network. In this paper binary entropy loss is used as the loss function, and adaptive momentum descent (Adam) as optimization algorithm [24] has been used to iteratively update the model weights. The resolution of input images is increased from 101x101 to 128x128 before giving it to the network. Image pixel are normalized by dividing it by 255.

IV. RESULTS

The model architecture code is written in python using keras library and tensorflow at the backend.Code is available at https://github.com/JASDEEP50SINGH/salt-segmentation-using-laplace-transform.To process the model described above we used a single NVidia GTX 1050 Ti GPU at our disposal. The full training and prediction cycle took about 1 hour for single channel input model and 2 hours for dual input channel input. The value of seed for random variable is set to 125. The results achieved on the validation and training data set during the training process are shown on figure 4.

Model is run for 30 epochs as loss does not decrease further. Whenever validation loss decreases, model weights are saved. From the last saved models weights, it provide 92.28 % accuracy (the percentage of pixels correctly classified in the.

(d)

Figure 4:(a) loss curve of dual input channel model, (b) loss curve of single input channel model, (c) Accuracy curve of dual input channel model, (d) Accuracy curve of single input channel model. As the number of epochs increases accuracy of both models improves and their binary cross entropy losses decreases. Overfitting can be seen as the losses start increasing after they reached their minimum value.

image) and .1825 binary cross entropy loss on validation data by dual input channel model. Single input channel achieves 91.31% accuracy and .2024 binary cross entropy loss on the same data. The Dual input channel outperform the single input channel

V. Conclusions

In this paper a network model with pre-processing of input data is proposed for an end-to-end automatic salt body detection in seismic image based on a convolutional neural networks. The encoder-decoder architecture allows for extracting essential information from training data, and results in high accuracy. The model has been tested on the dataset proved by TGS , as they hosted Kaggle Competition of salt segmentation. With limited amount of manually prepared training samples, the model successfully generalizes to unseen seismic slices produces accurate salt body detection results. The results are further improved by concatenating Laplacian of an image with input image.We believe that with further image pre-processing and data augmentation accuracy can be increased.

***Abstract*-The need of efficient data computation in the today's world is challenging as the data generated everyday enormously. So in this case the computation resources may be available on demand because of the cloud computing. In this paper an analysis based on the previous study have been discussed and analyzed on the methodological prospects. It includes the attributes like computational parameters, data handling mechanism and data security and authentication. This study also explores the mechanism for the effective data computation in terms of inter cloud environment. It includes the environment variability between public and private clouds.**

Keywords-Cloud Computing, Data Computation, Inter Cloud Environment, Public and private clouds

1. INTRODUCTION

The resource sharing now a days become easier due to the cloud computing [1, 2]. Currently it is an essential platform for the It industry, Business enterprise, University, etc. It is also a mainstay for the Internet of Things (IoT). There are several resources which can be available on demand through the Internet [3, 4]. So cloud computing mainly provides the utility and so it is also called utility computing [5].

For the better utilization of the cloud computing there is the need of efficient handling of the resources and there should be mechanism to provide some sort of ranking and acquiring the mechanism securely [6–10].

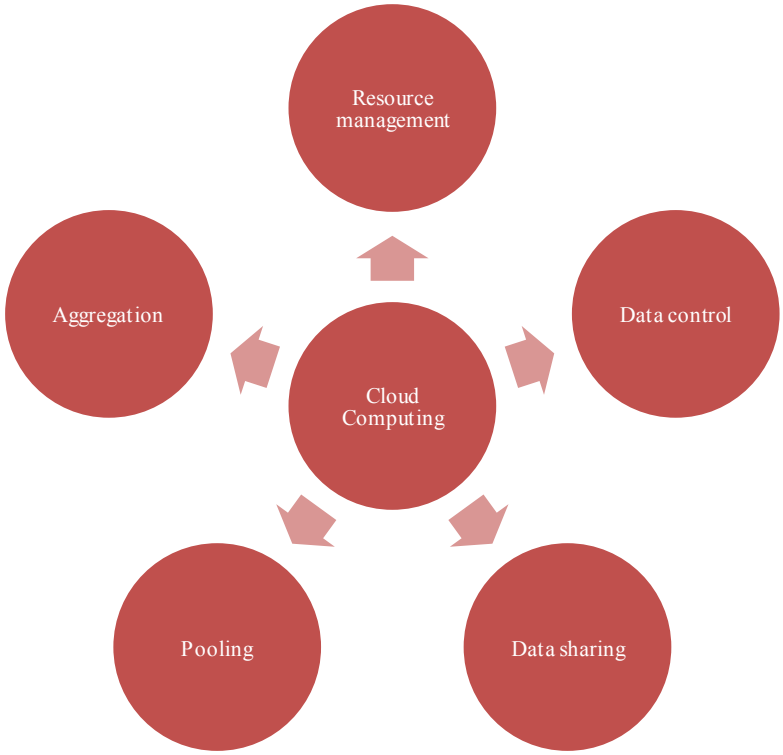

Figure 1 Cloud Computing System

In general cloud computing is categorized in four parts based on the deployment [11–14]. These are public, private, hybrid and community cloud. In terms of resource sharing public cloud is better but it is less secure. Private clod is more secure. In hybrid there is a concrete collaboration of public and private cloud. Community cloud provides the sharing of the resources between organizations [12]. In general based on the services it is categorized in three parts Infrastructure-as-a-Service (IaaS),

Platform-as-a-Service (PaaS) and Software-as-a-Service (SaaS) [12]. IaaS is mainly for the infrastructure like disk and servers (virtual). PaaS is mainly for the platform like database and execution framework. SaaS is mainly for the software resources like mailing services and application services.

The main objectives of this paper are:

1. To explore the methods in the direction of resource utilization and data sharing.
2. To explore the data handling mechanism.
3. To identify the pros and cons and discuss the solution.
4. To explore the security handling mechanism.

2. RELATED WORK

In 2018, Mao [15] discuss the impact of cloud computing environment with the intend of big data. They have suggested the big data transport channel model for improving the channel transmission. For the output features analysis they have used feature extraction and association rule mining. They have auto-correlation beam forming method for the channel equalization design. Their result suggests that their method has better channel equalization.

In 2018, Kim and Chang [16] discussed on privacy preserving techniques in terms of cloud computing. They have proposed a privacy preserving k-means algorithm for solving bit array comparison problem. They have also considered the center point based on the distribution mechanism. They have achieved 300% better performance.

In 2017, Jagli et al. [17] discussed the cloud computing in terms of fully integrated future Internet. They have suggested that the evaluation of best one is needed for efficient service selection and consideration for the development of the new model. They have proposed a model based on fuzzy clustering algorithm.

In 2016, Hong-Qiang et al. [18] discussed about the mobile cloud computing. They have worked on the user demand and their source approvals based on the demand for the fulfillment. For this they have proposed an efficient method based on fuzzy c-means algorithm for the resource scheduling.

In 2017, Lordan and Badia [19] discussed about the computing access in the cloud servers. Their framework that is framework that is COMPSs-Mobile provides the energy-efficient and high-performing applications. The structure gives a framework uninformed programming show that enables engineers to code standard Android applications whose calculation is straightforwardly parallelized and in part offloaded to remote assets. They have provided an outline of the programming demonstrate and depicts the interior parts of the toolbox which underpins it concentrating on the offloading and check pointing systems. It moreover presents the consequences of certain tests directed to assess the conduct of the arrangement and to quantify the potential advantages in android applications.

In 2016, Jing et al. [20] discussed about grey clustering and entropy. They have proposed a grey clustering classification model to evaluate cloud computing credibility. For this entropy is used. It is used for the purpose of weight determination of clustering. Their simulation supports the methods.

In 2016, Jagli et al. [21] discussed about the resource sharing. They have suggested that the SaaS the core of cloud computing. Hereafter interest for programming as a SaaS has been immensely expanded by end clients just as by a specialist organization, yet at the same time, it is a major testing task for cloud specialist coops to assess their administrations, gave to the end client. It is likewise troublesome for end clients to discover the potential programming administrations in the distributed computing condition. At first, depicts the inspiration for assessing SaaS on the distributed computing condition with the issue depiction. Besides, it's portraying the different issues furthermore, challenges for assessing programming administrations on the cloud figuring. Thirdly, it clarifies about the proposed work in assessing Software as a Service. At long last, the answer for the distinguished issue is executed and broke down the outcomes.

In 2017, Awada and Barker [22] discussed about the cloud computing providers. They have suggested a cloud-based management service (CMS) framework. The capability provided by this framework suggested are increased deployment density, scalability and resource efficiency. Their results shows that it is useful in cluster utilization, and reduction in execution time.

In 2017, Dutta and Sengupta [23] discussed about large data sets management. They have implemented k-means for this proposed especially for the enterprise cloud environment.

In 2017, Liu et al. [24] presented a hierarchical multi-cluster big data computing framework. It is based on the Apache Spark. Their system bolsters blend of heterogeneous spark figuring bunches. With a coordinated controller inside the system, it likewise encourages capacity for submitting, observing, executing of Spark work process. Their results shows the effectiveness in group creations.

3. PROBLEM STATEMENTS

The following problem statements have been identified based on the related study analyzed and discussed.

1. Data handling mechanism based on data clustering is missing.
2. Data categorization based on the weight based assignment is also missing.
3. How to handle the data securely in data sharing environment is also a big challenge.
4. Data mining techniques are missing in data sharing and handling.
5. Centralized authentication along with the cloud user control is missing in several research works.

4. ANALYSIS

Gap analysis based on the latest related works has been shown below in Table 1. Comparative analysis based on results is shown in Table 2.

Table 1: Result Analysis

S.no	Authors	Year	Work	Gap
1	Yu et al. [25]	2016	They have used knowledge workloads to predict the workloads of new tasks. For this they have used clustering algorithm. For the characteristic learning they have used neural network. Initial workload is used for the cluster determination. They have used Google dataset.	Other clustering parameters can be added.
2	Tar and Zaw [26]	2017	They have focused on document clustering in the cloud environment. They have proposed a cloud service and an ontology-based technique for identifying cloud service to improve the accuracy of cloud services searching. Their Approach has the capacity to perform cloud administration ideas from cloud administration sources. The fundamental thought behind our technique is cloud administrations utilizing a cosmology based strategy.	The security problem can be discussed.
3	Xiong et al. [27]	2016	They have discussed on resource gathering and data aggregation. They have in the wake of looking at three changed nation's hatchery's administration method, we basically talk about the best approach to structure a cloud-based hatchery stage including its design, principle capacities, and the interface. They expected that the stage can assemble and share a assortment of data and asset, similar to cash, human asset, hardware, office place, etc. So the stage is advantageous for the hatched endeavors, hatcheries, and the administration. For precedent, the stage can give singular administrations through huge information innovation. The stage can investigation the circumstance of hatcheries and caution the organizations in risky condition with the history huge information.	Different methods can be applied on different levels.
4	Yahyaoui and Moalla [28]	2016	They have worked on reducing the storage space. They have used classification for this purpose. For this different clusters have been created and each one represents different entity in the cloud space.	Prioritization should be included for the confliction management.
5	Xu et al. [29]	2016	They have worked in the direction of the predictive power calculation in the cloud environment. They have investigated the status of different machine and validate it.	It can be enhanced with the clustering mechanism.
6	Shangguan and Yue [30]	2018	They have presented MapReduce technique for parallelizing classification. The iterative preparing is changed into iterative Map and Reduce undertakings that can be executed in parallel. The K-Means bunching calculation is tested with the SPARK bunch sent on the OpenStack cloud figuring stage to outline the pertinence and viability of the methodology.	Other clustering parameters can be added.

Table 2: Comparative Analysis based on Results

S.no	Authors	Year	Method used	Results
1	Lee et al. [31]	2019	Trajectory-Aware Edge Node Clustering	The service delay is 2.6 second.
2	Koo et al. [32]	2019	Cloud-based C4I Security Architecture	Security requirements have been analyzed.
3	El-Sofany et al. [33]	2019	Cloud-based Model for Medical Diagnosis	The results shows that it is able to supports the results through fuzzy decisions that is Yes, Maybe, No.
4	Yan et al. [34]	2019	Deep unsupervised learning optimization algorithm based on cloud computing	The error rate is o.16%.
5	Islam et al. [35]	2019	Client Side Encryption in Cloud Computing	They have calculated the execution time for encryption and decryption of different packages like 4000kb, 5000kb, 6000kb and 7000kb.
6	Sharma et al. [36]	2019	Data Privacy in Cloud Computing	They have used AES algorithm with 128, 192, 256 bits length.

5. CONCLUSIONS AND FUTURE DIRECTIONS

This paper provides an explorative way in the direction of studying and analyzing cloud computing with respect to data handling, security and data sharing. This paper explores different related work to find out the problem statements which can be efficiently handle with the future prospects. It also highlights the gaps and the suggested mechanism for the advancement in the performance.

The future suggestions are following:

1. There is the need of working in the direction of data handling and sharing mechanism in efficient way.
2. There is the need of working in the direction of data security and proper virtualization with the ease in data sharing.
3. There is the need of data mining techniques for the pattern discovery in such a way that the load can be reduced or minimized.

***Abstract*— Fog is a major reason behind road accidents and road side causalities as it reduces visibility, limits contrast and distorts perception. This paper presents some concepts for maturing of a scheme which will be able to increase clearity in winter and foggy conditions using the light rays and heat properties. Various type of foggy environments, their effects on visibility range and remedial measures are discussed. We proposed the Infrared Vision (IV) for fog detection systems to improve object visibility in dense fog.**

***Keywords*— Fog, Fog lights, Infrared Vision (IV), IVFDS, Thermal light**

I. INTRODUCTION

The most dangerous enemy for transportation is dense fog as it reduces the visibility range drastically. Due to dense fog we not only find problem in ground level transportation but even in air as well as in water medium. Therefore, it is necessary to understand the fog formation and the factors related to its formation. In Northern India, during the winter period, a series of low-pressure and high-pressure zones move from Northwest to Northeast along the Himalayas cause dense fog formation while over northern India, ground elevation is the lowest along the Gangetic plains. With the result, cold air drainage from Himalayan higher plateau results in the building up of cold dense air in the trough region. This boosts the relative humidity and the formation of fog takes place. Another type of fog is formed due to the initiation of slightly humid winds from the South-west over the northern region, thus comparatively humid and warm air quash a significantly chilly surface, which forms fog. Further, expanding water and irrigation system are also one of the major reasons today for the formation of fog. The moisture from these bodies contributes to fog formation especially in the rural areas of Northern India.

Fog is a cloud of tiny water particles, ice particles, smoke particles or blend of all these types of particles. This phenomenon is also known as mist/haze if the visibility range is greater than 1000 meters depending upon anonymity caused by mentioned solid particles. The density of fog depends upon the size of particles. The falling velocity of particles abate with smaller size of the water drop. Fog formation can take place in more than one way. Firstly, the air is cooled down to its dew point which results in the occurrence of fog droplets. When the temperature of air is same as compared to the dew point temperature, condensation on tiny water droplets present in the air occurs. The second method for fog formation requires water to evaporate from the ground surface into the air, boosting up the dew point till the time condensation occurs.

Due to dense fog light dispersed down to the earth at a great angle with respect to the line of the sun's light is primarily in the bluish region of the spectrum. The atmosphere changes the evident colour of the sun by scattering of light. This is known as Rayleigh scattering. When violet and blue light undergoes scattering, the mean visible wavelength or colour of the sun shifts towards red. The scattering of light having short wavelength by molecules in the atmosphere is what gives the sky its bluish colour. When viewed across the thicker layer of atmosphere at sunrise and sunset, the sun appears more orange or red. When seen across the thinnest layer of air at midday, the sun shines closest to its real colour, but still it has a hint of yellow colour. The presence of smoke and smog also results in scattering of light and can make the sun appear more orange or red (less blue) in colour [7]. This same phenomenon makes the moon appear more orange or red when it is close to the horizon, but when observed it is slightly more yellow or white when it is high in the sky [7]. The yellow colour has the highest wavelength and does not scatter too easily this is why we prefer using this colour for our headlights so as to make its visibility range higher.

Section II presents earlier types of headlights used in automobile industry. Section III discusses about the proposed solution. Section IV highlights working of Infrared Vision Fog Detection System (IVFDS). Section V presents conclusion and future aspects of proposed solution.

II. TYPES OF HEADLIGHTS

Choosing the right type of headlight plays an important role to meet the requirement of high intensity light, power and long-lasting life. In this section we discussed the different types of headlights and their working principles widely used in the automobile company.

A. Halogen

Halogen lamps functions on halogen gas which elevates brightness. These bulbs are less efficient, as most of the energy is wasted in heat instead of light [4]. Halogen bulbs used in automobiles typically emit a yellow colour light. In terms of units brightness, halogen lamps have a throw of light about 100 metres [4].

B. Xenon headlights

Also referred to as HID (high-intensity discharge), xenon lamps are similar to the universal tube light. There is no filament present that gets heated up, instead, xenon gas is electrically charged [4]. This produces a bluish-white light which is close in colour to natural light [4]. Xenon lamps are more expensive than halogen but they generally last longer and are more efficient. As seen with tube lights, these lamps also have a small delay before lighting up and take some time

to come to full brightness, which is why the high and passing beams get an additional halogen bulb [4]. Another type of xenon headlight is Bi-Xenon. The term bi-xenon headlight 'bi' uses just one xenon lamp for the high beam, which is then either moved or shaded each time a low beam is to be provided [4]. A bi-xenon lamp is cheaper and also takes up less space in the lamp unit [4].

C. LED headlights

LED or light emitting diode discharges light from the movement of electrons and as such, is a simple and highly efficient system [4]. The advantage of LED lights is that they light up instantly, highly efficient and last far longer than other light sources. Thus, they are frequently used in tail-lights and daytime running lights. However, with technology advancing, the problem of lower light intensity is being overcome to the point where LEDs are finding application in headlights [4]. The additional benefit here is that LEDs can emit light that is closer in colour to daylight. These lights consume minimal energy and most people likes them for their designs, style and less cost [4].

D. Laser Lights

These lights trigger a gas with a laser beam, which then glows extremely bright, emitting a powerful and high intensity light [4]. The advantage of laser lights is that they are far smaller than their counterparts. Laser lights have the tendency to throw light for larger distance. This technology is at present available in a few luxury cars worldwide due its high cost.

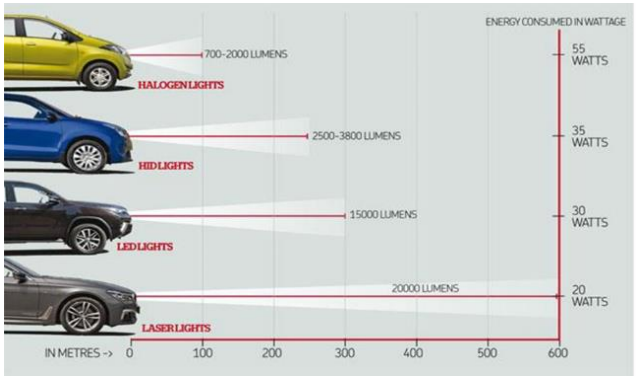

Fig. 1 Graph of headlights with its power range [4]

Fig. 1 show visibility range of various types of headlights. It is clear from Figure 2 that till date laser lights have capability to throw light for more distance as well as with less power consumptions. The less preferred light is halogen light as it has less visibility range as well as it consumes more power approximately 55 Watts [4].

Beside these lights it is necessary to discuss housing and various other components of headlights which play important role to control the emitted light from light source. The body of headlamps acts as a carrier for all the required headlamp components such as cable, reflector etc. Thermoplastics are majorly preferred for the material because of its rigid nature of protecting the body from external factors such as humidity, rain, heat etc. Out of these reflectors play a major role to control the directivity of the emitted light. To increase the efficiency of reflector materials may play a very crucial role. In previous time, most of the reflectors were made of sheet steel, while today, many unaddressed factors like outdated design, quality of material used, production tolerance etc. lead to the solution by using plastics (various thermoplastics) for reflectors. Their manufacturing is done by keeping the high accuracy of mould reproducibility in mind. Thereupon, the reflectors are coated so as to achieve the required surface quality. Aluminum or Magnesium can be used in the case of headlamps with high thermal stress to manufacture reflectors [3]. In the next stage an Aluminium reflection layer and later on a silicon protective layer is vapor-plated onto the reflector surface [3].

Another important parameter of headlight is projection module. Due to their accurate demarcated beam path and high luminous flux the use of projection modules has become quite often in modern headlamps. These modules can be used for wide range of headlamp and individual headlamp concepts because of the availability of different lens diameter, lighting function and easy installation. On the other hand, cover lenses are living up to the expectations by achieving the task of deflecting, scattering, focusing the luminous flux due to cover lenses with dispersion optics. The reflector collects it all in such a way that the desired light distribution, for instance the cut off line is produced [3]. The previous standard concept are now almost out of fashion and been completely replaced with non-patterned systems. Fig. 2 shows a cover lens generally used by headlight manufactures.

(a) (b)

Fig. 2 (a) Mostly used cover lens, (b) Cover lens without dispersion [3]

The improved version of cover lenses is cover lens without dispersion optics. Their main role is to protect the light from harsh weather conditions and rough soiling conditions. They are assigned to different purpose such as DE system used as inner lens, bi-xenon for high and low beam. Within the headlamp system fog lights separate the cover lenses directly in front of the reflector such as Free-form headlamps also known as FF totally without any additional patterning [3]. Glass is preferred mostly to form conventional cover lenses which must be free of errors such as streaks and bubbles. Though, the cover lenses are mostly made of plastic (polycarbonate having various advantages such as impact-resistant, light in weight, smaller production tolerances, more design freedom and special surface coating makes the lens scratchproof in compliance with ECE and SAE regulations [3].

There are four typical headlamp systems, paraboloid, FF-H4, Free-Form (FF) and Super-DE Headlamps (combined with FF headlamps) as shown in Fig. 3.

(a) (b) (c) (d)

Fig. 3 (a) Paraboloid headlamps (b) FF-H4 headlamps (c) Free-Form (FF) headlamps, and (d) Super-DE headlamps with FF headlamps [3]

The shape of reflective surface is parabolic in paraboloid lens. In distribution of headlamp light this is the oldest technology. They are rarely used nowadays. Still they make few appearances occasionally in large H4 headlamps and high-beam headlamps [3]. The reflector upper part is used in low beam from the front view as depicted in Fig. 3(a) [3]. The positioning of light source is carried out in such a way that upwardly radiated light on surface of reflector is downwardly reflected on the optical axis on the roadway as shown in Fig. 3 (b). To meet the standard legal requirements, light is distributed precisely in the cover lens [3]. The distribution of light is carried out by optical elements of two different shapes. The cylindrical vertical profile distributes light in horizontal direction and prismatic structures on a level with the optical axis. This further helps in distributing light in particular a way such that most crucial traffic spots get adequate amount of light as depicted in Fig. 3(c). The cover lens assembly has optical elements in paraboloid headlamp especially for low beam and to provide light distribution as desired as depicted in Fig. 3 (d). In this particular light distribution system, 2 light sources, 1 reflector, 3 bulb shields, and 4 cover lenses are used [3]. The useful light is approx. 27%,

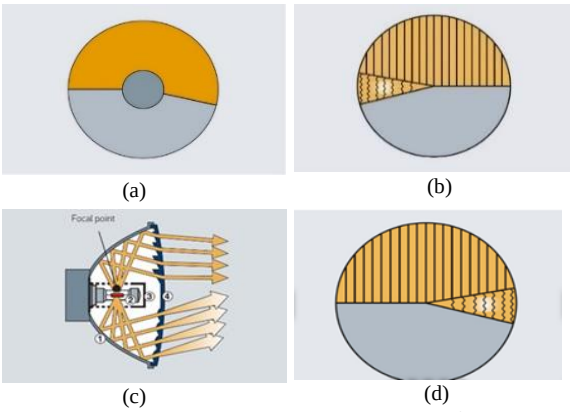

Fig. 4 Light dispersion due to cylindrical optics and deflection by prism in cover lens (seen from above) [3]

The reflective surfaces are freely formed within the space in Free-Form (FF) headlamps. Only computer can compute and optimize them [3]. The various areas of surroundings and road are illuminated by various parts of the reflector. This is specially designed in such ways to use all available reflective surfaces to produce the low beam as depicted in Fig. 4 (a) [3]. The aligning of areas is done in such a way that the light from reflectors is downwardly reflected for having higher visibility on the road as depicted as Fig. 4(b). The reflective surfaces made possible light beams deflection and scattering [3]. The use of clear, non-patterned cover lenses enables to provide the headlamp a brilliant appearance [3]. The horizontally arranged reflector segments generates the illumination and cut-off line of the right-hand edge of the road as shown in Fig. 4(c). The Fig. 4 (d) illustrates distribution of light on the cover lens of an FF headlamp. Nowadays all headlamp reflection systems are furnished with FF reflective surfaces.

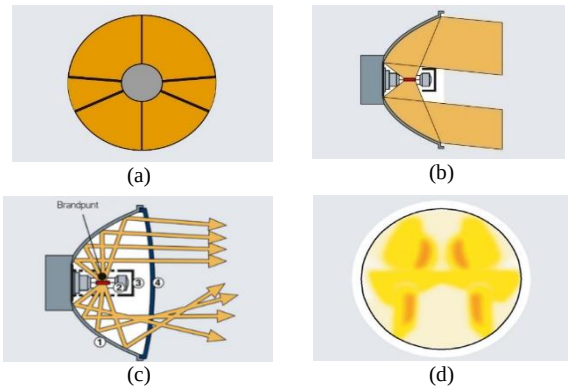

Fig. 5 Dispersion and deflection of light beam caused by reflective surface [3]

In this particular light distribution system, 2 light sources, 1 reflector, 3 bulb shields, and 4 cover lenses are used [3]. The useful light is approx. 27%, [3].

The projector type systems are employed in DE and Super-DE headlamps and they work in same way. The FF technology is used in design of the reflective surfaces [13]. In these headlamps, maximum light is captured by the reflector from the bulb as shown in Fig. 5(a). The light captured from reflector is then guided to fall over the shield and finally directed onto the lens as depicted in Fig. 5(b).

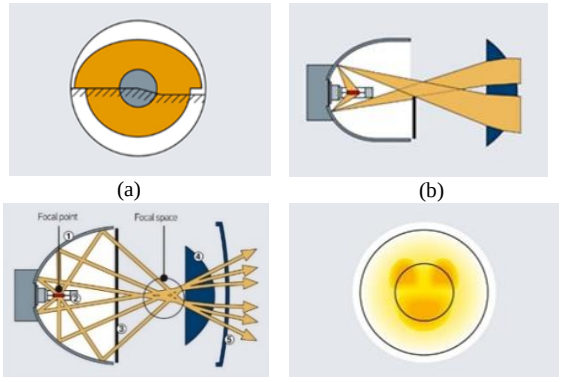

Fig. 6 Intensity of light in focal space and beam path (view from above) [3]

The alignment of light with the reflector in done in such a way that at shield light get distributed which is further projected onto the road with the combination lens as shown in Fig. 5(c). The Fig 5(d) shows a distribution of low beam on cover lens of a Super-DE headlamp.

The use of FF technology facilitates better illumination and wider scatter width on the road edges. To achieve greater visible range and relaxed driving during night time, the light is generally focused near to the cut-off line [3]. The FF reflective surfaces are vital part of all new projector-type systems for low beam. Generally, for greater light output, lenses having diameter between 40 to 80 mm are used. They also result in more weight [3].

As discussed about various types of headlights, the important points and issues related to construction and working of these lamps, there is still a need of improved version of headlamps as existing headlamps are not suitable for dense fog situation due to scattering and reflecting property of the light. The suitable type of headlight which could be the solution to the problems of low visibility due to fog are LED [8]. They have low power consumption, high life

and are eco-friendly. The scattering and reflecting properties of light could cause blindness for the driver in dense foggy conditions [8]. The projected light beam is unable to penetrate deep into the thick fog which makes the vision blurred. The laser-based headlights can be used to improve the vision and visibility for the driver due to high intensity and monochromatic nature of light. Still laser-based head lamps are not in practice due to its high cost and preferred in luxury cars. We require LED with high power and heating effects to achieve the desired result [10]. This approach of breaking down the water droplets by heating effect can be used in smart street lights [11] also they are installed on a specific height so they can also very well help in reduce the low visibility caused by fog.

In this paper, we have introduced a cost-effective solution to visibility problem during dense foggy conditions. We all might have noticed one thing that whenever sunrises the thick fog tends to evaporate. This happens because the fog which is formed due to the condensation effect, when sunlight passes through those tiny water molecules, they get evaporated and results clear sky. Therefore, the concept of evaporation needed to implement by some artificial means to make an effective headlamp. Therefore, some light emitting source which can produce light due to heating effect. Further, heat emitted light needs to be modulated on a carrier which ensures longer propagation distance with high intensity light. Further, high end projection lamps, lenses which can channel the light through them. Coating of Graphene layer must be used as it can withstand high heat temperature so that when the heat rays will pass through it the life line of the bulb in headlight doesn't degrades The light needs to be projected at such an angle and by projecting we need to control the spreading of the light so that the heating property of the light is hot enough to cause evaporation of the tiny water particles, hence the warm air through fog will travel forward causing the same heating effect and making the view much clear for the driver. The angle at which the light is being projected is assumed to follow parabolic profile so that the curvature of light traps the maximum fog under heating effect and clear the path from fog.

III. Proposed Solution

An experiment was conducted to justify the proposed solution to make visibility much more achievable by using thermal light headlight system. An artificial fog like condition was created at home by exhaling warm air on the mirror surface. The mirror surface being cold when it came in contact with the warm air caused condensation. The concept uses to create artificial environment is based on the principal of condensation as when we breathe out, we give out warm air which get freeze when comes in contact with mirror whose temperature is less than air. The moisture begins to come out from the air forming mist of tiny droplets just like fog. After creating artificial conditions just like fog, we noted the time it took to clear off the foggy surface back to clear mirror. So naturally it took around 1minute and 34 seconds.

Then we created an artificial working model just as of the conceptual model of thermal light headlight system. We focused a LED torch on the mirror surface very closely to generate the heating effect as to note what happens and what we noticed that after 1 minute the results were very different. The targeted area under the scope of LED light caused the foggy surface to turn normal into clear screen as the cluster of tiny water droplets the mist on screen broke due to the heating affect and two regions one still with foggy appearance and the other with clear visible appearance was noticed. After the conduction of this small experiment one thing was very much clear that focusing a light with heating properties does break down the condensation to evaporation state which will remove the foggy affect. Based on this small experiment it can be said that if this concept is introduced in headlights with much improved concave lens to converge and then emit light, much improved heating effect could be brought into implementation then it will break down the fog to increase visibility.

IV. Infrared vision Fog detecting system (IVFDS)

After so many discussions about the solution of this problem is not yet achieved. Now the problem has to be addressed not only for the light weight transportation point of view but also as per the requirement of heavy vehicle transportation too. Looking more deeply into the matter fog and its uncontrollable adverse effect on the other modes of transportation like Aeroplanes for air transportation, trains for road transportation, ships for water transportation. Presence of thick fog causes challenging problems for departure of scheduled container as well as passengers boarding their flight or ship which causes inconvenience to the people in form of cancelled flight, delay in importing and exporting of material causing huge bucks as a penalty to the government. So, to make this problem manageable the idea of Infrared vision Fog Detecting System (IVFDS) was proposed which ensures the measurement of the fog thickness for safety and employs thermal cameras to capture a rough idea and image of the any possible obstruction in the path [5]. Depending on the thickness of the fog the system will automatically adjust the intensity of the thermal lights to make sure that safety is not compromised. The preinstalled software will also make sure that it does matches the required conditions in terms to the fog density, the required light intensity and then if the conditions of the surrounding in any way compromises with the safety it will advise not to head start the journey.

For fog detection we will use fog sensors in our IVFDS system. Radar by disparity, operates better not with sound waves, but with electromagnetic waves [6] and this is a vital difference. Like ultrasonic, the waves when travelling collides with an object and as a result they bounce off. They travel at a known speed which is faster comparatively to the ultrasonic waves [6]. Radar is preferred above all because of its nature to not get affected by temperature, an improved consistency and accuracy. Radar also comes very handy and useful in other applications, such as operating in a vacuum, or in high pressure. One of the important reasons is dielectric constant of the target material [6]. Using materials with small dielectric constant does not reflect the electromagnetic wave, so radar passes right through it. To measure such materials having a low dielectric constant is just very gruelling so, to overcome the drawback of low dielectric property of the material which might cause less accuracy for the EM wave when it returns after bouncing back so Guided-Wave Radar (GWR) can also be used. Radar can also help us to detect

vehicles and their position in dense fog if our road visibility is still foggy [9].

A night vision system, based on thermal imaging technology that gives drivers a better view of the road beyond their headlights range. Using infrared technology, it allows driver to see hazards clearly in total darkness and can help in dense fog detecting nearby vehicles, people, and animals [5,12]. It spots the infrared energy (heat) and transforms it into an electronic signal, which is taken care of to generate a thermal image or video because the thermal image camera sees heat not light, it increases the visibility up to four times than headlights and it is not affected by smoke dust or fog. It works in both day and night and is not affected from glare of oncoming headlights.

