Figure 7 represents the MRI image having size of 64* 64 bits. More information is indicated by high intensity regions in the image. Decomposition is done using DWT algorithm. DWT is a technique used to convert the given information which contains mixed level of intensity of data into four subbands like low-low (LL) frequency band having high intensity of information, remaining frequency bands low-high (LH), high-low (HL) and high-high (HH) having less reliable information. Figure 9 represents DWT decomposition of the MRI image into four sub bands A, B, C, D. The subband A represents low-low (LL) frequency component which has more high intensity and hence more information from MRI image, the remaining subbands B represents the low-high (LH) frequency band, C represents the high-low (HL) frequency band and D (HH) represents the high-high frequency band. All these subbands viz. B, C and D contain less intensity regions of the image as we can see in the Figure 9. Figure 8 represents the CT scan image with size of 64*64 bits. The decomposition of the CT scan image is shown in Figure 10 with sub bands E, F, G, H. Here, it can be seen that E represents low-low (LL) frequency band having more intensity regions of the image and hence more information. The remaining subbands F represents low-high (LH) frequency band, G represents high-low (HL) frequency band, H represents high-high (HH) frequency band. Simple average approximation method of fusion rule is applied on MRI and CT scan LL images containing more intensity regions (more information) at low frequencies. The resultant image obtained after average approximation fusion is also like an DWT image which is having the combined coefficients of both MRI and CT scan image. The inverse DWT is applied on this combined/fused coefficient DWT image. Figure 11 represents the inverse DWT i.e. image fusion of MRI and CT scan images which contains more high intensity regions as compared to its constituent input images.

V. Conclusion

DWT method has been used in this paper for efficient feature transformation of the image using Average approximation Fusion rule. The suggested scheme has its own unique characteristics in the extraction of phase by enhancing the precision of identification. The application of FPGA Spartan3 image processing kit is used which demonstrates to be effective in the aspects of parallel processing and execution in real time. MRI and CT scan samples were gathered from the charts of the body. Using DWT and inverse DWT the fused image is obtained that has more precise information compared with original images. Average approximation fusion rule is used to fuse the images. So, the proposed scheme will help the physicians in making the ultimate choice for further therapy using a standalone hardware that is simpler and smaller. Future work will be focused on the enhancement of ranking precision by reducing redundant characteristics in DWT and its inverse.

***Abstract*— Data Distribution Services (DDS) has changed the way of the development process for complex distributed systems by tightly coupling QoS policies for achieving desired functionality at execution time. DDS middleware can be configured to handle edge-to-edge quality of service (QoS) policies. However, unpredictable environment imposes a greater challenge in the design and execution of these systems. The publish/subscribe middleware has improved the scalability and interoperability of the distributed systems. The stringent Quality of Services (QoS) standards imposes a greater challenge to developers. We propose a framework based approach for designing, development, and testing of distributed systems on top of Real-Time Innovations (RTI) and Open-Splice (OSPL) DDS middleware. The framework consists of ACGF Module which generates the code for application. DCF Module provides the abstraction from core functionality of DDS by using templates. Finally, ATF Module will help developer to test their application. This work will be beneficial for the development of different types of DDS applications rapidly.**

Keywords: Data Distribution Services (DDS); Object Management Group(OMG); Publisher/Subscriber Architecture; QoS; RTI; OSPL.

I. INTRODUCTION

DDS is an open standard for real-time distributed systems developed by Object Management Group (OMG) released in 2003 and revised in 2007. Real-time distributed systems can use DDS API's for Pub/Sub communication [2],[3]. DDS technology is used for the platform/target independent devices with secure data communication to all network devices (WSN, LAN, WAN). The environment is highly heterogeneous and requires dynamic pairing along with coordination of fast communicating entities. It is used as the integration technology for data sources and sinks. It provides an extremely high level abstraction along with a rock- solid infrastructure to build highly modular distributed systems [5]. It is like a universal glue that allows us to seal together highly heterogeneous environments while maintaining a single, elegant and efficient abstraction.

This paper proposed a framework based approach for designing, development and testing of distributed systems on top of Real-Time Innovations (RTI) and Open-Splice (OSPL) DDS middleware. The framework implementation is divided into three different modules named as Auto Code Generation Framework Module (ACGFM) generates source code for the application under develop; as per information provided by developer in the form of XML files as shown in Fig.2, DDS Communication Framework Module (DCFM) will provide the functionality related to DDS middleware to the application in the form of its own API's. Finally, Application Testing Framework Module (ATFM) will provide the interface to the developer for testing the application.

The remaining sections of the paper are as follows. Section II defines the evolution of DDS and its working model. Section III describes related work in the field by other researchers in design and modeling of DDS application. The design and implementation of framework is describes in section IV. Finally, in section V we conclude our paper with some future work.

II. BACKGROUND

Data Distribution Service (DDS) standards can be used for development of large scale computing machines as well as small IoT devices connected by network backbone (LAN/WAN). The DDS middleware provide flexibility to make an application scalable, location-independent as well as platform independent [12]. The QoS policies offered by DDS middleware provide the reliable communication for real-time computing devices [1],[3],[4]. The main functionality offered by DDS is Data-Centric Publisher Subscriber (DCPS) architecture. This architecture provides an interface to heterogeneous applications for reading/writing the data from Global Data Space (GDS). The software applications can exchange data in the form of Topics. The DCPS layer provides abstraction from the languages used for development [8]. The software application can exchange the information from other software applications after telling their intention to write the data as publisher by using Interface Description Language (IDL). In the same way software applications by telling their intention to read the data as an interested participant in the form of topic as subscriber [7].

The publish subscribe communication model as shown in Fig.1, enables real-time systems to exchange information by maintaining system performance, scalability and

interoperability [2],[9]. Publisher/ Subscriber model exchange information via central broker to avoid a single point failure. Interface Description Language (IDL) is used for defining the topics in .idl files.

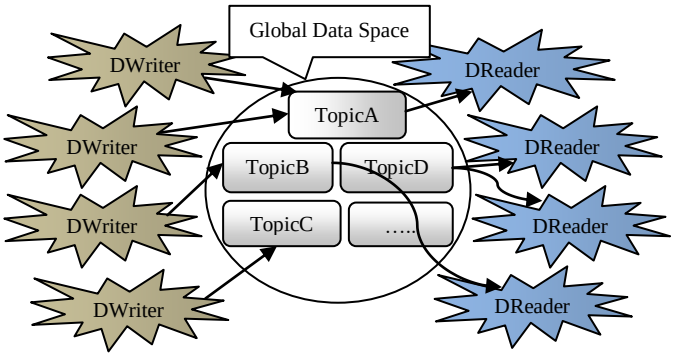

Fig.1. DDS Communication Overview

Architecture and key components of DDS are as follows [10]:

- **Global Data Space:** The software modules communicate with each other by writing and reading the data from Global Data Space(GDS).
- **Domain:** Domain is the main entry point for software modules. All modules are managed inside domain. Domain is a logical space inside the GDS for exchange of data. Software modules having same domain ID may only be able to communicate with each other in the form of topics.
- **Domain Participant:** This is the application that will be the member of Domain and it has right to manage DDS entities as an participient.
- **Publisher and Data Writer (DWriter):** The data writers has right to publish the domain specific data. Each publisher can have multiple data writers and the information about the data writer is maintained by the Publisher. The QoS policy defines the behavior of data writer and publisher.
- **Subscriber and Data Reader (DReader):** The data reader has right to subscribing the data from GDS. Each Subscriber can have multiple data readers and the information about the data reader is maintained by the Subscriber. The QoS policy defines the behavior of data reader and Subscriber. The data can be read from GDS with two approaches "listener-based (asynchronous)" or "waitset based(synchronous)".

III. LITERATURE SURVEY:

Many studies have been conducted regarding the challenges of the implementation of OMG DDS middleware in IoT objects. A lot of the investigations give varying insights into this area. However, what is common is the researchers' agreement on the pervasiveness of IoT and other distributed real-time systems (Alaerjan, Kim, & Al Kafaf, 2017) [1]. The increasing adoption of distributed real-time systems demands more support, with DDS being an example of publish-subscribe software that increases the communication and scalability aspects in IoT objects. The DDS has great significance in enhancing the quality of services (QoS) and promoting scalability; their absence means that these features will not be available. Consequently, according to Alaerjan, Kim, and Al Kafaf [1], one of the factors that hinder the implementation of the DDS middleware in the IoT objects and other distributed real-time systems has always been the absence of the DDS standard, which is required to offer the dynamic models for DDS.

The work on design and modeling aspects of OMG DDS is done by Inglés-Romero et al. [3]. He studies the QoS policies behavior of OMG DDS middleware for distributed systems. The selection and configuration of QoS is a great challenge for real-time systems. For system optimization, they have introduced the concept of communication templates for implementation of QoS in DDS middleware. These communication templates will give the flexibility to the designer and developer to enhance system performance by using adaptive QoS policies at run time. However, the work done by them has not covered any functional behaviour of DDS.

Corsaro et al. [4] talk about DDS and Java Message Service (JMS) standards for publish-subscribe systems, which aid in fully decoupling communication participants. According to Corsaro et al. [4], communication asynchrony is one of the challenges that the implementation of OMG DDS middleware faces.

Beckmann and Dedi [9] show how a lack of support for heterogeneous target platforms and limited interoperability are significant problems in the implementation of DDS middleware in IoT software. Although the OMG DDS is espoused as the breakthrough in addressing the issue brought about by the heterogeneous target platforms and interoperability, lack of DDS standards makes the implementation challenges persist. The problem of interoperability is not completely addressed by any off DDS vendor.

Hakiri et al. [11] propose an IoT network architecture that integrates Object Management Group's Data Distribution Services (OMG DDS) middleware and Software Defined Networking (SDN) as one of the solutions to the implementation problem.

The main problem is the lack of the DDS standards makes it difficult to understand DDS dynamic models and interoperability, which in turns not completely addressed by any vendors of DDS. The work offered in this research paper is a framework based development approach for software portability and reusability. By using the framework the developer can use the same piece of code written for one version of DDS to other version without rework. This work is more helpful in case of large number of heterogeneous IoT devices and coding is required for each and every IoT objects.

IV. FAST DDS IMPLEMENTATION FRAMEWORK

FDDS ("Fast DDS Implementation framework") is an approach by which software designer & developer can build DDS application easily for different type of DDS versions. This framework had provided the foundation classes to the software developers, so that they can use these classes for designing and building the DDS applications without worrying about the complex implementation of OMG DDS.

This framework systematizes the development process, by providing the rock solid infrastructure to the software developers for achieving the reusability of software application for different type of target environment. The framework functionality can be enhanced without effecting the implementation of application.

A. Brief Description of FDDS Framework

All communication of application being developed will be handled by FDDS framework. The functionality offered by framework is domain creation, registering topic, create publisher, create subscriber, create data reader, create data writer etc by re-implementing the DDS methods using class templates. The framework introduced here is a static library for reusability.

The application developer has to include the static library and header files in their project before calling the offered API's. The implementation of the framework is explained in the next section.

B. Implementation of FDDS Framework

The FDDS framework is divided into three modules:

1) Auto Code Generator Framework Module (ACGFM): This module generates the basic infrastructure for the application being developed; by generating the source code in the form of cpp and header files. DDS application development is completely dependent on the type of information exchanged between the publisher and subscriber in the form of topics.

The application developer has to write the topic information in the form of structure and data types in an .idl file. This .idl file is further used by rtiddsgen tool provided by the DDS vendor for compiling and generating the static library. Script for generating the library file is written in Listing. 1. The plug-in and support files generated in above process are carrying the send data, destroy data, print data, serialization and de-serialization methods as per the data structure provided in idl file. These files are used by the application and testing stub for further communication with DDS entities.

```
gcc -DUSE_IOSTREAM -I. -I. -I /opt/rti_connext_dds-5.3.0/include
-I/opt/rti_connext_dds-5.3.0/include/ndds  -DUSE_IOSTREAM -g -c
-DRTI_UNIX -o $f.o $f
```

Listing. 1. Script for generating the topics library

ACGFM is now ready for generating the application code by using the cpp and header files generated by the rtiddsgen. Firstly, this module collects the information about the list of publisher and subscriber with their data reader and data writer provided by the developer in the form of XML file as shown in Fig.1 and it stores the complete information in its local store. By using the file written C++ API's it will generate the cpp and header files carrying all methods and data types as per DDS requirement. The application raw source code is ready for further adding the functionality. In parallel it also generates the source files for the testing framework as per the topics selected by the developer. The application and tester generated in above steps are error free due to no human intervention for writing the code.

2) DDS Communication Framework Module (DCFM): This framework module is the heart for the application being developed. Applications by using this module can communicate with the DDS. The application has to register with DDS by providing the domain ID to which it intended to communicate. The threading and thread synchronization aspects of application is also handled by this module.

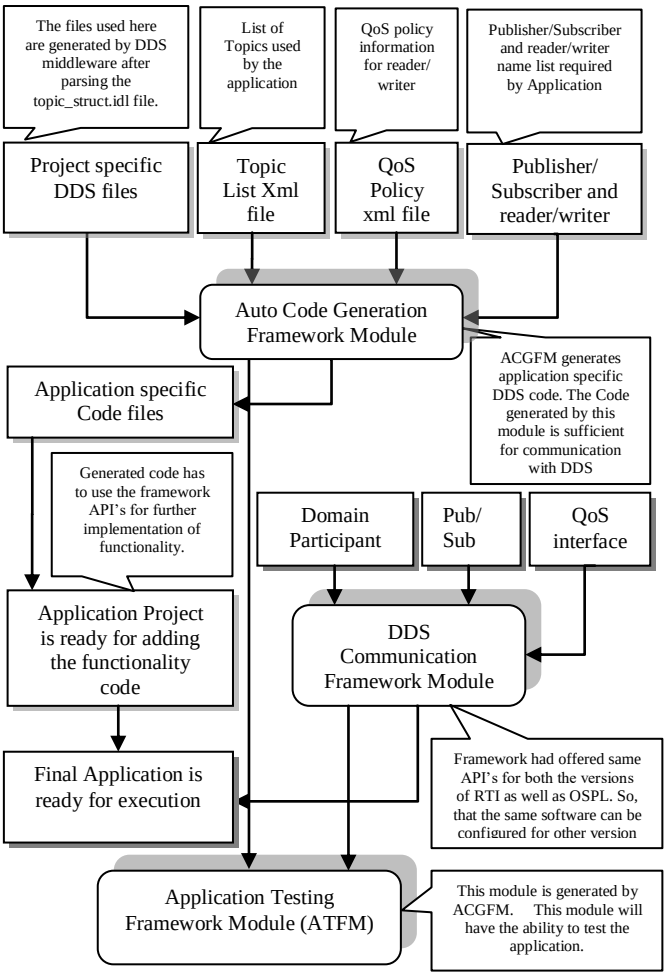

Fig. 2. Working Model of FDDS framework

The framework has re-implemented the DDS methods like

readData(), writeData(), TakeData(), LoanData(), disposeData() and many other methods for providing the simple interface to the DDS application developer.

The functionality of this module is divided into three interfaces. Each interface will provide the needed functionality to the application.

a) Domain Participant Interface: The Domain Participant Interface as shown in Fig.2 and Listing. 2, is the main entry point for the application for communication with DDS by extending its base class from the DomainParticipant class. The entities present in the same domain are only able to communicate with each other and not with other domain entities. The application developer has to enter the domain ID at the time of executing the application.

```
fDDSDomainParticipant::fDDSDomainParticipant(int fDDSdomainId) {
        ptrRtiparticipant = NULL;
        ptrRtiparticipant = DDSTheParticipantFactory-
        >create_participant(fDDSdomainId,
        DDS_PARTICIPANT_QOS_DEFAULT,NULL,
        DDS_STATUS_MASK_NONE);
    if (ptrRtiparticipant == NULL)
     {
        DEBUG_ERROR("create fDDS participant ->",ptrRtiparticipant);
     }
     DDS_SampleInfoSeq info_seq();
     ptrQosProviderRti = NULL;
}
```

Listing. 2. Domain Participant class Implementation

b) Publish/Subscribe Interface: The Publish/Subscribe Interface as shown in Fig.2, is providing the functionality related to publisher, subscriber, data-reader and data-writer to the application. This module is storing the information about the publisher and subscriber for further use by application. The application can request any of the publisher and subscriber by providing the string. The class templates implementation is used for achiving the abstraction from the core functionality of DDS.

c) QoS Interface: The Quality of services(QoS) controls the behavior of DDS systems by configuration a set of parameters, for Real-time Delivery, Redundancy, Persistence, Bandwidth as per system performance required to achieve. QoS Interface as shown in Fig.2 is responsible for attaching the QoS policies to publisher, subscriber, data-reader and data-writer. These QoS policies is decided by the system designer as per performance requirement of system under develop. A single QoS file is used for all the entities in the system. These QoS policies are provided by the designer in the form of XML file. Parsing of XML file is done by TinyXML parser.

sendData method implementation of framework	***sendData method implementation of application***
template <**class** T110,**class** T210> **inline int** sendData (T210 topic,std::string writerName) { DDSDataWriter* topicWriter= ptrRtiparticipant-	sendData<SEND_DATA_STRUCTDataWriter*, SEND_DATA_STRUCT*>(&obj,"DDSPublisher::system_Writer");

>lookup_datawriter_by_name(writerName.c_str());
if (topicWriter == NULL){
DEBUG_ERROR("lookup_datawriter>",writerName.c_str());
return -1;
}
DDS_InstanceHandle_t instance_handle = DDS_HANDLE_NIL;
T110 vDataWriter=(T110)(topicWriter);
DDS_ReturnCode_t retCode = vDataWriter->write(*topic,instance_handle);
if (retCode != DDS_RETCODE_OK){
DEBUG_ERROR("Write Error retCode->",retCode);
return -1;
}
return 1;
}	

Listing. 3. Framework snippet code of "sendData()"

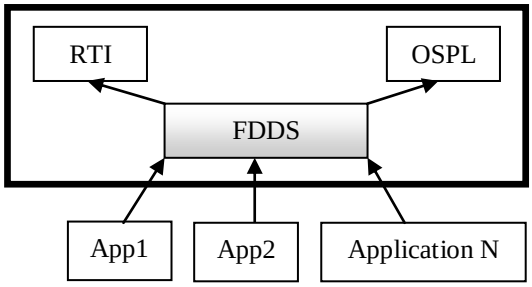

Fig. 3. FDDS framework overview

Fig.3 shows the framework based approach for implementation of RTI and OSPL DDS. The Application developed for RTI by adopting this framework need not required to be re-coded for OSPL because the framework has offered the same API's for both the versions to the developers. But Application developed without using the framework has to code the non functional requirement again for other DDS version. Listing. 3 Shows the implementation of send data method for framework as well as application. Application can write the data to GDS by making this API call. In the same way other API's are also designed and can be used by application.

3) Application Testing Framework Module (ATFM): This testing Module as shown in Fig.2, is auto generated by ACGFM and this module is using the DCF Module for communication with DDS. Only those features will be enabled in the testing framework which is selected as per the publisher, subscriber, data-reader and data-writer inputted in XML file. Developer can test his application by using this module and he did not required to build the testing stub for his application. ATFM is offering UI based manual interface to the developers.

C. Benefits of using framework in Software Development

The framework reduces, time to develop the application, by generating code for selected topics. This framework based approach has provided the infrastructure to the developers, so

that they did not require building the application from scratch. Some benefits of framework:

- **Reduction in Development Time:** The framework reduces the development time, by generating the code for the selected topics required to build the application. The code generated by the framework is able to communicate with DDS.
- **Less Domain Knowledge:** The developers only need to learn the basics of DDS. The complex functionality of DDS is abstracted by the framework by offering its own API's.
- **Reduction in Deployment Time:** The application developed using the framework reduces the time required to build and run the application on the target environment as half of code is auto generated.
- **Reduction in Testing Time:** The application developer only required to test the algorithmic aspects of the application.

V. Conclusion

In this research, an implementation of framework based approach; which provides its own API's for design and development of DDS application. By using the template based implementation application developer can achieve portability, reusability and get complete abstraction from the core functionality of DDS. The change in implementation of DDS will not affect the application and same application can be reused for other DDS version.

***Abstract*— Nowadays, Lung cancer is most common cancer for the people. According to statistics 4,30,000 people are affected by lung cancer. Computed Tomography is the popularly used diagnosis method for lung cancer. In contempt of accurate diagnosis at the early stages, there are some limitations for this method like time consumption and tumour boundaries are unclear. Delta Radiomics is another method used to analyze the image features with respect to time quantitatively for a region of interest and the extracted features are develop to improve the screening of lung cancer. In this paper the features of the cancer nodules are extracted by Delta Radiomics using the machine learning techniques. The Support Vector Machine (SVM) is used to predict the malignancy of the lung cancer nodules. The SVM is capable of analyzing compact features in a lung cancer nodule image and classification of an image is performed effectively for differentiating the various nodules. Therefore, SVM is suggested as the most suitable method for diagnosing and detecting the lung cancer.**

Keywords—SVM machine; lung cancer; diagnosing;Delta radiomics;

I. INTRODUCTION

Cancer is a genetic disorder that controls function of all the cells of a particular part of the human body as shown in fig 1.For a cancer affected person all the body cells are begin to divide continuously and spread to the surrounding tissues. When the cancer cell begins to develop it automatically stops the general new cell formation in a human body [1]. The cancer cells are become into a malignant tumour which can easily spread to the nearby tissues. Among various cancer types, Lung cancer is the second leading dangerous cancer that leads many death ratios [2].

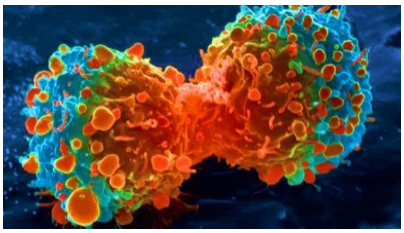

Fig 1: cancer cell

There are two types of lung cancer namely; non- small cell lung cancer and small cell lung cancer. According to the statistics of American Cancer Society, about 1,762,450 are newly affected by cancer and 6, 06,880 were died due to cancer in US. The Lung Cancer is generally detected using the Computed Tomography (CT) scan [3]. It is a medical imaging technology that produces 3D image structure of the internal body. It is most commonly used technique to do surveillance on a lung nodule. As it detected cancer early, It increases the survival rate of the cancer affected person. However, A medical specialist should screen large number of nodules for a proper diagnosis, It should a long time to have clarification. Thus, the CT method is highly time consuming and it is difficult to get a clear detail about the malignant tumour. Radionics is a medical process that helps to extract large set of features from a medical image using some algorithms. It gives quantitative feature extractions which are not visible through a naked eye [4]. The Delta Radiomics technique analyses the change in image feature over time so it is capable of examining the treatment response for the cancer affected person. As such delta radiomic analysis could be combined with the CT imaging for accurate and effective lung cancer screening [5]. In this study Support Vector Machine (SVM), a machine learning technique is being used as it can classify the interior and small features of an image data by reducing the dimensions. Along with reduction it can able to reconstruct the original input data. The classification is evaluated effectively for differentiating multiple nuclei as it can able to detect high level features [6]. Thus, in this process we utilized the CT images to generate screening and classified using SVM for

detecting lung malignant tumour cells [7]. The following sections are covered in this paper.

- The existing methodology of detecting lung cancer.
- A brief explanation about the proposed Methodology
- Experimental results and discussion
- Conclusion and future work.

II. RELATED WORKS

In [1] the author proposes a novel idea based on Structural Coherence Matrix (SCM) to classify the malignant and benign nodules of lungs and also their malignancy levels. SCM with four filters were applied on both grayscale Hounsfield unit images. In [2] the author analysed a performance by incorporating delta and non – delta features using machine learning methods to detect the lung nodule malignancy. They used two gene selection methods to extract lung cancer genes with the help of three machine learning methods namely, Multilayer perceptron, SM and Radial basis function neural network. In [3] the author presented a deep learning strategy called stacked sparse auto encoder (SSAE) for nuclei detection on high resolution [8] histopathological images of breast cancer.

III. LUNG CANCER CLASSIFICATION SYSTEM

The image dataset is used to locate the lung nodule by using the several steps such as Conversion to grey scale image, Image filtering and enhancement, Morphological operations, Feature Extraction and Classification. All the above-mentioned process is examined over the image dataset and the classification is done over the lung CT images. Figure 2 shows the lung cancer classification system structure.

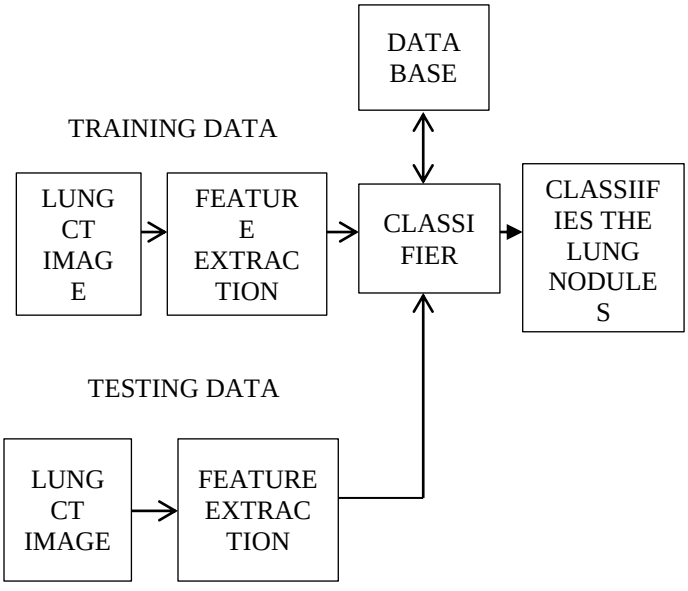

Figure 2: lung cancer classification system structure

A. Conversion To Gray Scale Image

The conversion of colour image to grayscale is simply converting the 3D pixel value (RGB) to 1D value. It is specially to reduce the complexity of processing and clear and accurate edge detection.

$$initial\ image = \ imread(lung\ CT); \quad (1)$$

The above eq (1) is to read lung CT image from the loaded dataset.

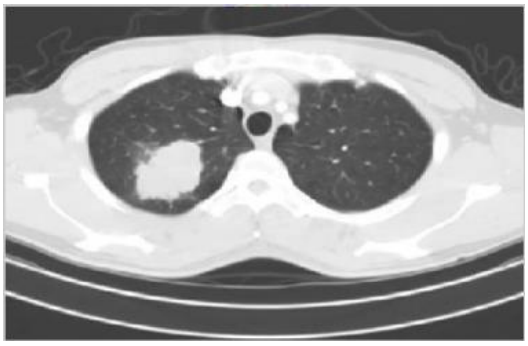

Fig 3: Input image

$$grayimage = rgb2gray(initial\ image); \quad (2)$$

Figure 3 shows the general input image. In general the gray scale pictures have a piixel values ranges from 0 to 255.It converts the RGB image to gray scale image indicates 24 bit image to 8 bit image. The eq (2) changes the given input lung CT image into 8 bit gray scale image. The color converted brain CT image is depicted in figure 4.

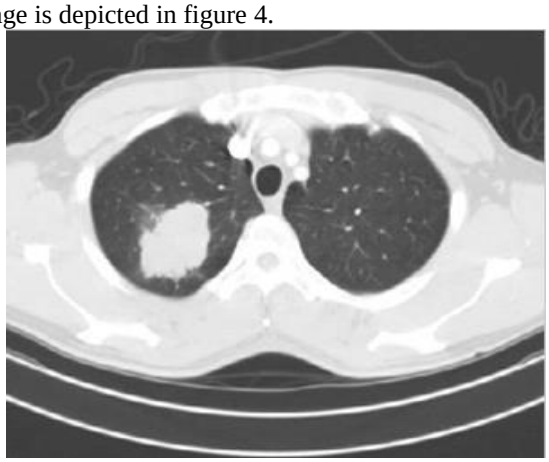

Fig 4: grayscale of the input image

B. Image Filtering And Enhancement

In many visual applications to get a clear analysis of image the image is being filtered and enhanced using some techniques. Filtering techniques are widely used to increase some special effects like brightness, contrast, tone, sharpness to the image under analysis [9]. Image enhancement is also to improve the image quality for further analysis especially both filtering and enhancement is to remove unwanted noise part in an image analysis.

$$adj = medfilt2(grayimage) \quad (3)$$

$$adj1 = hist\ eq(adj); \quad (4)$$

From the eq (3) and (4) we get the filtered (without noise) image of the given input. Here we used the median filter to remove the noise. Finally, we get the normalized histogram equalized image of the filtered lung CT image as shown in figure 5.

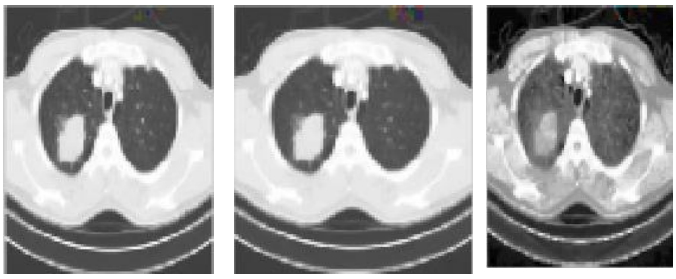

Fig 5: filtered output

IV. MORPHOLOGICAL OPERATIONS

In order to remove the non-tumour regions [10], we have to make use of morphological operators. All the edges of tumorous regions are mingled together with non-tumorous regions in dilation process the broken gaps at the edges are filled and there is a continuity at the boundaries.

$$mean = \frac{sum(C)}{sum(B)} \quad (5)$$

$$Var = \frac{sum(E)}{sum(B)} - mean * mea \quad (6)$$

$$std = (Var)^{\wedge 0.5} \quad (7)$$

$$where, C = A.* B; \quad (8)$$

$$D = A.* A; \quad (9)$$

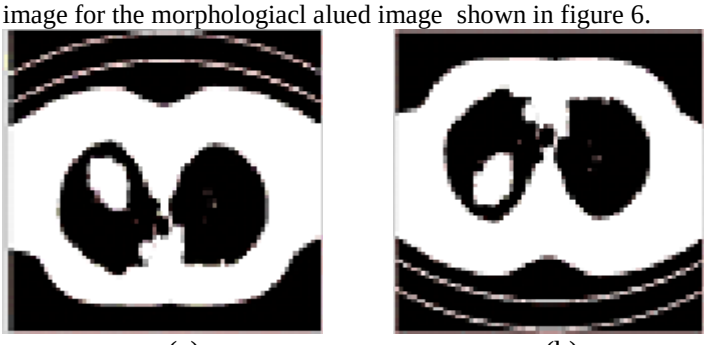
$$E = B.*\mathrm{D} \quad (10)$$

The morphological operation is to done by doing dilation and erosion process consecutively.

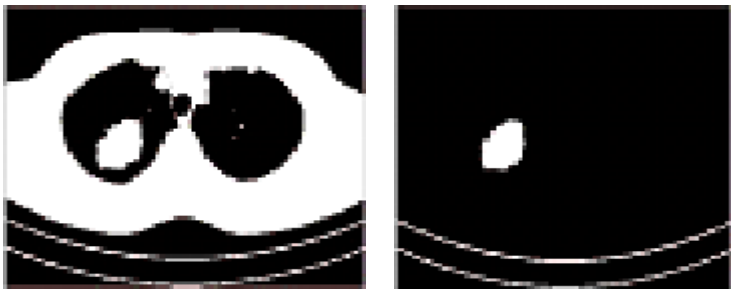
$$\text{dilate=imdilate(bwimage,('arbitrary^',20);} \quad (11)$$

$$erode = erodeimerode(img_{dil}, ('arbitrary', 20); \quad (12)$$

The equation (11) & (12) indicates the dilation and erosion to obtain the morpholocal resulte image.We arbitrarilty set structuring element value of 20 to the black and white lung CT image for the morphologiacl alued image shown in figure 6.



(a) (b)



(c) (d)

Fig 6: morphological operation

A. Feature Extraction

Image recognition is obtained through extracting several features and stored in database. Gray Level Co-occurrence matrix is used to extract the normal and affected CT images. The feature extracted are listed as follows

$$contrast = \sum_{i,j=0}^{n-1} p(\mathrm{i,j}) * (i-j)^2 \quad (13)$$

$$inverse\ difference\ moment = \sum_{i,j=0}^{n-1} p(i,j)/1 + (i-j)^2 \quad (14)$$

The above equation of calculating the homogeneity is to examine the compact (bounded space) of the image pixels.

$$energy = \sum_{i,j=0}^{n-1} p(i,j)^2 \quad (15)$$

$$Dissimilarity = \sum_{i,j=0}^{n-1} p(\mathrm{i,i}) + |i-j| \quad (16)$$

The SVM classifier uses a hyper plane tow classify the given inputs. Generally, the hyper plane is expressed

$$W^T X=0 \quad (17)$$

$$f(x) = b0 + \Sigma\,(ai * (x, xi)) \quad (18)$$

The classification is done by the following expressions

$$\text{Class1: } W.a_i + b \geq 1 \quad (19)$$

$$\text{Class 2: } W.a_i + b \leq -1 \quad (20)$$

All the positive values come under the hyper plane 1 and the negative values comes under hyper plane 2.

In order to maximize the marginal distance of the hyper plane we need to have a change in weights

$$Yi\ (xi \bullet w) \geq 1 \quad (21)$$

As we know the input vector, we have to find the maxima of the hyper plane margin

$$w = \sum_{i=0}^{n} ai\ yixi \quad (22)$$

V. MACHINE LEARNING CLASSIFIER

Optimized machine learning techniques [11] like SVM are highly interconnected to large processing element the feature contrast of an image is to calculate the area of the image pixels into darkest and brightest no genetic or inverse difference moment

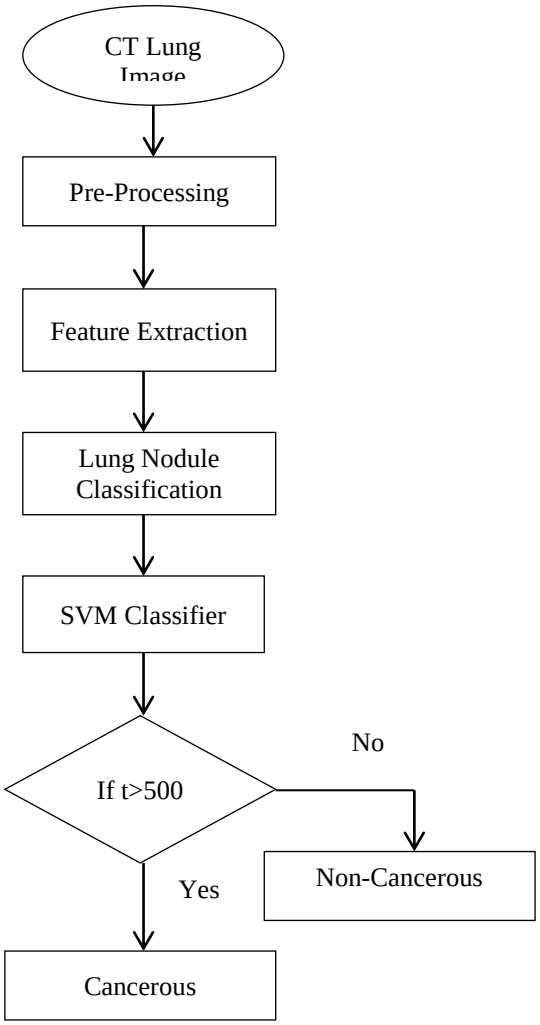


Fig 7: flow diagram of proposed model

Load the Input as Lung CT images.
STEP 1: read the input as CT lung image.
Init Image = imread (Filename);
Init Image= imresize (initImage,[300 300]);
[Rows, columns] = size (initImage);
STEP 2: Divide the data images into training image set and testing image set.
STEP 3: Pre-process the given image and get the grayscale, filtered and finally morphological output of the input image.
gray Image = rgb2gray (initImage);
Adj=medfilt2 (gray Image);
adj1=histeq (adj);
img_dil = imdilate (bwImage, strel ('arbitrary', 20));
BwImage = imerode (img_dil, strel ('arbitrary', 20));
SEP 4: Extract some features over the image such as contrast, homogeneity, dissimilarity, energy, correlation.
GLCM2 = graycomatrix (adj1,'Offset',[2 0;0 2]);
Stats=graycoprops
(GLCM2,{'contrast', 'homogeneity','energy','correlation'});
stats1=stats. Correlation (1);
stats2=stats. Contrast (1);
stats3=stats. Energy (1);
stats4=stats. Homogeneity (1);
STEP 5: Train the SVM classifier.
Step 6: Classify each input image as below.

Load the training, test and label data
Function class=svm(C)
Load train;
Load label;
% figure; title ('Train');
Data = svmtrain (round (train), label, 'show plot, true);
Class=sum classify (data, C,' show plot, true);
By using the kernel and RBF functions of the hyper plane
$W^TX=0$
The various group of class to be classified are
$W.a_i+b\geq 1$
$W.a_i+b\leq -1$
For proper classification by increasing the weights
$Y_i\ (x_i \bullet w) \geq 1$
The maximal marginal distance of the hyper plane kernel is calculated by $w = \sum_{i=0}^{n} ai\ yixi$

VI.RESULTS AND DISCUSSION

Lung CT images are taken as inputs. Different sample images are collected and given as input to the SVM training phase. Data base is categorized as 4 distinct classes [12]. For an automated disease detecting system it is necessary to compare the train sets with the healthy subjects. All the given images are examined for the presence, absence and condition of the disease. Figure 8 shows the sample lung CT image.

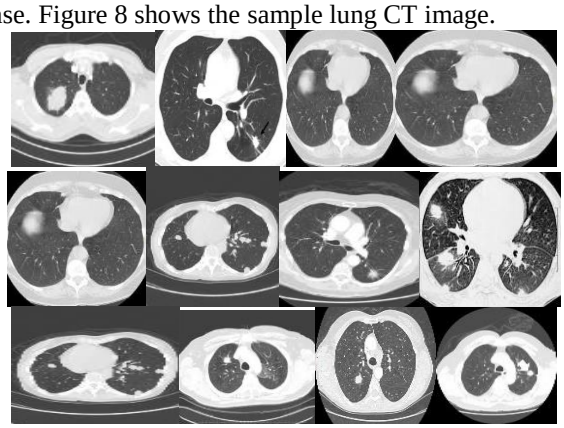

Fig 8: sample lung CT images

The table 1 represents the input image and the belonged class recognition sometimes there will be get the fault detection. In order to avoid the fault detection simulated for few times [13] and considers the result only when the minimum error is reached. The result which has appeared for maximum number of times can be taken as the class of input image. The sample dataset is classified with a good accuracy level where accuracy is a measure of capability to get maximum true results shown in eq(22)

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (22)$$

Table1: extracted features

SI No.	IMAGE	CLASS
1	Image 1	Cancerous
2	Image 2	Cancerous
3	Image 3	Non-cancerous
4	Image 4	Cancerous
5	Image 5	Cancerous
6	Image 6	Cancerous
7	Image 7	Cancerous
8	Image 8	Non-cancerous
9	Image 9	Cancerous
10	Image 10	Cancerous

Table 2: classification results

Image	Contrast	Homogeneity	Correlation	Energy
1	0.9300	0.7753	0.0637	0.7940
2	0.9451	0.9852	0.0642	0.7856
3	0.9281	0.0601	0.6524	0.8056
4	0.8990	0.7421	0.6548	0.7412
5	0.5661	0.4587	0.5421	0.4521
6	0.9522	0.7741	0.8714	0.7821
7	0.9854	0.8541	0.9874	0.7894
8	0.6452	0.6589	0.5214	0.7458
9	0.9877	0.7753	0.5547	0.7845
10	0.9960	0.7745	0.8947	0.7578

The above table 2 represents the feature extracted from the CT lung image dataset. The features are obtained from the GLCM for the different images [14].

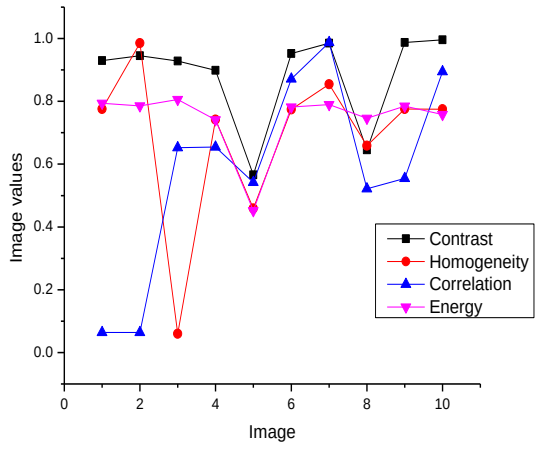

Fig 9: feature extraction

We obtained a accuracy level of 90.9% of given images. Sensitivity is the measure of maximum true positive values whereas the specificity is the measure of maximum true negative values shown in eq(23&24)

$$sensitivity = \frac{TP}{TP+FN} \quad (23)$$

$$specificity = \frac{TN}{TN+FP} \quad (24)$$

The percentage error is calculated for how much the values are accurate as follows in eq(25)

$$\%\ error = \left[\frac{FP-TP}{TP}\right] * 100 \quad (25)$$

The examined error rate is depicted in table 3.

Table 3: Error Rate

Image	MSE	RMSE	MAE
1	0.1293	0.17753	0.1637
2	0.1451	0.1852	0.1642
3	0.19281	0.1601	0.1524
4	0.1899	0.17421	0.1548
5	0.15661	0.14587	0.1421
6	0.19522	0.17741	0.1714
7	0.19854	0.18541	0.19874
8	0.16452	0.16589	0.15214
9	0.19877	0.17753	0.15547
10	0.1996	0.17745	0.18947

The table 3, depicted that the excellence of the error rate[15,16] and deviation of computed and predicted lung cancer results. From the analysis, system ensures MSE(0.177), RMSE(0.172) and MAE(0.164). Then resultant figure is depicted in figure 10.

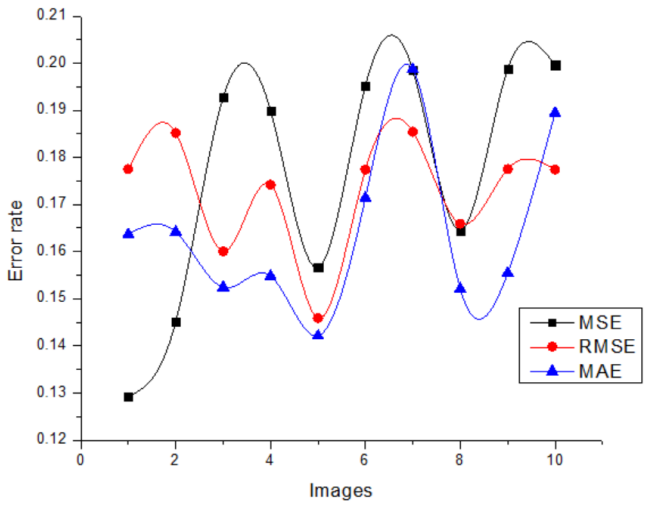

Fig 10: Error Rate

The above fig 10, depicted that the error rate of different images in which the introduced approach minimize deviation value from computing lung cancer effectively. In addition to this, the efficiency [17,18] of the system is depicted in fig 11.

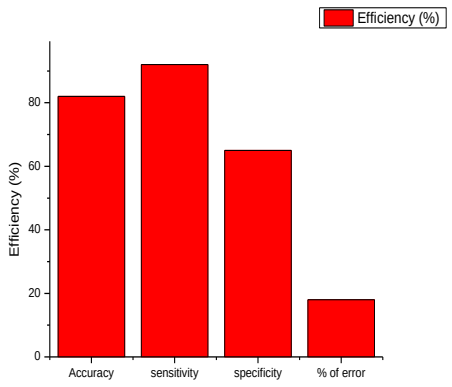

Fig 11: Efficiency

The above parameters are calculated from the obtained results [19,20]. From the above results it clearly depicted that introduced system successfully recognize the lung cancer from CT image effectively.

***Abstract*— With the development of the network control system, which is required for highly precise synchronizing of clocks, IEEE1588 protocol delivers an accurate clock synchronizing in the measurement and control devices. This system is precise at sub-microsecond level. In this paper, we have described a common approach with a brief examination of the synchronization principle. Here we described the state machine of the precision time protocol and the primary issues that affect the time precision. This paper also explains the achievement of time synchronization by implementing PTP and algorithm. In PTP, we implemented the best master clock algorithm (BMCA) for selecting a grandmaster in the networks. The IEEE1588 is for designing of software which consists PTP protocol engine, receipt and transmit controller. It is transplanted into Xilinx Zynq UltraScale+MPSoC devices and tested. This paper is based on designing for the requirement of a time synchronization of the networks.**

Keywords—IEEE1588; Clock synchronization; PTPd; reference design

I. INTRODUCTION

In recent years, the computer system had established various types application devices for networking environment. Along with development of the networking application, the demands have also increased for real time system and sharing information on the data. So, solve these issues the requirement of higher clock synchronization accuracy in the system. Right now, the SNTP is mostly used to clock synchronized as a system protocol in the network technology. SNTP is improved standard of the NTP [7]. These networks are precise up to millisecond (ms) level [2]. It can't meet the progressively strict necessity of the synchronizing in the trade.

To address problems in terms of accuracy while synchronizing of time in a measurement, control and communication between systems in industry, the IEEE1588 precision clock synchronization protocol had been proposed. The standard of IEEE 1588 got released in 2002, and the 2nd form released in 2008 [4]. The IEEE 1588 standard is "IEEE Standard for a Precision Clock Synchronization Protocol for Networked measurement and Control Systems", also known as Precision Timing Protocol (PTP) [7]. The IEEE 1588 standard defines precise clock synchronization in the highest distributed system. where could achieve sub-microsecond level (µs) precision. If we use hardware timestamp support for achieve nanosecond level (ns) [5]. It can totally fulfill prerequisites of time synchronizing of time in the control system such as local computing, network communication and distributed objects.

PTP application has minimum requirements of the processor performance and network bandwidth. It is also low administration effort and use via Ethernet networks but also via other networks. It uses for many applications like, automation, motion control, AVB, telecommunication etc.

II. OUTLINE OF THE IEEE1588

The PTP permits the clocks distributed across the standardized packet-based networks like Ethernet. The network is to be precisely synchronizing using a method wherever the distributed nodes exchanged timestamping packets.

In the synchronization, it is challenging to synchronize the networked computing devices to each other as far as clock. It's reported the measured values and provided that with a accurate device timestamp. the measured values can then be correlated to one another by these timestamps.

A. PTP Device Type

PTP device define 4 types clock are:

i. Ordinary clock works as a single port system. It may be only a Master or Slave clock.
ii. Boundary clock works as a multi-port system. It may be a Master and Slave clock.
iii. End to End transparent clock works as a multi-port system. It is used for a bridge between Master and Slave clock. It advances and adjusts all PTP messages by the bridge residence times accumulated in a distinct field, the correctionField inside the header of the PTP packets.
iv. Peer to Peer transparent clock works as a multi-port system. It is used for a bridge between Master and Slave clock. It advances and adjusts Sync and Follow_Up packets only. They are correcting accomplish by the bridge residence times and P2P delay are accumulated in special field, the correctionField inside the header of the PTP packets.

B. PTP Message Classes

Precision time protocol characterizes general and event message.
Event packets are timed packets in that precise timestamps are created at both transmit and receipt of the message. The arrangement of event message comprises of Sync, Delay_Req, PDelay_Req, Pdelay_Resp message.
General messages don't require accurate timestamp, yet it may comprise accurate timestamping for their related event message. The arrangement of the general message

comprises of Announce, Follow_Up, Delay_Resp, PDelay_Resp_Follow_Up, Management, Signaling message.

C. Clock Synchronization Principle

The IEEE1588 system clocks are equipped in a master-slave hierarchy. Firstly, the master clock is identified and after that, it's established two-way timing exchange. Where master state sends packets to slave state for start the synchronization. Each Slave state at that point reacts to master for synchronizing itself. This sequence is do again the specified networks.

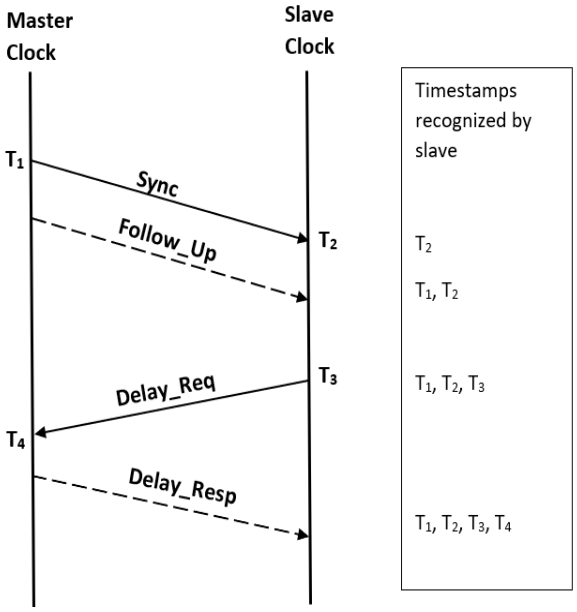

Fig. 1. IEEE 1588 synchronization message sequence

The message interchange procedure is as following:
a) The Grandmaster clock transmit a synchronization (Sync) packet to the Slave clock and registers the transmit timestamp T1.
b) Each Slave clocks accepts a Sync packet and registers the timestamp of response T2.
c) The master state carries to the slave state the timestamp T1 by:

i. Implanting the timestamp T1 in the Sync packet. This is one step clock for highest accuracy and precision.

ii. Implanting the timestamp T1 in a Follow_Up packet for two step clocks.

d) Each slave clock transmits a delay request (Delay_Req) packet to the Grandmaster state and registers the timestamping in t3 when a packet transmitted.
e) The Grandmaster Clock receives a Delay_Req packet from a Slave state and register the timestamp of response T4.
f) The Grandmaster takes to the given the slave a timestamp T4 by implanting the timestamp into a delay response (Delay_Resp) packet.
After completing this sequence, the slave has each of the four timestamps. The timestamps can be utilized to analyze the offset of the slave w.r.t. the master. The mean propagation delay of packets among the two clocks. PTP packet sequence example is shown in Fig. 2.

Delay & offset are calculated based on:
Delay = $[(T_2-T_1) + (T_4-T_3)]/2$
Offset = $[(T_2-T_1) - (T_4-T_3)]/2$

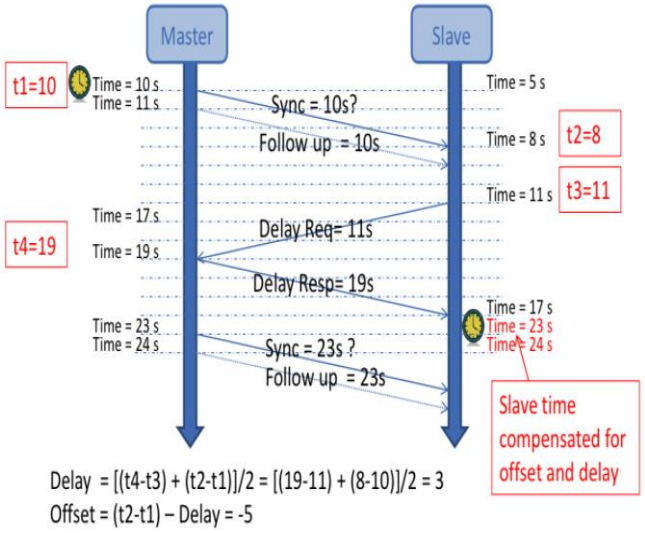

Fig. 2. Example of PTP packet sequence

Peer Delay hierarchy: It measures the port to port propagation time.

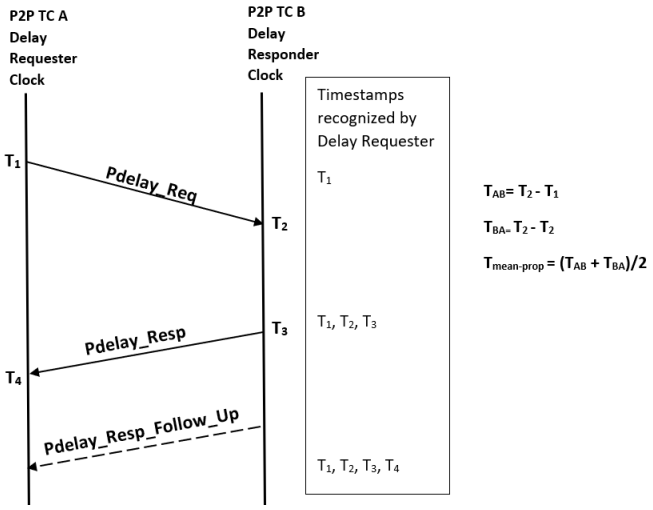

Fig. 3. P2P TC mechanism

In P2P TC operation the four big differences compared to E2E TC are:
1. Path Delay Request/Response messages are used
2. Sync packet is not required for delay calculation
3. The clock adds resident bridge delay + mean path delay to the correction field (instead of just the resident bridge delay)
4. Delay isn't necessarily measured between master and slave, it can be between any two devices hence the name peer to peer.

III. PTP State Machine

In the network, how clock master and slave clock is implemented can be shown as state machine as in the Fig. 4.

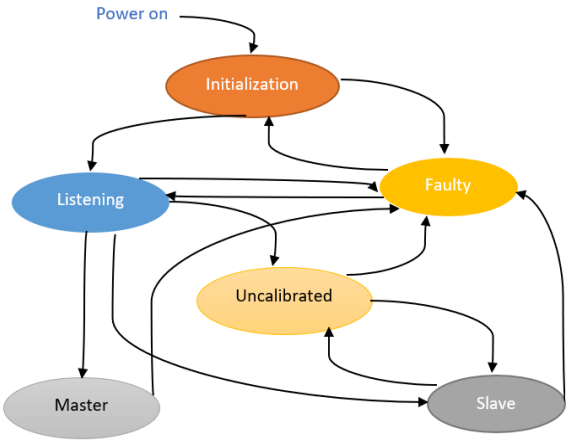

Fig. 4. State Machine

While the device is power on, the system should be initialized first so become enter the INITIALIZATION state. When initializing is finished then it will be going to the LISTENING state. Currently LISTENING state is listening to a system for gets Announce packets from different clock. After the timeout, in the event that it has not received one announce packet then at that point it assumes that the network has no grandmaster, so it will be entered MASTER state and take on the grandmaster role. At that point will send Sync, Follow_Up and Delay_Resp packets occasionally. It has received Delay_Req packets from slave states. Or if is receiving an Announce message from another network. It will choose an exact network as the grandmaster clock by BMCA. If a network is a grandmaster timer, it arrives the MASTER state. Else it will enter SLAVE state. Slave clock received Sync and Follow_Up packets from the master side. It's transmitted Delay_Req packet to the master side in random delay. While errors came, the state will be change to FAULTY state.

IV. Primary Issues That Affect the Clock Precision

a) Path Delay: In IEEE 1588, The path delay of precision time synchronization accept that communicate path delay shows symmetricity. In any case, it's difficult to fulfil the assumption absolutely in genuine system. Here few devices (e.g switches) which own their cache. When a system load is becoming serious, such devices can loss few messages. Likewise, the measuring of delay must not change. Such changes would result in delay jitter and delay asymmetry. It affects the directly synchronization precision. In a transmission would be decrease the variances of the delay. Here the finest way is to independently establish the test system.

b) System Time Drift and Jitter: Mostly the oscillators are crystal. Oscillators are subjected to mechanical, thermal, aging effects, and different factor. The phase and frequency of the master clock is work a input of the tracking control network. The slave clock is work for control object. Any variation in the performance of master clock, its affect a control network and bringing about the deviation together transient and steady state. In conclusion, the jitter and clock drift are lower, and accuracy is higher.

c) Location of the Timestamps: The timestamp accuracy is required for the accuracy of synchronizing of time in IEEE 1588. There are three positions P_1, P_2, P_3, which can be chosen as the timestamp, listed in the Fig. 5.

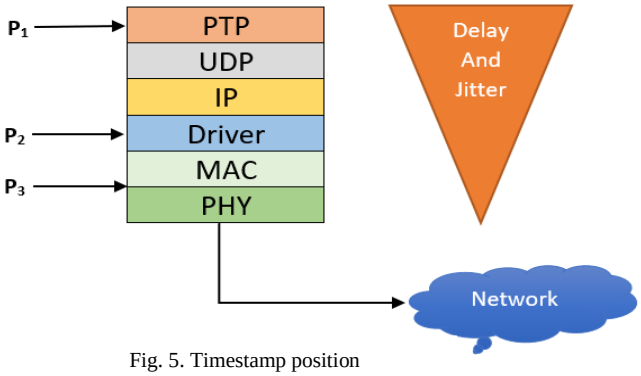

Fig. 5. Timestamp position

Here, the best point is P_3. Since its position is between the PHY and MAC layer. Its nearest to the base of Ethernet, so fault is the minimum. A point P_2 in driver layer is better than P_1 because its delay is within accepted range. But the point P_1 in the PTP application is the worst case because its delay is unpredictable. The specific implementation needs to consider about the propagation of timestamp to the application layer and other layers.

d) Clock Control: Addressing the deviation of the slave timer relies upon the control law. The constraints of control are set-up time, overshoot, adjust time and steady state deviation. These parameters will straight decide the performance of time synchronize of precision.

e) Others Factor: Apart from the above factors, there are few more factors which affect clock accuracy. For example, a delay created by transmit time of Sync, packet retransmitting in junction, time resolution, and otherwise [6]-[8].

V. PTP Analysis And Design Scheme

A model of precision time synchronization network module contains protocol engine, transmission and receipt control, port data sets and clock data sets. The complete architecture of the PTP network in describe in Fig. 6.

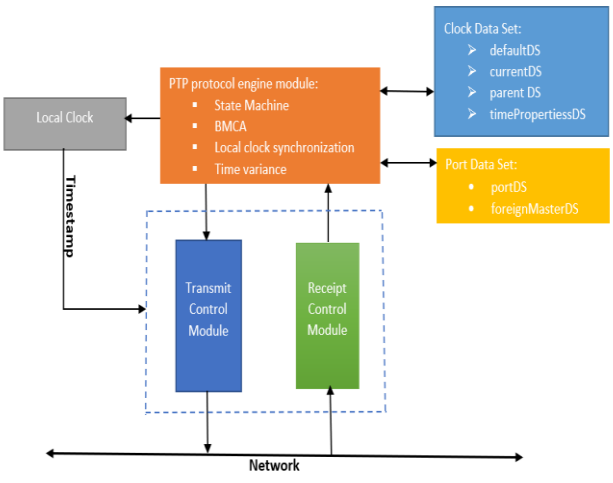

Fig. 6. Network model

A. The Protocol Engine Module

This is main part of precision time protocol network which includes packet calculation, state machine, maintains the data sets, and calculate time between network. It's also including and data interface between data sets, local clock and transmit and received segment. It can be divided into four parts: Best Master Clock (BMC), state machine, local time synchronization and time variance.