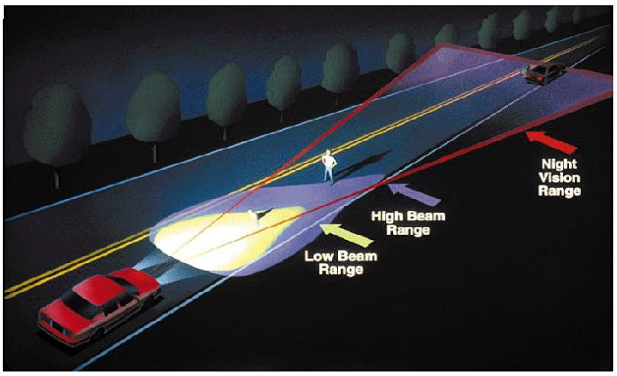

Fig. 7 The schematic illustration range of beam [5]

It will help us to know even if we are not able to see anything as it is not affected due to the fog or darkness. The image can be obtained on our windshield or on the Fog detection system. The sound alerting technology can be used in which if we don't want the image just the presence of any obstacle ahead of us will warn and alert the system and will generate beeping sound. This will also prove to be more economical because we have to make sure the technology should be economical and affordable for all. Fig. 7 illustrates the comparison of different beam ranges that can be used in IVFDS.

V. Conclusions and Future Scope

It is observed that the headlight preferred should be LED as they have low power consumption along with high durability and long-lasting properties. It is proposed that light should be projected in such a way that its heating properties could be used efficiently to reduce the fog. The fog detecting system based on infrared vision will make sure that there is no obstacle in the path of 8 ft to 10 ft. It uses the radio waves from the EM spectrum and does not need any medium to travel. The factors such as fog, hot, humid weather conditions won't affect it. It is also proposed that **IVFDS** will use radar and the magneto-inductive distance sensors for calculating the car speed and distance of impact. It will apply the emergency brakes without the knowledge of driver or it will also give a beeping sound to alert the driver so that when he applies the brake the throttle access is already cut off and it will lessen the impact and the frictional force on the driver.

It is a proposed idea which intends to improve the visibility problems in future faced due to the uncontrolled formation of fog.

Abstract— **The work is to design a 2x2 circular microstrip patch antenna array resonating at 2.4GHz and it is simulated for Wireless Sensor Network (WSN) applications by using HFSS tool. Circular patch antenna array is designed by depositing circular patches on FR-4 Epoxy substrate and is fed using microstrip feed lines. Fabricated antenna resonates at 2.391GHz. Antenna parameters such as Gain, return loss, Voltage Standing Wave Ratio (VSWR), Directivity, Reflection coefficient and radiation pattern are analyzed. 2x2 circular microstrip patch antenna produces more gain and less return loss compared to 2x2 rectangular microstrip patch antenna. The compact size and higher directivity compared to rectangular array makes it more relatively useful for WSN applications.**

Keywords—Microstrip Antennas; Circular array; Wireless Sensor Networks; Patch Antennas;

I. INTRODUCTION

Antenna basically converts electrons to photons or vice versa. The basic principle involved with the antenna is that the radiation is produced by the accelerated charge, As the separation between the conducting wires reaches the wavelength or more it tends to radiate so that the open end of the transmission line acts as antenna which launches a free space wave. The current on the transmission line flows out as the antenna end there, but the electric field associated will not die out. The radiation of antenna is in the form of circular wavefront at the transmitting antenna whereas at the remote distance the spherical wave transmitted by transmitting antenna arrives at receiving antenna as a plain wave, therefore antenna is a transducer or transition device between guided wave and a free space or vice versa [1]-[3].

On the basis of radiation, Omni-directional antennas are weak directional antennas because they radiate and receive less energy in all directions whereas Directional antenna radiate and receive in a particular direction.

In recent years, Microstrip patch antennas have gained a lot of importance because of their characteristics including light weight, high efficiency, high gain, high directivity and minimum return loss which will help in communication with different range of frequencies and used in applications such as remote sensing, medical fields etc. [4].

Circular antenna shows better results in terms of return loss and VSWR compare to rectangular one. Also, circular antenna shows better result when bandwidth and side lobes are considered. The radiation efficiency is similar in both the antenna which helps in compactable in similar kind of applications [5].

Antennas with more directivity can be used in improving network performance as they increase the alleviating contention and the communication range which can be used primely in Wireless Sensor Networks (WSNs). Along with directivity of the antennas, the compact size of microstrip antenna which are far better than the other enclosed or fabricated types of antenna also helps it in being suitable for WSN application use [6].

In this paper, firstly the related works that have been referred for this paper as a preliminary study have been briefed out in II. Then, we then begin with how the design is done starting from single antenna element in obtaining the array in III, followed by describing the gist of antenna parameters in IV, Further we demonstrate the simulated and testing results in V and compare the set of results for single circular element, simulated and fabricated circular array and the values of that of rectangular array in VI. Finally, we conclude with the future improvements that can be done over the designed antenna array.

II. Related Works

A similar rectangular patch antenna array for LTE applications are studied in [7]. The antenna is designed for 2.1 GHz applications and resonates at 1.86 GHz. Also, another rectangular antenna array is designed in [8] that works in S, C, X- bands. The array arrangements of 1x2 and 1x4 for 2 and 4 antenna elements respectively have been studied in that paper. Roger RT/duroid material with dielectric constant 2.2 and height 1.588 has been used as a substrate material. Microstrip inset line feed has been used for feeding the rectangular patch antenna.

III. Design Procedure

The design procedure can be broken down into two stages viz., Single element design and Array design.

A. Single Element Design

A circular element is characterized by a single parameter i.e., radius of the circle, denoted by a. Given the type of substrate used, desired operating frequency f_r, the radius a can be determined using expression (1) [9].

$$a = \frac{F}{\left\{1+\frac{2h}{\pi\varepsilon rF}\left[ln\frac{\pi F}{2h}+1.7726\right]\right\}^{0.5}} \quad in\ cms \qquad (1)$$

Where,

$$F = \frac{8.791*10^9}{fr\sqrt{\varepsilon_r}} \qquad (2)$$

B. Array design

1) Geometry: The geometrical arrangement of 2x2 is chosen while interelement spacing and the feedline widths are to be determined with the Transmission-line formulae.

2) Inter-Element spacing: Inter-element spacing of λ/2 is chosen in order to obtain the symmetric radiation pattern in both the directions uniformly, i.e., along $\theta = 0^0$ & 180^0 [10].

*3) Coaxial probe dimensions:*The signal from the microwave source is fed to the antenna through coaxial probe, whose dimensions are found using the following expression for characteristic impedance, Z_0 (3).

$$Z_0 = \frac{138*log_{10}\left(\frac{D}{d}\right)}{\sqrt{\varepsilon_r}} \qquad (3)$$

Taking ε_r = 4.4, choosing outer diameter, D=3.4mm, We obtain inner diameter, d=0.7mm. The design is shown in the Fig. 1.

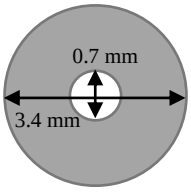

Fig. 1. Dimensions of designed coaxial feed

4) Feed-line widths: The supply from microwave source fed through coaxial feedline are further distributed amongst elements using inset feed lines, whose widths (w) are determined using Transmission line equation [11] shown in (4).

$$Z_0 = \frac{81.0}{(\varepsilon_r+1.41)^{1/2}}\, ln\frac{5.98h}{0.8w+t} \qquad (4)$$

Where, h and t are height of substrate (1.6 mm) and thickness of track (0.035 mm) respectively.

The dimensions of the parameters involved in the antenna design are listed in the Table I.

TABLE I. Values of the Antenna Dimensions

PARAMETER	DIMENSION
Height of the Substrate, h	1.6 mm
Dielectric Constant of substrate (FR4 Epoxy), ε_r	4.4
Radius of the patch, a	17 mm
Inter-Element Spacing	62.5 mm
Thickness of the track, t	0.035mm

The obtained design on HFSS 15.0 is shown in Fig. 2.

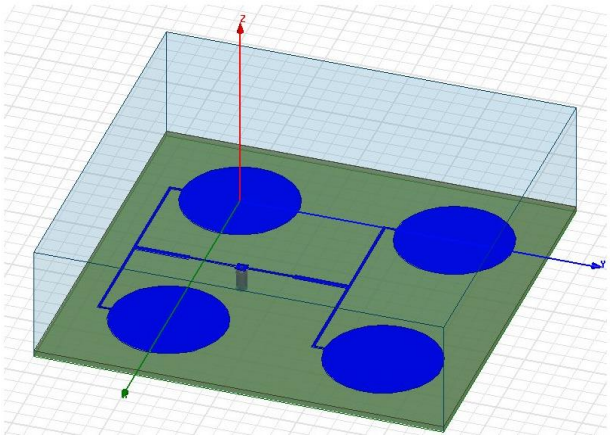

Fig. 2. Antenna design on HFSS 15.0

The fabrication is done and it is depicted in Fig. 3.

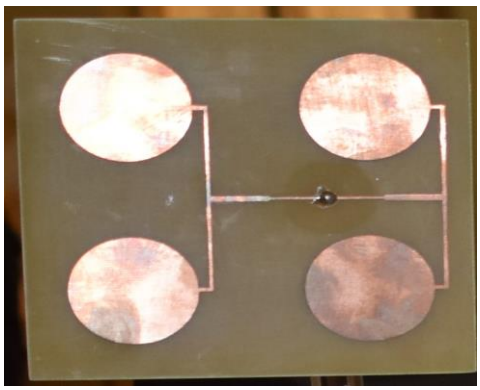

Fig. 3. Fabricated Antenna Design

IV. Parameters of Interest

A. Directivity (D)

Directivity is the pattern used in order to measure how directional an antenna's radiation pattern is. Directivity of a non-isotropic source is determined as the ratios of radiation intensity of the antenna in a reference direction to the radiation intensity of an isotropic source. Isotropic antennas radiate in all directions and hence their directivity will be 1 [12].

$$D = \frac{U}{U_0} = \frac{4\pi U}{P_{rad}} \tag{5}$$

Directivity can also be defined in terms of beam solid angle Ω_A as below

$$D = \frac{4\pi}{\Omega_A} \approx \frac{4\pi}{\theta_E \theta_H} \quad (\theta_E \text{ \& } \theta_H \text{ in radians}) \tag{6}$$

$$D = \frac{32400}{\theta_E \theta_H} \quad (\theta_E \text{ \& } \theta_H \text{ in degrees}) \tag{7}$$

B. VSWR

VSWR gives how efficiently the transmission of power takes place from the source to load. In perfectly matched systems 100% of power is transmitted. Therefore, the VSWR for such systems will be 1. It can be expressed as maximum voltage over minimum voltage of a standing wave.

$$VSWR = \frac{V_{MAX}}{V_{MIN}} = \frac{V_{fwd} + V_{ref}}{V_{fwd} - V_{ref}} = \frac{1 + \sqrt{\frac{P_{ref}}{P_{fwd}}}}{1 - \sqrt{\frac{P_{ref}}{P_{fwd}}}} \tag{8}$$

C. Reflection Coefficient (Γ) and Return Loss (RL)

Reflection coefficient is the one that describes how much of electromagnetic wave is reflected back due to impedance mismatch. It is expressed as the ratio of reflected voltage to forward voltage.

$$\Gamma = \frac{V_{ref}}{V_{fwd}} = \frac{VSWR-1}{VSWR+1} \tag{9}$$

Return Loss (RL) of an antenna can be used as an indication of how effectively the transmitted power of an antenna gets reflected. Since the return loss is the measure of how small the reflection is, more the return loss, less is the reflections and therefore the VSWR.

Return loss in terms of reflection coefficient is

$$RL(dB) = 20log_{10}(\Gamma) \tag{10}$$

D. Gain (G)

Antenna gain indicates how strong an antenna can send or receive a signal in specific direction. The usual description is with respect to the gain of an ideal isotropic lossless antenna. In terms of powers, P_r and P_t, it can be given as below:

$$Gain\ (G) = 10log_{10}\left(\frac{4\pi d}{\lambda}\sqrt{\frac{P_r}{P_t}}\right)\ (dB) \tag{11}$$

E. Antenna Efficiency(ε_r)

The efficiency in regard to an antenna gives the idea about how effective an antenna is in converting frequency power provided at its feedline into radiated power. This can also be defined in terms of gain and directivity as

$$G = \varepsilon_r D \tag{12}$$

V. Simulated Results and Testing

A. Simulated Results

The antenna design is simulated on the simulation tool, HFSS 15.0 and the results are obtained which are found to be almost same as the testing values obtained with the fabricated setup.

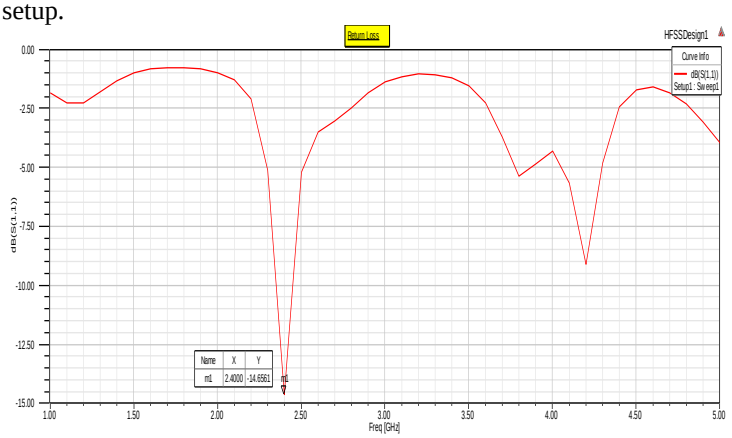

Fig. 4. Simulated value for Return Loss of Circular array

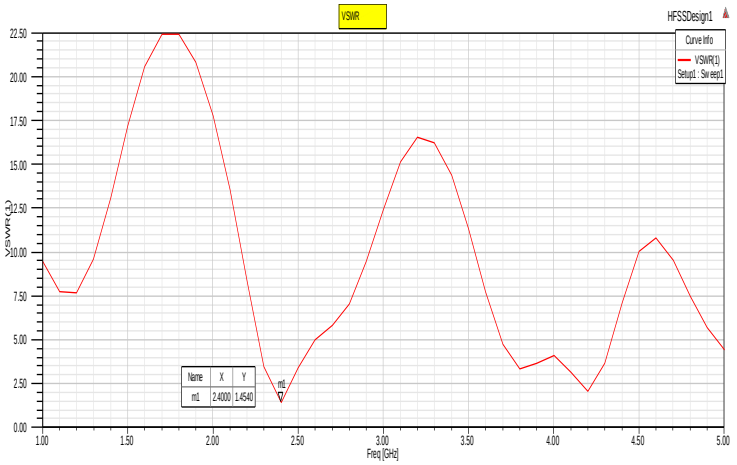

Fig. 5. Simulated value for VSWR of Circular array

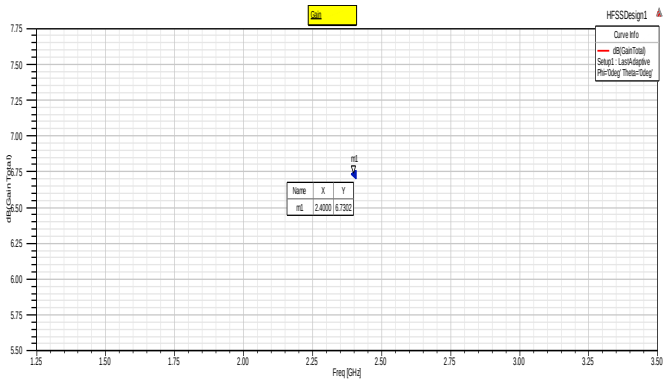

Fig. 6. Simulated value for Gain (in dB) of Circular array

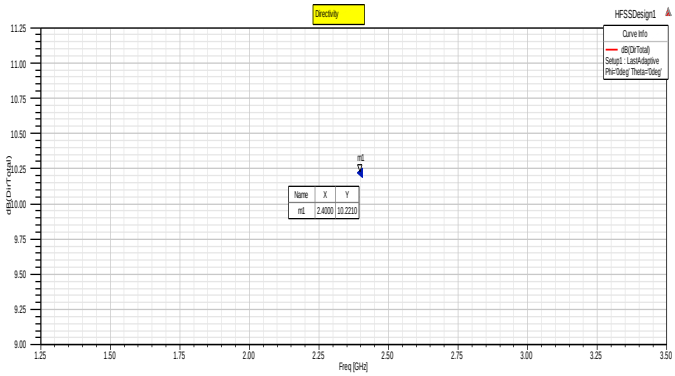

Fig. 7. Simulated value for Directivity (in dB) of Circular array

As shown in the result plots, the antenna array resonates at 2.4GHz as desired. Where, the values of Return loss, VSWR, Gain and Directivity are -14.6561dB, 1.4540, 6.7302dB and 10.2210 dB respectively. Reflection coefficient calculated with its relationship with VSWR is found to be 0.1850.

B. Testing

The minimum distance to be maintained between the Transmitting and receiving antenna are found to be more than 6.6 cm ($2d^2/\lambda$). Here d is diagonal length of the array antenna. Placing the arrays 42 cm away from each other we tested the fabricated antennas for transmission.

Fig. 8. Testing Setup

The transmitted power (P_t) and received power (P_r) are found to be 6.668mW and 50.582µW. From these values gain is calculated and is equal to 5.6dB. The forward power (P_{fwd}) and reflected power (P_{ref}) in an antenna are measured to be 933µW and 1.12µW respectively. Hence, values of VSWR and reflection coefficient are 1.07 and 0.0338. The θ_E and θ_H are found 50^0 and 55^0 hence the directivity is 10.712dB.

The obtained values over testing is tabulated in the Table II.

TABLE II. OBTAINED VALUES ON TESTING

PARAMETER	VALUE
Operating Frequency, f_r	2.391 GHz
Return Loss (dB)	-29.4216
VSWR	1.07
Gain(dB)	5.6
Directivity(dB)	10.712
Reflection Coefficient, Γ	0.0338

VI. PERFORMANCE COMPARISON

The performance comparison between the simulated and fabricated antennas over the rectangular antenna array [8] is tabulated in Table III.

TABLE III. PERFORMANCE COMPARISON

PARAMETER	CIRCULAR ARRAY		RECTANGULAR ARRAY [8]
	SIMULATED VALUE	FABRICATED VALUE	
Operating Frequency (GHz)	2.4	2.391	2.35
Return Loss (dB)	-14.6561	-29.4216	-18.32
VSWR	1.4540	1.07	1.74
Gain(dB)	6.7118	5.6	2.63
Directivity(dB)	10.5220	10.712	6.84
Reflection Coefficient, Γ	0.1850	0.0338	0.27

A circular array of 4 antenna elements was fabricated and tested to obtain parametric values. The obtained parametric values are found to be nearly same as the simulated values. Parameters like return loss, VSWR and Reflection coefficient are found to be better in the fabricated antenna than that of simulated values. In comparison with the rectangular array of 4 elements [8], all the parameters except for that of directivity, where the rectangular array seems to behave more isotropic than that of circular array. Additionally, return loss is found to be much better in the fabricated array with respect to that of rectangular array.

VII. CONCLUSION

A 2x2 circular antenna array that resonates at 2.39GHz frequency is designed using HFSS 15.0 simulation tool and is fabricated and tested to obtain the antenna parametric values. The fabricated antenna values are comparatively similar with respect to the simulated values. It is found to yield better values in terms of Gain, Return loss, Reflection coefficient and VSWR over rectangular array antenna. Wireless Sensor Network applications employ antenna that are highly directional as the data flow from the nodes are unidirectional

towards the control node, which in turn, is directional with the other antennas with other networks. Hence, the designed array can be used in applications of Wireless Sensor Networks due to compact size of microstrip antenna and comparatively high gain in accordance with that of rectangular antenna array at 2.4 GHz frequency. Parameters like the gain and directivity can be further improved by increasing and employing the number of antenna patch elements. It can also be made of lesser patch element size by using a relatively higher dielectric constant material.

ACKNOWLEDGMENT

We thank our Institution, Bangalore Institute of Technology and our Department, Department of Telecommunication Engineering for providing us laboratory facilities for experimenting and testing. Also, we are grateful for Technilab Instruments for helping us in fabrication and fundamental testing of the Antenna.

Abstract*—In wireless sensor networks (WSN) key management is a working research subject. As we have large number of key management schemes (KMS) that are designed for sensor network, it is not easy for network designers to know which KMS is perfect fit in a specific WSN operation. This paper presents an exhaustive overview of different schemes along with their advantages and disadvantages. As KMS is the stepping stone of any security mechanism in a sensor network, its effectiveness depends on the underlying scheme. KMS in a WSN guarantees communication between one or two pairs node batch. We have analyzed different schemes based on parameters such as storage cost, communication cost and resilience against node capture.

Keywords— Wireless Sensor Network, Key Management, Computation, Storage.

I. INTRODUCTION

Deploy wireless sensor network (WSN) is a remote, sensitive and sometimes unmanned hostility, environments at a high risk of physical attack. Topology, network size, and sensor density that make it complex to implement the placement of a node before deployment is unknown. Also, wireless communication requires usage of spatial multiplexing. Sensor nodes share media in many other nodes. Thus providing security with wireless sensor network is very difficult. The disparity of the continuity of information in WSN increases all attacks quickly, putting the entire network at risk it is a short time. So in addition to protecting the wireless link we have to limit the range of node capture between sensor nodes Attacks are a very important issue in WSN security.

The main factor is the nature of wireless transmission that leads to WSN vulnerabilities in various situations Malicious networks attack many security mechanisms Proposed against potential attacks In WMN, the non-exhaustive list includes locations technology [3], [4].

Wireless connection, unattended deployment, closedown interaction of nodes makes security a big challenge. In the physical environment. It is helpless against different assaults, for example, getting the knot and transport. Interference also rejection of work also by Information provided by wireless sensor networks Significantly increased. All transmitted information needs to be protected which is exchanged over the network. So one of the first requirements is to distribute encryption key to WSN during setup phase Sensor nodes are used to protect information exchanged with each other each combination or Node set [2].

Every key management scheme (KMS) requires sensor node to store some key information. It is an primary parameter to evaluate its performance. The main storage overhead is the storage capacity required for each sensor node that is used for storing key material. Sensor node with limited storage, so the key management solution should be storage efficient. Most of those already suggested key management scheme based on key pre-allocation of keys. These are schemes are inefficient because each node requires large memory However, several ideas have been proposed recently. The scenario has Reduce these storage requirements

The architecture of WSN is given in Fig. 1. In this architecture given components are shown sink node, user and nodes. All components are connected to the internet and wireless medium. In this source and target are given figure.

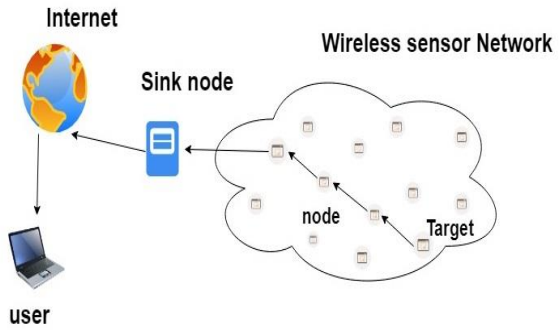

Fig 1: Architecture of Wireless Sensor Network

A. *Key management in WSN*

It is set of process and mechanisms that support effective exchange of keying information among sensor nodes [12]. WSN security requires data confidentiality, authentication, data integrity, availability, durability access Control. Key Management Security solutions in WSN include scalable,

robust and lightweight. Lightweight, effective and efficient management of keys and keys Distribution mechanism and use of the WSN certificate Because the attacker is not secure, one common key Get the key easily. So you can build a WSN Environment to distribute keys in the following manner Scheme:
Data is provided to provide a secure connection Encrypt and authenticate with the key. the key Safety management and distribution planning Applications in such networks should provide scalability. Reliability and confidentiality of integrity and flexibility. From Share one key to communicate with WSN It is not safe because the other party can easily find the key. Thus, the sensor network is used to manage different keys How to ensure communication.

B. Security constrainment

Scalability: The WSN security solution must support in a large network, you must be flexible and work well with tremendous increases.

Authentication: Authentication is a security feature that guarantees messages sent by authentication. There are four main types of resource authentication Technology: One-way, bi-directional or reciprocal authentication , triple authentication, implicit Degree. commonly, input verification allows the recipient to confirm that data is already Posted By requested vendor. If two parties communicate, input verification Achieved in a pure way symmetrical Technique.

Confidentiality: Sensor networks do not leak from Read Sensor the surrounding network. In several appliance, nodes can pass sensitive data a standard way to preserve sensitive data by encrypting data using a private key that is only owned by the beneficiary. In the monitored connection mode, create Secure channel between node and base station, and then route the other secure channels as needed.

Integrity: Data integrity communication that the data received by the recipient does not change in the transfer of the discount. Implement data integrity through authentication. This feature is more powerful.

Lightweight: Because of the power reduction of the sensors Solutions need to use less power by reducing calculations without affecting security services.

Fault-Tolerant: I know wireless media I cannot trust them. The contract can be attacked without notice. Therefore, design your own security solution with these issues in mind and remove problem.

Storage Cost: Capacity costs or storage costs characterized as sensor nodes by exploiting wireless sensor systems heterogeneity. In storage we store the important information of the node.
Computation Cost: It is a parameter to major the performance of key management during key updating, recovery to the key sever. Storage cost and computation cost both are dependent to each other.
Resilience Node capture attack: Node capture attack is define when external adversary can capture Sensor node accesses important information of keys to break the security of linked nodes. This type of attack greatly undermines the security, integrity, and confidentiality of the network. When an attacker captures a series of sensor nodes, these nodes can be modified based on software programming and hardware configuration. You can then use one of the sensor nodes to initiate a further attack on the network.

This paper presents an exhaustive survey of different matrix based KMS. We have evaluated these schemes on different parameters like storage cost , computation cost and resistance against node capture. It aims to provide an insight to different researches about the efficiency and scalability of different schemes for various WSN applications.

This paper organized as follows: Section II describe the introduction of wireless sensor network and key management and second section contribution of this paper. After this existing schemes for key management scheme are explain and make a table I as well as make a table II to define parameter use in table II. After this make a graph between no of nodes and total storage cost for existing scheme given table I and write the conclusion and future work of this paper.

II. EXISTING KEY MANAGEMENT SCHEMES

Du et al presented [1] a predefined random key allocation scheme is utilized to utilize distributing learning, where every node just needs to convey a little piece of the keys required for other pre-master allotment frameworks. [9],[10]. To realize Same level of connected memory minimization. It neither alone reduces the memory requirements of memorization consuming sensor nodes. But more important. It is essentially Network Optimization flexibility for Capture the node.We used our offer to show these improvements analysis and simulations outcomes.
Perrig et al presented a security scheme in wireless sensor system in [2] to explain the networks security services and how to secure a system to various attacks and describe. We need a safe and proficient key distribution mechanism to make keys for large-scale sensor network effectively.
Bahl at el presented [3] Radar a structure RF-based client area and following framework and RADAR works recording and handling signal data to the numerous base stations and present the experimental results of the Location accuracy is high.
Yang et al presented [4] analyse the trilateration limitation and proposed a new novel based scheme inherits the easiness, efficiency of trilateration on time and improve the performance of local nodes also prove correctness and optimal design showing in this paper.
Blom et al introduced the key dissemination based upon[5] the lattice based key administration plot. Blom scheme depends on greatest Distance Separable code utilizing The generator

matrix G of direct code (N, k) on GF (q), N is the length of the secret phrase, k is the elements of the code, i.e. G, are matrices (k × N).Element of GF (P). Where q is the power of prime numbers. MDS The code [6] is characterized by the separation d = N - k + I. Equal to state that any column of k are straight G It's free. Thus, the code can only be specified by: Find out the k element of the line We cannot disclose code information [11].

The program is implemented in two phases. The first is the pre-appointment key and the second is the main stage of incorporation.

Key pre-distribution phase:-

$(\lambda+1)\times$n=public matrix G;

$(\lambda+1)\times(\lambda+1)$ =private symmetric random matrix D.

Key establishment phase:-

K = $(D \times G)^T \times G$, point Kij =Kji figured from open and secret matrix.

the nodes i and j registers the pair astute key as Kij = row x colj = row j x coli=Kji.

Katz et al presented [6] cryptography CRC press in this cryptography algorithm explained also so many algorithm symmetric and asymmetric key cryptography and how to use these algorithm for security and encryption, decryption and shared key cryptography.

Chien et al presented an EPKEM Plan proposed [7] Cheng and Agarwal [8] supports large networks and can Provide a complete network connection, but appears to be vulnerable to Capture the node attacks. They tried to make the network more flexible to catch attacks on the nodes. Unfortunately, this program has not yet provided resistance to Capture the node attacks. The second question that makes this solution What cannot be used is non-scalability. The tertiary question in this solution is that each sensor node compulsory a large storage cells, making it unsuitable for deployment on WSN with many nodes.

Cheng et al exhibited [8] a proficient pairwise key foundation plot for static wireless sensor systems. In this paper, successful designs to build up and oversee two-path changes to accomplish arrange availability and adaptability of fixed wireless sensor systems have proposed. This arrangement underpins enormous networks sizes and has less availability and arithmetic contrasted with current master pre-designation plans.

Eschenauer et al presented [9] a distributed sensor networks Distributed sensor network (DSN) is a mobile network that includes a sensor contract with limited computing and communication capabilities. This paper proposed the main management scheme. Designed to meet the operational and security requirements of the DSN network also show the re-keying concept without computation and communication capabilities.

Chan et al introduced [10] an irregular key redistribution conspire additionally three system for key foundation utilizing the pre-distribution strategies. First is q-composite key, second is multipath reinforcement scheme and finally present a random wise pairwise key scheme. During capture of each node, it completely preserves the confidentiality of other parts of the network and allows for revocation based on authentication and reconciliation between nodes.

Rahman et al introduced [11] a novel for scrabble key administration conventions for remote sensor networks also characterize which conventions are use in key administration thus many think in this novel.

Ankit Gupta et al presented a new plan [12]to overcome this problem deficiencies of two scheme [5] ,[7] and improve the system's Resistance to node catch assaults. In this the solution provides full connectivity and less overhead and more energy efficient. It also provide greater scalability support. In this the third stage of the scheme is the scheme [9]: the pre-allocation of the key, the creation of the double key, and the erasure of the obsolete parameter.

Chaurasia et al presented a [13] mainly focus on weaknesses of Chien [7] and suggest a plan which is placed on Blom's [5] to eeliminate weaknesses from previous plans. Proposal the program offers better protection against attacks captured on node analysed to Chien et al 's scheme. The calculation cost is a bit high, but its memorization requirements are much lower. It is used to store the keys can support more nodes. In this network and using the XOR operation overhead being limited and provides better scalability.

Zhang et al presented a [14] create a key security problem key in wireless technology. technology. Engage Network This paper proposes a new matrix based The pairing key is included by deploying the design in the wireless network. Latest plan is very useful Storehouse sensor node and light correspondence No important accounts provided. In addition, our solutions are scalable, also protected. Opposition attack capture node. The basic design concept This solution This is a heterogeneous wireless network.

Praveena et al presented that [15] they have seen how Modern Encryption Standard version –II algorithm can be used in this document to accomplish safe communication. Compared to any conventional technique, the technique is also very adaptable. Any Java or Matlab can develop a program for encryption or decryption. Even simplified changed vernam cipher is used for the variable block size or variable key, and encryption is achieved in two forms.

Jyothirmai et al presented a [16] Wormhole and black hole attack have been major safety threats that undermine the efficiency of that same Wireless Ad Hoc Network routing protocol. It's tracking and separation is the primary issue for increasing the +quality of a network. In this Major the performance using various parameter Packet shipping ratio, performance, end-end delay, good performance and overhead routing by analysis of the amount of nodes in the network and blackhole nodes.