- The state machine is responsible for change between different states. Earlier one state arrives another, around for few works. Later a change, the device could start clocks for few packets. For example, Sync, Delay_Req packet periodically to transmit. In various states, the device will be handle relating packets, containing packed packet and unpacked packets. Its procedures forms synchronizing of time etc.
- The principle of local time synchronize procedure is to examine Sync packets from the peripheral master state. At that point when network is in SLAVE clock, it wants to decide that a present master state a best clock. Currently the slave state has accepted Follow_Up packet. At that point among master state and slave state. Here timestamping on four timestamps by three times handshakes. An Offset and Path Delay may be calculated.
- Whereas here might be many master clocks to an equivalent system. So, chosen as a best master clock from local clock by compared several key points by use a BMCA. The BMC contains of two parts: data set comparison DSC (data set comparison) and SD (state decision) process. In data set comparison algorithm, Compares the properties of two clocks, as indicated by their respective data sets and it's used to analyze state port on every timer.
- Time variance is a significant character of the local timer. By method for periodically gathering atomic clock and local clock values. Its deviations of the quartz oscillator rate could include in a local time. Regarding to Allan variance method, is measure the time deviations. It's store results in the timer registers.

B. PTP Transmit and Receipt Controller

The PTP characterize general and event messages. The General messages don't require a precise timestamp and Event message is generated accurate timestamp on both side transmission and receipt. In the delay request-response mechanism, the PTP messages are used to generating and communicating the timing info for time synchronization. This module is using UDP for receipt and transmits precision time protocol packets in multi-cast method. The timestamps will record by the physical layer of system stack. Then event packets are transmitted and receipt to rise the synchronizing of precision.

C. BMC Algorithm

The Best Master Clock Algorithm (BMCA) always runs on all boundary and ordinary clocks in the network. Being run constantly, the clock is able to adapt to dynamic changes in the network, e.g. in case of a grandmaster change or partial blackout in the network. BMCA uses data sets consisting of fields from two clocks to compare which clock is more eligible for being a grandmaster clock. Whenever a new potential grandmaster enters the network, all clocks will compare the data set from the old grandmaster with the new candidate. BMCA compares every field one by one, displayed below in decreasing precedence, only comparing the next field if the previous fields in the data set are identical [4].

Priority1 A field specified by the user ranging from 0 to 255, where a higher priority takes precedence in the BMCA.

Clock class The type of clock used by the device, ranging from an atomic calibrated clock to a slave only clock. A clock of the highest class shall never be used as anything other than a grandmaster clock [8].

Clock accuracy The accuracy of the clock specified in units of time, ranging from accuracy of 25 ns to an accuracy of less than 10 seconds.

Clock variance Static statistics of the variance and stability of the clock.

Priority2 Just like the priority one field, but with lower precedence.

Unique Port ID Often the physical MAC address of the port, this is only used in case of a tie and has no actual relation to the accuracy of the clock.

This way, two different devices comparing the same datasets (device A comparing itself to device B and vice versa) will always come to the same decision of which clock should be the grandmaster.

VI. PROPOSEL

In this paper, we have discussed and elaborate IEEE1588 protocol. We have reduced the offset and delay of PTP application based on IEEE1588v2 by using hardware timestamping between MAC and PHY (Physical) layer. IEEE1588v2 is revised version of IEEE1588. IEEE1588v2 defines shorter synchronization frames to save network bandwidth.

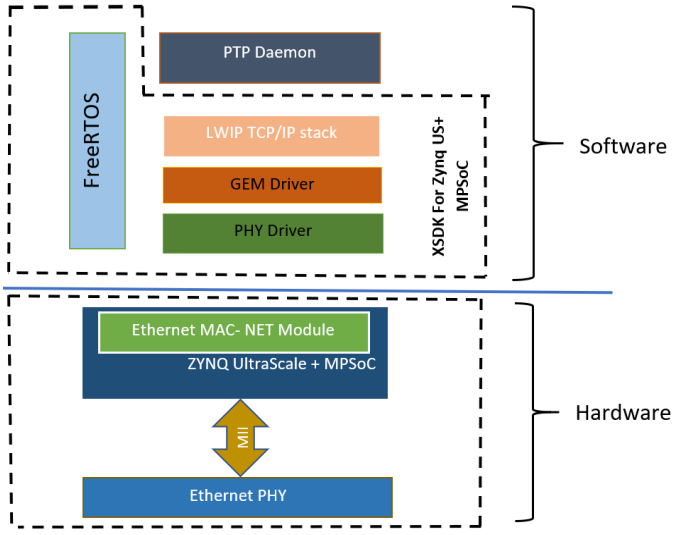

Fig. 7. PTP solution for Zynq US + MPSoC

Under FreeRTOS operating system, it works on peer delay mechanism. It will be creating a hardware timestamping between the PHY and MAC layer and running PTPd application on the hardware platform of Xilinx Zynq UltraScale Plus MPSoC board. We will be used lwip TCP/IP network stack for communication. After testing, the

deviation of time synchronization can be up to nanosecond (ns) level. The proposal shown in Fig. 7.

VII. CONCLUSION

Here, we have analyzed a principle of precision time protocol application, PTP state machine and issues affect of accuracy time synchronization. The design and implementation of IEEE1588 is elaborate. An improved design is used for hardware timestamp and a new method to synchronize clock of PTP application based FreeRTOS OS for Zynq UltraScale Plus MPSoC FPGA is proposed in this paper.

***Abstract*— This work proposes a method for the implementation of PTPd (Precision Time Protocol deamon) with the Gigabit Ethernet Module (GEM) Interface for test devices. The programmable real-time clock and timestamp unit was implemented in the programmable logic to achieve the synchronization accuracy of sub-microsecond. PTPd has been reconfigured and implanted into a FreeRTOS operating system to create a PTP state machine and the IEEE1588 IP core software driver has been created to give the application layer access to the precise timestamp in the link layer. This paper evaluates in detail the matter of the IEEE 1588 standard and provides a "Xilinx ZynqMP UltraScale plus SoC + MAC + PHY" technique, a hardware solution for stamping the arrival and departure period of PTP packets. Where packets are obtained between MAC and PHY layers from Media Independent Interface (MII). The result indicates that the solution can detect the messages transmit and receipt for synchronization accurately.**

Keywords*— *Xilinx ZynqMP UltraScale Plus SoC, IEEE1588v2, Time synchronization, Timestamping

I. INTRODUCTION

Nowadays, Time synchronization is alignment of time as well as advance of the over distributed network. it's critical in many applications such as real time application control system network or video applications and voice related applications [2]. there is frequency synchronization phase synchronization and timing synchronization. We can take a look at touch upon those along the way and it is important to coordinate action between distributed nodes or distributed computers and also, it's needing to trigger the measurement and then actually measure the same time over the different nodes also referenced events which can trigger all over distributed nodes.

In IEEE1588, it is about distributing the time reference time to the other nodes using the packet so it's the distribution of precise time over the packet-based system [3]. we can synchronize our frequency time or phase using IEEE1588 and it's providing high accuracy time over your network typically a sub microseconds range and it's based on hierarchical structure so master clock provides a time to your slave. the slave can synchronize the time of the master clock.

The objective of this paper is to develop a general system for IEEE1588 synchronization protocol in the GEM network, using Xilinx ZyncMP UltraScale Plus MPSoC as a platform for measuring synchronization performance parameters. For system synchronization, data synchronization and test data analysis, these parameters are essential. Based on the parameters, additional consideration is given to facts affecting synchronization and a optimized method is proposed and introduced the precise of sub-microsecond synchronization in test.

II. OUTLINE OF THE IEEE1588

The IEEE1588 system clocks are equipped in a master-slave hierarchy. Firstly, the master clock is identified and after that, it's established two-way timing exchange.

PTP message sequence with timestamp

In this figure 1, how PTP protocol message sequence actual works.

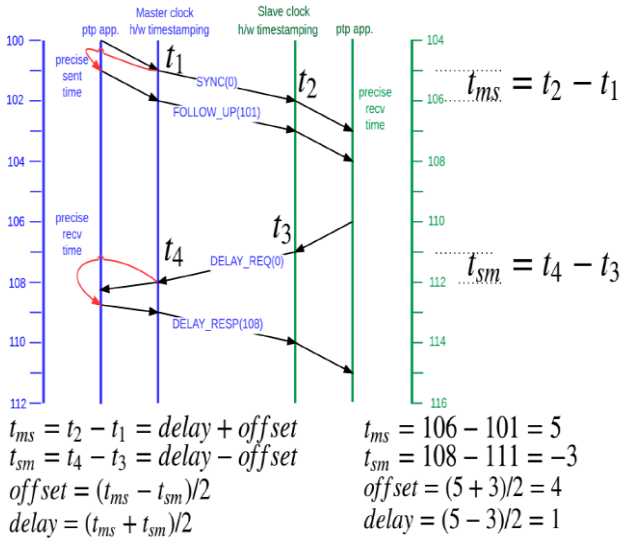

Figure 1. PTP message sequence

We put another line here that application and then this is the actual time stamping put it on a slave side as well master side. It is the hardware timestamping that reads the actual time. Master PTP application sends the packet out before we send the packet to the wire you don't know the time, so the sync that's the first message is called SYNC with no unknown time that's 0 here, but as soon as the packet is on the wire, your chipset says it's okay this packet sends t1 time. Using this t1 time put it in the next packet Follow_Up message sending. we sent previous packet at 101 second so at this point on a slave knows when it is sent the actual master says it sent and when it arrived here hardware says I receive this packet t2. The next sequence slave software

says send a packet as soon as Delay_Req packet is on the wire we know the t3 time sent it to master and then master received a packet. Then it received it knowns actual accurate timestamp t4 put it on to the next Delay_Resp packet. Which is the till they respond by the way this is still a request from the slave and then we send a delay response saying that after received your delay request packet. at this time so once sleep get all this packet collected then sleep can calculate that offset of between master and slave and then delay between two networks.

III. IEEE 1588 IMPLEMENTATION FOR XILINX ZYNQMP ULTRASCALE PLUS SOC

The zcu102 Evaluation Kit (for Xilinx ZynqMP UltraScale plus SoC) is used as the hardware platform for the hardware timestamp based IEEE1588v2 Precision Time Protocol. The solution uses the Xilinx SDK, which includes the GEM driver, the PHY driver, the ported FreeRTOS kernel, and the ported lwIP TCP/IP stack for the zcu102 board. The IEEE1588v2 Precision Time Protocol is implemented by the PTP daemon application. It's shown in fig.2.

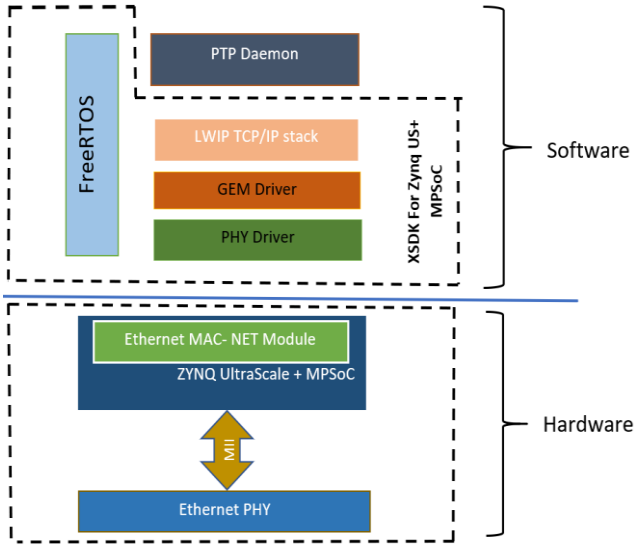

Fig. 2. PTP solution for Zynq US + MPSoC

i. Hardware components

Zynq UltraScale+ MPSoC is the Xilinx second-age Zynq platform, the combination of a processing system (PS) and user-programmable logic (PL) into the same board [8].

The PS includes the Arm® flagship Cortex®-A53 64-bit dual-core or quad-core processor and Cortex-R5 dual-core real-time processor. Apart from the earlier cost and integration benefits previously provided by the Xilinx Zynq-7000 devices, Xilinx Zynq UltraScale+ MPSoC and RFSoC boards also provide new benefits and features.

ii. Software components

The software of the IEEE 1588 usage incorporates the Xilinx SDK for the for Xilinx ZynqMP UltraScale plus SoC device hardware platform and the PTP daemon. The Xilinx SDK is a software structure for creating applications on the Xilinx MCUs, including GEM drivers, middleware, and FreeRTOS real time operating system.

a) lwIP TCP/IP stack

The lwIP implements a TCP / IP networking stack that is lightweight for embedded systems. lwIP is an open source available in C source code format providing under the Berkeley Software Distribution (BSD) style license. This stack is used to reduce the use of RAM through a full-scale TCP for use in embedded systems. The Xilinx SDK provides lwIP stack customized to run on different Xilinx installed frameworks [10]. It can be run on ARM-based Xilinx Zynq UltraScale+ MPSoC related all programmable SoC. The main stack is an IP implementation, on top of which you can choose to include the UDP, DHCP, IGMP, TCP and many other protocols according to your required and the memory size is available in the designed system.

b) FreeRTOS real-time operation system

FreeRTOS is an open source RTOS. It is real time operating system kernel or real time scheduler targeting embedded devices. It utilizes embedded application to fulfill its requirements in hard-real-time. The FreeRTOS features provided by the kernel are multithreading by tasks, queues, software timer, semaphore, mutexes and event groups. FreeRTOS kernel port is available for Xilinx Zynq UltraScale+ MPSoC, ZynqMP SoC and other Xilinx devices use FreeRTOS kernel 10.0 version.

c) *GEM hardware support for PTP*

The controller detects the transmission and receipt of PTP event packet Sync, Delay_Req, PDelay_Req, and PDelay_Resp. Master-slave clock synchronization is a two-stage method.

- The master will correct the offset between the master and the slave clocks by sending the slave a sync frame with a follow-up frame with the exact time the sync frame was sent. On the master hand, the GEM controller assists modules and the slave detects precisely when the master sent the sync frame and the slave got it. Then the slave adjusts his clock to suit the master clock.

- Correct the delay in transmission amongst the master and the slave. The slave sends the master a delay request frame that sends a response frame for delay reaction. On the master hand, the GEM controller assists modules and the slave detects precisely when the slave sent the delay request frame and the master got it. Then the slave has sufficient data to adjust his clock to account for the delay.

IV. TIMESTAMPING

A. Software Timestamping

Using a conventional Ethernet module, the PTP protocol can be fully implemented in the software shown in fig. 3. The delay variance implemented by the software stack operating on the master and slave systems implies that only a constrained accuracy can be obtained since the time stamp data is implemented at the application layer. As the Master has no hardware clock, both its own internal oscillator drift and the master's oscillator drift must be compensated for the

slave-running PTP daemon, degrading time synchronization precision.

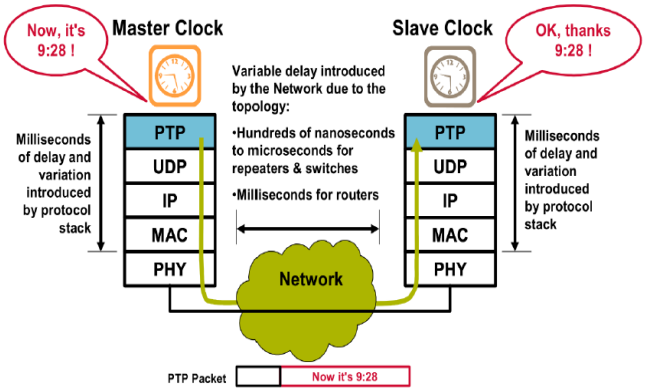

Fig. 3. Software Timestamping

B. *Hardware Timestamping*

Take timestamps nearer the physical interface, namely to the MAC or PHY layers to reduce the effect of the stack protocol delay shown in fig. 4. Master and Slaves with a Hardware time stamp then PTPd are providing time synchronizing accuracy less than 1 microsecond with independent of their operating system and network load.

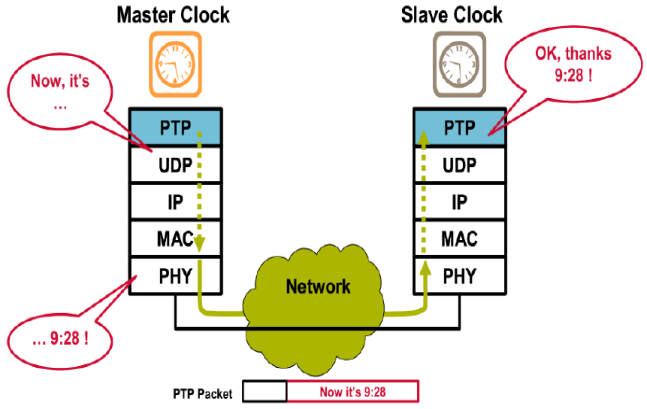

Fig. 4. Hardware Timestamping

In this proposed method, use hardware timestamping for reduce the stack protocol delay and make with FreeRTOS environment for board. It allows synchronization with significantly improved accuracy.

V. THE WHOLE PTPD DESIGN

The whole scheme is divided into three layers i.e. application, driver and hardware layer. The application layer understands the BMC algorithm, the packet processing and the PTP message transfer method based on the IEEE1588 protocol. We used PTPd is a open source software. It's achieved the software state machine. The original PTPd is established in the application layers by stacking the TCP / IP network protocol. This is a software timestamp which controls only with synchronization in milliseconds levels. We are need to solve the low precision of the software timestamp and to create an accurate hardware event trigger and improved the PTPd application.

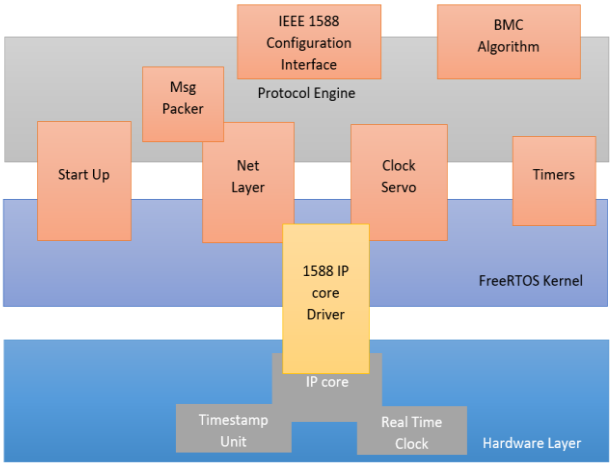

Fig. 5. The whole design of IEEE1588v2

The entire system after enhancement is shown in the Fig. 5. Here adding a scheduling process of IEEE1588 IP core for optimized the clock synchronization accuracy.

The core of the IEEE 1588 IP comprises primarily of three components: register module, timestamp module, real time clock module. The register module functions as an interface layer between the FPGA-based software and the IEEE1588 IP core.

A. *Timestamp Module*

The PTPd package format designed with ethernet based on IEEE 1588 standards, the specific standards of timestamp module are following:

a) 110bit timestamp (78bit time message, 32bit PTP packet recognition).

b) Support PTP packet format for two layers (Ethernet+PTP) and PTP packet format for four layers (Ethernet+IPv4/IPV6+UDP+PTP).

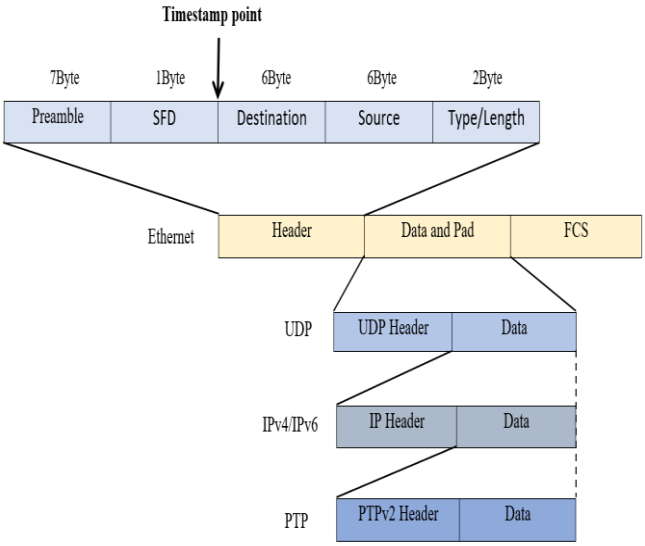

Fig. 6. IEEE1588 package format

The Timestamp module displays the data input stream consistently. PTP package format is shown in Fig. 6. Here two successive 1 at the end of the Ethernet packet SFD (start frame delimiter), this time characterize as timestamp point [6]. Currently, real-time clock time is being saved. Then we check the messages if the message is a PTP event message then the timestamp is store otherwise discard the timestamp.

B. PTP Packet Format

All PTP packets need a header, body, and suffix. This is a common header for all PTP messages [7]. IEEE1588v2 header format shown in Table 1. Here are two main points to define these messages.

Header 1588 V2									
Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
reserved								1	5
flagField								2	6
correctionField								8	8
reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField								1	32
logMessageInterval								1	33

Table 1. IEEE1588v2 header format

a) messageType

MessageType's value shall show the PTP message type as described in Table 1. Message type fields (1-4) for PTP event packets are accessible in the PTP header.

Message Type	Message class	Value(hex)
SYNC_MESSAGE	Event	0
DELAY_REQ_MESSAGE	Event	1
PATH_DELAY_REQ_MESSAGE	Event	2
PATH_DELAY_RESP_MESSAGE	Event	3
Reserved		4-7
FOLLOWUP_MESSAGE	General	8
DELAY_RESP_MESSAGE	General	9
PATH_DELAY_FOLLOWUP_MESSAGE	General	A
ANNOUNCE_MESSAGE	General	B
SIGNALING_MESSAGE	General	C
MANAGEMENT_MESSAGE	General	D
Reserved		E-F

Table 1. messageType

b) sequenceId

The sequenceId field value is allocated for Sync, Pdelay Req, and Announce packets by the originator of the packet. This field needs to be recorded to match packets.Real-time clocks modules

C. Real-time module

In the IEEE1588 protocol, this module supports the format and function are as follow:

i) 48-Bit seconds, 32-Bit nanoseconds and 32-Bit sub nanoseconds domain.
ii) In the real time clock can be used external clock oscillator for better stabilization.
iii) We designed clock setting and offset setting interfaces for the PM (phase modulation) function to adjust the clock value, the modify resolution is 2^{-8}ns.
iv) We have built FM and temporary FM interfaces for FM (frequency modulation), the period modulation resolution is 2^{-32}ns. 32bit counters are given to count temporary FM's efficient time.
v) For accurate measurement can be used hardware PPS output support.

D. Software And Driver Design

The specific access to the register address through the AXI bus completes the development. The IEEE1588 IP core is consistently configured by writing the control register. At this stage we read the status of the data registers for the real-time clock and timestamp values.

The IEEE1588 IP core requirement for multiple registers is being implemented. For the FreeRTOS software platform, the more information about driver supports implementation. The default PTPd source code exists for the Linux, NetBSD, FreeBSD, Mac OS X operating systems. So PTPd porting on FreeRTOS with lwIP and Xilinx SDK drivers for the Xilinx ZynqMP UltraScale plus SoC devices. The operation network related code, system related code, Hardware timestamp related code must be added or ported in the drivers. In the PTPd, the changes or ported work on the system time routines, software timer, system services, interact with network socket and some modification of the PTP protocol. These ported work covers under the FreeRTOS. The configuration FreeRTOS tasks with Xilinx ZynqMP UltraScale plus SoC board.

We are created three task threads using FreeRTOS in the PTPd application:

- *main_thread* task: It is created in the main function. This task initializes the lwIP TCP/IP stack, static IP address setting, netmask and gateway address configuration. It's also initializes MAC address configuration; Ethernet hardware initializes and starts the PTPd application task. After initializing the lwIP and PTPd tasks it's deleted itself by calling vTaskDelete function.
- *network_thread* task: In the TCP/IP initialization, it's created by main_thread task. This task run in the main lwIP task to access the lwIP core function.
- *ptpd_thread* task: this task runs the PTPd application and created this task denotes either the master or the slave clock.

In the lwIP driver, there are initializing the IEEE1588 timer, enabling the IEEE1588 timer, Setting the time function, getting the time function, adjust the IEEE1588 timer frequency, and getting the hardware timestamp for transmit/receive frames. These are the initialization function used in the IP core to initialize all the resisters.

Based on the above process, the improved PTPd mechanisms to achieve the scheduling of PTPd hardware resources.

VI. TEST AND RESULT

A. Hardware Setup

For the test hardware setup, used two ZCU102 board (Xilinx ZynqMP UltraScale plus SoC) and connected each other. The setup has a point to point configuration where using the Ethernet cable for connected two ZCU102 board. To prevent asymmetric transmission delay interference, master and slave ports are linked with the same switch. At this stage, a significant factor influencing synchronization efficiency is the difference between slave and master oscillator frequencies. A hardware setup shown in fig. 7. Specific jumper setting is not used in the test.

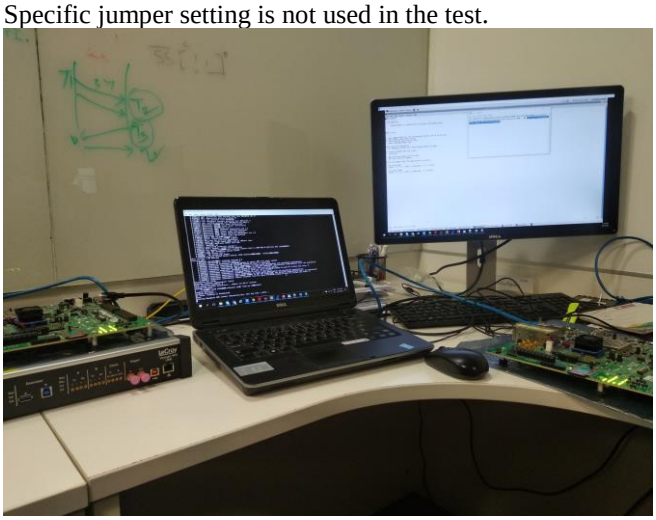

Fig. 7. Hardware Setup

B. Result

Under the FreeRTOS environment, this paper program implements the PTPd application's main function. The program runs on the psu cortexa53_0 hardware platform and used board support package (BSP) of Xilinx ZynqMP UltraScale plus SoC devices.

ptp4l Master clock output- Grandmaster:

We're going to start out listening to see if there's anybody else out there that's doing PTP. Since this is the only endpoint on the node right now, there's nobody else out there. So eventually, timeouts will start happening. You'll start realizing that, well, apparently there's nobody out there, so maybe I need to become the master. Since you're the only one out there, you'll probably get selected as the best master. And you'll become the master, and ultimately, you'll become the grandmaster it's shown in fig. 8.

Fig. 9. Slave clock output

Over that hour, after we locked, we stayed within +/- 100 nanoseconds of the master offset. It's shown in figure. PTP application is precise clock synchronization in nanoseconds is successfully used hardware timestamping. It's shown in fig. 10.

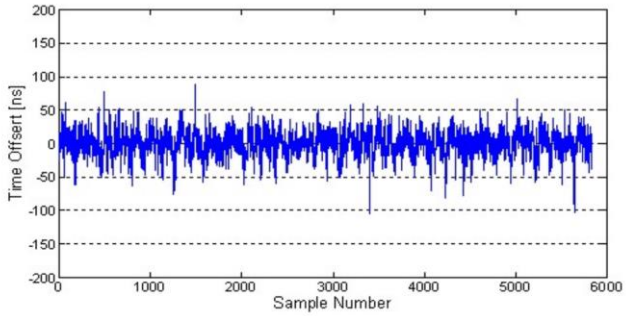

Fig. 10. Clock Synchronization test

VII. CONCLUSION

In this paper, we achieve under the FreeRTOS environment the hardware solution of GEM Ethernet in PTPd application based on IEEE1588v2 on the Xilinx ZynqMP UltraScale plus SoC platform, the program has high clock synchronized with high accuracy, excellent portability and scalability.

***Abstract*—Implantable antennas for biomedical applications are on leading edge of research for medical diagnosis such as glucose monitoring, tracking, pacemaker etc. Biomedical applications require antennas that are very small in size but can meet designated requirements. In this paper a 24mm x 34 mm cupcake shape fractal patch antenna is designed and simulated using CST software. The designed antenna operates in 2.45 GHz frequency band called industrial, scientific and medical band (ISM band). Designed antenna's reflection coefficient, VSWR, surface current, gain and far-field plot are simulated and observed. The designed antenna provides 670 MHz (27%) bandwidth in the band of 2.20 - 2.87 GHz. This antenna is miniaturized and compacted to be utilized as an implantable antenna for biomedical applications.**

Keywords—antenna; DGS; fractal;ISM band;patch;biomedical applications.

I. INTRODUCTION

There is a growing need of antenna design for efficient medical diagnosis and treatment. Implantable antennas are being used for glucose monitoring, endoscopy, pace maker etc [1]. For these applications there is need of small size, light weight and compact antennas. Antenna size can be miniaturized using fractal concept. The basic idea behind fractal design is that the same shape is repeated again and again but at different scales. Fractal patch antenna design results in smaller sizes and multiband frequencies. Octagonal and decagonal shaped fractal patch antennas are designed for S, C and X band applications [2]. Similar to octagon and decagon, a circular and elliptical shaped fractal patch antenna is fabricated and tested for multiple applications [3]. A 30mm x 40mm UWB antenna on Rogers's substrate is designed for lung cancer detection [4]. A wearable micro strip patch antenna of square shape spiral cut is simulated at 2.45 GHz frequency for body centric wireless communication. Three layer model using skin, fat and tissue is designed. PTFE (polytetrafluoroethylene) is used as a substrate [5]. A miniaturized dual-wideband circular patch antenna of radius 7mm is designed. The antenna radiates on 403.5 MHz MICS band, 433.9 MHz ISM band and 2.45 GHz ISM band. Single layer model is designed and simulated of volume 100 x 100 x 22 mm^3. A 600MHZ impedance bandwidth and maximum gain of -33.06 dB is achieved [6]. A review on implantable patch antennas for biomedical telemetry is given and challenges and solutions are discussed [7]. A hexagonal shape micro strip patch antenna is simulated for biomedical applications at 2.45 GHz [8]. Small size implantable micro strip antenna for MICS band is designed for body centric communication [9].

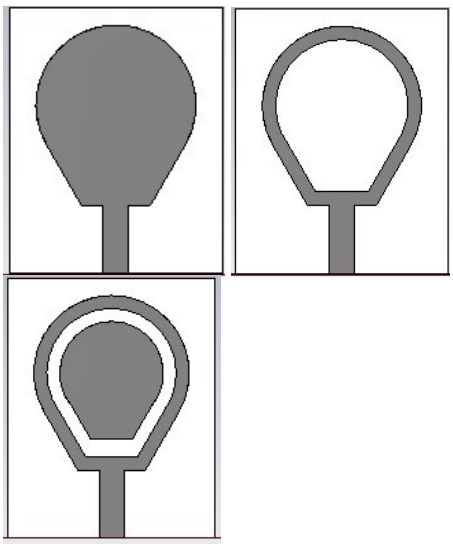
Defected ground structure (DGS) is simple design used for enhancement of antenna parameters. A double U shaped defected ground structure proposed on simple trapezoid monopole for bandwidth enhancement. Wider bandwidth is achieved from 790 MHz to 2060 MHz [10]. Many papers on DGS is reported in literature [11-13].

II. ANTENNA DESIGN

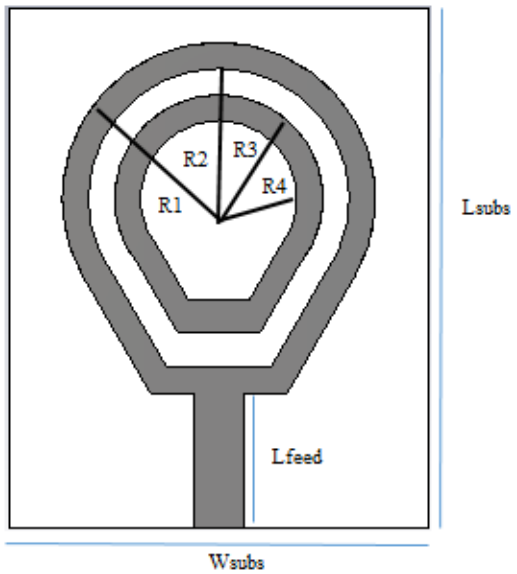
Antenna is designed on Fr-4 substrate with dielectric constant of 4.4 and thickness of 1.6mm. Fr-4 is considered because it has low dielectric losses and easy availability. The substrate size is 24mm x 34mm. Fr-4 substrate has PEC ground on bottom layer and PEC patch on top layer. Patch

design is cupcake shape [4]. The antenna design in this paper is of a fractal patch antenna in cupcake shape, inspired by [4]. The antenna design is shown in figure 1.

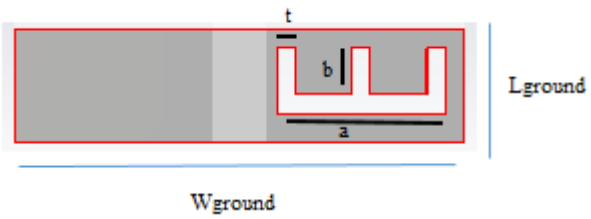
First of all, a circle of radius 9mm is selected, then a hexagon (circle radius=7.8mm) is drawn. To achieve half hexagon, a rectangle is subtracted and inserted into hexagon. Now half hexagon and circle is added and cupcake shape is obtained. To make this cupcake patch fractal, again same cupcake shape of smaller size is designed and then boolean subtracted from initial design. Initially antenna ground of size 24 x 8.6mm^2 is considered. Fractal cupcake upto iteration-3 is shown in figure 1. Cupcake shape is used because it has no sharp edges and can be used in implantable devices in biomedical applications.



(a) Iteration-0 (b) Iteration-1 (c) Iteration-2



(d) Iteration-3



(e) Ground with DGS

Fig1. Cupcake fractal patch iterations and ground

For better resonance and bandwidth enhancement E shape slot (DGS) is inserted into ground as shown in fig 1 (e). The size of antenna ground is 8.6mm x 24mm. The designed antenna is simulated using CST software. Antenna is designed till itetaion-3. Optimized dimensions of proposed antenna is given in Table I.

TABLE I. FINAL ANTENNA DIMENSIONS

Dimension name	Size (mm)	Dimension name	Size (mm)
L_{subs}	34	L_{ground}	8.6
W_{subs}	24	W_{ground}	24
R1	9	a	9
R2	7.5	b	5.5
R3	6	t	1
R4	4.5	L_{feed}	12

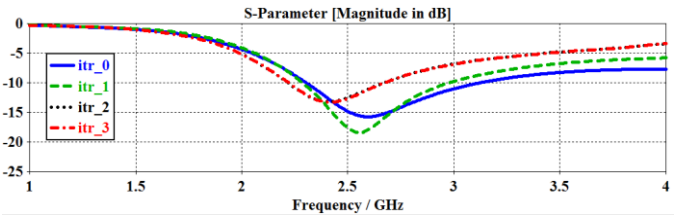


Fig 2. Compared S11 of different iterations without DGS

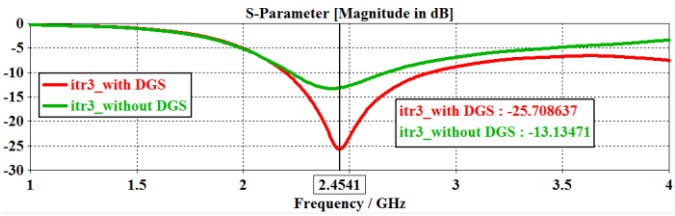

Fig 3. Iteration -3 reflection coefficient with and without DGS

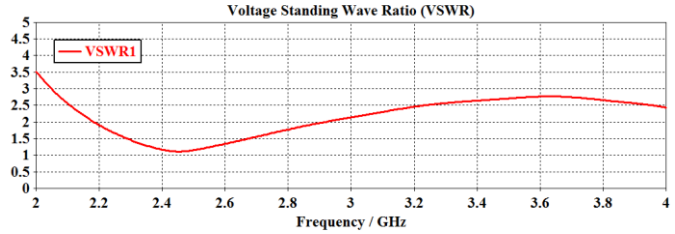

Fig 4. VSWR of iteration-3 with DGS

The compared reflection coefficients of all iterations are shown in fig 2. In iteration-0 antenna resonance frequency is 2.59 GHz (2.3-3.1 GHz), but this resonating frequency is not useful for medical applications. In next step, fractal concept is applied and iteration 1, 2 and 3 are designed. In iteration -3, resonating frequency of 2.45 GHz (2.20-2.87 GHz) is obtained. Reflection coefficient at ISM band centre frequency 2.45 GHz is -25.70 dB. Voltage standing wave ratio (VSWR) of iteration-3 is shown in fig 3. As a general rule the VSWR of under 2 is considered very good antenna design. It can be seen from fig 3 that for frequency range 2.20-2.87 GHz, VSWR is in between 1 and 2.

Iteration-3 results are summarized in table II. Here acceptable bandwidth and positive gain are achieved. The frequency band of 2.4GHz to 2.5GHz is reserved for industrial, scientific and medical (ISM) applications.

TABLE II. BANDWIDTH AND GAIN OF ITERATION-3

Iteration	Fr(GHz)	Fl(GHz)	Fh(GHz)	BW (MHz)	Gain (dB)
Itr-3	2.45	2.20	2.87	670	1.69

The centre of ISM band is 2.45 GHz. Current distribution in both patch and ground is shown in fig 4. Fig 5 shows gain at frequency 2.45 GHz, which is 1.69dB.

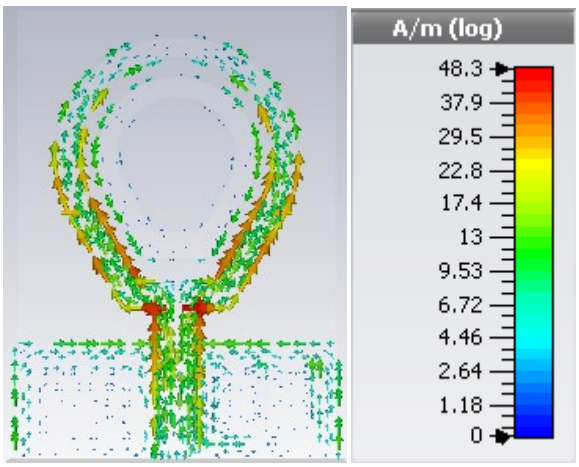

Fig 5. Surface current distribution at 2.45 GHz

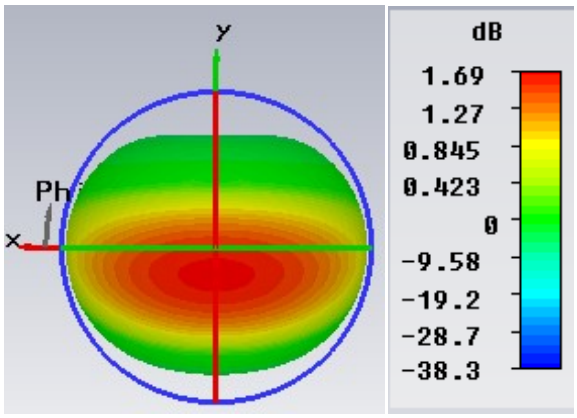

Fig 6. Gain at 2.45 GHz

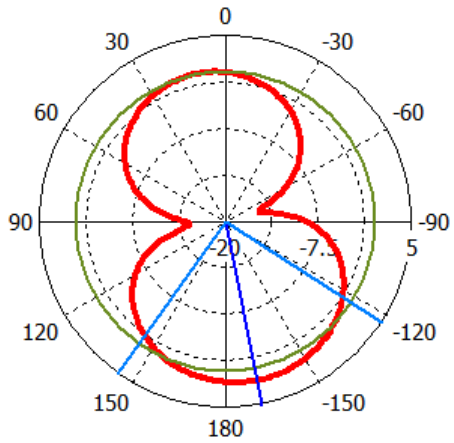

Fig 7. Far-field radiation pattern at 2.45 GHz

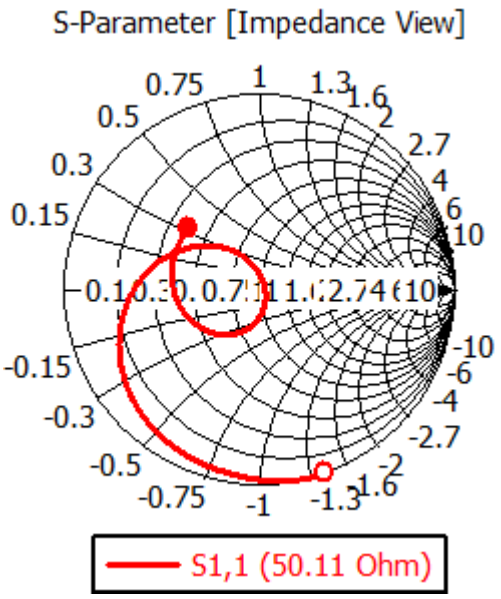

Fig 8. Smith chart of antenna

Simulated Far-field radiation pattern of antenna is shown in fig 7. The pattern is nearly omnidirectional as antenna size

is small. Figure 8 shows smith chart of antenna which gives 50.11ohm impedance, which clearly shows that there is good impedance matching.

Future applications of this antenna can be in the field of ambient computing. Further improvement will be designing of rectenna(rectifier antenna) for ambient energy harvesting. A hexagonal shaped fractal patch antenna for ambient computing is presented in [14]. The proposed antenna provides better impedance bandwidth and gain as compared to [6].

III. CONCLUSION

In this paper, a cupcake shaped fractal patch antenna with simple configuration, light weight and compact size is presented. This antenna is designed for implantable medical applications. Defected ground structure (DGS) are introduced in ground to achieve better impedance matching and bandwidth enhancement. The operating range frequency of this is 2.20-2.87 GHz. The ISM band of 2.4-2.5GHz falls within the operating range of this antenna.

***Abstract* - Searching of literaure is the prime processes in any research to gain insights on the progress carried out on specific probles. Literature search in biological science and bioinforamtics is more complex as the researchers has to find the relre vant articles specifi to the biological components like DNA, RNA, Gene, PROTEIN. Pubmed is a literature database which cosists of millions of articles submitted by researcher based on the experimerntal studies. Analysing Gene for the study is important for studies and experiments related to diseases. In this paper a bi-directional methdology is propsoed to extract literarure from pubmed abstracts using web scrapper and web crawler by providing gene names and map gene with Gene card Database. In the second approach a methdology is provided to analyse Gene expression profiles from GEO database using EDA and Map the significant gene reterived to the Pubmed and Gene Card database. The differentially expressed genes are grouped after performing PCA and clustered using k-means. Lung cancer is major cancer reported in WHO and hence in this study the Lung cancer is used as the usecase to test the methdology proposed. The experiemnts are implemented using Python. From the experimental results it is found that the propsoed approach reduce the time for searching the literature.**

Keywords - Clustering , K-means, PCA, Pubmed, GeneCards, EDA, Web Scrapper

I. INTRODUCTION

Lung cancer can be classified into "Non-small cell lung cancer (NSCLC) and Small-cell lung cancer (SMLC). Among lung cancer cases 85% of the reported cases are found to be NSCLC which spreads quickly [10]. The subtypes of Non-small lung cancer are Aqueous cell carcinoma, Adenocarcinoma, and Large cell. 5% of lung cancers are lung carcinoid tumors which are sometimes mentioned as neuroendocrine tumors. In this work lung cancer dataset is used for implementing the methodology.

Technological developments in the domain of genomic and proteomics helped to identify the causes of genetic variations at gene level which are reported in bioinformatics databases. Huge volumes of data are deposited at various repositories of NCBI, EMBL AND DDBJ. There are exists various classified databases which accumulate results reported by researchers in their experimental studies. Pubmed is a literature databases which accumulated millions of research findings submitted around the globe. Pubmed literature is used as an important research tool among various researchers to gain insight on different experiments and the association of biological entities. Cancer related to experimental analysis also requires integration and association of related entities such as mapping genomic sequences with structures, diseases gene, pathway and functionalities. Gene expression profiles are mainly used to analyze the variations of gene in various experimental conditions in diseases, diagnosis to understand their functionalities and pathways.

Researchers will search biomedical literature databases to study on the different experiments reported in articles with respect to disease and their genomic and proteomic entities. Manual searching of the database is time consuming and complex. The objective of this project is to download pubmed abstracts related to any specific diseases, gene name and other attribute for Literature search and extract the genes related to lung cancer to analyze the gene expressions using web scrappers.

In this paper a methodology is proposed to extract gene names from the pubmed abstract using web scrapper and map with diseases genes to group gene using clustering Remaining paper is organized as follows. Section 2 provides a brief view on computing techniques, followed by objective and methodology in section 3. The experimental results are discussed in section 4 followed by conclusion in section 5.

II. COMPUTING TECHNOLOGY

Web scraping software technique used for extracting information from websites. Web software access the World Wide Web directly using the hypertext transfer protocol, or through a web browser. Web scraping is scraping a web page fetching for information and extracting based on keywords and URIs. Web crawlers are also used to extract the data from websites [9]. Web scraping is used to scrape the web sites. It is not possible to scrape the specific data from websites or web pages, with web crawlers contents can be extracted from[3] multiple pages and also form specific parts using selectors like "css or Xpath", in a structure way. The components built in scrappers contain spiders, search engine, downloader, item pipeline, items and scheduler. The components of scrappy are shown in Fig.1

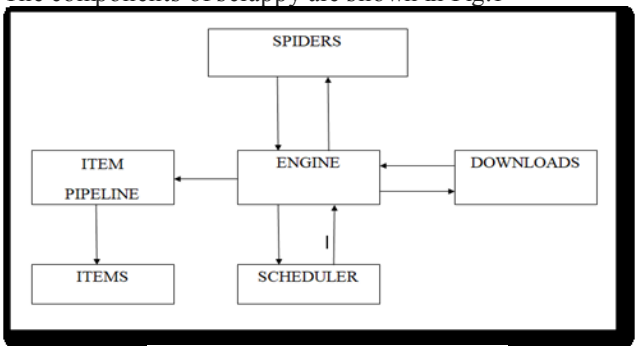

Fig. 1. Web Scrapper: Components

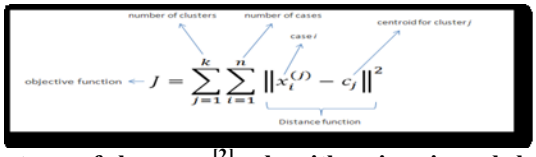
Web scrappers are used to extract pubmed abstracts related to small lung cancer genes. The detailed methodology is discussed in the methodology given below.

Principal Component Analysis

Principal component analysis is a statistical procedure used to reduce for dimensionality reduction based on orthogonal transformation where possible set of correlated observations are set into values of linearly uncorrelated variables called principal components. The main idea of the principal component analysis is reducing the dimensionality of the attributes by maintaining the variations by transforming the variables into a new set of variables as principal components. The principal components are represented using the mathematical representation as eigenvectors of a covariance matrix, and which are orthogonal. In this work dimensionality reduction is used as the Gene expression profile has high dimensions and there will be larger variance among same set of genes. PCA is used to identify the principal components in genes which help to improve the performance of the process.

K-Means Clustering

K-means clustering [2] algorithm is an unsupervised algorithm which is used to group items naturally based on the similarity patterns of the data. The similarity measures decide the grouping of items and various distance based similarity measures are used to group objects in the dataset.



The steps of k-means[2] algorithm is given below as follows:

Input: - k i.e, the number of clusters and the set of points (x_1, x2…, x_n).

1. Choose the 'k' value i.e, k- determines [4] the number of groups the items in the dataset belong.
2. Initially randomly 'k' data points as chosen as centroids ($c_1, c_2,…,c_k$)from the vector space.
3. Repeat until convergence :
   i) For each data point is :
      a) Find the nearest centroid c_j using similarity metrics (i.e) Euclidian distance
      b) Assign x_i to that nearest cluster j
   ii) For each cluster find the new centroid which is the mean of all the x_i points assigned to that cluster j.
4. Terminate when none of the cluster assignment change.

The iteration can be terminated on specific criteria k-means clustering is used in this work to group similar genes related to lung cancer extracted from pubmed abstracts.

III. OBJECTIVE AND METHODOLOGY

The objective and Methodology of this work is to extract abstract from the Pubmed database related to Lung Cancer using Web crawler and map genes related to Lung cancer using gene expression profiles of small lung cancer in Phase I. Perform EDA to analyze the term associations of biological entities like Gene names, and analyze the variation of gene expression profiles of lung cancer types and group genes using clustering in Phase II to provide an insight on the most frequent genes used for analyzing lung cancer in literatures. The objective is implemented in two phases. The methodology for extracting and mapping gene's is given in Fig. 2 for Phase I and in Fig. 3 for Phase II.

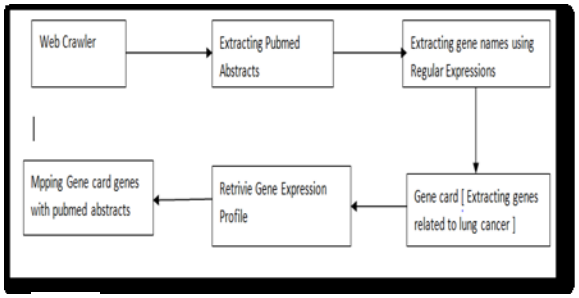


Fig. 2. Framework: Gene Expression Analysis

Phase I: Data Extraction Steps

1. As the first step the web crawler scrappy from python library is used to crawls the pubmed abstracts related to lung cancer.
2. The Gene names from the extracted abstracts are retrieved using regular expressions.
3. The Genes related to small lung cancer is extracted from the Gene card database with expression profiles to map the gene causing lung cancer presented in pubmed abstracts.

The gene expression profiles are analyzed in Phase II using extensive descriptive analytics.

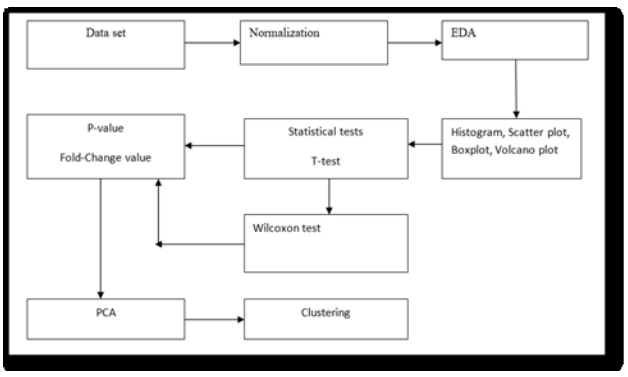

Fig. 3. Framework for EDA and Statistical Tests

Exploratory Data Analytics (EDA)

Exploratory data analysis[5] (EDA) is an approach to analyzing data set to summarize their main characteristics, with visual methods.EDA provides a clear insights for checking assumptions model fitting and hypothesis testing,

and handling missing values and make transformations. The EDA Visualization for Gene Expression Profile is given in Table 1.

Table 1: EDA[7] Visualization Vs. Gene Expression Profile

Visualization Vs. Gene Expression Profile	
Type of Visualization	***Gene Expression Profile***
Histogram is used to understand the deviation in the data set which provides a summary on discrete or continuous data.	Histogram is used to analyze the spread of the values. It is also used to identify the fold changes also to find the distribution of the data and plotted for p-values
Box plot is used to analyze the data distribution based on IQR, minimum and maximum.	Boxplot helps us to analyze the difference of variations of gene expressions
Scatter plot display relationship between two sets of attributes. It pairs up values of two quantitative variables in a dataset and displays them as geometric points.	Scatter plot is used to analyze the relationship between the different and similar genes.
Volcano plot is used to identify the variations in the large data sets.	Volcano plot helps us to analyze the significant changes with respect to fold values.

Gene Expression Analysis using EDA

The expression profiles are analyzed as given below

1. Normalize the data into logarathmic10
2. Perform the histogram, box plot, scatter plot, volcano plot analysis for gene expression profile.
3. Perform T-test and Wilcoxon[5] test to analyze significance of the gene and plot analyze histogram, boxplot, scatter plot, volcano plot with the p-value to find the fold change.
4. Group, identify and extract genes which are similarly expressed and differentially expressed

IV. RESULTS AND DISCUSSION

Phase I: Document Count

The web scrapper is implemented using Python library is used to search Pubmed database for abstracts groups related to lung cancer. The keywords such as Small Cell and Non small cell lung cancer are given as input to the scrappy. Around 4000 documents are downloaded from the pubmed database.

The pubmed abstracts downloaded are searched for gene causing lung cancer which is extracted from Gene Card Database. Around 30,000 gene were searched in the abstracts to find the frequency of occurrence which is given in Table 2

Table 2: Phase I: Document count

Document count		
S. No	***Pubmed***	***Frequency of genes***
1	Downloaded 4000 abstracts	300000 in Gene Card for Lung Cancer
2	Mapping of Gene card database genes for Abstracts	14000 [at least one time] 928 [more than 50 times]928 gene are at least one time

To analyze the functionalities of gene, expression profiles are downloaded from GEO database related to Lung cancer. The data adenocarcinoma and squamous cell carcinoma GDS3627 is downloaded for homospaiens which contains 58 samples and 54675 instances.

Phase II : Gene Expression Analysis

The limma and Bioconductor packages are used for analysing differential gene expression analysis using R and Python. Differentially gene expression were analysed using a double filtering approach based on fold change t-test and Wilcoxon test. The EDA is presented in the sections below.

A. Histogram

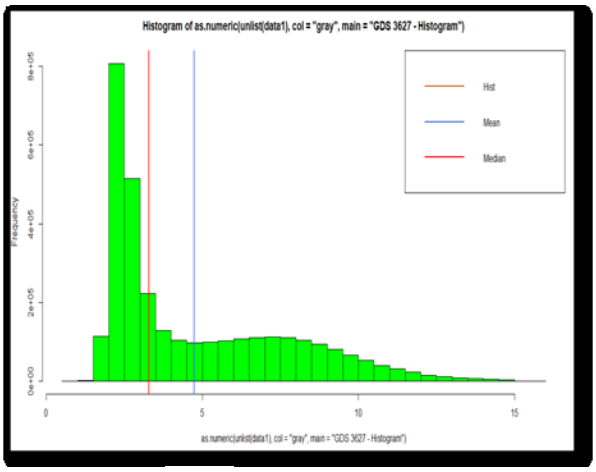

Fig. 4. Histogram for GDS3627

The histogram is shown in Fig. 4. is without normalization found to be right skewed and more genes have higher expression values greater than mean. Hence Histogram analysis after normalization is done which is show in Fig. 5.

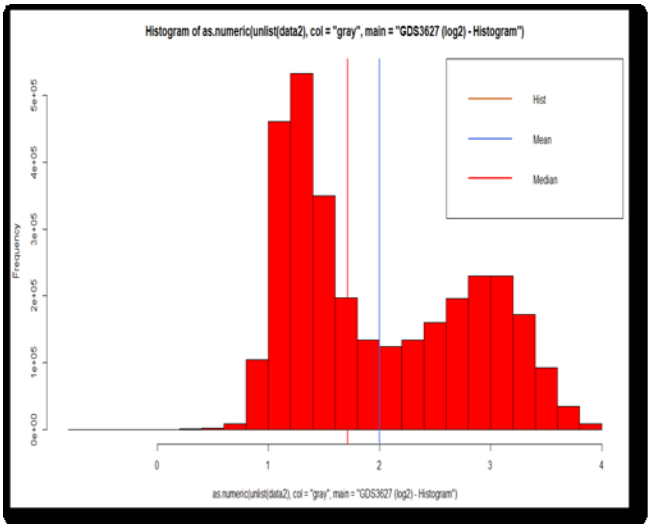

Fig. 5. Expression profile: Normalized – Log10

The distribution is found to be bi-modal distribution with two different groups. The first distribution belongs to adenocarcinomas and the other to squamous cell carcinoma. The data distribution can be further slice to review the expression values. After scaling the data the genes falls between 0 to 4 on x-axis. 60% genes are lies between 1 and 2. All the remaining genes fall between 2 to 4 on the x-axis.

Based on the inference the t-test is performed to compare the expression profile between two different groups in the same experiment for which the histogram fold difference is show in Fig. 8.

Parametric Test T-Test

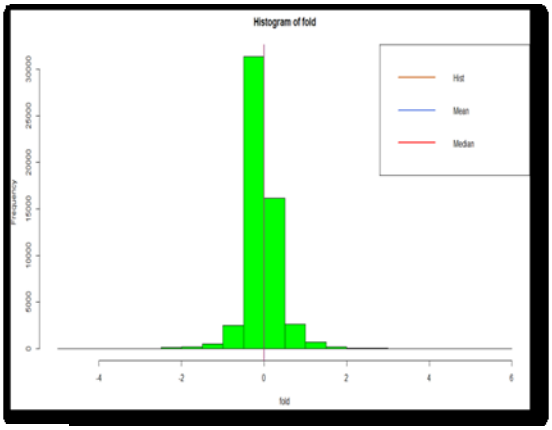

Fig. 6. Difference between the two means fold change

Fold change [5] is a biological significance difference between the means of the conditions. The histogram given in Fig. 6. refers to the fold values [the difference between the two mean's]. The fold value is between -2 and +2 with a fold value as 2.4 to measure the quantity of the attributes.

B. Scatter Plot

Scatter plot is a Bivariate plot used to find the relationship between two variables X and Y. It is normally used for analyzing the correlations among the variables. The scatter plot is drawn between the average mean of a type and the average mean of type b.

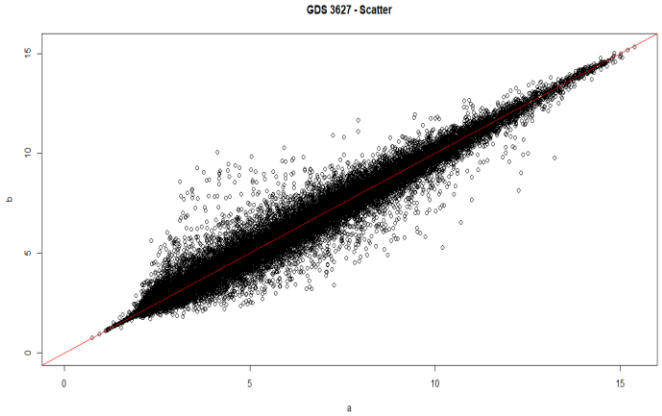

Fig. 7 Scatter plot: Adenocarcinomas vs Squamous cell carcinoma

In Fig. 7. Scatter plot line is drawn between to the cancer types Adenocarcinomas vs Squamous cell carcinoma. The relationship between these two groups are found to have a strongly correlation. The correlation value of the attributes is 0.98. That means of the attributes are positively correlated and the red line is connecting the mostly correlated attribute variables of the two groups.

C. Volcano plot

Volcano plot[7] given in Fig. 8 is used to plot the expression profiles for Fold_cutoff value (2) and p-value cutoff (0.05). The result is shown below.

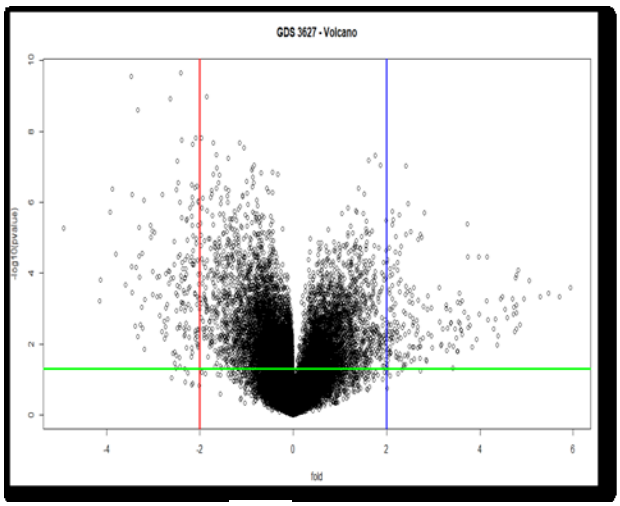

Fig. 8. Volcano Plot

The Volcano plot is shown in Fig.10. represent for the fold cutoff value 2 and the p-value is 0.05. The points found inside the boundaries are found to have similar expression profiles where the data points that are out of the boundaries red, blue and green show the genes expression profiles with are largely varying and differently expressed. Some outliers with are single, are also available which are out of boundaries. The x-axis has fold value (2) and the y-axis is logarithmic p-value. The word cloud for similarly expressed gene and differentially expressed gene is shown in Fig. 9. and Fig. 10

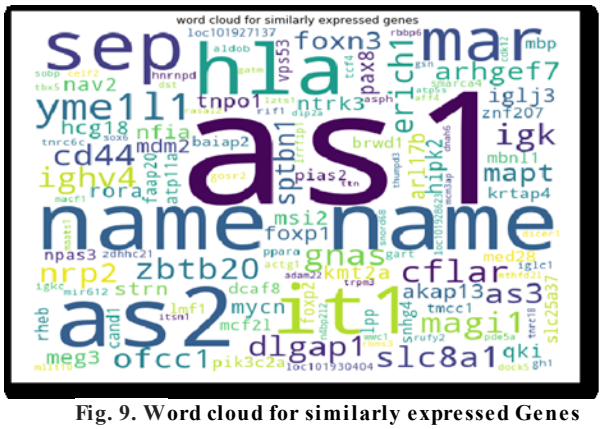

Fig. 9. Word cloud for similarly expressed Genes

Inference:

The Fig. 9. provides a word[12] cloud view of the similarly expressed genes. The 54389 genes are similarly expressed and the size of the gene names based on the frequency of the gene. Gene names as1, as2, is the highest frequency related to small lung cancer. The genes gsn, dst, ash2l are found to the have lowest occurrence.

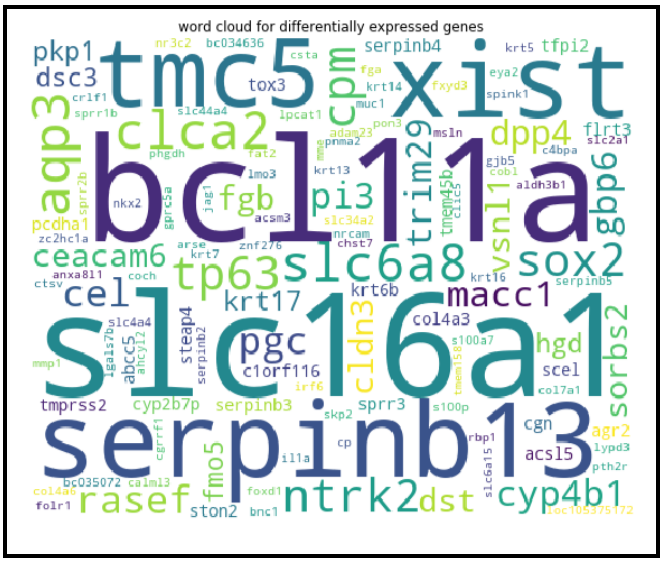

Fig. 10. Word cloud for differentially expressed Genes

Inference

The Fig.10 represents word-cloud of differentially expressed genes. 218b genes were found to be differentially expressed genes. The genes that have high frequency are XIST, BCI11a, serpinb13 and genes that are less frequency bnc1, nav1, muc1.., etc.

D. Mapping of Significant Gene: Pubmed and Gene Card

Based on the EDA expression profiles the gene which are within the fold and which satisfied the p-value condition >0.05 are filtered which is shown in Fig. 11.

	Name	Count
4	KRT5	1
7	HLA-DQA1	13
8	PI3	106

16	DST	2

Fig. 11. Count of Filtered Genes > pvalue 0.05

115 genes satisfied the condition and verified for references in 4000 Pubmed abstracts downloaded. Out of 115 genes 29 genes are mentioned in pubmed abstracts atleast one time and 8 genes were found to be mentioned more than 100 times. The gene P13 is found to be mentioned 106 times PI3. This methodology will help the researchers to extract the relevant abstracts specific to gene for further analysis. The gene expression profile gene are also mapped with GeneCared genes and also verified for their occurrence in Pubmed abstracts which is shown in Fig.12.

	Name	Count
0	TP53	109
1	BRCA2	5
2	EGFR	998
3	PTEN	80
4	MLH1	16
5	BRCA1	13
6	KRAS	142
7	ERBB2	8
8	ATM	17
9	CDKN2A	9

Fig. 12. Count of occurrences

The gene EGFR has occurred in 998 pubmed abstracts and the 90% genes has not even mentioned in the abstract downloaded. 1200 genes are referred atleast in one abstract out of 30000 genes. The word cloud of Gene card genes extracted from Pudmed abstract is given in Fig. 13

Fig. 13. Word cloud for Gene card Genes

E. Clustering Of Differentially Expressed Genes

Based on the T-test statistics 115 genes were found to be similar and the remaining genes had wide variation in their expression .the genes with wider variation's are clustered using k-means clustering algorithm. As the sizes of the gene samples are more Principal Component Analysis [PCA] is performed to reduce the dimensionality.

a) PCA

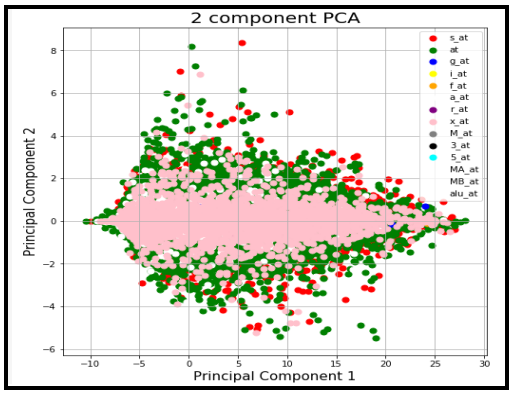

Fig. 14. PCA Results

The Fig.14. represents the principal components and subgroups of genes which are found to be overlapped based on their probe values. There are 14 different types of probe available for analyzing the gene expression. Among 14 types maximum number of genes are overlapped and can observe that 3% of genes that are not overlapped from the sub types of at, x_at, s_at sub types of genes.

b) Clustering: The genes are clustered [4] using the principal components. The differentially expressed genes are grouped in four clusters is shown in Fig. 15.

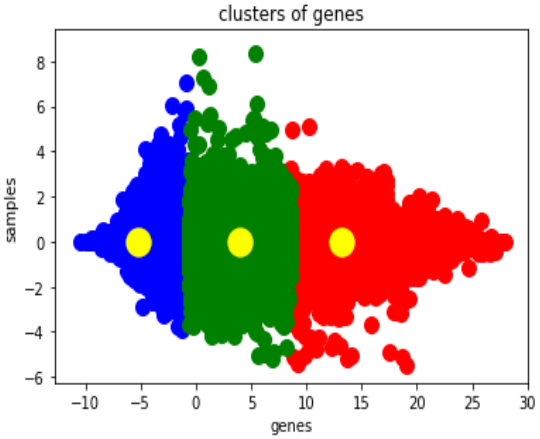

Fig. 15. Differentially Expressed Gene Clusters

- Cluster 1 represents the data 8827 genes are grouped in cluster 1.
- Cluster 2 represents the 32213 numbers of genes grouped.
- Cluster three represents 13063 numbers of human genes.

Out of three clusters the second cluster i.e green labeled cluster having the number of genes is very high compared two remaining two genes.

V. CONCLUSION

A methodology is proposed to extract abstracts from Pubmed databases using web crawler based on Keywords using regular expressions. The abstract are used to retrieve gene names and map with gene card to find the disease gene for lung cancer in Phase I. In second Phase a methodology is proposed to analyze Gene expression profiles with EDA and cluster differentially expressed genes after performing PCA. The Proposed methodology will help researchers to search literatures in an efficient way and Map gene to disease database with reduced time. Comparison of gene expression profiles are not done due to limitation of processing capability. In future the expression profile will be analyzed by applying MapReduce model using Machine Learning Algorithms.

***Abstract*— With exponential growth of IoT-based systems and the world being heavily dependent upon it, ensuring security in such systems becomes an issue of prime interest. With the advancement of technology, several security mechanism have been proposed, but securing the unknown threats is still not widely adopted. IoT visibility vulnerabilities propose a potential threat to the secured and highly sensitive data within the network. In this proposed work, deep neural networks have been trained to predict and secure some of the vulnerabilities which are still unknown to the authorized users. Our proposed ,mode achieves an accuracy of 95% over the predominant security measures with a precision of 87%.**

Keywords—IoT visibility, vulnerability, deep neural networks, security and privacy

I. INTRODUCTION

The last decade experienced a huge development in the automation and Smart architecture design. The quality of modernization received a boom with the advancement in the integration of the physical world with Wireless communication and sensor networks through applications (apps) and remote devices for quality infrastructure management design and environmental monitoring system. Smart Building Automation, Smart Housing, Smart City Management, Sustainable Energy management systems, etc are built on the top of IoT, hence it is one of the fastest emerging fields in the history of computing and is expected to grow to 10 billion by 2020 and 22 billion by 2025[52]. The data statistics of IoT devices is estimated up to 5 quintillion bytes of data per day[53]. The IoT technology is also being leveraged for highly secure applications like healthcare management, confidential information retrieval, etc. These high-end applications of IoT devices often experience malicious attacks, so these devices must be secured from all possible vulnerabilities.

IoT architectures are inherently complex and are designed with specific integrated features. Hence, the vulnerability may exist in a minimal-scale but a high consequential attack on the IoT system is still challenging. The potential solution is to identify the traits in the architecture and must contain specific considerations to meet the security demand. However, most of the vulnerabilities are not specifically visible and the malicious environment remains unattended. Hence, the adversary can exploit this environment to achieve physically access to sensitive data. The IoT network along with the private information in the communication channel remains exposed to the attacker. The IoT architecture cannot support complex security structures because of their limited computation power. Complex security structures of the IoT are due to not only limited computation, communication, and power resources but also trustworthy interaction with a physical domain, particularly the behavior of a physical environment in unanticipated and unpredictable modes, because the IoT system is also part of a cyber-physical system; autonomously, IoT systems must constantly adapt and survive in a precise and predictable manner with safety as a key priority, particularly in settings where threatening conditions, such as in health systems, might occur. Moreover, new attack surfaces are introduced by the IoT environment. Such attack surfaces are caused by the interdependent and interconnected environments of the IoT. Consequently, the security is at higher risk in IoT systems than in other computing systems, and the traditional solution may be ineffective for such systems.

II. Related works

Considerable amount of research has been done on (i) protocols and enabling technologies, (ii) application domains, (iii) context awareness, (iv) legal frameworks, (v) attacks against IoT, (vi) access models, (vii) security protocols, and (viii) intrusion detection techniques. Practical surveys on IoT security have not taken into account the ML/DL approaches for IoT security. Firstly, Surveys [1-7] demonstrated the challenges in network security, cryptographic encryption, authentication, access control and application security in IoT systems. Granjal, Monteiro and Silva [8] focussed on the IoT communication security. A survey was conducted on intrusion detection for IoT systems by Zarpelão et al. [9]. Weber [10] dealt with legal issues and regulatory approaches for determination of whether IoT frameworks satisfy the privacy and security requirements. Roman, Zhou and Lopez [11] analyzed security and privacy in the distributed IoT context. Survey [12] was particularly concerned of ransomware attacks. Xiao et al. [13] researched on various machine learning methods for protecting data privacy and security in the IoT context. Other survey papers [14, 15] shows how the uses of data mining and machine learning methods for cybersecurity can support intrusion detection. Surveys have also reviewed misuse and anomaly detections in cyberspace research [14, 15].

III. Introduction to IoT Security Architecture and Visibility Issues

Weber and Studer in [16] discussed available legal frameworks whereas, Zhang et al. [17] approached IoT security by analyzing results and reports in relation to IoT incidents. Data mining techniques were analyzed to design a capability which crawled Internet publications, including academic research, news, blogs, and cyber reports and through correlation of real IoT incidents with the available security solutions, the authors were able to unveil five seriously weak areas in the context of IoT security viz LAN and environmental mistrust, over-privileged applications, insufficient authentication and implementation flaws. With a plethora of research works discovery of botnet architectures and detection mechanisms in the context of traditional computing [18-21], Anagnostopoulos at al. [22] focussed on the mobile environment. Indeed, they also proposed two new commands and control (C&C) architectures which can be exploited by an attacker to test well-hidden botnet attacks with the minimal C&C cost. The IoT Visibility Vulnerability architecture is shown in Figure 1.

Burhan et al. [23] proposed a layered IoT architecture. These architectures typically have three-five layers and different functionality. Insecurities were identified and the authors went on to propose a six-layer architecture to patch these security challenges and took into context big data.

As an alternative work, Alaba et al. [24] analyzed IoT security by proposing various IoT deployment solutions, particularly distinguished between four classes, including, application, architecture, communication, and data. A major discussion came forward that heterogeneity of IoT devices along with resource limitations propose a serious issue, which prevents the development and scalability of standard security solutions. Gendreau and Moorman [25] reviewed intrusion detection techniques proposed for IoT and proposed that prevention of unauthorized access is a challenging goal due to the limited computation power of the IoT devices. Zarpelao et al. [9] also put in intrusion detection research efforts for IoT and differentiated them based on detection method, placement strategy, security threat, and validation strategy.

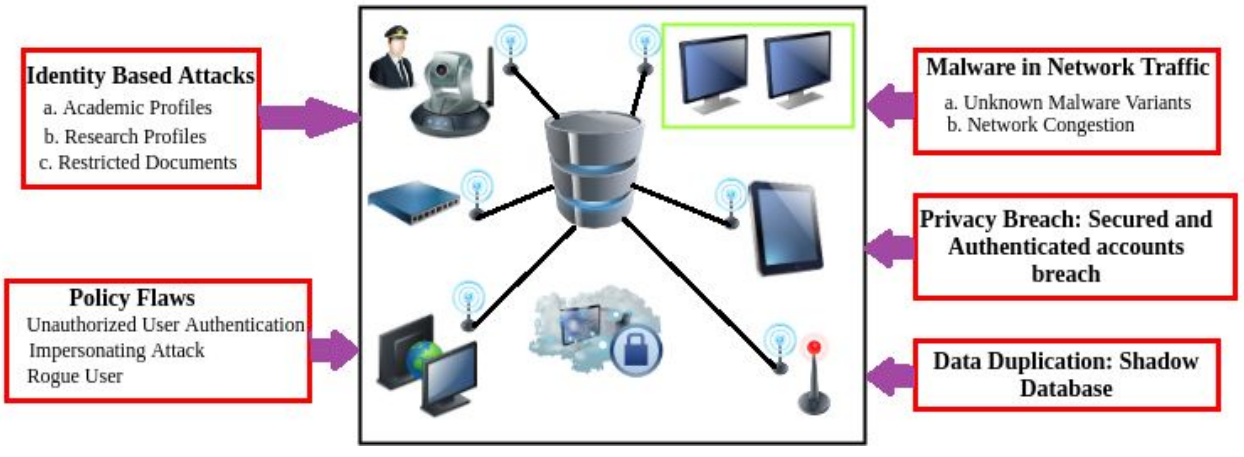

Figure 1: Architecture Diagram of IoT (Internet of Things) Visibility Vulnerabilities

IV. IoT Visibility Vulnerabilities

An exhaustive analysis of the research works related to the field of IoT security yielded nine classes of IoT vulnerabilities. It has been observed that the majority of IoT devices operate autonomously in unsolicited environments [26]. Often with an easy attempt, an adversary is able to obtain unauthorized physical access to these nodes and get control over them. Consequently, an attacker causes physical damage to the devices, unveiling deployed cryptographic schemes, duplicating their firmware using malicious node, or corrupting the control mechanism or the stored data. Representative research contributions in this context include [27-32]. An attacker might be able to drain the stored energy by creating a flood of legitimate or corrupted messages, rendering the devices unavailable for genuine processes or users. [33-36] have well covered this area of research. Alternatively, an attacker might exploit ineffective authentication approaches to add spoofed malicious nodes or violate the data integrity, thus intruding on IoT devices and network communications. Such cases can result in lost, destroyed, or corrupted public and private keys as shown in[37-42]. Data protection is of paramount importance in IoT realms, especially those operating in critical CPS (i.e., power utilities, manufacturing plants, building automation, etc). Although encryption gives considerable amount of confidence in securing, an attacker might be able to circumvent the deployed encryption techniques as shown in [43-48]. Open port vulnerabilities pose a plethora of vulnerabilities as shown in [49].

V. Analysis of Network Traffic Data

IoT Visibility specifies the knowledge of all of the activities being recorded on the network, all the modules running on the nodes, and data is being incrementally stored in the cloud databases. Naive methodologies of network visibility for example, tap or span port, might not be sufficiently useful for ensuring IoT security. To effectively manage the vulnerability present in the architecture, the proposed methodology implements knowledge-based identification of the visibility traits. Some of the vital points regarding this technique are elucidated below:

A. Public Policy Management

Policy Management is one of the background security measure of IoT systems. Data produced by IoT devices include sensitive and confidential data, such as medical, private and military data must be protected against unauthorised access [50] and must have stoing policy-based authorization. The solution to poor implementation of policy management involves finer-level access controls with layers of role-based authorization.

B. Intrusion Problem

In active threats, the attacker is not only skilful in eavesdropping on communication channels, but also in modifying IoT systems to change configurations, control communication, deny services and so on. Attacks may include a sequence of interventions, disruptions and modifications. For example, potential attacks on an IoT system may involve the following active attacks: impersonation[11], malicious inputs, data tampering and DoS.

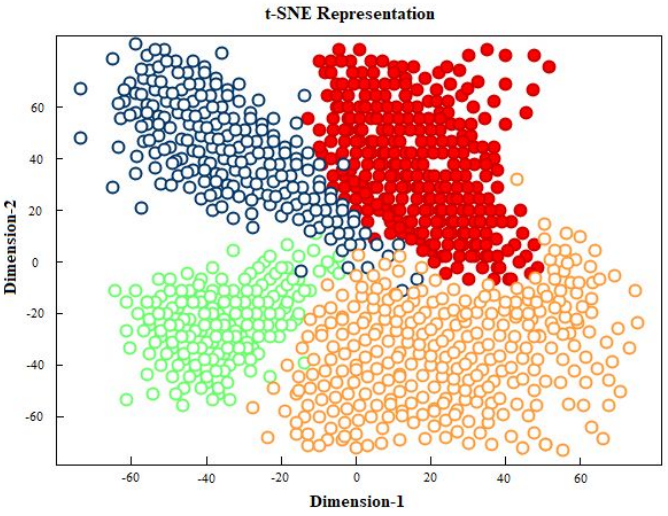

Figure 2: t-SNE Representation of the Malicious Attacks on the IoT systems

C. Security Awareness Issues

A potential passive threat is experienced due to lack of enough security over the communication channels of the network. Any attacker can get access to protected information from sensors, actuators, security and surveillance cameras. Health data, being private and sensitive is at central risk. Due to the lack of security awareness coupled with vulnerabilities present in the communication channels causes violation of privacy.

D. Vulnerability Assessment

An adversary can easily penetrate through networks layer as well as physical layer to discover finer vulnerabilities in the IoT system. This results in authentication breach of the centralized database and a shadow database is in performance which goes unnoticed.

E. Access and Authentication Issues

It is essential to identify the requirements of the authentication process as well as the security architecture of various IoT systems. The trade-off between security and safety in IoT medical devices is of utmost importance considering the privacy and sensitivity of information. Also, the trade-off can arise between an effective authentication system and battery-based devices or between security and privacy.

VI. IoT Visibility Testing using Deep Neural Networks (DNN)

In the present context, the applications of Deep Learning (DL) to IoT systems has been an impactful research domain [51]. The main advantage of DL over statistical Machine Learning algorithms, is its high performance while dealing with large

and non-parametric datasets. The proposed IoT system, as shown in Figure 3, produces a massive amount of both structured and unstructured data; thereby making DNNs most suitable for this system.

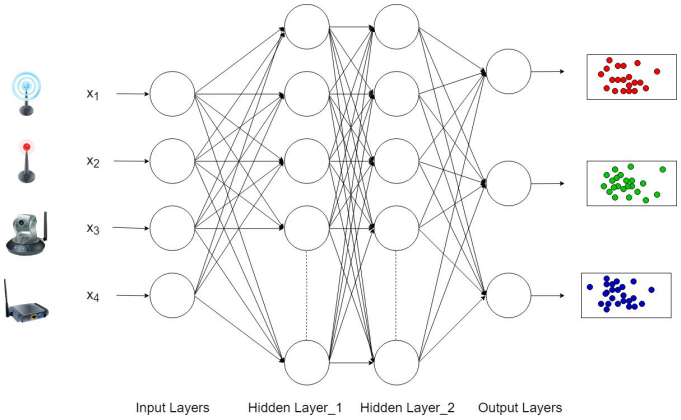

Figure 3: Deep Neural Network Architecture for visibility vulnerability prediction

VII. Experimental Analysis of IoT Visibility Vulnerabilities

This research experiment initially involved the study of various cases of breach of security in IoT devices, mostly in high performance systems, confidential organizations. We took into account various adversarial attacks, major as well as minor and came up with various techniques, both distributed as well as concentrated. We are able to demonstrate how deep neural networks have helped improve the accuracy upto 95% and 87% precision.

The Receiver Operating Characteristics curve (ROC curve) is plotted to visualize the ability of the proposed architecture and the simultaneous diagnostic analysis of the vulnerability prediction is made. Precision Recall curve is made to summarize the relationship between TPR (True Positive Rate) and the positive predictive value of the proposed model.

IoT visibility vulnerabilities	Prediction values		
	Existing	Accuracy	Usability
Identity-based attacks	30%	98%	Academic Accounts
Malwares	50%	95%	LAN
Privacy breach	20%	99%	Research accounts
Data Duplication	40%	96%	Public IoT data

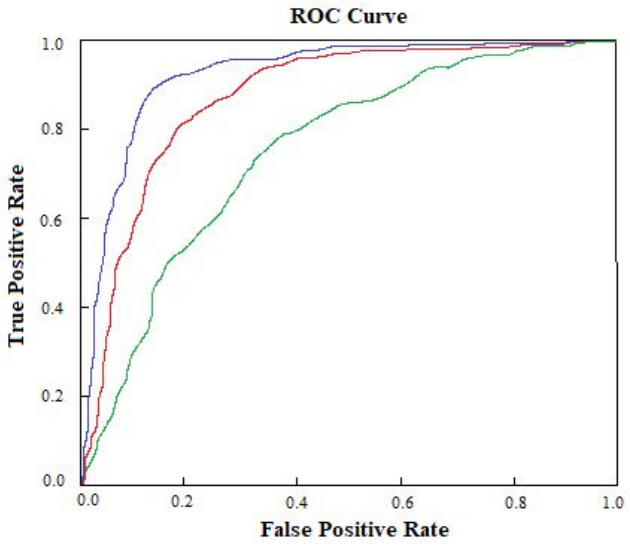

Figure 4: ROC Curve

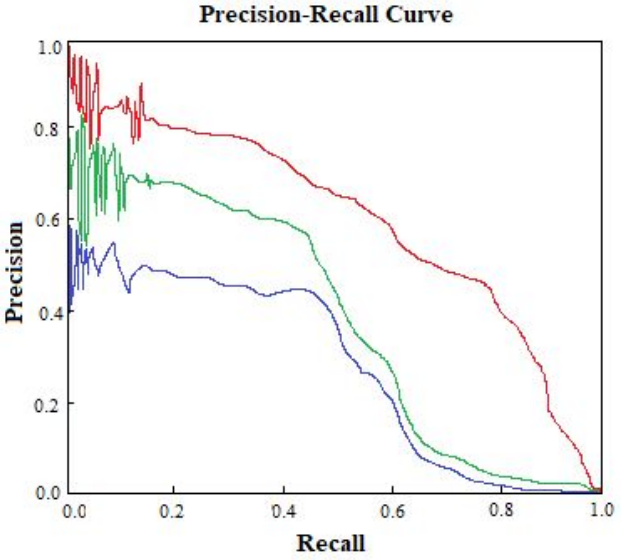

Figure 5: Precision-Recall Curve

VIII. Future Works

The future prospects of the research is to implement cognitive technologies for efficient understanding and to provide a potential solution eradicating the flaws in contextual deep learning methods. Further, quantum efficiency can also be studied to reach out the maximum level of proper identification of vulnerabilities.

Abstract—**This paper proposes an autocorrelation based chordiogram image descriptor (ACID) for image searching and retrieval. The standard 4D chordiogram image descriptor is a ordered collection of local edgel chordiogram (LEC) of all the patches of image and it encodes length of the line segment among the pair of edgels, orientation of each edgel and degree of angle among the line segment and horizontal plane for every pair of predominant edgels in a patch whereas proposed approach uses autocorrelation for computing the LEC and it exploits the spatial correlation and above mentioned features of standard LEC among the identical pair of edgels at distance d. The novelty of proposed CID is, it captures localized texture, spatial details besides to the geometric details offered by the standard CID except length of the line segment which is 1 in the proposed approach. The proposed ACID leads to better retrieval with resilient to illumination, scaling, translation, noise and small rotation. In our proposed approach, geometric details also more localized one. The experiments have been done for demonstrating the worth of proposed ACID on four different types datasets: (i). Gardens Point Walking, (ii) St. Lucia, (iii) UA Campus, (iv) Self photographed image. The results confirm the supremacy of proposed ACID approach by means of average retrieval precision and average retrieval rate over the state-of-the-art approaches**.

Keywords— Chordiogram image descriptor, Local edgel histogram,.Autocorrelation, Illumination, Orientation, Edgels.

I. INTRODUCTION

Shape information plays an imperative role in the computer vision and pattern recognition. Quality of image is stoutly coupled with the quality of shape. An outstanding shape descriptor must exhibit resilient to illumination, scaling, translation, rotation, appearance and noise [1]. Recently, various shape descriptors based on statistical, geometrical and topological approaches are reported. From the perspective of shape, there are 2 classes of shape descriptors: region and contour based approaches [2]. First one exploited the information of pixels within the shape. On the contrary, second one exploited the details from the edge pixels or contour. Since contour based approaches are very simple to process and can be viewed as long and regular structures instead of discontinuities [3] and is a significant component in object identification and image segmentation, lots of contour based approaches have been reported including distance among the random pair of pixels on contour [4], angle and length ratios among centroid and edge pixels [5]. The similarity among two shapes is computed using the shape context descriptor which is attached to each pixel and it exploits the histogram of residual pixels relative to it and results in global discriminative characterization then the similarity among two shapes is calculated using the differences in the sum of shape context among the corresponding pixels in two shapes [6].

The Border/interior pixel classification descriptor (BIC) considers both contour and region details and is reported by Stehling et al., [7]. In BIC, two different histograms are utilized for characterization and it counts the location and intensity of border/interior pixels. Color edge co-occurrence histogram is reported Jiebo et al., [8] and it computes distribution of separation between pairs of color edges. Histogram based on edge distribution at local level is suggested in [9] for retrieval using Sobel operator. But, due to its unsatisfactory retrieval results, [10] suggested an approach using the absolute location of edge and its global composition to improve the retrieval rate. Shim and Choi [11] proposed a method based on the color distribution of directional and non-directional edges and is combined with color histogram for image matching. A histogram of directions of keypoints is used in SIFT [12] and SURF [13], and are resilient to uniform scaling and illumination and partially resilient to affine distortion. Similar to SIFT, SURF and edge orientation histogram, the histograms (distribution) of directions (orientations) of gradients is reported in [14] and named as histogram of orientation gradients (HOG). Inspired by the discrimination power of HOG, HOG is represented in the form of pyramid in [15] for efficient computation and co-occurrence of HOG is presented in [16].

Based on the facts of series of edgels in the image and the dependencies among the edgels exhibit autocorrelation that characterizes texture in an image [17, 18], our contributions is autocorrelation based shape descriptor, is used for characterizing the repeating patterns in edgels over

consecutive non-overlapping regions of an image based on the correlation among identical edgels. In computer vision and pattern recognition, autocorrelation have been incorporated for more than a decade, but, only few works have been reported for contour based shape descriptors including edge orientation co-occurennce matrix [19] that exploits the spatial correlation for texture orientation which is extracted from the directional variation in the intensity; the correlation between neighboring edgels in accordance with the orientations is reported in [20] and coined a term Edge orientation autocorrelogram (EOAC) and it dig out rich shape, textures and spatial details in an image and the author proved that EOAC is appreciably better than edge histogram descriptor (EHD) [9, 21], and resilient to illumination, viewing position, translation and minute rotation. Along the way, Seetharaman and Sathiamoorthy advances EHD and EOAC [17, 18, 21] for both gray-scale and color images using Full Range Autoregressive (FRAR) model with Bayesian Approach which extracts incredibly minute and fine edgels and is confirmed that their edge based approaches significantly excellent than the conventional EHD [9] and EOAC [20] and the proposed approaches are also resilient to noise to some degree. In general, all edge detectors reported in the literature including Canny, Sobel, Roert, Laplacian and Prewitt are producing the output in gray-scale. Even for color images also, edge detectors change the image into gray-scale for identifying the edges [18, 21]. Thus, according to [17, 18, 21, 22], conventional edge detectors not succeed in identifying incredibly minute and fine edgels in color images owing to the variation in spectral and chromatic details. Moreover, [22] described that computing the edgels from H or S or V space alone also not succeed in computing incredibly minute and fine edgels owing to the variation in spectral and chromatic details and such a loss influences the accuracy of retrieval [22].

Though color edges are providing supplement details to content based image retrieval (CBIR), in this work, we are paying attention towards retrieval system for place recognition with illumination invariant based on edgels. In connection to this, several new approaches have been recommended in the past including chordiogram image descriptor (CID) based on the boundary pixels computed from the segmentation process [23], MROGH [24], LBP [25], BRIEF [26, 27] and CENTRIST [28], using deep descriptors in convolutional neural networks [29, 30]. Recently, CID [31] is presented by Wang et al., which is an accumulation of distribution of chord information of sub-images. That is the authors [31] divide the image into numbers of non-overlapping patches to decrease the influence of lightning. Since CID is robust to edge detector [31], the authors used one of the aforementioned edge detectors [31] to identify the edgels. Later on, for every pair of predominant edgels in each patch image, the distance among the edgels, orientations of each edgel and degree of angle between a line segment among pair edgels and horizontal axis is computed for every patch and the collection of aforesaid geometric details are called as local edgel chordiogram (LEC) [31]. The ordered collection of LECs of all patch images is called as CID. Though CID is well against illumination, translaton, in-plane rotation and scaling, it is significantly affected by the noise. Thus, the patches with noise are eliminated during the matching operation in [31] by avoiding the larger similarity results between the corresponding patches of query and target images.

The authors reported that the CID exploits the spatial structure from the image, independent of intensity and color details [32], well defined by local geometric elements, and thus it is an apt approach for place recognition with resilient to illumination. Accordingly, we are paying attention only in increasing the efficiency of shape descriptor called chordiogram image descriptor (CID) which is reported for appearance-based place recognition robust to illumination variant [31]. Since the autocorrelation assess the texture present in an image [17, 18] as aforementioned, the proposed chordiogram image descriptor is computed using autocorrelation function and it exploits the following

1. Spaial correlation among the edgels and find out the change of its correlation with distance d.
2. Orientation of edgels
3. Degree among line segment between a pair of edgels and horizontal axis

The experiments on standard dataset using the proposed four dimensional CID has better discrimination power then the state-of-art schemes based on edges.

The organization of paper is as follows. Section 2 discuss about chordiogram image descriptor. Sections 3 describe the CID based on autocorrelation function. Section 4 and Section 5 deal with experimental results and conclusion respectively.

II. CHORDIOGRAM IMAGE DESCRIPTOR

Given image is divided into number of non-overlapping rectangular patches, numbered from 1, 2, 3, . . . , N. Each patch is characterized using LEC. To compute LEC, salient edgels are identified for each patch then local geometric features are computed from the salient edgels. Later, the LECs of all patches are collected in an order to construct a CID. The chord details of an image patch are computed from each pair of salient edgels coordinated at p and q and is described as in [31] as follows

$$C_{i_{pq}} = (\ell_{pq}, \phi_{pq}, \theta_p, \theta_q) \quad (1)$$

Where $\ell_{pq}, \phi_{pq}, \theta_p$ and θ_q designates the distance among edgels p and q, angle between line and horizontal plane, degree of orientations of edgels p and q about normal directions respectively, and the values of ℓ_{pq} ranges from 0 to diameter of an image patch and ϕ_{pq}, θ_p and θ_q falls in range 0 and 2Π. The values of ℓ_{pq} is discretized in logarithmic space and are divided into η_d bins where d is the distance and is fix to 4 [31]. ϕ_{pq}, θ_p and θ_q are quantized into 8 bins of 50 degrees each [31]. Thus, CID is a 4D histogram and is normalized as in [31], and it encompasses chord details for every pair of salient edges in an image patch.

Since CID is not sensitive to edge detector, in the experiment, Sobel operator is incorporated to calculate the edges in each patch. After computing the edgels, response of each edgels are computed and are sorted. Then, proportion p of edgels having higher responses are chosen as in [31] to compute the LEC i.e. the salient edgels are chosen from the image patch with the intention of reducing the computation cost by means of considering the less numbers of salient edgels and the selected salient edgels must exploits the shape details of patch and it must provide robustness against illumination and small rotation. Thus, the set of chosen salient edgels has two information: one is response of edgels and another is proportion p which decide the dimension of set of salient edgels and is decided experimentally as in [31] using n=pm where m and n denotes number of edgels and chosen salient edgels respectively in image patch and p is constant for all patches. Finally, the computed LECs of all patches are collected in an order to form CID and is described as [31]

$$F = (C_1, C_2, ..., C_N) \tag{2}$$

Where $C_1, C_2, ..., C_N$ are the LEC of patches 1, 2, ..., N respectively.

III. AUTOCORRELATION BASED CID

This paper presented a novel characterization approach for an image using autocorrelation based CID, is just a step forward approach of [31]. The main objective is computing spatial correlation among the identified identical edgels and exploring the variation of its correlation with distance d then for each pair of the edgels at the centre of the sub-image and its identical edgels at distance d, we also compute the orientation of each edgel and degree of angle among line segment and horizontal plane for every pair of edgels in a sub-image of size 3x3 in a patch. The proposed approach recommends that the ACID has convinced discrimination power.

The identified edgels are depicted in a table and is indexed by value of *edgel* and distance. The entry in a table designate the probabilities of finding an edgel with value i at a correlation distance *d* from an edgel with value i. That is the proposed ACID considers spatial correlation among the identical edgels only and it fixes the correlation distance to 1 owing to least correlation distance offers the in depth local properties of an image. Table 1 depicts the proposed spatial correlation among identical edgels at distance 1 where the first and second columns depicts the edgel with value i and probability of finding an edgel with value i at correlation distance 1 from an edgel with value i. The autocorrelation among identical edgels are described as in [33] for as follows

Let *I* be an n x n image, an edgels in *I* are $e_1, e_2, ..., e_m$. For an edgel $E = (x, y) \in I$, let $I(E)$ represent its edge value. Let $I_e \overset{\Delta}{=} \{E | I(E) = e\}$. Hence, the notation $E \in I_e$ is synonymous with $E \in I, I(E) = e$. For convenience, [33] use the L_∞ norm to assess the distance among edgels that is for edgels $E_1 = (x_1, y_1), E_2 = (x_2, y_2)$, [33] define $|E_1 - E_2| \overset{\Delta}{=} \max\{|x_1 - x_2|, |y_1 - y_2|\}$. [33] denote the set $\{1,2,..., n\}$ by $|n|$.

Definitions. The histogram *h* of *I* is expressed for $i \in |m|$ by

$$h_{e_i}(I) \overset{\Delta}{=} n^2 \Pr_{E \in I} \left| E \in I_{e_i} \right| \tag{3}$$

For any edgel in the image, $h_{e_i}(I) \big/ n^2$ gives the probability that value of edgel is e_i.

Let a distance $d \in |n|$ be fixed a priori. Then, correlation of *I* is expressed for $i, j \in |m|, k \in |d|$ as

$$\gamma_{e_i, e_j}^{(k)} \overset{\Delta}{=} \Pr_{E_1 \in I_{e_i}, E_2 \in I} [E_2 \in I_{e_j} \ \| E_1 - E_2 | = k] \tag{4}$$

Given any edgel of value e_i in the image, $\gamma_{e_i, e_j}^{(k)}(I)$ gives the probability that an edgel at distance *k* away from the given edgel is of value e_j. The autocorrelation of *I* exploits spatial correlation among identical edgels only, and defined as in [33] by

$$\alpha_c^{(k)} \overset{\Delta}{=} \gamma_{e,e}^{(k)}(I) \tag{5}$$

In our work, the image is divided into numbers of patches and in each patch, to estimate the proposed ACID, we moved the 3x3 non-overlapping mask over an image from left to right afterwards from the topmost left corner of image for each identified edgel values. For instance, in Fig.1, when we move the 3x3 mask over an image for computing the autocorreltion value of an edgel with value 255, we found an identical edgel at the center of the first 3x3 sub-image and it has two identical edgels at distance 1. Thus, we estimate the probability as mentioned above in eq.(5) and we estimate the orientation of each edgel [17] in each pair of edgels and say θ_1 and θ_2 and the degree of angle of line segment between the each pair of edgel and horizontal axis is computed and say ϕ and is depicted in Fig.1(b). Now the 3x3 mask is moved in left direction and there is no edgel with the value 255 at the centre of the mask. Thus, the mask is moved further, in the 3rd 3x3 sub-image also there is no centre edgel with the value 255 but in the 4th one there is an edgel in the centre of sub-image with the value 255 and it has one identical edgel at distance 1. Therefore, for the 4th sub image we estimate the autocorrelation among the identical edgels as mentioned above in eq.(5) and the θ_1, θ_2 and ϕ are computed. This process continues for each identified edgel values in the patch. Finally, we obtained an autocorrelation of edgels as mentioned in Table. 1. and a set of θ_1, θ_2 and ϕ values and these values are represented using separate histograms and called as LEC. Similarly, the LEC for all the patches in an image is computed and the LEC of all the patches are collected in an order to

form a ACID. Thus, the proposed ACID approach is a 4D histogram.

Fig.1(a) Sample image of size 6 x 6

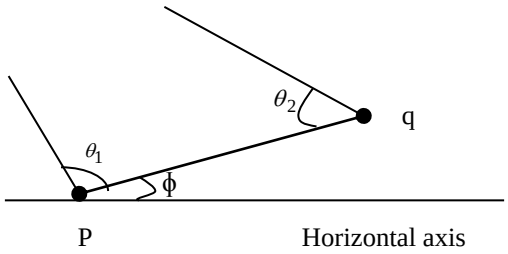

Fig.1(b). Computation of orientation of edgels p, q and angle between the horizontal axis and line segment of edgels p and q

As a result, we trust that proposed ACID is significantly superior in retrieval rate and considerably equivalent in computational cost to the CID approach [31] owing to the texture and spatial details exploited by autocorrelation function in addition to more localized geometric features among identical edgels. In the ACID approach, the 4D histogram is normalized to attain lighting variations to some more extent [31].

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Datasets

In the experimental study, Gardens Point Walking [34], UA Campus [31], St. Lucia [31] databases and some self photographed images are incorporated. Few example images from the benchmark databases is shown in Fig.3. The Gardens Point Walking database contains of 3 classes of images namely day-left, day_right and night_right and each class consists of 200 images and are captured twice in day i.e., in a day and night and the dimension of the images are roughly 960 X 540. St. Lucia database contains images captured at five different times among early morning and late afternoon of a day and a day after two weeks and totally it has ten classes. We also utilized some self photographed images shooted at different time of a day in the experiments and it has 1140 images totally and size of images are roughly 1280 x 720 and 1040 x780. All the databases contains images captured at various times with sever and mild illumination changes.

B. Similarity Measuremnt

The dissimilarity among query and target image descriptors are evaluated by the dissimilarity measure derived from Pearson's correlation coefficient and is illustrated in [35] as

$$D(I,O) = 1 - |P| \tag{6}$$

where

$$|P| = \frac{n\sum_{i=1}^{n} I_i O_i - \left(\sum_{i=1}^{n} I_i\right)\left(\sum_{i=1}^{n} O_i\right)}{\sqrt{\left[n\sum_{i=1}^{n} I_i^2 - \left(\sum_{i=1}^{n} I_i\right)^2\right]\left[n\sum_{i=1}^{n} O_i^2 - \left(\sum_{i=1}^{n} O_i\right)^2\right]}} \tag{7}$$

where I_i designates query image descriptor vector, O_i is a target image descriptor vector and n designates the dimension of the descriptor vector. Higher |P| value represent query and target images are highly correlated.

In the proposed methodology, according to [31], dissimilarity measure between all corresponding patches in an image are computed and are ordered in descending manner and from the ordered distance values, higher distance values are removed with the assumption that either of those patches or both are affected by noise and it provides false matching [31]. Therefore, the sums of n least similarities are summed finally to find the best matching among query and target images.

C. Evaluation measures

The evaluation of proposed ACID is calculated in terms of precision, average retrieval precision (ARP), recall and average retrieval rate (ARR) [36]. For query image I_q, the precision ($P(I_q)$) and recall ($R(I_q)$) are described as follows:

$$Precision: P(I_q) = \frac{\text{Number of relevant images retrieved}}{\text{Total number of images retrieved}} \quad (8)$$

$$Recall: R(I_q) = \frac{\text{Number of relevant images retrieved}}{\text{Total number of relevant images in the database}} \quad (9)$$

$$ARP = \frac{1}{|DB|} \sum_{i=1}^{|DB|} P(I_i) \;\; |n \le 10 \quad (10)$$

$$ARR = \frac{1}{|DB|} \sum_{i=1}^{|DB|} R(I_i) \;\; |n \ge 10 \quad (11)$$

Where DB denotes total number of images in each class.

D. Results and Discussion

The efficiency of suggested ACID is analyzed for image retrieval that robust to place recognition and illumination invariant by carrying out experiments on four databases. The results attained by the proposed ACID are examined as follows.

Each image in the benchmark database is selected as query image in all experiments. The proposed approach collects n target images $T=(T_1,T_2,...,T_n)$ from the database for each query utilizing the fusion of ACID and Pearson's correlation coefficient measure.

Table. 2 summarizes the time cost of ACID and CID approaches. Experiments are done on the images collected from the Gardens Point Walking database. The efficiency of the suggested ACID approach is estimated in terms of ARP and ARR is depicted in Fig.3 and Table 3. Fig.3 depicts the retrieval performance for top 100 matches of proposed ACID and CID by passing different query images from the Gardens Point Walking database. Table 3 summarize the performance proposed ACID in terms ARR. From Table 3 it is observed that ACID attains better performance over the CID approach.

Fig.3b and Table.3 illustrates the efficiency of suggested ACID approach and CID in terms of ARP and ARR on UA campus database. From Table.3 and Fig.3b, it is observed that proposed ACID showing better performance than the CID on UA campus database. Fig.3c shows the graphs depicting the efficiency of suggested ACID and CID in terms of ARP and APR on St.Lucia database. From Table.3 and Fig.3c, it is evident that proposed ACID outperforms the CID on St.Lucia database for image retrieval.

Finally, self photographed images are taken for evaluation of performance. The results of proposed ACID and CID in terms of ARP and ARR are depicted in Fig.3d and Table 3. Although the time cost of proposed ACID is slightly higher than CID owing to the computation of autocorrelation, it attains better retrieval performance due to the inclusion of textural and spatial details along with the geometric details and also more robust to place recognition, illumination, scaling, translation and small rotation.

The visual results of ACID descriptor for query image with top 5 matches in ascending order of distance among query and target images is illustrated in Fig 4 and Fig.5. From Fig.4 and Fig.5, it is visibly obvious that proposed ACID is illumination to invariant and for query image of day right class, the proposed ACID also retrieve images from the day left and night right. The experiments are done on core2 Quad computer with 2.66 GHz, 4GB of memory.

V. CONCLUSION

In this paper, a new descriptor named autocorrelation based chordiogram descriptor (ACID) is suggested for place recognition and illumination invariant images. The ACID calculates the spatial and textural details along with geometric details based on the autocorrelation function. The effectiveness and robustness of proposed ACID is tested by considering the results on 4 benchmark databases. The detailed examination of the results demonstrated a significant increase of proposed ACID in terms of ARP and ARR as compared to CID. In future experiments, the proposed ACID can be improved in terms of time cost.

***Abstract*— Information or data is a very crucial resource. Hence securing the information becomes a critical task. Transfer and Communication mediums via which we send this information do not provide data security natively. Therefore, methods for data security have to be devised to protect the information from third party and unauthorized users. Information hiding strategies like steganography provide techniques for data encryption so that the unauthorized users cannot read it. This work is aimed at creating a novel method of Augmented Reality Steganography (ARSteg). ARSteg uses cloud for image and key storage that does not alter any attributes of an image such as size and colour scheme. Unlike, traditional algorithms such as Least Significant Bit (LSB) which changes the attributes of images, our approach uses well established encryption algorithm such as Advanced Encryption Standard (AES) for encryption and decryption. This system is further secured by many alternative means such as honey potting, tracking and heuristic intrusion detection that ensure that the transmitted messages are completely secure and no intrusions are allowed. The intrusions are prevented by detecting them immediately and neutralizing them.**

Keywords*— *Security; Multimodal; Framework; Steganography

I. INTRODUCTION

Steganography represents the mechanism of concealing secret and confidential data inside an image and the user can only decrypt it using a special password or application. Fig. 1 depicts the classical steganography model.

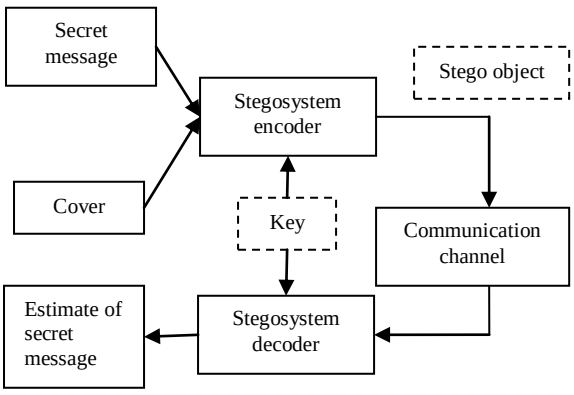

Fig.1. Classical Steganography Model

The problem statement calls for the creation of a steganography model where there is no modification of the target image and an additional authentication layer that is necessary before the secret message is retrieved. Additionally, it must be possible for any sort of data of any arbitrary size to be sent over the channel, including executable, documents and media like images and videos. The data must be actively protected end to end even when it is being transferred over the cloud. We are primarily driven by the lack of solutions to send steganography data attached to some object/image that would require the receiver to have both an image or physical copy of the steganographed image as well as a second point of authentication (the ARSteg app) which would let the user unmask image or document information hidden within the target image. Current solutions to this involve using algorithms like LSB alteration that requires modification of the source image and brings into the picture very miniscule file size limits and issues like loss of data and noise due to in-transit compression of the sent target image. We intend to solve the above issues using Augmented Reality Steganography, which would discard limitations such as file size limit and significantly improve the security implementation. A cloud security module ensures sandboxing of any received executable data, preventing it from causing any harm to the end user device.

The objectives of this works are as follows:

- To transfer encrypted data (text, images, videos, audios,3D Model) mapped to an image marker
- Implementing security mechanism such as pseudo authentication and fingerprint to secure the application from intruders and a backdoor system to self-destruct when app integrity is compromised
- To analyze the received message in a cloud sandbox environment and quarantine the malicious message
- Create a service based on cloud for Vulnerability Assessment and Penetration Testing using active Machine Learning

The devised framework considers a novel idea of steganography, using augmented reality. Unlike classical algorithms of steganography like LSB, ARsteg does not

modify the image size or colour which makes it difficult for the intruder to differentiate it from a normal image.

II. Related Work

This section describes the related works done regarding detectability of steganography methods and augmented reality. We've done a survey on the most popular steganography methods including LSB and found that there was significant literature that exposed its weaknesses, published in several reputed scientific journals.

In [1], the authors have developed a steganalytic method which is based on how pixel differences are distributed statistically. The technique detects the existence of steganography based on LSB matching embedded in natural images of high resolution. Chandramouli et al. [2] have performed detectability of steganography methods applied to text, images, audio/video information in a cover file.

We have also gone over improvements of existing methods by various techniques such as randomization and probability embedding. Karim et al. [3] have devised an innovative method for image steganography centred on LSB. The location of the hidden information is randomized to create the secret key.

Hence, the hidden information can be extracted by possessing knowledge about the retrieval methods. To overcome this challenge, our work stores the hidden information in diverse positions of the image LSB depending on the secret key. Therefore, the extraction of hidden information through the knowledge about the retrieval methods becomes difficult.

The probability of pixel change was reduced to one-third when one-third LSB embedding was performed by [4] without foregoing the embedded capacity, when compared to earlier methods of steganography based on LSB. This embedding resulted in a robust technique when compared with well-known LSB detectors.

III. Design of the Multimodal System

This section discusses the design of the multimodal system for transmission of the encrypted data. Fig.2 shows the transmission of the encrypted data.

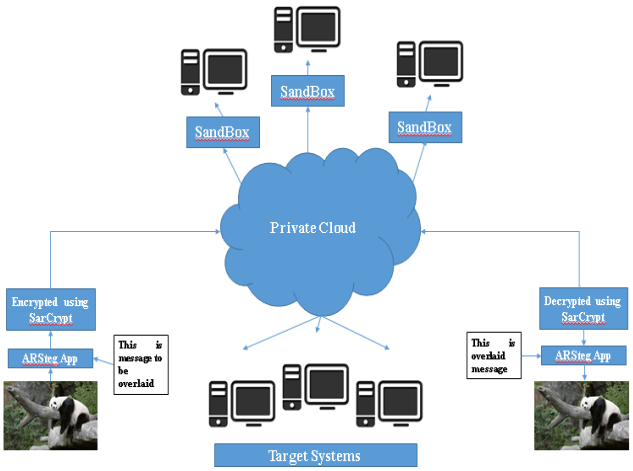

Fig.2. Transmission of encrypted data

The transmission of the Encrypted Data happens over a secure HTTPS channel to the server where the authenticity of the Message is checked using the Secure Hashing Algorithm (SHA256) to check if it valid or not.

Secure transmissions prevent the attacks such as loss of data and ARP spoofing. The information leak detection and prevention (ILP), Information Leak Prevention (ILP), Content Monitoring and Filtering (CMF) or Extrusion Prevention systems represents the hardware and software implementations that identifies and stops the unauthorized data transfer from an organizations computer to outside. These implementations ensure the secure data transmission.

Secure communications for internet related tasks like internet faxing, web browsing, instant messaging, e-mail, and additional data transfers are provided by the Transport Layer Security (TLS) and Secure Sockets Layer (SSL).

Fig.3 depicts the data transmission between sender and receiver.

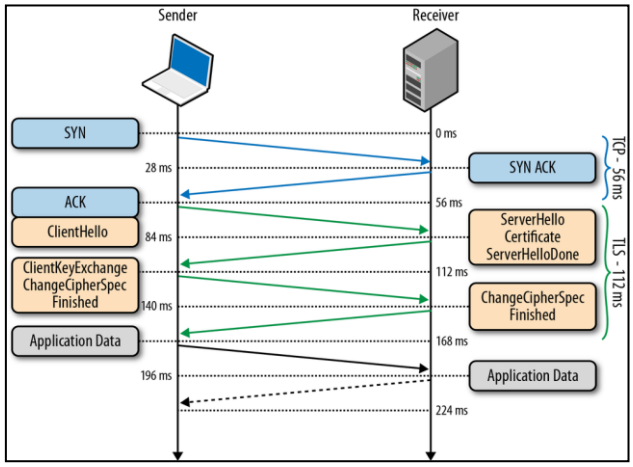

Fig.3. Data transmission between sender and receiver

In Fig.3, initially, the client transmits a Client Hello message to the server. The Client Hello includes the following information.

- **Client version:** The client transmits the different protocol versions of TLS/SSL where the preferred version which is usually the latest version is placed 1st on the list. For instance, TLS 1.2 possesses the client version 3.3 since TLS 1.0 is considered as a miner revision of SSL. Hence TLS 1.0 is 3.1; TLS 1.1 is 3.2 and so on.
- **Client Random:** It represents a random number of size 32 bytes. The key generation for the purpose of encryption is done by the client random and the server random.
- **Session ID:** It denotes the session id that will be utilized for the connection. If session_id is not empty, the server searches for earlier sessions that was cached and continues until that session match is found.
- **Compression methods:** These are utilized to compress the SSL packets. By utilizing compression

techniques we can attain lower bandwidth usage and hence achieve faster transfer speeds.

- **Cipher Suites:** These denote combinations of algorithms related to cryptography. Characteristically, the cipher suite is composed of one cryptographic algorithm related to each of the tasks like key exchange, encryption of bulk data, and authentication of messages. The cipher suites list is transmitted by the client in the order of preference. The connection is established by the client utilizing the first cipher suite sent.
    - Cipher suites are identified by strings. A sample cipher suite string is: TLS_ECDHE_ECDSA_WITH_AES_128_ GCM_SHA256. This string contains the following information:
    - TLS is the protocol being used
    - ECDHE is the key exchange algorithm (Elliptic curve Diffie–Hellman)
    - ECDSA is the authentication algorithm (Elliptic Curve Digital Signature Algorithm)
    - AES_128_GCM is the data encryption algorithm (Advanced Encryption Standard 128 bit Galois/Counter Mode)
    - SHA256 is the Message Authentication Code (MAC) algorithm (Secure Hash Algorithm 256 bit)

Fig.4 illustrates the mechanism of data transfer between the TLS client and the TLS server.

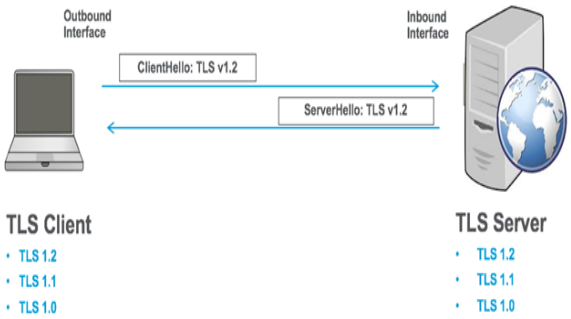

Fig.4. Data transmission between TLS Client and TLS Server

A secure SSL/TLS connection is established through various steps. The grouping of asymmetric and symmetric encryption is utilized by the SSL/TLS security protocols. The server and client negotiate the used algorithms and exchange the information related to key.

The TLS 1.2 connection is utilized with the objective of explaining this complex process. Handshake forms the most significant task of establishing a secure connection. Significant information is exchanged by the server and client during the TLS handshake.

A. Security Framework

With respect to computer security, the term “sandbox” represents a security mechanism for dividing programs which are running to reduce the spread of system failures or vulnerabilities in software. The sandbox is frequently utilized to implement programs which are not tested or trusted. These programs may come from third parties / suppliers / websites / users who are not verified and trusted. This mechanism ensures that the host machine or the operating system is not harmed. The utilities like scratch space on memory and disk is provided by the sandbox in order to ensure that the resources are tightly controlled. The sandbox restricts the network access which allows the inspection of host system or reading from the input devices.

The sandboxes can be perceived as a particular example of virtualization in which it provides an environment which is highly controlled. The sandboxes avoid the harm to host devices by testing unverified programs on virtual environments. Fig.5 depicts the app scenario with and without sandboxing technique.

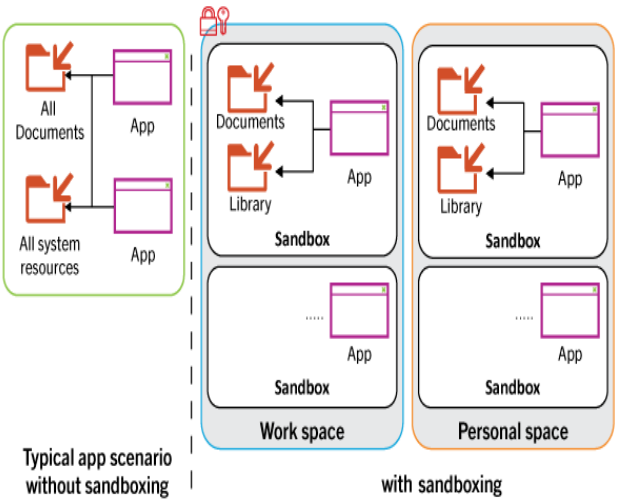

Fig.5. App scenario without sandboxing

The application would function normally without Sandboxing and the message received will be directly sent to Scanning and Identification. This would lead to a major Vulnerability in our system as the message received can be potentially dangerous and can harm the system.