Priyanka et al presented a [17] vulnerability estimation model that can be used to to strengthen any security mechanism. It exploits various vulnerable factors to build an attack matrix that is later used by network designer to increase the system resistance against node capture attacks

TABLE I. Comparative analysis of existing schemes

S. No	Scheme	Nun	Nus	Storage cost	Computation Cost(C_c)	Resilience node capture attack
1.	Blom's 1985		1	$2(\lambda+1)\|q\| \times N$	$\lambda+1$	yes
2.	W.Du.J.Deng 2004	$P_t(a+b)\tau$	$P_t(1-2a-2b)\tau$	$\tau((\lambda+1)\|q\|+\|q\|) \times N$	$2\lambda-1$	better
3	Chien al's 2008			$(N+3)\times \|Key\|$	$NT_{mul}+T_h+(N+1)T_{add}$	No
4	A.parakh and S.Kak 2011		1	$3N\|q\| \times N$	2N	yes
5	Avinash Chaurasia,Utkarsh Dubey,R.k Ghosh 2012			$(\lceil\sqrt{N}\rceil+2)\|Key\|$	$(N+1)T_{mul}+T_h+T_{pow}+(N-1)T_{add}$	Yes
6	Yuexin $Zhang^1$,Li Xu^{1*},Yang $Xiang^2$, and Xinyi $Huang^1$ 2013	4	7	$\varepsilon_H \times 7$ $\beta \times (\lambda+1)\|q\|+(\|q\|+log_2^N+log_2^\xi H) \times N$	$2\lambda+1$	No
7	Ankit Gupta 2014			Floor($\sqrt{N}$)	Less	No

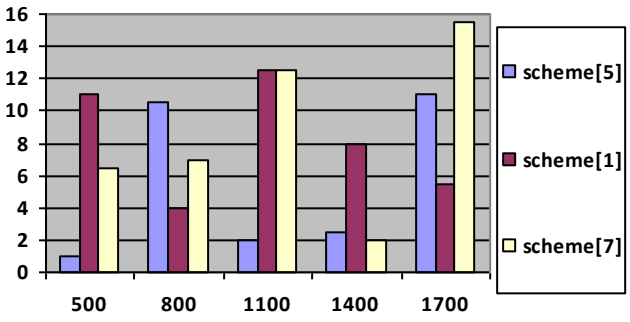

Fig 2. Relationship b/w number of nodes and total storage cost of different schemes

TABLE II. Symbols and their meanings

N	The number of nodes of the sensor
λ	The security parameter of the system
β	Number of sensor nodes per sub-area
ε_H	Number of key locations
P_i	Local Connectivity
N_{un}	Number of key shared spaces between neighbouring nodes
N_{us}	Number of key spaces shared between neighbouring nodes from the same regions
C_c	Computation cost of sensor nodes
τ	Key space
T_{mul}	The cost of beating one
T_h	Calculate the cost of a one-way hash
T_{add}	Single plus cost
T_{pow}	Increase the cost to a certain power
$\|Key\|$	Stored number size

III. Result and Discussion

Table I gives the comparative analysis of different schemes for WSNs. Different parameters such as storage cost, Computation cost and resilience against node capture are used to quantify the performance of different schemes. The performance of any KMS depends upon computation cost and this depend on key length and network size as well as storage cost. Blom's [5] scheme based on matrix and show the node capture attack and node are self-deployed. Zhang [14] scheme was based on deployment and pairwise matrix based in this no node capture attack and computation cost is depend on network size and connectivity between nodes were better. All schemes are analyzed and result are shown in the table I. Fig 2 Show the relationship between total storage cost and number of nodes in this all given scheme in table I.

Each sensor node in Blom's et al scheme [5] is associated with key-spaces, and for each key-space, the node is loaded with the corresponding row of its matrix A. So, the total number of storage cost are $2(\lambda+1)|q| \times N$ and scheme [1] are $\tau((\lambda+1)|q|+|q|) \times N$ and scheme [7] are $(N+3)\times |Key|$.
The cost of light storage at the sensor node is achieved by exploiting the heterogeneity of wireless mesh networks: mesh routers have more storage space than sensor nodes.

In scheme [5], each sensor nodes needs to store $2(\lambda+1)|q| \times N$ bit key material bits for whole networks and similarly the total cost in scheme [1] $\tau((\lambda+1)|q|+|q|) \times N$ Fig. 2 show their relationship when $\lambda = 18$, $\tau = 13$ obviously, the total storage cost of scheme [5] change the values of some points because of depends system security parameter and unique key seed $|q|$ and analysis of all the parameter in Table I. In scheme [7] is also depends on the size of number stored in node.

CONCLUSION AND FUTURE WORK

The Wireless Sensor Network, a set of sensors, performs many of the integrated functions of remote data transfer to remote base stations. Security is the key to strong communication between nodes in WSN. In this paper we describe the classification of the wireless sensor network key management scheme and compare various parameters like, storage cost, computational cost and resilience attack and some scheme focused on local connectivity. Future work improvement is to real time, by considering security, to increase the security and minimize the storage cost of Wireless sensor network as well as computation cost and make a good connectivity between nodes.

***Abstract*- Document Classification is the problem of assigning documents into predefined category making it easier to manage and sort documents. There are several algorithms using which the problem of classification can be solved. We use feed forward neural network with multiple layers (also called multilayer perceptron) trained using backpropagation algorithm for the problem for categorization of resume to make management of these documents easier. Neural networks can learn and model non-linear and complex relationships and model generalize solutions that can predict on unseen data. Applications of neural networks are character recognition, image processing and stock market prediction. Backpropagation algorithm which trains the neural net is a supervised learning approach which learns from errors in order to minimize it, thus, requires a lot of training and storage to produce efficient results.**

Keywords- Multilayer Feed-Forward Neural Network, Backpropagation, K-Nearest Neighbour, Support Vector Machines, Naïve Bayesian, Neural Networks, Artificial Neural Network System.

I. Introduction

With increase in a large amount of information there is always a need to classify documents into a specific category which normally requires manual user intervention. One such problem arises in classification of resumes. Companies receive large number of resumes on a daily basis and have a slight amount of time to have a quick look on every single resume to know for which job specification it belongs. Usually manual intervention is involved for this task. We studied different classification algorithms for solving the problem. The purpose of this paper is to provide a solution using Deep Neural Network for simplifying the task of classifying resumes to predefined category or specification to which it belongs. Using backpropagation algorithm, we trained a neural network model on dataset of resume. We also trained a standard SVM and KNN model on the same dataset and compared their accuracy on testing data and presented the results.

II. Literature Survey

There are many ways in which the problem of document classification can solved. Some of those ways are: K-Nearest Neighbour (KNN), Support Vector Machines (SVM), Naïve Bayesian (NB) and Neural Networks (NN).

A. K-Nearest Neighbour

K-Nearest Neighbour is a non-parametric method for classification. Here, each document is represented as a node or object in euclidean space. K-Nearest Neighbour is an example of classification algorithm in which the objects are categorized into classes considering the smallest distance between the class and the object [3]; The disadvantage of K-Nearest Neighbour is that it takes a large amount of time for classifying objects if the training dataset is large since it has to choose few objects by calculating the distance of each test object using all the data points in the training set.

B. *Naïve Bayesian*

The second method for text categorization is Naive Bayesian. It is different from K-Nearest Neighbour by the fact that it is trained using the training data beforehand to classify the new examples. Naive Bayesian does the classification of documents based by calculating prior probabilities of the predefined categories/classes and probability that a certain attribute value belong to a specific category. Here, we assume that attributes are not dependent on each other; However, this assumption may violate the fact that attributes are not dependent on each other in a text classification application. Also it does not take into account the number of occurence which may be potentially useful [3].

C. *Support Vector Machines*

The next approach is the use of SVM for text categorization. This is a more popular machine-learning algorithm than the other two mentioned above. SVM is based on the idea of classifier which is linear. The idea of SVM is different from that of perceptron model in the sense where if a distribution of training examples are not linearly separable, then the examples need to be mapped into another space where the distribution becomes linearly separable.

D. *Neural Networks*

An Artificial Neural Network (ANN) is an information-processing model inspired by the biological nervous system to process information. Its model replicates the most basic functions of the brain. Artificial Neural Network possess large number interconnected nodes or neurons. They perform computation in parallel way but are configured in a regular architecture. ANNs collective behavior is recognized by their ability to learn, recall and generalize the training patterns to that of a human brain. One of the methods of Artificial Neural Network System (ANS) named Backpropagation can be used to solve text categorization problem. There are good reasons for using it for text categorization. ANS provides a better solution for problems that cannot be solved sequentially or by sequential algorithms. Other applications of artificial neural network include matching of images [5]. They result in better performance. Backpropagation algorithm is widely used among the rest of the algorithms given by ANS. Backpropagation is very useful in recognizing complex patterns and performing nontrivial mapping functions. Neurons are processing elements in the neural network. The lines that connect the neurons are called weights. Every line of processing elements is a layer of a network; Though there can be multiple layers present in ANS in BackPropagation network (BPN) generally there are three.

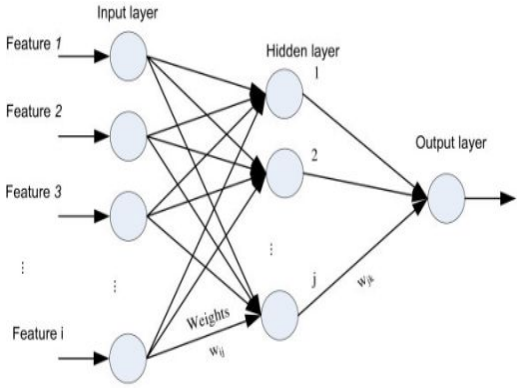

Figure 1 Architecture of neural network

III. IMPLEMENTATION

The general procedure for document classification :

A. *Word Extraction*

In the first step, we are required to convert the document that has many stream of characters into tokens or words for identifying features. In IR, this tokenization process either known as word extraction or word breaking.

B. *Stop Words Removal*

Many words like “a”, “the” are not very helpful in indexing, we need to remove these words from the words that are extracted from previous step. Since these words fall in every English paper they hardly assists in determining the class of that document. We can't differentiate between types of document with these words. The procedure of removing such non influential words from the group of words created by word extraction is called as stop words removal. For this step we create a group of stop words that are to be withdrawn from extracted words.

C. *Word Stemming*

In a document there can be many variations of a word that may be present. One example of this is the word “appear” may also exist as “appearing”, “appeared”. These words basically provide the same meaning but are in different formats. Thus for classification it is desired to combine such variations into one form each. This process of combining joining dissimilar variations of the matching word into a sole form is known as stemming. The module that performs the function of stemming is called a stemmer.

D. *Weights to terms*

We create a vocabulary of terms from document set by measuring the importance of the terms. We assign to each term a weight which indicates the comparative significance of the term in a document. For term frequency(TF), we calculate the total occurence of each term in a document. For inverse document repetition, defined as:

$$IDFi = Log(N/n) \quad (1)$$

Where IDF=inverse document frequency of ith index term, N is nothing but the number of papers in the group and n is an integer number of document ith index terms appear.
For term weighting, which is the multiplication of the term frequency (TF) and the inverse document frequency (IDF):

$$Wji = TFji \times IDFi \quad (2)$$

After calculating the TF-IDF values of each term in a document set, we establish a threshold calculated using mean of all the values and include the terms with higher TF-IDF value than threshold into the vocabulary set. We create bag of words representation of each document using this vocabulary set and pass it on to the neural network.

E. *Neural Network Based Classifier*

For categorization of the documents, vectors representing the documents are handed over to the start level which is input layer of the neural network classifier as input signal. These input signals are then circulate forward along the neural network so that the result which is output of the neural network is calculated in the output layer. We use sigmoid as the activation function in the output units, the result output of the neural network classifier is nothing but the classification vector which contains the values in the scale [0, 1]. This real-valued categorization vector produce a group classification decision, in which the ith vector component represent the likelihood that the input document associate to the ith group [2]. The neural network is trained to reduce errors using backpropagation learning wherein the weights in the layers are adjusted based on output loss function calculated for a particular input. The loss function is absolute difference between the actual and observed values.

Testing:

The dataset collected is randomly separated for training and testing the model. The testing dataset that was held back from training is first preprocessed: words are extracted, stop words are removed and stemming is done. Bags are created of each document using vocabulary set created during training and sent to the now trained neural network for predicting the document. Neural network classifies document to a category based on the certain words appearing in the document.

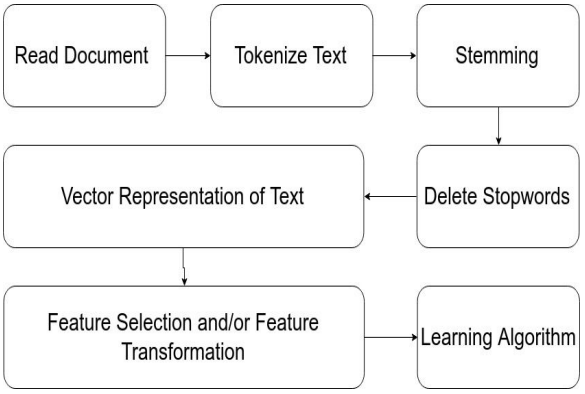

Figure 2:Module division

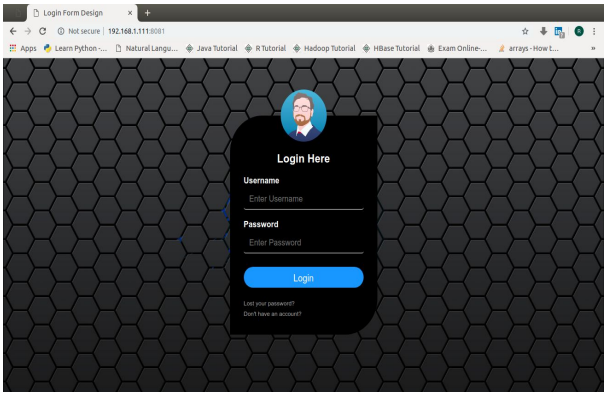
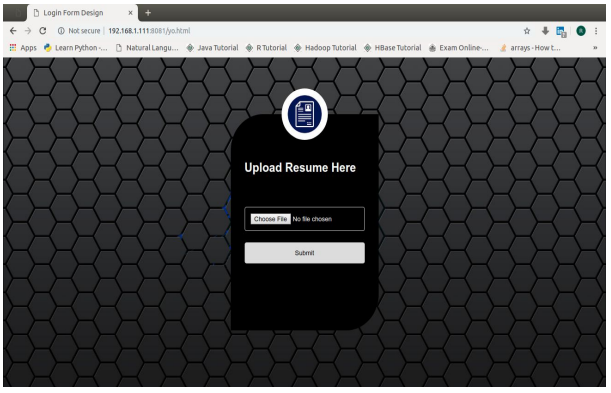
UI Screenshots:





IV. RESULTS

We have implemented three different machine learning models namely K-nearest neighbour, Support vector machine and Neural networks to compare the results.

The training and testing data were common to all three models whose details are as follows

TABLE 1:DATA SAMPLE SIZE

Labels	Training data size	Testing data size	Correct Result	False Result
1.Data Science	150	50	47	3
2.Fashion	75	25	22	3
3.Finance	112	38	35	3
4.HR	81	27	25	2
5.Software	150	50	47	3
	Total=568	Total=190		

The accuracy of each model when trained and tested over the above mentioned data is represented in a tabular format below

TABLE 2:ACCURACY COMPARISON

Model	Accuracy
KNN	61.5%
SVM	82.6%
NN	92.3%

Since the data points are very large in number we have to limit the number of object to which the KNN calculates the distance to find out the similarity factor between the objects, this reduces the accuracy of KNN model largely.

The textual data is an unstructured and correlated data. A particular data point may resemble more than one class. Thus mapping of these data points into another space to achieve a linear separable problem induces an error in classification which affects the accuracy of SVM.

The neural network model is trained using backpropagation algorithm to reduce the error in output by adjusting itself for a particular input, breaking down the problem into smaller parts and ability to handle complicated and unstructured data help it to largely outperforms the other two classifiers into taken into consideration.

IV. Conclusion

In this paper, we have mentioned the need for classification of resume documents and identified different machine learning algorithms used for classification. We have listed the various advantages and disadvantages of each algorithm. While bayesian classification is suitable for low dimension, KNN grows with number of documents. SVM cannot scale well with number of documents. Neural network can be self-adaptive and suitable to complex problem. Classification of resume can ease the task of managing large number of resumes of different types.

For future scope, the neural network model can further be trained to classify more categories of resumes. Much larger dataset is required for accomplishing this task. Documents classified to certain category can be ranked using some machine learning algorithm to find the best applicant for a job.

V. Acknowledgement

We would like to thank our guide Mrs.Suruchi G. Dedgaonkar, for her ideal enlightenment, helpful feedback and persistent motivation from start to end of the project. Her treasured recommendation were of vast help throughout our project phase. Her perspective condemnation kept us working to make this project in an exceptional way. Working under her was a tremendously brilliant training for us.
We would also love to present our heartfelt appreciation to all our friends and colleagues who contribute in the survey, without which this research work would be insufficient.

***Abstract*—Data acquisition of electric drive is very much relevant in the context of electric vehicles. Different data like IGBT temperature, diode temperature, coolant temperature, electric machine coolant temperature, motor torque, electric machine speed data etc. have to be acquired and analyzed in electronic control units. Data samples are processed in RAM using various algorithms and relevent information is extracted and transferred to ROM as various maps. These information are useful in life time estimation, failure analysis and optimum design of various electric drive components. Histograms and rainflow counting are conventionally adopted methods in data acquisition. Histograms may include irrelevant information and also require large memory space. Normal offline rainflow counting also demands large memory, which necessitates the need for an optimum memory consuming data acquisition algorithm. An online rainflow counting algorithm based on three point method can minimize the RAM space consumption by significant amount. The data counts remains same as in offline rainflow algorithm. Instead of using histograms for data like electric machine speed, data counts for only the relevant operating range can be stored, which minimizes memory requirement. Also level crossing counting is another algorithm which can be adopted where we are interested only in threshold crossings of the parameter acquired, for example the threshold crossing of inverter phase currents, which can cause serious damage to the system. Memory requirement minimization achieved by the above mentioned algorithms are validated by simulation.**

***Index Terms*—offline rainflow algorithm, online rainflow algorithm, level crossing counting, histograms.**

I. Introduction

Different data acquisition algorithms are used for processing and storing electric drive data. Histograms are conventionally used storage method, which consumes large memory space. Other advanced counting methods are used for filtering and storing input data without losing much granularity. Level crossing counting, as per ASTM standards is implemented, where preset threshold crossing information of acquired data is required[2]. In peak counting the peaks and valleys are counted based on a preset level. Peaks higher than the reference level and valleys lower than the reference level are counted[2]. Simple range counting and maximum edge counting are other conventionally used cycle counting methods[2].Rainflow counting is another widely implemented algorithm in cycle counting and fatigue analysis. Different variants of this algorithm is used. Rainflow algorithm based on pagoda roof analogy proposed by Endo and Matsuishi is the basis for all rainflow varients[3]. One of the most widely implemented rainflow algorithm was proposed by Downing and Socie. This three point algorithm was specified in ASTM E 1049-85[2]. Rainflow cycle counting algorithms provide means for comparing obtained variable amplitude load history with constant amplitude load pattern. Rainflow algorithm identifies closed hysteresis loops in the stress - strain plane and provides a method for treating open loops[4]. Other modern methods like Moshrefifar and Azamfar counting were later proposed, but rarely adopted due to complexity in the procedure[5]. In the above method rainflow counting is widely adopted and efficient method, but consuming lot of memory. An online rainflow counting based on the three point algorithm can considerably reduce the RAM consumption[6]. The input data samples are filtered and processed and relevant data is extracted at the instant when the input samples are obtained and the samples are discarded, reducing RAM memory consumption. The online three point rainflow algorithm can be used in data acquisition of various electric drive parameters like IGBT temperature, diode temperature, coolant temperature, electric machine speed etc. in the electric drive.

II. Offline Rainflow Algorithm

A. Algorithm

For a sample load-time history as in Fig. 1, let 'X' be the current range, 'Y' be previous range adjacent to 'X' and S be the Starting point in the history. The three-point offline algorithm as per ASTM E 1049-85[2] is specified below,

A) Read next valley or peak. If end of data then go to step F.
B) If the number of turning points is less than three then go to step A. Update X and Y with three most recent valleys & peaks that are not eliminated.
C) Check the magnitude of ranges Y & X.
  A) If X<Y, go to step A.
  B) If X>=Y, go to step D.

D) If Y includes S them go to step E, if not count Y as a full cycle and remove the turning points in Y & go to step B.
E) Range Y is counted as a half cycle and remove the initial point in Y and set next point in Y as starting point and go to step B.
F) Count remaining ranges as half cycles.

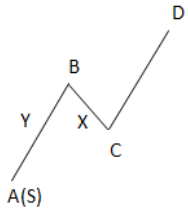

Fig. 1. Sample load history showing ranges and starting point.

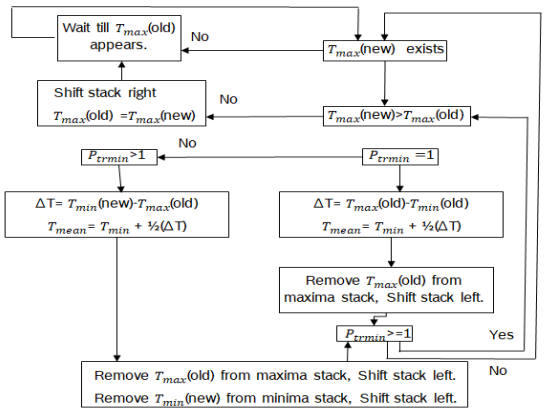

Fig. 2. Online Rain-Flow counting algorithm working on maximal values.

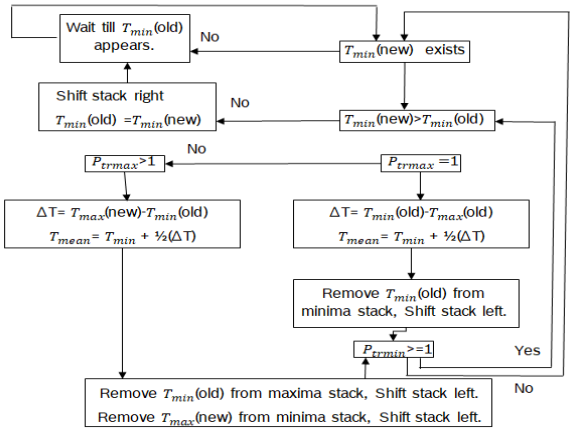

Fig. 3. Online Rain-Flow counting algorithm working on minimal values.

B. Challenges in implementing offline rainflow algorithm

The offline rainflow algorithm is not suitable for real time applications. The load history for significant time should be stored for proper cycle formation from the data. The algorithm cam be applied only on a stored load history. It have a buffer which accommodates the consequent turning points (minima & maxima). The buffer size should be determined before the algorithm is executed. For this the duration between successive usage of the rainflow algorithm, should be predetermined before the algorithm execution. The buffer should have the capacity of holding the entire loading range of the system under consideration. This involves large quantities of data demanding substantial computational resource to process the data during algorithm execution. In real-time applications, coding should be carefully done so that other real-time activities of the ECU are not interrupted.

III. Memory Optimizing Algorithms

A. Online Rainflow Algorithm

The turning points are processed as it occurs. Two buffers are used for this purpose. After processing, the turning points are discarded thus minimizing memory consumption. The load-time history need not be stored. Half and full cycles are extracted in a recursive manner, depending on the buffer contents. The procedure used for obtaining the full and half cycles is similar to the one used in offline rainflow method, and the cycle counts are therefore same for same loading sequences. Pre-ordering of input data points in ascending or decending order as in offline rainflow is not required. The online three point algorithm is depicted in fig. 2 and fig. 3, where, T_{max}-Element of maxima stack, T_{min}-Element of minima stack, P_{trmin}-Element of minima stack elements, P_{trmax}-Element of maxima stack elements. The MATLAB simulation of both online and offline three point rainflow on IGBT temperature input in the range, [20^oC-120^oC] and coolant tempearture input in the range, [20^oC-120^oC] gives similar maps, shown in fig. 4 and fig. 5 respectively, which implies there is no loss of data in the online method.

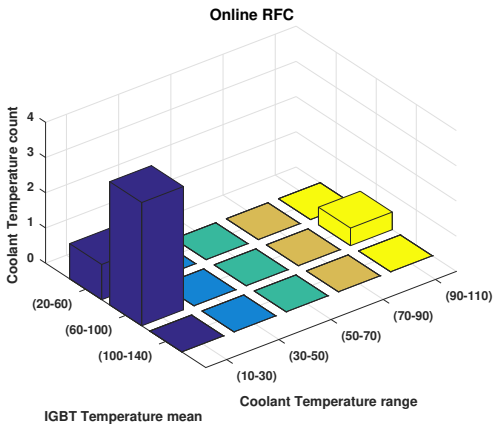

Fig. 4. Online rainflow counting(3D map).

B. Histograms

Histograms are used to represent the distribution of normal data accurately. It is the probability distribution estimate of a continuous variable (quantitative variable). For constructing

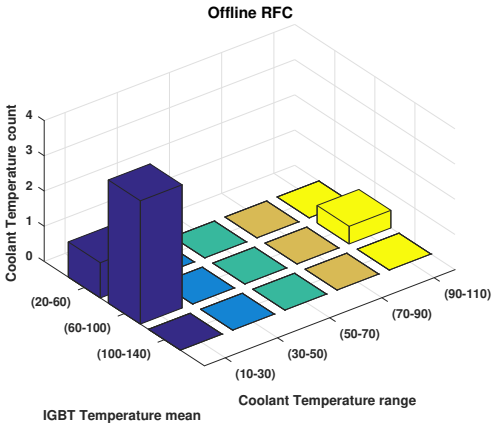

Fig. 5. Offline rainflow counting(3D map).

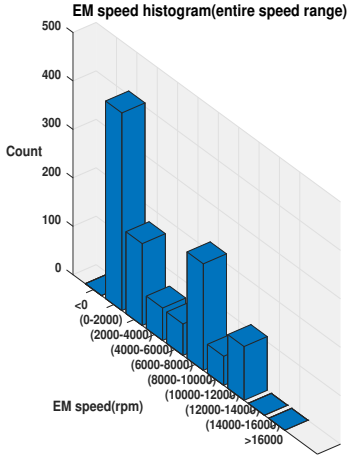

Fig. 7. EM speed histogram for entire speed range(1D).

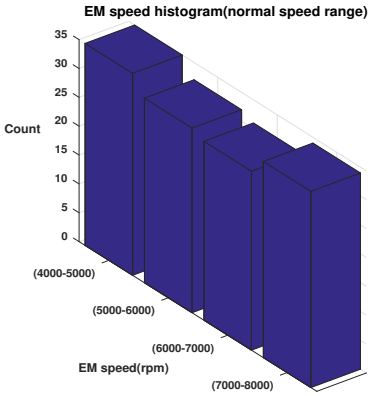

Fig. 8. EM speed histogram for entire speed range(1D).

histograms, the initial step is to make bins of input parameter's value ranges. This means, dividing full operating range of values to series of intervals and then counting how many values is lying in each interval. The bins should be consecutive and non - overlapping. Considering the electric motor speed histogram, the speed may be divided into ten sections as depicted in fig. 6, each section may require a four byte for the count. Thus a total of 40 bytes will be required for the entire histogram in the memory. For the normal driving speeds(40Kmph-160Kmph), the EM speed will be a factor (gear ratio) times the driving speed. This lies between a specific rpm range say, 4000rpm-8000rpm. Histogram for entire EM speed range will be having more sections than this one. Thereby the memory requirement is minimized and also the granularity of the map is now increased as depicted in fig. 6. Only four sections are present in this map. So for each sections of 4 bytes, a total of 16 bytes will only be required, saving 24 bytes of memory. Simulation results for electric motor speed inputs for three minutes are given in fig. 7 and fig. 8.

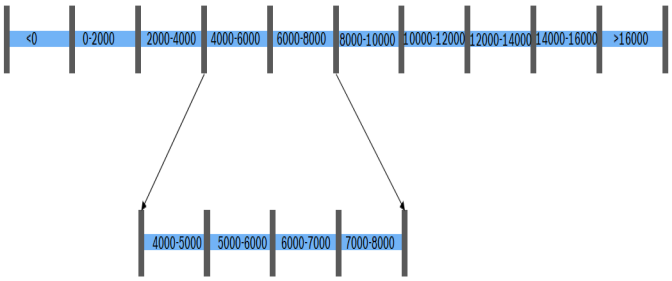

Fig. 6. EM speed histogram sectors for entire speed & normal speed ranges(rpm).

C. Level crossing counting

In level crossing counting, counts are registered when the input data exceeds preset levels. This method can be adopted where we are interested only in threshold crossings of a parameter, which may can have serious effect on the system under consideration. For example, Consider the scenario of a vehicle moving down hill, the electric motor's speed may increase beyond its rated limit which can have adverse effect on the machine. So recording such threshold crossings are of much significance. For such an application the level crossing counting can be used instead of recording a complete histogram. Simulation results of electric motor speed crossing of the rated limit, 16,000rpm for speed inputs for three minutes given in fig. 6 shows that it may require only a byte or two for storing the level crossing counts. Thus the memory requirement can be minimized by a considerable amount than in the case of storing the entire motor speed histogram which may be requring number of sections, having a larger memory requirement say, 4 bytes each.

IV. Conclusion

Different memory optimizing methods were identified for acquiring electric drive parameters. An online rainflow algorithm which minimizes the RAM memory requirement by

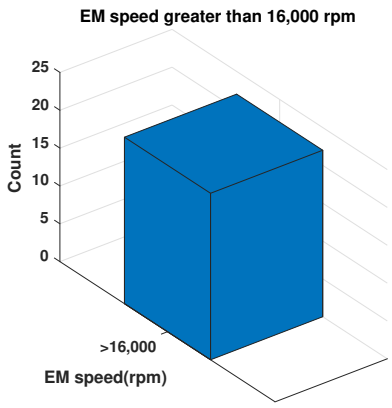

Fig. 9. Offline rainflow counting(3D map).

avoiding the requirement of load history storage can be used in storing parameters like IGBT temperature, diode temperature, coolant temperature etc. Instead of histograms for entire operating ranges , storing only map for normal operating ranges for parameters like electric motor speed memory requirement can be considerably minimized. Level crossing counting can be adopted where only threshold crossings of the acquired parameters are of interest, saving memeory space.

Data acquisition is very much relevant not only in automotive field but also in all areas where a stress cycle analysis is required, as in life time estimation of wind turbine parts, fatigue analysis of mettalic parts of different machines etc. In hybrid electric vehicles the data acquisition functionality will be handled by a particular electronic control unit (ECU) which will be handling other real time electic drive functionalities say, controlling the gate circuit of the electric motors inverter. For such other important real time functions to be performed un - disturbed and efficiently, sufficient memory should be free. So for a functionality like data acquisition, which take up large RAM and EEPROM space, the data acquiring algorithm should be carefully selected. Algorithms should be selected such that the acquired data should maintain maximum possible granularity and consuming minimum memory possible. So techniques with optimum memory usage in data acquisition is of great future scope.

***Abstract* — This paper proposes a capacitor switching logic for a multi input Single Ended Primary Inductance Converter (SEPIC) with efficient Maximum Power Point Tracking (MPPT) scheme for multiple non aligned solar panels. The proposed scheme is an improvement of time division multiplexing control of multi input converters for low power solar energy harvesters. In the proposed design, the capacitor switching logic gives the flexibility of selecting panels on demand providing additional advantage of isolation. For better accuracy an efficient algorithm has been implemented for determining MPPT. The MPPT is practically determined in each cycle when the corresponding capacitor is connected to converter. Using SEPIC converter at the output provides a constant 15V for charging the battery for solar panel voltage range from 8V to 25V. The design improvements will bring increased efficiency for medium power solar systems.**

Keywords— Maximum Power Point Tracking (MPPT), Single Ended Primary Inductance Converter (SEPIC), Perturb and Observe (P&O), Incremental Conductance (InC), Time Division Multiplexing (TDM), Maximum Power Point (MPP).

I. INTRODUCTION

The primary source of energy which helps to retain life on earth is Sun. The importance of extracting energy from renewable sources like solar, wind and tidal gives a solution for the depleting non renewable energy sources. It is considered as green technology as it does not emit any greenhouse gases.

The sun radiates solar energy by electromagnetic waves over a range of wavelengths from 290–2500 nanometers defined as solar spectrum. The solar spectrum consists of three bands namely Ultra-violet (UV) light (290nm–380nm), Visible light (380nm–780nm) and Infra-red light (780nm–2500nm). In the solar spectrum, 51% of the energy is distributed in the infra-red band, 47% in the visible band and 2% in the UV band. A photovoltaic system (Solar panel) is used to generate electricity from solar energy. For the construction of solar cells, monocrystalline and polycrystalline silicon is being used. The mono- crystalline technology creates a homogeneous silicon crystal that achieves a conversion efficiency of 14 to 21% whereas the polycrystalline is a combination of different silicon crystals and achieves a conversion efficiency of 13 to 16.5%. Polycrystalline photovoltaic (PV) cell is cheaper due to the simplest process of fabrication. Compared with silicon solar cells, GaAs solar cells is considered to be ideal for space applications as it possess higher photo electric efficiency, better thermo stability and stronger irradiation resistance [1]. The solar panel efficiency can be improved further by using mirrors and lens to concentrate the solar light to the panel. This concentrated photo voltaic technology (CPV) will provide same power output with lesser solar cell compared with normal panels [2]. The power generated from a solar panel depends on the irradiance which is defined as the amount of power per unit area that is directly exposed to sunlight. At a distance of one astronomical unit (AU) from the sun, the irradiance is approximately 1,368W/m^2 which is defined as Solar constant. The earth atmosphere attenuates the sunlight so that less power arrives at the surface of the earth approx. equal to 1,000W/m^2.

Some applications use multiple PV panels with dissimilar orientations for extracting maximum solar power in a day profile. When aligned configuration of PV panels is used, peak power is obtained at a particular time from both the panels resulting in higher depth of discharge of battery in a daily power profile. Hence the non aligned panels is proposed in [3] provides a smoothened profile by smaller depth of discharge. The method of using non aligned panels will improve the battery life. In [3] time division multiplexing scheme is being implemented for selecting the solar panel. But the above work has got the drawback of sequential switching of solar panels to keep the voltage within the hysteresis window and thereby in Maximum Power Point (MPP) region.