IV. Results

The ARSteg framework consists of two components, the user app and the UMS Dashboard. The User App is our novel implementation of steganography using Augmented Reality scanning. The encryption used is Public-Private Key encryption. The application operates in following modes:

1) Add AR-User first enters the type of data (text, image, video, audio and 3D model) that needs to be sent, following which, user can choose a particular image from gallery or capture it with camera. On click of encrypt button, the image and the

corresponding overlaid information is uploaded on Cloud. The data is stored on the cloud with the sender's information and encrypted with our own algorithm.

2) Scan AR - On the other side, any other authorized user can scan the image using our application and view the hidden message overlaid on it.
3) It has various levels of authentication including generic username and password, finger print, face recognition, and OTP making it difficult to hack into data.
4) It has also a Honey Pot feature known as "Pseudo Authentication". Our database has some common username and password stored that hackers generally test on the login portal. Whenever a hacker uses them he gets into a pseudo application with wrong information. The hacker is fooled into thinking that he is using genuine information and does not think of other ways to hack into the application. Hence, our application becomes more secure.
5) We also have a User Management System that keeps track of the application activity on all the devices which works as an intrusion detection system. If the application gets installed to some unauthorized location (determination using fcm token), it will notify the UMS Admin and he can take control of the device. UMS admin can perform camera capture, location access and storage access, uninstall the application from the particular device and use self-app destruct option.
6) To safeguard the applications from hackers and de-compilation process we use Pseudo Authentication.
    a. Commonly used usernames and passwords will be added in the database and as soon as they match with the user input, the user will be redirected to a fake page with fake details.
    b. This is to engage the hacker from trying out other ways and making him believe he is having the correct data.
    c. Addition Security
    d. We would also have biometric authentication system such as Fingerprint, Face Recognition etc.
    e. Decompilation tested against apktool.

Fig.6 shows the User Login interface where the person who wants to log in can enter his User ID and Password.

Fig.6. Login screen

On entering an incorrect password, a flag is raised on the backend and the malicious actor is unaware that he is now pseudo-authenticated, making sure that brute force attacks are ineffective. Password attempts are limited by a time out. Our database has some common username and password stored that hackers generally test on the login portal.

Fig.7 illustrates the demo mode select screen where the user can either choose to create a new ARSteg message or scan for steganographed images using his phone camera.

Fig.7. AR interaction screen

Here, the user has the option to add a new AR image or scan an existing AR image. In ADD AR option, the user first enters the type of data (text, image, video, audio and 3D model) that needs to be sent, following which, user can choose a particular image from gallery or capture it with camera. On click of encrypt button, the image and the corresponding overlaid information is uploaded on Cloud. The data is stored on the cloud with the sender's information and encrypted with our own algorithm. On the other side, in the scan AR option any other authorized user can scan the image using our application and view the hidden message overlaid on it.

Fig.8 illustrates the process of sending a message.

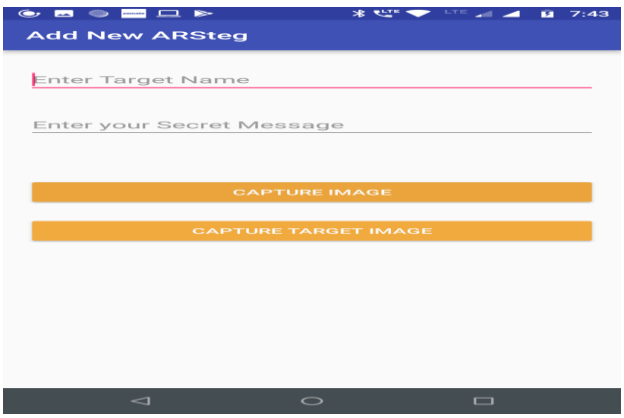

Fig.8. Sending a message

Fig.8 demonstrates the workflow for creating an ARSteg message, by selecting the name of the target, a secret message (metadata), the image/media that has to be embedded into the

steganographed image and finally the actual object/image that the steganography is to be performed on. The secure transmissions are done to stop attacks such as ARP spoofing and general data loss. The TLS and SSL cryptographic protocols are utilized to deliver secure communication over the internet.

Fig.9 shows the steganographed image viewfinder.

Fig.9. Steganographed Image Viewfinder

Fig.9 illustrates the screen used to capture the image/object that the steganography will be performed on. This is a viewfinder for the user's device camera.

Fig.10 demonstrates the metadata view for non-image data.

Fig.10 Metadata view for non-image data

Fig.10 illustrates a steganographed image / object being decoded and the metadata in addition to the associated encoded media being demonstrated on the user's viewfinder. Here, we send a JSON Object which has the following structure:

- "content-type": *"Image"/"text"/" video"/"3d"/" executable",*
- "data": "*Encrypted Data*",
- "signature": "*Signed Data Signature*"
- "hash": "*Hash of the data*"
- "sender": "*Public Key of the sender*"

The outcomes of the work are summarized below:

- We have managed to create a full stack solution backed by Vuforia [5] and Unity [7] to perform AR-Steganography
- App was bundled with remote self-destruct and tracking functionality.
- ML powered heuristics detection was used to find malicious activity and flag it.
- Pseudo Authentication used to deter potential malicious actors by honeypotting them into a false user account
- Backend with UMS (User Management System) allowing us to monitor and trigger events on the user apps as mentioned above
- Inbox functionality for temporarily storing received steganographed images
- Data received analyzed in a sandbox environment and checked for malicious intent
- All the network systems will be scanned for vulnerabilities based upon Open Ports, OS Information, Update patches etc.
- The entire service will be running on a Cloud Architecture [8].
- The network data can also be sent to the cloud server for detection for anomaly in the real time.
- This would highly reduce the false positive occurred during the scan.

We have contrasted and compared existing Augmented Reality platforms to determine a suitable framework for building our application. Our work was compared with the existing works by Santos et al. [5] and Zhang et al. [6]. These works have modified the source image and are constrained by file size limits. In our work, these drawbacks were successfully overcome by using the Augmented Reality Steganography. Furthermore, the harm to the end user device is avoided in our work by the usage of cloud security module with sandboxing technique.

V. Conclusion And Future Work

In this work, we have created a full stack solution backed by Vuforia and Unity to perform AR-Steganography. The App was bundled with remote self-destruct and tracking functionality. The ML powered heuristics detection was used to find malicious activity and flag it. Pseudo Authentication was used to deter potential malicious actors by honey-potting them into a false user account. The Backend with UMS (User Management System) allowed us to monitor and trigger events on the user apps as mentioned above. Inbox functionality for temporarily storing received steganographed images. The received data was analyzed in a sandbox environment and checked for malicious intent. All the network systems were scanned for vulnerabilities based upon Open Ports, OS Information, Update patches etc. The entire service was run on a Cloud Architecture. The network data can also be sent to the cloud server for detection for anomaly in the real time. This would highly reduce the false positive occurred during the scan.

We have hence created a robust system for securely transferring text, images, audio/video, executable data over a steganography image with support for a layer of authentication. A robust cloud sandbox and heuristic detection mechanism coupled with a UMS was developed to counter any intrusions into the system.

Future Prospects include the development of an active machine learning algorithm to detect and deal with threats posed by executable files sent over this system & Self-training of this model by automatically executing threat vectors on this system.

ACKNOWLEDGMENT

We are thankful to the Ministry of Human Resource Development (MHRD) for organising Smart India Hackathon 2018, which allowed us to showcase the potential of this product and to the Indian Space Research Organisation (ISRO) for sponsoring the work, taking this idea forward, guiding us throughout our work, and helping us to constantly improve our product.

We further thank the All India Council for Technical Education (AICTE) for enabling this sort of interaction between the institution and government organisations in order to create innovative products.

We are thankful to C Chandrasekhar Reddy for helping us and guiding us throughout the Project Timeline.

***Abstract*— Industry uses different types of materials as microstrip substrates. This paper introduces steel, and thus explores its scope as a microstrip substrate. Its metallic nature creates a barrier, from using it as substrate. A low cost rectangular microstrip patch antenna using a multilayer substrate is proposed here. Martensitic steel of grade 440C and thermocol forms a layered substrate. The magnetic properties of steel and dielectric properties of thermocol helps for achieving good antenna parameters. Designed patch antenna has noticeable return loss of -24dB in 400MHz. Also directional radiation pattern with gain of 0.3dB has been obtained. It shows a narrow bandwidth of 3MHz which is due to the conductivity of steel. VSWR obtained is 1.13 which shows a tremendous matching with transmission line connected to it. The results shows that, newly introduced multilayer material can be used as microstrip substrate for low frequency structures. It can produce almost the same results, which a local substrate can. It can be used for wireless charging using low frequency and thus an application of RF energy harvesting.**

***Keywords*—Microstrip substrates, Martensitic steel, Thermocol, Patch antenna, wireless charging, RF energy harvesting**

I. INTRODUCTION

Rate of use of electronic devices like mobile phones, Wi-Fi modems, laptops etc are increasing year by year. By that, chances of harvesting radio frequency energies are becoming dominant. The harvested energy can be best used for wireless charging, and it provides a new dimension to mobile device manufacturing. Wireless charging method can be helpful in different situations. An electromagnetic harvester is implemented in South Korea, which can be used as a power requirement for ice removing device. These type of devices are used to remove ice and snow from power transmission lines[1]. Antennas are the main part of any Radio Frequency(RF) harvesting systems. The proper designing of antennas helps to build an efficient harvesting systems. Microstrip antennas are most common in RF circuits industry because of its countless advantages including low-profile, low-weight, and conformablity[2]. Microstrip antennas having a good bandwidth, better matching, and minimum reflection loss, acceptable radiation intensity, along with compact size can serve a good role in communication systems.

Materials used as substrates are predominantly dielectrics. Substrate properties heavily influence antenna parameters. Research on developing novel materials for substrates are going on. The applications is inherent to development of low profile communication systems for next generation technologies. Metamaterials are certain type, in which both ϵ_r and μ_r values are negative. They are used to build antenna arrays that helps for hyperthermia treatments[3]. Patch antennas with substrate as paper, coir, rubber are the outcomes of such experiments. These environmental friendly antennas can produce better results compared to GaAs antennas. This is one of the material which is available locally, and studies shows that it creates some environmental issues. Low cost patch antenna using cement as substrate can be used for indoor applications including WLAN, wireless sensors for IoT applications[4]. The introduction of non conducting magnetic substrates into the field adds the miniaturization capability to the existing structures[5]. They have ϵ_r, relative permeability $\mu_r$value, in between 10-15 range. Nickel-ferrites are such materials, which has both dielectric and magnetic properties. The mechanical, dielectric and magnetic properties for Nickel-ferrite composite materials are analyzed in[6]. Another flexible magnetic composite material having Z phase Co hexaferrite particles is used as substrate for making a quarter wavelength antenna in [7], the miniaturization capability was 2.4x with increased performance.

The existing wireless charging systems uses high frequency. 2.45GHz is the most, commonly available frequency used for any RF circuits or wireless charging circuits. It has some difficulties including heating effect, high voltage etc. Introduction of low frequency wireless charging can overcome these disadvantages. Conformable antennas at lower frequency helps to implement low cost wireless charging systems. Like other conventional substrate, here explores the possibility of development of antennas on a conducting material. A rectangular patch antenna at 400MHz is investigated employing steel as substrate. The return loss degradation due to steel conductivity is compensated by employing a multilayer substrate including commonly available thermocol. The radiation pattern for multilayer structure is analyzed.

Section II describes the properties of steel. Methodology and HFSS(High Frequency Structure Simulator) simulation results are included in section III and Section IV respectively. Section V gives the conclusion.

II. MATERIAL PROPERTIES

A. Steel

Iron and carbon are the main components of steel. Elements such as Nickel, Manganese, Phosphorous, Sulphur etc were introduced in it to form different grades having different properties. Carbon steel, Alloy steel, Stainless steel and Tool steel are the major types of steel. Stainless steels are commonly available in market. It has 10-20% chromium content, highly corrosion resistant. Austenitic steel, Martensitic steel, Ferritic steels are three types of stainless steel. In this, austenitic steels are nonmagnetic. Ferritic and martensitic steels are magnetic in nature. The model implemented here needs a magnetic steel. The available steel in market with comparatively low cost, and having appropriate properties is 440C grade steel. It is used for making knives, cutting tools, dental and surgical equipment. A study presents comparison of ten types of magnetic steels in terms of their magnetic properties[8]. The properties listed in Table I is taken from the same. Since steel can be considered as a metal the relative permittivity is taken as 1. The below mentioned values are used for steel in material development section of HFSS.

Parameters	Values
Relative permittivity	1
Relative permeability	160
Electric conductivity	$1.6X10^{6}$
Density	$7611Kg/m^{3}$
Dielectric loss tangent	$6.366X10^{-3}$
Magnetic loss tangent	$3.978X10^{-5}$

TABLE I
ELECTRICAL AND MAGNETIC PROPERTIES OF GRADE 440C STEEL

III. METHODOLOGY

As a first step, a rectangular patch antenna has been designed in HFSS, over the steel substrate. Since it is a magnetic material the length of patch has been computed by using[9][10]. The obtained value was too large. As a result, the length of patch has reduced by(1/128) times. Width of patch is calculated using equation (1)[11].

$$W = \frac{c}{2f_r}\left(\sqrt{\frac{2}{\mu_r + 1}}\right) \quad (1)$$

Where W is width of patch, c is velocity of light in vacuum $3*10^{8}$m/s, f_r is resonant frequency which is 400MHz, μ_r is relative permeability of steel which is 160. Obtained value was 4cm, that has increased by 3 times, for getting the required resonating frequency for a good return loss. Finally steel material having dimension 25cm x 25cm x 1.6cm has been fixed. Antenna has been designed at 400MHz frequency. Transmission line feed is opted in the design.

A. Feed Line Design

Fig. 1 shows the plot between width to height ratio vs characteristic impedance of transmission line for 1.6cm steel thickness. w is the width of transmission line and it is taken as 5mm from graph which corresponds to 38Ω.

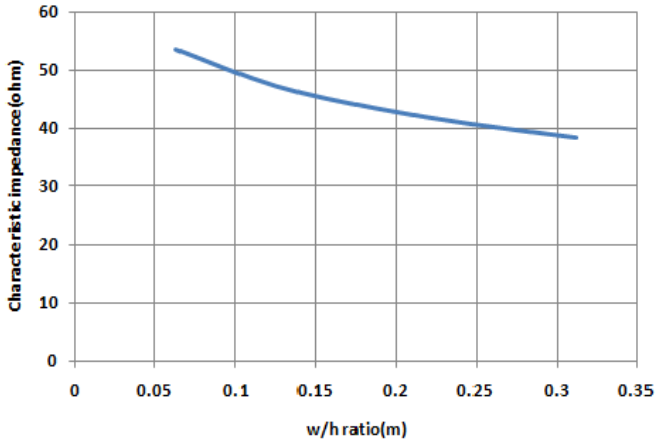

Fig. 1. (w/h) ratio Vs characteristic impedance of feed line

B. Patch Antenna Design on Steel Substrate

The mostly preferred is rectangular shape, because of its simpleness. The final dimension of antenna is listed in Table III. It is having rectangular shape with length of patch greater than width of patch. Fig. 2 shows the s11 Vs frequency plot of antenna. The s11 value is -0.27dB for 500-600MHz frequencies. It indicates a very high return loss.

Parameters	Values(in cm)
Length	21.3
Width	13
Feed line length	3
Feed line width	0.5

TABLE II
DIMENSIONS OF PATCH

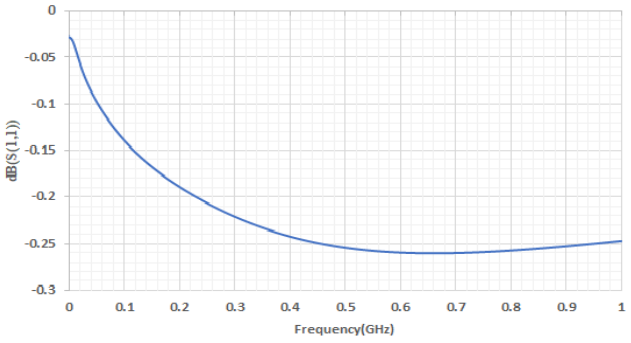

Fig. 2. Return loss of patch antenna on steel substrate

C. Antenna Design on Layered Substrate

Antennas having multilayer substrate posses advantages including antenna miniaturization. Periodically arranged magneto-dielectrics substartes are analysed for design of electromagnetic structures in VHF-UHF bands in[12]. A perfect dielectric on top of steel can compensate the conductivity of the same. A locally available material thermcol has been chosen for that. Thermocol is also called polystyrene, its a

hydrocarbon, derived from monomer styrene. Its ϵ_r is taken as 2.5. A thin layer having 4 mm thickness is used here. Fig. 3 shows the return loss Vs frequency graph of multilayer substrate antenna.

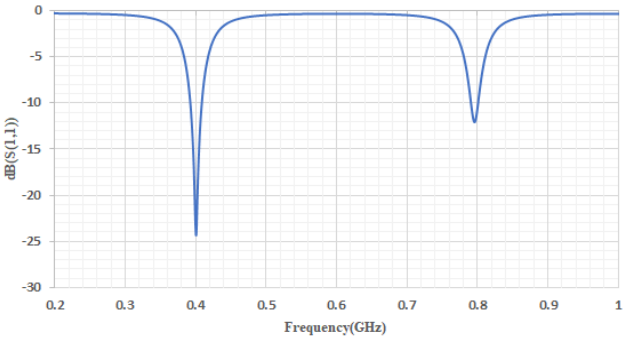

Fig. 3. Return loss of patch antenna

It shows that dielectric properties of thermocol layer helped to improve the return loss. Fig. 4 and Fig. 5 shows the E-plane and H-plane radiation pattern obtained after simulation. Fig. 6 shows Voltage Standing Wave Ratio(VSWR) Vs frequency plot. Antenna has a markable VSWR value 1.13.

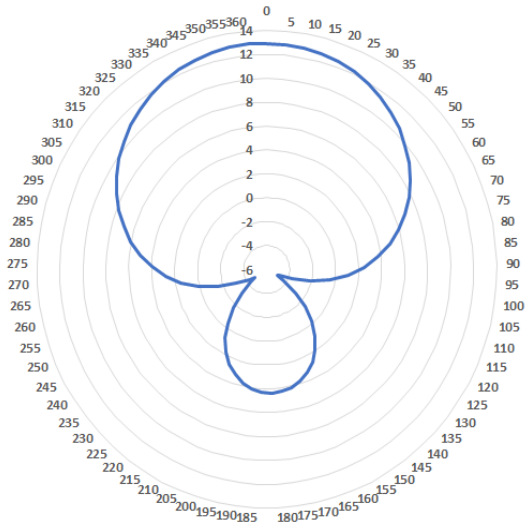

Fig. 4. E-plane radiation pattern

IV. RESULTS

Patch antenna on steel substrate is analysed first. Fig. 2 shows s11 Vs frequency plot for the same. The exponentially decaying graph shows that, antenna on steel substrate is less efficient to transmit or radiate electromagnetic waves. The reflection coefficient obtained is -0.27dB, which is very high, indicating that most of the power is reflecting back to feeding port. Then considering combined effect of magnetic and dielectric materials, commonly available thermocol layer is added to the design. Resulting return loss plot is shown in Fig. 3. Antenna achieves a noticeable return loss of -24dB

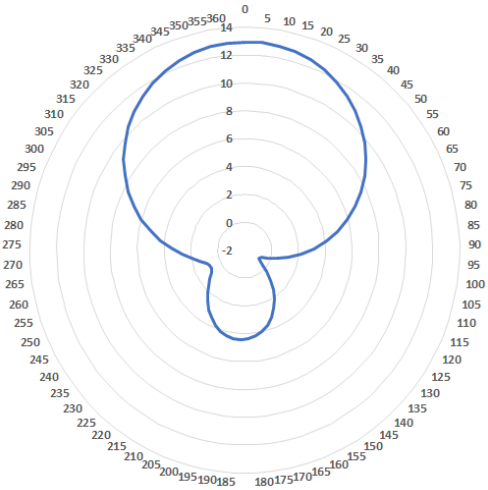

Fig. 5. H-plane radiation pattern

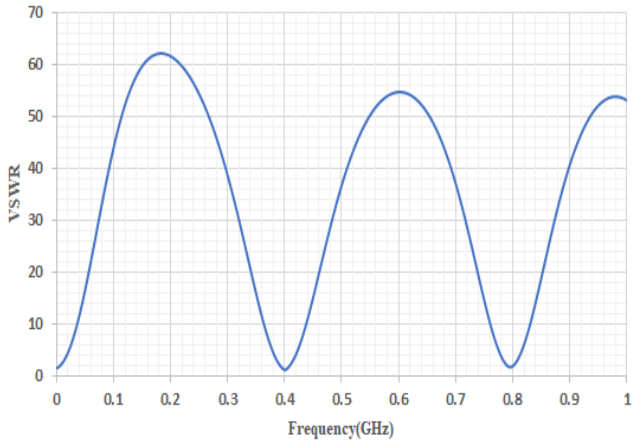

Fig. 6. VSWR Vs frequency plot

for 400MHz. -3dB bandwidth can be calculated from Fig. 3, and it is 3MHz. E-plane and H-plane radiation patterns in Fig. 4 and 5 shows that it can attain a directional pattern. The less gain of 0.3dB is attributed to conductivity of steel. VSWR is an important antenna parameter. It is a measure that numerically describes how well the antenna is impedance matched to the transmission line it is connected to. The value of VSWR obtained is 1.13, which indicates a good match.

As an analysis, microstrip antennas on other frequencies can be designed using the same substrate combination. For that design purpose, the following points can be best used. The increase in steel thickness further by 1mm, results a decrease in resonating frequency by 1MHz. When thermocol thickness is reduced by 1mm, frequency of operation reduces by 14MHz. When there is a slight air gap is introduced, return loss can be improved. It is found that increase in patch width by 10mm, improves the return loss by -5dB. 10mm increase in length of patch reduces resonating frequency by 35MHz. So keeping these points patch antenna on multilayer substrate can be designed for any frequency, respective to the applications. Also, further increase in relative permeability

can brought back many features including miniaturization.

V. CONCLUSIONS

A low cost microstrip patch antenna on multilayer substrate, formed by steel and thermocol has been designed in HFSS. The antenna is designed for low frequency 400MHz, which is in UHF spectrum. The antenna has a directional radiation pattern with 0.3dB gain. It can be used for charging applications in low frequency, and thus for RF energy harvesting systems. The simulated results shows that the combination of a conducting magnetic material and perfect dielectric can produce good results, which a microstrip antenna on a locally available substrate can.

***Abstract*— Cyclic Redundancy Check (CRC) is one of the most important method to detect the errors occurred during the transmission of any data. Errors are detected in communication due to internal and external factors. This paper presents an implementation and analysis of encoder and checker of CRC8 which takes 16-bits of input data to create 24-bits code-word and can detect errors up to 8-bits. The proposed design is functionally synthesized with VHDL and verified using Xilinx ISE 14.7 Software. The hardware implementation of this design is done on Xilinx Artix-7 FPGA board. Simulation based results are reported in this paper.**

***Keywords*— CRC, Error detection, Communication, code-word, Encoder.**

I. INTRODUCTION

In a digital transmission system, error occurs when bits are changed in between the transmission and reception of data in a channel. Error takes place when binary 1 is transferred and binary 0 is there at the receiver or when binary 0 is transferred and binary 1 is there at the receiver. There are two types of errors: one is single bit error and the other one is burst error [1]. A single bit error is a sequenced error that modifies single bit and does not changes other bits. A burst error is an error in continuous sequence of bits which may have error in any number of bits [2]. A single-bit error occurs when white noise is present, because of slight arbitrary worsening of the signal-to-noise ratio, which is adequate to complicate the receiver's conclusion on a single bit. Burst error may occur due to impulse noise or waning in a mobile wireless environment. It occurs more as compared to single-bit error [3].

In optical links, the error is due to the presence of physical components like optical driver, connectors, optical fiber and optical receivers, etc. Errors may also occur because of optical dispersion and optical attenuation [4]. There are three types of Error detection techniques. First is Single parity check, second is Cyclic Redundancy Check, and the third one is Checksum technique. Cyclic Redundancy Code (CRC) is basically an error detecting code that is used to detect error in digital transmission system and storage devices [5]. The redundant word used in CRC is because it expands the input message without adding useful information to it. The detected error then can be corrected by using error correction codes which can identify and remove the errors present in transmission network [6]. CRC operates using binary 0 and 1. It's operation is based on modulo-2 addition (logical XOR) and multiplication (logical AND). Systematic codes is used for coding the scheme [7]. Let m(x) be polynomial of input message, g(x) be the generator polynomial and c(x) be the polynomial of code-word. We have c(x) = m(x)g(x) which can be represented as systematic form as $c(x)= m(x)x_{n-k} + r(x)$, where r(x) is the remainder occurring when $m(x)x_{n-k}$ is divided by g(x). The transmitted message c(x) contains k-information bits followed by 'n-k' CRC bits [8].

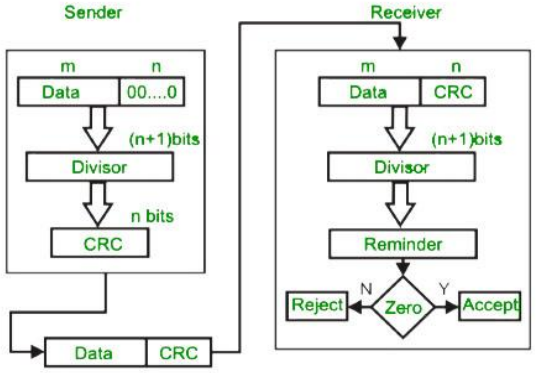

Figure 1: Basic structure of CRC

In figure 1, a simple structure of CRC is shown. It consist of two modules. One is Sender in which input message is given and another is Receiver in which the coded message is received. CRC is a process of encoding a data at sender and decoding it at receiver [9].

II. PRINCIPLE OF CRC

Cyclic Redundancy Check (CRC) is an error detecting method in which a transferred message is appended with a few redundant bits from the sender and then the code-word is plaid at the receiver using modulo-2 arithmetic for checking errors. The message is then communicated from the encoder and is received at the receiver where a CRC check is conceded out. This procedure supports to regulate any error in communication system over the channel. The total number of errors which a CRC may detect, depends on the generator polynomial. The degree of generator polynomial will decide the number of detected error. For example, CRC8 can detect errors up to 8-bit [10].

The most important step in the implementation of CRC algorithm is selecting a generator polynomial. The polynomial should be selected such that it maximizes the error-detecting capabilities and minimizes overall collision probabilities [11]. CRC can be divided into following types:

Table 1: Standard CRC and their polynomials

S. No.	CRC	Polynomial	Application
1.	CRC4	$x^4 + x^3 + 1$	Telephone
2.	CRC8 CCITT	$x^8 + x^7 + x^2 + x + 1$	1 wire bus
3.	CRC10	$x^{10} + x^9 + x^5 + x^4 + x + 1$	ATM AAL
4.	CRC16	$x^{16} + x^{15} + x^2 + 1$	HDLC/USB
5.	CRC16 CCITT	$x^{16} + x^{15} + x^5 + 1$	X.25/Modem
6.	CRC32	$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + 1$	Ethernet

Table 1 shows different types of CRC based on generator polynomial and their application in communication system. The selection of generator polynomial should be done before the user computes the redundancy check of a communicated message. The generator polynomial must have a non-zero coefficient in the LSB and MSB positions and its degree should be greater than zero [12].

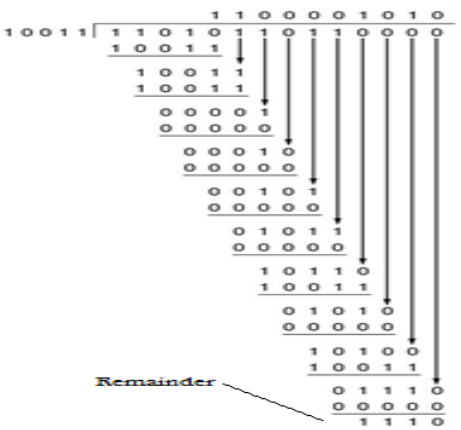

Figure 2: Division in CRC

Figure 2 shows the binary division in CRC. This is the basic operation in the implementation of CRC. In this, a 10-bit input is divided with 5-bit generator bits. As a result, CRC remainder is obtained [13].

III. PROPOSED DESIGN & SOLUTION

In this paper, Encoder and Checker are designed for CRC8 which uses $x^8 + x^7 + x^6 + x^4 + x^2 + 1$ as generator polynomial that is used in DVS-S2 (Digital Video Broadcasting – Satellite Second Generation). The input message given to Encoder is of 16-bits. This 16-bit message is binary divided with the given generator polynomial by which 8-bit CRC remainder is obtained. This remainder is then appended with the original input message which becomes the 24-bit input data for the checker. At checker, this 24-bit input data is again binary divided with the generator polynomial. The result of CRC Checker will show that how many bits are corrupted. The proposed design is synthesized using VHDL (VHSIC HDL) i.e. Very High Speed Integrated Circuit Hardware Description Language which describes the method for modelling and designing of Digital Circuits and Digital logic systems. It is verified using Xilinx ISE 14.7 software and for hardware implementation, Xilinx Artix-7 FPGA (Field Programmable Gate Array) board is used.

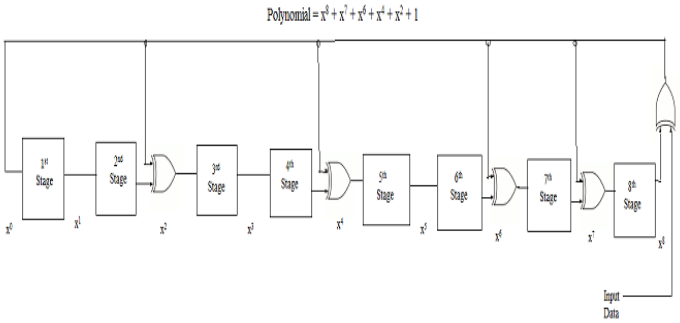

Figure 3: Designing of proposed CRC8

Division operation of CRC is based on modulo-2 operation. The divider circuit of CRC consist of shift registers and mod-2 adders. Figure 3 shows the hardware implementation of CRC8 by using $x^8 + x^7 + x^6 + x^4 + x^2 + 1$ as generator polynomial which consist of eight stages of shift registers and five EX-OR gates. Using this polynomial, we can detect error up to 8-bits.

Implementation of Encoder Algorithm

a. Read the message vector.
b. Take the generator polynomial order 'k'.
c. Shift the message vector 'k' times and store it order as 'n'. Compute (n-k).
d. Shift generator polynomial (n-k) times and store the result 'h'.
e. XOR the generator polynomial and message vector and store the result in 'x'.
f. Determine the highest polynomial index position of 'x' where 1 is occurred and take it as 'n'.
g. If n >=k go to step 4.
h. Concatenate the check bits with the message bits.

Implementation of Checker Algorithm

a. Read the received data and take its order as 'n' and store it in 'h'.
b. Take the order of generator polynomial as 'k'. Compute (n-k).
c. Shift the generator polynomial left (n-k) times and store the result in 'e'.
d. XOR the generator polynomial and received vector and store the results in 'x'.
e. Determine the highest index of 'x' where 1 is occurred and take it as a 'n'.
f. If n >= k go to step 3.
g. Store 'x' in rem.
h. If rem =0 then the received data is error free else data contains error.

IV. SIMULATION RESULTS & DISCUSSION

Authors have implemented the coding of proposed design and simulated using Xilinx ISE 14.7. Simulation based results are reported in this paper as shown in the figure 4 to figure 13.

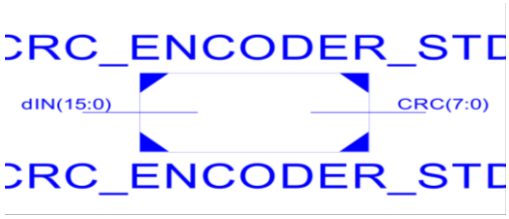

Figure 4: 1st level RTL of CRC Encoder

Figure 4 shows the symbol of CRC Encoder. This is the first level RTL of Encoder. It shows 16-bit input d_{IN} and 8-bit output CRC.

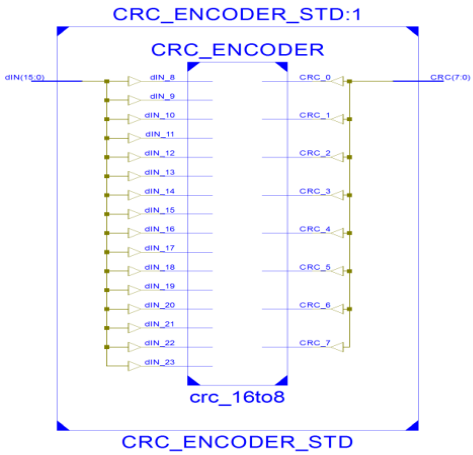

Figure 5: 2nd level RTL of CRC Encoder

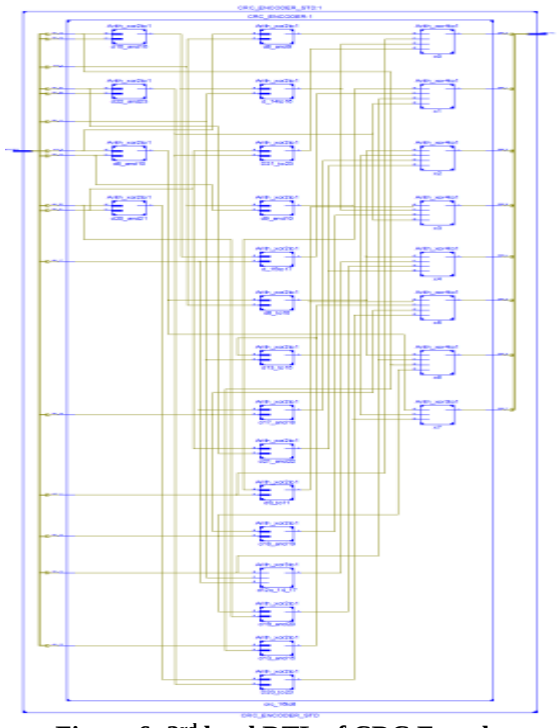

Figure 6: 3rd level RTL of CRC Encoder

Figure 5 and 6 shows the 2nd and 3rd level RTL Design of proposed CRC Encoder. In this, d_{IN} is the 16- bit input dataword and CRC is the 8-bit encoder output. This encoded output is appended with the input dataword which is being transmitted to the receiver.

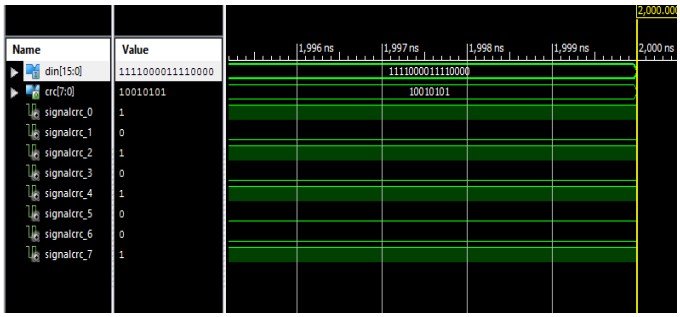

Figure 7: Output Waveform of CRC Encoder

Figure 7 shows the output waveform of CRC Encoder. In this, the given input is d_{IN} = 1111000011110000 for which the output obtained is CRC = 10010101. Now this value of CRC will be appended with the input data d_{IN} which will be the input of the CRC checker. Therefore, the input of CRC checker will be 24 bit code-word which is 111100001111000010010101.

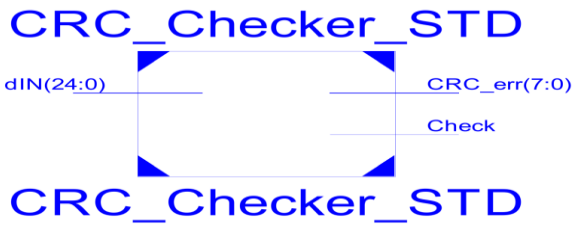

Figure 8: 1st level RTL of CRC Checker

Figure 8 shows the symbol of CRC Checker. This is the first level RTL design of Checker. It shows 24-bit input d_{IN} and two outputs. One is 8-bit CRC_err and other is check.

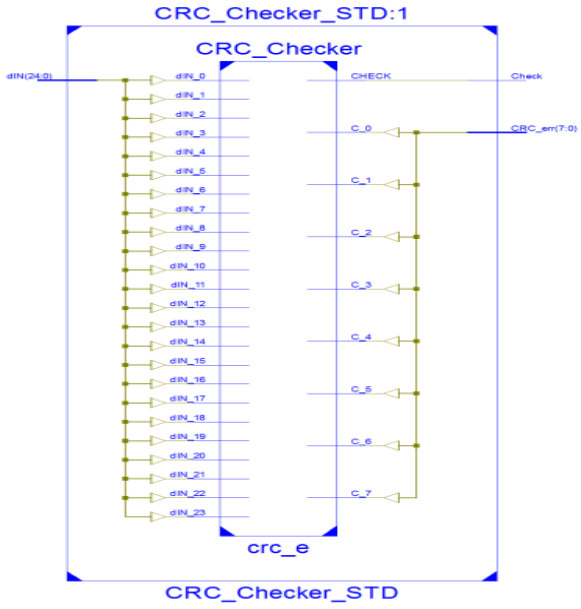

Figure 9: 2nd level RTL of CRC Checker

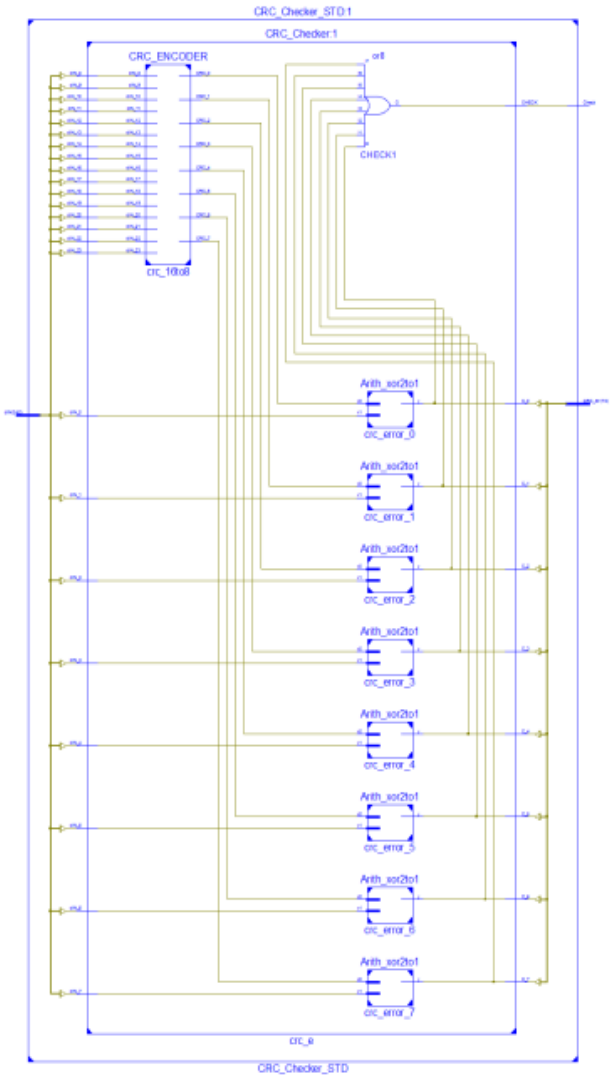

Figure 10: 3rd level RTL of CRC Checker

Figure 9 and 10 shows the 2nd and 3rd level RTL design of proposed CRC Checker. The input of CRC Checker is a 24-bit input d_{IN} [0, 24] and the output is 8-bit CRC_err and Check. The check=1 when the input is corrupted in between the encoder and checker i.e., when the input given to checker is other than the correct input.

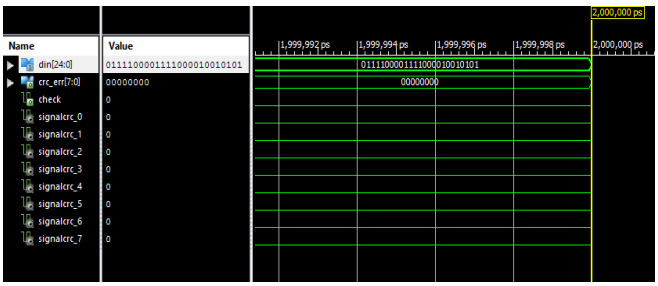

Figure 11: 1st Output waveform of CRC Checker

Figure 11 shows the output waveform of CRC Checker for input d_{IN} = 111100001111000010010101. For this input, output CRC_err = 00000000 that means no error since the input is same as the coded input i.e., 24 bit code-word. Here Check = 0 because no error is detected.

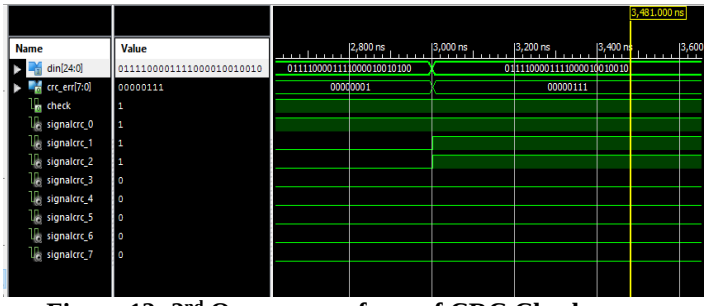

Figure 12: 2nd Output waveform of CRC Checker

Figure 12 shows the output waveform of CRC Checker for input d_{IN} = 111100001111000010010100 and d_{IN} = 111100001111000010010010. For the first input, output CRC_err = 00000001 that means 1-bit error is detected since the input differs from actual code-word by 1-bit. For the second input, output CRC_err = 00000111 i.e., 3-bit error is detected because this input varies from code-word upto 3-bits. Check=1 in both the cases since error is detected in each case.

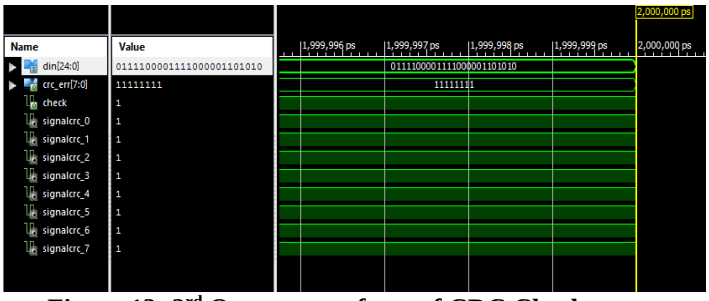

Figure 13: 3rd Output waveform of CRC Checker

Figure 13 shows the output waveform of CRC Checker for input d_{IN} = 111100001111000001101010. For this input, output CRC_err = 11111111 means all bits are corrupted. It represents 8-bit CRC error with check = 1. In this, the redundant bits which were appended with the input are all inverted with respect to the actual redundant bits.

These were the output waveforms of proposed CRC Checker/Decoder with different inputs and different CRC errors.

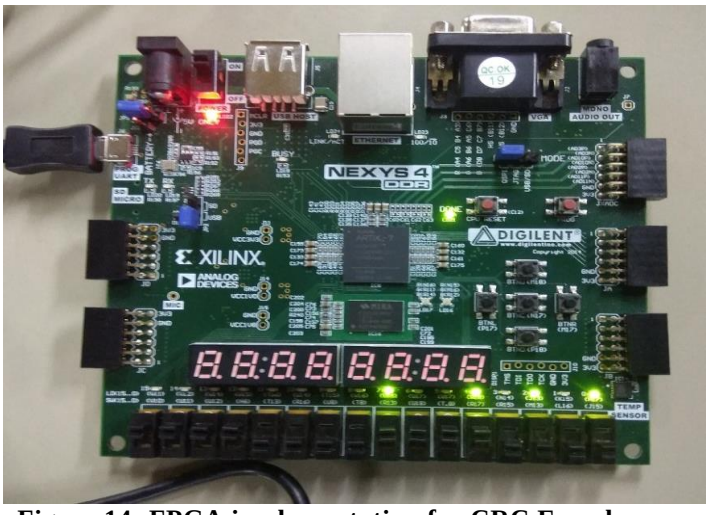

Figure 14: FPGA implementation for CRC Encoder

Figure 14 shows the FPGA implementation of CRC Encoder. The FPGA board used is Artix-7 with package CSG324. The input given to this encoder is d_{IN} = 1111000011110000 and the output obtained is CRC= 10010101. The input d_{IN} is given to the board through the switches shown in figure and the output CRC_err is shown from LED. For the LED blow, 1 is considered and 0 otherwise. Table 2 shows the details of Artix 7 FPGA board used for implementing CRC Encoder.

Table 2: Xilinx Tools used in proposed CRC

Family	Artix 7
Device	XC7A100T
Package	CSG324
Synthesis Tool	XST(Verilog/VHDL)
Simulator	ISim(Verilog/VHDL)
Language used	VHDL

Table 3 compares the results of proposed design with the previous design for CRC Decoder/Checker.

Table 3: Comparison of Proposed CRC

Slice Logic Utilization	Previous Design [8]	Proposed Design
Number of Slice LUTs	36	20
Number of bonded IOBs	41	33
Power (W)	1.064	0.042

Table 4 describes the logic utilization summary. Few parameters like LUT's, Power, Memory and Delay are obtained during the implementation of 16-bit Message polynomial and 8-bit CRC.

Table 4: Results of Proposed CRC

Slice Logic Utilization	Encoder	Checker
Number of Slice LUTs	13	20
Number of occupied Slices	5	8
Number of LUT Flip Flop pairs used	13	20
Number of bonded IOBs	24	33
Average Fanout of Non-Clock Nets	2.58	2.2
Delay (nsec)	1.481	2.737
Total memory usage (KB)	317684	316916
Power (W)	0.042	0.042

V. CONCLUSIONS

In this paper, the method of calculating the remainder for CRC and creating code-word for a given message is described. Figure 12 shows the output waveform of CRC checker and error received in code-word up to 8-bits. Table 4 shows the overall parameters obtained for CRC Encoder and Checker. The delay in the output for encoder is comparative lower than checker circuit. The overall result shows that low hardware usage which is required for implementation of any system.

***Abstract*— The internet of things is the decentralized type of network in which various type of active and passive attacks are possible. The active attacks affect network performance in terms of certain parameters. The version number is the active type of attack it leads to denial of service in the network. The various methodologies are proposed by the authors for the isolation of version number attack in the network. In this work, the various methodologies for the detection of version number attack are reviewed in terms of various parameters. The novel approach can be designed for the isolation of version number attack which should be less complex and detect malicious nodes in least amount of time. In this paper, two scenarios are compared which are DODAG protocol scenario and version number attack scenario. It is analyzed that version number attack has low throughput and has high packet loss as compared to DODAG scenario.**

Keywords— Version number attack, IoT, Malicious nodes

I. INTRODUCTION

A technology in which several sensors, smart nodes, and objects are connected to each other in order to perform communication without using any human efforts is known as the Internet of Things (IoT). Depending upon the link amongst objects, the objects function autonomously. Analysis of collected data to make decisions, providing lightweight data and extracting the data by accessing and authorizing the cloud-based resources are some of the actions performed by IoT nodes. The users, services, sensors as well as objects are linked to each other very closely through IoT. The applications ranging from smart grid healthcare applications to intelligent transport systems deploy IoTs within them. The number of smart devices and intelligent services provided through IoT networks has been outgrowing due to the huge business opportunities provided in the IoT scenarios [1]. The cloud-based IoT networks have been developed due to the relativity of IoT devices on the cloud infrastructure such that the data can be transmitted across applications. There are mainly IP based web and IoT applications which provide transmission using TCP and UDP. However, among most of the IoT applications, there are few commonly used message distribution functions. Various applications implement these functions in interoperable standard ways [2]. Very similar to the client/server protocol, a publish/subscribe protocol architecture is designed which is called MQTT (Message Queue Telemetry Transport). Due to its simple structure and ability to avoid high CPU and memory utilization, MQTT protocol is known to be of huge important. Another protocol that is designed from the financial industry is the Advanced Message Queuing Protocol (AMQP). The TLS/SSL protocols are used here to manage the security. To ensure that less power and memory embedded devices are being used, CoAP is applied for communication. Various network layer protocols also have been designed. The most commonly known IoT standard for MAC is the IEEE 802.15.4 [3]. A frame format is defined in this protocol in which the source and destination addresses are defined in headers along with the manner in which nodes can communicate. Low power multi-hop networking is applied lately in IoT because it is not suitable to use frame formats applied previously in traditional networks since they cause overhead in these systems [4]. For ensuring high reliability, less cost and meeting the communication requirements of IoT, channel hoping and time synchronization are used. Another lighter version of original IEEE 802.11 wireless medium, access standard is the IEEE 802.11ah. The IoT requirements are met here by reducing the overhead. The most commonly used wireless standards are the IEEE 802.11 standards. For all the digital devices, these protocols have been used on large scale [5]. A category of Directed Acyclic Graph that is rooted at the sink and uses RPL routing protocol for organizing the routers is called Destination Oriented Directed Acyclic Graph (DODAG). The DODAG Information Object (DIO) messages are originated periodically by the DODAG root for initiating the formation of DODAG. The link-local multicast is used to advertise this generated DODAG. Information related to the root identity of DODAG, the used routing metrics, and the depth/ rank of originating router are included within the DIO messages. Depending on the information advertised by its neighbors within their DIOs, the router that joins the DODAG defines its own rank. A simple example of building process of DODAG is shown in figure 1. Node 3 is beyond the radio range of root node among all the three client nodes shown in the figure. The DIO control message is broadcasted with its rank and id is broadcasted to the client nodes when the root node initiates the generation of a network topology [5]. Here, DAO messages are sent in

response from the client node 1 and node 2 to the root for joining DODAG as they are in the radio range of the root. The Client node 3 waits for a period of time to hear from the root node but does not receive any response. Thus, the neighbor nodes start sending DIS message proactively to the solicit DIO. The DIO message that is received earlier to the client node 3 is forwarded if in any case this DIS message is received by client node 2. A DAO message is sent back to the client node 2 by the client node 3 when it receives the DIO message. This message will then be forwarded to the root node from client node 2. Thus, the construction process is completed when the client node 3 joins the DODAG at the end.

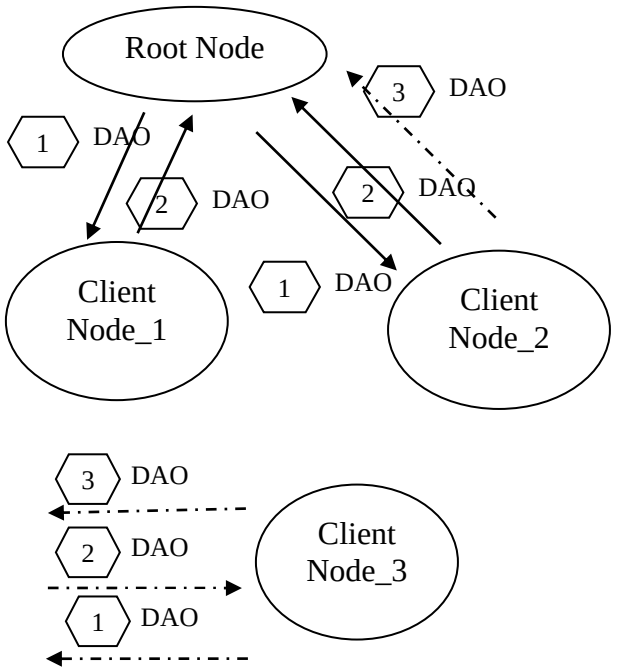

Fig. 1: DODAG construction process [10]

For ensuring that the global repair process of RPL is under control and all the nodes available in DODAG are updated as per the routing state, the root node uses version number [6]. The lifetime of IoT system is reduced due to the presence of version number attacks in it. Attacker can perform this attack with very less expense and the network can be overloaded by exploiting the global repair mechanism that is included as an immune system of protocol. With the presence of several inconsistencies in the network, a global repair is initiated by the root. The version number of DODAG is incremented for rebuilding the complete DODAG. DODAG Information Object (DIO) is the control message in which this version number is carried. Comparisons are made among the existing version number and the one received from its parent by every receiving node. In case of higher received version, the current rank information is ignored, the trickle timers are reset and a new procedure for joining the DODAG is initiated [7].

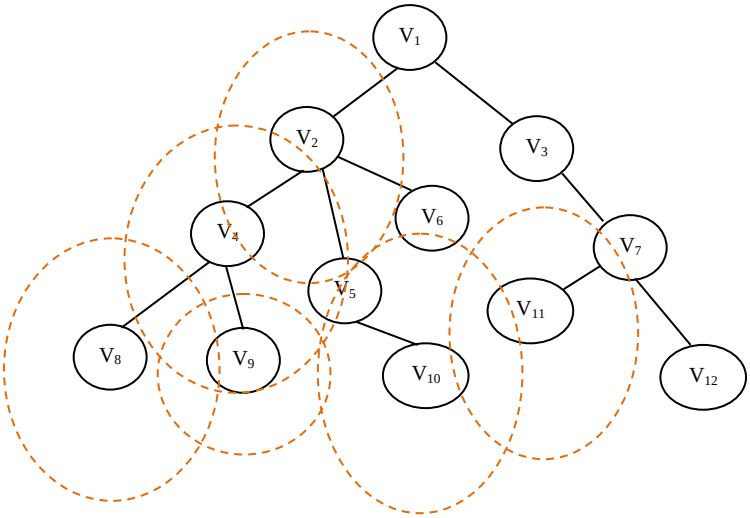

Fig. 2: Illustration of a version number attack

A loop free topology is guaranteed in this global repair although its cost is very high. It can be known that the node did not migrate to the new DODAG version if the previous value of version is being advertised in DIO messages. The other nodes must not select such a node as preferred parent. At the time of global repair, two versions of DODAG can exist at similar time. However, data packets that exist in old version can transit in new version for avoiding loops. The previous version is not considered as DODAG and there is no guarantee of availability of loop free topologies as the network is still beyond convergence state. Across DODAG, the version number must be propagated unchanged so that any possible inconsistencies of the network are avoided. For ensuring the integrity of version number available in received DIO messages, no technique has been provided in RPL [8]. The network can be harmed here when a malicious node might modify this value in its own DIO messages. The trickle timer is reset, the version is updated and the new version is advertised to the neighbors using DIO messages once a malicious DIO is received with a new version number.

This research work is based on the version number attack in the internet of things. In the introduction section, the introduction about the DODAG protocol is described in detail. The description about the version number attack is also given in the introduction section. In the second section is related work is described in detail. The problem formulation section illustrated the problems in the previous research work. The research methodology section describes the novel approach for the detection of malicious nodes in the network. In the last section, result and discussion is described in which two scenarios are compared which are DODAG protocol and version number attack in IoT.

II. REVIEW OF LITERATURE

Ahmet Arıs, et.al [9] proposed two simple alleviation approaches for the elimination of RPL version number attacks. The updates of the version number from the way of leaf nodes were eliminated by the first mitigation approach. The first approach gave information about the toughness of the locations for virtual numbers. The efficiency of the proposed approach was verified by using a number of topologies. In future, more experiments can be performed in the area of various virtual number invasions situation. The examination of the hybrid mitigation approach can also be performed in the near future.

Anthea Mayzaud, et.al [10] presented a novel classification approach for the categorization of the attacks found besides the RPL. For this approach, mainly three classes of attacks were considered. The lifespan of the network was reduced by the invasions against resources. The intruder node capture and the examined a wide part of the network in case of attacks. The researchers have proposed a lot of approaches for the prevention of these types of attacks based on different properties. The implementation and the management of the security modes were not mentioned by the RPL specification technique. Thus it was concluded that the transaction among different security levels was a major challenge for the accepted structure of RPL networks.

Amit Dvir, et.al [11] suggested the use of a new routing protocol for the elimination of the issues presented in the Low power and Lossy networks. This protocol was named as IPv6 routing protocol. The main objective of this routing protocol was to grant the functionality in the Low power and Lossy Networks. An updated version named DODAG was used for reconstructing the routing topology. It was also suggested that for the prevention of initial intruder, same approach should be used, for publishing the decreasing value of rank. In this method, a wider part of the DODAG was combined with the DODAG through the intruder for forwarding a long part of the network traffic. Thus with the use of this new security component, the illegal increase in the version number could be avoided.

Anthea Mayzaud, et.al [12] presented a novel classification approach for the categorization of the attacks found besides the RPL. For this approach, mainly three classes of attacks were considered. The lifespan of the network was reduced by the invasions against resources. The intruder node capture and the examined a wide part of the network in case of attacks. The researchers have proposed a lot of approaches for the prevention of these types of attacks based on different properties. The implementation and the management of the security modes were not mentioned by the RPL specification technique. Thus it was concluded that the transaction among different security levels was a major challenge for the accepted structure of RPL networks.

Zeeshan Ali Khan, et.al [13] proposes some new approaches for IDS which were very suitable for the tiny devices. For managing the status information about the neighbors, the proposed approach used the faith management technique. The proposed approach proved very successful for singling out nastily behaving units. After the recognition of attacker node, it was eliminated from the network. The presented approach was most suitable against the three types of RPL protocol attacks. The presented approach could also be used for other type of inclusions. For the validation of MATLAB simulations, a test bed involving Z1coponents will be developed in near future.

H. Abdo, et.al [14] proposed a novel approach for ensuring the security and safety in case of industrial threat investigation. For this purpose, a conventionally used safety investigating system named bowtie analysis was combined with the newly developed version of security analysis. A comprehensive demonstration of the risk scenario was presented by the combination of attack tree and bowtie analysis approach in terms of safety and security. For the evaluation of risk range relied on two term similar parts, a new mechanism was presented. The one part was for security while the other part was for safety. The tested results showed that the proposed approach performed well. In future, a more reliable and tough likelihood estimation technique will be developed by the researchers.

Ahmet Aris, et.al [15] presented a deep study of RPL version number attacks. The investigation of the attacks was also performed which was based on different scenarios. The investigation was performed on a practical network topology containing both mobile and stationary nodes. A probabilistic approach was used for calculating the attacks probabilities. The performance results were demonstrated according to the different valves of p. The outcomes of the simulation depicted that the mobile attackers and the distantly placed nodes had almost same effects on the network performance. In future, a study about the coming behavior of DIO information for the recognition of possible position of virtual number attack will be performed.