Among the different algorithms used for determining MPP, the P&O and Incremental conductance (InC) method are the most efficient algorithms [4]. Under rapidly changing atmospheric condition InC algorithm is superior compared to P&O, but complexity of implementing InC algorithm in hardware makes P&O method attractive [5][6]. For space applications where accurate tracking is required, P&O or InC method is used. Fractional open circuit voltage or fractional short circuit current method is used for applications where accuracy is not a factor. The reference design uses fractional open circuit voltage (FOV) method whereas the proposed design uses a variant of P&O algorithm to determine MPPT.

This paper proposes an improvement for the scheme presented in [3]. A capacitor switching logic with efficient MPPT scheme has been implemented to obtain improved efficiency. Flexibility of selecting panels on demand provides an additional advantage of isolation. Also the SEPIC converter at the output of the panel provides a constant DC voltage for charging the battery in the entire I-V curve of the panel.

This paper is organized as follows: Section II presents the reference scheme on which improvement has been attempted. Section III describes the proposed architecture. Section IV details about the simulation studies carried out with the mathematical modeling of elements in the design and Section V describes the hardware implementation.

II. REFERENCE SCHEME [3]

A low power, low cost solar energy harvester for non aligned panels using a TDM scheme for selecting multiple panels to a single boost converter with fractional open circuit voltage MPPT scheme is presented in [3]. The scheme is as shown in Fig.1

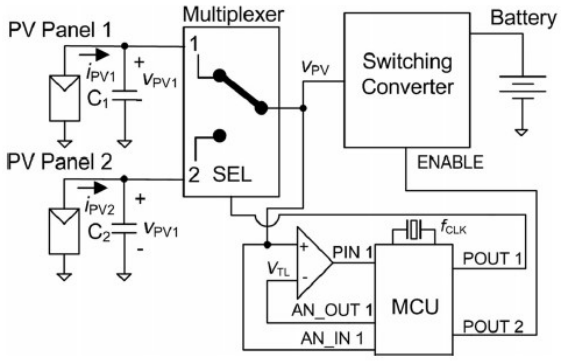

Fig.1 : Reference Scheme [3]

Capacitors (C1 and C2) are permanently connected to the panel and the each panel is selected by a multiplexer. The selected panel is connected to the input of a boost converter and the output of the converter is used to charge a battery [7][10]. The converter is enabled and the logic is selected by a micro controller unit, based on the reference parameters measured. FOV method is being implemented to determine the maximum power point (MPP) of the panel.

Since the panel is hardwired to the capacitor and the capacitor voltage is limited between the hysteresis window during the operation for achieving MPP, the open circuit voltage which is required to determine the MPP voltage can be measured only if the capacitor is allowed to charge to the open circuit voltage. Also the sequential loading of the panel is required to ensure that the capacitor voltage does not cross the upper threshold level of hysteresis window. ie, the switching converter should have a higher current discharge capability than the total current generated by multiple PV panels.

III. PROPOSED SCHEME

In the proposed scheme, pair of switches has been included between the solar panel and the capacitor compared to the reference scheme which provide simple control scheme to make the system in MPP tracking mode even if current discharge capability of the switching converter is less than the sum of currents generated by multiple PV panels. This scheme provide additional feature of isolation between the source and the load and between the sources. A variant of efficient MPP algorithm of perturb and observe is being implemented and calculated in each cycle to give accurate MPP tracking. A SEPIC converter has been used to provide constant DC voltage for charging the battery. The proposed scheme is shown in Fig.2

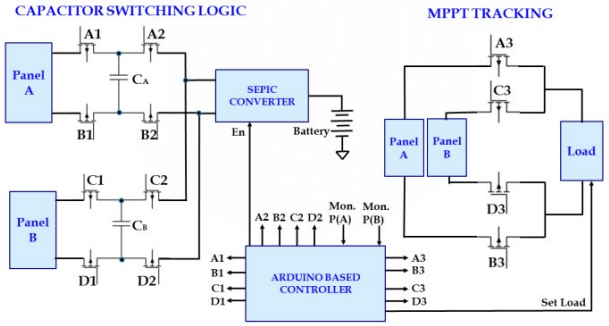

Fig.2 : Proposed Scheme

During initial power on, the open circuit voltage of capacitors is measured and the capacitor with higher voltage is connected to the converter. Assume that voltage across capacitor C_A is greater than voltage across the capacitor VC_B, ($VC_A > VC_B$), then the capacitor C_A is connected to the converter by turning on the switches A2 and B2. During this time, MPP of the solar panel A is determined and the capacitor C_B is charged from solar panel B till upper threshold of hysteresis window (+20% of V_{MP} of panel B). If VC_A falls below the lower threshold of hysteresis window (-20% of V_{MP} of panel A), the capacitor C_B is connected to the converter. During this time, MPP of solar panel B is determined and the capacitor C_A is connected to panel A. In order to determine the MPP of panels, P&O algorithm is used. The solar panel is loaded from no load to short circuit current and the voltage and current is acquired to compute the power. In order to load the solar panel, corresponding switches (A3 and B3 for panel A and C3 and D3 for panel B) are turned on. The load current is varied from 0mA (No load current) to 580mA (Short circuit current) by changing the reference voltage from 0V to 580mV. The maximum power point is practically determined during each cycle accurately. Fig.3 shows the schematic diagram of the capacitor switching logic.

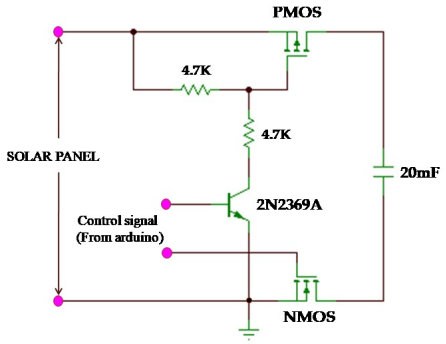

Fig.3 : Electronic load for MPPT Characterization

The control voltage drives the transistor to saturation to make the PMOS turned on till $V_{GS} > 2V_{TH}$ of the PMOS. The NMOS with low $V_{GS(TH)}$ can be driven directly from the arduino controller.

Fig.4 shows the schematic diagram of the electronic load used for MPP characterization.

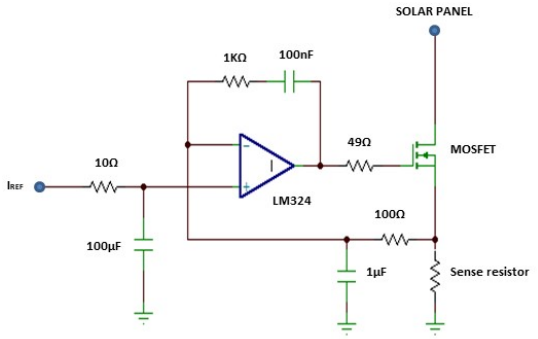

Fig.4 : Electronic load for MPPT Characterization

The current through the sensor resistor will be tracked towards the reference voltage to provide the required loading for the panel. The panel voltage and the load current is measured and characterized from no load to I_{SC} to determine the maximum power point. Sense resistor (1Ω) with temperature coefficient of ±20ppm/ºC is chosen for the application. The RC filter is used to avoid the noise. The panel voltage is scaled down by a factor of 5, buffered and acquired via analog input of Arduino controller. The voltage equivalent of the sense current is buffered and acquired via another analog input of Arduino controller. The voltage and current measurements are multiplied to calculate the instantaneous power of the panel. Fig.5a shows the voltage monitoring scheme and Fig.5b shows the current monitoring scheme.

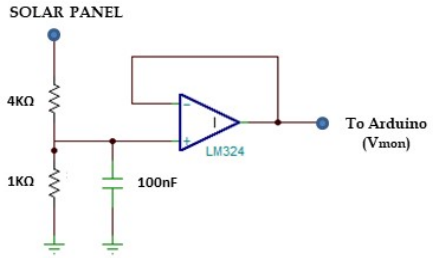

Fig.5a : Voltage monitoring

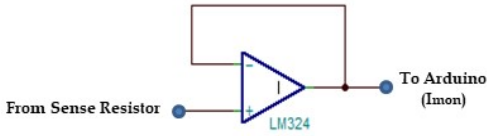

Fig.5b : Current monitoring

Fig.5 : Voltage and Current monitoring

The maximum power point tracking for each panel is determined when the corresponding capacitor is isolated from the panel and the capacitor is connected to converter. A variant of perturb and observe algorithm is being used to determine the MPP of each panel. The panel is loaded from no load to maximum load in steps of 20mA and instantaneous power is calculated from the voltage and current measurements. The voltage (V_{MP}) corresponding to the maximum power output is taken for calculating the hysteresis window (±20% of V_{MP}). Reducing the hysteresis band increases the rate of switching between the panels where as increasing the hysteresis band takes the operating region beyond optimum MPP. So a hysteresis band of ±20% is selected for the proposed design.

The Single Ended Primary Inductance Converter (SEPIC) is used in this design to provide a constant voltage for charging the battery. The SEPIC DC-DC converter provides positive regulated output voltage (+15V) even if the input voltage is above or below the output voltage (8V to 25V). Since the configuration of SEPIC converter requires two inductors, off the shelf coupled inductor is used to reduce the footprint. Coupled inductor will also provide better output ripple performance [8][9]. SEPIC converter is shown in Fig.6

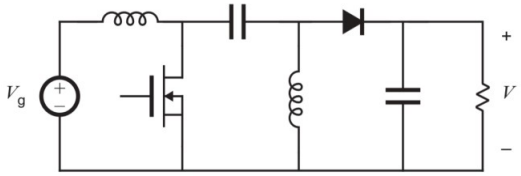

Fig.6 : SEPIC Converter

The input to output voltage relations for a SEPIC converter is given by equation 1.

$$Vo = \frac{D}{1-D} * V_{in} \tag{1}$$

When integrated with the solar panel, the equivalent impedance seen by the solar panel is given by

$$R_{eq} = \frac{V_{in}}{I_{in}} = \left(\frac{1-D}{D}\right)^2 R_{load} \tag{2}$$

For any R_{load}, equation 2 yields

1. As D→0, R_{eq}→α : Open circuit for panel
2. As D→1, R_{eq}→0 : Short circuit for panel

Thus, the SEPIC converter can sweep the entire I-V curve of a solar panel. Also the input ripple current for a SEPIC converter is very low w.r.t the input ripple current of a boost converter.

The battery will be charged at constant voltage continuously if the panels have sufficient irradiance. Multiple panels can be used for continuous voltage output. If the irradiance is not sufficient for continuous operation, then battery will be charged with pulsed current depending on the irradiance. But the panel is ensured to be operated at MPP point at any available irradiance.

IV. SIMULATION

Simulation studies of solar cell, MPPT algorithm and SEPIC converter were carried out using MATLAB and Simulink software prior to finalizing the design for optimum performance.

The mathematical modeling of the solar cell is important for analyzing the power extracted from the solar panel and also to characterize the power-voltage characteristics at different irradiance level and temperature of the panel. Simplest of which is single diode model. Equivalent electrical model of a basic solar cell is given in Fig. 7

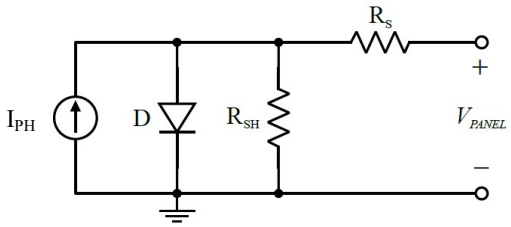

Fig.7 : Electrical model of a PV Cell

The basic mathematical equations governing the current output from the panel is given by equation 3.

$$I_{PH} = I_D + I_{SH} + I_{PANEL} \tag{3}$$

where,

I_{PH} : Generated Photo current
I_D : Diode current
I_{SH} : Shunt Current
I_{PANEL} : Output panel current

The diode current is given by equation 4.

$$I_D = I_{SAT}\left(e^{\frac{V_D}{nVT}} - 1\right) \tag{4}$$

where,

$$I_{sat} = I_s \left(\frac{T}{T_0}\right)^3 e^{qEg/nk} \left(\frac{1}{T_0} - \frac{1}{T}\right)$$

The shunt current is given by equation 5.

$$V_D = V_{PANEL} + Rs * I_{PANEL}$$

$$I_{SH} = \frac{V_{PANEL} + Rs * I_{PANEL}}{R_{SH}} \tag{5}$$

The generated current for a given temperature and irradiance is given by equation 6.

$$I_{PH}(S,T) = I_{PH}(S_0,T_0) + \alpha T(T - T_0)\frac{S}{S_0} \tag{6}$$

The power output from the panel decreases with decreasing irradiance and the power output increases with decreasing temperature of the panel. The P-V and I-V characteristics of the panel at different solar irradiance (1000W/m^2, 800W/m^2, 600W/m^2, 400W/m^2 and 200W/m^2) at constant panel temperature of 25°C [6] is given in Fig.8 and P-V and I-V characteristics of the panel at different panel temperature (30°C, 40°C, 50°C, 60°C and 70°C) at constant solar irradiance of 1000W/m^2 is given in Fig.9

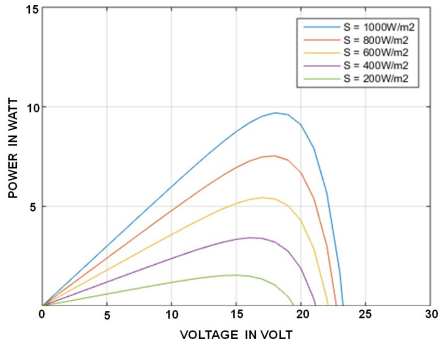

Fig.8a : P-V characteristics for different irradiance at 25°C.

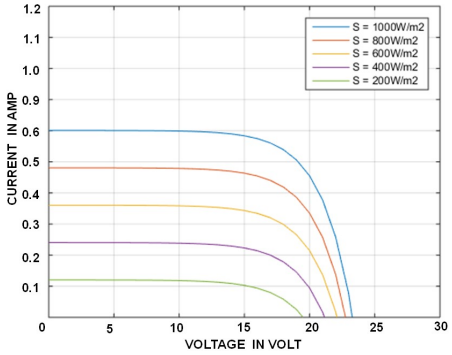

Fig.8b : I-V characteristics for different irradiance at 25°C.

The V_{MP} of the panel is expected to be between 15V and 17V for different irradiance and the short circuit current is expected to be decreasing w.r.t decrease in irradiance level. The I_{MP} determines the charging current for the capacitor and thereby to the load.

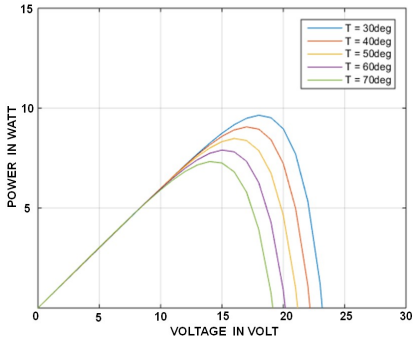

Fig.9a : P-V characteristics for different temperature at 1000W/m^2.

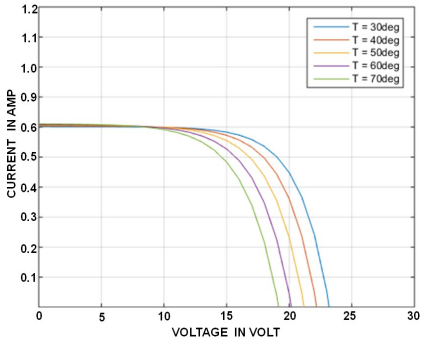

Fig.9b : I-V characteristics for different temperature at 1000W/m^2.

The power output decreases w.r.t the increase in the panel temperature and I_{MP} decreases with increase in panel temperature.

SEPIC converter is simulated using the simulink model as shown in Fig.10. The component values used in the design are L1, L2 : 470µH, C1 : 220µF, C0 : 1000µF and RL : 10Ω. The frequency of the pulse generator is set at 400kHz corresponding to the switching frequency of the converter [9]. Compared to boost converter, the SEPIC has the additional advantage of blocking the input from getting connected to output by the series capacitor, in case of converter disabled for isolating from battery under full charge condition.

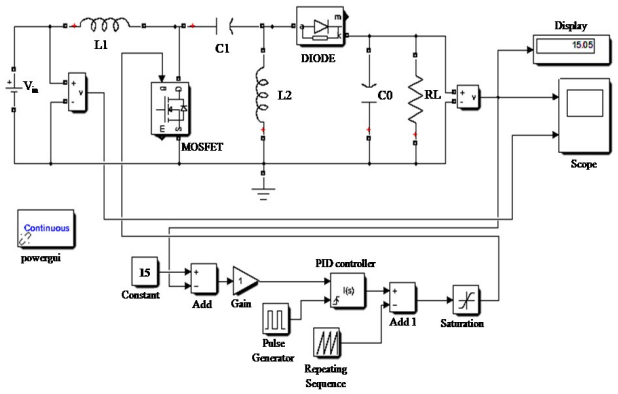

Fig.10 : SEPIC Converter.

The simulation was carried out with input voltage varied from 8V to 25V in steps of 2V and load varied from 20mA to 1.5A and the output voltage is found to be constant at +15V. The inductance and capacitance values are chosen to meet the output voltage ripple within 50mVpp. The simulation result of a SEPIC converter at an input voltage of 24V and load current of 1.5A is shown in Fig.11

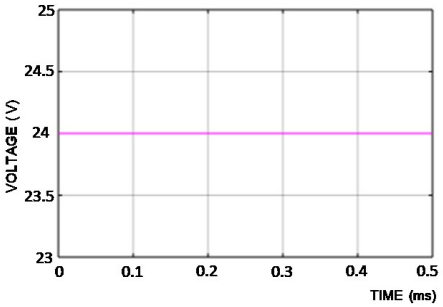

Fig.11a : Input voltage

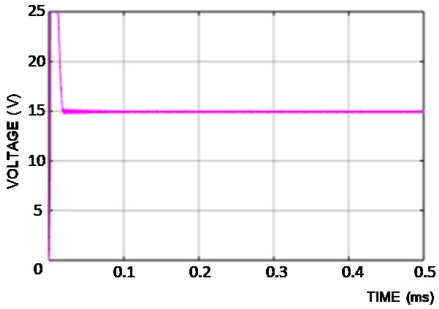

Fig.11b : Output voltage

V. HARDWARE IMPLEMENTATION

The proposed scheme is implemented in hardware to evaluate the performance. The hardware is configured around Arduino Mega 2560 controller, which generates required switching commands based on the upper and lower threshold voltage levels, calculated from the MPP voltage of each solar panel for the capacitor switching logic.

The Arduino Mega 2560 has 15 PWM outputs and 16 analog inputs available out of the 54 digital input/output pins. It also has 4UARTs and operate with a 16 MHz clock frequency. The hardware implementation is shown in Fig.12

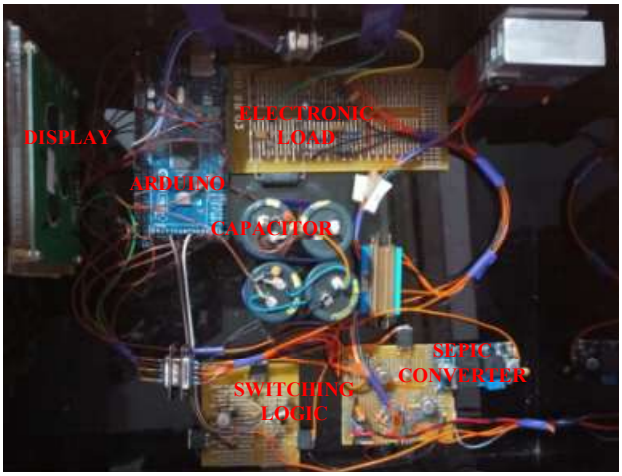

Fig.12 : Hardware model.

Micro Sun make (Model : MS1210) 10W panel is used in the hardware. The open circuit voltage is 22.32V with short circuit current of 0.6A. The maximum power point voltage is 18.1V and the maximum power point current is 0.55A. The MPP voltage of each panel is determined in each cycle by loading each solar panel, when the corresponding capacitor is connected to the converter. The voltage, current of each solar panel during MPPT characterization and voltage across each capacitor is acquired through the analog input of the arduino and digitized by 10 bit ADC in the controller. The maximum power, voltage and current at the maximum power point is displayed in a LCD display.

The XL6009 is a current mode controller used for SEPIC converter and the switching frequency is 400kHz. The converter can be disabled by driving the enable pin of the PWM controller low. The output is scaled down to 1.25V and compared with reference voltage to generate error and thereby adjusting the duty cycle.

The solar panels, the capacitor switching logic circuits implemented using Arduino mega 2560, SEPIC converter and 12V lead acid battery is configured as per Fig.2. The capacitor voltages (VC_A and VC_B) and the output voltages are acquired through Arduino, and is plotted using serial plotter as shown in Fig.13

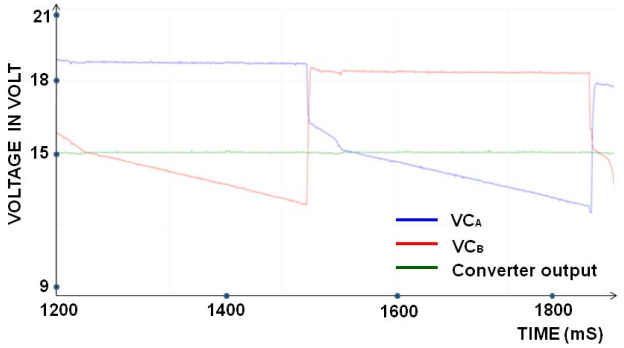

Fig.13 : Voltage waveforms.

P-channel MOSFET is used as switch in the positive supply line and N-channel MOSFET in the return line for simplified drive circuit. The energy, voltage, and capacitance of a capacitor are related by

$$E = \frac{1}{2}(CV^2)$$

The initial energy (E_0) and final energy (E_F) stored in the capacitor is, given by

$$E_0 = \frac{1}{2}(CV_0{}^2)$$

$$E_F = \frac{1}{2}(CV_F{}^2)$$

$$\Delta E = \frac{1}{2}(CV_F{}^2) - \frac{1}{2}(CV_0{}^2)$$

Time required to charge the capacitor is given by eqn.7, where P denotes the power

$$t = \frac{\frac{1}{2}C[V_F{}^2 - V_0{}^2]}{P} \quad (7)$$

During the initial turn on, the initial energy stored in the capacitor is zero and hence the time taken to charge a 20mF capacitor to the V_{MP} voltage of 17V by a 10W panel is 289ms. During the operational cycles the capacitor voltage is charged when connected to panel and discharged when connected to the converter. The capacitor voltage is varied between the 40% hysteresis window and thereby the capacitor charging time from lower threshold voltage to upper threshold voltage is 180ms approx. The output power and the efficiency of the converter determine the input power required to meet the load requirement. This determines the charge discharge cycle duration in the proposed scheme.

Considering the quadratic model of the MOSFET, the drain current equation can be written as equation 8.

$$I_D = \mu C_{ox}\frac{W}{L}\left[(V_{GS} - V_{TH})V_{DS} - \left(\frac{V_{DS}{}^2}{2}\right)\right] \quad (8)$$

$$\text{for } \{V_{DS} < (V_{GS} - V_{TH})\}$$

The gate drive circuit of the MOSFET is designed in such a way that the V_{GS} will provide a drain current which is more than the short circuit current (the maximum expected current from the panel). The resistive divider gate bias ensures the MOSFET turn on till the capacitor voltage greater than $2V_{TH}$ (twice the threshold voltage).

Since the proposed scheme has twelve MOSFET switches, the losses in the MOSFET have been quantified w.r.t to the power converted. The losses can be classified into conduction loss (P_C), switching loss (P_{SW}) and gate charge loss (P_{GC}) [11][12].

$$P_C = (I_D^2\, R_{DS(on)}) \quad (9)$$

$$P_{SW} = \frac{1}{2}(V_{DS}\, I_D\, [t_r + t_f]\, F_{SW}) \quad (10)$$

$$P_{GC} = (Q_g\, V_{GS}^2\, F_{SW}) \quad (11)$$

From equations 9, 10 and11 the conduction loss is calculated be 4mW, switching loss of 1µW and gate charge loss of 1µW. Total MOSFET loss is 0.6% and including the steady state losses in the converter, the total loss is 7.5% of 10W.

CONCLUSION

By implementing capacitor switching logic, option of disconnecting the capacitor from the panel gives the flexibility of selecting panels on demand for characterizing panel for determining MPPT. This feature brings better ground isolation between panels, and between panel and converter thereby better noise performance. The proposed scheme will characterize the panel to determine the MPP point in each cycle and thereby setting the hysteresis window which provides accurate operating condition. Also a variant of perturb and observe algorithm is used to determine the MPP in each cycle compared to fractional open circuit voltage method which is inaccurate. SEPIC converter will provide a regulated output, which makes the system independent of the load, as it cover the entire I-V characteristics of the panel.

As a future scope of work, optimization in the hardware can be attempted considering the actual load requirement. Optimized design w.r.t miniaturization, power and cost can be considered. MEMS capacitor, MEMS switches and switched capacitor converter can be used to implement the scheme for ultra low power application.

***Abstract*— In a world rural area keeps declining and smart cities keep evolving. data is one of the most important resources to maintain as terabytes of data is collected from a single city. data is analyzed using big data analysis and it can be stored by using the fog computing and it also describes how fog computing is effective in IoT when compared to cloud-based computing and how fog-based computing is emerging and how it is leading. it describes cloud and fog architecture and how the data is processed in those architecture and we are going to learn about a new experimental architecture. it is merger of both fog based and cloud-based. Fog computing is technology, which is rapidly in use so, we will discuss some of its applications. The data is used to achieve a proper life where people can live safe and it is also used for analyzing various factors of like economy and employment and to understand its patterns to achieve development. There are many challenges to maintaining the data through fogging these challenges are mentioned along with that the security problems that followed from cloud to fog.**

This paper mainly tells us how fog computing would be the future of IoT and how it would change the world.

Keywords*— *Big data, Data mining and analytics, Smart city, Cloud computing , fog computing.

I. INTRODUCTION

Due to the increase in the urbanization. Cities are rapidly extended their area and along with that population growth has been increased in tremendous amounts. now about fifty-four percentage of the population of world are now living in cities.

It was 30% back in 1950[1]. In 2030 two by third of the population of the world would be live in urban regions and people who are already living in urban areas of countries with developing economies would increase twice in number and the area of these cities could be tripled based on latest UN reports. The proportion of the urban population is expected to increase to 68% by 2050[2].

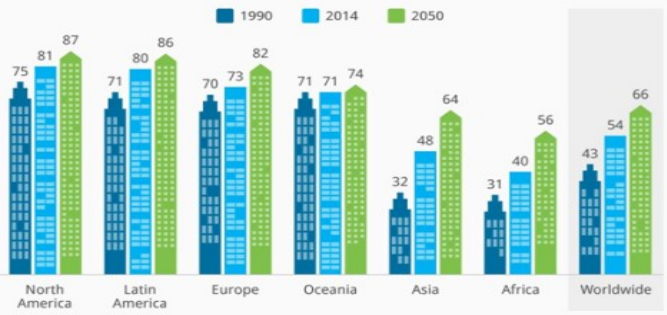

Fig1: Urban population increasing ratio

With the growth of the population of the world will add another 2.5 billion folks to urban areas until 2050. Based on the reports 90% of increase would take place in Asia and Africa.

It is very hard for governments to provide facilities like transportation and water supplies to all the citizens living in that area despite population growth. Big data can be very helpful for the analysis of information in edge computing and in also used in cloud-based computing [3]. Data can be easily analyzed in the fog because of its distributed approached and data can be easily tracked from where it is coming and where it is going to be uploaded. we can provide much security to citizens data

There is much evidence that would suggest that fog computing helps in formatting and sorting data. there are many challenges in these data collection [4]. The challenges may include maintaining sustainable environmental, ideas that would help in developing of both the social and economic conditions of the society and decision making were everyone's opinions are valued. We can create a clever infrastructure and solving these challenges would help achieve to better social life for citizens. Aim of developing this model is provide improved versions of the present smart cities by providing various approaches to collection, integration and analyses of data to help in provide a better life for citizens.

II. BASIC FOG COMPUTING CONCEPT

Smart cities are the traditional cities and as urbanization is at a rapid extent their great need of managing the data that is in these smart cities. Data should be properly managed so that it can be analyzed for various applications. data analytics process of the smart city has quite complexity. Cloud computing is mostly used for maintaining such large data but there are quite disadvantages of using it. There can be many alternatives to cloud computing [6]. When we are talking about the alternatives .one of the best alternative is fog computing .accessing of the data is very easy in fogging when compared to the cloud and the fogging is an extended service of the cloud computing where data is stored nearer to the source and mainly the data can be stored between the cloud and source at a particular point where the data accessing and storage would be easy.fog computing can be called as the edge of the network, this particular name is given because the data is just stored above the ground. accessing data from the cloud becomes more difficult with low internet speed and bandwidth is the most common problem which leads in the difficulty in accessing [7]. Fogging would be the best solution for all the above-

mentioned problems. The following diagram shows the detailed description of fogging.

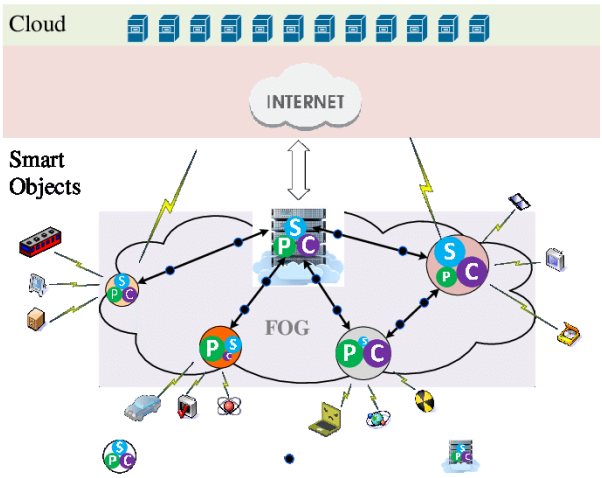

Fig2: Interplay between IoT , Fog and Cloud[4]

III. CLOUD ARCHIETECTURE FOR SMART CITES

Smart cities can provide various solutions which are used to solve real time challenges related to urban regions[8]. there are many challenges and these challenges be providing sustainable environmental, ideas that would help in developing of both the social and economic conditions of the society and decision making were everyone's opinions are valued.

First, we should learn about the cloud architecture for the idea then we can modify that cloud architecture by introducing the fogging into it as the extended form or extended service of the cloud. the architecture of the cloud is given below

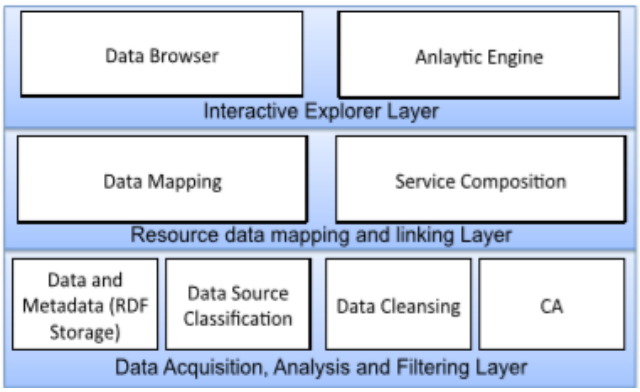

Fig3: Cloud Architecture

It is a three-layered approach and each layered has its own importance.
The bottom layer of this architecture consists of various data warehouses which have data being collected from various data mart and it has a distributed approach and many sensors are connected to this layer and all the data pre-processing steps are performed on the data.

In the middle layer mapping of data based on their Meta characters and linking is performed here this would help in finding new cases and makes the relationship between the attributes stronger. data is collected from various data marts as data collected would have many unique values this would be great help for data linking.

These data browsers present in the upper layer is used to browse the variables and indicators

From the datasets based on the metadata of those variables and indicators and the analytical engine, a great help for the end users use to find the data from the cloud.

difference between cloud computing and for computing. To know about the data storage and data need to understand both the technologies architecture.

IV. FOG ARCHITECTURE OF SMART CITY

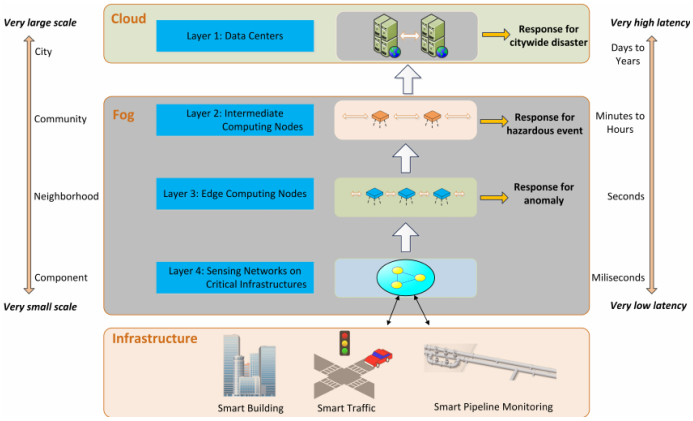

Figure 4: The 4-layer Fog computing architecture in smart cities, in which scale and latency sensitive applications run near the edge.[2]

Layer 4, in this layer sensing action is performed and this can be performed on the data collected from various nodes with consist of many sensors which are of low cost and they are high reliability and they are spread over large public areas so we can monitor different changes and data generated is large from these sensors .data is collected at every node is send to the layer above it..