Hezam Akram Abdul-Ghani, et.al [16] proposed a new internet of things suggestion approach relied upon constructing blocks policy. This was basically a four layered reference model. An inclusive IOT invasion model was developed including four main phases. Firstly an IOT asset relied invasion plane comprising of four mechanism was presented. In the second phase, a pattern of IOT security aim was defined. The IOT invasion classification for every component was identified in the third phase. In the final phase, violation of security aims and the association among every attack was identified. A set of solution was also for protecting each asset was also identified in the last phase also. For the very first time, an IOT invasion model relied on building block reference model was developed. The tested results clearly depicted the effectiveness of the proposed model.

Anthea Mayzaud, et.al [17] proposed a recognition strategy for addressing the version number attack issues in RPL network. A solution based on distributed monitoring design was implemented for the conversation of node resources. After obtaining the recognition information from all monitoring nodes the intruder localization procedure was performed by the attacker. A lot of tests were conducted for the evaluation of the above approach. With the help of

strategic monitoring nodes placement, the false positive rate could be reduced. In future, many more complementary experiments based on real infrastructure with some other classes of components will be performed.

Seungyong yoon, et.al [18] proposed a novel well-implemented structural design of distant security handling server. This approach was proposed for ensuring the safety of IOT devices in an IOT handling scenario. A number of security constraints were managed and provided in an integrated and systematic manner by the remote security management server. The presented approach helped in the prevention of various unpleasant incidents in the IOT scenario in advance. With the identification of these attracts, the damage caused by these attacks could be minimized. In case of the occurrence of the attack, the prevented measures could be adopted. The various tested results indicated that the presented approach performed well on certain parameters like safety and security.

TABLE I. TABLE OF COMPARISON

Reference No. & Author's Name	Technique	Advantages/ Features	Disadvantages/ Improvements
[9] Ahmet Arıs, et.al	Two simple alleviation approaches for the elimination of RPL version number attacks are proposed.	The efficiency of the proposed approach was verified by using a number of topologies.	The analysis of the multiple VN attackers' situation was not performed in this study.
[10] Anthea Mayzaud, et.al	A novel classification approach for the categorization of the attacks found besides the RPL in which mainly three classes of attacks were considered.	The researchers have proposed a lot of approaches for the prevention of these types of attacks based on different properties.	This proposed technique is only able to secure the networks that include one malicious node and thus, the future work can be extended for making improvements in this technique to ensure that systems with multiple malicious nodes can be secured.
[11] Amit Dvir, et.al	The main objective of this routing protocol was to grant the functionality in the Low power and Lossy Networks.	In this method, a wider part of the DODAG was combined with the DODAG through the intruder for forwarding a long part of the network traffic.	The proposed technique was only implemented in standard systems for evaluations and the future work can be extended by implementing this technique in RPL and real wireless sensor deployments.
[12] Anthea Mayzaud, et.al	A novel classification approach was proposed for the categorization of the attacks found besides the RPL. For this approach, mainly three classes of attacks were considered.	It was concluded that the transaction among different security levels was a major challenge for the accepted structure of RPL networks.	The proposed work was not evaluated in real infrastructures that included additional classes of devices that were implemented in RPL protocol.
[13] Zeeshan Ali Khan, et.al	For managing the status information about the neighbors, the proposed approach used the faith management technique. The proposed approach proved very successful for singling out nastily behaving units.	For the validation of MATLAB simulations, a test bed involving Z1coponents will be developed in near future.	The proposed technique is not enough computing intensive due to which several issues are being faced.
[14] H. Abdo, et.al	A novel approach was proposed for ensuring the security and safety in case of industrial threat investigation. For this purpose, a conventionally used safety investigating system named bowtie analysis was combined with the newly developed version of security analysis.	The tested results showed that the proposed approach performed well.	The issue of uncertainty still exists after implementing the proposed approach which can be resolved by making improvements in this approach in future.

[15] Ahmet Aris, et.al	The investigation of the attacks was also performed which was based on different scenarios. The investigation was performed on a practical network topology containing both mobile and stationary nodes.	The outcomes of the simulation depicted that the mobile attackers and the distantly placed nodes had almost same effects on the network performance.	It is still easy to drain the resources and reduce the lifetime of networks if the malicious node is placed on mobile network identity.
[16] Hezam Akram Abdul-Ghani, et.al	A new internet of things was proposed suggestion approach relied upon constructing blocks policy.	For the very first time, an IOT invasion model relied on building block reference model was developed. The tested results clearly depicted the effectiveness of the proposed model.	No standard method has still been defined for securing the IoT systems.
[17] Anthea Mayzaud, et.al	A solution based on distributed monitoring design was implemented for the conversation of node resources. For the identification of the attacker in the proposed approach, the collaboration of observed nodes was exploited.	With the help of strategic monitoring nodes placement, the false positive rate could be reduced.	Only one certain parameter is emphasized here by the proposed technique which makes it possible for the technique to lack in accuracy and privacy aspects.
[18] Seungyong yoon, et.al	This approach was proposed for ensuring the safety of IOT devices in an IOT handling scenario. A number of security constraints were managed and provided in an integrated and systematic manner by the remote security management server.	The various tested results indicated that the presented approach performed well on certain parameters like safety and security.	The proposed approach is only tested on limited scenarios, which does not define its vulnerability to attacks in all other scenarios.

III. PROBLEM FORMULATION

The IoT network is much vulnerable to various type of security attacks. The DODAG is the routing protocol of IoT which establish path from source to destination based on the version number. The version number attack is trigger by the attacker and attacker increment version number which leads to establishment of path which have loop. The two version number attack mitigation techniques are proposed [18] in IoT. In the first technique, the virtual number attackers are mitigated based on the direction of leaf nodes. The version number attackers which are remained in the network will be mitigated with the second technique. In the second technique, the node will not update its virtual number until it has majority vote. The proposed technique [18] does not detect the multiple version number attack from the network. The mitigation scheme can be tested over the sensor devices which have low battery power and resources

IV. RESEARCH METHODOLOGY

The proposed methodology is based on the detection and isolation of version number attack in IoT. The proposed methodology is based on the trust based technique for the isolation of version number attack. The proposed approach isolates version number attack in DODAG attack. The implementation strategy will be based on the following steps:-

- Deployment of the Network: - The network will be deployed with the finite number of sensor devices and with the base station. The sensor devices are responsible to sense various types of conditions like temperature, pressure etc.
- Trigger of version number attack:- The malicious nodes will be formed in the network which are responsible to trigger version number attack. The malicious nodes will update the version number in the DODAG protocol.
- Trust Calculation:- The trust based scheme will be proposed in this research for the mitigation of version number attack. The trust based scheme will work, in the three phases which are pre-processing, trust calculation and trust updation.
- Analyze network performance: - In the last phase, the network performance will be analyzed in terms of certain parameters to check effectiveness of the proposed technique. The network performance will be analyzed in terms of throughput, packetloss and energy consumption.

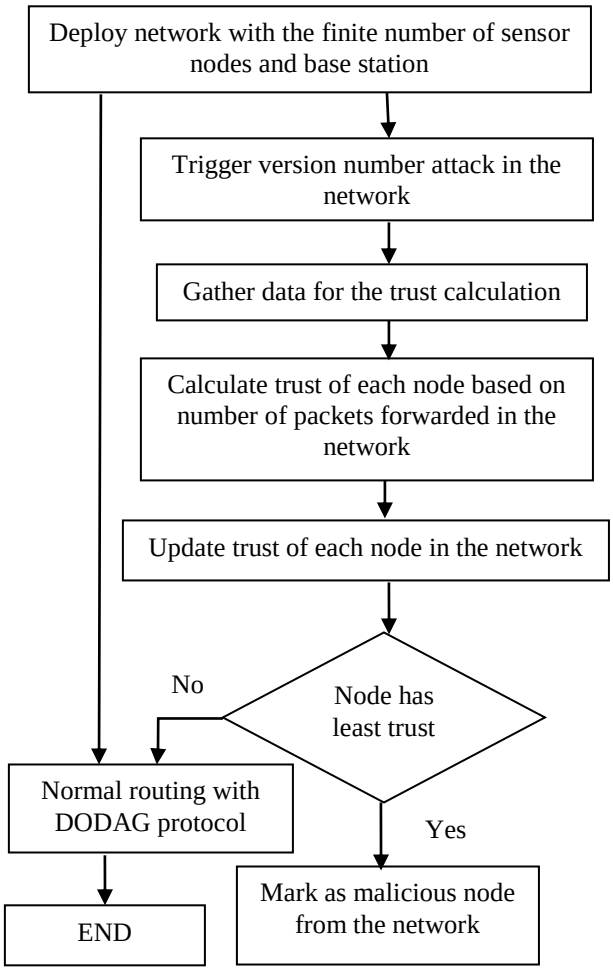

Fig. 3: Flowchart of Methodology

V. RESULTS AND DISCUSSION

This research work is related to isolation of version number attack in Internet of things. The version number attack is triggered in the DODAG protocol. In the result and discussion section, the two scenarios are compared which are DODAG protocol and impact of version number attack on performance of DODAG protocol in terms of throughput and packet loss.

TABLE II. SIMULATION PARAMETERS

Parameter	Values
Simulator	Ns2-2.35
Number of nodes	32
Area	800 * 800 meter
Antenna type	Omi-directional
Channel	Wireless channel
Propagation Model	Two ray

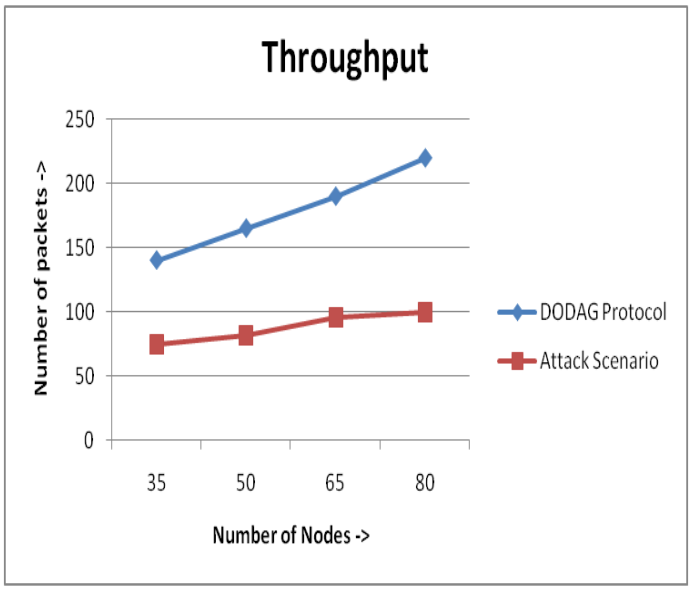

Fig. 4: Throughput Analysis

As shown in figure 4, the throughput of the DODAG protocol is compared with the attack scenario in which version number attack is triggered in the network. It is analyzed that when the attack is triggered in the network, throughput is reduced to certain extent as compared to attack scenario.

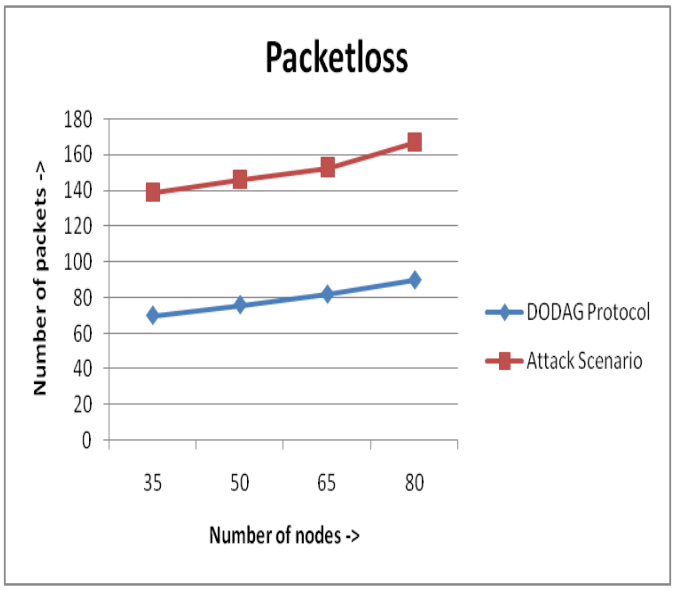

Fig. 5: Packet loss Analysis

As shown in figure 5, the packet loss of the DODAG and Attack scenarios are compared. It is analyzed that attack scenario has the greater packet loss as compared to DODAG scenario.

VI. CONCLUSION

In this paper, it is concluded that internet of things is much vulnerable towards various type of security attacks. The version number attack is the active type of attack which affects network performance. The various techniques which

already proposed are reviewed in this work. It is analyzed that some techniques are too complex and take much time for the isolation of malicious nodes. In future novel technique will be proposed for the detection of malicious nodes. The proposed technique will detect malicious nodes in least amount of time. In this paper, the DODAG protocol is compared with the attack scenario in which version number attack is triggered in IoT. The implementation results shows that throughput of the network is reduced when the version number attack in the network. The packetloss of the attack scenario is increased when the version number attack is triggered in the DODAG protocol. In future, proposed methodology will be implemented for the detection of malicious nodes in the network.

Abstract *– Water is most valuable in human beings but, now a day's water level in water resources are decreases fastly. Because of less rain fall the need of water is increases. Huge growth of residential areas have increases water demand to accomplish their daily needs. People use water for different ways and everyone use different amount of water as their needs. In this project, to focusing on real time monitoring of water supply in IOT based and also controlling a valve w.r.t. distributed same amount of water in all consumers, maintain a water quality and also maintain a water level in a main water tank. Basically this system is applicable for buildings/society.*

Raspberry pi is used for collected all sensor data (Flow sensor, Ultrasonic sensor, Turbidity sensor) and store it to cloud server. Thingspeak server is used as cloud for store a data and Firebase cloud server is used to showing real-time data in android application.

Keywords*: Raspberry pi, Stepper motor, IOT, Network Protocol – Wife Protocol, Application protocol- HTTP, Android app, Flow measurement, Automated Supply.*

1. INTRODUCTION

Water is basic need for all living beings. Now a days, Economic growth is increasing drastically and water demand of consumers are increasing. Therefore, in urban areas, we need to monitor a supply of water continuously and distributed equally. Here it focused to solve an issue of improper water supply and automatically maintaining water level of water in main water tank. Supply water in all consumers automatically.

In this research work, it is proposed to develop an IOT based remote water monitoring and controlling system by monitoring a flow rate at the consumer end and to control a water level in main supply tank is controlled using ultrasonic sensor and water pump. It also maintains a water quality by adding chlorine content in water. This web based system compatible with mobile phones to know the status of control room from remote locations. These recorded data is showing in real-time in mobile android application.

In this paper, solving a main issue for distributed equal amount of water, water quality and equal flow rate in all consumers. For maintaining equal flow rate to using stepper motor fitted manual control valve to change a position of valve with the help of rotation of stepper motor. This system is design on-line billing system for end- users. Therefore end-users are paying only for water used and thereby reducing the complaints.

1.1 EXISTING SYSTEM

The existing method provides a controlling electrical supply of motor to changing its speed for maintaining equality of flow rates to all consumers. Or another method is used a solenoid control valve of 4 direction to maintain equal flow rates. It will operate in manually/automatically.

1.2 PROPOSED SYSTEM

Before explaining the proposed system let us know about why we need to maintain a usage of water. Cities usually used source water from rivers, lakes, and ground reservoirs. A level of water quantity in these resources are decreasing rapidly because of less rainfall and increasing a use of water in cities. For providing water to all need to be control wastage of water. Our system focus on, Internet of Things which is a new concept to make city as a smart city with different application. Main objective to implement this project is to design and develop a low cost reliable and efficient technique to make proper water distribution and controlling its quality and flow rate to all so that we can solve water related problems. Proposed consist of Raspberry pi used as a mini computer, different sensor such as ultrasonic sensor, water flow sensor and turbidity sensor are used. Arduino collects the dada from sensors and send it to raspberry pi then raspberry pi is controlling a flow of water

with the help of changing a position of stepper motor which is fitted in shaft of manually operated control valve. Continuous monitoring is possible in central server and android application.

.

2. LITERATURE REVIEW

In [1] implemented an anti-theft control system for drinking water supply. Flow sensor is used for finding thieves.

In [2] the author is implemented an IOT based water supply monitoring and controlling system. In this system, to calculate a flow of water passes through flow sensor and also check a soil content in water and operated solenoid valve automatically fully ON/OFF.

In [3] the author is implemented an Automation in drinking water supply distributed system and testing of water. Author used a PLC and SCADA to check a water quality and added chlorine content in water.

In [6] Microcontroller Based Water Level Indicator and Controller system is developed for automatically control a level of water in tank using AT89C52 microcontroller and level sensor is used.

3. SYSTEM DESCRIPTION

3.1 Block Diagram :

Following figure 1 shows a block diagram of hardware used in system.

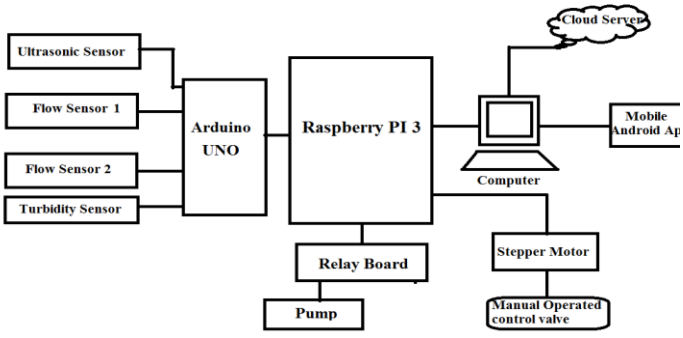

Fig. 1 Block Diagram of a system

System consists of Raspberry pi, Arduino UNO, Ultrasonic sensor, Flow sensor, Turbidity sensor, Water Pump, Stepper motor fitted Manual control valve.

3.2 Design and Implementation :

3.2.1 Flow Chart :

For this project, Arduino UNO and Raspberry pi are used to monitor a level of water in main water tank and control a water pump. Water is distributed equally and monitoring a flow rate and controlling a manual valve using stepper motor for changing its direction continuously. And turbidity sensor measures a quality of water and by adding chlorine in water to maintain a water quality.

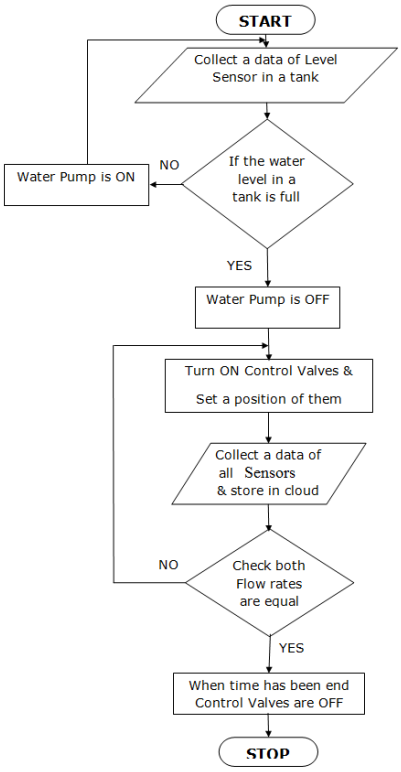

Fig.2 Flow chart of a system

In the above figure 2 shows, a process of our system. After starting a system firstly checks a level of water in tank and w.r.t. to water level pump should be ON/OFF automatically. Then turbidity sensor checks a water quality of water in tank and added chlorine w.r.t. turbidity, then control valves are open and flow sensors are starts recording a data and these recorded data sends to cloud. Using these flow rates controlling a stepper motor fitted manual control valves position for maintaining a equal flows. After time ends control valves are turns fully OFF.

3.2.2 Implementation :

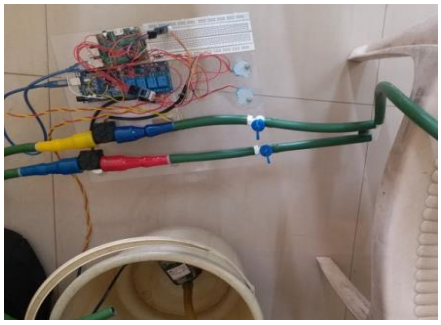

Fig. 3 Hardware of a system

Above figure 3 shows a hardware of a system, all modules can be implemented Raspberry pi and Arduino UNO. Automatically monitoring and controlling of

water supply can be well executed by all sensors data to the raspberry Pi module. Flow sensors are used for measuring a flow of water easily which passes through the consumer's pipeline. And turbidity sensors are check a quality of water.

Following components are used in system:

1. Ultrasonic Sensor:

HC-SR04 sensor is a ultrasonic module for non-contacting distance measurement. Ranges from 2cm to 400cm. this sensor uses sonar to measure distance with high accuracy and stable readings. This module consists of transmitter, receiver and control circuit. An ultrasonic sensor is fitted on the top of the main water tank. Ultrasonic sensor works on the transmitting and receiving a ultrasonic pulse at the speed of sound from the liquid surface. This sensor works on a time difference between transmission and reception of ultrasonic waves are calculated using formula of speed of sound, Speed=Distance/Time. Using this formula, easily measure a distance between the source and target. Distance= Speed*Time/2.

Installation of this sensor is easy on main water tank.

2. Flow Sensor:

This sensor is used for calculating a flow rate of water which passes in a pipeline of consumers. And also using this flow rate to calculate a total flow of water passes in a pipeline. For determining a liquid flow rate in such cases is Q= V * A. where Q is flow rate of water through pipe, V is average velocity of the flow and A is cross sectional area of the pipe. Equation –

Liters = Pulses / (7.5 * 60).

Flow sensors are mounted on every consumer's pipeline.

3. Turbidity sensor :

This sensor is used for checking a water quality in water tank. And using these recorded data to maintain a water quality by adding chlorine in water.

4. Control valves :

A manual control valve is used having fitted a stepper motor's shaft on the top of the control valve handle. This construction is used for maintaining an equal flow rate to all consumers. System checks all consumer's flow rate and compare these flow rates and if these are not equal then stepper motor is trying to control a equal flow passes in a pipelines to changing a stepper motor's shaft angle/direction. This controlling action is done through a raspberry pi. When consumer consumes its water quantity which are to be specified valves are closed. And if consumer needs more water then they should pay more for extra water.

5. Relay :

Relay is a switching device which is operated in a 5v/12v DC power supply. It is used for to switch ON /OFF a water pump. This relay is to be operated through a Raspberry Pi 3 controller.

6. Internet of Things :

The interconnection via the internet of computing devices embedded in everyday objects, enabling them to send and receive data. It has ability to transfer data over a network without requiring human to human or human to computer interaction.

In this project, Thingspeak and Firebase cloud servers are used to store a data.

Thigspeak server is a open IOT platform with MATLAB an analytics. It is used to store and retrieve data from things using a HTTP protocol over the internet. It provides apps that let you analyze and visualize your data. Firebase cloud server is used for store a real-time data continuously and showing a real-time data continuously in android mobile application which have developed.

Firebase is Google's mobile platform that helps you quickly develop high-quality apps.

In this project, all sensors data are recorded to Raspberry Pi through Arduino UNO and using Raspberry pi sent these data to both clouds Thingspeak and Firebase using IEEE 802.15-WiFi network protocol and used HTTP application protocol for sending and retrieving data to cloud.

3.3 Software :

The programming language is used in this project is PYTHON in Raspberry Pi and C in Arduino UNO. PYTHON 3.5 version is used for programming in Raspberry pi 3.

4. RESULT

After all connection are done, through putty login pi is start in laptop and run a command sudo python filename. Once a command executed project starts our execution in step wise which is mentions a flow of project in previous section. To store a recorded data used for Thingspeak and firebase. Thingspeak cloud server is displaying these data in a graph format. Following Figure 4 shows a Thingspeak web screen. Which is displaying a data of level of water in tank and both flow sensors recorded data in separate graphs. These graphs are used for monitoring and using these graphs further predication is easily done.

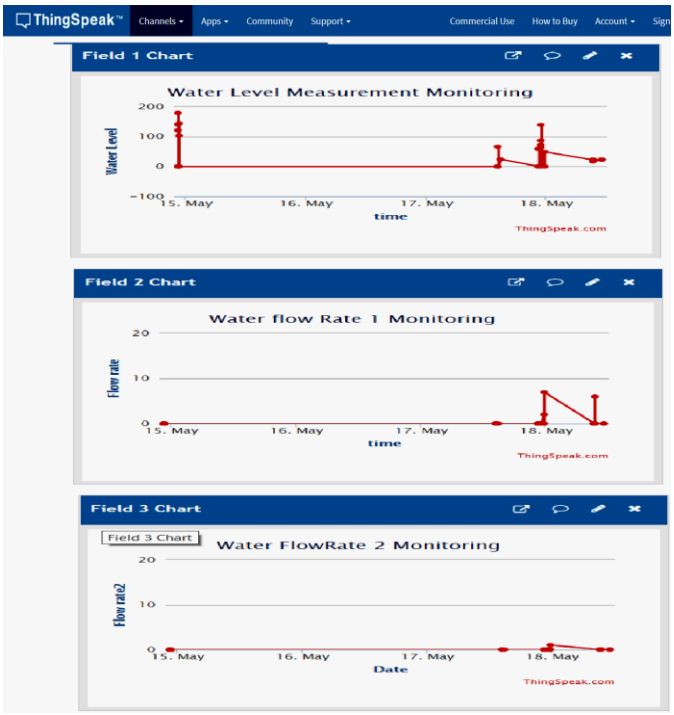

Fig.4 Thingspeak web monitor of a system

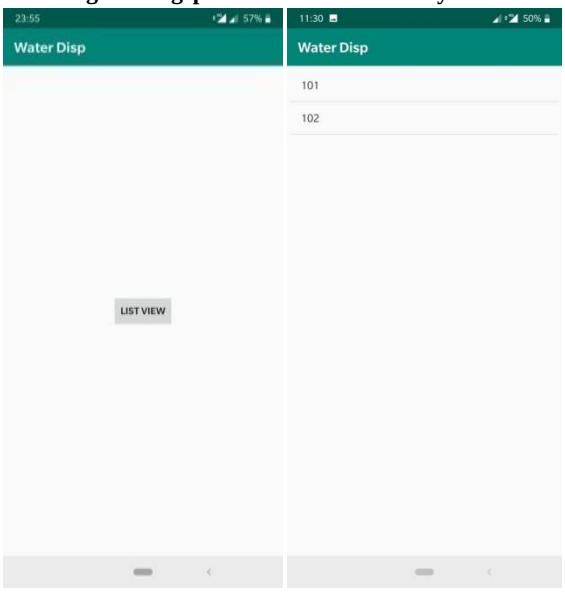
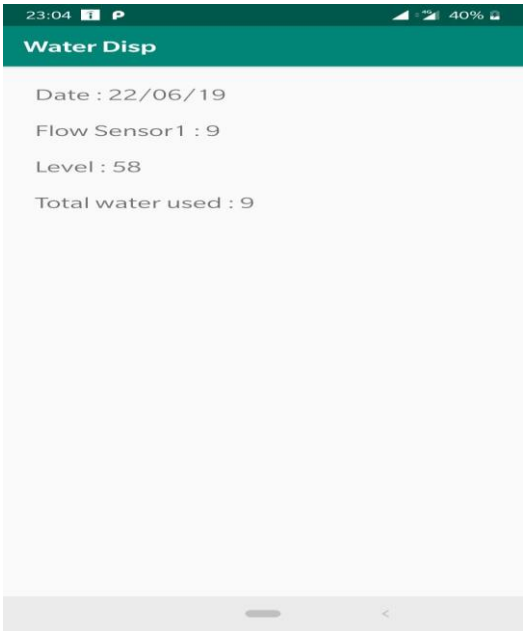


(a) (b)



(c)

Fig.5 Android Application screens sequentially

The above fig. 5 shows an android mobile application screens. After opening an application 1st window is displayed, this is home screen of application. When click on button "LIST VIEW" different locations are listed in 2nd window. Then following figure 5(b) is displaying a list of flat numbers after clicking on any one in a list, a data of flow rate, level of main water tank and total water used in this flat consumer are displaying continuously with current date which are displaying in a figure 5(c). And on-line bill is generated for end-user for consuming its water.

5. CONCLUSION

Our proposed system is truly based on IOT. Using this system secure and continuous monitoring is possible No need to go on field for monitoring so manual work has been reduced it makes system more efficient, reliable, low cost and accurate. Data monitoring is easy from anywhere controlling is done automatically w.r.t. changing a flow rate. Flow rate is maintaining equally to changing a control valves position. Maintain a water quality by adding chlorine automatically. And also automatically maintain a water level in main water tank. Using this system, to reduce a water wastage. Water distribution as per Geographical survey and population density. Develop a web based and automatic Meter reading system. Therefore, 24*7 safe drinking water is provided.

In future this system is used for a specific area and city. Easily increase a number of connections and for using this system easily finding a theft of water and leakage of pipe.

***Abstract* - PV System is one of the most clean and preferable source of energy. In this article, the PV System is used in special type of inverter known as Hysteresis Current Control (HCC) Inverter. The proposed system incorporates boost converter which uses tracking algorithm known as maximum power point tracking (MPPT). Various tracking mechanisms are available for extraction of maximum power, Two MPPT techniques used here are Perturb and Observe (P&O) method and Incremental Conductance (IC) method. The MPPT methods help the system to function more effectively. The output of the converter is given to a two level inverter. The inverter works on current control technique in which line current is forced to follow a reference current within a specific band. At last, the current output harmonics of the proposed system is compared with MPPT and without MPPT technique by using MATLAB simulation environment. Considering the THD values, it is found that MPPT optimized PV system gives better result.**

Keywords – Hysteresis Current Control (HCC), Incremental Conductance (IC), Perturb and Observe (P&O)

I. INTRODUCTION

For more than hundred years, we are dependent on the traditional source of energy like coal, oil, natural gas etc. But these fuels are increasingly depleting and there is a strong need of alternate source of energy. Also the problem with the conventional source of energy is that it creates atmospheric pollution and other health related problems in human beings. So there is a need of clean and sustainable source of energy. Due to these above reasons, it makes renewable source of energy as area of interest in research in recent times [1, 10]. There are variety of renewable source of energy such as solar, wind, hydro, geothermal energy etc. In this paper, the solar photovoltaic with the use of MPPT is the main focus of study [12].

Solar radiation is the virtually unlimited source of renewable energy. The solar PV converts light energy that is photon from the sun into electrical energy. A solar cell is the main building block of photovoltaic power generation. The PV panel output power varies inversely with temperature and directly with amount of solar radiation (irradiance).

It is important for the researchers to get maximum power from the solar cell. MPPT technique is used in order to get utmost performance from the solar panels. Two MPPT methods have been used here. P&O is a MPPT method in which the output power of solar panel is given a perturbation, and with the change in power, change in voltage is occurred according to which the duty ratio of the boost converter is varied for obtaining maximum power.

In IC method, the terminal voltage of array is as per MPP voltage. It works on basis of relationship between incremental and instantaneous conductance of PV array. The MPPT techniques are implemented by controlling the duty cycle of DC to DC boost converter. In order to get AC, another converter is used that is the inverter.

The inverter works on technique which follows the current within a specific band. Here inverter line current tracks a reference signal for obtaining switching optimization which leads to excellent effective response and high efficiency in steady state condition. In this paper, single band HCC inverter is used with RL load. Finally, the THD of inverter output current is compared with MPPT and without MPPT method.

II. PV ARRAY

A Photovoltaic system is a collection of solar panels built to exploit solar radiation by using solar cells. PV systems can be classified on basis of their functions, operations, configurations and how they are interconnected with the loads and sources. The two well-known classifications are Grid connected and Standalone system [4]. The PV modules are connected in series and parallel to form an array. The PV panels are generally rated by the maximum output power under standard operating conditions such as operating temperature of 25^0C / 298K, irradiance of 1000 watt per square meter and Air mass of 1.5 spectral distributions.

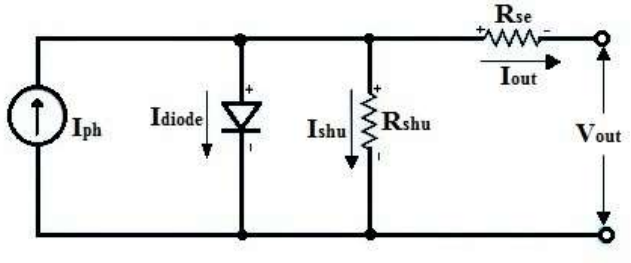

Fig. 1. Equivalent circuit of PV cell

From the above figure equations can be framed as [1]:

$$I_{out} = I_{ph} - I_{diode} - I_{shu}$$

$$I_{ph} = \left[I_{sc} + K_i \bullet (T - 298) \right] \times \left(\frac{G}{1000} \right)$$

$$I_{diode} = I_o \left\{ e^{\left(\frac{V_{diode}}{N \bullet V_T} \right)} - 1 \right\}$$

$$V_T = \frac{K \bullet T}{Q} \times N_{cell}$$

$$I_{shu} = \frac{V_{diode}}{R_{shu}} = \frac{V_{out} + I_{out} \bullet R_{se}}{R_{shu}}$$

$$I_{out} = I_{ph} - I_o \left\{ e^{\left(\frac{V_{diode}}{N \bullet V_T} \right)} - 1 \right\} - \left\{ \frac{V + I_{out} \bullet R_{se}}{R_{shu}} \right\}$$

Where I_0 is the reverse saturation current, I is the current through shunt resistor R_{shu}.

III. MAXIMUM POWER POINT TRACKING

Maximum Power Point Tracking is a technique used in PV System for deriving maximum power from solar module under all circumstances [11, 12]. Broadly, there are two types of MPPT techniques such as mechanical MPPT and electronics MPPT.

Mechanical MPPT is based on the solar angle incidence and mechanical moving of solar panel according to it. Electronic MPPT is based on the use of algorithm in order to extract maximum power from solar cell.

As the temperature and irradiance varies the load characteristics changes. This load characteristic is called MPP. The process of searching for optimum point & maintaining load characteristics there is called MPPT. In this paper, two types of MPPT algorithm are used that is P&O method and IC method.

1. PERTURB AND OBSERVE METHOD

P&O method is also denominated as hill climbing method. It is one of the most common forms of MPPT algorithm [11]. In this method, a small perturbation is given in the voltage of PV Module, like a small increment which results in change in power (ΔP). If ΔP increases or is positive, the operating point moves towards optimum point (V_{mpp}, I_{mpp}). Thus voltage is further changed in the same direction till it reaches optimum point (V_{mpp}, I_{mpp}). If ΔP decreases or is negative, the operating point moves away from optimum point (V_{mpp}, I_{mpp}). When stable condition arrives the algorithm oscillates around maximum power point. In this method if duty cycle taken is large value then there will be more oscillation around MPP and there will be power loss, to solve this problem we can reduce the value of duty cycle to a small value. But if the value of duty cycle is taken to be very low the time required to reach MPP will be more.

2. INCREMENTAL CONDUCTANCE METHOD

IC method works on adjustment of the PV Module terminal voltage. It is based on relationship between incremental and instantaneous conductance [10]. The system is assumed to reach the optimum point (V_{mpp}, I_{mpp}), when the change in the output conductance is equal to negative output instantaneous conductance. The mathematical formulation is given below.

P = V X I

Differentiating both sides w.r.t V

$$\Rightarrow \frac{\partial P}{\partial V} = I \times \left(\frac{\partial V}{\partial V} \right) + V \times \left(\frac{\partial I}{\partial V} \right)$$

$$\Rightarrow \frac{\partial P}{\partial V} = I + V \times \left(\frac{\partial I}{\partial V} \right)$$

For obtaining the maximum power, $\partial P/\partial V$ must be equal to 0

$$\Rightarrow \frac{\partial P}{\partial V} = 0$$

$$\Rightarrow V \times \left(\frac{\partial I}{\partial V} \right) = -I$$

$$\Rightarrow \left(\frac{\partial I}{\partial V} \right) = \frac{-I}{V}$$

$$\Rightarrow \left(\frac{\partial I}{\partial V} \right) + \left(\frac{I}{V} \right) = 0$$

If $\frac{\partial P}{\partial V} > 0$ or $\frac{\partial I}{\partial V} > \frac{-I}{V}$, left to MPP,

If $\frac{\partial P}{\partial V} < 0$ or $\frac{\partial I}{\partial V} < \frac{-I}{V}$, right to MPP

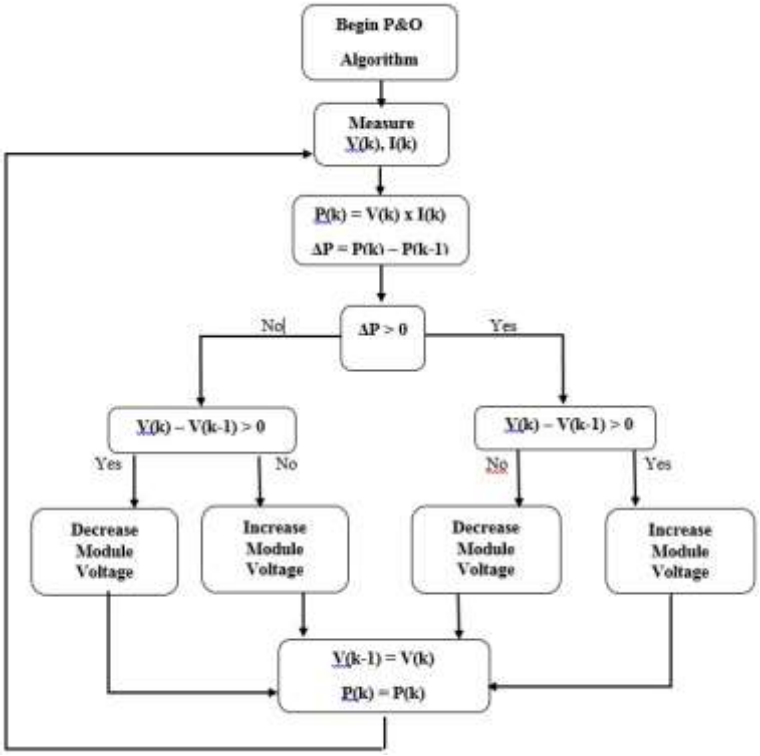

Fig. 2. P&O Algorithm Flowchart

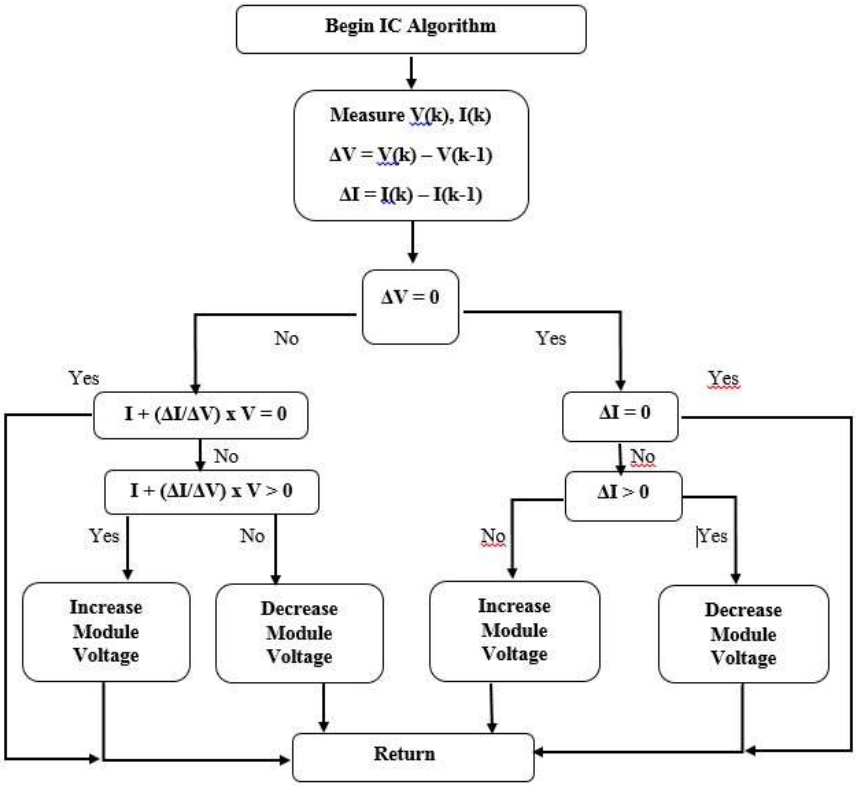

Fig. 3. IC Algorithm Flowchart

IV. BOOST CONVERTER

It acts as interface system between PV the module and the inverter. It is a type of dc-dc converter in which the average output dc voltage V_0 is greater than the input dc source voltage V_{exc} . When the converter is ON for a period of T_{on}, the inductor stores charge during this time. When the converter is OFF for a period of T_{off}, the current is forced to flow through the diode and the load. Due to which, the output load voltage is defined by $V_{out} = V_{exc} + L\left(\frac{di}{dt}\right)$ exceeds the source voltage V_s. The capacitor gives the stable voltage at the output. The equation governing the input and output voltage is given by [9]:

$V_{out} = \frac{V_{exc}}{(1-\alpha)}$, where α is the duty cycle and can be represented as:

$$\alpha = \frac{T_{on}}{T}$$

$$T = T_{on} + T_{off}$$

V. HYSTERESIS CURRENT CONTROL (HCC) INVERTER

HCC inverter is based on current control technique in which line current of inverter is forced to follow a reference current within a specific band known as Hysteresis Band [2, 6-8]. In HCC inverter switching pattern depend on feedback of inverter current which is different from PWM case where inverter current can be pre-detected.The tracking of inverter line current to reference current is done on an instantaneous basis. The difference of reference current and line current gives the error signal, which is then passed through a relay with a band or the Hysteresis band. The maximum and minimum value of this error signal is $e_{\max}$ and $e_{\min}$ respectively [3.5]. The output of the band is given as input as gated pulse to one pair of IGBT and the inverted signal to the other pair of IGBT using logical NOT gate. The produced output voltage is bipolar in nature and it switches from plus DC voltage to minus DC voltage, and vice versa, to control the output current so that it remains in the hysteresis band. The equations are given as:

$$e(t) = i_{inv}^{*} - i_{inv}$$

$$e_{\min} \le e(t) \le e_{\max}$$

If $e(t) = e_{\min}$, then $v_{inv}(t) = V$ and turn ON S1 and S4 else if

$e(t) = e_{\max}$, then $v_{inv}(t) = -V$ and turn ON S2 and S3

VI. THE PROPOSED SYSTEM

In the proposed system, the PV module is connected with a boost converter which boosts up the voltage and also gives stable voltage to the inverter. Here the simulation is done without MPPT in case 1. The simulation is done using P&O MPPT technique in case 2 and with IC MPPT technique method in case 3.

1. Without any MPPT Method
As the title suggest this part was done without the use of any MPPT technique. The PV array block is already present in MATLAB 2015a.

2. With P&O MPPT Method
All the specification remains same in all the blocks except pulse generator block which is replaced by P&O block. The P&O block takes the PV voltage and PV current as input and the output of the block is used to give pulse to the controlled switch of the boost converter.

3. With IC MPPT Method
All the specification remains same in all the blocks except pulse generator block which is replaced by IC block. The IC block takes the PV voltage and PV current as input and the output of the block is used to give pulse to the boost converter switch. It also has another input as step block to on and off the switch in the algorithm.

The proposed model is presented in fig.4.The reference current is taken as to be a sinusoidal current. The output of the relay block is kept '0', when off and '1' when on. The specification of PV array is declared at the beginning. The Model No. of the PV Module is Soltech 1STH-215-P. The switch of the boost converter is actuated by using pulse generator block of Simulink. The specification of the pulse generator block is given below:
Amplitude = 1
Time Period = 0.0001 sec
Pulse Width (% of Time Period) = 50%
Pulse Delay = 0

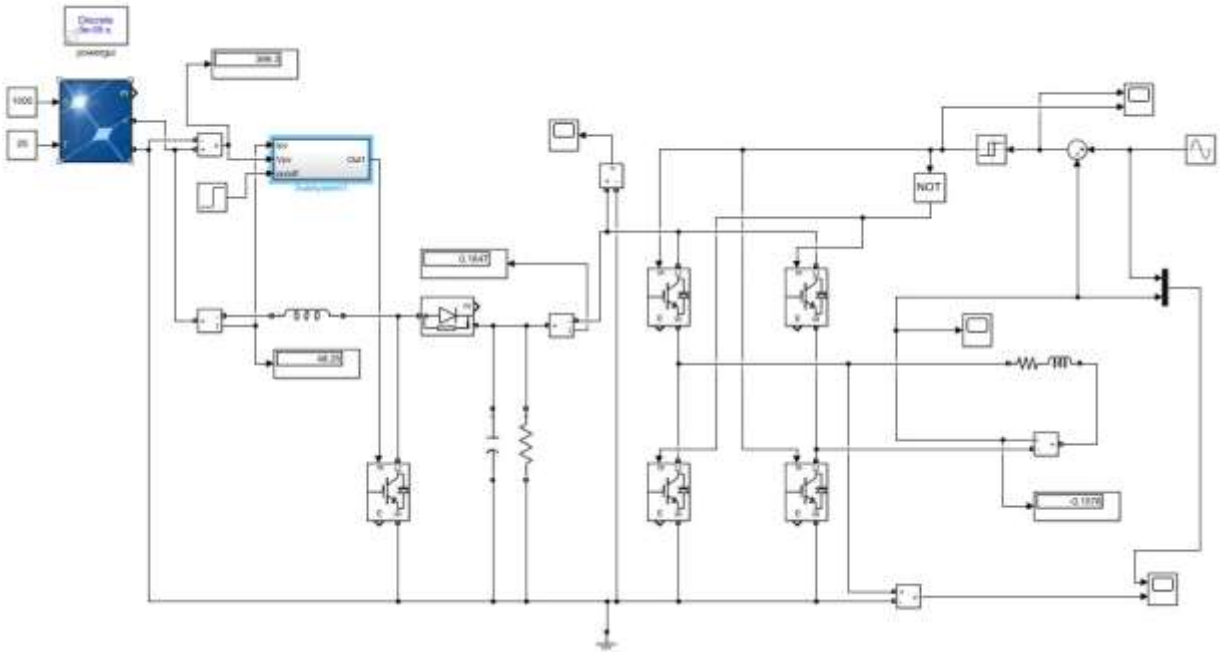

Fig. 4. Simulink model with IC Algorithm

VII. SIMULATION RESULTS

1. Without MPPT

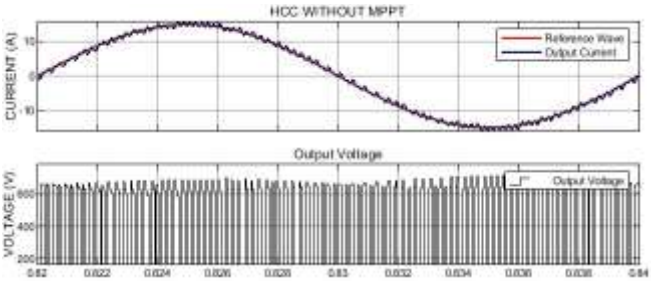

Fig. 5. Output current & voltage waveform

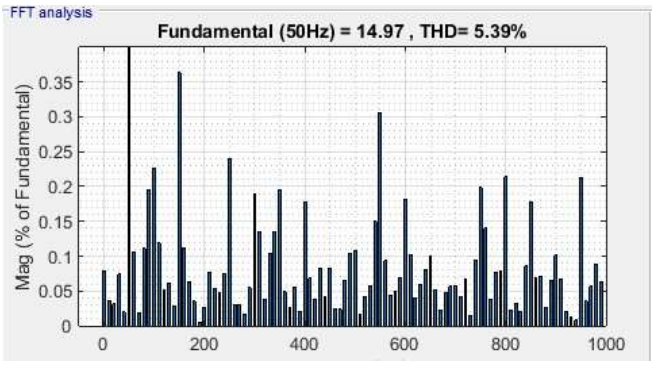

Fig. 6. THD Analysis

2. With P&O MPPT Algorithm

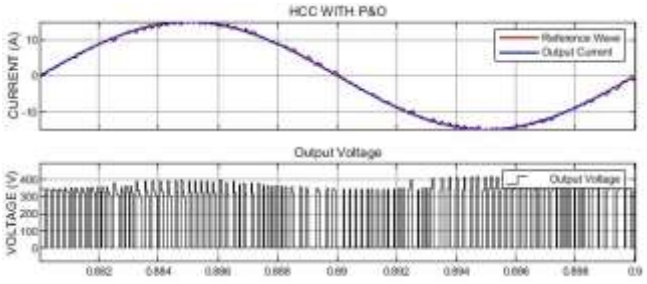

Fig. 7. Output current & voltage waveform

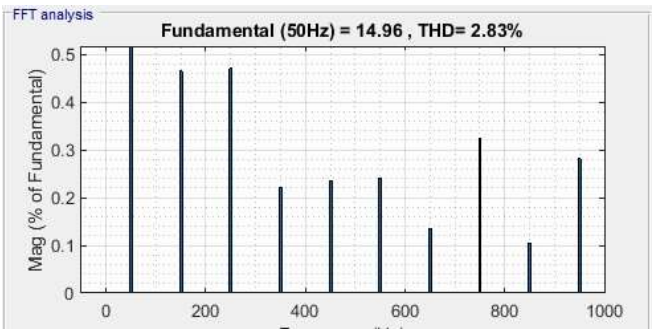

Fig. 8. THD Analysis

3. With IC MPPT Algorithm

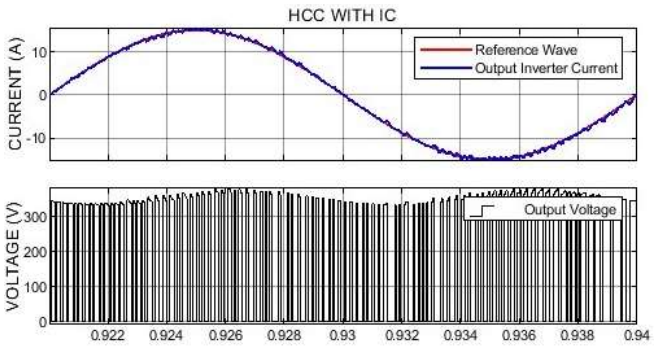

Fig. 9. Output current & voltage waveform

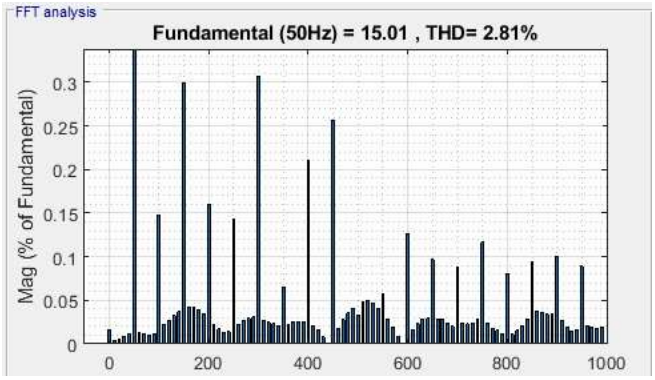

Fig. 10. THD Analysis

VIII. RESULT

Reference current Amplitude = 15A
Simulation time = 1 second
Frequency = 50 Hz
Start time = 0.5 second
No. of cycles = 5

Methods	*Without MPPT*	*With P&O MPPT*	*With IC MPPT*
THD	*5.39%*	*2.83%*	*2.81%*
Current Amplitude	*14.97*	*14.96*	*15.01*

IX. CONCLUSION

This paper presents about a Standalone solar PV integrated to the Hysteresis Current Control inverter. The solar PV is first connected to boost converter which is then connected to the inverter. At first the switching pulse of boost converter is controlled via pulse generator to generate appropriate duty cycle. The THD was calculated. The same process was repeated but this time the switching action of boost converter was controlled by P&O block which takes PV module voltage and current as input and in return controls the duty cycle of boost converter. The THD was found. The above process was again repeated by using IC block using voltage and current of PV array as input along with an on/off switch to control the pulses of boost converter. Considering the THD values, the method using MPPT techniques were better than the conventional method. The Implementation of IC MPPT technique was better than the P&O MPPT technique on the basis of harmonic analysis. The use of hysteresis current control inverter, which gives excellent effective response and high efficiency in steady state response, not only controls the current ripple within hysteresis band but also reduces overall harmonics.

***Abstract*— Now a day's environmental pollution becomes important issues in metropolitan cities and industries. The sudden growth of industries, infrastructure and transport vehicles have been producing environmental issues like greenhouse effect and diseases caused by harmful gases present in the environment which directly effect on human's health and thus needs a special monitoring system. To resolve have an effect on the environmental pollution issues, here we have a tendency to implement IoT based pollution monitoring and control system. Where it detects the deleterious gases present in the environment. The proposed IoT technology scrutinizes level of co gases released during industry process, temperature and humidity using sensor technology and Raspberry pi. Each process will have a separate data monitoring and controlling mechanism. The device are going to be put in through a BLYNK native server mobile application which is able to show the live updates of the environmental pollution level of the industries or remote space The thought of IOT helps to access knowledge from remote locations. The most plans behind the implementation work is to form a true time absolutely machine-controlled management mechanisms exploitation IoT.**

I. INTRODUCTION

In Traditional methods for monitoring environmental pollution predominantly require high investment costs for laboratory analytical device and instruments, large maintenance, training and highly specialized human resource. The utilize of electronic equipment is authentic for measuring the secular trend of environmental pollutants, which is interconnected to the reactivity and transport on regional and local scale, but it is very expensive for the evaluation of the long-term toxicological risk on human health[1]. In fact, continuous equipments require high costs of maintenance and, since they are often hugely experienced they can be only used in a minimum number of sites.

It does not allow a detailed mapping of exposure in biggest areas. Furthermore, pollution parameter collected by automatic analyzers is not satisfactory for a swift exposition and except used to compare the data with pre-defined restraint or pollution level standards, it's not always practical [2].

Therefore, there is increasing insistence for the industrial environmental pollution monitoring and control systems. Environmental pollution has become biggest problems for each country; particularly it's developed country or developing country. Environmental pollution issue are increasing speedily particularly in metropolitan areas of developing countries wherever industrial enterprise and increasing range of vehicles results in liberate ton of environmental pollutants [3].

The projected IoT blynk server system senses the pollution level and transmits over thingSpeak webpage server mistreatment web. Once the gas, temperature and wetness level will increase higher than industries commonplace level, there's large quantity of harmful gases gift within the air like CO, smoke, LPG, alcohol, and NOx. The projected work can show the pollution level in PPM on the liquid show and thingSpeak website and blynk native server. It's obligatory to watch trade pollution and management for future and healthy living for all owing to flexibility and low value web of things (IoT) is obtaining utilized daily[4].

IoT is vital play major role in communication technology. it is an integrated communication technology in which all devices and any objects connected any remote location and any time. The IoT uses smart digital and analog interface to connect and interact with embedded devices, sensors and social contexts. These objects are having identities, virtual personalities operative in good environment. The IoT development provides numerous applications on different domains, such as consumer, home, industrial, manufacturing, utilities, energy resources, transportation, environment, safety, security, retail, healthcare, bio sciences automation, smart grid and many others [5].

Air Pollution has surfaced globally as a result of relating to industrial development. Transportation by road is also one of the major causes for air pollution, which contribute to weather change that has hazardous domestic and global consequences. These are increasingly emerging to reach the human needs. An efficient monitoring system is required to monitor and assess the conditions in case of increasing the prescribed gas level of parameter. The extent to which environment gets affected is observed and send to the user through the android app. Sensor devices are placed at remote industries to gather the information to predict the behavior of a Specific space of interest.

Objectives

Internet of things plays a major role in industries where large number of devices or objects interconnected through internet. These devices communicate with people and other things and provide the sensor data to webpage and blynk local server or cloud storage. The main challenge of the project is to detect and monitoring level of harmful gases released during industry process, temperature, humidity and other factors impact the environment. All data are monitored through thingspeak and blynk local server.

II. RELATED WORK

In existing work had introduced the wireless solution, based on GSM network for the monitoring and controlling of temperature and humidity in industrial environment [3].

In the previous system, pollution monitoring system implemented by using LABVIEW software and zigbee technology [8]. This method is to form a system for monitoring pollution parameters and to notify pollution control system when anyone of the factors crosses the threshold value declared by industry.

In the past, different methodologies and techniques which were used in some of the research works.WSN plays major role in intelligent environment monitoring in this work they are mainly focusing on making the city environment smart, by deploying WSN all across the city, public and private transportation systems [10]. By accessing all the dynamic global sensor networks, environmental behaviors are collected as a streaming data base to identify the environmental conditions.

The architecture and prototype of the IoT system was developed. An algorithm for air pollution source estimation using Mobile Sensor Networks. In industrialization, especially the workers have been suffering from some endangering situations, so monitoring and controlling the parameters which causes pollution is necessary in industrial environment.

III. PROPOSED WORK

The monitor and management of pollution parameter is risk challenges from deteriorates industries or remote space. The most intent of the research paper is to develop a value, accuracy and vigorous system to regulate the pollution parameters inflicting pollution and to diminish the impact of those parameters while not poignant the plant or natural atmosphere.

The implementation of current project is to design an IoT blynk server based mostly system to scan and monitor pollution parameters and send the information to pollution management authorized person. Once any of that parameter reaches on maximum of industries standards. A mechanism victimization Internet of things is introduced during this projected methodology, which is able to mechanically monitor once there's a disturbance moving the environments. The projected IoT technology scrutinizes level of co gases free throughout industries method, temperature and humidity victimization device technology and Raspberry pi.

Each method can have a separate knowledge observation and dominant mechanism. Internet of things provides operation interface and manipulation of information from remote industries or location and it's appropriate for interactive surroundings for transferring the information. The most plans behind the implementation work are to form machine-controlled management mechanisms exploitation IoT.