Layer 3, in this layer nodes are present with power consumption rate would be less than usual and performance of these nodes are also high .local group of sensors and connected to this layer regular analysis should be performed and alerts should be send during the danger and feedback should also be send to respective authorities to improve the local conditions.

Layer 2 may contain nodes which lie between different set of nodes, every intermediate node is connected to a group of edge devices at upper layer and it uses its geospatially collected data to discover the risky events happening.

When any hazardous event is identified it makes fast moves to stop the damage and save the infrastructure and layers 2 and 3 provides feedback which and these feedback act just like the human reflexes that safes us from the dangers. Consider an example, where gas pipeline's certain part has leakage and if the fire starts in that part these intermediate nodes would shut down the whole system [9]. it would reduce the loss to the life and property. Meanwhile, the output of data analysis of these two layers is fed into the to top layer for analysis of behaviour and conditions to be monitored for longer time period and controlling and monitoring of city-wide data can be possible at top layer. long-term data is stored which can be analyzed. It allows spontaneous decision making which makes the municipalities to take better actions across whole city during a natural disaster or large-scale service interruption.

Using this 4-layered approach we can detect the threats easily and we can reduce the damage to the human life's an environment. by using this approach, we can analyze the data many times and problems are rectified immediately we compared to the cloud. Now a day's data is being available for everyone which is termed as open data. which is used for many purposes most of the important purpose is to provide better life for citizens and it helps in visualizing future infrastructure and to improve the present one and all this data is provided by government.

Management of data for each unique domain is used to collect the data from various sources and analysis performed on that data.
By managing such type of data we can get the particular information about the specific thing for suppose we consider the places or areas of a city .we can store the data of all the places in the nodes and we can analyze the crime rate of the area as we already have all the information of the particular area it is also easy to maintain the accident spots of that area. We can analyze many more things about the area by using that data like the real estate and many more because of the tremendous amount of the data present in it and the data trafficking is high whereas in fog-based computing data trafficking would be quite less.
.

IV. FOG-CLOUD-DATA MANAGEMENT

It is a new technique through which data can be more efficiently maintained. Fog-to-Cloud (F2C) Data Management experiments have been conducted on the city of Barcelona.

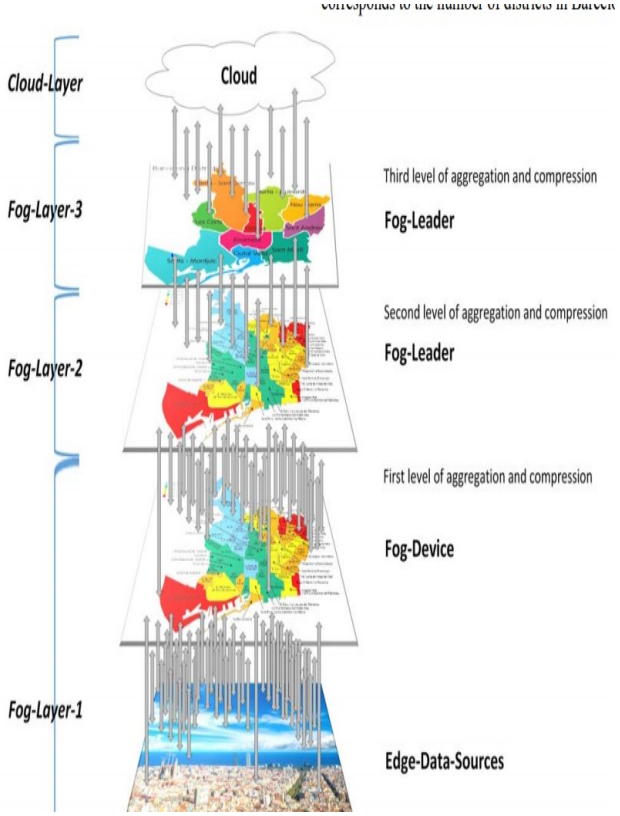

Fig 5: Representation of the F2C data management in Barcelona.[5]

Sensors collect all types of data and this data is classified in data classification phase. Information collected is categorized into five types mostly it is based on energy ,noise, urban, garbage and parking. Where data is again sub divided into types like energy can be divided into solar or wind etc and we can divide noise based on the vehicles or the loudspeakers.

Edge-data-sources collects the data from various sources performs classification in the lowest level. and all classified data is aggregated in fog-layer2 and compression is also done in the same layer. fog-leader is also one of the data classification phases. Sensors are distributed over a large area in Barcelona and layer 1 is spread over 73 respective areas of fog and second layer is spread over one kilometre which has total of ten main areas [5].

V. SECURITY CONCEPTS OF CLOUD COMPUTING THAT FOLLOWED FOG COMPUTING

There are total of 12 critical issues which might act as threats and affect the safety.

A.Advance Persistent Threats (APT)

these would be nothing but the attacks that compromise the security of the companies

B. Access Control Issues (ACI)

This leads in poor management. Unauthorized entries are made and make changes in the software

C.Account Hijacking (AH)
account is being used by unauthorized people who are not allowed to use the account.
D.Denial of Service (DoS)
because of the finite resources even the authorized people cannot use the service sometimes.
E.Data Breaches (DB)
this data breaches cause crisis situation because of the loss of the confidential data.
F.Data Loss (DL)
loss of data can be done by faults in the software or by malicious activates or even by natural resources.
G.Insecure APIs (IA)
The providers of various computing use API's for client use and it is used to provide the security for the applications that we have developed.
*H.System and Application Vulnerabilities (SAV)*Attackers can enter the system by finding loopholes in the system like bugs.
I. Malicious Insider (MI)
A person with authority and he decides to use that power in a wrong way by performing the malicious activity.
J.Insufficient Due Diligence (IDD)
this many occurs when any organization rushes in designing and implementation of the project.
K.Abuse and Nefarious Use (ANU)
If the supply of the resource is for free. it may be used for some malicious activity.
L.Shared Technology Issues (STI)
this is mostly occurring due to shared resources, platforms and infrastructures with more people

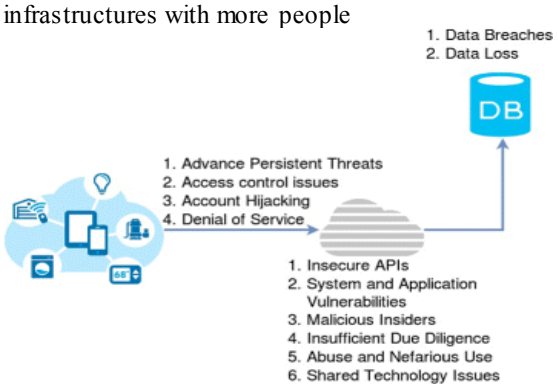

Fig. 6: Potential security issues of Fog Platform inherited from Cloud computing.

Above figure shows how virtualization and other issues of Cloud platform can affect Fog platform as well [10].

VI. APPLICATIONS OF FOG COMPUTING:

A. *Smart Home*

Rapid development of IoT has created many smart devices and sensors are even present at home. there are many home security devices like smart locks and recorders which are can be audio or video or both. Once fog computing platform sets up, every sensor would act as a client[11]. The server-based application is installed in every virtual machine. on this Virtual machine, the advance processing logic is being implemented, which shares the secure.

B. *Smart Grid:*

This is an electricity distributing system where meters are arranged at regular intervals. There is a centralized server with gathers all the information .it also used to analyze that data and inform to the system if any dangers happen. using fog computing, SCADA is added with a decentralized model with micro-grids, which improves scalability and provide security with fog computing, the grid will turn into a hierarchical system which acts as an interface between fog and SCADA. in this kind of systems, fog is in charge of communications with another grid and another fog[12].

C. *Smart Vehicle*

Fog computing can be integrated into automobiles they are 2 ways of integration [14], they are infrastructure-based and autonomous. the formal would be VTube, it basically depends on fog nodes that are placed along the roadside; these nodes are responsible to send/retrieve information to or from the vehicles. The further mentioned in, every fog can communicate to its users within and may be from another fog. There are many applications for fog computing in automobiles. Popular applications would be traffic light scheduling, congestion mitigation, precaution sharing, parking facility management, traffic information sharing, etc.

D. Health Data Management

This have been a delicate topic as the data collected of the patients should be kept confidential because this data is cause harm and disturbs privacy of the patient. By edge computing, the data of the patient will be stored locally so data can be accessed quickly[13]. data collected and stored in those fog nodes like in our Smartphone gadgets. the data is preserved and competed in a more secure manner so there is no way of data leakage. Modification of data can be done easily in patients' fog-node.

E. *Wind Farms*

Wind turbines are a very sensitive piece of equipment. according to the weather you make changes to increase the output. The problem is that most wind farms are located in remote areas. "Edge intelligence" enables us to analyze data locally in real-time without relying on continuous network availability.

F. Trains

As part of the rise in the Internet of Things, trains and tracks are being built with sensors with locomotives acting as the central hub for all the data which has been collected from these sensors. Due to the fast movement of trains, it is difficult

to maintain the connection with "the cloud". it is better to install some fog computing nodes in your locomotive.

G. Pipelines

Gigabytes of data is generated alone from the 100-mile long pipeline [15]. there can be many tetra bytes of data can be collected from a single pipeline. fog computing plays an important role in this case because we can easily detect any leakages if we collect the data at regular intervals cloud only needs to know only important data so it is better to use fog computing.

VII. CHALLENGES IN FOG COMPUTING:

There are several challenges for implementing fog computing and they are

A. Choice of Virtualization Technology

Virtualization can provide a better environment for fog computing. There is a question about which to choose hypervisor or container, we already know that Cloudlet has been utilizing virtualization technique of hypervisor paradrop is choosing the container-based technology because it is lightweight when compared hypervisor and hardware is used for these two technologies[16]. the container cannot host different OS on a single node.

B. Fight with Latency

There are some conditions which lead in having latency at high range in fog computing platforms. Those kinds of latencies would destroy client experience with the fog computing. There are several ways in bringing latency back some of those methods are

- Data aggregation.
- Node mobility.

C. Network Management

Management of the network would be difficult be difficult until you apply techniques like software defined network and network functions virtualization and combination of both can be used to, but it is not easy to combine them to. there can be many difficulties in it. there can be difficulties in design and different directional bounding and genuine design of network can lead to difficulties in design.

D. Security and Privacy

Main priority at every level is to maintain the privacy and security for users and it is also one of the main challenges too. we have use may restrictions on the access and we have to check whether unauthorized people have entered system this makes the model strong.

VIII. CONCLUSIONS

In this paper we have discussed how the population in cities has been increasing and how new technologies should be used for the creation of better cities. How data can be more efficiently accessed and stored in the fog-based computing when compared to the cloud. It also compares the architectures of both cloud and the fog for better data management of the data. it also differentiates between the fog and the cloud computing and it can be done based on the certain characteristics and it highlights some security problems that followed to the fog from cloud. we have also discussed the challenges and the applications of fog computing. In the end we conclude that by adopting fog computing technique we can make better smart cities.

***Abstract*— Here we discuss the integration of sensors with the cloud and their applications which is the highlighting aspect in the future IOT. These concepts are very much important in developing smart cities. These smart cities improve the quality of living. It is estimated that by 2025 there will be atleast 88 smart cities around the world. This idea results in healthy, sustainable and secured environment but, will take lot of investment and time to build. In this paper, we will discuss the areas where the IOT involved to develop a smart city.**

Keywords— sensors; cloud computing.

I. INTRODUCTION

Cloud is the advanced technology of storing and protecting data. Cloud storage is based on the virtualization techniques. In this the uploaded data will store on remote servers and accessed through internet or Cloud. For instance, uploading files to drive that will store on google cloud. The major advantage of cloud, we can access the data that we have uploaded anywhere in the world. Sensors are the devices that sense the physical parameters such as pressure, temperature etc., and gives the signal which can be measured electrically[1][2]. The integration of sensors with cloud can results in many useful applications but this is a bit complex activity. The data in cloud can be pushed to our mobile phones so that the common information can get to know by many people around. In the case of sensor cloud integration, sensors sense the data and transmit it to cloud .This transmission can be done in different ways.

II. HOW THE DATA GO TO CLOUD FROM SENSORS?

A. Sensors to cloud:

The data transmission from sensors to cloud takes place in different ways. At the early stage (1970 to 1980) the transmission process is done by using ethernet which is a wired process but some places do not have wired internet which turns as a disadvantage to this process. This doesn't involve in radio link[5]. This process send information directly from sensor microprocessor to the cloud.

B. sensors to mobile network to cloud:

In this case, the data flows from sensors to mobile phone with the cable(wired). From mobile to mobile tower which involves in radio waves this is a wireless process. After this, the data go to the tower and then to cloud through the cable (wired).This is the cost effective process to the user.

C. sensors to wifi routers to cloud

In this process the data from sensors move to wifi radio through cable (wired) after there to wifi router through radio waves which is wireless process. Wifi routers are connected to cloud by the Ethernet. In another way, from mobile routers the data leave to mobile towers and then to cloud through Ethernet.

D .sensors to mobile to cloud

This is the advanced technology which is in progress. This is used by the mobile phones with the wifi and BT(Bluetooth) radio. Data flows from sensors to BT radio and from there it flows to smart phone to wifi router. From wifi router to cloud.[4]

III. OUTLINE FOR SMART CITIES

Let us assume, Smart cities functions like our body. All the buildings like the muscles in our body, greenery and parks like lungs that provide oxygen and make our life possible. We have roads as veins and arteries which moves the goods and the people (carries the information). Our body has 5sensors which sense the parameters like hot, cold etc., and pass the information to the brain[14]. Similarly, We construct sensor network to the city which senses different parameters, collects the data in the city and transmit it to the cloud. By this sensor layer we can develop many applications that access the data present in the cloud.

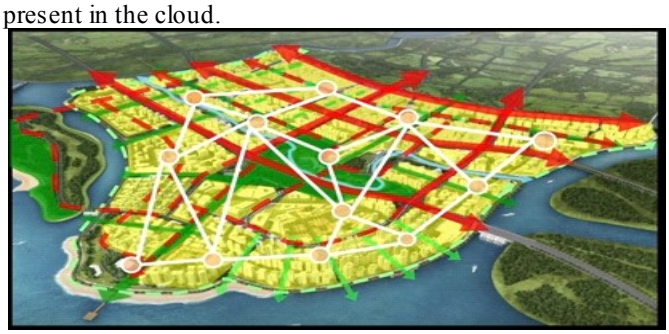

Fig1: Outline for smart cities

A. Smart planning:

Smart planning is to provide a better environment. Firstly, they collect all the information about the city like roads, buildings and parks etc., and also collect data about energy use and waste, save it in database[6]. By this information they can obtain a 3D map of the city. This map gives the status of the city to the developers. The developers continuously observes the changes in the city, update the details to the people in the city through mobile apps or electronic boards.

IV. SOME IOT APPLICATIONS

A. Smart parking:

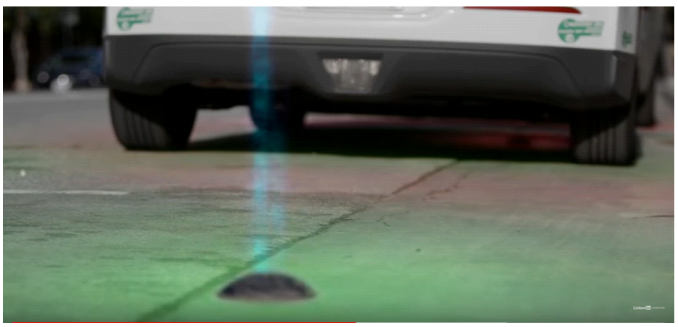

Fig2: Smart parking with sensors

When the city turns out of the traffic cars literally look around for the parking area which ultimately leads to congestion. To overcome this, smart parking came into existence[7]. In smart parking the sensors are affixed into parking slots and these sensors are responsible for giving the information whether the slot is preoccupied or not. This information can be viewed in our mobile phones and the one who drives the vehicle can get to know where the parking place available ,this ultimately saves the time, decreases the traffic and also unexpected damages[8].
To achieve this Nwave wireless parking space sensors are used that track the changes in earth magnetic field caused by presence of iron mass of an object(like vehicles). The status is then transmitted through radio, by a communication network to the cloud.

B. Traffic flow simulation and prediction:

The following are the different applications used in congestion control which is the major headache in the cities

i . In this application, they will push the map filled with traffic conditions (vehicles) of the city ,by seeing that the driver can able to know which way has congestion and can avoid that way .By this we can also know which way is shorter to reach our destination.

ii) Bus passenger count sensor:

Fig 3: Bus passenger count with sensors

From this application we can able to know whether the bus is crowded or not. This can be done by using **bus passenger count sensor.** A single sensor (connected to camera) is fixed at the entry/exit of passengers which is able to increase the count on entry of a passenger and decreases on exit[9]. The passenger movement (exit or entry) can be differentiated by camera which supports the image processing techniques. This complete information is send to cloud. People can access this information via corresponding app by providing the details like bus number.

iii. Fuel level sensor:
When the car is going to be out of fuel the **fuel level sensor** sense it and the software (at the steering) automatically displays alert message along with the data about the gas stations that are nearby.

iv. Connected cars:

Connected car technology is huge and a flexible network of multiple antennas, embedded software, sensors and technologies that provide the communication in order to navigate in this world[10]. The car is given with the internet and the car location and details can be shared by means of internet. It has the responsibility of making decisions with accuracy consistency and speed. These requirements will become more complex when humans lose control over steering wheel and brakes to the autonomous vehicles they can be controlled.

C. Elderly care:

Now-a-days many of the citizens are worried about their parents who will be at home alone when they went to job[11]. To overcome this we will fix sensors in the rooms in which their parents roam, these sensors monitors the movements of

their parents and gives the statistical data to their smart phones.

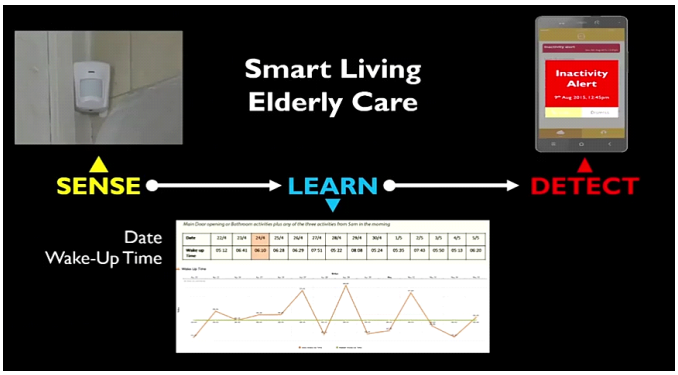

Fig 4: Smart Living Elderly care

D. power consumption:

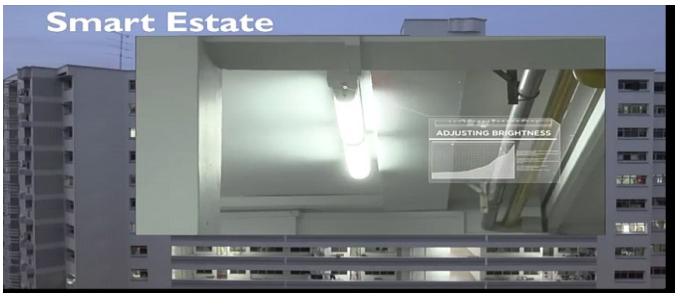

Fig 5: Smart Estate with sensors

In apartments, smart sensors are fixed in the corridor which senses the person movement and brightens the light at that particular place and glooms the remaining lights. Thus less power consumption is achieved.

E. Tele-health:

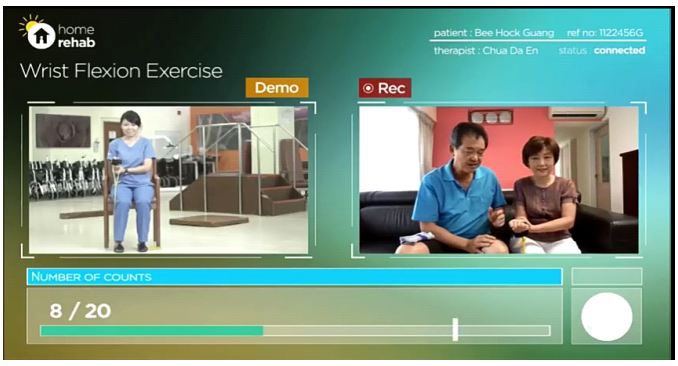

Fig 6: Tele-health is to monitor the patient's heath

The intention behind this tele-health is to monitor the patient's body without moving to the hospital [12]. The doctor can estimate the blood pressure of the patient as the patient catches the sensor. This is also useful for physiotherapy, the doctor can count the number of times the patient is moving his hand for a particular time and if there is any emergency they can suggest the patient to come to hospital.
This approach is used in elderly care where we can use the bed room sensors, call for help push button, toilet sensors etc.,

F. Shadow analysis:

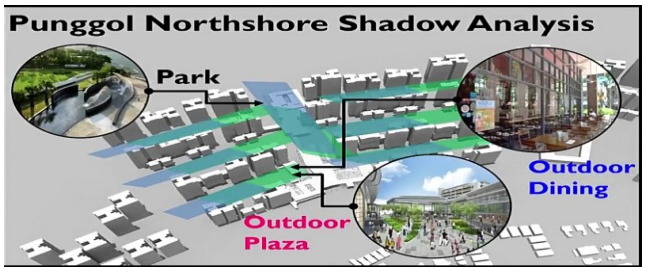

Fig 7: Punggol Northshore shadow analysis

This analysis will make us to know about how much time a particular place will have the shadow [11]. By this we can able to decide where to have which place. For instance, we like to have childcare center in such a place where most of the time it is covered with shadow such that the children can play freely the whole day.

G. Smart estates:

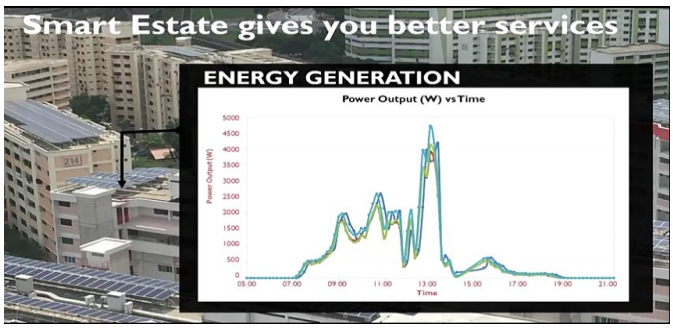

Fig 7: Smart Estate with sensors

In many of the cities we will have the solar panels spread over the buildings, in this case we fix **Uv or solar sensors** to the solar panels sensors to the panels and trace the energy collection by plotting a graph in the computer, by this if there is decreased or poor energy collection by any panel we can able to notice that the panel is not working and be replaced .In another case ,if the panels extending to some extent are collecting the low energy it will be cloudy or rainy in that particular area.

H. logistics:

i. Goods tracking and maintenance :

Good tracking and warehousing is one of the most important parts of the connected logistics. Affixing of small inexpensive sensors will allow companies to easily

track items, monitor their status, condition and construct a smart warehouse system. This idea will also help to check the goods where the human inspection is difficult.

ii. *Location tracking system*:

Location tracking can make the companies to get to know about the driver activities and the location whether he delivered the respective product or not. This can be done using the GPS tracking system this can be largely used in companies like uber, zomato, ola etc.[13].

V. SUSTAINABLE DEVELOPEMENT

Any country in the world, sustainable development will play vital role for its development. In our country about 67.8 percentage of current is produced by using coal which is an indigenous non-renewable resource. Uninterrupted usage of these resources will affect the future generation. If we keep on continuously using them the future generation will get affect in order to reduce that sustainable development should be must in the city.

Solar houses are nothing but construction of houses in which the power that we used to access the electrical appliances inside the house is generated by the solar energy. This can be done by converting solar energy to electrical energy by means of a solar panel and a battery. When the battery is depleted the home appliances will take the energy from the electrical grid.

This ultimately reduces the electrical charges to the common citizen. This is an Environmentally friendly process because it doesn't involve in any pollution raising activity like in thermal power.

VI. CONCLUSION

In this paper we discussed about the different applications used in developing of smart cities through IOT. Smart applications in industry, houses, hospitals, transport are covered which make a person to lead a comfortable life. IOT in transport is very importance because it can prevent many lives to be lost. Applications that are environmental friendly can make the city and the people clean and healthy.

***Abstract*—India is an agricultural country with the staple food being rice and wheat. The farmers serve as a backbone to our nation. But, the livelihoods of the agriculturists are at stake. They incur heavy losses due to crop failure and natural calamities. The emerging technology has provided many solutions to upgrade their lifestyle, but still there are challenges. Our main motive is to design a farmer friendly application- Agri Succor to sell their commodities directly to the customers at a reasonable market value without any mediator with the help of volunteers. For the efficient utilization of our mobile application by the farmers, we have incorporated features like information in regional language, crop-disease identification and sell their products directly. This application will emerge out as an essential productivity tool for the farmers if implemented in future**

Keywords—Farmers, Agri Succor, crop disease identification, mobile application

I. INTRODUCTION (*HEADING 1*)

We all are much aware of the fact that India is an agricultural country and tea, cotton and spices are the main exports. Rice and wheat are the most important crops in India because they are the staple food. However, our country, especially Tamil Nadu does not have an accessible agricultural information system for the farmers to gain knowledge on any of the agriculture related problems and solutions. So, there is not much scope in promoting agricultural activities to farmers who serve as a backbone to our nation. But for the past decade or so the lives of the farmers are at stake due to losses incurred during the land cultivation, harvest and natural calamities. The field of information technology has a huge impact on people nowadays and hence, there are many solutions commercially made available for the upliftment of the farmers. Yet, none of them proved to be such helpful in improving their livelihoods. There are also many mobile applications that are specially designed for farmers. Most of these apps mainly focus on only one particular feature like crop management, usage of pesticides, etc. Still, such applications lacked in some aspects as the farmers are unaware about the existence of such applications. Even if they are aware about those applications, the farmer does not know how to access it even though it is in his native language as he might be illiterate.

Our proposed project provides an ultimate solution to all the problems above mentioned. With the assistance of the Tamil Nadu Agritech portal[1], we will handle this situation by establishing a buy-sell platform exclusively for the farmers welfare with almost all kind of facilities.

The main objective of our application is to design a farmer friendly mobile application. So, we have named our app as 'Agri Succor'- Agriculture Helper. The proposed app is interlinked to the TNAU Agritech portal [1] for getting authentic information. Through this application, the farmers can sell their products produced on their farmlands directly to buyers at a reasonable market price. This application bridges the gap between the farmers and consumers through the most crucial role players- the volunteers. There is no intermediate involved in this process. The most astonishing feature of our application is that it is available in the regional language. We also provide another important characteristic – voice to text conversion. As a result, the farmer can enter the details either in text or in speech format. The farmers can get agriculture related information from other fellow farmers or volunteers connected through this application. The solutions for the farm related problems are extracted from the Tamil Nadu Agricultural Agritech application. An additional aspect is employability is created for the volunteers.

First of all, we discuss about the related works about the existing mobile applications on agriculture. Then, we explain about our proposed system which includes the architecture, methodology, as well as the implementation of the Agri Succor application. It is followed by the advantages of the application.

II. RELATED WORKS

A. CCMobile App: CC stands for Connected Crops[2]. User can read the environment metrics like temperature, humidity, etc. Sensor readings are available through SMS or email alerts, graphing and the climate factor historical data. It optimized crop management but it covered only the climate factor

B. Spray Guide: Spray Guide[3] calculates the amount of solute, the amount of solvent, the mixing time and the spraying areas ,etc. Users can share their experience together with data and results to others over their social accounts.by using the this app ,produce quality product but this is not supported crop diseases detection.

C. IFFCO Kisan: It is offered by Indian Farmers Fertiliser Cooperative Limited (IFFCO). IFFCO Kisan[4] seeks advice from the agricultural experts and scientists about crops, agriculture cycle, etc. It is used to provide good Water management but not in the regional language

D. Mandi Trades: Mandi Trades[5] is a buying or selling platform by marketing of farm products. It Uses location intelligence to get a map-based view of both buyer and seller info, along with the geographical proximity. This app eliminates middlemen but it is not ensure the quality check.

E. myRML Farmer: Farm and crop specific precision solutions built with the help of India's top most agriculturists. myRML[6] Works by using specific tools it was designed to analyze or provide information on different aspects of farming habits. It provides high level guidance but there is no provision for weather forecast.

F. AgriSync: AgriSync[7] enables farmers and advisors to connect and resolve support issues using a mobile video customer service platform. It allows the advisor's organization to see open cases, resolution status and farmer feedback in real-time.

G. RainbowAgri Market: RainbowAgri[8] helps in digitizing and branding agriculture. It is a simple mobile and web based tool to profile the farmers, organize and manage farming communities.

III. PROPOSED WORK

The proposed system is designed to provide a friendly interface especially to the farmers. The three main roles of our application are farmers (sellers), volunteers and buyers. The personal details of all the users are highly confidential and secure. In this mobile app, the farmers can provide details about their farmlands and groceries that are being cultivated in their land. The information can be entered either in text or voice format that too in his/her own language. Once the crop has been harvested, the farmer can upload the image of the plant. The plant is checked for the pesticides level and the disease is identified in the app. The recovery solution for the same is provided either in video, audio or text format which are obtained from the Tamil Nadu Agritech application. Once the plant is quality checked, it can be viewed by the buyers who can purchase them at an affordable market price and delivered with the help of the volunteers. Hence all the facilities are available under one roof.

The architecture of the proposed system is shown in Fig.1. The architecture depicted below shows the overall structure of our project. The database plays a major role in gathering and retrieval of data.

a. Collection of Data: The input can be given as text, voice or else as image when the crop is diagnosed for any disease with the help of TNAU application. The interested buyers and sellers can register in this app using the buy- sell platform. The interested volunteers can enroll themselves for uploading the agriculture related news, new government schemes for the betterment of the farmers.

b. Retrieval of Data: The farmers can get the authentic information on crop disorders, recommended pesticides, buyer & seller information, product details and recovery solutions in text, voice and video formats in the corresponding native language. The data which is gathered need to be organized as a report. Using crucial strategies, the data is converted to report before sending them to the farmers, volunteers and consumers. This result can be either in the form of text or voice as per the wish of the user. Data retrieval is the defined as the process of identifying and extracting data from a database, based on a query provided by the user or application. It is achieved through the usage of SQL Processing.

All the features in the architecture are realized through the implementation process

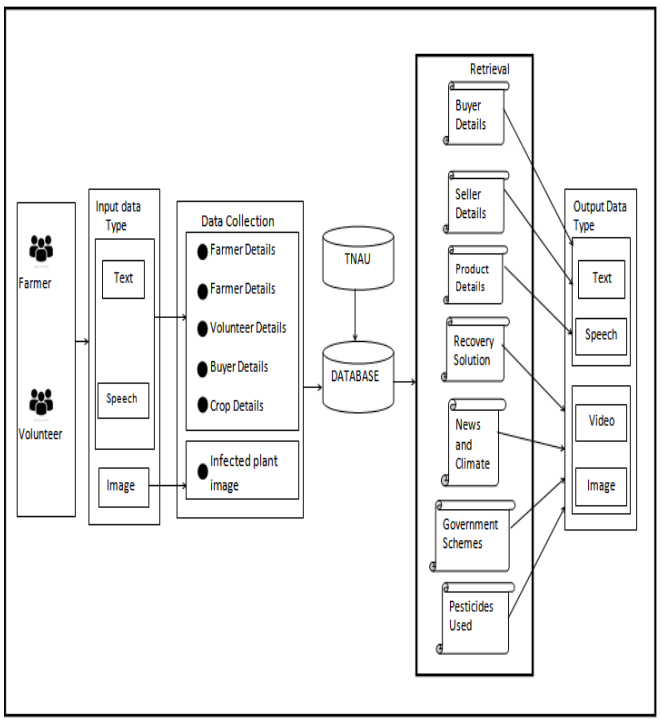

Fig.1. Architecture of the proposed system

A. IMPLEMENTATION

The implementation of the Agri Succor app is divided into three sections:

1. **Interface design:** It consists of three form designs for the use of farmers, volunteers and buyers.