IV. SYSTEM SPECIFICATION

In proposed work use of Internet IoT to subscribe the industrial pollution presence of certain toxic gases pollutants. This system design represents the working flow based on IOT industrial pollution monitoring and controlling, which is shown in Fig. 1

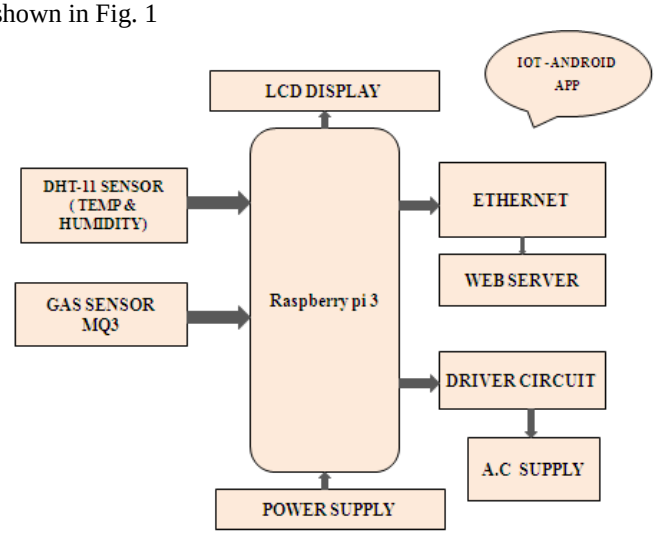

Fig.1 Block Diagram of Proposed Work

A. Working Principle:

This module proposes the use of a Raspberry pi board which collects the temperature and humidity parameter from the DHT-11Ssensor, ADC converter, CO2 concentration using MG-811 and the MQ-3 sensor senses smoke level in the atmosphere and amends output as a result in the form of an analog signal.

The pollutant parameters are updated into on-line information. Before data are passed to the Raspberry pi, it should be converted in to the digital value. The ADC0808 converts the detector analog values to corresponding digital values then raspberry pi will the additional process. this technique design represents the working flow supported IOT industrial pollution monitoring and dominant.

Fig 2 shows the circuit diagram of IoT based pollution monitoring system. A system will detect the hazardous gases that are emitted by industries across the particular area. It simultaneously provides data to authority and organization. The main goal of the planned work is to display the pollution level in WebPages based mostly harmful gas detective work and alerting system. The toxic gases like ammonia, nitric oxide, CO2 and various gases relating to the corresponding industries were sensed and processed by raspberry pi3 .it displayed each and every second on liquid crystal display and the level of pollution monitored online through blynk local server and thingspeak WebPages using MQTT protocol. The DHT 11parameters send in the online and blynk mobile app for every minute. By enable the Show Data button in the app, the numerical values and graphical data will be displayed.

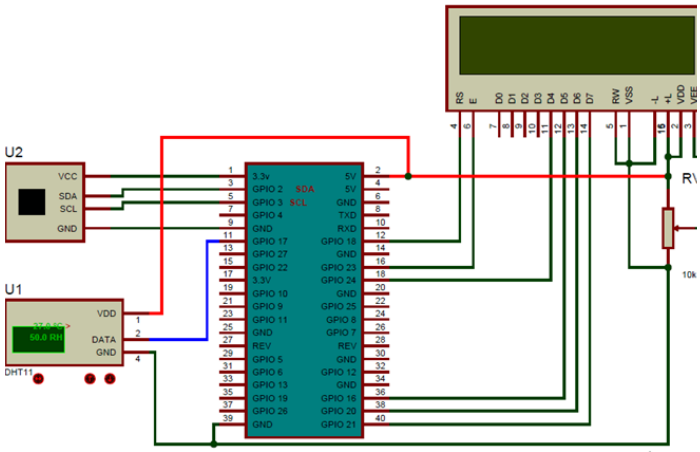

Fig.2 Interfacing DHT11 Sensor with Raspberry Pi

These mq3 and DHT 11sensors are popular for use in remote industrial pollution monitoring, soil monitors, and home automation systems. Only a single data line between an MCU like Raspberry Pi and the temperature Sensor is sufficient for exchange of information and it simultaneously provides data to authorized organization in turn leading swiftly diffusion of the unfavorable situation

V. HARDWARE DESCRIPTION

A. Co2 Sensor

Air pollutant sensor is a embedded sensor device used for detecting the pollutant in air. it is necessary to Measure the nitric oxide and carbon dioxide is important in monitoring factory air quality mq135 for measuring a different kind of gases. it detect Ammonia, Nitric oxide, alcohol , smoke and Carbon dioxide. it can be used in industries and environmental parameter measuring application. this sensor has low prize and particularly suitable for Air quality pollution monitoring application

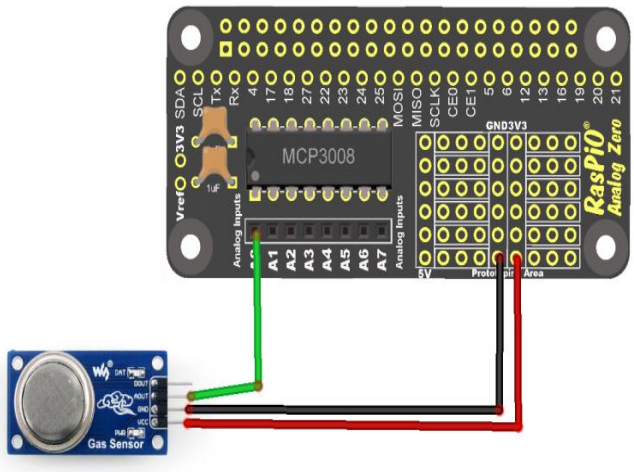

Fig. 3 Interfacing Mq3 Sensor with Raspberry Pi

B. DHT-11 Sensors

It is very effective sensor to sense and measure the environment temperature and humidity. The features of DHT11 sensor humidity ranges is 20 to 90% RH and temperature range is of 0 to 50°C in degree Celsius and supply voltage is +5 V.It has three pins such as Vcc, ground and analog output pin. It is interfaced with a high-performance raspberry pi microprocessor. This technology gives the high precision and long-term reliability. These sensors contain a resistive element and a sensor for negative temperature coefficient temperature measuring devices.

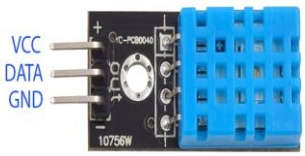

Fig. 4 DHT 11 Sensors

C. Driver Circuit

The relay driver circuit is interfaced with raspberry pi. If the pollution level is exceed maximum value, the Raspberry pi send signal to driver circuit. It automatically triggers Load or supply voltage.

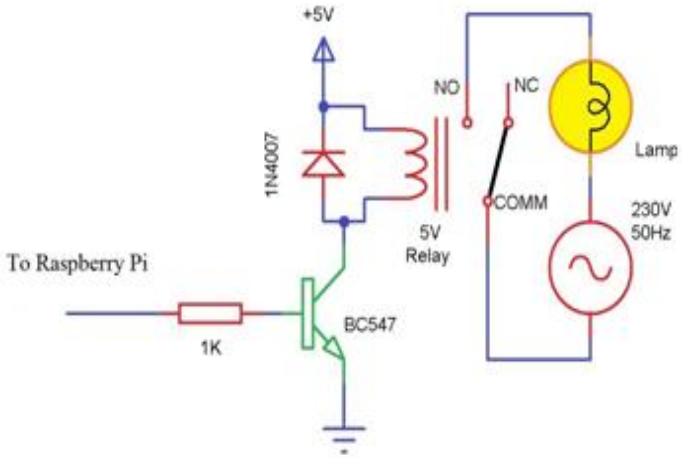

Fig 5 Interfacing relay with Raspberry pi

D. Raspberry pi

The Raspberry Pi is also called as a single printed circuit board micro computer. Raspberry Pi3 is a 1.2 GHz 64-bit quad core processor, on-board 802.11n Wi-Fi, Bluetooth and USB boot capabilities. The Raspbian operating system is stored in memory card. The DHT 11 and gas sensor is interfaced with raspberry pi GPIO pins. It process the measuring parameter and it transmit the data to web server and android BLYNK application

Fig. 6 Raspberry pi 3 board

V. RESULTS AND DISCUSSION

The implementation of proposed work is done by using raspberry pi, sensor and WIFI and blynk android application. Ethernet Shield is implemented by giving the A.C power supply and monitors by using the mobile controlled android applications. Connect the DHT11 sensor in pin A0. Ethernet shield is mounted on the Raspberry pi. .the industries environment parameters are monitored through blynk local server mobile application using internet of things via WIFI or Ethernet cable.

A. Thingspeak Webpage Result:

Fig.7 Shows Temperature and Humidity Using ThingSpeak Server

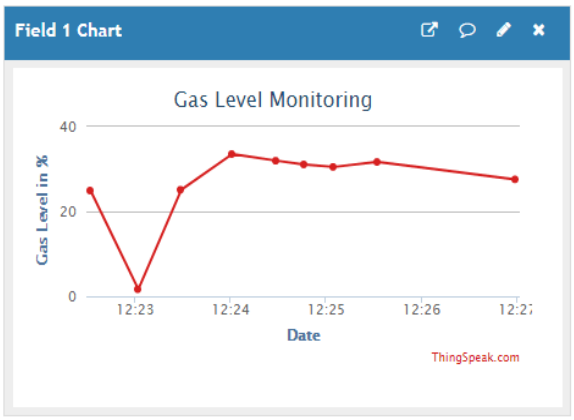

Fig.8 Shows Gas Level Monitoring Using ThingSpeak Server

Fig 7 and 8 shows the graphical wave form of industrial environment gas and temperature and humidity parameters. The Raspberry pi sends the sensor data to IoT thinkSPeak cloud server.

B. BLYNK – IoT APP Result

Address mistreatment the computer IP, we will explore the temperature and humidity value in browser in online Blynk IoT app platform was developed for the net of Things applications. This server doable to manage associate will show device info victimization raspberry pi hardware remotely from any location

This server operated regionally and it's chargeable for communication between golem devices and real time embedded devices .it will management the thousand of embedded devices and objects

A Blynk library is to activate communication with the server and processes all the incoming and out coming back commands from your Blynk app and Raspberry pi. This native server will store information and visualize it effectively. It give the superb preciseness and high performance.

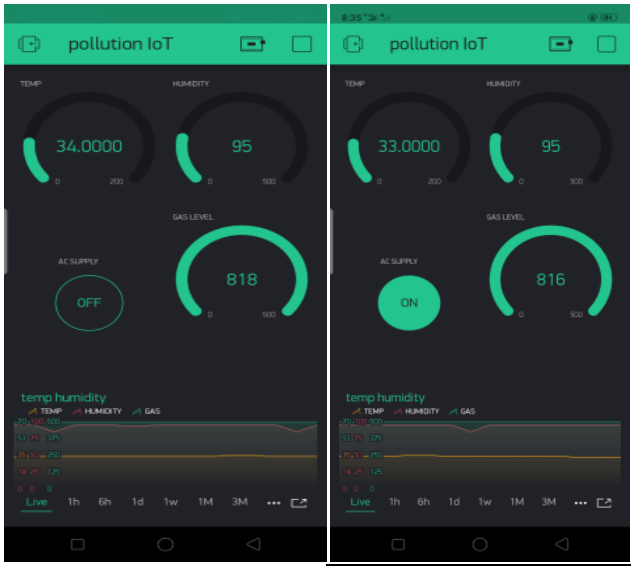

Fig.9 Result of IoT BLYNK ANDROID APP

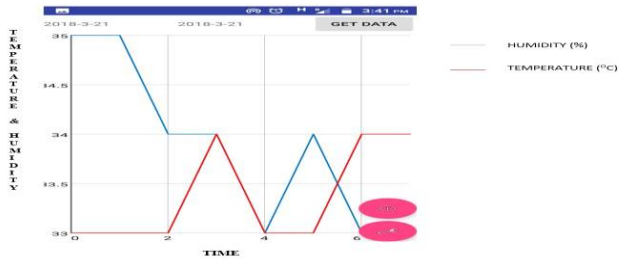

Fig.10 Final graphical output in android app

Fig 9 and 10 show the result of sensor data using IoT android Application Blynk Local server .All sensor information are transferred to android Mobile Blynk Application through Internet. The mobile application also display the data in graphical form

C. Applications

- Industrial application
- Environmental application
- Transport pollution control

VI. CONCLUSION

The most powerful technology IoT primarily based atmosphere observation pollution system was designed, implemented by mistreatment blynk local server and thingSpeak environment. The temperature gas, wetness level are monitored terribly glorious through net.

It's quite helpful as compared to manual observation and additionally it's reliable because it is not possible to watch continually the pollution, humidity and temperature parameter manually. to examine the temperature and wetness measure and so we will recover the system in less time and faults before any unsure failures so leading to important price saving in addition as up system reliableness. The performance between accuracy and price is achieved by creating use of single printed circuit board digital computer Raspberry pi and applicable sensors resulting in a well grounded system.

The attainment and robustious of the industrial pollution monitoring and control system can further be improved by implementing sensors for controlling pollution level thereby improving the industrial and natural environment. The blynk local server and android app contributes quick response rate and the diffusion of the critical situation can be made faster than the manual methods.

ACKNOWLEDGMENT

I, S.Ramalingam and Co-Author D. Kalaiarasan of this paper are thankful to Dr.K.Baskaran, Professor and HEAD EEE Dept. Alagappa Chettiar Government College of Engineering and technology, Karaikudi, Tamilnadu, India, for their valuable guidance and continuous support and for being a constant source of inspiration. And we are also thankful to our beloved friends for their huge motivation.

***Abstract*—- In the current era of internet, with continuous flow of information to web, it is a difficult task for a user to choose the right information. Information belonging to analogous type is provided by diverse service providers and it is a challenging to diagnose the reliability of information. This paper implements a framework to determine the reliability by calculating credibility value of each web portal through analyzing information published, link details, spam details of information available and updation details of web portal. Credibility score is assessed by evaluating page rank value, black list web sites, average number of hits of different pages, two quality factor values trustworthiness and timeliness. Web crawler gives page link details of varied number of web sites based on the query given by user. Finally, web sites are ranked and listed based on the credibility of web portals, which ease the job of users in assessing reliability of information available in internet.**

Keywords*—Credibility, Web crawler, Content analysis, PR, Trustworthiness, Timeliness, Spamhaus, Blacklist.*

I. INTRODUCTION

Credibility is simply the capacity of belief. The credibility convinces users that they have reached Web site that provides useful information. Websites create an interesting challenge in evaluating credibility because no two websites are created the same way. There are many factors that lead to large volumes of non-credible and unreliable information which are published on the Web [2]. With the fast progress in technologies in the web services, there is an outflow of information to the web [4].

Internet plays a vital role in every field and it has become a part of every human beings life. Everyone depends on internet for information which helps them in different ways. In case of students, they rely on internet for education purpose, for their research, seminar and so on [9]. Internet has both advantages and disadvantages. One of the main disadvantages is that it sometimes provides low quality information, which user is not bothered about. There is a continuous flow of information to the web within minutes which can be both fake and real ones. As of now web size is bigger, hence most of the times we may not know which websites gives abstract reliable information [5]. For that we need to analyze the web links and the details provided by the service providers.

There are many research methods available in the present web-based search process to find the credibility of a web pages, which reveals the existence of real and valid information. Details of the web page like author's biodata, spelling and grammar mistakes, sites blocked by firewall, contents blocked and so on are considered as the main factors which the user can easily check to find out whether the web page is a credible one or not. But, still there are other quality factors such as consistency, trustworthiness, timeliness, completeness to find out whether a webpage is credible or not. So, here in our research work, we show the credibility value by considering few factors such as timeliness, trustworthiness, page rank value, and check whether a domain is blacklisted or not.

In this research work we focus on providing the best quality results to the user by assessing content credibility with quality factors of web sites since credibility is an important factor [1]. Initially, when a search request is given by the user [10], the set of web sites are identified based on the request. Web Crawlers are used to find web sites and the link details of the different pages in those web sites. The link details are used in the page rank calculation. The quality factor timeliness is assessed based on the last updated date and the trustworthiness of web site is assessed based on spam word count along with black listed web sites details. All the above calculated values are aggregated to get the credibility of the web sites which is used to rank web sites. Finally, web sites with highest rank are displayed as search results which provides a highly reliable information to end users.

The remaining section of this paper is defined as: Section II analyses the related work. Section III explains the proposed system methodologies. Section IV displays the results. Section V completes the paper with a brief conclusion.

II. RELATED WORKS

This section of the paper shows the researches and works that have been done relating to the assessment of web content credibility. In various surveys, different methodologies have been presented and compared several approaches towards the calculation of content credibility.

In the paper *Credibility Evaluation based on deep learning*, the assessment of credibility is based on Deep Learning Algorithm. Nowadays, Credibility of a recommendation system

is given prime importance. [7] Due to high recommendation system in the e-commerce platform, there are chances of false information getting added up in the system by the network intruders.

In 2014, Liu Shengzong and others proposed a new recommendation algorithm taking both the user credibility and similarity into account [7]. They analyzed the three main credibility factors, such as the adoption rate of the user's evaluation, the correctness of the scores and the number of scoring, and then established the relationship between the credibility and the three factors. The result obtained was that the analysis has limitations on assessment of user credibility and cannot evaluate effectively all around. Hence the traditional credibility assessment algorithm cannot assess the user credibility accurately.

This made to propose a new credibility algorithm based on Deep Learning Algorithm and the average user reliability value as a criterion, a second assessment of the credibility is applied to other users, the results of which are arranged in ascending order [7]. The result was that it removed suspicious user ranking and created a trustful adjacent group target user. The accuracy of the recommendation system was improved, and the risk coefficient of the recommendation system were also reduced in the later experiments.

The *PageRank algorithm using Markov Model and Hidden Markov Model* are used to rank websites in the google search engine. Markov Model gives a robust probability contraption to characterize sequential data. In this model, the user selects the webpage and based on the incoming and outgoing links of that webpage, ranks are determined. Hidden Markov Model is a simple way to model sequential data and finds its application within mapper/reducer. PageRank is one among the link analysis algorithm. In this algorithm, the probability distribution is between 0 and 1 [3]. It returns the importance of a webpage based on its rank whenever a search is performed by the user. Markov Model was also used to find the score of each site using the concept of Markov chain. It predicts the behavior of a state that transits from one state to another state and considers only the current state which contains all the future information.

Markov Model is a mathematical system model that predicts a probability distribution associated with the current state. [3] This model is defined by a Markov chain in which page *i* will be the probability in a stationary distribution on a Markov Model on all web pages. The transition states are considered as webpages and theoretically Markov chain means the certain fraction of time the surfer chooses a random page from the web. Hence Google search engine uses Markov chain to deal with random surfers by ranking the pages [3]. Hidden Markov Model deals with solving problems like encoding, decoding and training. The model has hidden and observed states where the observed states are given with the outputs and hidden states are to be determined. This model can also be used to find the score of each page for returning the page according to their importance. Therefore, the study has found out that the search engine uses Page rank algorithm and Markov model for determining the score of the page in web server and have implemented the HMM (Hidden Markov model) for map reduce function or for distributed sorting of data.

In the research *Understanding and Predicting Web Content Credibility using the Content Credibility Corpus*, they created a predictive model of Web content credibility evaluations, based on human evaluations. Based on a large dataset of Web content credibility evaluations, using text mining and crowdsourcing techniques, a comprehensive set of factors that affect credibility evaluations was derived and therefore it was used as labels in interfaces for rating web content credibility [2]. The impact of each factor was analyzed based on credibility evaluation scores. Based on the newly identified factors, a predictive model for Web content credibility was proposed. The model can be used to determine the significance and impact of discovered factors on credibility evaluations. These findings can guide future research on the design of automatic or semi-automatic systems for Web content credibility evaluation support.

In the paper *Websites and Webpages Credibility and Trust Evaluation*, the elements required to evaluate Websites and pages credibility are based on Website, Web pages, and authors credibility metrics are evaluated. This research aims to study the credibility of web pages by interpreting the credibility guidelines into several measurements [16]. The credibility is studied from three perspective, they are: - Domain or website will be measured in terms of domain age, number of indexed pages in various search engines such as Google, inlinks, outlinks, number of broken links, website size, number of authenticated pages, trust rank, and so on. Web page/file: each web page or file will be measured in terms of freshness, popularity, trust, inlinks, outlinks, and age. Author: the authors will be measured by number of citations and for example the number of indexed pages in Google.

Our work focuses on ranking of web sites based on credulity factor of web sites. It is calculated based on the link, content details and quality factor evaluation. Credibility assessment helps to enhance the search results by ranking the web sites to provide the list of reliable websites to the end users.

III. METHODOLOGIES

In the general search scenario, search results are based on the content matching of the text provided with the already existing web resources. Optimized text matching algorithms are used to select relevant resources, but it is highly essential to assess the reliability of the information provided. Otherwise, users will be misguided by the fake information provided by fraudulent web sites. So, calculating the credibility of a website is very important because it can produce huge benefits to end users.

The goal of our research work is to provide reliable information that can be both trustworthy and knowledgeable related to the users search [6]. In the search page implemented, whenever a user searches something, it will display results based

on the credibility score. To check credibility of a website, three important modules are implemented i) Site link extraction using web crawlers. ii) Predicting Page Rank value iii) Calculating two quality factors. Quality factors Timeliness and Trustworthiness are considered to determine the credibility of a website to produce better results.

PageRank algorithm is implemented with link and hit count details of the web pages. User can input a keyword and the crawler works in behind fetching webpages to show up in the search result. In the process of initial web site selection process, it considers only the exact text matching feature. Then, for each website, PageRank score is calculated based on the number of incoming and outgoing links, number of hits is calculated based on the clicks the user gives to a website. The two factors are calculated by checking the number of spam words in the content, identifying whether the website is blacklisted or not and checking the last updated date of the website. All these values will account to give the final credibility score of a website. The credibility score is displayed along with the search result, so that the user will have better understanding about the website content.

A. Site Link Extraction Using Web Crawler

Web crawling is a process of finding information from millions and trillions of webpages. The crawler browses the World Wide Web to retrieve webpages related to the search. From the fetched webpages we can determine the number of inbound and outbound links. The links which show up in the search results are stored in the database for further processing. The implementation details of the web crawler invoked when a search query is given by the user is explained as follows:

Algorithm for Web Crawling

Input: Data user wants to search for.
Output: Indexed Links crawled from Google.

i. Input a keyword to search.
ii. Using the source URL to crawl the web page
iii. Fetching content of the webpage for the corresponding search
iv. Extracting outgoing links from the page
v. Crawling the new pages
vi. Duplication of links are avoided
vii. URLs are maintained in a database

B. Predicting Page Rank value

PageRank algorithm was found by Lawrence Page and Sergey Brin which is used to rank webpages based on inbound and outbound links. Page links details stored in the database for a search results are retrieved, and page rank value is calculated. For each page a corresponding rank is obtained. Inbound links means the number of external links that point to the corresponding webpage. Outbound links can be defined as the number of links pointing to the external webpage. The value of inbound and outbound links of each domain is calculated and displayed distinctly. A transition matrix is simulated to output the final probability distribution. Adjacency matrix is given as input and can be calculated using a simple iterative algorithm. The importance of each page depends on the rank of the inbound page to it. The more inbound links, the more weightage the webpage have. This output is considered for further calculation.

Algorithm for Page Ranking Algorithm

Input: Details of webpage which user search for.
Output: Page Rank Value for corresponding webpages.

i. Identify the web domain for which page rank value is to be calculated.
ii. Identify the number of outgoing links and incoming links
iii. Apply the page ranking formula for the corresponding inbound and outbound links
iv. $PR(p) = (1-d) + d(PR(Ti) / C(Ti) + \ldots + PR(Tn) / C(Tn))$ where p is the page for which page rank is to be calculated, d takes value between 0 and 1, T_i represents the page directed to page p, PR( ) represents the page rank value, C( ) represents the number of outbound links.
v. Repeat the steps 1-4 for 'n' the number of pages.

Thus, page rank value for each web site is calculated which is used for final credibility calculation.

C. Calculating Quality Factors

Next, in order further improve our work we consider two quality factors such as trustworthiness and timeliness.

1. Trustworthiness: Trustworthiness of a web page basically means truthfulness of information provided in the web page. There are many alternatives to check whether a page is trustworthy or not. To calculate the trustworthiness value, we use two parameters- number of spam words and check whether the domain is blacklisted or not.

i). Find the Spam Count: Spam words are those words which are unsolicited and bulk words, for e.g.: - profit, discount and so on. The meta tag of each web page is parsed and the number of spam word is counted.

ii). Check whether a link is blacklisted or not: To check whether the link is blacklisted or not, we use the spamhaus.org. *Spamhaus* is an ISP (Internet Service Provider) which allows the distribution of the spam web pages. So, if a link is present in the sbl- xbl blocklist it means that the web page is blacklisted. Sbl-xbl is a database of IP address of the blocked list. Blocked list means those service providers are providing infected information or they are considered as spammers proving false information to misguide the end users. Thus, it is

easy to identify whether the web page is trustworthy or not. Untruthful pages could be omitted, and only valid reliable pages should be considered and given high credibility scores.

2. Timeliness: Timeliness is the second quality factor which means the last updated date. In this fast-developing era, 90% of people all over the world seek for latest information. So, it is necessary to bring the latest information is to them by providing the recently updated webpages related to their search. This can be done by finding out the date when the corresponding web domain was recently updated. There are different methods to figure out. One of the methods that we implemented is using the *Whois* API, where all the details of each webpage is stored. From this API, we can retrieve the last modified date of the webpage and the established date of that corresponding webpage. Later, the dates are ranked which helps user to identify the last modified webpage more easily.

D. Credibility Score Calculation

All the above parameters calculated in the above modules are considered for credibility score calculation. Page Rank values are considered and pages with higher values are given good ranks. The spam count is considered and if the spam count is in the minimum threshold range they are given rank 1 otherwise bad ranks are given. In the similar manner, recently updated web sites are given good ranks than other pages. Then, credibility score CS of web site i is calculated as:

$$CS(i) = PR(i) + D(i) + H(i) + S(i)$$

where PR is the page rank of the webpage, D is the rank based on the last updated date of a webpage, H is the number of hits of each webpage in the system and S is the output spam rank. The output credibility values $CS(i)$ is used for the final ranking of the web sites. The search results of the given query display the web sites only based on that ranking. Thus, the research work produces the list of web sites which provides only reliable information more valuable to the end users.

IV. RESULTS

Our work focuses on credibility score calculation after finding the value of page rank and quality factors. For computation of quality factors and page rank implementation, the dataset with the number of inbound links, outbound links of a specified set of web sites. Timeliness and Trustworthiness value of those web sites are also calculated using the predefined existing API's. Timeliness value is the output date rank which is ranked on basis of last modified date and the Trustworthiness value is the output spam rank which is ranked on basis of the total count of spam words present in different pages of the web site. Web sites with higher spam count is given worst rank as they provide unreliable and fake information. We consider the following websites for evaluation of credibility value: -

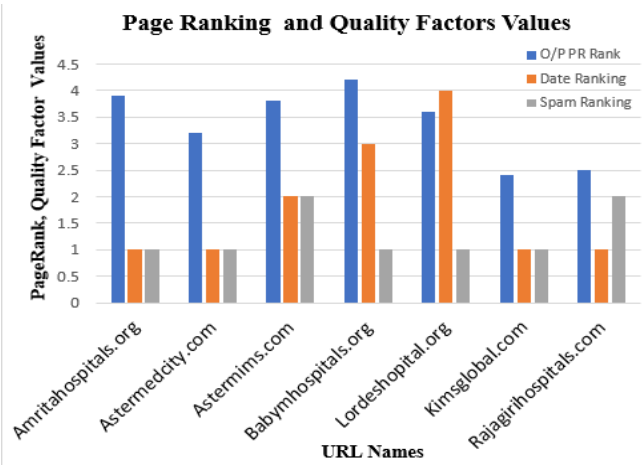
TABLE 1 : WEBSERVICES AND CORRESPONDING WEB PAGES

WEB SERVICE	*URL NAME*
ws1	Amritahospitals.org
ws2	Astermedcity.com
ws3	Astermims.com
ws4	Babymhospitals.com
ws5	Lourdeshospital.org
ws6	Kimsglobal.com
ws7	Rajagirihospitals.orgs

TABLE 2 : SAMPLE OUTPUT OF PAGERANK ALGORITHM AND QUALITY FACTORS CALCULATION

URL	Inbound Links	Outbound Links	Output Page Rank	Last Modified Date	Output Date Rank	Total Spam Count	Output Spam Rank
ws1	15	601	3.9	24/05/2019	1	62	1
ws2	16	526	3.2	24/05/2019	1	76	1
ws3	14	381	3.8	11/12/2018	2	82	2
ws4	14	174	4.20	28/02/2017	3	65	1
ws5	14	716	3.6	18/03/2016	4	73	1
ws6	13	631	2.4	20/05/2019	1	74	1
ws7	11	863	2.5	09/01/2019	1	90	2

Table 2 defines the rank for each web service based on factors that we have considered. To calculate the output page rank, number of inbound and outbound links are considered. The more inbound links, the more weightage the webpage has. Last modified date is extracted from the Whois API, and hence the output date rank is determined. The output spam rank is calculated based on the total spam count. If the spam count is between 0-80, rank will be initialized to 1, if the count is between 81-100, then the rank will be incremented by 1.



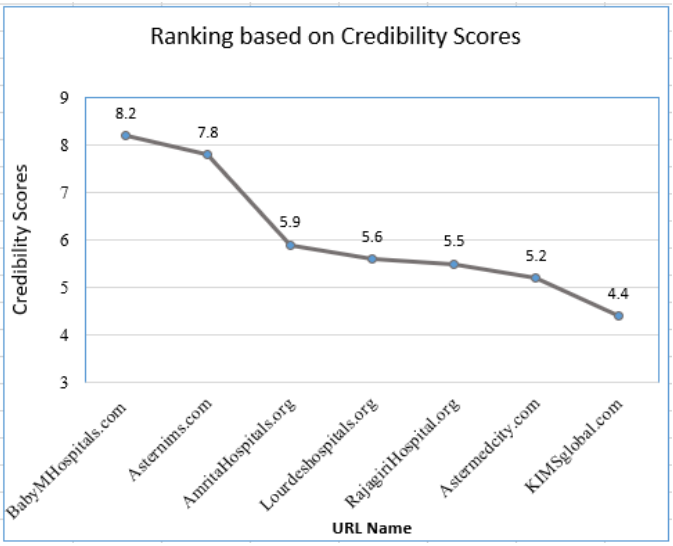
(Fig 2)

In Fig2, the graph represents the ranking of each web page depending on their output page rank, date rank, and the spam rank. Each ranking is done within a range, i.e. from 1-5.

TABLE 3 : INTERMEDIARY RESULTS USED FOR THE CREDIBILITY CALCULATION

URL	***OUTPUT PAGE RANK***	***OUTPUT DATE RANK***	***OUTPUT SPAM RANK***	***FINAL SCORE***
Amritahospitals.org	3.9	1	1	5.9
Astermedcity.com	3.2	1	1	5.2
Astermims.com	3.8	2	2	7.8
Babymhospitals.com	4.2	3	1	8.2
Lourdeshospital.org	3.6	4	1	5.6
Kimsglobal.com	2.4	1	1	4.4
Rajagirihospitals.org	2.5	1	2	5.5

Fig 3 shows the ranking of web sites based on the final credibility score of each web site in the increasing order. URL ID is considered along x-axis and the Credibility score is displayed along the y-axis. Web sites with high credibility score is given best ranking.



(Fig 3)

Thus, the research work is able to rank the web sites based on the credibility value and display them as the search results for query given by user. User is delivered with the links of web sites which provided reliable information as fradualent and fake site are removed and pages which are highly refered are given more weightage.

V. CONCLUSION

Present internet era demands for extensive research work to identify the best web site from among the huge amount of similar web sites to provide reliable information. Reliability is assessed through varied measures like trust worthiness of the service providers, quality aspects provided by services and so on. This paper describes the framework for calculation of credibility score with the following aspects of web sites: link details, spam details, black list, trustworthiness and timeliness of web sites. Web crawlers and page ranking algorithm is used for determining the rank of web sites. Trustworthiness and Timeliness of web sites are also calculated as users gives more importance for them. Then, credibility score is calculated using the aggregation of all the above factors, which helps users to identify the most reliable web site. In future the credibility assessment of other quality factors like completeness, durability and integrity could be done to further enhance the website ranking.

ACKNOWLEDGMENT

First, we thank the Chancellor of Amrita Vishwa Vidyapeetham, Sri Mata Amritanandamayi Devi, for her love and blessings. We are extremely thankful to Dr. Subbulakshmi S, Assistant Professor, Department of Computer Science and Applications, Amrita School of Engineering, Amritapuri for her primary support throughout the project. We also express our sincere gratitude to all the Faculty members of Department of Computer Science and Applications, Amrita Vishwa Vidyapeetham, Amritapuri for providing help and guidance.

***Abstract* — Two Stage Sample and Hold Circuit: In first stage, two-identical sample and hold circuits are connected in cascaded topology. In second stage, the output from first stage of sample and hold circuit is rectified again and the current conveyor is used as a switch which is controlled by the bias current pulses. Both the stages of sample and hold circuit are synched with each other and operate at same bias current with low power consumption. The features of proposed circuit has more accurate results with high linearity as well as more flatter output output waveform at the hold time. The proposed sample and hold circuit has been simulated using 0.18 µm complementary metal oxide (CMOS). The major interest is the simulation of an analog switch used in the circuit.**

Keywords* — *Sample & Hold Circuit, Current Conveyor, Low Power Consumption, Analog Switch.

I. INTRODUCTION

In electronics, all signals get processed in digital format as they are easy to store & transfer but in the physical world every single signal get processed in analog format and so comes the job of an electronic engineer who knows how to convert analog signal into digital signal with more efficiency in order to store and convey the information present in the signal from one place to another. For converting analog signal into digital signal, sample and hold circuit [1] is used. It create the samples of input voltage and hold these sample for definite time. Current conveyor [2] is used for its high frequency application and fast switching ability. Analog mixing stages and analog to digital converters are often needed between the antenna and the digital circuitry in various systems hence sample and hold circuit [3] is used in data conversion systems.

Sample and hold circuit is also used in the De-glitcher circuit to avoid the noise in signal and in analog de-multiplexer. Operational amplifiers do not perform adroitly when output current signal is required and therefore, application of current conveyor circuits comes into play as they operate without any global feedback, and also, they show different high frequency behavior results in comparison to operational amplifier circuits.

Proffered sample and hold circuit is controlled in two phases of clock. In first phase of clock, it tracks the input and in second phase, it holds the input. The circuit uses a square wave as a clock signal. Also, charge injection, pedestal error and aperture jitter etc. are some indubitable errors that are witnessed in a S/H circuit . Nowadays, sample and hold circuit is extensively used in biomedical systems. In this circuit, second generation current conveyor (CCII) [4] is used because it has one high and one low impedance input rather than the two low impedance inputs of first generation current conveyor. Current conveyor circuit is a three port network X, Y and Z. Second generation current conveyor can easily be used to process both current and voltage signals. CCII has two outputs Z+ and Z-. In Z+ pin, direction of current is same with X terminal and opposite with Z- pin. In the proposed circuit, current conveyor is used as a switch in sample and hold circuit. When CCII is used as a switch, a clock pulse is given, at low level of clock, voltage is transferred from Y terminal to X terminal and current is transferred from X terminal to Y terminal but at high level of clock, all pins go in the high impedance level. In two stage sample and hold circuit, output waveform is more accurate when compared with mono stage because in first stage, input is continuously varying which results in variation of output at the time of holding but in two stage, variation is less at the output of first stage which results in more flat output during holding time. Clock is given simultaneously for both the stages and synched with each other, hence both the stages operate simultaneously which in turn means they track and hold in same time.

Proposed circuit has highly efficient and desired results when compared with previous circuits in the data conversion system.

II. BASIC STRUCTURE OF CCII

Second generation current conveyor is different from the first generation conveyor in the manner that the There is no current flowing into Y terminal because terminal Y is a high impedance port while Z terminal is current output and X terminal is voltage input in CCII. So therefore unlike first generation current conveyor, CCII can easily be used for both current and voltage signal. Two type of conveyor present in CCII negative and positive. In positive conveyor, current direction of output terminal is same as that of input terminal but in negative conveyor, current direction of output terminal is opposite to that of input terminal. Both type of conveyor's symbol are shown in FIG 1.

The matrix representation of second generation current conveyor is

$$\begin{bmatrix} I_y \\ V_x \\ I_z \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & \pm 1 & 0 \end{bmatrix} \begin{bmatrix} V_y \\ I_x \\ V_z \end{bmatrix}$$

In CCII voltage appear at terminal X is same as voltage appear at terminal Y act as a voltage follower and current

flowing in terminal Z is same as flowing in terminal X act as a current follower, connected together.

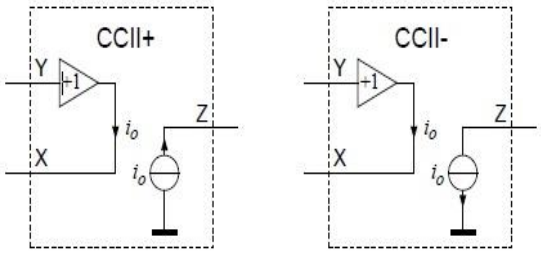

FIG 1: *Symbol representation of CCII+ and CCII-*

In sample and hold circuit, current conveyor is used as a switch which is administered by a current pulse. The operation of switch is to pass signal from one terminal to other terminal in a more methodical way without substantial signal loss. Hence, current conveyor passes the signal with minimum loss as well as it controls the signal when it passes through it.

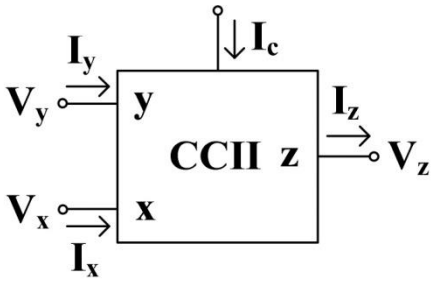

FIG 2: *Symbol of CCII with Bias current*

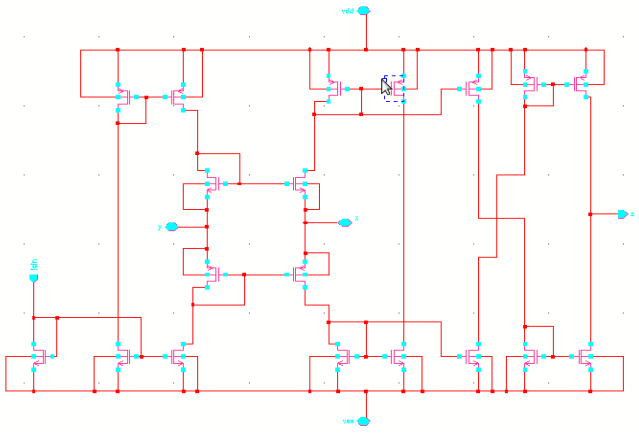

FIG 3: *schematic of CCII*

Current conveyor mainly depends on the current mirror circuit which plays a pivotal role in following the current as well as voltage between the terminals. Current mirror is used in this circuit due to which current will be identical in multiple branches and this current passes with same impedance of MOS. Hence voltage between the MOS terminals will also be same. Bias current is controlling the flow of current as it is controlling the MOS through which it is flowing. In FIG 2 Symbol of CCII with Bias current is shown and its schematic is shown in FIG 3 which is made up with NMOS and PMOS.

III. PROPOSED CIRCUIT

Sample and hold with two stages is simply cascaded two single stages where second stage rectifies the output of first stage. In single stage one CCII, one capacitor and one resister are used. Here, capacitor simply stores the charge at the time of holding and resister is used for timing constant along with the capacitor. CCII works as a switch which controls the switching for tracking and holding time. For switching timing, quiescent current is rendered in the form of current pulses.

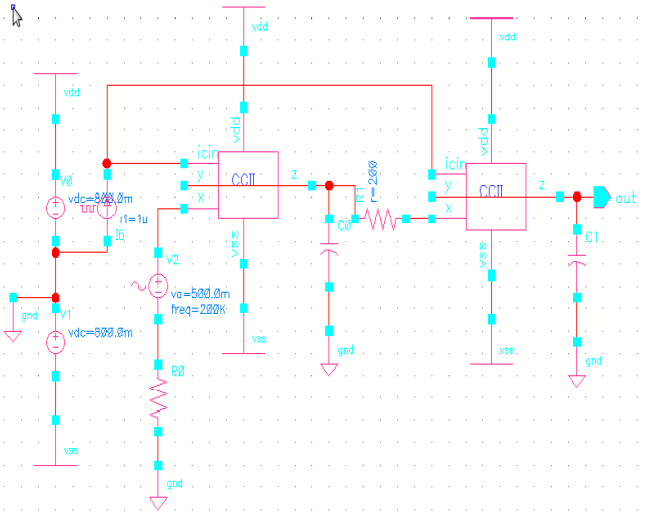

FIG 4: *Schematic of proposed circuit*

Same quiescent current is given for both CCII so that they can hold and track simultaneously. Schematic of proposed circuit is shown in FIG 4. Here, output of first stage is given to input of second stage which rectifies the output of first stage. Both stages are synched with same clock pulse because same input passes through both the stages. Hence, delay should be minimum for both the stages. Here, we cannot have high value capacitor because as we increase the value of capacitor, output of sample and hold circuit will decrease. If we again rectify that output from same circuit, output will be flatter compared to previous outputs. In first stage, more variations are present in the input at the time of holding the signal because of which output of first stage is not flat and capacitor discharges quickly. In second stage, at the holding time, less variations are present in the input hence, output is flatter compared to output of the first stage.

For more canonical results, we can increase the number of stages but the complication with the increment is that as the number of stages increases delay increases and because of increased delay, stages are not synched with the clock. For this reason, cascading of more stages is not possible but in two stages, results are more accurate. At the time tracking, gain of the CCII is approximately unity, so same voltage is transferred from X terminal to Z terminal. CCII is used as a voltage follower if we short terminal Y to terminal Z because voltage of X terminal is same as of Y

terminal and Z terminal has low impedance, so it is used for current driving.

Output of two stage sample and hold circuit is influenced by sampling frequency f_c (f_c=1/ t_c) where t_c is the time period of current pulses, where current pulses are used as a clock for CCII. Output of the circuit also depends on the time constant τ which is multiplication of the R and C (τ = RC) so, at the final output both the time constants are present.

Time constant for first stage is

$\tau_1 = R_1C_1$

Time constant for second stage is

$\tau_2 = R_2C_2$

So, time constant for final output is

$\tau = \tau_1 + \tau_2$

At the output of second stage, capacitor slowly discharges because time constant increases and output is more accurate compared to first stage output.

Then output voltage can be written as

$V_{out} = V_{in}(1- e^{1/\tau f})$

Output is dependent on time constant (τ=RC) and sampling frequency because the holding time change due to change in the sampling frequency.

IV. NON-IDEAL EFFECT

In previous circuit, all results are contingent on ideal parameters but parasitic is contemplated, all parameters will vary because every circuit has its own resistance and capacitance and at high frequencies, it will come in effect. Parameters of CCII also changes when changed parameters are taken into consideration and the matrix no longer contains unique zeroes and ones. Thus, new matrix representation will be

$$\begin{bmatrix} Iy \\ Vx \\ Iz \end{bmatrix} = \begin{bmatrix} Yy & Air & Gmr \\ Avf & Zx & Avr \\ Gmf & Aif & Yz \end{bmatrix} \begin{bmatrix} Vy \\ Ix \\ Vz \end{bmatrix}$$

Where A_{if} and A_{vf} are the current forward and conveyor voltage gains respectively, near to unity and A_{ir} and A_{vr} are the current reverse and conveyor voltage gains respectively, near to zero. Y_z, Z_x and Y_y are the limited terminal impedance and admittances. In certain applications, the trans-conductance G_{mf} from terminal Y to Z is significant, although the reverse trans-conductance G_{mr} seldom has any effect on the circuit behavior. If the current and voltage gains errors are taken into consideration, (3) can be rewritten as

$$V_{out} = V_{in}\ (1 - e^{1/\tau_n f})$$

Where $\tau_n = (R+R_x)(CC_x)$, R_x is the parasitic resistance and C_x is the parasitic capacitance.

In simulation result, we got resistance value as approx. 500KΩ and capacitance as 10fF. Here value of resistance is high so, it will be taken in to consideration. In ideal case, both should be less otherwise at the time of tracking, the circuit will be prone to errors.

V. POST LAYOUT SIMULATION

Two stage of sampled and hold circuit has been simulated on Cadence Virtuoso. QRC extraction has been also evaluated and compare results with the schematic results. Zero DRC error and zero LVS error with the comparison between results without QRC and with QRC have less variation. In post layout simulation utilize the minimum area with minimum parasitic effect. After post layout simulation GDS file has been generated with same output waveform in both the results. Area of the layout is 2269.6598 µm square.

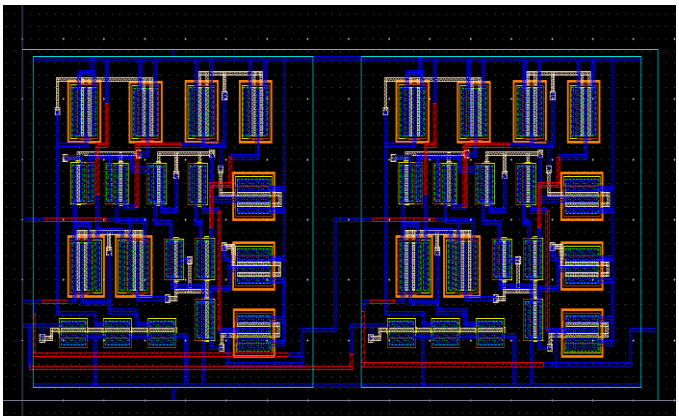

FIG 5: Layout of Proposed Circuit

VI. SIMULATION RESULTS

In this proposed circuit, all PSPICE simulation is carried out in cadence virtuoso and 180nm technology. All files are taken from gpdk180 library. The aspect ratio of NMOS is 300nm in length and 3µm in width and aspect ratio of PMOS is 300nm in length and 8µm in width. Power supply voltage is ±0.8 volt and peak to peak output voltage is 0.6 volt.

Value of biased current is 1µA and given in the pulses form with period of 1µs. This biased current, control the whole scenario as well as control the time of sample and hold period. When I_c is 0µA (Logic 0) then no transition of input to the output and this condition is called hold condition, at that time maximum resistance offering at the input by the circuit of 500KΩ. This condition is shown in FIG 7 where input is in sinusoidal form but out is straight line and output voltage is approximate zero. When I_c is 1µA (Logic 1) then transition of input to the output done without any loss because at that condition circuit offering low resistance approximate 1KΩ.

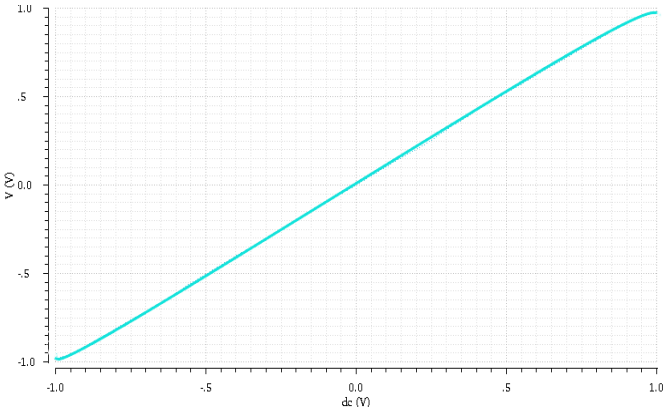

FIG 6: DC Transfer characteristics of CCII

DC transfer characteristic of CCII is shown in FIG 6. It shows the change in output voltage with respect to the change in input voltage which is depicted by the linear curve. Where input voltage is varied from -1V to 1V, output voltage varies from -0.98V to 0.98 V.

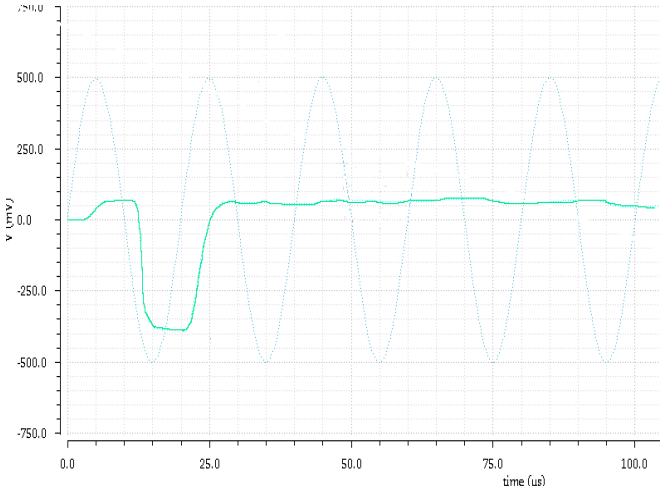

FIG 7: Output wave at hold condition

For sampling and holding the signal, sampling frequency of 1 MHz is applied to the circuit which is shown in the below FIG 8 , where, at high level of clock, it holds the signal and at low level, it tracks the input.

Output waveform is shown in FIG 8, where one is input wave and other two waves are output of the first stage and second stage. At the time of holding, output of first stage is not flat, at that time capacitor discharges quickly but in the second stage output is flatter and capacitor discharges slowly, time constant is 45µs which is calculated by external and parasitic capacitance and resistance.

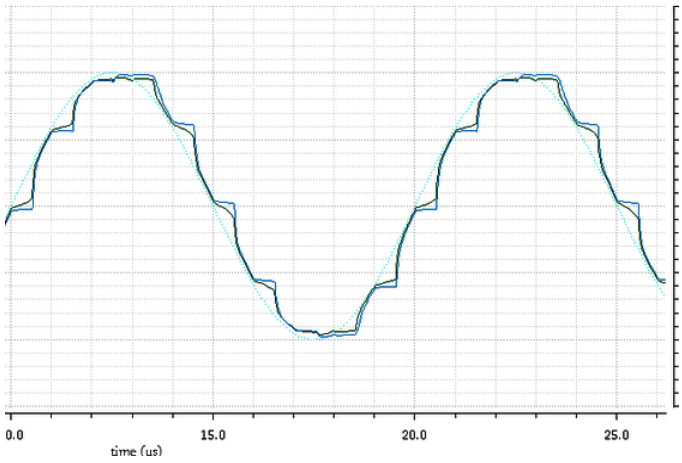

FIG 8: Output waveform

Total Harmonic Distorortion (THD) is -45 dB at clock frequency of 1MHz and V_{p-p} is ±0.8 V which is shown in FIG 9. All parameters are calculated at 100kHz input frequency.

TABLE I. COMPRASION TABLE BETWEEN PROPOSED CIRCUIT AND PREVIOUS CIRCUITS

Parameter	This work	M. Kumngern [4]	Chatterjee et al [5]	Ferreira et al [6]	Swigun et al. [7]

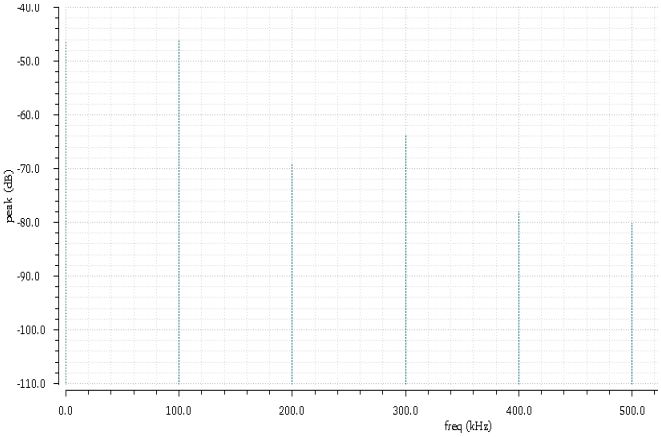

FIG 9: Total Harmonic Distortion

VII. CONCLUSION

Two stage sample and hold circuit is proposed in this paper where efficient and desired output is delivered by the current circuit compared to previous circuit. When two stage is used in the circuit it effects the output waveform at the time of holding. In this proposed circuit used the current conveyor as a switch and that circuit is offering the less power as well as increase the speed of the circuit. Main work of current conveyor is switch and minimize its effect on the circuit expect the switching. The circuit shows more flatter output at the hold time when compared to any other circuits which in turn increases accuracy in the digital form. Layout of that circuit also need the minimum area as well as effect of the parasitic is minimum so change in the results is minimum. The proposed S/H circuit offers high-speed, high linearity and is free of non-over lapping clock signal requirements.

***Abstract*— The most important factor to increase knowledge is to share what is learned. This approach of sharing what is learned is incorporated in robotics so that the robots can solve day to day problems by learning when required. The proposed knowledge interchange format (KIF) deals with communication amongst heterogeneous robots through the cloud. Keeping in mind the size of data, the emphasis has given to generate a representation of the path for robots that can be processed parallelly and saved in the cloud, enabling the sharing of knowledge between robots. In order to achieve this compatibility, a path as a set of characters or a string is considered with a convention that is predefined so that no matter how much the robotics evolves, it can always interpret a string. The string is tested in a Hadoop map-reduce program to process the paths parallelly and provide the best path from the cloud.**

Keywords—knowledge interchange format, cloud ,heterogeneous robots, hadoop map-reduce.

I. INTRODUCTION

The impacts of automation technologies are already being felt throughout the economy [1]. The worldwide number of industrial robots has increased rapidly over the past few years [2] . The falling prices of robots, which can operate all day without interruption, make them cost-competitive with human workers. In the service sector, computer algorithms can execute stock trades in a fraction of a second, much faster than any human. As these technologies become cheaper [3] , more capable, and more widespread, they will find more applications in an economy driven society.

Over the years, internet has been providing many updates of the programs running in personal computers and servers. Internet had also enabled people to share and obtain certain information through the vast information stored in the World Wide Web (WWW) [4]. With the introduction of Distributed Computing, computers started expanding their resources like memory and processing power by pooling from many computers participating in the system. The cloud computing technology took a leap forward by facilitating devices to use storage and computing capability which are connected to use it [5]. As a result devices smaller and lighter with low power for its operation started depending on cloud. Cloud provides processing power to these devices thereby reducing the cost of processing power and decreases the time of execution for getting quick result [6]. The power consumption for these devices becomes lesser since it takes lesser time in processing.

Cloud facilitates connection of billion new devices to it [7] [8]. Due to rapid growth of electronic devices in recent time, there are also various mobile operating system (OS) developed to run those devices. Operating system like android OS (Google Inc.), bada (Samsung electronics), blackberry OS (Research In Motion), iphone OS/ iOS (Apple), palm OS (Garnet OS), symbian OS (Nokia), web OS (Palm/HP), windows mobile (Windows phone) are few mobile operating system commonly used for mobile devices [9]. Besides, with the evolution of internet of things (IOT) recently, small devices with different platform are also able to connect and talk to each other through cloud [10]. As cloud provides platform for devices likewise robots with less processing power will not only be able to communicate each other but also share knowledge base redundant data through cloud.

II. REALATED WORK

Since there exist a variety of robots with different types of hardware, robots use different robotic platforms. This is one of the main reasons why it is difficult to write software for robots and share the data when they are connected with cloud. With the motive to simplify the task of creating complex and robust robot software behavior across different platforms, robots operating system (ROS) an open source framework was developed [11]. Motive of ROS was to meet the set of challenges that where encountered while developing service robots as part of projects like Stanford AI Robot (STAIR) and the Personal Robots (PR) program [12] [13]. ROS being open source has contribution from different communities many new tools and libraries are updated. Still there are lots of people who are against the use of ROS [14] [15]. Reasons being, lack of support for some packages. Libraries are written and shared whenever there is a need for such libraries but failed to maintain bugs free, making it obsolete after a certain period of time ultimately. Still, the programs for robots are dependent highly on the hardware on which the robot is based. Hence reusing of program code across varied platforms is difficult [16] [17]. The lack of standard interfaces [18] [19] [20] [21] to robot hardware components also continues to be a great challenge in all areas of robotics.

With a well define knowledge interchange format (KIF), ontology can be used to develop a new generation information system [22] [23].Thus it may help merging and mapping of the information from different data source and preparing them in such a way that end user can use it. The same concept can be deploy in the field of cloud robotics where robots can interact with each other and enables robots to share and reuse their existing information/ knowledge [24] [21].

III. METHODOLGY

A Knowledge Interchange Format (KIF) [25] is designed for the interchange of knowledge among different computer programs. Typically, when a program reads a knowledge base in KIF, it converts the data into its own internal form of specialized pointer structures, arrays, etc..and all computations are done using these internal forms. When a program needs to communicate with another program, it maps its internal data structures into the common format viz; KIF through which the other computer communicates. Thus it can also be used for exchange of knowledge between the robots of different architectures. Hence a Knowledge Interchange Format (KIF) plays a vital in enabling the robots of different hardware to interpret a common format easily without much complexity, even in case of robots with lesser hardware configurations. Though there are several ways of representing knowledge interchange format for robots as mentioned in [27] [28], a parametric representation which deals with the low level representation is considered for masking the heterogeneity to an extent.

The knowledge is a 'map representation' in the form a continuous variable string representing a path taken by robot. Considering a robot takes only left, right, back or front, a representation of the path is discussed below.

The general format of the variable string considered in this study is:

[Distance/Angle] [Direction].....[Stop]

An Example: 30R90L45RS will cause the robot to move 53 cm distance on Right,, than take 90 cm Left, 45 cm Right and S is delimiter for stopping the robot as shown in figure 1.

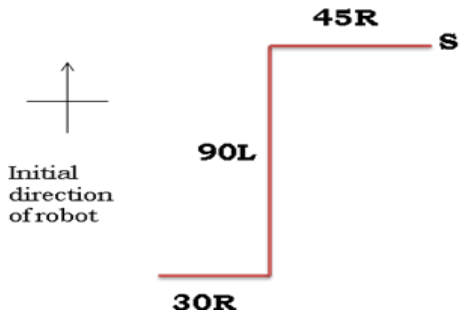

Fig. 1. Path map representation using continous variable string.

When the path gets stored in cloud, the destination and source gets added at the front of the string and all the intermediate nodes are added so that the string will look like

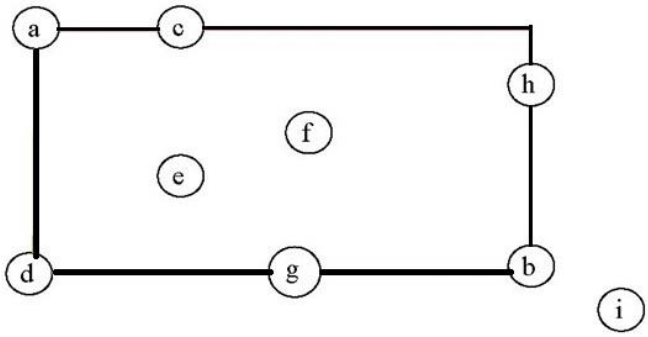
ab|50Lc60B40Rh30FS|

where,

ab= source destination pair

|= delimiter

A score/weight is added after the last delimiter '|'to assign or choose the likeability of paths. The integer value represents the distance.