Designing the interface of the application involves three main modules:

a. ***Farmers login***: The farmer login is shown in Fig.2.It consists of the entire details of the farmer including his location, type of crops cultivated in his farmland, price of his farm products, etc. given as text or voice with the option for regional language if required. This information is stored in the database. The farmer can even upload images of his commodities to check the level of pesticides used as well as check for any crop related disorders. He can have access to remedial measures for the crop diseases. In addition to this, he can keep a tab on the agriculture related news and schemes. He can even provide suggestions for the crop diseases to assist other fellow farmers. He can sell his produces to the consumers directly with no intermediary between them.

b. ***Volunteers login:*** The Volunteers login is shown in the Fig.3.The regular updates regarding agricultural schemes, climate and suggestions on crop cultivation are provided by the volunteers. Their main duty is to create awareness among the farmers regarding all kind of agricultural information. The much needed employability is given to these volunteers for their dedicated work. The delivery of farm products to the customers are done with the help of these volunteers

Fig.2. Farmers login

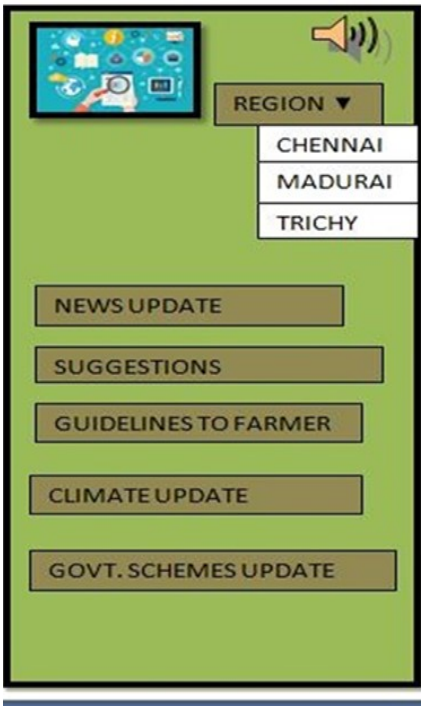

Fig. 3. Volunteers login

c. ***Buyers login***: The Buyers login is shown in Fig.4. The consumers who are willing to buy the farm products directly from the farmers need to enter their information. Once they select the items of a specific farmer, notifications are sent to the respective farmer. The ordered items are safely delivered to the customer.

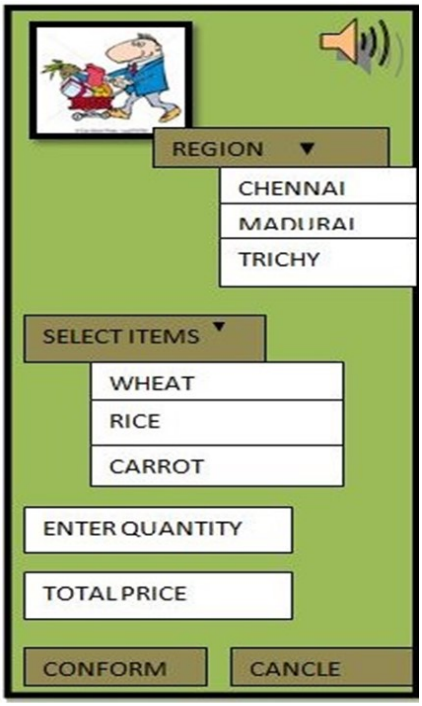

Fig. 4. Buyers login

2. **Voice to text conversion:** For extraction of voice signal, we use Mel-Frequency Cepstral Coefficient algorithm [9] and Minimum Distance Classifier. Support Vector Machine methods are used for speech classification. These techniques are highly efficient in converting the speech to text and vice versa.

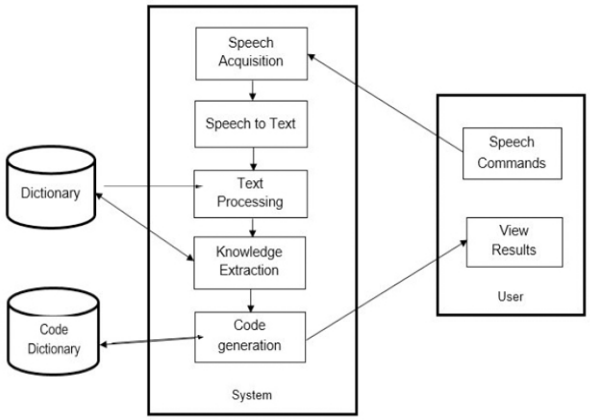

Fig.5.Voice to text conversion

3. **Disease identification:** Crop disease identification is done with the help of suitable image processing techniques. The procedure involves classification, feature extraction, multi-scale signal analysis, pattern recognition and projection

IV. BENEFITS

The Agri Succor will indeed be beneficial in almost all aspects. Some of the most important advantages of the proposed system are listed below:

a. Through the use of the application, both the standards of agriculture and farmers can be raised up.
b. The details can be given as voice or text input.
c. It also increases the job opportunities for the unemployed youth.
d. The commodities are freshly handpicked and delivered to the customers at a reasonable market value.
e. The application can be accessed in the regional language.
f. Instant updates on agricultural schemes, climate, crop diseases and their solutions are provided by the farmers and volunteers.
g. Quality check of the farm products before marketing them ensures that only disinfected items are sold.
h. The remedial measures for the crop diseases are provided in terms of text, voice and video. Considering the above pros of our application, we hope that this project will truly enhance the lifestyle of the farmers.

V. CONCLUSION

Through this mobile application, most of the problems faced by the farmers are provided immediate solutions and guidelines. If this initiative will be implemented in future, unemployability will be reduced to a considerable extent. Moreover, the betterment of the farmers could surely be realized. This application will emerge out as an essential productivity tool for the farmers.

***Abstract*— Automation of detecting the shape and boundaries of object in the image is necessary in various object recognition and computer vision tasks but in case of underwater images it poses several challenges because of their degraded quality due to poor lighting conditions, scattering and absorption of light in underwater. A method to detect the object in underwater images is presented in this paper in which degradation of image is dealt by adjusting the image intensity values in order to enhance the contrast of the image. Further, segmentation is done using adaptive thresholding followed by detection of boundaries of object using Sobel operator and then morphological operations are performed to detect the object in underwater image. The results of the proposed method are qualitatively compared with Otsu's thresholding and Fuzzy C-means Clustering (FCM) for segmentation by visual perception and objectively by PSNR and SSIM which gives better and acceptable results on the considered underwater test images.**

Keywords—Object detection; Image enhancement; Image segmentation; Edge Detection; Morphological operations.

I. INTRODUCTION

Within the last few decades, the underwater image processing area has received a considerable attention due to its wide variety of application range from counting of fishes for biological research to the inspections of the structures in underwater for the offshore industries. In order to fulfill the above applications, the detection of objects is necessary in first to make further practice of the task successful. But there are many challenges in the underwater image processing as the physical properties of the water behave differently in water, change of the appearance of a same object with the variations of depth, currents, organic material, temperature and moreover a new set of challenges appear as soon as camera goes into water [1]. The deterioration of materials quickly due to corrosion in water along with waterproofing of cameras and modifications to experimental setups makes them costly, both in resources and time. Underwater images often suffer from low contrast and color-distortion, because of scattering and absorption of light when traveling through water. Color change occurs because of varying degree of attenuation by travelling of light in water with different wavelengths [2]. Due to above reasons the enhancement of the underwater image is a necessary preprocessing task in the underwater image processing. Software methods like histogram equalization, fusion, contrast stretching and polarization have also been used to improve the quality of image [3]. An attempt to enhance the image by modifying contrast-stretching manipulation is done by Yang et al. [4]. Detection of the object from enhanced image is comparatively easier than from raw underwater images. Image segmentation is the easiest way to convert grayscale image to binary image in order to make it easier to analyze and more meaningful and can be done by thresholding methods. Roy et al. made a comparison of different adaptive thresholding techniques in order to choose the most precise method to binarize the image based on texture, contrast, resolution etc. of an image [5]. Segmentation can also be performed using morphological operations [6]. Edge detection techniques gives connected curves indicating object boundaries of the objects which leads to decrement of the amount of information to be processed, filtering out meaningful information. Several attempts to identify object by detecting edges in underwater images is made [7-8]. One of the most important edge detection application in images is the detection of objects present in the image. There are many edge detection techniques used for object detection and image segmentation [9-11]. Edge detection and object detection using morphological operations is also done in [12-13]. Liya et al. has detected object by using morphological operations along with feature extraction [14]. Sudhakar et al. has done foreground extraction from underwater images by using block based enhancement, thresholding and morphological operations [15]. Although, these methods are beneficial but little attempts were made for object detection in underwater image using morphological operations. In our work after the contrast enhancement we have used segmentation followed by edge detection using adaptive thresholding and Sobel operator respectively. Finally, morphological operations i.e. dilation, region filling and erosion is applied to the image in which edges are being detected by Sobel operator. The structure of rest of the paper contains explanation of the proposed work in

detail which is described in section II. Section III consists of the results for considered underwater images. Finally, we have concluded the work in section IV.

II. Proposed Approach

In this paper, a method has been proposed for detection of objects in underwater images consisting of four steps shown in fig. 1. (i) Here, to deal with degradation of image, adjustment of intensity of image is done to enhance contrast of image. (ii) Further, segmentation is done using adaptive thresholding and (iii) Sobel operator used for edge detection. (iv) Finally, morphological operations are performed to detect the foreground object in underwater image.

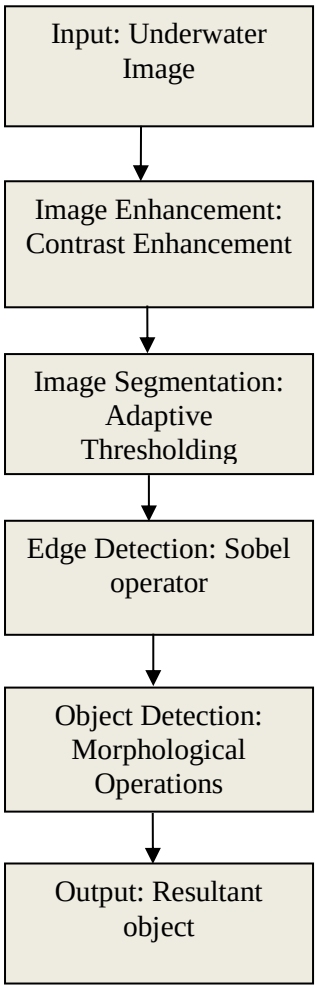

Fig. 1. Flowchart of Proposed Method for Object Detection in Underwater Image.

(i) Image Enhancement:

Underwater images are adversely degraded, hazy in nature and appearance, affected by poor lighting in under water and several atmospheric phenomenon of scattering and absorption of light which affects the quality of image. Due to these factors contrast of the image is heavily affected, therefore, adjustment of intensity of image is done on the grayscale image of the original underwater image by saturating the bottom 1% and the top 1% of all pixel values of the image in order to enhance the contrast of image helping us to distinguish the presence of various objects in the image as shown in fig. 3 (a).

(ii) Image Segmentation:

Image segmentation divides an image into different segments to simplify the image representation and make it more meaningful and easier to analyze. This is typically used to identify the boundaries and objects in images. Here, segmentation of image is done on the enhanced image to convert grayscale image into binary image using adaptive thresholding. In adaptive thresholding, threshold value is changed dynamically over the image and threshold value at each pixel location is dependent on the neighboring pixel intensities. The thresholded image using adaptive thresholding can be seen in fig. 3 (b). Here, the adaptive threshold *Thresh (p, q)* at pixel location *(p, q)* in the image is calculated by first selecting a $a \times a$ region in the image around the pixel location and then calculating the weighted average of the $a \times a$ region by taking the average (mean) of all the pixel location that lie in the $a \times a$ which is represented by *Average (p, q).* Finally, the value of threshold *Thresh (p, q)* is calculated by subtraction of constant parameter *z*, from the weighted average value *Average (p, q),* calculated previously. Therefore, the threshold value *Thresh (p, q),* at pixel location *(p, q)* can be given by:

$$Thresh\ (p, q) = Average\ (p, q) - z \quad (1)$$

(iii) Edge Detection:

Edge detection is an image processing technique used to detect the boundaries of objects in the images. It aims at recognizing the points in an image at which the brightness of image changes sharply and organizing these points into a set of curved line segments termed as edges. Therefore, the image obtained from previous step is further used to detect the boundaries of the object present in underwater images by Sobel operator. The aim of this process is to get clear and more prominent lines of the object as shown in fig. 3 (c). Sobel operator is preferred over others to identify the edges of the object in the underwater image because of its simplicity over others and that it detects edges and their orientations too. A Sobel filter has two 3x3 kernel created for both the X and Y axis of the image shown in fig. 2 in which Y kernel is just a 90 degree rotation of the X kernel. The Sobel filter kernel 2d-convolution is then applied on the image to emphasize lines on the X and Y axis.

-1	0	1
-2	0	2
-1	0	1

(a)

-1	-2	-1
0	0	0
1	2	1

(b)

Fig. 2. Masks used by Sobel operator (a) Horizontal mask G_x and (b) Vertical mask G_y.

The horizontal and vertical kernels are combined together in order find the absolute magnitude, |G|, of the gradients at each point which is given by below function:

$$|G| = \sqrt{G_x^2 + G_y^2} \quad (2)$$

(iv) Morphological Operations:

Morphology has a broad set of operations in digital image processing in which images are processed according to its shape. A structuring element or kernel over the input image is used in these operations and a corresponding output image with same size is produced. A comparison between the pixels of the input image is done along with the neighborhood pixels and corresponding output pixels are obtained. The size and shape of these neighborhoods affects the result of the morphological operations. The following operations are used in our proposed method to remove the noise or the holes present in the background of the image in order to increase the clarity of the object in the image:

Dilation

Dilation is the process of expansion. Dilation operation "grows" or "thickens" the objects in binary image. This lengthening and thickening is controlled by a structuring element. Dilation is useful for filling small holes while preserving the size and shape of the objects in the image and is depicted in fig. 3 (d).

Region Filling

Region filling operation fills the holes in an input intensity image. Hole is an area in which dark pixels are surrounded by lighter pixels. Figure representation is shown in fig. 3 (e).

Erosion

Erosion operation "shrinks" or "thins" the object in the binary image. Structuring element controls the extent and manner of shrinking. Erosion simplifies the structure of an object or their parts and make the structure disappear if width is equal to one. It might also lead the several complicated objects to decompose into simpler ones. Figure representation is shown in fig. 3 (f).

Algorithm: Object Detection in underwater image

Input: Underwater hazy image

Output: Object detected image

i. Take a real underwater image.

ii. Adjusting the pixel intensity of image to enhance contrast of the image.

iii. Obtain a segmented image by applying adaptive thresholding on the enhanced image by using equation (1).

iv. Apply Sobel operator to detect the edges of the segmented image making the edges more prominent.

v. To complete the edges discontinuities apply dilation operation.

vi. For filling the region inside object's boundaries use region filling operation.

vii. To remove small background objects erosion operation is applied.

viii. Detected object can be seen in final image.

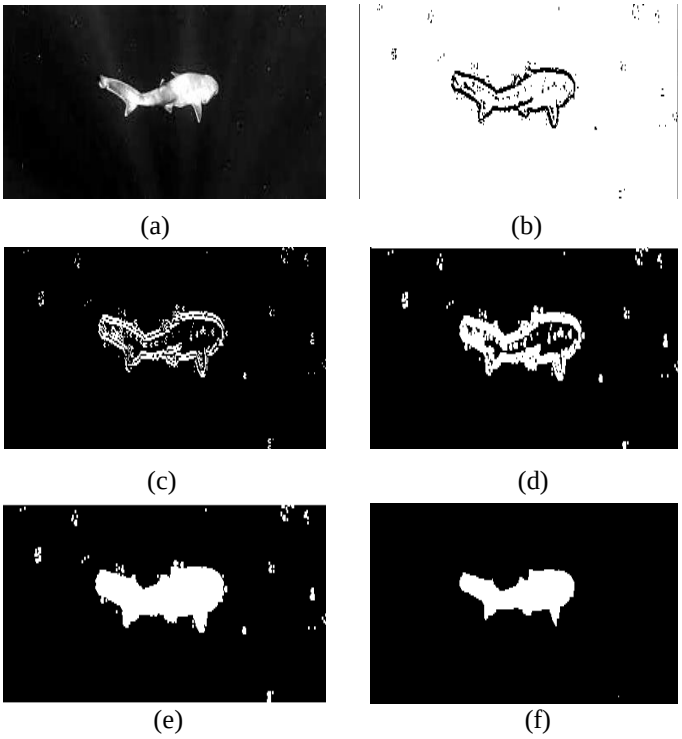

Fig. 3. Visual representation of the steps of the proposed method: (a) Contrast enhancement, (b) Adaptive Thresholding, (c) Sobel operator, (d) Dilation, (e) Region Filling and (f) Erosion .

III. RESULTS AND ANALYSIS

In the experimental results we have evaluated our method on real underwater images as shown in fig. 4-8 (a). The dominant color observed in the images is blue because of its wavelength and therefore, dominance of blue pixels can be clearly observed in images. We have done both objective and subjective comparison of our method with the conventional segmentation techniques i.e. Otsu's thresholding [16] and Fuzzy C-means Clustering (FCM) [17]. We have used Matlab 2016 toolbox running at core 1.70 GHz processor for implementation of all existing and proposed methods which are considered in the paper.

The objective criteria i.e. PSNR and SSIM [18] are considered as significant parameters for the quality of image. Peak Signal-to-Noise Ratio is used to measure compression quality between the original and reconstructed image. The higher PSNR represents the better quality of the reconstructed image. On the other hand, SSIM is defined as structural similarity index which is used for measuring the similarity

between two images. SSIM is a perception- based model in which the degradation of image is a perceived change in structural information, while also including both luminance and contrast masking terms for incorporating important perceptual phenomena. The value of SSIM index is between -1 and 1, and value 1 indicates perfect similarity in images and is reached only in the case of two identical images. Therefore, we can say that an image should possess high PSNR value and high SSIM close to 1 for an image to possess higher quality. Table I and Table II shows the comparison of the performance our method for considered images of underwater with that of Otsu's thresholding and FCM based on evaluation parameters: PSNR and SSIM, respectively and shows that our proposed method gives better results than other methods considered.

The subjective criterion has been fulfilled by considering the restored object in image and comparing it with Otsu's thresholding FCM for segmentation. In fig. 4 and 6 (b-d) we can see that fish boundaries are clearer and the shape of fish is more appropriate in the proposed method. In fig. 5 (b-d) the turtle's shape is complete in comparison to other methods. Similarly, the diver in fig. 7 (b-d) and fishes in fig.8 (b-d) is more fairly detected and visible by our method rather when compared with Otsu thresholding and FCM. Therefore, it is observed that images we get by our proposed method produces better results than other methods considered for object detection.

IV. CONCLUSION

In this paper, we have proposed an object detection method using adaptive thresholding, Sobel operator and morphological operations in underwater images. In our approach the main idea to detect object is that edges or the shape of the object is detected prior to the application of morphological operations in order to detect the object clearly. The proposed method consistently give better results on the considered underwater images when compared with conventional segmentation techniques Otsu's thresholding and Fuzzy C-means Clustering (FCM). The present work can be extended by focusing on the accuracy of the shape of the objects and detection of main object along with the background small objects using soft computing based methods.

***Abstract*— The thyroid hormone is produced by thyroid gland. This hormone regulates the body's metabolism. Hyperthyroidism and hypothyroidism are the two abnormalities which is caused by the release of too much or too little thyroid hormones respectively. In this study, Random Forest (RF), Support Vector Machine (SVM), and K-Nearest Neighbours (K-NN) classifiers are compared to assess the efficiency of these classifiers in Thyroid disease diagnoses using the thyroid disease dataset that is taken from UCI machine learning repository. The overall classification accuracy of the RF, SVM, and K-NN are 98.50%, 97.02%, and 95.81% respectively. The result shows that the RF classifier performance is better than SVM and K-NN for the diagnosis of thyroid disease using UCI dataset.**

Keywords*— *Thyroid disease diagnosis, Computer-aided diagnosis, Machine learning classifiers.

I. INTRODUCTION

The thyroid gland is one of the endocrine glands that produce thyroid hormone to regulate the body's metabolism [1]. The Levothyroxine (T4) and Triiodothyronine (T3) hormones are produced by thyroid gland. These hormones play a major role in converting nutrients into energy and thereby helps in regulating body temperature, heart rate, and even brain function. Hyperthyroidism occurs when the hormones produced by the gland is more than the requirement of the body. However, hypothyroidism occurs when the hormones produced by the gland is less than the requirement of the body [2]. Severe hyperthyroidism and end-stage hypothyroidism may cause deaths [3] [2]. During pregnancy, it can lead to health problems for the mother and baby [4].

About 70% risk of developing the thyroid disease is found to be associated with genetic background. Also, the contribution of environmental exposures such as perchlorate in rocket fuel, polychlorinated bi-phenols, and radiations (from nuclear fallout and medical radiation) in the disease risk is significant. Most of the environmental exposures reduce thyroid hormone levels [5]. Recently, the thyroid disease risk is found to be linked with systemic lupus erythematosus, an autoimmune disease [6]. There is some evidence of the correlation between thyroid disease and the low level of vitamin D [7].

The amount of T3 and T4 hormone in the blood is controlled by another hormone known as Thyroid Stimulating Hormone (TSH). Low T4 results in more production of TSH that initiates thyroid gland to produce more T4 & vice versa [8].

The different thyroid function tests such as TSH, T3, T4U, Total T4, and Free T4 Index (FTI) are done to assess the various functions related to the thyroid gland. A normal TSH and normal T4 is indicative of normal functioning of the thyroid gland, a low TSH and elevated T4 indicates hyperthyroidism, a low TSH and low T4 indicates secondary hypothyroidism, and a high TSH and low T4 indicates primary hypothyroidism. T3 tests are used for determining the severity of the hyperthyroidism or to diagnose the hyperthyroidism [9].

The classification algorithm is based on supervised learning methodology where the labeled data is used for learning. These algorithms require very large labeled training sets which consist of many features or attributes.

Finding meaningful information from the thyroid datasets of the patients with regard to the thyroid disease diagnosis is important. This paper compares the performance of three classification algorithms, namely, RF, SVM, and K-NN for the diagnosis of thyroid disease by analyzing labels (TSH, TT4, T3, FT4, and T4U) in hyperthyroid, hypothyroid, and normal subjects.

The rest of the paper is organized as follows. Section II briefly describes the related work. Section III presents the methodology that includes the description of the dataset used, a brief introduction about ML classifiers (RF, SVM, K-NN), and the performance metrics used in the analysis. Section IV presents the results and discussions. Section V concludes this

paper.

II. RELATED WORK

Researchers have used various machine learning algorithm for the diagnosis of thyroid diseases. For instance, authors of [10] use Wavelet Support Vector Machine and Generalized Discriminant Analysis to develop an expert system for thyroid disease diagnosis. They achieved the classification accuracy of about 91.86%. Polat et al. [2] hybridize the artificial immune recognition system with fuzzy weighted pre-processing to diagnose the thyroid disease. The classification accuracy of their model was 85%. Feyzullah Temurtas [3] suggests the diagnosis of thyroid disease using Neural Networks. They obtained the accuracy of 93.19%, 94.81%, and 90.05% using multilayer, probabilistic, and learning vector quantization neural networks respectively. Gharehchopogh et al. [11] propose a Multi-layer Perceptron (MLP) which is trained via back propagation learning algorithm for the classification of thyroid disease. The classification accuracy of 96.8% was achieved.

III. METHODOLOGY

A. Dataset description

The dataset for this study is acquired from the UCI machine learning repository. The dataset consists of 7200 instances, 21 attributes of which 15 attributes are categorical and six attributes are numerical. All the instances in the dataset are labelled to one of the three classes: hyperthyroidism, hypothyroidism, and normal subject.

Table 1. Thyroid disease dataset description.

Number of attributes & instances	Values
Total number of attributes	22 including one label set
Attributes with categorical values	15 with two possible values 0/1
Attributes with numerical values	6
Total number of instances	7200
Number of attributes used for analysis	5

The number of instances belongs to hyperthyroidism, hypothyroidism, and normal subject classes are 166, 368, and 6666 respectively. The distribution of instances among three classes shows that the dataset is highly imbalanced. Further for the analysis purpose, the whole dataset was split into a training dataset and test dataset in the ratio of 80/20. Therefore, there are 5760 instances in the training dataset and 1440 instances in the test dataset. Out of the 21 attributes, only 5 attributes are used for the analysis. These attributes represent the various thyroid function tests that indicate the level of thyroid hormones in the blood and are indicative of thyroid disease. These attributes are as follows [12]:

(i) TSH that ranges between 0.4 to 5.0 milli-International Unit per liter.
(ii) Total T4 (TT4) ranges from 4.6 to 12 micrograms per deciliter of blood.
(iii) T3 that ranges between 100 to 200 nanogram per deciliter of blood.
(iv) Free T4 Index (FTI) or FT4 that ranges between 0.7-1.9 nanogram per decilitre of blood.
(v) T4 Uptake (T4U).

B. Support Vector Machine

SVM constructs the hyperplanes in a multidimensional space for the classification task. This space separates classes of different class labels. It is able to deal with non-linear and high-dimensional data. With RBF kernel, the performance is further improved in case of non-linear and high dimensional data. The drawbacks of SVM include: (i) selection of kernel function is difficult as the performance varies with different kernel functions and datasets, and (ii) time-consuming training phase incurs high computational cost [13]. The extreme data points in each class represent the support vectors while the decision boundary between them is the hyperplane which is drawn in such a way that the distance between the support vector and the plane should be maximum.
In this study, the SVM model is trained by using the training samples and the model is tuned by tuning the various parameters to get the optimum result. The parameters used for tuning are Kernel function, C parameter, and gamma coefficients. Kernel function does the mapping of data to different space. The various kernel functions are Linear, rbf, poly, sigmoid, precomputed or a callable. In this study, the SVM model is tuned by using rbf and sigmoid kernel function. The parameter C is the regularization parameter that has the ability to generalize the SVM to perform well on the unseen data. It controls the tradeoff between the achieving a low training error and a low testing error. A large value of C corresponds to a small margin whereas a small value of C corresponds to the large margin between support vectors and hyperplane. In this study the SVM model is tuned at various values of C. Gamma is the kernel coefficient for rbf, poly, sigmoid kernel function which adds complexity in the classification.

C. Random Forest

Random forest (RF) builds multiple decision trees and combine them toger to obtain a more robust, accurate and stable prediction. It adds additional randomness to the model while growing the trees. This algorithm searches for the best feature among a random subset of features for splitting a node.

In RF classification approach, voting strategy is used where each tree votes for a particular class. The rows or instances are then classified into the class for which maximum number of trees have voted. Due to more robustness, the performance of RF it better than AdaBoost, which is also an ensemble learning

technique. The performance of RF is better than DT because, when there is noise in the attribute, trees become deeper and hence overfitting problem occurs. However, RF is less influenced by the noise in the attributes as different sample of the training data is used in the process of averaging the deep decision trees [13]. In this study, the RF model is tuned by varying the n_estimators parameter which represents the number of trees in the forest.

D. K-Nearest Neighbor

K-NN classifies a data point based on how its neighbors are classified. It computes the distance between the new instance and previously known instance to classify the new instance by using the voting strategy. The information about previous instances is given in the training set. It is simplest among all ML classifiers [13]. In this study, the K-NN model is tuned by varying the value of K and compared with each other to get the best classification performance.

E. Performance Metrics

Following performance metrics are used to analyze the performance of different ML classifiers.

Precision: It is used to measures the classifier exactness. It is also known as positive predictive value (PPV).

Recall: It measures the classifier completeness. It is also known as sensitivity or hit rate, or true positive rate (TPR).

Specificity: It measures the proportion of actual negatives that are correctly identified and also called a true negative rate (TNR).

Accuracy: It measures the fraction of predictions our model got right. It can be calculated as the total number of correct predictions divided by the total number of test cases.

F1-Score: It measures the balance between precision and recall.

Class weighted accuracy: It can be calculated as the ratio of the sum of each class size multiplied by its individual accuracy to the total number of test cases.

IV. Results and Discussion

The aim of this paper is to assess the classification efficiency of different ML algorithms on the thyroid disease dataset acquired from UCI. Table 2 shows the classification performance of different ML algorithms in terms of precision, recall, specificity, accuracy, and F1-score for each class. All the models were tuned to enhance the performance. The SVM gives the best result with the *RBF* kernel function and when the values of the parameters C and gamma coefficient are 100 and 1024 respectively. The RF gives the best result when the value of the parameter n_estimators is 32 and K-NN gives the best result when the value of the parameter n_neighbors is set to 1.

It can be observed from Table 2 that for all the classes the RF model gives the best performance in terms of all the performance metrics. It was seen that the performance of the SVM model was improving on increasing the value of the parameter C and best performance is achieved when the value of C is 100 but further increase in the C value results in the performance deterioration. Because the optimal value of C parameters should be large when the feature values in the dataset is small. However, for large value of C, the misclassification rate increases which results in poor performance. Similarly, for RF, the performance increases by increasing the value of the n_estimators as for the higher value of n_estimators, the performance of RF increases. When the value of n_estimators is 32, the best performance is achieved. The further increase in the value of n_estimators results in no change in the performance. However, for the K-NN model, the performance is best at k=1 and starts decreasing by further increasing the value of K. The overall class weighted performance measures for all the classification model is presented in Table 3.

Table 2: Performance of different ML algorithms.

Classes	Performance metrics	Classification models		
		SVM (%)	RF (%)	K-NN (%)
Hyperthyroidism	Precision	91.66	92.68	84.84
	Recall	84.61	97.43	71.79
	Specificity	99.78	99.78	99.62
	Accuracy	99.35	99.71	98.84
	F1-Score	88	95	77.77
Hypothyroidism	Precision	76.8	86.51	69.56
	Recall	75.90	92.77	57.83
	Specificity	98.59	99.11	98.44
	Accuracy	97.27	98.74	63.15
	F1-Score	76.36	89.53	96.08
Normal subjects	Precision	98.18	99.46	97.01
	Recall	98.48	98.86	98.48
	Specificity	80	94.26	65.51
	Accuracy	96.94	98.47	97.74
	F1-Score	96.94	99.16	95.81

Table 3: Overall class weighted performance for the different classification model.

Overall Class Weighted Performance Measures	Classification models		
	SVM (%)	RF (%)	K-NN (%)
Precision	96.77	**98.54**	95.26
Recall	96.80	**98.57**	95.49
Specificity	81.60	**94.69**	70.67
Accuracy	97.02	**98.50**	95.81
F1-Score	96.78	**98.52**	95.35

Figure 1 shows the overall class weighted average performance of SVM, RF, and K-NN with respect to the different performance parameters. For all the performance parameters (precision, recall, specificity, accuracy, and F1-

score), the best performance is achieved by RF followed by SVM and K-NN.

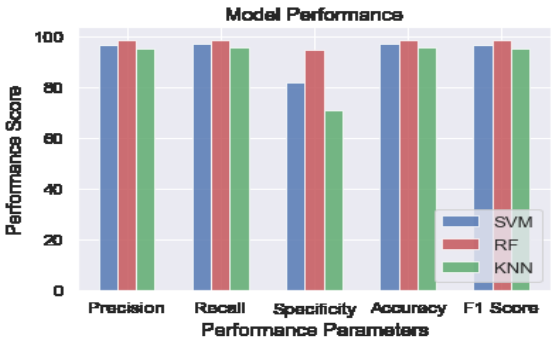

Fig. 1. Overall performance measure comparison for all the classification model

V. CONCLUSION

The paper presented a comparison of three different ML techniques namely, SVM, RF, and K-NN applied for the classification of the thyroid disease into hyperthyroidism, hypothyroidism, and normal subjects. The dataset for this study was acquired from the UCI machine learning repository. To evaluate the performance of different ML algorithms, various performance metrics such as precision, recall, specificity, accuracy, and F1-score were used. Although all the models may be used for the classification, the RF classifier outperformed SVM and K-NN. The maximum weighted average accuracy achieved by RF was 98.50 %. However, the accuracies achieved by SVM, and K-NN are 97.02%, and 95.81% respectively. RF also gives the best performance on all the performance metrics in comparison to SVM and KNN. In future, it would be interesting to assess the classification performance of metaheuristic algorithms on this dataset.

***Abstract*—A multispectral image when fused with a panchromatic image acquired on common location to produce another multispectral image with added spatial resolution, the image fusion is known as 'Pansharpening'. Developement of pansharpening algorithms and their quality assessment are the most debated topics of research from the last few decades. In this paper, the authors attempt to compare performances of selective Multi-Resolution Analysis based pansharpening algorithms listed as High-Pass Filtering, Smoothing Filter-based Intensity Modulation, Modulation Transfer Function-Generalized Laplacian Pyramid based algorithms, Indusion and Wavelet Transform based algorithms. These algorithms are applied to two datasets, acquired by QuickBird-2. The performances are evaluated based on popular image quality metrics. This performance analysis will surely help in evaluating the best possible tradeoff between spectral resolution and spatial resolution for fused image produced by the selected algorithms.**

***Index Terms*—Remote sensing, image fusion, pansharpening, panchromatic image, multispectral image, multi-resolution analysis**

I. Introduction

Pansharpening produces an image rich in spatial and spectral resolutions from the fusion of a multispectral (MS) and panchromatic (PAN) imagery; provided both images are acquired on same location [1]. The PAN images are rich in spatial resolution of even lesser than 1 m and MS images are deficient in it, but hold up to eight spectral bands [2]. The physical constraints of the satellite sensors cannot provide rich spatial and spectral resolutions in unique image product. But, the demand for higher resolutions of both types is continuously growing for several remote sensing tasks [3]. These help groundwater prospects mapping, forecast of agricultural output, forest cover mapping, snow & glacier studies, wasteland mapping, visual image analysis, object recognition, change detection, etc. One of the promising attempt to fulfill this demand is seen in terms of 'data fusion' [4]. The pansharpening is a part of this larger research domain 'data fusion' and evolved as a solution with great importance to the problem of physical constraints of satellite sensors. Pansharpening can be regarded as a branch of traditional image fusion.