IV. IMPLIMENTATION

A. *Testing in Hadoop MapReduce*

To explain the environment with different stations and paths, an example with destination 'b' and source 'a' and two paths is shown in Figure 2, wherein the String 55Rc105F15Rh55FS represents one of the path from 'a' to 'b' marked by the thin line while the String 70Bd100Rg55FS represents the other path from 'a' to 'b' marked by the bold thick line.

In the bold thick line of Figure 4.1, the source is 'a' and the destination is 'b', and 'c' and 'h' are two intermediate nodes. There might be situations where robots need the path from 'c' to 'h', so it becomes necessary to list the intermediate nodes in the representation. The details of intermediate nodes in the representation have been provided by writing it in small letters to uniquely identify that it is an intermediate node. The representation of bold line will now be as ab|55Rc105F15Rh55FS| which implies that 'a' is source, 'b' is destination, after moving 55 cm right it reaches c and it moves 105 cm forward and then take right turn and move 15 cm to reach h and then finally reaches 'b' after moving forward for 55 cm and then stops.

Fig. 2. Representation of robots environment in graph.

For the simplicity of searching the paths from intermediate nodes after the first delimiter, the list of intermediate nodes are added to it and is represented as:

ab|ch|55Rc105F15Rh55FS|9.

In the above given string

- 'a' is the source.
- 'b' is the destination.
- 'c' and 'h' are the intermediate nodes.
- Robot starts from 'a' and moves 55 cms right to reach 'c'.
- Robot then moves 105 cms forward and then 15 cms right to reach h.
- From 'h' it moves 55 cms forward and then stops at 'b'.
- Number after the last delimiter is the score generated after processing.

B. *Processing of Paths*

Most often, the data gathered during traversing and finding paths by the robot is very large. As there will be collection of large no of paths, these data will eventually form big data and are usually stored in the Cloud. Since the traditional computing techniques cannot be used to process

these data sets, the parallel processing using Hadoop Map Reduce is commonly used to process the paths in parallel [29].

Map-reduce is a highly parallelized programming model that can be used for processing large data sets. The task of partitioning the input data, scheduling the programs execution in different clusters, making it fault tolerant, and managing inter machine communication is taken care by the run time system [29].

Hadoop is an Apache open source framework written in Java that allows distributed processing of large datasets across clusters of computers using simple programming models. The Hadoop framework application works in an environment that provides distributed storage and computation across clusters of computers. Hadoop [29] is designed to scale up from single server to thousands of machines, each offering local computation and storage. Hadoop has been setup in standalone mode on Ubuntu 14.04 system. The setup runs on a single Java Virtual Machine (jvm). It becomes easy to test and debug the map reduce programs. Less amount of sample sets are used so that the default properties are set for standalone mode to run the map reduce programs. 10 sample paths as shown below have been generated for the environment.

ab|10L5Rc20R50Fg50fS|0

vk|20Rl10LS|0

ab|10L20Rd50FS|0

The last field is filled with zero which indicates that these paths has never been shared or processed. Once the request for any source destination pair is made, a Map Reduce program is executed to find all the strings that match the required source destination pair. There might be many intermediate nodes between the source and destination in the representation that forms a better path. Hence the entire string is checked to find the paths that might be intermediate nodes. To find all the paths matching some pattern there is no need to combine intermediate key-value pair and hence Reduce is not needed. Map takes path and outputs if it matches the pattern. This is not a good idea if there is a single large document, but works well if there are many documents. In a realistic scenario there might be many documents as there may be large number of robots. Therefore using of Map Reduce is justified.

C. Mapdriver Class

The task of map driver class is to control the entire job. It is the top level class and the main entry point. The main function in this class takes commands by an argument which is the input, output file and the source destination pair.

The job object gets instantiated, File input format and file output format describes the input and output specification for the job and creates path objects based on arguments variable. The output path gets created by Map Reduce job and output files are deposited there. The behavior for file input format is to read key value text separated by delimiter. WaitForCompletion method is called which launches the job and returns success or not. Now the mapper and reducer class are called. The flowchart for Mapdriver class is shown in Figure 3. The framework handles all the details all the numbers of mappers required and how to read distributed input file.

D. PathMapper

PathMapper extends the Mapper class to implement the map function. In a distributed computing model, data gets send from node to node via Remote Procedure Call and data must be serialized and desterilized as it goes. Hadoop built in data serialization format is called writable. Writable class exists as a wrapper for almost all Java primitive types.

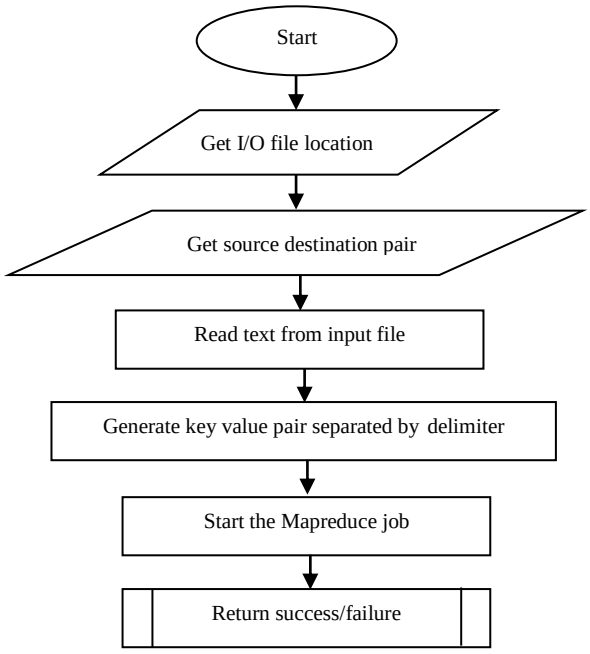

Fig. 3. Flowchart of MapDriver.

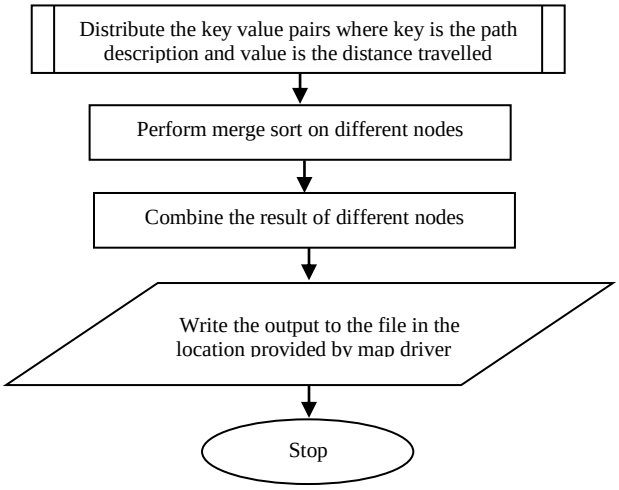

Fig. 4. Flowchart of PathReducer.

The declaration for the costumed Mapper class extends the class Mapper. The Mapper class uses parameterized types to define the types of key values for both input and output. The input key and input values are text, output keys are text and output values are integers. To implement map function, map method is overridden.

The map function searches if source and destination exists in the representation. If source and destination exists then the distance from source to destination is calculated by parsing the string and a list of key value pair where key is the string from source to destination and value is the distance to reach from source to destination. The flowchart for PathMapper is shown in Figure 6.

TABLE I. GENERATING SCORE FOR PATHS

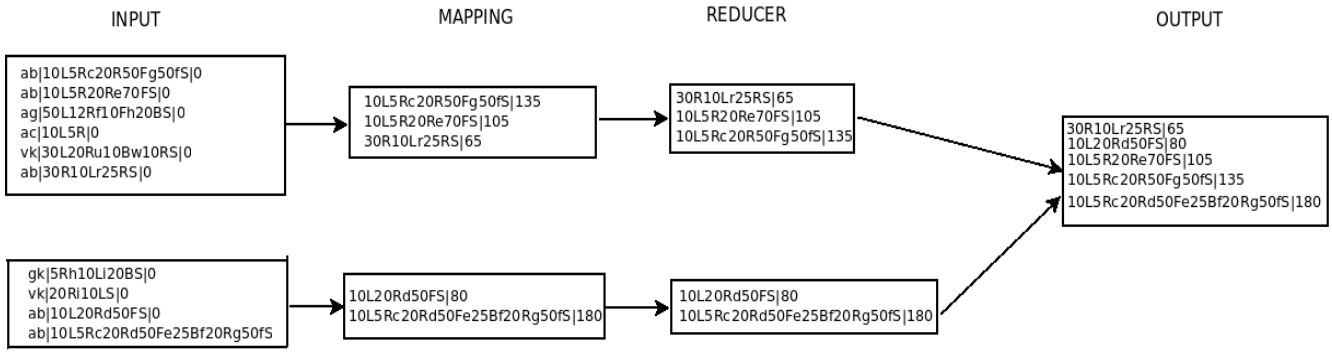

Fig. 5. Result of mapreduce programs.

The input and output key are text whereas the input and output values are integers. To implement the reduce function reduce method is overridden. The reduce function distributes the key value pairs to various node, where based on value the paths are sorted at each step. The sorting technique used is merge sort. At each node merge sort is done and later the results from each node are compared and combined. The sorted data from each node are checked with each other to finally output the sorted data. These data are stored in the output file at the location provided by MapDriver class. The flowchart for path reducer is shown in Figure 4.

E. Path Reducer Class

The PathReducer class extends the class reducer. Just like the Mapper the reducer class uses parameterized types to define the keys and values. The input and output key are text whereas the input and output values are integers. To implement the reduce function reduce method is overridden. The reduce function distributes the key value pairs to various node, where based on value the paths are sorted at each step. The sorting technique used is merge sort. At each node merge sort is done and later the results from each node are compared and combined. The sorted data from each node are checked with each other to finally output the sorted data. These data are stored in the output file at the location provided by MapDriver class. The flowchart for path reducer is shown in Figure 4.

F. Running Program on Hadoop Cluster

To run the program on Hadoop cluster, a jar file of the package PathFinder consisting of following classes is built.

- MapDriver
- PathMapper
- PathReducer

This jar file is copied to cluster where Hadoop job will run. MapReduce has a feature which lets the entire cluster to be Network File System (NFS) mounted which allows the cluster to be treated as any other disk and use native Linux commands to move data in and out. The input sample file is also copied to the Hadoop File System (HFS). The map-reduce program is run where the input location output location is provided as arguments. The output file is generated in Hadoop clusters which are copied to local file system, where a Java program to assign weights to the paths is run.

G. Assigning weights

The distance from source to destination is calculated by adding each integer value that exists in path representation. The distance is added at end of the string based on the distance the strings are sorted. Once the file contains sorted strings , weights are assigned to each strings , where w = r - p; r is the reward assigned to each string and p is the penalty, rewards are assigned in descending order, if there are n no of paths then p = n for n, p = n-1 for n-1 and the penalty is assigned in reverse order. ‘w’ is calculated and stored with the paths. Next time if the robot needs the path to same source destination pair then it can choose the path with highest weights and in case if there is some problem with the weight i.e. the path is broken or any obstacle is found then

robot can requests the path that has the next high weights. Table I shows the generation of weights for 6 different paths that exist from ‘a’ to ‘b’.

a) Input Samples

The input sample set is stored in a text file path.txt and copied to Hadoop file system.

V. RESULT AND DICUSSION

Reduce program is run on Hadoop clusters where the location of input file and output file is provided by arguments. The program is run to find the paths from source ‘a’ and destination ‘b’ the intermediate key value pair after finding distance from ‘a’ to ‘b.’ The reducer takes the key value pair generated by map function and sorts the value using merge sort which is combined to generate the required output. Figure 5 shows the input output and the intermediate key value pairs generated at each step of Map Reduce. The Mapper searches for all the paths from a to b and generates

The objective is to introduce a Knowledge Interchange Format (KIF) or variable length string for the heterogeneous robots to communicate on a generic cloud robotics platform. Emphasis has been given to generate a representation of path for robots (keeping in mind the size of data) that can be processed parallely and saved in cloud, enabling sharing of knowledge between robots. A variable length string data interchange format is considered for representing a path. Representation is made simple for compatibility across all microprocessors. The variable length string is tested in Hadoop MapReducee to simulate cloud processing.

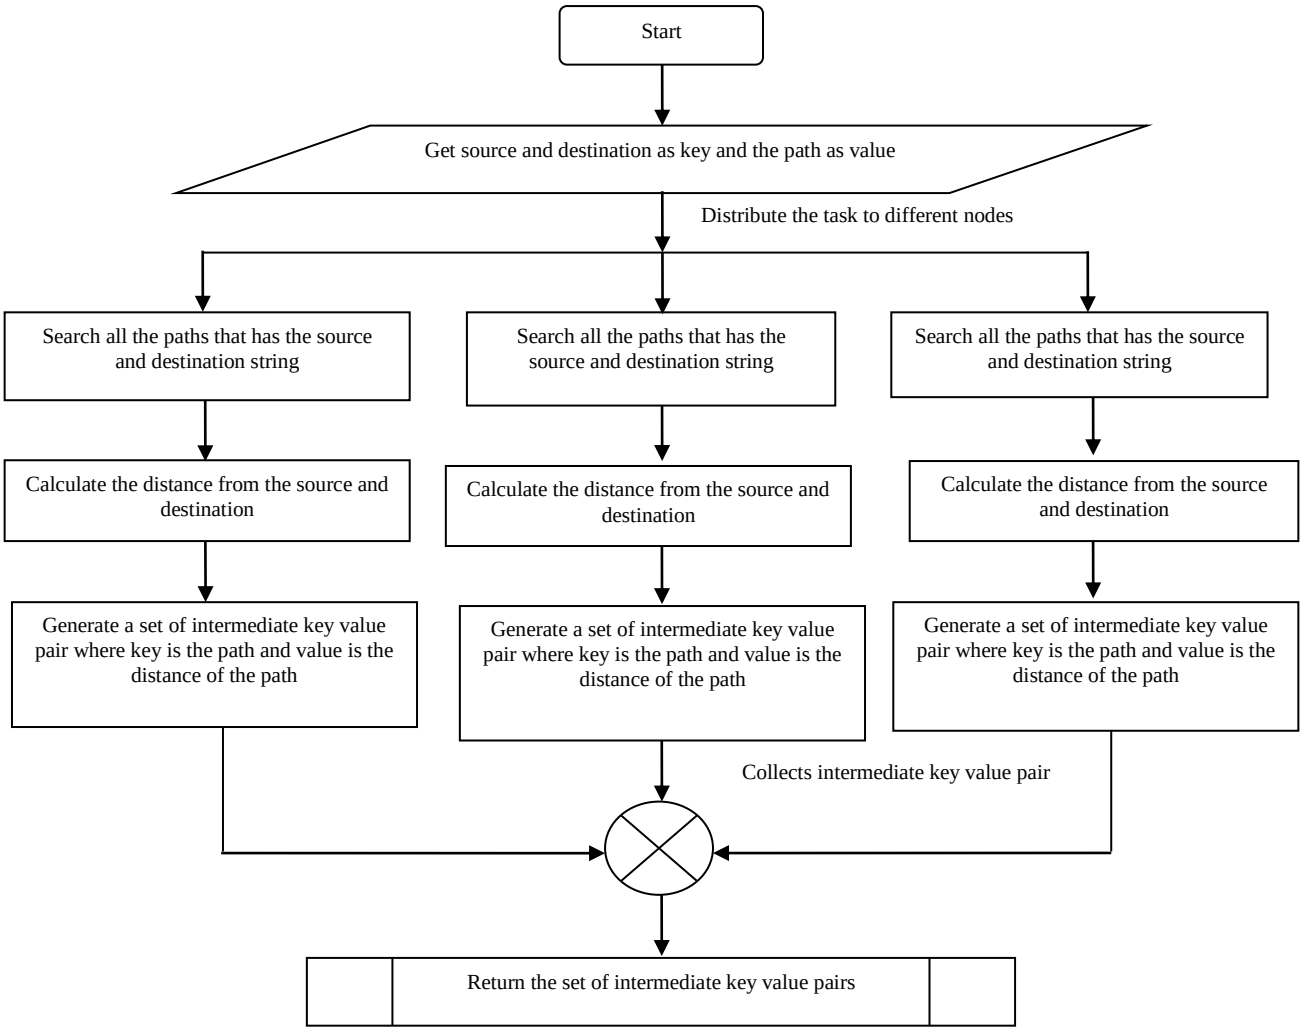

Fig. 6. Flowchart of PathMapper.

VI. LIMITATIONS

The Path map is designed with an ideal environment without considering obstacles and odometry error.

VII. FUTURE SCOPE

The Knowledge interchange can be extended to store other information such as object models, information about particular environment knowledge, than a path map.

Further, it can be implemented in educational robots like lego minstrom nxt and boebot through a thin middleware.

***Abstract*—The tremendous growth in usage of internet technology has pawed way for advancement of diverse wireless networks. One of the wireless networks that have gathered a lot of attention is Wireless Mesh Network (WMN). WMN is being preferred because of its numerous advantages such as better coverage area, communication with other networks, cost effectiveness, increased network capacity and is compatible with all IEEE 802.11 standards. Low Capacity, management of the traffic and gateway nodes and end to end fairness problem are the major issues in the employment of WMNs. In order to reduce the existing challenges in WMNs load balancing plays a vital role. In our work we have proposed a load balancing protocol to overcome the problem of congestion using residual energy and delay. The simulation results are derived and they prove that our proposed protocol enhances the performance and life time of WMN compared to standard protocol with reference to residual energy, throughput, packets received jitter and delay.**

Keywords—WMN, Load balancing, Energy, Delay

I. INTRODUCTION

A wireless mesh network is an infrastured network which is based on mesh topology. The architecture of a WMN [1] consists of three major components which are clients, routers and gateways. The clients are often laptops, desktops, tablets, and mobile phones etc. which are end devices. The router performs the task of traffic management through gateways. In a mesh network, even when a single node fails to operate, the communication is not hampered as the rest of the nodes are still able to establish communication with each other either directly or via intermediate nodes. Thus this uniqueness of WMNs has made them highly reliable, resilient and offers a higher degree of redundancy. The integration of WMN [2] technology can also be implemented along technologies such as 802.11, 802.16, 802.15 standards in cellular technologies.

A WMN can be visualized as a distinctive wireless Ad-hoc network. However a WMN has a systematic i.e. configuration and delivers a dynamic and cost effective deployment of network over a specific geographical area. An Ad-hoc network is a unpremeditated network where communication can be established only when the wireless devices come in each other's communication range. WMN [3] can also be used for wide variety of applications such as transport systems, wireless sensor network, surveillance system, broadband home networking, building automation, health and medical system, community and neighborhood networking.

A mobile node consumes its battery energy not only when it actively sends or receives packets but also when it stays idle listening to the wireless medium for any possible communication requests from other nodes. Thus, energy efficient routing protocols minimize either the active communication energy required to transmit and receive data packets or the energy during inactive periods. In some protocols the active communication energy can be reduced to reach the receiving node by adjusting the node's radio power just enough to reach the receiving node. The optimal routing path that reduces the total transmission energy needed to send the data packets to the destination can be determined by using the transmission power control method. When there is no data to send or receive each node can retain the inactivity energy changing its mode of operation into sleep power down mode or simply turn it off like in other protocols. Considerable energy saving can be achieved here, if the network conditions is specified with low duty cycle of communication activities. But for guaranteed data transmission when many nodes are sleep and not forwarding packets for the next nodes it may require much well designed routing protocols. Load distribution approach in another powerful approach for optimizing active communication energy. It maximizes the new lifetime when selecting a routing path by avoiding over utilized nodes and also balances the energy usage among nodes. Though each protocol will have advantages and disadvantages and is convenient for certain situation, it is not clear that any one algorithm or a clan of algorithms is ideally suited for all situations. However, it is possible to offer a better energy saving routing mechanism by combining and integrating the existing solutions. Many efforts have been directed to develop energy aware-MAC and transport protocols to tackle energy efficiently in other network layers. In layered network architecture each layer is supposed to operate in isolation. But to maximize the energy performance some recent studies have recommended the cross layer design.

The paper is arranged in the following manner. The existing technology related to proposed work is discussed in second Section. The proposed routing scheme EBL-AODV is completely described in third section. The simulation results, performance comparison and analysis are presented in fourth section. The inference of the paper is in fifth section .

II. RELATED WORK

In this work we have proposed a modified AODV protocol called Energy-Delay Based Load Balancing Ad-hoc on Demand Protocol (EDBL-AODV), which considers residual energy and path delay as a routing metric during route discovery.

Aron et al. [4] have described a novel distributed topology control algorithm whose main objective is to reduce the consumption of energy by each node during transmission and extending lifetime of the network. It is a three phased topology control algorithm which involves establishing accessible neighborhood topology, constructing minimum energy local topology view and finally determining transmission power. Thus the above algorithm overcomes the topology control problem in hybrid WMNs equipped with heterogeneous wireless devices and altering transmission ranges by taking decisions based on information gathered locally and scaling it for large WMN.

Panagiotis et al. [5] have proposed a new energy efficient multi cost routing algorithm for WMN. According to the new routing algorithm, a vector of cost parameters are calculated at each link using appropriate operators for selecting an optimal path. The parameters are hop count, power required by the node to transmit and the remaining energy at each node. There are two models- Network evaluation model and dynamic one to one communication model under which the performance of the proposed protocol is evaluated. In the former evaluation model, the network aims to transmit maximum number of packets available preceding energy depletion. In the latter model, the data packets are generated uninterruptedly as the nodes are competent of periodically recharging their energy. This protocol is said to enhance the durability of the network.

Awad et al. 6] have proposed a cross layer optimization algorithm subject to a delay deadline constraint. The assumption is that all packets successfully received should have their end to end delay less than their corresponding delay deadline. The proposed algorithm optimizes network and physical layer by exploiting different control parameters viz. path selection parameter in the network layer, the transmission and modulation energy in the physical layer. The protocol is a little time consuming as for every path in the network, all cross layer parameters are calculated through all paths in the networks. The authors [7] have proposed a novel routing model called ERDB-AODV protocol in which remaining energy in the battery and energy draining rate are incorporated as additional metrics for an optimal path selection. Thus, the hop count, available energy at the node and the rate of energy consumption are considered as important factors of the path selection. The protocol avoids nodes with higher energy consumption and lesser energy levels to extend the lifetime of the network. However, this may affect the traffic to traverse a long path to reach destination despite successful transfer.

III. Energy-DELAY Based Load Balancing AODV Protocol

We have proposed a novel routing protocol Energy-Delay based load balancing EDBL-AODV which is improved form of DBL-AODV and which considers both energy and delay for path selection. EDBL-AODV has a modified routing table entry, route discovery and selection process. The additional constituents included in EDBL-AODV are expiration time field, hop count field and advertised hop court for achieving maximum possible paths. The operation of EDBL-AODV routing protocol can be described in Figure 1.

The source node broadcasts the RREQ packet. For immediate nodes with the help of RREQ packet computes the minimum unused energy depending on the incurred energy consumption and delay. The energy consumed can be obtained by the equation:

EC = Power Received or Transmitted * (8 * Packet size / Bandwidth).

$$EC = P * \left(8 * \frac{PS}{B_w}\right) \quad (1)$$

where, EC = Energy consumption.
P = Power Received/Transmitted.
PS = Packet size.
B_W = Bandwidth.

The relay nodes enter the delay and calculated energy consumption in RREQ message. They also check sequence number for a new route and update the same in routing table. The destination node replies to the source node via RREP message. During route selection, the same node chooses an optimal path possessing lesser delay and maximum residual energy.

The delay is calculated in the algorithm is as given below

Delay= (time at which RREQ received at current node) - (time at which RREQ sent from previous node) (2)

The average delay (D_a) is calculated by

$$D_a = \frac{\sum(Tpr - Tps)}{T} \quad (3)$$

where, T_{pr} = Packet received time
T_{ps} = Packet sent time.
T = Total data packets received.

The path selection (PA) process is performed by using

P_s = Max $[\sum\{(\frac{B1r}{B1f})\ (\frac{B2r}{B2f})\ \ldots\ldots\ldots(\frac{Bnr}{Bnf})\}]$ and Min$[\sum\{(D_1)\ (D_2)\ \ldots\ldots\ldots\ldots\ldots(D_n)\}]$ (4)

where, n = advertised hop count
B_r = remaining energy in node
B_f = full energy in node
D = time delay

IV. Performance Evaluation

The effectiveness of EDBL-AODV algorithm is verified by comparing it with the AODV protocol algorithm using Qualnet simulator. The parameters for all simulations are shown in Table 1. We change the number of nodes from16 to 120. For Each node density higher CBR is generated to create the congestion. We used five different quantitative measures to compare the performance of the proposed and existing protocol. In this comparative study, our proposed protocol 'EDBL-AODV' maintains network life time, higher throughput, and lesser delay unlike in AODV protocol.

We fix the packet size as 1024 bytes and change the number of node densities from 16 to 120 to observe the impact of load and node densities on the network performances. The performances of AODV and EDBL-AODV protocols are shown in Fig.1 to Fig.5.

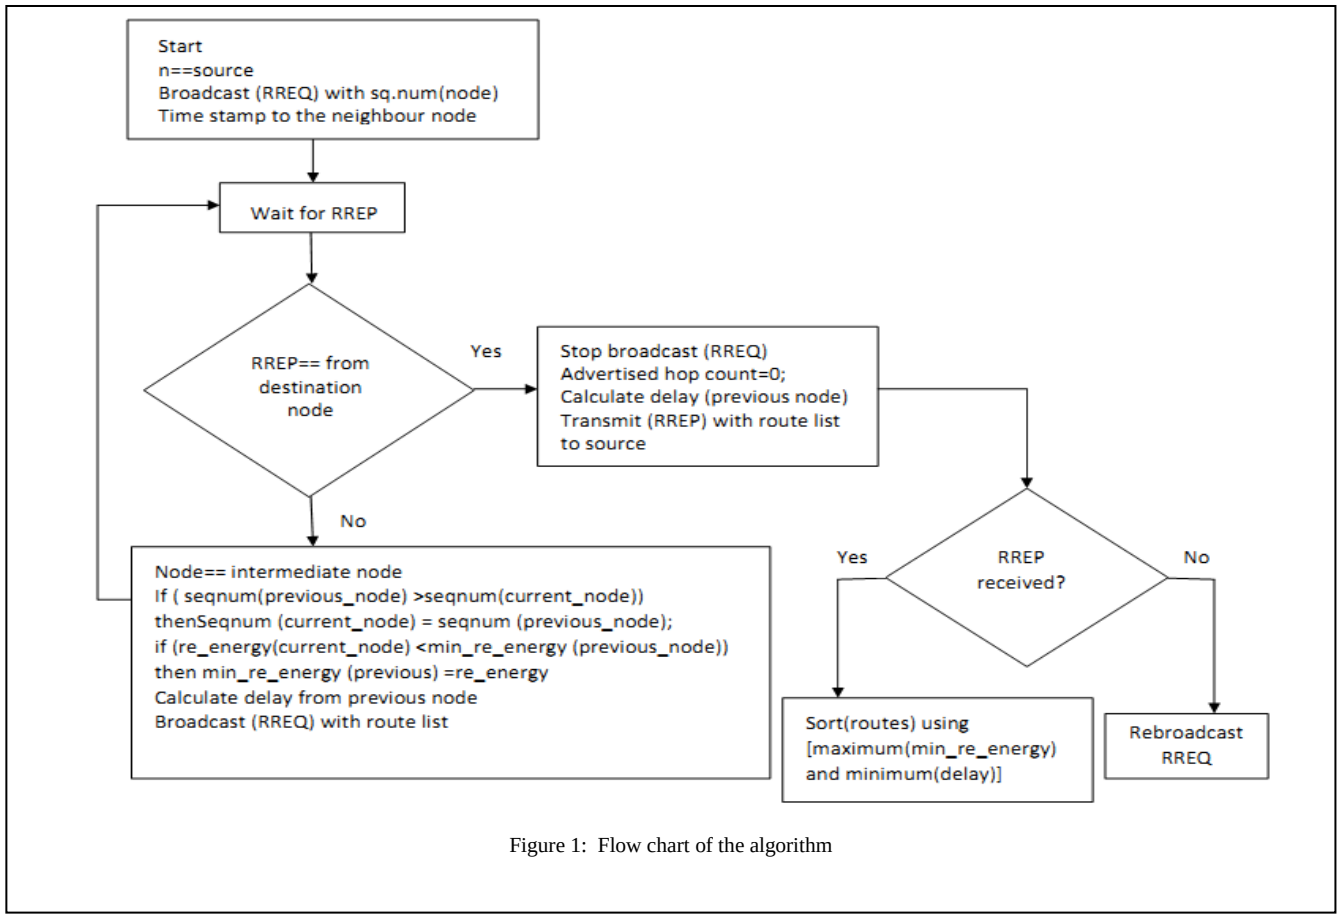

Figure 1: Flow chart of the algorithm

Table 1.Simulation Parameters

Parameter	Value
Protocols	AODV, EDBL-AODV
No. of Nodes	16, 25, 45, 70, 90, 120
Radio type	802.11b Radio
MAC Protocol	802.11s
Antenna Model	Omni-directional
Path Loss Model	Two ray propagation
Traffic Type	CBR

Fig.1 shows throughput comparison with respect to node density. As the number of nodes increases, the average network throughput of EDBL-AODV is always higher than AODV because data transmission is performed based on less delay, path having higher residual energy and minimum number in less time.

Fig. 2 shows that the total number of messages of nodes path. Due to less delay, more number of bits is transmitted received of EDBL-AODV remains higher than AODV with different number of node density since packet transmission is mainly based on less delay and minimum distance path. Due to this consideration, packets are transmitted evenly without any occurrence of node failure. Therefore, higher amount of packets is transmitted. As shown in Fig. 3, the average end-to-end delay of EBL-AODV is lower than that of AODV. Since AODV RREQ packet is modified by introducing delay parameter. Routing is performed using the delay parameter; less delay path is selected for packet transmission. Therefore, end-to-end delay is reduced. For the existing model, AODV packet transmission is performed based on minimum distance which increases congestion and leads to delay, which is even true for Jitter.

Fig. 5 shows that the residual energy of EDBL-AODV is higher than AODV for different node densities. This is because packets are transmitted based on higher residual energy, less delay and minimum distance path. Due to this consideration, packets are not queued at nodes which lead to less resource utilization and less energy consumption.

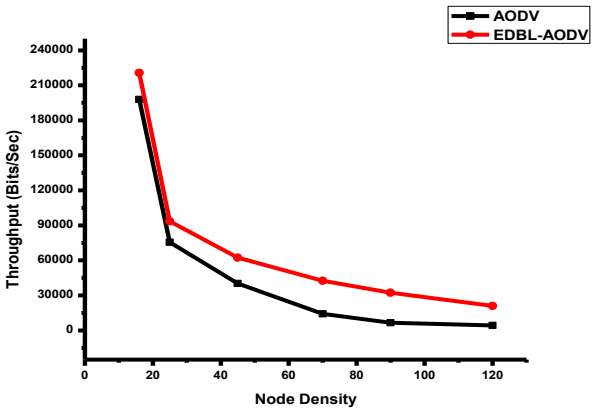

Figure 2: Variation of throughput v/s node densities

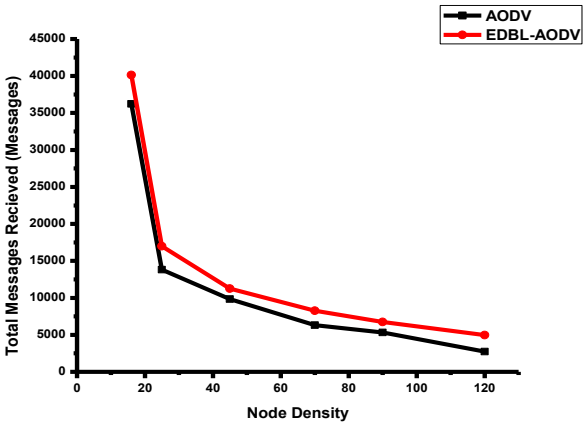

Figure3: Variation of total messages received v/s node densities

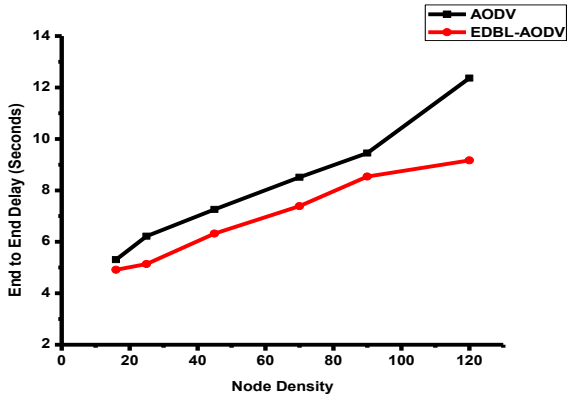

Figure 4: Variation of End to End Delay v/s node densities

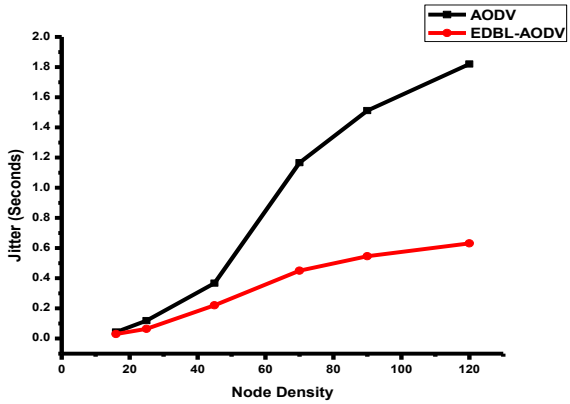

Figure 5: Variation of Jitter v/s node densities

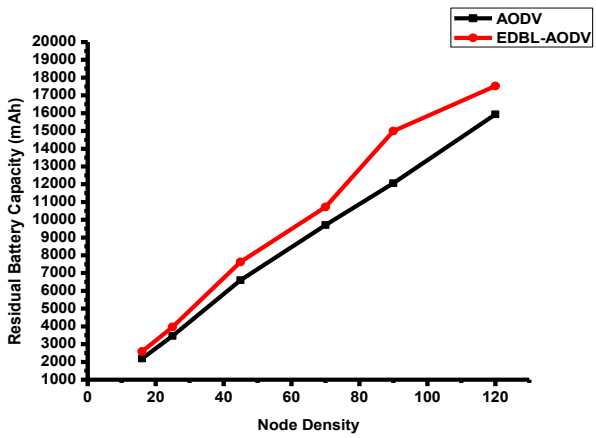

Figure 6: Residual Battery Power v/s node densities

V. Conclusion

In our proposed work energy efficiency is enhanced considerably by reducing routing overhead and delay. Comparative study has been carried out with existing routing protocol and the results are exhibited. Simulation results showed that the proposed protocol improves performance of the network and prolongs the lifetime of a WMN in comparison with the standard protocol. On an average, there is an overall increase in throughput of 12 to 14%, total number of messages received 15 to 18%, decrease in energy consumption of 4 to 6% and decrease in end-to-end delay of 6 to 8% when compared between proposed and existing algorithm.

***Abstract*—Fatigue driving is suspected to be a primary cause of vehicle related crashes. Driver fatigue resulting from lack of rest is a significant factor in the expanding number of the mishaps on roads. A warning system can possibly reduce the accidents related to drivers drowsiness. By putting the camera inside the vehicle, the system can read the expressions of the driver and search for the eye-developments which demonstrate that the driver is never again in condition to drive. In such a case, a warning sign ought to be issued. Our face contains a great deal of supportive data; we can utilize the condition of eyes to discover the tiredness. In this paper, a methodology has been proposed for the eye state recognition dependent on convolutional neural network (CNN), which eventually calculates the percentage of eyelid closure (PERCLOS), and blink frequency to figure out the level of the drowsiness. A real-time monitoring unit is additionally created to alert the closest control unit about the status of drowsiness of the driver. Google Cloud Platform is used for training CNN and the trained model is implemented on Raspberry Pi. The trial results demonstrate that the presented technique has reduced training time of CNN network model, high acknowledgment exactness of condition of eyes and can distinguish the drowsiness viably.**

Keywords - Fatigue Detection; CNN; Eye State recognition; Google Cloud; Raspberry pi

I. Introduction

With the increasing traffic collisions, it's carried genuine misfortunes to the country and public. Research demonstrates that the languid driving is one among the most reasons for traffic collisions. As of late, a few nations and governments as of now are giving more consideration to the driving well being issues. Researches for driver drowsiness detection have crucial importance.

Exhaustion and diversion are a piece of regular day to day existence for many individuals. They decrease response time, watchfulness, readiness and focus and as a result the the capacity of performing exercises, (for example, driving) is disabled. The causes leading to falling asleep behind the wheel are fatigue, alcohol intoxication, similar route, riding at night, driving after a heavy lunch, taking Medication.

The drowsiness detection techniques based on computer vision is a non-intrusive way. The features of the face can be determined by dissecting the progressions of facial appearance, for example, squinting (blinking), eye conclusion length, yawning, etc. Conventional image processing strategies for computing flickers which normally include a blend of Eye Localization, Threshold to discover the white portions of the eyes and deciding whether the "white" portion of the eyes vanishes for a time frame (demonstrating a squint or blink).

It is acknowledged that tiredness will appear as fast and consistent glinting, signaling or head swinging, and yawning constantly. PERCLOS [1] is seen as a reliable measure for predicting tiredness and has been melded in commercial things, for instance, Seeing Machines and Lexus. Other facial advancements, for instance, internal forehead rise, external temples rise, lip expand, jaw drop and eye flicker(blink) have additionally been known to be markers for tiredness. As of not long ago, Most vision-based detection relied on hand-created facial and head development checking characteristics. As a rule, hand-created features have demonstrated constrained adequacy in genuine situations which may incorporate drivers wearing shades and huge variety in light.

On the other hand, features of the face learned from an image in light of deep learning have been increasingly viable in genuine real-world situations. Choi et al. [2] built an algorithm for gaze zone detection depends on features learnt using a Convolutional Neural Network (CNN). Utilizing the learnt facial features, support vector machine (SVM) is used to anticipate drivers gaze looking zone. K. Dwivedi et al [3] utilized a 3-layered CNN to learn features of the face of distinguished face locale from the info picture. The yields of the last layer are considered as the extricated features. On the basis of the extricated features, the binary classifier was trained and utilized for drowsiness prediction. The strategy

based on this has higher acknowledgement accuracy. CNN [4] [5] can extract features adaptive and make the features to have a superior capacity of portray, CNN has better features expressive, keeping away the manual feature extrication.

In this paper, we have designed an image securing framework dependent on continuous(real time) pictures and propose a discovery technique about the state of eyes utilizing CNN. As appeared in Fig. 1, the method on a very basic level joins three segments: extricate the territory of eye, state of eye states, sleepiness or exhaustion recognition and alerting the driver and the nearest control room and there by the concerned authorities can take necessary actions like reaching the site in case of any adversaries or stop the vehicle to avoid any mishaps.

The remainder of the paper is created as pursues: Data set preparation, segment 2 demonstrates the proposed system. The Segment 3 demonstrates the training of the neural network.The condition of eyes acknowledgment(recognition) is appeared in segment 4. The Segment 5 demonstrates an alert framework. The Segment 6 shows the exploratory results for driver fatigue identification. The Conclusion is discussed in section 7.

II. Proposed System

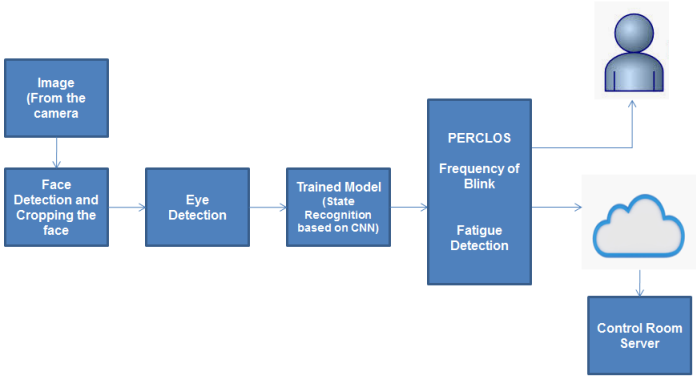

Fig. 1. Block Diagram of the Proposed System

A schematic of the proposed framework is appeared in Fig. 1 The framework comprises of two phases. First stage is to prepare and train the neural system and the second stage is the development of the detection system to test the condition of eye utilizing the neural network system which would be trained in the first stage.

Camera image is taken frame by frame and then input to the Haar Cascade classifier to detect the face.Different Haar Cascade classifier for the eye is then used to extract the eye portion which is then key in as input to the detection system to recognize the eye state.Based on PERCLOS [1] and blink frequency,determines the fatigue level and alert the driver and nearest control room in case of experiencing fatigue.

III. Training of the Neural Network

The various Steps associated with the training of CNN is indicated in Fig. 2

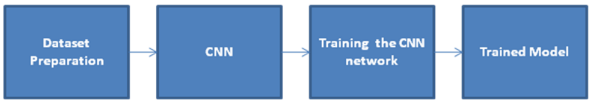

Fig. 2. Different steps in CNN training

A. Data set Preparation

Eye state recognition is a troublesome undertaking in the unconstrained true situation which is loaded with challenging varieties brought about by individuals and sorts of condition changes including darken, lighting, impediment, and mask. To distinguish the state of eye, need to train a binary classifier for open and closed eyes. To do this, we used a dataset to train our classifier. For open and closed eyes, we used cropped images of size 24x24 from the dataset. The complete dataset contains 4864 images and are then labelled as open and closed. Sample images are indicated in Fig. 3.

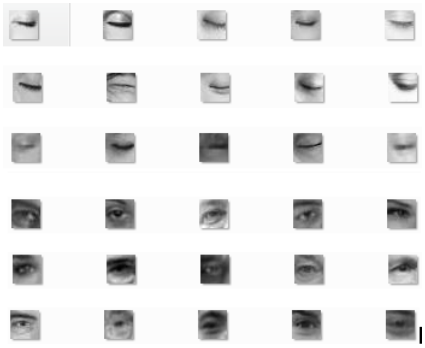

Fig. 3. Sample eye images

B. CNN Network

The architecture of CNN network is shown in Fig. 4.The CNN Architecture is similar to a binary classifier to identify whether the given image is a Dog or Cat. Input image(open and closed eye) of size [24*24*1] has the raw pixel values. The CNN network used in the system has three Convolutional filters. Each Convolutional filer has a ReLu initiation(activation). CONV layer computes the yield of neurons that are associated with neighborhood regions in the input, each registering a dot product between their weights and a small locale they are associated with in the input. First layer convolution results in volume [24x24x32] as we used 32 filters. RELU layer [6] does an element wise activation function, the max (0, x) thresholds at zero. First Relu activation layer results is such that the size of the volume ([24x24x32]) stays unaltered. Each Convolutional filter follows a Max-pooling layer. POOL layer down samples the operation along the spatial dimensions (width, height), resulting in volume of [16x16x12] in the first layer of Max Pooling.

Similar two operations performed with different filter size. Then a dropout layer to reduce the unwanted neurons which then followed by a fully connected layer with ReLu activation. Dropout randomly sets a fraction rate of 0.25 input units to

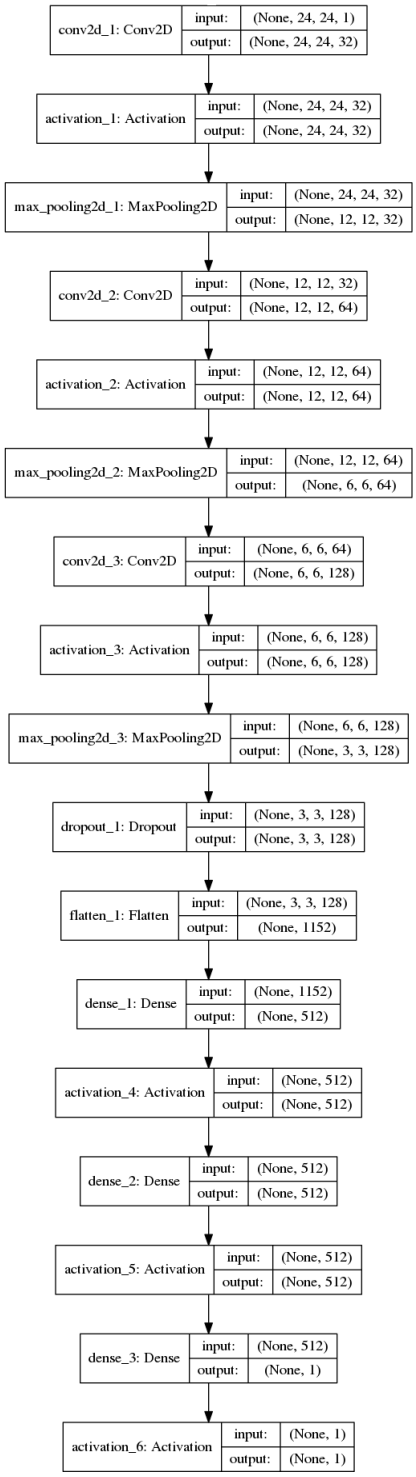

Fig. 4. Architecture of the CNN Network

0 at each update during training time as it helps prevent over fitting. Flatten layer is used to flatten the input. Three dense layers is induced to act as fully connected neural network layer so that each input node is connected to each output node. A single neuron is induced with Sigmoid activation for the binary classifier. Adam optimizer is used as it is an optimize algorithm to updated the weights in the network iterative in the training data set and for the loss function binary cross entropy is used to predict the losses.

C. Training of the CNN Network

Before loading the labeled images, CLAHE (Contrast Level Adaptive Histogram Equalization) is applied to evacuate the noise and to improve the picture. Then scaled the values of the images between 0 and 1 to makes the learning process faster. Finally trained the network for 50 epochs with batch size of 32 and 152 iterations. Epoch is the number of iteration related to each input samples in the data set. The network uses 50 epochs as large values of epochs could lead to train more times which gives better exactness. A complete data set is carried back and forth through the neural network only once is an EPOCH. The trained model is saved as a HDF5 (Hierarchical Data Format) file format. On Google Cloud training of the entire images took around 6 minutes. The recording of training metrics which includes the loss and the accuracy for each epoch at the end of the training in Google Cloud Platform is shown in the Fig. 5.

Each epoch took around 8 seconds and each step took around 52ms. So total time taken for training is 8 seconds x 50 Epochs, which is around 6 minutes.

As shown in the plot of accuracy Fig. 6, it is visible that the model reached almost same accuracy level at the end of the epochs.As shown in the plot of loss Fig. 7, it is visible that the model reached almost same loss level at the end of the epochs.

Fig. 5. Training Summary in Google Cloud Platform

IV. EYE STATE RECOGNITION

The different steps involved in the eye state recognition is shown in Fig. 8

A. Image Capture and Preprocessing

Read each frame from the camera. The captured image which is an RGB image needs to convert to gray scale image with a depth of 1. This ensures the depth of the image is same as of the trained image.

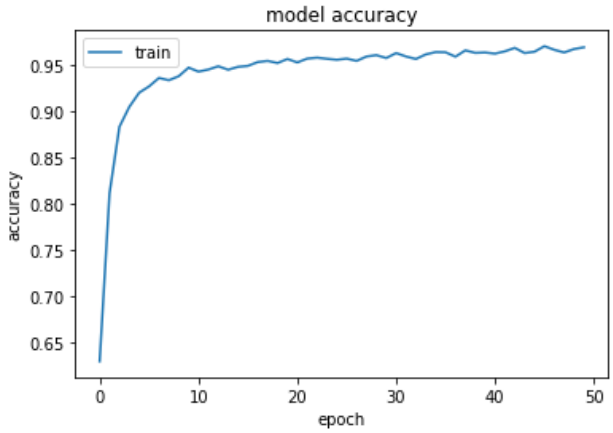

Fig. 6. Plot of Model Accuracy on Training Data

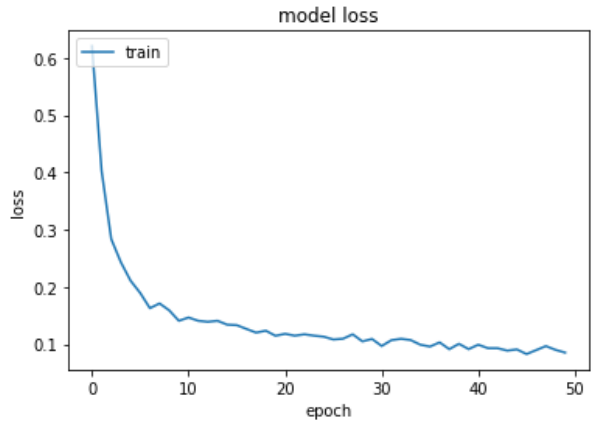

Fig. 7. Plot of Model Loss on Training Data

B. Image Enhancement

To enhance the image, CLAHE (contrast-limited adaptive histogram equalization) is applied. It enhances the contrast of the grayscale image by transforming the values. This contrast-limited adaptive histogram equalization (CLAHE) produces images that do not excessively enhance the noise content of an image, but provide sufficient contrast to visualize structures within the image. CLAHE processed images have a more natural appearance and make it easier to compare distinct regions of a picture.

C. Face and Eye detection

Object recognition is ordinarily characterized as technique for distinguishing the presence of objects of a specific class. In image processing, it is a strategy to discover an item or object from pictures. There are various approaches to characterize and discover objects in a frame. One way is depended on color identification. Be that as it may, it's anything but an effective technique to identify the article as a few diverse size objects of same shading might be available. Haar-like highlights, created by Viola and Jones [7] based on the proposition by Papageorgiou et. al in 1998 is a most efficient way to recognize items. Haar-like highlights are computerized picture highlights utilized in article identification or these are square shape molded dim and light regions having comparable sort of highlights like our face. The cascade classifier includes various stages, where each stage comprises of numerous frail highlights or features. The framework recognizes the subject by moving a window over the whole picture and by forming a solid classifier. The yield of each stage is marked as either positive or negative implying that an item was found and negative implies that the predetermined article was not found in the picture.

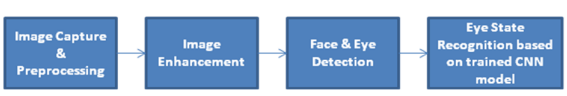

Fig. 8. Steps in Eye State Recognition

To detect the face and eye region, different haar cascade classifier is used to give better accuracy. Using Haar cascade classifier, face and eye region is cropped for various states. Fig. 9 shows the various states. A human region blinks both the eyes simultaneously. Hence one region is enough for the model to predict the state.

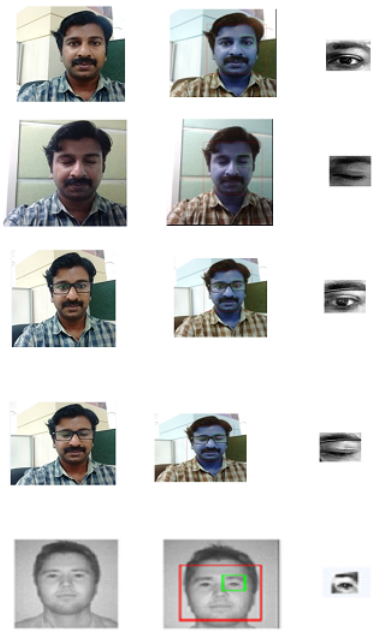

Fig. 9. Cropped Face and Eye
Source: Infrared Image is adapted from
http://www.scface.org/examples/001_cam8.jpg

D. Eye State Recognition Based on Trained CNN model

When the face and eyes are identified, the trimmed picture should be resized to 24X24.The resized picture is then sustained to prepared CNN model to make a prediction. The model has a binary classifier with a sigmoid neuron that gives

as yield as the likelihood of an eye to be open and on the off chance that the likelihood is more than 50 percentage, at that point the condition of eye is open and on the off chance that it is under 50 percentage, then condition of the eye is shut. The Fig. 10 shows that eye state recognized with a good accuracy.

Fig. 10. Prediction of Open and Closed State

V. Alert System

Once the eye states are identified and if the driver experiences drowsiness, then alert is send to driver in the form of sound.A buzzer is connected to Raspberry pi to raise alert in the form of sound.Initially the buzzer is set to low.Depends on eye states,alert is raised by applying high(Vcc) to the GPIO pin which is connected to the buzzer.Buzzer produces sound until the driver is alerted. In addition, a real-time alert system is established to send the alert to the nearest control unit to be monitored by the authorities concerned such as POLICE. The idea of such a system is to ensure that the authorities who are nearby will get the alert message and the vehicle details. The authority can take quick action either stopping the vehicle by calling the driver or reaching the location the site immediately in case of any accidents. However, the priority is to alert the driver.

The Fig. 11 illustrates the schematic diagram of the general MQTT system. The proposed system uses MQTT protocol to send the alert message from a vehicle (MQTT publisher) to the nearest control room (MQTT subscriber). MQTT is a standout amongst the most generally utilized conventions (protocols) in IoT world. It is a Message Queuing Telemetry Transport convention. A lightweight informing convention that utilizes operations to publish / subscribe to exchange information between customers and the server. Its small size, low power consumption, limited bundles of information and simplicity of execution make the convention perfect for the world of ”machine-to-machine” or ”Internet of Things” world. Each vehicle is being uniquely identified by the topic number and the alert message is then publish to a folder with that unique number to a server(Mosquitto Test Server) via internet. The subscriber (control room) subscribes the topics and continuously monitors the topic folder and in case of an alert received from any vehicle, it displays the details on a screen as indicated in Fig. 12 there by alerting the concerned authorities.

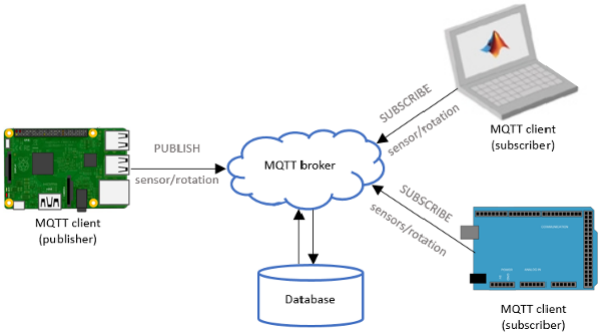

Fig. 11. MQTT System

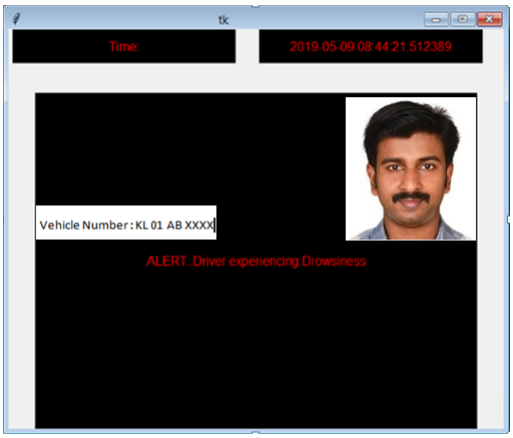

Fig. 12. An Alert Console in the Control Room

VI. Experiment and Results

A. Experimental Platform

Google Cloud Platform with Debian GNU/Linux9 Operating System,1 x NVIDIA Tesla K80(GPU) is used to train the CNN network. Raspberry Pi 3 Model B+ as shown in Fig. 13 is used to implement the detection system and to raise alert. The trained model is copied from Google Cloud Platform to Raspberry Pi and Logitech Camera is used to capture the real-time images. A buzzer is connected to Raspberry Pi to raise the alarm in case of drowsiness. MQTT and Mosquitto Test Server is used to send the alert to the Control Room. The whole application is build using Python 3.5.3, OpenCV 3.4.4, Keras 2.2.4 and Tensor Flow 1.11.0.

Fig. 13. Raspberry Pi Connected to Camera and Buzzer

B. Results

The driver drowsiness can be measured using PERCLOS and blink frequency. The PERCLOS [1] [8] (Percentage of eyelid closure). It is calculated as (1):

$$f_{PERCLOS} = \frac{n_{close}}{N_{total}} \times 100\% \quad (1)$$

Where n_{close} is the total number of eye closed frames and N_{total} is the total number of frames over a period. PERCLOS measurement gives alertness if drivers eye state is closed for a period of 5 to 6 seconds.

PERCLOS is used when driver closed his eyes for a period of 5 to 6 seconds as it indicates person is slept which can cause accident severely. Fig. 14 indicates that person is slept for a while in the beginning as the PERCLOS [1] [9] is more than 80%(n_{close} is around 30 of 35 total frames within a period of 5 to 6 seconds).

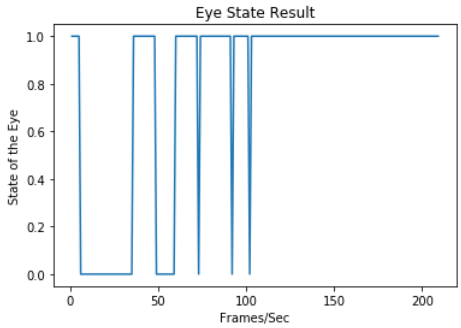

Fig. 14. Experiencing PERCLOS of 80% in the beginning

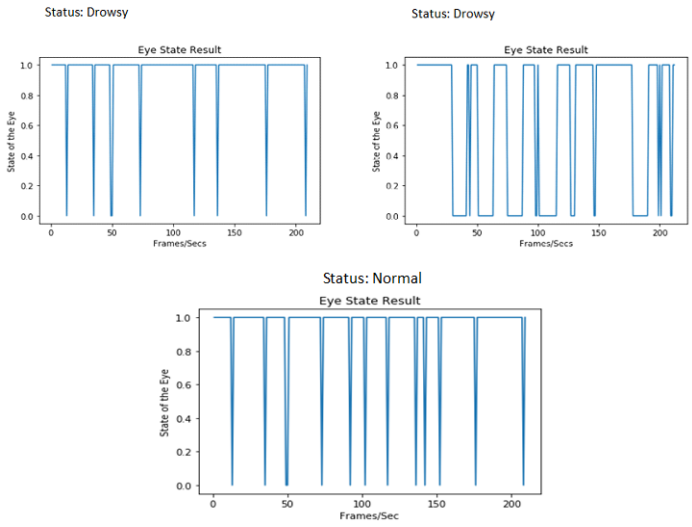

Fig. 15. Eye State Results

According to studies in [10] normal healthy person blinks eyes 10 to 15 times per minute and in case of drowsiness experiences blinks of more than 15 per minute. Driver may experience drowsiness as well if the blink frequency is less than 10 blinks per minute. The Fig. 15 depicts the status of the three different states obtained from the real-time image captured which shows that the system detects the blinks as per the expectation.Though the work done by [11] uses its own data set of around 7000 images, the Table I shows that the proposed system with 4864 images using Google Cloud platform fairs way better with training time than with the previous work.