A. Related Work

Survey of pansharpening algorithms can be found in [5]. The algorithms proposed so far are mostly categorized in two major groups viz. Multi-Resolution Analysis (MRA) [6] and Component Substitution (CS) [7]. The algorithms employing features of both approaches are treated as hybrid [8]. MRA involves an iterative decomposition scheme that constructs an order of 2D-signals holding progressive reduced contents. Here, the content of information is considered as spatial frequency. The decomposition can range from single level to more complex techniques. Thus, MRA is alternatively referred as 'pyramidal approach' [9]. This paper compares the performances of the most recent MRA based pansharpening algorithms listed as High-Pass Filtering (HPF) [10], [11], Smoothing Filter-based Intensity Modulation (SFIM) [11], [12], Modulation Transfer Function-Generalized Laplacian Pyramid based algorithms [11], [13]–[15], Indusion [11], [16] and Wavelet Transform based algorithms [11], [17]–[19].

The outline of the paper is arranged as: Section II briefs the fusion process opting MRA. The selected MRA based image fusion algorithms are presented in Section III. Application of algorithms to image datasets together with a discussion on results is addressed in Section IV. Lastly, the conclusions are noted in Section V.

II. MRA Approach to Image Fusion

The generalized procedure opted by MRA approach involves an iterative decomposition scheme that constructs an order of 2D-signals holding progressive reduced contents, which is obtained by the exploitation of particular analysis operators in repeatable manner.

The result of image fusion exploits computation of subtracting the low-pass filtered PAN image from itself. High-spatial resolution fused product is mathematically defined as:

$$F = M_{up} + g(P - P_L) \tag{1}$$

Where, M_{up} is the MS image now resized to match PAN level, g is the gain factor for spectral bands in MS image, P accounts for the PAN image, P_L is the low-pass form of PAN and F holds the result of image fusion. P_L for (1) is computed as:

$$P_L = \sum_{k=1}^{N} w_k (M_{up})_k \tag{2}$$

Where, w represents optimal weights for spectral bands of MS image denoted as $k = 1, ..., N$.

III. MRA Based Image Fusion Algorithms

This section describes the working procedures of popular MRA approach based image fusion algorithms.

A. High-Pass Filter

In HPF, the PAN image is operated by a small spatial filter of high-pass type. Outcome obtained due to this contains the high-frequency component i.e the information related mostly to spatial details. This spatial filtering removes most of the spectral details. The results of high-pass filtering are added to the MS image rich of spectral resolution in pixel-wise manner. Ultimately, the algorithm combines the spatial details from PAN image to spectral details of MS image [10], [11]. The brief steps of HPF fusion are provided in Algorithm-1.

Algorithm-1: HPF
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define spatial filter H.
Step-3: P_L = Filter P using H.
Step-4: $F = M_{up} + (P - P_L)$

B. Smoothing Filter-based Intensity Modulation

By using a ratio of PAN image to its low-pass version, spatial information can be modulated. In SFIM algorithm, modulation is performed to a registered MS image deficient in spatial resolution. There are no alterations to spectral properties and contrast of MS. SFIM is actually extended development from the Pixel Block Intensity Modulation (PBIM) technique. The brief steps of SFIM are given in Algorithm-2.

Algorithm-2: SFIM
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define smoothing filter H.
Step-3: P_L = Filter P using H.
Step-4: $F = \dfrac{M_{up} \cdot P}{P_L}$

Relationship of P to P_L cancels the contrast of spectral, topographical type in the PAN image. It retains the only high-spatial resolution edges. This algorithm is thus considered consistent to the spectral information along with contrast of the input MS image [11], [12].

C. Pyramidal Algorithms

Consideration of Modulation Transfer Function (MTF) with respect to image sensing is important while performing image fusion. These functions for the MS imaging sensors may differ from each other based on decay rate. Also, they differ from MTFs of the PAN image sensor. Typically, the MTF is a bell shaped function. The magnitude value is very much lower than 0.5, when measured at the cutoff Nyquist frequency. It is to avoid aliasing. Generalized Laplacian Pyramid (GLP) is a multi-scale and oversampled structure. For MS sensor, MTF when used to design the GLP reduction filter, it gives 'GLP with MTF matched filter (MTF-GLP)' image fusion [11], [13], [15]. It is briefed in Algorithm-3.

Algorithm-3: MTF-GLP
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define filter H w.r.t. MTF of QuickBird-2.
Step-3: P_L = Filter P using H.
Step-4: Downsample P_L.
Step-5: Interpolate P_L by 23-coeff. polynomial.
Step-6: $D = P - P_L$
Step-7: $F = M_{up} + D$

Further, a signal-dependent injection scheme 'MTF-GLP with High-Pass Modulation (MTF-GLP-HPM)' is also possible [11], [13]. It is given in Algorithm-4.

Algorithm-4: MTF-GLP-HPM
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define filter H w.r.t. MTF of QuickBird-2.
Step-3: P_L = Filter P using H.
Step-4: Downsample P_L.
Step-5: Interpolate P_L by 23-coeff. polynomial.
Step-6: $F = \dfrac{M_{up} \cdot P}{P_L}$

Two more versions 'MTF-GLP-HPM followed by Post-Processing (MTF-GLP-HPM-PP)' [11], [14] and 'MTF-GLP using Context-Based Decision (MTF-GLP-CBD)' [11], [13], [15] briefed in Algorithm-5 and Algorithm-6 are also evaluated in experimentation.

Algorithm-5: MTF-GLP-HPM-PP
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define filter H w.r.t. MTF of QuickBird-2.
Step-3: P_L = Filter P using H.
Step-4: Downsample P_L.
Step-5: Interpolate P_L by 23-coeff. polynomial.
Step-6: $F = \dfrac{M_{up} \cdot P}{P_L}$
Step-7: F = Post-processing F according to [14]

Algorithm-6: MTF-GLP-CBD
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: Define filter H w.r.t. MTF of QuickBird-2.
Step-3: P_L = Filter P using H.
Step-4: Downsample P_L.
Step-5: P_L = Interpolate by 23-coefficient polynomial.
Step-6: $g = cov(P_L, M_{up})/var(P_L)$
Step-7: $D = P - P_L$
Step-8: $F = M_{up} + (D \times g)$

D. Indusion

Image fusion algorithms generally interpolate MS image by a bicubic method and finally adds spatial contents of the PAN image to the MS image. Indusion algorithm instead make use of induction scaling technique to get better correlated, sharper and well registered interpolated images. In this algorithm, a pair of Cohen–Daubechies–Fauveau (CDF) 9/7 tap biorthogonal filters is utilized to take out the spatial information of the PAN image, that is further merged to an interpolated MS image [11], [16]. The fusion process is briefed in Algorithm-7, where M represents original MS image.

Algorithm-7: Indusion
Input: M, P **Output:** F
Step-1: Define spatial filter H.
Step-2: $P_L = P$ filtered using H.
Step-3: $P_L = P_L$ decimated by 9 coeff. polynomial.
Step-4: $P_{Leq} = P_L$ equalized to M scale.
Step-5: $P_{up} = P_{Leq}$ upscaled by 7-coeff. polynomial.
Step-6: $M_{up} = M$ upscaled by 7-coeff. polynomial.
Step-7: $P_{Heq} = P$ equalized to match M_{up} scale.
Step-8: $D = P_{Heq} - P_{Leq}$
Step-9: $F = M_{up} + D$

Though the 9/7 filter pair is symmetric, it do not effect in any kind of shift in result image.

E. Wavelet Transform based algorithms

Wavelet transform provides framework for decomposition of input images into a variety of new images. Every new image has a different degree of resolution. Literature shows undecimated discrete wavelet transform called as "à trous" algorithm very effective for pansharpening [18]. Despite nonorthogonality which may affect the spectral excellence of the fused product, the advantageous characteristics like the capability of being easily matched to the MTF of imaging sensor and the shift-invariance property produces accurate pansharpened image. Given an image, it constructs the approximations in a sequence by having consecutive convolutions using filter obtained by scaling function. Here, scaling function refers B_3 cubic spline profile. The differences from two successive approximations are computed in the form of wavelet planes. The foremost wavelet plane from the PAN image possess spatial content that is unavailable in MS image. The image fusion achieved by additive method is referred to as Additive à trous Wavelet Transform (ATWT) [11], [18] and briefed in Algorithm-8.

Algorithm-8: ATWT
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up} scale.
Step-2: $P_L =$ à trous wavelet transform of P.
Step-3: $P_L =$ Inverse wavelet transform of P_L.
Step-4: $D = P - P_L$.
Step-5: $F = M_{up} + D$.

The alternative implementations viz. à trous Wavelet Transform-Model-2 (ATWT-M2) [11], [17] and à trous Wavelet Transform-Model-3 (ATWT-M3) [11], [17] that are respectively briefed in Algorithm-9 and Algorithm-10 are also evaluated.

Algorithm-9: ATWT-M2
Input: M_{up}, P **Output:** F
Step-1: $W_P =$ à trous wavelet transform of P.
Step-2: $W_M =$ à trous wavelet transform of M_{up}.
Step-3: Equalize W_P to match W_M.
Step-4: $X =$ Injection of W_P in W_M.
Step-5: $F =$ Inverse wavelet transform of X.

Algorithm-10: ATWT-M3
Input: M_{up}, P **Output:** F
Step-1: $W_P =$ à trous wavelet transform of P.
Step-2: $W_M =$ à trous wavelet transform of M_{up}.
Step-3: Covariance based equalization of W_P to W_M.
Step-4: $X =$ Injection of W_P in W_M.
Step-5: $F =$ Inverse wavelet transform of X.

Additive Wavelet Luminance Proportional (AWLP) [11], [19] image fusion is briefed in Algorithm-11 and also tested.

Algorithm-11: AWLP
Input: M_{up}, P **Output:** F
Step-1: Equalize P to match M_{up}.
Step-2: $P_L =$ à trous wavelet transform of P.
Step-3: $P_L =$ Inverse wavelet transform of P_L.
Step-4: $D = P - P_L$.
Step-5: $S =$ Average of M_{up} band images.
Step-6: $IR = M_{up}/S$.
Step-7: $F = M_{up} + (D \times IR)$.

IV. Experimental Results and Analysis

The comparative performance of MRA based image fusion algorithms is obtained and analyzed in this section, where two remotely sensed image datasets acquired by QuickBird-2 satellite are considered. The performance evaluation is done using MATLAB R2019a on the system configuration of core i5 3^{rd} generation processor with 6 GB RAM.

A. Datasets

The details of datsets are shown in Table I and visualized in Fig. 1. The datasets have four bands viz. Blue (B), Green (G), Red (R), and Near-InfraRed (NIR), for MS image covering the visual and near-infrared regions of the spectrum.

B. Experimentation and Performance Measurement

For the two datasets, we perform two experiments applying the MRA based image fusion algorithms discussed in section III. Performance evaluation is carried on a selected region of size 256×256 pixels for MS and 1024×1024 pixels for PAN

TABLE I: Dataset Specifications for QuickBird imagery

Specifications	Dataset-1: Jaipur	Dataset-2: Sundarbans
Satellite Sensor	QuickBird-2	QuickBird-2
Spectral Bands	4-band MS and PAN	4-band MS and PAN
Spatial Resolutions	MS: 2.4 m and PAN: 60 cm	MS: 2.4 m and PAN: 60 cm

image of each dataset. Resultant images after image fusion are displayed in Fig. 2 and Fig. 3 for corresponding datasets. The PAN to MS ratio considering spatial resolutions is 4.

The performances of applied MRA based image fusion algorithms are quantified by measurement of quality metrics. The numerical values for Quality w/ No Reference (QNR) [22], Spectral Distortion (D_λ) [22], Spatial Distortion (D_S) [22] and Spectral Angle Mapper (SAM) [22], [23] are obtained using Full-Resolution assessment [24], whereas Root Mean Square Error (RMSE) [23], *Erreur Relative Global Adimensionnelle De Synthese* (ERGAS) [22], [23], Spatial Correlation Coefficient (SCC) [1] and Quality index Q4 [22], [23] are computed using Reduced-Resolution assessment [24]. Table II shows quality metrics for first experiment, where best result for every parameter is shown in bold, next prominent result is underlined and next to it is shown in italic. Table III correspondingly show quality metrics for second experiment.

C. Objective Analysis

To find the best performance among the selected MRA based image fusion algorithms applied to two different datasets, it is necessary to analyze comparatives of quantitative measurements.

A comparison of QNR values is plotted in Fig. 4. Desired value of QNR is ideally 1. Fig. 5 shows a comparison of D_λ values. D_λ represents spectral distortion and it is a measure of loss. It is totally undesired and ideal value should be 0. To observe both the comparative plots, it is noticed that ATWT-M2 has achieved overall highest results. Next to it, we find Indusion performing at second level. MTF-GLP-HPM-PP remain last to compute desired values of QNR and D_λ.

A comparison of spatial distortion in resultant images can be seen in terms of D_s values in Fig. 6. This metric is achieved at most desired value by Indusion, while ATWT-M3 performs second. More spatial distortion is measured in the result of MTF-GLP-HPM-PP method.

The desired SAM index is also 0. Measurements of SAM are compared in Fig. 7. AWLP computes the most desired value of SAM among other methods. The performance of MTF-GLP-HPM is to be credited next to it, while ATWT-M3 provide highest value of SAM.

Comparatives of RMSE and ERGAS values are plotted in Fig. 8 and Fig. 9 respectively. It is observed that ATWT-M3 has achieved overall most desired results. Next to it, we find ATWT-M2 performing at second level. Indusion remain last to compute desired values of RMSE and ERGAS index.

Fig. 10 shows a comparison of obtained SCC values by all algorithms on all datasets. SCC computes percentage of spatial details injected to final resultant images. On comparison, ATWT-M3 method has achieved highest values, while performance of ATWT-M2 achieves second level. Comparatively Indusion method performs weak in computation of SCC.

A quality content in fused image is derived from computation of Q index. To look at comparison in Fig. 11, ATWT-M2 method maintains highest value. The performance of ATWT-M3 is at second level. Indusion method achieves overall lowest value of Q-index.

Finally, a comparison of time taken by image fusion algorithms to generate high resolution resultant image is plotted in Fig. 12. SFIM results with fused image at lowest computational complexity. HPF also performs very fast to image fusion. ATWT-M3 consumed highest time. Next to it ATWT-M2 also requires considerable time for fusion procedure.

D. Subjective Analysis

After the image fusion by MRA based algorithms is achieved, user is the ultimate judge of results at end use. Hence, visual inspection of resultant images for all the datasets is made.

It is observed for both the datasets, that MTF-GLP-HPM-PP method results in highest spatial distortion in fused images. The results produced by Indusion and MTF-GLP methods are also affected with spatial and spectral distortion. ATWT-M3 and ATWT-M2 are partially successful to reduce these effects,

but resultant images of these methods are mostly affected with blur. Comparatively, AWLP, ATWT and MTF-GLP-CBD shows better visualization of fused images with respect to input images.

V. Conclusion & Future Scope

The performance evaluation of eleven MRA based algorithms for pansharpening of MS images from two datasets is carried out. The experimental results objectively verify that ATWT-M3 and MTF-GLP-CBD fusion algorithms mostly outperform other state-of-the-art algorithms. But, visual inspection further noticed blur effect in resultant images produced by ATWT-M3 and found comparative better visualizations of objects in resultant images of MTF-GLP-CBD along with AWLP and ATWT. ATWT-M3 and ATWT-M2 have resulted in highest computational complexity, whereas HPF and SFIM performed fast pansharpening. Among the selected algorithms, MTF-GLP-CBD proved its potential achieving quality metrics and computational complexity at optimum.

After analysis of the comparative results based on different quality metrics and visual inspection, a need of more so-

phisticated image fusion algorithm to overcome the observed limitations is underlined. Currently, the selection from available Multi-Resolution Analysis based image fusion algorithms must be specific to application at hand.

***Abstract*— In the era of digital communication data sent through networks has increased. Providing security to data which is in the form of image, text, video, audio has been big challenge. For copyright information and authentication of the data, biometrics authentication is used. At the same time protection of biometrics data is also essential parameter. To increase the security level of biometric data watermarking technique is used. In this, paper we proposed block based biometric fragile watermarking technique which detects slight changes in the watermarked data. Fragile watermark technique generates watermark depending on the embed watermark. In this proposed method authentication data inserted into the least significant bit (LSB) of cover image. The experimental result shows the quality of the image by using conventional LSB technique, with use of key.**

Keywords—Biometric authentication, fragile watermarking, Block based embedding

I. INTRODUCTION

The growth of modern communication, security in network and cloud services is necessary. To provide a security to mitigate the issue of the copyright, unique identification, authentication of that data is very big challenge in network community.

For owner identification and authentication there are types of techniques [1] like passwords, PIN (Personal Identification Number) codes, biometrics etc. But accurate identification can be obtained by using biometrics traits. There are two types of biometrics traits namely physiological and behavioral respectively [1]. Physiological traits consist of fingerprint, hand, iris, face, DNA etc. Similarly, behavioral traits consist of keystroke, signature, voice etc. Security of biometric system is very important. To prevent biometric system from attacks encryption, steganography and watermarking [2] are possible solution. In encryption once the data is decrypted, data is no longer protected so for biometric security encryption is not preferred. Steganography and watermarking used to provide security but steganography is basically used for secret communication not for authentication and ownership protection.

A watermark is defined as the embedded information that is inserted into the cover signal. A watermark can be in form of image, text, biometric etc. In this paper we will concentrate on watermarking based biometric template authentication system.

Watermark technique is divided into three stages: (1) generate watermark and embed that watermark into original media (2) transmit watermark data in the network and (3) detection of embedded watermark [3]. Based on robustness, watermarking technique is classified into two types for authentication like robust watermarking and fragile watermarking [3]. The difference between fragile and robust watermarking is if there is any modification with authenticating data it is not noticeable in robust watermarking. But in fragile watermarking changes are noticeable. So, to identify every possible tampered region in watermarked data fragile watermarking technique has been used [4]. The spatial domain includes Least Significant Bit (LSB) algorithm [5, 6, 7], patch work [8], texture block coding [8] etc. The frequency domain includes Discrete Fourier Transform (DFT) algorithm [6, 9], Discrete Wavelet Transform (DWT) algorithm [6, 10, 11], Discrete Cosine Transform (DCT) algorithm [6, 12, 13].

The rest of the paper is organized as follows. In section II literature review of different watermarking techniques is given. In section III block based technique is explained in detail. The proposed method is describe in Section IV. Experimental results are shows in section V. Section VI conclude the paper.

II. LITERATURE REVIEW

Sabhanayagam et al. [14] presented types of biometric traits and its advantages and disadvantages. Biometric authentication system uses person's biometric data or template and based on comparison of this template with the same person's enrolled data or template. As biometric data of a person is not replicable and it is not secret, numerous attacks are possible in biometric system. Anil et al. [1] shows block diagram of the biometrics system and some attacks like fake biometric, replay old data, override feature extractor, synthesize feature vector, override matcher, modify template, intercept the channel and override decision in the biometrics system.

In [15] Cox et al. present applications of watermarking technique such as, owner identification, authentication, copy protection, broadcast monitoring, medical applications etc. Watermark can be classified as presented in [16]. According to

robustness there are three types namely robust, fragile and semi fragile watermarking. In robust watermarking changes are not noticeable and it can prevent attacks like noisy attack, geometrical attacks etc. In fragile watermarking, changes are noticeable so we can identify that there is any changes with the data. Watermark can be destroyed in this type of technique [3]. Semi fragile is affected from some type of attacks [3] and it is capable to tolerate some limited changes. Based on perceptivity, watermark can be classified into visible which can be observed by human eyes and invisible watermarking which cannot be observed by human eyes [3].

According to data extraction techniques there are three watermarking techniques like blind, semi-blind and non-blind. In blind watermarking original data does not need during extraction process. In non-blind watermarking during extraction process original data is needed.

Watermark can be inserted into the intensity values in spatial domain [16]. LSB is the simplest technique than others and most commonly LSB technique can be used. In this technique watermark is embedded in to the LSB of an image. Verma et al. [17] Proposed watermark image using LSB algorithm in colour for copyright protection. Brindha et al. [3] Proposed Biowatermarking for palm print image using LSB technique. LSB technique divided into two categories: insertion and substitution. Brindha et al. [3] divide palm print image into four quadrants and select fourth quadrant to embed secret data.

He et al. [18] proposed self-recovery fragile watermarking using block neighbourhood tampering characterization to improve the performance of tamper detection and tamper recovery. An image is divided into 8□8 blocks to create an information chain. This technique breaks block-wise dependency and makes technique vulnerable to the counterfeiting attack. Li et al. [19] Proposed multi-block dependency fragile watermarking technique for fingerprint image protection using LSB to prevent fingerprint image from isolated-block tamper. To make watermarking technique not vulnerable to the counterfeiting attack, they are using block wise dependency based watermarking technique. They proposed watermarking technique using LSB for authentication and tamper localization using block division. Security strength and tamper localization can be used for to evaluate the performance of the fragile watermarking.

An image is represented in the form of frequencies in transform domain [16]. Ui et al. [20] proposed a digital image watermarking algorithm based on DWT, DCT and SVD for robust watermarking of digital images in order to protect digital media and copyright efficiently. They used DCT, DWT based blind watermarking for host image and select middle frequency for embedding secret data. Brindha et al. [3] implemented Biowatermarking using DWT, DCT algorithms and for embedding they used palm-print image. For decomposition of an image in DWT haar filter can be used. For embedded an image has been divided into four bands which are HH, LH, LL and HL. They used zigzag scanning to select middle frequency for inserting watermark bits in DCT. Mita et al. [21] Proposed robust biometric based on DCT watermarking algorithm for template protection. They have used finger print feature vector and iris feature vector as watermark. To make system robust against some signal processing and channel attacks they proposed spatial and spectral feature based block discrimination and coefficient estimation strategy.

This research is carried under the minor research project Watermarking based Biometric template authentication System “New era of securing many fold biometrics: research on forensic and cyber security augmentation”, supported by grant from GUJCOST, Government of India. III. BLOCK BASED TECHNIQUE

To detect tampering and to authenticate digital image fragile watermarking technique have been proposed. Fragile watermarking technique can be classified into two types namely pixel based fragile watermarking and block based fragile watermarking [22]. In pixel based fragile watermarking technique the authentication data is calculated from the pixels. But this technique is vulnerable to oracle attack [23]. Block based fragile watermarking technique have been proposed to resist this type of attack. In this type of technique cover image is divided into each image blocks and watermark has been embedded into that image blocks. Wong et al. [24] proposed the block wise fragile watermarking technique to detect and localize unauthorized tampered block but that method is vulnerable to vector quantization (VQ) attack [25] and collage attack [26]. These attacks can solve by a self-recovery fragile watermarking for image authentication. This technique also used to improve the performance of tamper detection and tamper recovery [27]. The generalized embedding process of block wise dependency based watermarking is as shown in fig. 2. In this technique blocks are connected in the chain which fails to detect block tamper. For example if Xi0 block suffering from tampering, then watermark is generated from block Xi0 is not same as watermark embedded into the LSB of Xi1 block. Similarly, watermark generated from Xi1 is not equal to watermark embedded into Xi2.

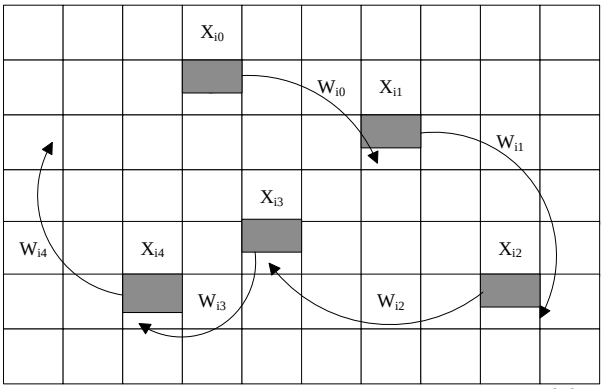

Fig. 1 Block wise dependency based watermarking scheme [19]

IV. PROPOSED WATERMARK EMBEDDING TECHNIQUE

In proposed technique we are using fingerprint as biometric traits.

For security requirement image is divided into 10x10 block. Fig.2. shows multi block dependent structure, 100 bits watermark is generated from each block and it is equally partitioned into ten parts. Each part is embedded into another image block to construct multi block dependent structure as shown in fig. 2.

Block diagram of watermarking generation and embedding process is as shown in fig. 3. LSB of the cover image X is set to zero and noted as X1. An image X1 is divided into its image

blocks $X1_i$, where i=1, 2, ……., N_b with size of 10×10. Where N_b is the number of image blocks.

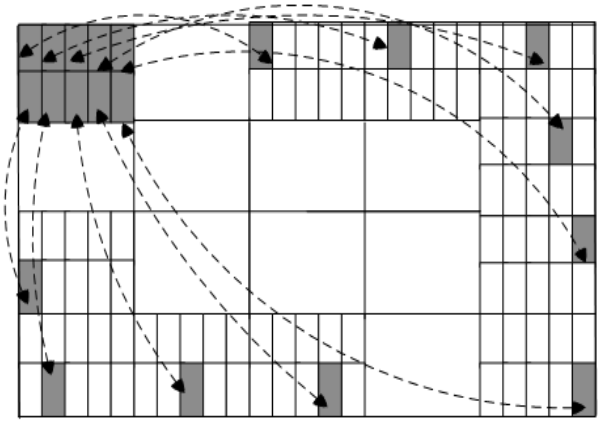

Fig. 2 Multiblock dependent structure [19]

Using jumble watermark bits at random position 100-bit watermark is generated for each image block. In this part, watermark data is embedded into the LSB of the image block at random position.

We have used fixed random numbers to generate key of 100 bits, which is used for encryption to make system secure.

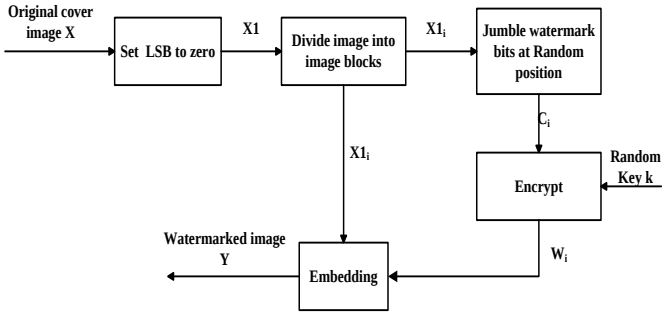

Fig. 3 Block diagram of watermark generation and embedding

To encrypt random position exclusive OR (XOR) operation is used. Using generated key $k = k_1, k_2, \ldots \ldots, k_{100}$ and encrypted random position, watermark bits are generated using eq. 1 $W = W_1, W_2, \ldots \ldots W_{N_b}$ for each block.

$$W_{ij} = C_{ij} \oplus k_{ij} \qquad (1)$$

Where $1 \le i \le N_b, 1 \le j \le 64$

The generated watermark is embedded into the each block of LSB of the original cover image. After embedding, watermark image Y is generated. The process of watermark generation and embedding process is illustrated in below algorithm.

For $i \leftarrow 1$ to N_b
$LSB(X1_i) \leftarrow$ watermark bits
$W_i = C_i \oplus k_i$
$LSB(X1_i) \leftarrow W_i$
$Y \leftarrow X1_i$

Algorithm for watermark generation and embedding

To find the quality of the watermarked image PSNR (Peak Signal to Noise Ratio), MSE (Mean Square Error) and SF (Similarity Factor) are used.

$$MSE = \frac{\sum_{i,j}[f(i,j) - f_w(i,j,a)]^2}{M \times N} \qquad (2)$$

Where $M \times N$ is the size of images. f, f_w are original image and watermarked image respectively.

$$PSNR = 10 log_{10}\left[\frac{b^2}{MSE}\right] \qquad (3)$$

Where *b* is the largest value of the image (typically 255).

Similarity Factor is measure of the similarity of pixel intensities between the original watermark data and watermark data after extraction process.

The formula of similarity factor is given by

$$SF = \frac{\sum_i \sum_j I(i,j) \times I_1(i,j)}{\sum_i \sum_j I_1(i,j)^2} \qquad (4)$$

Where *I (i, j)* is the original watermark data and I_1 *(i, j)* is the watermarked data after extraction process. The value of SF is in between the range [0, 1].

Block diagram of watermark extraction process

The block diagram of watermark extraction process is as shown in fig 4. Let's take test image Y which is received watermarked image. Firstly, do same process as done in process of watermark generated to generate watermark. Divide an image into image blocks $Y1_i$ with size of 10×10. Using XOR operation of key and random position watermark bits are extracted from LSB of the image. And compare with original embedded watermarks.

The process of watermark extraction is illustrated in below algorithm

For $i \leftarrow 1$ to N_b
LSB($Y1^*_i$)←watermark bits
$W_{i1} = C_i \oplus k_i$
Compare W_i and W^*_i

Algorithm for watermark extraction process

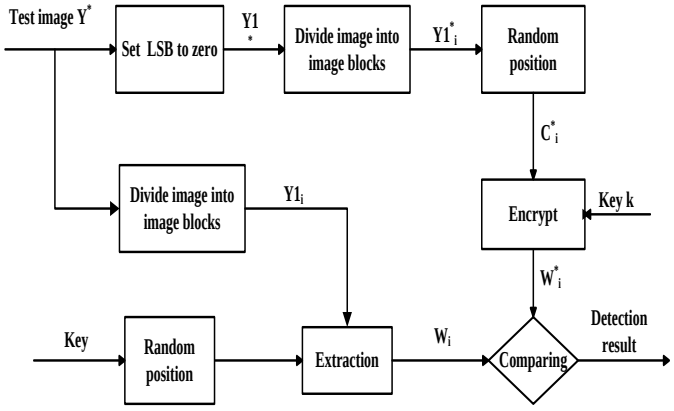

Fig. 4 Block diagram of watermark extraction process

V. EXPERIMENTAL RESULTS

The database for experimentation is created by taking fingerprints of 10 persons from fingerprint scanner named FPCapture_Access_v4.0.2 kit. The fingerprint image is taken as a host image for watermarking. The cover images used for hiding the watermarked bits is taken from standard inbuilt images in MATLAB version 2018. Total 5 different noise attacks are used to prove fragileness of watermarked data. The performance of the proposed watermarking algorithm is evaluated based on SF metrics. The result analysis is detailed in table I. In the result shown in Table I, SF is computed between original watermark data and watermark data after extraction.

TABLE I. COMPARATIVE ANALYSIS OF PERFORMANCE EVALUATION OF WATERMARKING

Sr. No.	Noise	Conventional LSB technique [6]		Proposed method	
		SF %	PSNR	SF %	PSNR
1.	Without noise	100	57.4743	100	51.149
2.	Salt & pepper	93.2692	25.0494	89.968	25.162
3.	Gaussian	3.2446	20.3780	0	20.31
4.	Poisson	1.36	27.3429	0	27.32
5.	Speckle	2.484	18.62	1.13	18.62

Table I shows the comparative analysis of the results of watermark embedding algorithm using conventional LSB technique [6] and proposed algorithm for 5 different noise attacks. As it can be observed form table I, SF is decreasing in proposed algorithm as compared to techniques in [6]. Thus it can be said that tampering is affect much while reconstructing the hidden image from watermarked image. So, we can say that proposed algorithm prove fragileness of the watermarked data. Hence, proposed fragile watermarking algorithm reconstructs not well in case of tampering done due to noise during transmission.

VI. CONCLUSION

The aim of securing biometric traits is being addressed by the proposed watermarking algorithm. This paper addresses novel frame work for biometric fragile watermarking to embed watermark data in block wise manner. Experimental result shows comparative analysis between secret key generation in the presence of noise to find SF. From comparison it is evident that block based technique with jumbling and with key is more suitable for finger print authentication. Experimental result shows that embedded watermarks data are visually insignificant and maintain quality of fingerprint image. The proposed method can detect similarity between embedded watermark data and watermark data after extraction and shows that after attacking SF is decreasing which signifies proposed algorithm is suitable for fragile watermarking. The block based watermarking algorithm provides advantage of enhancing security of the hidden biometric trait.

To make the system robust against various attacks, different techniques of watermarking can be used in future for the Protection of biometric data.

ACKNOWLEDGMENT

***Abstract*—Cloud storage service is an efficient solution for increasing storage needs of organizations and individuals. In order to ensure security and data privacy, users may encrypt their data before uploading to cloud. In such cases same or different users may up-load same data in encrypted form and it results in the existence of duplicated data. Data deduplication is a technique designed to identify and eliminate redundant data. When users are uploading data in encrypted form, then deduplication is a challenging problem. This project proposes a deduplication system in cloud storage that supports big data deduplication also. The sytem is based on symmetric encryption and re-encryption. The system aims at paragraph-level deduplication of text data files. A token will be generated for each paragraph in a file before uploading to cloud. When a new request for uploading is received, system checks the existence of duplicate files using these tokens. If the file is already exists in the cloud, then system rejects uploading, else system will perform deduplication using re-encryption algorithm.**

Keywords: Cloud Computing, Data De-duplication, Re-encryption.

I. INTRODUCTION

Cloud computing is the on request accessibility of resources, mainly storage of data without direct involvement of user. Cloud storage deliver resources to users over internet. Clouds which are larger in sizes have functions which is distributed over more than one location from central servers. Clouds are of different types. Some are restricted to a single company or organization and it is called enterprise clouds. Some are available to more than one organizations and they are called public clouds and some are combination of both public and private clouds and they are called hybrid clouds. Amazon AWS is the largest among public cloud.

High-capacity networks, economical computers and storage services results in the rapid growth of cloud computing. Cloud computing mainly aims at making the resource sharing economical. By linking together resources over network cloud computing delivers wide collection of information sources to users. Cloud computing provides data processing services to users by offering data storage, computing and so forth. It offers a large collection of data sources by combining resources over a network. It should possess some attributes namely, adaptability, flexibility and fail resistance.

A cloud service provider can retrieve the data contained in the cloud at anytime. Because of this cloud computing has some security problems[9],[13]. The information stored in cloud can get modified or deleted by any other user. In some cases, cloud users may have to share their data with third parties because of some law purposes. In such cases, users will be informed about this in the privacy policy and users can start using cloud services only if they are agreed to it.

Anyway in order to stop unauthorized retrieval of data, users can encrypt their data before storing to cloud[8]. Based on the report of Cloud Security Alliance, main security threats in the cloud are hardware failure, data loss leakage and insecure interfaces [10]. In a cloud storage information belongs to different users are placed on same server. Hackers are ready to spend large amount of time to retrieve all this information. Because a large cloud may contain information of many companies and by attacking this information hackers can get control of these companies and it is termed as hyper jacking[12]. Some examples of such attacks are icloud 2014 leak and Dropbox security breach.

A. Data deduplication in cloud

Presence of duplicated data is a crucial problem in cloud computing. Storage of same data more than once is termed as data duplication. Storing duplicated data results in the wastage of storage space. Even though cloud has large memory, duplicated information results in disuse of large memory and make data processing complex. As a result, deduplication turned out to be vital in cloud data processing. Deduplication aims to lower storage expenditure. This saving will make the cloud more profitable. Governing encoded information with deduplication is a significant issue.

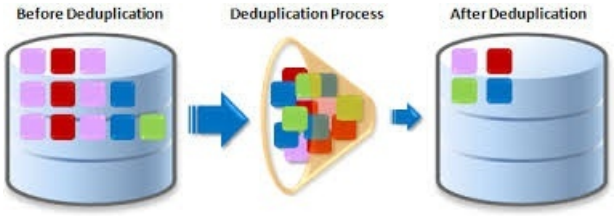

Fig. 1: Data deduplication

Data deduplication is refered as the technique to identify and eliminate redundant data. Many solutions are there for

deduplication of raw data. But in order to ensure security users may save their data in encrypted form in cloud. In such cases deduplication need to be implemented on encrypted data. Deduplication of encrypted data is a challenging issue.

Data deduplication is one of the hottest technologies in storage right now because it enables companies or users to save a lot of money on storage costs to store the data and on the bandwidth costs to move the data. This is great news for cloud providers, because if you store less, you need less hardware. If you can deduplicate what you store, you can better utilize your existing storage space, which can save money by using what you have more efficiently. If you store less, you also back up less, which again means less hardware and backup media. If you store less, you also send less data over the network in case of a disaster, which means you save money in hardware and network costs over time. It is proved that deduplication in cloud results in high cost savings because it can reduce up to 90-95% storage needs for backup applications [6] and up to 68% in standard file systems [7]. These storage savings will benefit cloud users and cloud business.

At a high level, the deduplication process works using software that eliminates redundant data and storing only unique first instances of any data. Any other copies of the same data found by the software are removed, and in their place will be a pointer or reference to the original copy. The deduplication process is transparent both to end users and the applications they use.

Drilling down into the process more, deduplication software typically generates unique identifiers for data using cryptographic hash functions. Deduplication at the file level is inefficient because even if a minuscule part of a file is altered, such as a single bit, a whole new copy of that file will be stored. So this work aims at block-level deduplication on file contents.

The rest of this paper is as follows: Literature survey is discussed in Section 2. Section 3 describes the architecture and different modules of the deduplication system. Section 4 discusses the result. Finally, Section 5 is the conclusion with brief description about the present findings and future direction.

II. RELATED WORKS

Many mechanisms have been developed for deduplication on encrypted data in cloud. Each of them differs in their approaches.

Mihir Bellare, Sriram Keelveedhi and Thomas Ristenpart [1] proposes the primitive method for deduplication on encrypted data, Message Locked Encryption (MLE). As the name implies, in MLE the message is locked under some key. As the key for encryption is derived from message itself, same key is used to encrypt similar messages. So it is easy to recover key used for encryption. This scheme is not resistant to brute-force attack.

Mihir Bellare, Sriram Keelveedhi and Thomas Ristenpart [2] proposes a system architecture that supports secure deduplicated storage which resists brute-force attacks, and realize it in a system called DupLESS. In DupLESS, a group of affiliated clients (e.g., company employees) encrypt their data with the aid of a key server (KS) that is separate from the SS. Clients authenticate themselves to the KS, but do not leak any information about their data to it. As long as the KS remains inaccessible to attackers, system ensure high security. Although DupLESS provides resistance to brute force attacks, it is suitable only for small-sized data.

Xue Yang, Rongxing Lu, Kim Kwang Raymond Choo and Xiaohu Tang [3] proposes another system for deduplication of data. Main aim of this mechanism is to reduce the time taken for search of redundant data. For that this mechanism constructs a decision tree for removal of redundant information and this tree is built based on binary search tree. In this system two companies or organization can have direct agreement with cloud and each client should be afliated with any of those two domain. Each organization or domain will have separate decision tree. After receiving files, cloud will create a decision tree to save these files and this tree is used to check whether newly received file is already existing or not. Result shows that deduplication using decision tree can reduce time complexity of duplicate search significantly.

Xin Tang, Linna Zhou, Yongfeng Huang and Chin-Chen Chang [4] designs a system for removal of redundant data from encrypted information. The working of this system is based on symmetric encryption and Proxy Re-Encryption (PRE). Main merit of this system is that it supports deduplication of big data. This system aims at file-level deduplication. So even a file with small difference with another file will be uploaded as a new file.

From the above methods , it is clear that deduplication on encrypted data is a challenging issue, especially when data size is large. The major problems in existing deduplication systems are listed below:

- To ensure data security and user privacy, data will be stored in an encrypted form to cloud.
- Many of the existing system do not support deduplication on encrypted data especially big data.
- Many of the existing system is not resistant to brute force attack [1],[5].
- Existing system supports only file-level deduplication.
- Secure deduplication in cloud is an arising challenge.

Deduplication on encrypted data is a challenging issue, especially when data size is large[11]. The proposed system aims at a deduplication system which supports block-level deduplication on encrypted files and is resistant to brute force attack.

III. PROPOSED DEDUPLICATION SYSTEM

This project proposes an efficient deduplication system in cloud that supports big data deduplication also. It is resistant to brute force attack and it also manages the storage with deduplication without the direct involvement of data holder. The working of the system is mainly based on paragraph-wise token generation of text data, symmetric encryption and re-encryption to manage encrypted data storage with deduplication.

A. System Architecture

The system contains three entities. They are:

- User: Users transfer and save their data in cloud.
- Authorized Party: The responsibility of authorized party(AP) is to manages deduplication of information.
- Cloud Service Provider (CSP): All uploaded files will be saved in cloud.

The general architecture of the proposed system is shown in figure 1.

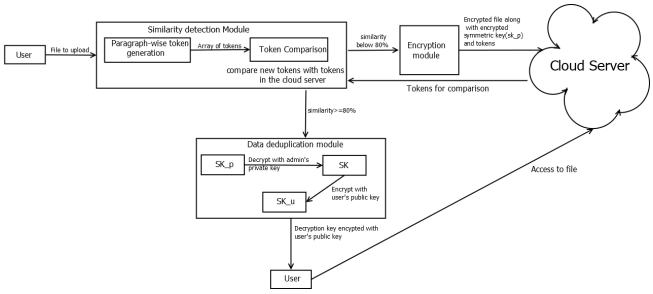

Fig. 2: System Architecture

B. System Modules

The system mainly consists of three modules:

- Similarity detection module - A hash value or token will be generated for each paragraph in a file before uploading to cloud server. These tokens are used for detecting similarity between files.
- Encryption module- If a file shows no similarity to existing files in server, then that file will be encrypted using symmetric encryption method before uploading to cloud server.
- Data deduplication module- When a user is sending duplicate file to cloud server, uploading will be rejected and access to already existing file will be granted to user.

1) Similarity detection: Cloud server will contain some files and corresponding tokens. Tokens are generated for each paragraph in the file using any standard hashing algorithm. When a new file is coming to the system, that file will be split into paragraph using regular expression and tokens will be generated for each paragraph. These newly generated tokens will be compared to tokens corresponding to each file in the cloud server, which has almost similar size of new file.

This comparison is done using retain all() function in java. The retain all() function retains same tokens among newly generated tokens and already existing tokens in the cloud server. If this function returns no to-kens, then it means that there is no similarity and file can be uploaded, so system will go to file encryption module.

If the retain all function returns some tokens, then we take the number of tokens it returned corresponding to each file and the calculate the percentage of similarity the new file shows to that particular file. Similarity percentage can be calculated by:

$$similarity\ percentage = \frac{number\ of\ common\ tokens}{total\ number\ of\ tokens\ in\ new\ file} * 100 \quad (1)$$

The system takes the highest similarity percentage and if it is greater than or equal to 80%, uploading of new file will be rejected and access to the file to which the new file shows highest similarity should granted to new user. To grant access to already existing file, the system will move to data deduplication module.

2) Encryption module: When a user is sending any file to system to get uploaded, the system checks if that file is already existing or not. If the system found that such a file is not existing, then system encrypts that file using symmetric encryption and uploaded to server. The system randomly generates a symmetric key each time a new file is encrypting and this symmetric file will be encrypted with admins public key to get cipher key and this cipher key will be uploaded to server along with the encrypted file and corresponding tokens.

Symmetric Encryption:

- In this encryption technique, a symmetric key which is created by using any standard key generation algorithm and message to be encrypted is given as input. The algorithm encrypts that particular message using the given key and creates cipher message.
- User perform this operation to make their message secure from illegal access.
- This encrypted message can be decrypted using same key which is used for encryption.
- User perform this decryption to decrypt the encrypted data saved in cloud.

3) Data deduplication module: When a client is sending a file which is similar to another file pre-stored by another client, duplication happens. At this time cloud contacts AP to stop uploading of redundant file by granting access to already existing copy of this file to new user. AP allow new user to access duplicate data by providing decryption key of already existing file to new user. AP provide the decryption key to new user using re-encryption algorithm. The overall procedure in this module is explained below.

Deduplication process:

- This process can be described as tuple (E,R,KG,D), in which each element is algorithm.
- Here KG represents standard algorithm for generating keys, E represents algorithm to create encrypted form of input data using the input key and D represents algorithm to create decrypted form of encrypted data which is given as input using the given decryption key.
- Key generation algorithm will produces private key and public key for a particular user.

- The above generated public key and a message will be given as input to encryption algorithm and it creates a ciphertext $C_A = E(pk_A; M)$.
- Then the private key and ciphertext will be given as input to decryption algorithm and it creates the decrypted message $M = D(sk_A; C_A)$.
- R represents re-encryption algorithm. In this algorithm output of E, corresponding decryption key and another public key and private key pair will be given as input.
- Initially the R algorithm will decrypt the cipher key, which is the output of E with its decryption key and this decrypted key will again encrypt using new public key and return.
- The R algorithm will return this re-encrypted key and new private key to D. And the D algorithm will decrypt the re-encrypted key using the given private key and return to user.
- Here, In this system the symmetric key used for file encryption is given as input message to the encryption algorithm and admin's public key is given as key.
- So the output of encryption will be $ck = E(pk; K)$. Where,
  - K is symmetric key for file encryption
  - pk is admin's public key
  - ck is encrypted key or cipher key
- When a new user need to access this symmetric key K, system will go to re-encryption algorithm.
- Here, the R takes as input ck, sk, pk_1 and sk_1. where,
  - sk is admin's private key
  - pk_1 is new user's public key
  - sk_1 is new user's private key
- Initially, R will decrypt ck using sk to produce K. That is, $K = E(pk; ck)$.
- Then this k will be re-encrypted using pk_1 to produce re-encrypted key rk. That is, $rk = E(pk_1; k)$.
- Then this rk will be return to user.
- User can decrypt rk using sk_1 to produce symmetric key. That is, $K = D(sk_1; rk)$.
- Now the user can decrypt the file using symmetric key K.

4) System Procedures:

- Step 1 - System setup: For authorized party(Admin) and each user, a public key and private key pair is generated randomly using any standard keypair generation algorithm. Admin's public key is broadcasted to all users.
- Step 2 - Data token generation: A token will be generated for each paragraph in a file using any standard hashing algorithm.
- Step 3 - Duplication check: User u_1 send a file M to CSP. CSP checks if the duplicated data is stored by finding whether the tokens for M already exists or not. If the check is negative, the file M is encrypted with randomly generated symmetric key DEK_1 and DEK_1 is encrypted with admin's public key (pk_{AP}) to get cipherkey (CK_1). This encrypted file, corresponding tokens and CK_1 will be saved in cloud server. If the check is positive refer to Step 5 for deduplication.
- Step 4 - Duplicated data upload and check: User u_2 later on tries to save the same data M at CSP following the same procedure of Step 2 and 3, Duplication happens and CSP informs it to AP.
- Step 5-Deduplication: CSP decrypts (CK_1) using admin's private key and re-encrypt it using u_2's public key pk_2 and return this re-encrypted key to u_2. Then u2 can get DEK_1 with its private key sk_2.

At this moment, both u_1 and u_2 can access the same data M saved at CSP. User u_1 uses DEK_1 directly, while u_2 gets to know DEK_1 by decrypting it with sk_2.

IV. Results And Discussion

The proposed system was coded and implemented in Java using Eclipse IDE and database is created in MySQL. Text files, word files and pdf files of different size is given as input for result analysis.

A. Similarity detection

Time taken for this phase includes,

- Time for token generation
- Time for token comparison

For token generation SHA-256 hashing algorithm is used here. MD5 and SHA is the prominent method for generating hash values. For unstructured files SHA is better in terms of operation time. Table 1 shows the difference in timetaken for MD5 and SHA-256.

TABLE I: Difference in time taken for hashing using MD5 and SHA-256

Size of file	MD5 Time taken (ms)	SHA-256 Time taken (ms)
12.4KB	843	838
18.2KB	865	861
1MB	987	963
13.6MB	1184	1132
38.6MB	2318	2213
901MB	3459	3129

Table II shows the time taken for similarity detection between text files, word files and pdf files of different sizes.

TABLE II: Time taken for similarity detection

File Size	File Extension	No. of files with similar size	Total No. of Tokens	Execution Time
1 MB	txt	5	3940	4 s
3 MB	txt	5	16021	5 s
5 MB	txt	5	23941	8 s
1 MB	doc	5	9971	6 s
3 MB	docx	5	14760	8 s
1 MB	pdf	5	7719	36 s
3 MB	pdf	5	5161	51 s
5 MB	pdf	5	10381	63 s

B. File Encryption

In this system symmetric encryption is used for file encryption. AES-128 encryption is used here.Table III shows time taken for encryption for different file types.

TABLE III: Time taken for file encryption

SIZE	FILE EXTENSION	TIME
1MB	txt	3s
3MB	txt	3s
5MB	txt	3s
1MB	doc	2s
5MB	doc	3s
10MB	doc	3s
1MB	pdf	3s
3MB	pdf	3s
5MB	pdf	4s

From the above comparison tables, it is clear that AES encryption is not much time consuming. There is not much variation in execution time with increase in the file size. For similarity detection, operation time is increasing with increase in file size. For text files and word documents, there is no considerable increase in time. But for pdf file there is much variation in execution time with increase in file size.

The file uploading process, recovering decryption key and database updation takes only some nanosecond time.

Below figure shows the view of database.

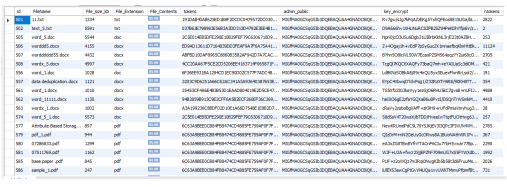

Fig. 3: Database containing files

V. Conclusion

In a secure and well organized cloud storage, removing redundant data has got much importance. Particularly in case of big data storage, removing redundant information will greatly improve utilization of space. Day by day need for cloud services for storing large amount of data is increasing and as a result need for efficient deduplication technique is also arising. Huge data load on storage systems are emphasizing the focus on development of novice techniques to remove duplicate data. With the evolution of data deduplication and its various techniques, cloud computing has potential to remove unnecessary duplicates. Deduplication is an important technique for reducing storage cost, bandwidth and energy consumption.

Many of the existing system aims at file level deduplication and does not support deduplication on encrypted data. So this work aims at block-level deduplication on file contents. The proposed method is capable to find percentage of similarity among files. System perform deduplication on files which shows 80% or above similarity to already existing files. The security of the proposed system is ensured by symmetric key encryption and re-encryption theory.

In Future, this system can be expanded to manage the storage with deduplication when there is any updation or deletion of files and implementing Map Reduce algorithms to reduce execution time. Also the system can be expanded to perform deduplication on other medias such as audio, video and images.

Acknowledgments

I would like to thank Dr, Swaraj K.P. for providing a valuable assistance to complete this research work.

***Abstract*— The world is moving towards autonomous vehicles and the vehicle is exposed to various types of communication, like Vehicle-to-vehicle (V2V), Vehicle-to-Grid (V2G) and Vehicle-to-Everything (V2X). This communication facilitates telematics, diagnostics and over the air software update features. The vehicle is also connected via various interfaces like Wireless Fidelity (Wi-Fi), Bluetooth (BT), Universal Serial Bus (USB), and On-board Diagnostics (OBD) to the external world for various purposes. This opens possibility for several cyber-attacks through external ports, network interfaces if there are no adequate cyber security mechanisms implemented, and cybersecurity risks are not treated. Controller Area Network (CAN-bus) is a central nervous system of the modern vehicle and most of the in-vehicle communication takes place on it. Unfortunately, the CAN-bus is inherently insecure and lacks basic security features like authentication and encryption. The insecure nature of CAN-bus in a vehicle lead to several security exploits and malicious activities which put driver and passengers at risk. Therefore, security measures need to be implemented in the automotive network.**

This paper addresses CAN vulnerabilities, critical attacks on CAN and security measures to protect CAN bus such as cryptographic measures, firewall and methods to detect and prevent such attacks. Certain approaches have been identified and we are going to discuss these approaches in this paper. However, this paper attempts to bring together essential background knowledge required to work on security for CAN network in automotive embedded systems.

Keywords*— *CAN Vulnerabilities, Attacks on CAN, Security Measures, Packet filtering firewall, Binary Decision Diagram-BDD.

I. INTRODUCTION

In the past two to three decades vehicles are becoming more advanced, more autonomous, more complex in terms of automotive electronics. An embedded system that controls an electrical subsystem is called an Electronic Control Unit (ECU) in a vehicle. There are more than 70 ECUs in a modern car which provides entertainment, navigation, central locking mechanisms, and other safety systems like adaptive cruise control, automated lighting, anti-lock braking system, airbag control, traffic warnings, Collision avoidance etc. There should be quick and reliable communications between these electronic modules for the normal operation of the vehicle. The electronic control modules, the sensors, actuators, and other devices communicate through the in-vehicle networks like Controller Area Network (CAN), FlexRay, Local Inter Network (LIN), and Media Oriented Systems Transport (MOST) as shown in the Fig.1 and Ethernet for higher bandwidth. CAN protocol is considered as a de-facto communication standard for various electronic control units to communicate between sensors, and other devices. As the cars get exposed to the outside world through the internet connectivity, Bluetooth wireless link to connect cell phones to have hands-free calls and Telematics functionalities, this results in increased number of attacking surfaces and entry points for hacking. There is no source identifier or authentication and encryption built into CAN packets. Because of these shortcomings, it is easy to sniff the CAN packets on the network as well as to masquerade as other ECUs and send CAN packets. Therefore, security measures need to be implemented in the automotive network. Firewalls can be considered as the first line of defense and restrict malicious CAN packets entering the in-vehicle network from the external world.

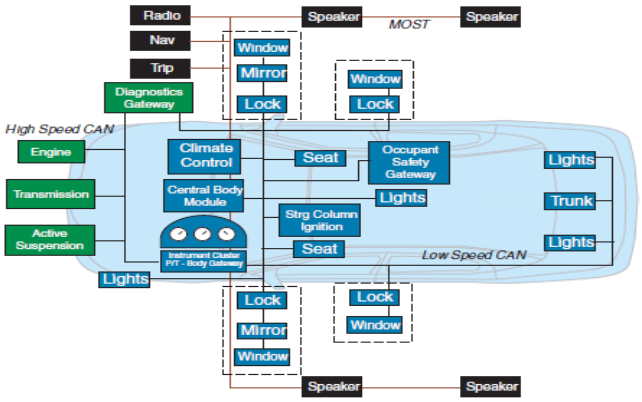

Fig.1. Typical Automotive Network [1]

This paper is divided into different sections as follows. Section I, Introduces the In-vehicle network. Section II is focused on CAN protocol format, CAN vulnerabilities and critical attacks on CAN. Mitigations and security approaches are explained in

Section III and also introduce firewall, its types and the significance of the firewall. The literature survey is focused on firewall technologies which are explained in the Section IV.

II. BACKGROUND

A. *Controller Area Network protocol (CAN-bus)*

In 1985, Robert Bosch developed a serial bus communication protocol for the in-vehicle network called CAN-bus. The protocol was officially released at the Society of Automotive Engineers (SAE) conference in 1986, Detroit, Michigan [2]. There are several versions of the CAN specification were published. There are two parts PART-A and PART-B in the latest standard 2.0 published by the Bosch in 1991. Part-A is for the standard format with an 11-bit identifier CAN 2.0A and Part-B is for the extended format with a 29-bit identifier CAN 2.0B [3]. The CAN standard and extended format are shown in Fig.2.

ISO 11898 standard is released by ISO (International Society of Organization) in 1993 and divided into two parts. The CAN protocol defines the lowest two layers of OSI (open system interconnect) data link layer (ISO 11898-1) and physical layer (ISO 11898-2) for high speed CAN. Later ISO 11898-3 is released, which is for the CAN physical layer for low speed and fault tolerant CAN. In 2012, Bosch released CAN FD 1.0 (CAN with Flexible Data-Rate), which was developed to meet the automakers demands for more accurate and for real-time applications, this is designed for transmitting and record data along with errors between devices and microcontrollers without the help of host computer This specification has different formats which allow different data lengths and for operating with a faster bit rate once the arbitration is decided.

As the CAN-FD is compatible with present CAN 2.0 specification, CAN FD devices can be connected on the same network along with CAN 2.0 devices. There are several CAN-based higher-layer protocols that are standardized. The user choice is according to the application. These are used in a variety of applications including industrial automation, autonomous devices, defense and underwater vehicles and medical equipment. CAN protocol is a message based and it is denoted as a Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA), where the protocol listens to other nodes in the network for avoiding collisions. The CAN also contain error detecting and error handling methods. It can handle bit rate up to 1 Mbps when the physical distance between the nodes is less than 40m within the network. Four different message formats are present in CAN, they are data, remote, error and overload frames.

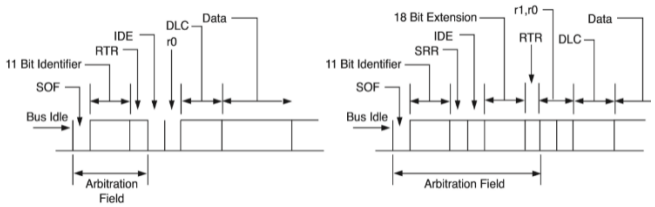

Fig.2. CAN message frames [1].

The CAN data frame is explained in detail and is as shown in the Fig.3.The data frame begins with the Start-of-frame (SOF) bit which is of the single dominant bit, next is arbitration field which consists of eleven-bit Identifier and RTR-bit (Remote transmit request). The RTR-bit must be ‘dominant' in the data frame and ‘recessive' in the remote frame. Followed by the control field which includes data length code (DLC) and two bits for future expansion are reserved. The data length code is four-bit wide which defines how many bytes of data is present in the data field. The data field can be zero to eight bytes of data. The data field is followed by cyclic redundancy checksum (CRC), which enables the receiver that the data received is not corrupted. Acknowledge field (ACK) contains two bits and these will be ‘recessive' at the transmitting station. It is replaced by a dominant bit by the receiver to acknowledge that it received the valid message. Both Data frame and Remote frame ends with EOF (End-of-frame) which contains a flag sequence of seven recessive bits.

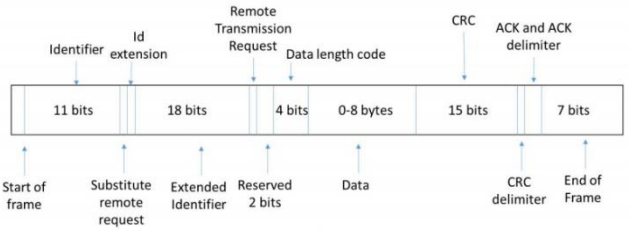

Fig.3. The CAN message format

B. *Arbitration*

As stated earlier, messages are identified by the static identifier (ID). All messages are transmitted over the bus based on the priority. The priority of the messages resolved by the arbitration. The conflict occurs whenever two or more transmitting nodes are sending messages over the same network and at the same time. Arbitration helps to overcome this conflict. Messages with lower Arbitration ID will get the bus and the message transmitted. Arbitration is handled by CAN transmitter. By comparing the value being processed and the value on bus, CAN transceiver checks both the values. If the values are same then it continues transmission else stop transmitting. The transmitted value is AND’ed bit wise with value on the bus. So, the transmitted value is 0 and the bit on the bus is 1, the result zero will be transmitted. Thus, the lower value node wins the arbitration. Due to arbitration DoS type of attack is possible if an attacker send high priority messages for an example sending sequence of dominant bit ‘0’. The bus will not be available for other ECUs to transmit messages and this may affect the normal operation of the vehicle.

C. *CAN Vulnerabilities*

The lack of inherent security mechanism of CAN lead to attacks from physical attack surfaces through OBD port and from wireless attack surfaces such as GPS, GSM module, Bluetooth and Wi-Fi. Various attacking surfaces are shown in

the Fig.4. Table1 gives the summary of vulnerabilities, different possible attacks and security measures for CAN network.

Table 1: Summary of violated security aspects, potential attacks and security measures (to CAN network)

Violated Security aspects	Vulnerabilities of CAN protocol	Possible Attacks	Security Measures
Confidentiality/privacy	Message broadcasting	Eavesdropping	Encryption algorithms
Integrity	Lack of authentication/ addressing	Sniffing/Spoof	Cryptographic hash functions, MAC or Digital signatures
Authenticity	Lack of authentication	Masquerading	MAC or Digital signatures
Availability	Lack of addressing/authentication	Replay, Injection, flooding/DoS attacks	IDS, IPS and Firewalls
Non-Repudiation	Encryption	Sniffing	Forensics support

Weakness of vehicle security arise from the widely used CAN is highlighted in [4], and it is listed below

- Message Broadcasting: Once the message is sent on the CAN bus it is present at every node of the network. Any node or controller has access to it can accept or reject. A passive attacker can read a message by having access from the diagnostic port or by inserting a malicious node on the CAN bus. Eavesdropping can take place which is kind of sniffing on the network.
- Lack of addressing: Nodes in a typical CAN network does not have identification address, all nodes (real or malicious) can send and receive information anytime inside the network without the verification that a source of the information is valid.
- Lack of Authentication: As the source authentication is not present, it is not possible to ensure if message received from valid source. Therefore masquerade attack takes place, in which an attacker acts as an authorized user of the system.
- A common point of entry: Once an attacker gains access to the CAN network, there is no limit that what are the parameters they can obtain within the network. Diagnostics port is the common gateway to the in-vehicle network where all the systems connected. Example OBD-II port provides access to all the systems.
- Limited Bandwidth: Complex authentication or security algorithms requires more bandwidth and processing power for robust communication. But, CAN with 11-bit and 29-bit identifier message structures provides only 64-bit of data in payload and less data for security purposes. The complex authentication algorithms could not be implemented on CAN bus because of the limited bandwidth.
- Lack of Encryption: The robust encryption could not be implemented as there is no higher bandwidth is available in the present CAN bus. For a few sensitive messages and security-related protocol need protection against eavesdroppers. Encryption is necessary for critical data exchange between any two in the CAN network.

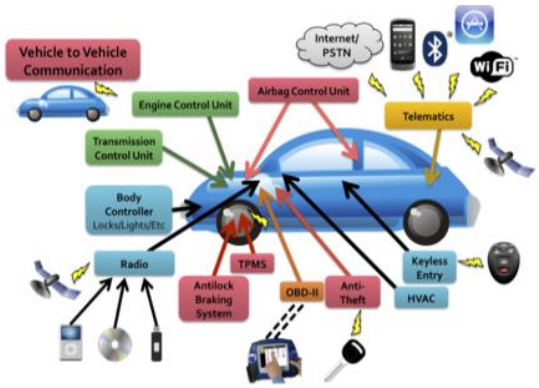

Fig.4. Possible entry points of the modern car [4].

D. Critical attacks on CAN

- Replay attack: The attack in which the transmitted data is delayed or repeated maliciously. Masquerade attack is followed by a replay attack where it needs to pretend to be some other node and retransmits the copy of the message it has received from the CAN bus. The copy of the message may be unaltered or modified. Even though there are tables to match the message id to the sender and determine the identity of the sender at the other nodes but there is no concept to authenticate it. Aruljothi and Priyadarshini [5], have demonstrated a practical wireless attack using a real vehicle in a connected vehicle environment, and they also propose a security protocol for CAN as a countermeasure designed in accordance with current CAN specifications with RKP(random key pre-distribution).
- Injection: In this attack, injecting malicious message on the network appearing to be legitimate. It involves disturbing normal operations of the vehicle. This attack can be done by the node in the trusted network. Any node can send any message in the CAN network.
- Denial of Service (DoS): DoS is a cyber-attack in which the resources are unavailable to intended users temporarily or to damage permanently and weakening the performance of the system. Flooding the network with higher priority messages by sending the sequence of dominant bits continuously. By inducing too many errors to the target node or device where the node on CAN bus goes to so-called bus-off state and removed from the CAN bus so it cannot send or receive further messages. Doing this can disable a device (e.g. critical safety systems) and compromises certain vehicle functionalities. Murvay and Groza [6] have explained about DoS attacks at different layers of

CAN protocol. Concentrated more on DoS attacks of Data link layer as it's very difficult to mitigate with application layer mitigations techniques.

- Man-in-Middle attack: Secretly, an attacker receives and pass the message and alters communication between two nodes for a certain period. Robert Buttigieg et al [7] have explained how the rogue device is inserted in CAN network as a man in middle attack using Proof of Concept (POC) by instrument cluster and vehicle simulator. The main aim of their project was to look into the lack of security in the CAN-Bus protocol, in particular, the lack of authentication of devices and the lack of data encryption. This experiment focused on the possibility that an unauthorized man in the middle device can be connected to the CAN-Bus with the ability to send spoofed messages.

III. SECURITY APPROACHES

A. *Authentication*

There is a possibility of changing the program of an authorized node and spoof the messages on the CAN network and also add a rogue device as there is no authentication. Many researchers have been working to implement effective authentication mechanism for the in-vehicle network. These measures should be implemented at every node of the network. [8] specifies use of Message Authentication Code (CMAC) for authenticating each ECU and CAN messages to prevent spoofing attack. Nicolas Bravo et al [9] proposed Public key/secret key authentication scheme for CAN by using Hash-based Message Authentication Code (HMAC). One pair of public and private keys were given to each node of the network where it shares the signed messages.

B. *Encryption*

Encryption is a cryptographic approach to hide the intelligence of the message from unauthorized users. Complete security of any information is not secured by encryption alone. Authenticity, integrity and confidentiality are ensured by using various cryptographic algorithms. Symmetric and Asymmetric are the two different cryptographic algorithms. Asymmetric algorithms such as RSA (Rivest–Shamir–Adleman), Elliptic curve cryptography (ECC) use different keys and ensures more reliability than symmetric algorithms like Advanced Encryption Standard (AES) which uses a single secret key. To meet the vehicle communication requirements such as computation, capacity, and timing, a combination of symmetric and asymmetric algorithms are used. Asymmetric encryption methods are used for secure key distribution and symmetric encryption for secure communication broadcast inside the vehicle-bus system. Public Key cryptographic techniques are more effective for securing communications with external entities including telematics, service providers and internal communications between safety-critical systems, sensors against cyber-attacks.

Cryptographic algorithms require intense computation to have effective secure communication considering acceptable latencies. Hence, to protect the confidentiality of stored keys, certificates and user credentials requires hardware support. These cryptographic algorithm requirements are beyond the resources available in typical automotive microcontrollers today. A Tiny Encryption Algorithm, Feistel type cipher was used to encrypt the message on CAN bus for a particular microcontroller and proved that this algorithm can be used to hide confidential data on the CAN bus from eavesdropping.