TABLE I
COMPARISON OF WORKS

Reference	Network Structure	Training Time
[11]	Two Convolutional layers, Two Max Pooling layers with ReLu activation and one fully connected layer	42 Min
Proposed System	Three Convolutional layers, Three Max Pooling layers with ReLu activation and three dense layers	6 Min

VII. CONCLUSION

In this proposed system, we have developed a driver fatigue system based on eye states using CNN.Haar Cascade classifier is used to detect face and the eye from the image.The training system is implemented on Google Cloud Platform which reduces the time taken for training drastically compared to the previous works. The trained model file is implemented on Raspberry Pi to detect the eye states and raises an alarm in case the driver experiences drowsiness. Also developed a real-time monitoring system to send the driver fatigue alert to the nearest control unit to take necessary actions. Future work can be focused on attaching GPS to the system (vehicle) to send the location details as well to the control unit.

***Abstract*- This paper present amelioration power quality of hybrid power system integration with PV, wind and battery system by FACTS device .In transmission and distribution system power quality is major restraint . FACTS device have many merits in transmission like flexibility and high speed. Benefit of this system is the diverse sources can be connected to at one junction of power line, because of this these method are ascertaining to be an efficacious and ductile method for the development of the system. Harmonics produce when two diverse source connected to grid and it removed by using UPFC. The unified power flow control is the most promising device of fact family at which study in this paper is concentrated. In the study of this paper UPFC is modeled and interpretation of UPFC in a hybrid-grid connected system is examined. The extraordinary feature of the UPFC is such that it can control flow of real and reactive power as well as voltage amplitude at the same time at the UPFC nodes. The planned model is simulating in MATLAB/Simulink software.**

Keyword- MPPT, Voltage Regulator, UPFC,Hybrid system

I.INTRODUCTION

Now a days energy generation move towards the renewable sources because existing traditional energy sources are becoming more overpriced. In the some last some decades the renewable energy field is growing too fast in every aspects whether it is economical or environmental. The renewable energy sources are become essential need of power sector. At the time different sources like sun, wind, tidal etc. are utilized for generate electricity. Solar and wind energy acquiring more regarding generate electricity because it has insignificant impact of pollution on the environment.

This paper exhibit modeling and control of hybrid model which is comprise with PV, wind, battery. Output of the hybrid system is fluctuate according with solar irradiance, temp and wind speed and output characteristics is unstable. In grid associated system it is very crucial to supervise on electric power transfer. Diverse type of facts controller deliberate to raise capability of transmission line. UPFC is produce full control on electric network among different facts controller. This model made of PV array, wind turbine, battery storage, DC-DC converter, voltage controller & UPFC controller. To gain maximum power we are implementing MPPT technique for both energy sources and DC-DC converters are applying to boost the output voltage. Here Voltage regulator is integrated for control the pulse for inverter which is converting generated DC to AC. UPFC is utilizing to minimize voltage rise problem in output voltage of gird associated hybrid system, so improve power quality of system. MATLAB/Simulink is applied for PV/Wind simulation model.

II.PROPOSED SYSTEM MODELING

A.PV SYSTEM

Photovoltaic system comprise PV array which is an set of series & parallel coupled PV cells. To produce high voltage, current, power PV cells coupled to one item, PV module. when the system come under sun radiation, which particle have the energy level more than the limiting gap energy of p-n

diode consumed and found electron hole pair corresponding to radiance, so spark light.

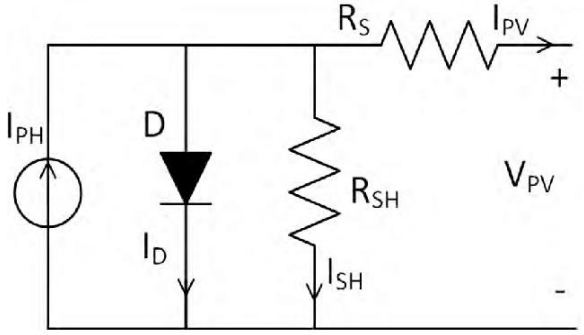

Fig.2 basic solar array diagram

The equation of current which supplied to load is given

$$Iop = Ipvi - Irev\left[\exp\left\{\frac{Vd + I1Rse}{qi\,Vtv}\right\} - 1\right] - \left[\frac{Vd + I1Rs}{Rpa}\right]$$

Ipv=PV current
Irev= reverse saturation current of diode
Vd= diode voltage
a_i=constant of ideality
Vth= thermal voltage
Rse=Resistance arrangement in series
Rpa= Resistance arrangement in parallel
Equation 2 show PV current of cell, in term of temp.& radiation

$$Ipvi = (Ipvi - stc + Kic\Delta Ti)\frac{Gi}{Gsitc}$$

Fig.3 show PV & IV aspect of PV module at 25^0 &45^0 temp. Given in fig

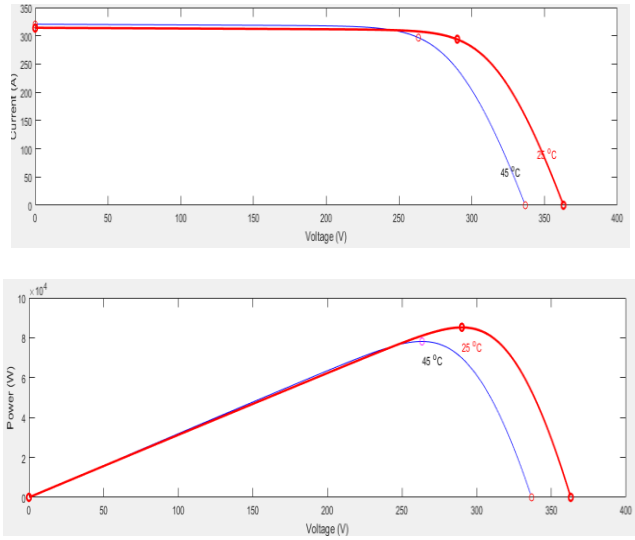

Fig.3 PV&IV characteristics

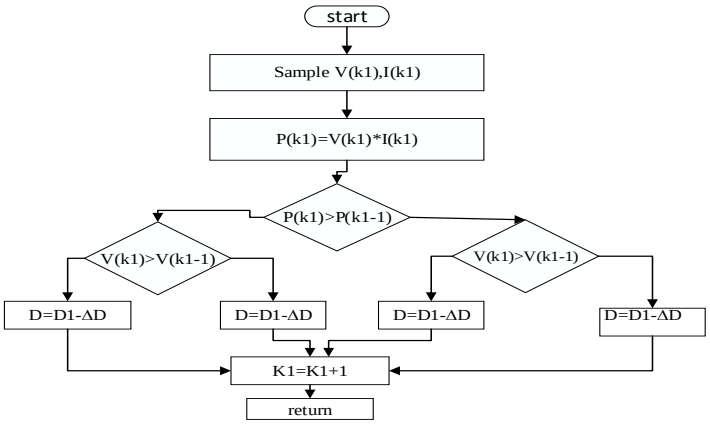
Max. Power= P_{max1}= $V_{max1}I_{max1}$

B.MPPT TECHNIQUE

We notice from attribute of PV module shown in fig 3 so we found that a maxima point exist there. To gain maxima power various technology applied .here P&O MPPT technique used for PV module



By changing the value of duty cycle, converter output voltage is maintain constant .the solar PV array output show

$$Vpv1 = (1 - De)Vout1 \qquad (2)$$

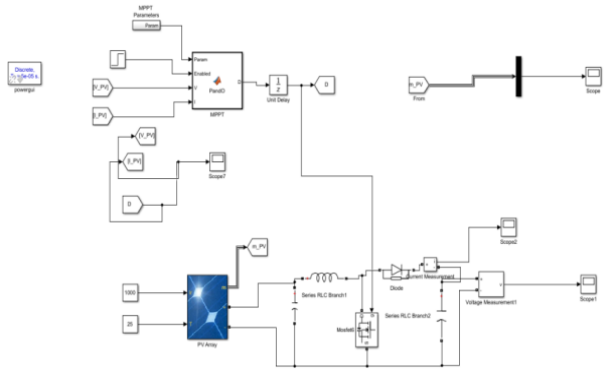


Fig.4 modeling of PV array with MPPT technique

C.WIND SYSTEM MODELING

Wind system is a device which convert wind energy to electricity form .it is comprise with wind turbine PMSG generator, uncontrolled rectifier which convert AC to DC form.Fig.5,6 show the governing mechanism for wind system which command the mechanical torque, wind speed, mechanical input and modeling of wind turbine respectively.

Expression for kinetic energy= ½ mv^2

The wind power produce by wind turbine based on aerodynamic characteristics can be expressed

$$Pi = \frac{1}{2}(p1(\gamma i, \beta i)p1\pi V^3 R^2)$$

Mechanical power for wind system is expressed as

$$Pmechp = Cpc(\alpha, \gamma)\rho A/2$$

Here ρ =1.225kg/m^3 which is denote air density,C_{pc} is represent power coefficient constant V_{wind} is wind speed in(m/s) area of rotor is shown by A. Cqs is torque coefficient and it is related with Cps as

$$Cqs = \frac{Cps}{\alpha}$$

$$\alpha = \frac{Rw * \omega s}{Vswind}$$

$$Tw = \frac{Psmech}{\omega s}$$

Cps = performance coefficient

ρ = air density

Vswind = speed of wind

A = swept area of turbine

Rs = wind turbine radius

Tw = wind turbine torque

ωs = angular freq.

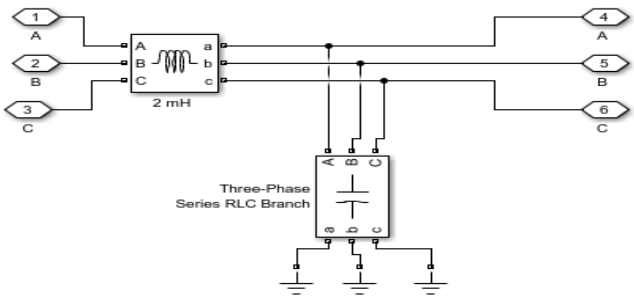

Fig.8 modeling of three phase LC filter

F.VOLTAGE REGULATOR

Voltage regulator is used for control the inverter by PWM signals at desired frequency. The PWM signals contain three phase sinusoidal signal with 120^0 phase difference. These signals compare with carrier signals and generate control pulse for inverter. Vph is phase voltage at fundamental frequency.

$$Vph = \frac{(2\sqrt{2})}{\pi}\cos\left(\frac{\pi}{6}\right)Vdcs1 \qquad (4)$$

Vdcs1=input voltage for inverter

To produce desired pulse for DC to AC converter PID control PWM technique used

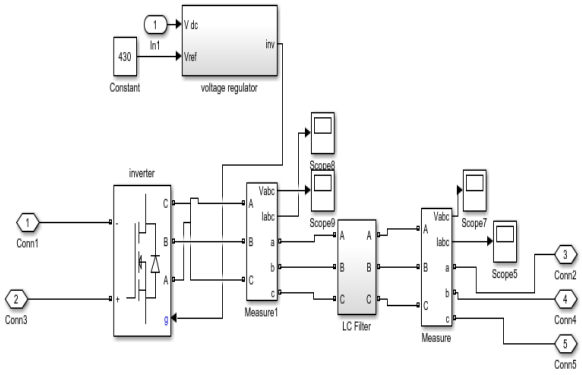

Fig.9 modeling of voltage regulator controlled inverter

G. UNIFIED POWER FLOW CONTROLLER

To control different parameters of transmission power system UPFC is used which is an ultimate facts device .the main characteristics of UPFC is control the active and reactive power. It is used for remove the impact of necessary disturbance on transmission system.it is connected to end of the transmission system.it is consist static shunt synchronous controller (STATCOM) and static series synchronous controller (SSSC) with DC link. UPFC output give to filter to eliminate the harmonics which is produce by IGBT & MOSFET device introduce in UPFC circuit.

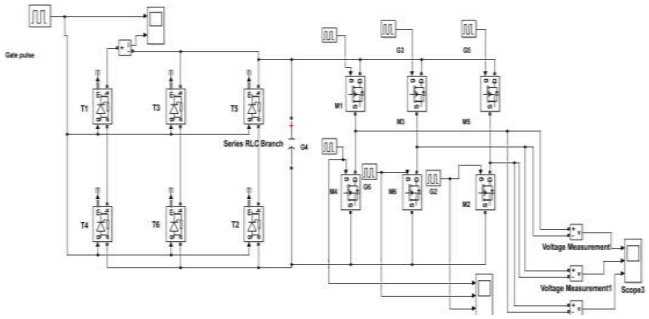

Fig.10 modeling of UPFC

By introduce fig.10 UPFC voltage dip profile improved at specified time and current flow continuous. Voltage spikes balanced and active & reactive power improved.

III.SIMULATION AND RESULT

Fig.10 is present simulation of grid connected hybrid system which is containing solar and wind energy sources and control by voltage regulator. To enhance power quality of grid connected hybrid system UPFC facts device is applied. Solar irradiance & wind speed is taken as input for simulation. Fig.10 indicates solar output and wind generation system. Grid connected Hybrid system is run for 1 sec in MATLAB/Simulink software. Fig.11, 12 present DC boost voltage after using converter which is increase PV array voltage to a DC high level voltage with MPPT (P&O) algorithm & output of wind turbine in which PMSG wind turbine generate AC voltage then convert to DC voltage by using rectifier, Fig.13 show coupling voltage after both PV/Wind subsystem connected to a common DC link. Fig.14 shows three phase output voltage after using converter. Fig 15, 16 show voltage and current interruption of grid connected hybrid system, grid side voltage without UPFC respectively.Fig.17 shows voltage and current with UPFC which improve the voltage spikes and recover the voltage interrupt problem.Fig.18 show grid side voltage with UPFC which remove the voltage spikes.

IV.CONCLUSION

This paper present power quality improved by UPFC of a grid connected hybrid system which is contain solar and wind energy source, controlled by voltage regulator. Simulation of UPFC controlled hybrid system is carried out by MATLAB software. The operation of system is analyses at different wind speed and irradiance level. The introduce grid connected hybrid system is evaluation at wind speed at 12m/s and solar PV panel at irradiance 1000w/m^2 and temp 25^0 form t= 0 to t=1sec. is applied then coupled both DC voltage to DC link is controlled by voltage regulator and performance is estimate & refined. To accomplish the necessity of electricity in a remote area utilized grid connected hybrid system. The advanced system functioning is accomplished in MATLAB/Simulink software and results are shown.

***Abstract*—Secure encryption algorithms with advanced key executive techniques constantly help to achieve privacy, verification, and security of the data and curtail the overheads of the system. Currently, the prominent cryptographic technique is the Advance Encryption Standard (AES). The 128-bit pipelined cipher AES components adopt the symmetric-block cipher algorithm for encryption of the data. Our application achieves a high-level of encryption of 25.6 Gbps with an effective inter-and-intra-round layout. This module is designed on Xilinx ISE® Design Suite 14.7 and optimized for faster conversion speeds as the module is based on the pipeline architecture to perform the repeated array of operations known as the round. The designed module is suitable for high-security data communication, image processing, and other embedded applications. Pipelined architecture reduces the time associated with each encryption process and decreases the total time it takes for a plaintext block to encrypt.**

Keywords*—Advanced Encryption Standard (AES), high throughput, pipeline architecture, cryptography, FPGA implementation

I. INTRODUCTION

The information is required to be secured and protected from any unauthorized access. The majorly accepted security enhancement solutions to prevent data theft to any third-party or unauthorized public access is the use of cryptography. Cryptography is the study and practice of technique s in the existence of third parties to secure the trans mission of data [1]. An encryption algorithm is an important component of the safety of the network. In recent times, cryptography has extended to algorithms based on demand. Modern cryptographic algorithms can offer safety services such as information privacy, data integrity, authentication, non-repudiation and control of access. Pipelining is a strategy to improve the AES encryption and decryption algorithm throughput. The amount of turns in the algorithm and the main generation depends on the AES encoding [2]. The Data Encryption Standard (DES), commonly accepted in safety products, is a well-known cryptographic algorithm. However, 56-bits key length is short and is not suitable for long-term security. The emergence of reconfigurable systems such as FPGAs made it simple to hardware the execution of complicated algorithms, which makes velocity improvements substantial.

The 10-round AES-128 bit includes a main module extension that produces 10 keys during the 10-round process. These keys are either produced, stored and subsequently used during the ten rounds or calculated per round on a fly. By using the iterative looping concept as well as the main extension module that calculates the keys on a fly, the proposals decrease the delay and the use of multistage pipeline ensures the best throughput possible. DES, AES, Triple-DES, RC4, etc. are the different symmetric-key algorithms types [3]. Elliptic-Curve cryptography, RSA, etc. are the various types of asymmetric-key algorithm.

Including ease of use, ease of upgrade, portability, and flexibility, all are the benefits of software application approach for AES. However, an application of software approach provides only restricted physical safety, particularly for important storage [13]. Conversely, the hardware implements cryptographic algorithms (and their associated keys), which can't be read or altered readily by an external attacker, are naturally more physically safe. An absence of flexibility regarding algorithms and parameter switching's is the downside of conventional Application Specific Integrated Circuits (ASIC) hardware applications. Reconfigurable hardware systems such as FPGAs are a promising option for block cipher execution.

II. BASIC ARCHITECTURE OF AES

Joan Daemen and Vicent Rijmen developed the algorithm for AES cipher. Group of bits forms a block and these blocks are used in the AES algorithm making it a block-cipher algorithm. Each block has a fixed-length. Encryption makes the information indecipherable as a cipher-text [4]. Decryption converts the cipher-text into the original

plain-text. AES symmetric cipher block can make use of 128, 192 and 256-bits of cipher-keys to operate the 128-bits of data. Each iteration is called round in the algorithm. 128-bits, 192-bits, and 256-bits of data require 10, 12 and 14 rounds respectively to process the original information into the cipher-text [5]. This paper presents the pipelined AES architecture which uses (AES-128) 128-bits as key-length for encryption 128-bits data. A matrix is formed known as the state by the arrangement of the 16-bytes grouped from the 128-bits data.

The size of the matrix is based upon the block size being utilized which is further composed of four rows and Number-of-bits (Nb) columns [5]. Each block is made up of 32-bits (4-bytes). The state matrix in the block design is a 4x4 matrix. Also, the cipher-key is composed in the same manner as of the state. The operational round in each iteration consists of quite a few procedural steps. Each step contains 4 similar but distinct phase, incorporating the step that is dependent on the encryption-key itself [6]. The different stages follow as,

- Sub Bytes
- Shift Rows
- Mix Column Transformation
- Add Round Key

AES algorithm data flow path is depicted in Fig. 1.

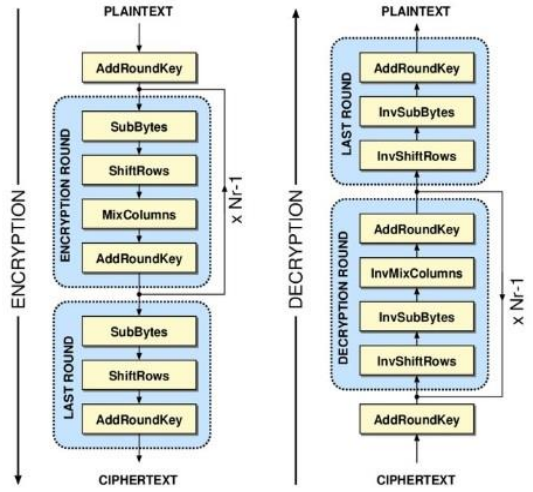

Fig. 1 AES algorithm architecture [16]

III. AES INTERNAL STRUCTURE

The initial key is combined with the input data at the first stage of the encryption phase, known as the preliminary round. Multiple repetitions succeed immediately after the initial round and follow up to an analogous modification for the final. The processes performed in each round are as follows:

A. Sub Bytes

The 16-bytes input is replaced (non-linear conversion) by referring to a predetermined Look-Up-Table (LUT) known as the Substitution-box (S-box). A 4x4 matrix is obtained as the result of the sub-byte conversion [7]. The Galois Field characteristics are fulfilled in the design.

B. Shift Rows

Each row in the 4x4 matrix is shifted to the left. The shift takes place as follow:
The data in the first row is not altered. Data is left-shifted by 1-byte, 2-bytes, and 3-bytes in the second, third and fourth row respectively [8]. A new matrix is obtained where the same 16-bytes are rearranged forming a new data matrix.

C. Mix-Column Transformation

The mix column conversion is governed by the Galois field multiplication. Herein each byte is replaced by a precise calculated value. Each multiplication data (r(x)) is determined by the formulae stated as below [9]. The mix columns theory is calculated using the below formula [18].

$$\begin{bmatrix} r_0 \\ r_1 \\ r_2 \\ r_3 \end{bmatrix} = \begin{bmatrix} 2 & 3 & 1 & 1 \\ 1 & 2 & 3 & 1 \\ 1 & 1 & 2 & 3 \\ 3 & 1 & 1 & 2 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{bmatrix}$$

Where the conversion r0, r1, r2, and r3 are the outcomes. After the information undergoes a replacement in the S-boxes, a0 – a3 can be gathered from the matrix. It performs a linear operation on the columns of the matrix. This AES-architecture method needs more energy and a big chip area due to its complex circuitry.

D. Add Round key

The 128-bits of data is now present in the form of a 4x4 16-bytes matrix which is XOR-ed with the 128-bits round-key [10]. After the last round, the output is the Encrypted 128-bits data. The 128-bits data considering 16-bytes again goes for the related round if the current iteration is not the last one. The 10-cycle encryption is concluded with the achieved 128-bit data as output. The AES algorithm structure is as shown in Fig. 2.

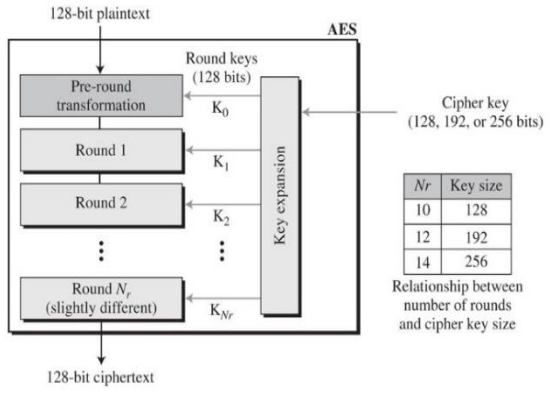

Fig. 2 AES algorithm Structure [17]

IV. Sequential And Parallel implementation

Sequential implementation of the AES method initially converts the plain text into a status array and then XORed with the entry cipher key for the add round key process. This is then done with the unit which consists of four subunits: Sub Bytes, Shift Rows, Mix Column and Add Round Key (round 1 to round N-1). This is followed by another unit with three sub units, Sub Bytes, Shift Rows and Add Round Key. The application covers a small area because it utilizes the same equipment from round 1 to round N-1. Fig. 3 shows the 3-stage AES implementation sequentially.

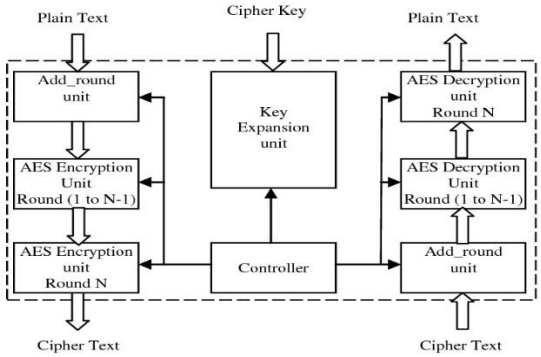

Fig. 3 Sequential 3-Stage AES implementation [13]

The combination method is used to reduce the delay and to boost the performance and the usage of the pipeline method, a further increase in the output can be achieved. In this method, after each rounding unit, a128-bit register is used to momentarily store the information. The highest frequency of operation is obtained from the 1-round delay [11]. High working velocity and frequency are the main benefits of the pipeline method. Fig. 4 shows the implementation of pipeline Rijndael and AES-128.

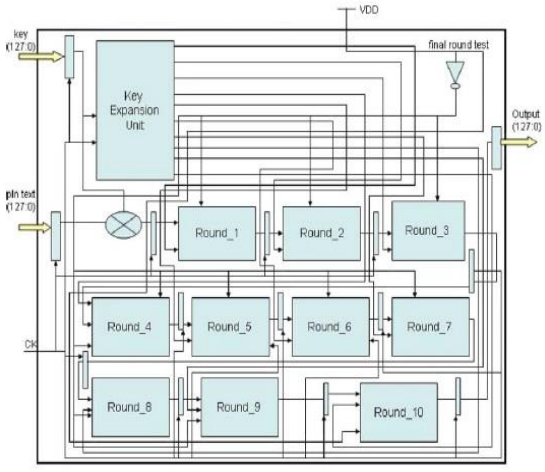

Fig. 4 Implementation of pipeline Rijndael and AES-128 [15]

V. Proposed Module And Verification

The aim of the AES implementation with pipeline architecture helps to achieve greater throughput with optimized delay. In the design, top module forms rounds relate key expansion with the use of pipeline architecture. Instantiate key expansion that feeds each round with round-key. According to the algorithm, the 1st cipher-key is XOR-ed with the plain-text [12]. Connect all the round with key-expansion and instantiate them. The final round consists of three stages only and so a delay register should be used with the key-expansion to balance the output. The module is designed on Xilinx ISE® Design Suite and this design can be tested and verified on hardware using Virtex®-6 FPGA. The first AES silicon implementation that delivers 2.29 Gbps of non-pipeline architectural performance. The T-Box was the first AES application to have more than 10 Gbps output, which included a mixture of sub-bytes, shift lines, and blended AES columns. With a 30-70 Gbit/s output, a fully piped AES processor works in a more difficult way. The conversion of the AES Mix Columns works in a four-column database and is separate for each column. In a single loop, 60% of the total latency results in the delays of execution of mix columns. Parallelism is therefore presented in the block of mixing columns. This increases the output of the execution of the mix columns.

The functional verification of the module is done with the help of the test-bench. The expected output and tested vectors are stored in the files. The top-end module (Top_PipelinedCipher_tb) for the test-bench covers 284 test patterns composed in AES validation suit document (AESVS). The compilation and simulation are optimized using do files for automation. For gate-level simulation, the first stage after synthesis and implementation is to place-and-route the simulation model and generate the Verilog net-list with the user-constraint file (ucf). The design hierarchy of the module at each level is shown in Fig. 5.

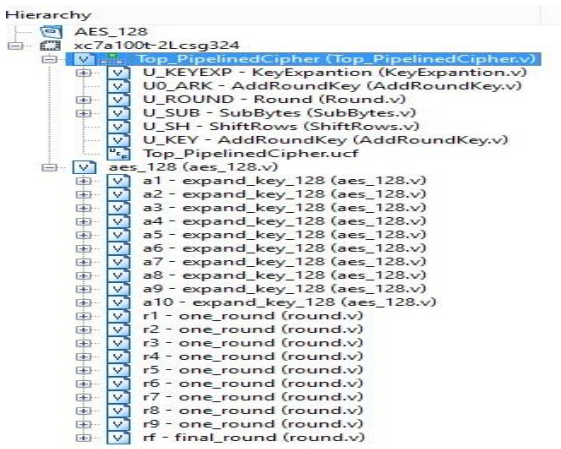

Fig. 5 Module hierarchy

VI. Experimental Results

The utilization of resources is less for the AES and the performance is high due to the pipelined approach. The AES processor based on S-box architecture provides a throughput of 1.5-2 times higher than that of the AES processor based on the common LUT S-box. As the S-box based on LUTs are faster, it is feasible to apply the LUT-based advance to S-box hardware approach as the starting point so as to further improve it through pipelining. Fig. 6 shows the top-level module which takes a 128-bit input and gives the output of 128-bit and Fig. 7 depicts the RTL expanded view of the module displaying the submodules and clock-gating implemented inside the module. The module operates at constraint frequency of 200 MHz and the clock time-period 5ns.

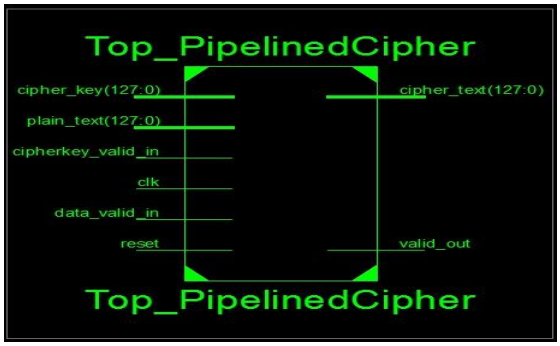

Fig. 6 Top-level view

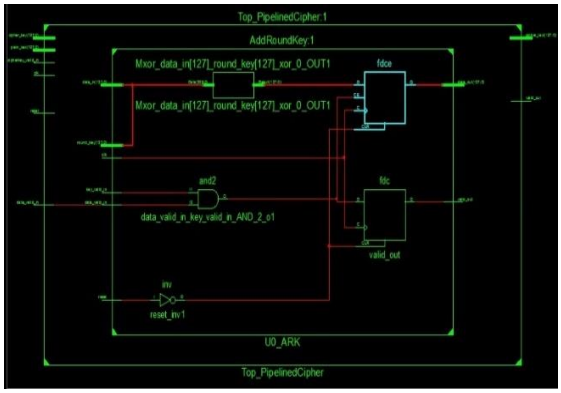

Fig. 7 Expanded RTL design

The simulation result of our designed module is shown in Fig. 8 i.e. AES encrypted output, where the input is taken from the test-bench (or manual input) and also the Encryption/Decryption modules are incorporated inside the Top-level module. The module's encrypted data and the simulation results are verified. The plain-text "2123233353addcc25213453125312534" it's AES encrypted output is as "d0b440f3b845ff73f542a095ba257798". To boost the output of AES encryption, the execution of both matrix components is done by implementing two parallel components simultaneously using the eight phase parallelism method. Parallel block performance is improved and their implemented area is reduced.

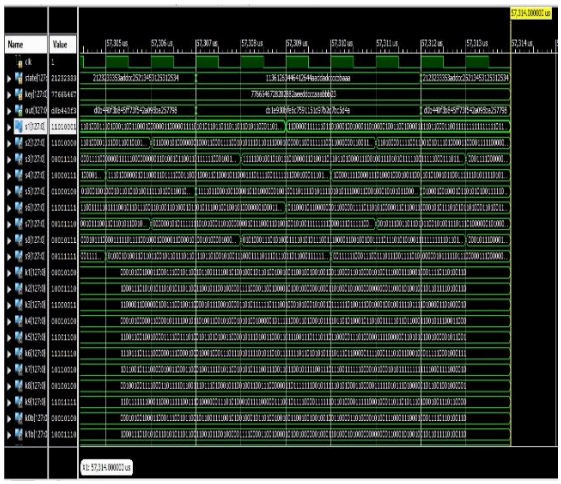

Fig. 9 AES Encryption module simulation waveforms

The latency and throughput are calculated as below:
Latency is the time delay from input to the required result.

- $Latency = constraint\ freq./period$

Latency = (41) clock-cycles*period (5ns)

$$41 \times 5 = 205ns$$

Throughput is the rate at which the information is processed by any system. It is measured in bits/sec.

- $Throughput = data/time$

$$Throughput = \frac{128}{5ns} = \frac{25.6bits}{ns} = \frac{25.6Gbits}{s}$$

VII. Conclusion

In our proposed work, we have designed a pipelined AES-architecture which has high throughput. Registers are inserted in the design at appropriate points to achieve the objective. For the proposed pipelined AES, the throughput achieved is 25.6Gbps with 200MHz of constraint frequency. We can use this architecture in many application-based designs such as voice-communication, video processing, banking systems, and image processing and mobile-network security. We can adopt this module in high-security data communication and prevent third-party attacks on our systems. The design can be included in many embedded applications to enhance the conversion speed and security of the system.

ACKNOWLEDGMENT

This work is carried out in the laboratory of School of VLSI Design and Embedded Systems at NIT Kurukshetra. The authors acknowledge the generous, technical and EDA tools support by the faculties and management of the department.

***Abstract*—This paper introduces AC to AC converter for Single phase Pulse Width Modulation (PWM), which can solve the commutation issue by employing AC to AC converters without detecting the input voltage polarity. With a salient structure of SC and connected inductors. The PWM ac to ac converters replaced by the SC design and a coupled inductor by the standard leg hence the boost inductor buck and boost type suggested converter is developed. In this commended work the suggested converter has requirement of two coupled inductor and this coupled inductor is combined with the boost inductor. The input inductor of suggested converter could be much compact than that of standard Pulse Width Modulation (PWM) AC to AC converter. The MATLAB-2016 b setting presents the simulation-based buck-boost ac to ac converter.**

Keywords—AC-AC Converter, Pulse width modulation (PWM), Switching cell (SC), Coupled Inductor(CI), Boost Inductor,MATLAB.

I. INTRODUCTION

In power electronics, interleaving is a commonly used method. If more than one Pulse Width Modulation (PWM) converter is paralleled, each conversion carrier can be shifted in a phase and certain harmonics can be canceled at the output. The angle for phase change is generally 180 ° for two parallel cases, whereas other values can be determined to achieve certain design objectives [15]. In many applications, such as industrial heating & illumination the suggested regulator can upgrade or down output voltage to input voltage. The Phase Angle Control (PAC) control system is widely used in a variety of applications. In comparison with the standard Pulse Width Modulator (PWM) regulator, the suggested regulator also restricts more harmonic yield voltage [13]. A crossover technique reduces the output present ripples of coupled inductors [1]. The voltage control is needed in manufacturing systems, as it provides different benefits such as small-size, easy configuration, elevated effectiveness, low-cost and so on [9]. The greatest difficulty in the design of a boost converter is how to manage the large energy flow at the plant and high voltage [7]. The suggested converter inductor can have a much lower input than the standard PWM AC to AC converters [11].

Fig1. Represents the Standard direct pulse width modulation (PWM) AC to AC Converter with type of buck-boost give signals from the gate (optimal) which can be implement with switching cell structure and boost inductor in this paper.

II. Composition Of Suggested Converter

The suggested converter consists of a fundamental switching cell, Boost inductor and coupled inductor. This fundamental SC structure is formed by employing a switching device and a diode that are connected to three terminals :(+), (-) & (→)/ (←). Figure.2. represents the suggested Single phase Buck Boost type Pulse Width Modulation (PWM) AC to AC converters.

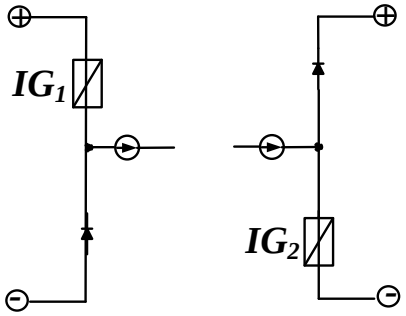

Fig.2 Fundamental SC structure

Fig.2 represents the fundamental switching scheme which is combination of any switching element and diode. Here S denoted in fig 2 any swiching element. The P-cell and N-cell two fundamental turning cells, and their electronic circuit-powered application[5].

The suggested converter consists upper side and lower side legs. The upper side leg has two switches [S1 & S2] ,two diodes [D1 & D2], a coupled inductor, a capacitor and a Boost inductor. Same as lower side can be formed. The two capacitors [C1 & C2] are added across each phase side to form a current path when S1 & S2 are both turned OFF. These capacitors are used as input or output filter. Furthermore serve as simple snubber capacitor to suppress switch voltage overshoot. energy factor and effectiveness and lower passive filters are better used, PWM ac choppers are preferred.[3].

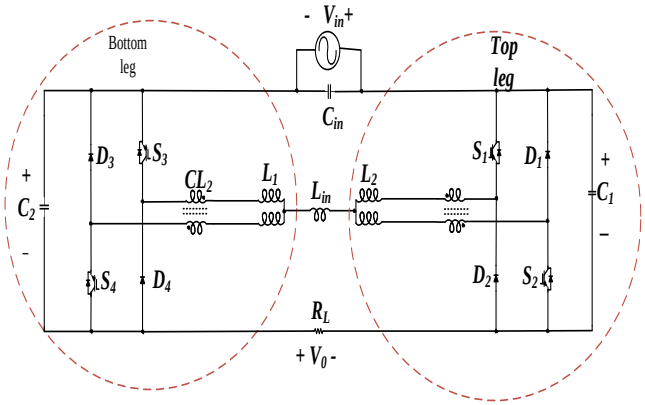

Fig 3. Suggested Buck-Boost single Phase PWM AC to AC converter

Fig.3. denoted suggested converter which is combination of SC structure, coupled inductor and boost inductor.

III. Analysis Of Ripple Current For Inductors

In this part of the paper the input inductor and two coupled inductors are investigated. The proposed converter is aimed at reducing the ripple without an increase in the inductor value. This is why the converter technology is interlinked.[6].

A. *INPUT INDUCTOR*

From the waveform fig.5 it is noticed that input inductor L_{in} is made smaller in the suggested converter for Buck Boost type than the input inductor in the standard Boost type AC to AC converter. Fig.4 represents input current of coupled inductor.

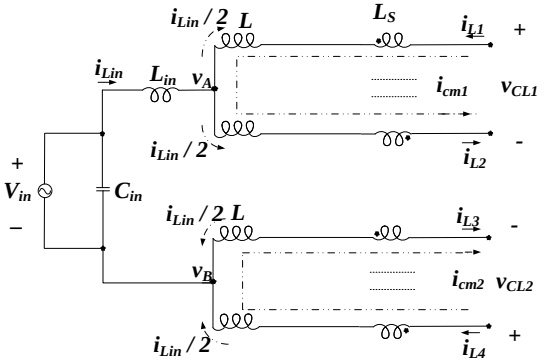

Fig.4. Boost inductor input current and mode of common

B. *INPUT INDUCTEOR DESIGH-* The calculation for current ripple in the L_{in} is mentioned as below

$$\Delta i_{L_{in}} = \frac{(0.5-D)D}{L_{in}} v_0 T_s \qquad (1)$$

Thus, when D = .25 with Vo = $Vo_{.max}$ then the occurring current ripple is maximum. Where T_s is the switching period of the converter.

C. *COUPLED INDUCTOR*

As coupled inductors have perfect coupling so the coupled inductor is assumed for the suggested converter to calculate the current ripple in the common mode.

D. *COUPLED INDUCTOR DESIGN-* The current ripple can be derived for the common mode as follows –

$$\Delta i_{cm1} = \frac{vc_1}{4L_s} DT_s \qquad (2)$$

$$\Delta i_{cm2} = \frac{vc_2}{4L_s} DT_s \qquad (3)$$

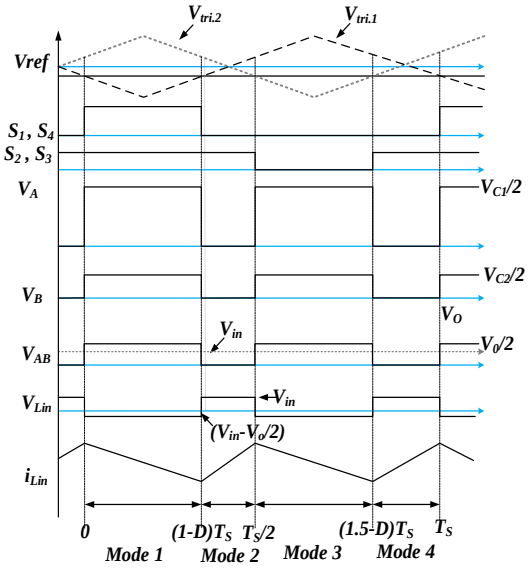
The ripple current equations can be calculated in each mode & maximum current ripple occurs when either Vc_1 or Vc_2 is which are explained as-

The winding currents equations of coupled inductor can be rewritten as –

$$\Delta i_{L_x.max} = \left[\frac{1}{L_S} + \frac{1-2D}{L_{in}}\right]\frac{v_0}{4} DT_s, x = 1,2,3,4. \quad (8)$$

Although a converter's output current ripples can decrease significantly due to the interleaving effect, even with the interleaving PWM method, the inductive current ripples cannot be decreased. A combined inductor is one way to fix this issue.[4].

$$\Delta i_{L_{in}.conv} = \frac{(1-D)\,D}{L_{in.conv}} v_0 T_s \quad (9)$$

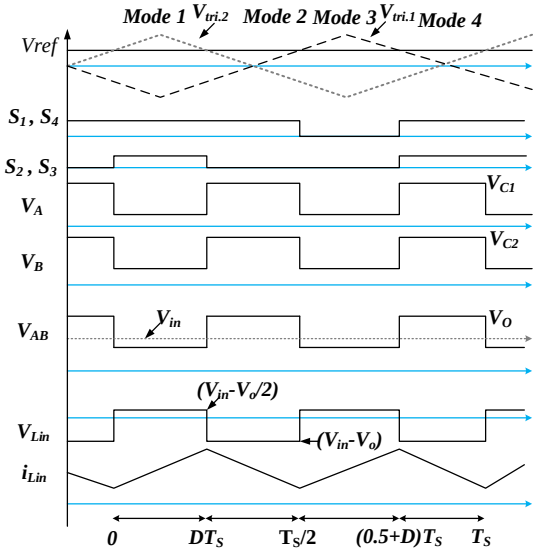


(a)

Fig.5. represents the comparison of key operational waveforms when duty ratio is less than 0.5 which is shown by waveform (a) and its opposite waveform (b) shows when duty ratio (D) value is greater than 0.5.

Where ideal gate switching is given for switching device and common mode current is also calculated for these input boost and coupled inductors which combine with switching cell structure.

In fig 5 represented switching of four converter which denoted by S1, S2, S3, S4 given by comparison of a triangular wave with reference or compare with duty cycle. Duty cycle is denoted by D. which is time interval of switch S2 and S4.



(b)

Fig.5. Key operational waveform analyzes if 0.5 < D > 0.5 for (a)&(b)

Fig.5 the effect on the common mode DC current element of switching turn ON and OFF delays when duty ratio is less than 0.5 which is shown by waveform (a) and its opposite waveform (b) shows when duty ratio (D) value is greater than 0.5.Small distinction mid of these four-switching devices can therefore fix the saturation issue by having adverse voltage drop across the boost and coupled inductors. Fig(b) Small distinction between S1 and S2 (or S3 and S4) can fix the saturation issue by having adverse voltage drop across the inductors.

With the converter elevated changing frequency procedure, the amount of the suggested converter magnetic parts can be further decreased as the diodes in the suggested system are internally chosen with very quick retrieval diodes. The necessary output inductance of the standard ac to ac converter (Lin.conv)is significantly higher than that of the converter suggested. For example, when D= 0.45, the Lin.conv is nearly 11 times Lin. Consequently, the total quantity of the suggested the standard ac–ac converter.

These types switching have four mode conduction period voltage input and output voltage waveform is shown in simulation model which leads to input inductor voltage in buck-boost ac to ac converter.in output current of inductor has some ripple current which highest on the 0.25 duty cycle and minimum in 0.5 duty cycle to finding ripple current using equations which expended in little ripple to compare issues and producing the switching frequency to reducing harmonic and power stages calculation in the process.

So, these types of key operational waveforms are shown above in two parts and represented effects of turn on and off delays also.

Fig.(b) shows input inductor current IL_{In}, input voltage V_{in}, output voltage V_0

Fig.7. MATLAB Simulation results

Fig.7 represents the simulation of the proposed converter. According to the parameter design simulation parameters are selected input voltage (v_{in}=110v_{rms}), output voltage (v_o=220v_{rms}), output power (p_o=200 w) and D =0.4.

V. Conclusion

In this paper the behavior of a coupled inductor is explained on the inductor and output current ripple in the brief. Since Single Phase Step up and down Buck Boost is suggested in this paper which can further implemented for the three-phase system in future point of view. Furthermore, this suggested grid technology is used for Wind Power Generation Scheme. Coupling inductor is applied as high frequency circuits because of high frequency circulating currents. Parallel inverters can be more stably operated in high present applications compared to non-coupled cases. With a coupling impact, the present filter inductor waves are decreased.

Abstract*—Retinal disease classification of Color Fundus Images using Computational Imaging has been widely accepted. This paper proposes a transfer learning approach for Retinal Disease Classification using Deep Learning. Deep learning methods are widely used due to higher performance and accuracy but at the cost of time. A large amount of time and processing power is required to train a dataset and achieve considerable accuracy. Transfer learning reduces a load of using huge data-sets, thereby reducing the time complexity of the training data. We have selected VGG19 model to fine-tune the network for the extraction of knowledge. The VGG19 model is fine-tuned with a retinal database. The results contain accuracy the network on changing various hyper-parameters like learning rate, number of epochs, optimizer algorithm to find a suitable set of parameters for higher accuracy. The motivation for using Deep Neural network is the fact that it has multi-fold benefits like better performance compared to traditional machine learning techniques, higher accuracy, automated feature extraction and easier to design and process.

I. INTRODUCTION

Retina is the photosensitive portion of our eyes which is delicate, crucial and responsible for the vision. Even minor damage to these tissues can result in symptoms like distorted vision, blurry vision and even loss of sight. These symptoms if left unattended can result in serious diseases like vision impairment or even temporary or permanent loss of sight. Hence it is very crucial to detect and attend to these diseases to the earliest. There are various different diseases that can be caused due to effects in the retina like Glaucoma, Diabetic Retinopathy, Retinal Tear, Retinal Detachment, Macular Degeneration etc., The rectification of these diseases is necessary as early as possible. In order to rectify the disease, it is necessary to figure out the type of disease. This paper provides a solution to this problem by detecting the disease through transfer learning, a deep learning method. Deep Learning requires a lot of data to train and it may require a lot of time and memory as well but this is an efficient method once the neural network model is trained of the data set completely. It effectively detects the retinal disease and even classifies them, making it easier to cure. The issue that usually occurs in traditional machine learning models and the neural network is the time and processing power which is required to compute the output. In order to improve the accuracy, new data should be fed to the system, but in case the system has a huge dataset, high processing power, and time commitment is required to get decent accuracy. In this paper we propose a system that transfers its knowledge from a relatively pre-trained model and implements this on our dataset, to update the weights and biases. This knowledge transfer between machine learning algorithms is known as Transfer Learning. The profit of using this methodology is it retains most of the neural architecture of the pre-trained model and tunes the architecture to minimize the loss for the un-trained model. Hence it requires less computing and is much faster as compared to the traditional CNN and Machine Learning algorithms.

II. LITERATURE REVIEW

In a very few decades, biomedical imaging and retinal image computing have gathered the attention of various researcher as the output of the computation system is considered better than verbal dictation of the system or other traditional methodologies. Prior works in this field are done by [1], [2] have used machine learning methods to generate an accuracy of 81-86%, [3] compared popular algorithms to produce and increase the accuracy in classification, while [4] uses simple image processing for detection of defects. This paper uses transfer learning as it is suitable for small scale data set [5]. The motivation of the proposed system was from [6], according to which VGG19 [7] model showed a decent accuracy as compared to other models.

III. SYSTEM SPECIFICATION AND OVERVIEW

A. Hardware Specification

When designing a prototype, the performance always depends upon the hardware specifications, the better the hardware, the less is the execution time and higher is the processing power there by increasing the overall performance. This section of the paper provides a detailed outline of the hardware specifications that we used to get to the result of this paper. The neural net model was designed and deployed on a system with the following specifications.

TABLE 1: HARDWARE SPECIFICATIONS

Sl. No.	Specifications	
	Name	***Value***
1.	Processor	Intel Core i5-8300H Processor
2.	RAM	8 GB DDR4 2666MHz
3.	GPU	NVIDIA GEFORCE GTX 1050 Ti (4GB GDDR5)

B. Software Specifications

PyTorch is a python based neural network computing frame work. We have used PyTorch to design and execute the neural network model. PyTorch is completely python based and hence it is preferred by us as it is very friendly with the native python based packages like Numpy, Scipy, Python Imaging Library (PIL) etc., VGG-19 is a pre-trained deep neural model which is 19 layers deep. We have preferred this model for fine-tuning our custom dataset and to transfer knowledge as it is faster and more efficient [8].

TABLE 2: SOFTWARE SPECIFICATIONS

Sl. No.	Specifications	
	Name	***Value***
1.	Language	Python 2.7
2.	Frame Work	Pytorch
3.	GPU	Cuda 9.0
4.	Pre-trained Model	VGG-19

The GPU used (Refer table 1) supports Cuda 9.0, which increases efficiency of the model [9].

C. Pre-trained Model – VGG19

VGG network was designed in [10], which proposed simple and effective network architecture for efficient accuracy and was trained on a million images.

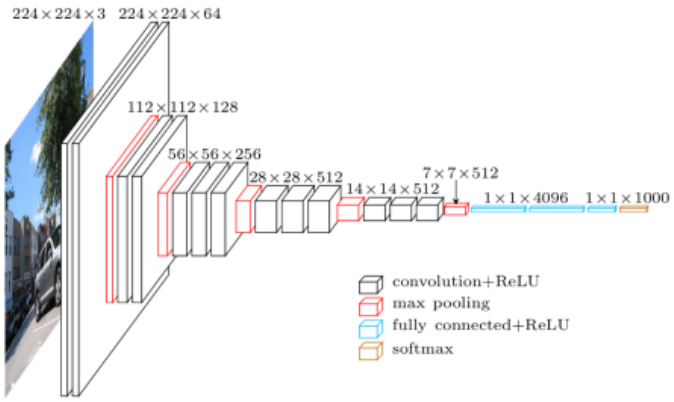

Fig.1. VGG Architecture

IV. METHODOLOGY

This section of the paper explains the architecture of the proposed system and the method incorporated to reach to the conclusion.

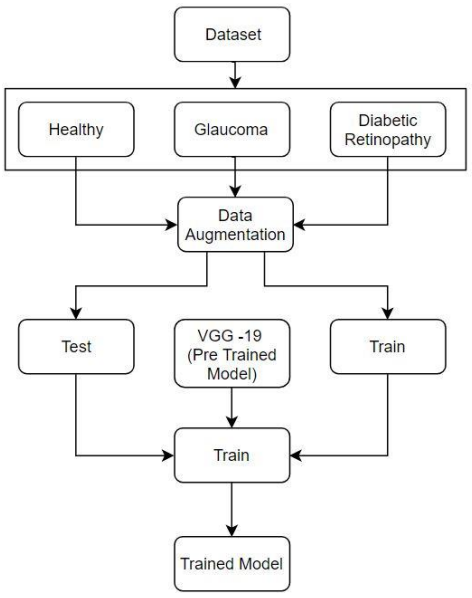

Fig.3. Model Representation

The dataset contains three types of images, healthy, glaucoma and diabetic (Refer to Fig. 5). These images are segregated into different folders. Here VGG network (Visual Geometric Group) [11] is used. First we go through preprocessing followed by extraction of features and then finally identification of images.

A. Preprocessing of images

Since the dataset [12] has less number of images, more images needs to be created because this helps in increasing accuracy of the model. We went through the process of data augmentation for this purpose. The process of data augmentation involves rotation, flipping and cropping of images. This helps in creating more number of images [13]. Not only does it just increase the number of images but also it increases the overall robustness of the model there by making it more accurate.

B. Extraction of features from image

This step involves extracting specific features from the images which later will be used in identifying and segregating the images into healthy, glaucoma and diabetic. For this processes VGG-19 [14] network is used, it was created by Oxford. VGG can contain 11-19 layers but here all 19 layers are used. This convolution network is built using layers having size of 3*3. The diagram below gives the description of layers in VGG [11].

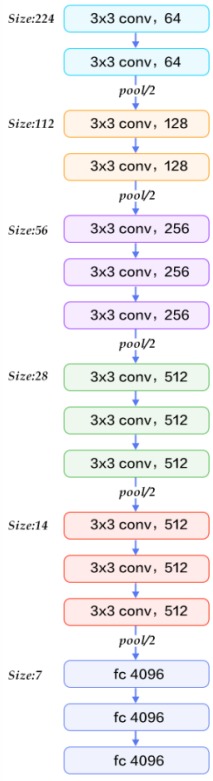

Fig.4 Layers of VGG (https://qph.fs.quoracdn.net/main-qimg-e657c195fc2696c7d5fc0b1e3682fde6)

C. Identifying the images

After getting the desired accuracy, we have saved the trained model into a dictionary format which we use for inference on the required data. In order to predict, we pass the retinal color fundus image through the model which identifies the features from the image and predicts the retinal disease. The results for the experimentations are discussed in the next section.

V. RESULTS AND DISCUSSION

In order to figure out the best preferred hyper parameters, or the optimum hyper parameters, we have used a brute force approach by plotting the epoch vs. accuracy curve at different frequently used learning rates. The accuracy of the model is changed by changing the number of epochs keeping a constant learning rate. It is observed that greater than 90% (Refer to Table 3) of the accuracy is reached in most cases. The model successfully classifies the images into healthy, glaucoma and diabetic (Refer to Fig.8).

VI. CONCLUSION AND FUTURE SCOPE

It can be concluded that this method can be used for classifying and identifying various diseases in eyes and can prove to be helpful in medical purposes. The proposed method is accurate and can be used for mobile and early detection of retinal diseases. The number of classes used for this network is 3 (Healthy, Glaucoma, Diabetic) but number of retinal conditions can be included and a more accurate and variable network model can be created for better identification of retinal diseases using the proposed method.

Abstract:
Compressor logics are used to speed up the processing time. These structures are used for addition of Partial Products in multipliers. It reduces the complexity by reducing number of stages in addition. This paper speaks about addition of partial products using Vinculum BCD compressors under Vedic Mathematics. The proposed architecture reduces 7.04% of delay over VBCD and around 20% delay on conventional BCD multipliers when it was synthesized and simulated on vertex 6 platform using Xilinx 14.2i.

Keywords: Vinculum numbers, Compressors, multipliers

Introduction

In recent years nationally and internationally researches on Vedic mathematics is growing very much because of its efficiency, fast and ease of learning all algebraic and arithmetic operations. It was acknowledged by all over world that Vedic mathematics is faster than conventional methods.
Vedic mathematics is a part of Adharva Veda. It explains about the formulas pertaining to various Engineering branches, sculpture, Mathematics, and all other sciences which are an emerging field for research. These formulae are suitable for building digital circuits and can be implemented using binary and decimal number system. The work was focused on addition of partial products using compressor logic in Vedic Multiplier (Urdhav Triyakbhyam method)

The paper is organized as follows. Section I presents Vedic mathematics and its algorithm for an 8bit multiplication. Section II describes Compressor logic. Multiplier using Compressors is proposed in section III, Section IV shows simulation results and finally conclusion is provided in section V.

I. Vedic Mathematics:

1.1 8bit Vedic multiplier Line Diagram

Figure 1 shows step by step procedure of multiplication[15].

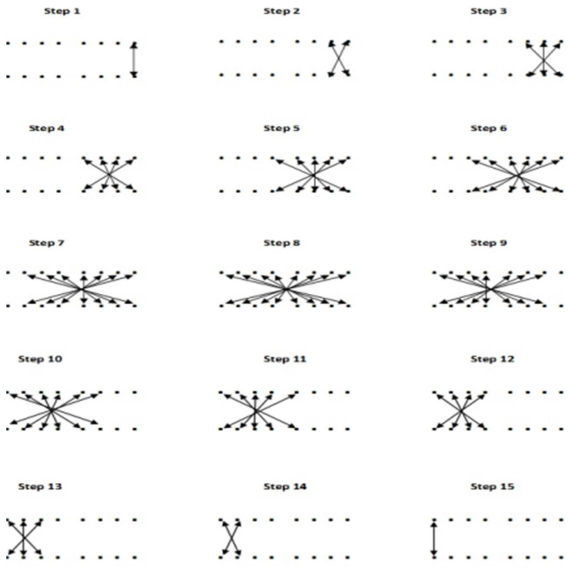

Fig 1: 8-bit Vedic Multiplier line diagram

Figure 1 describes step by step procedure of multiplication and final product is obtained by appending results from step 1(LSB) to step 15(MSB).

1.2. Conventional Multiplier Vs Vedic Multiplier

In Conventional Multipliers Final Product is obtained by shifting and addition. Considerable amount of time gets wasted in shifting bits. As number of bits increases, execution time increases which in turn increase hardware and power. Vedic Mathematics supports parallelism where large modules are separated into small modules. It has regularity and concurrency in structures. Complexity can be reduced by using small modules instead of large module.

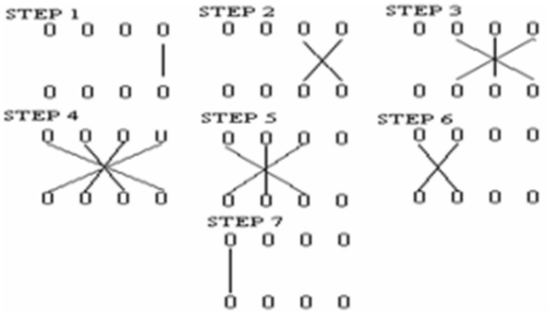

Fig2. 4x4 bit Vedic Multiplier Line diagram .

II. Adder Compressors

To achieve high speed and Low power digital or signal processing architectures we use different adder structures[8][18]. Compressors play a vital role in reducing delay and complexity. These are very useful in multipliers in adding partial products[19].Compressors with N-bit input provides Sum and Carry bits as outputs [8][5]. In literature there exist 3:2 compressors to 7:2 compressors. In our paper we used 3:2 compressors. 4:2 compressors have four inputs (a, b, c, d) with outputs sum and carry[8][15]. It receives an input C_{in} from the previous module and produces output C_{out} to the next compressor module as shown in figure 7.
Output C_{out} should be independent of input C_{in} to accelerate the carry save summation of the partial products.

VBCD Compressors

A decimal compressor consists of three operands a,b,c and Cin with Sum and Carry as outputs as shown in figure 4[18]. Algorithm is explained as below.

Algorithm for VBCD Compressor

$step\ 1$: $Read\ input\ operands\ as\ x, y, z\ of\ 4\ bit\ each\ in\ VBCD\ form$
$step2$: $Set\ output\ digits\ as\ Sum\ and\ Carry\ bits$
$step3$: $Add\ bit\ wise\ operands\ using\ Full\ Adders\ and\ check\ for\ Sum\ and\ Carry\ bits$
$case\ 1$: $If\ sum < 5\ or\ if\ sum < -4\ and\ carry = 1\ discard\ carry\ bit\ and\ take\ Final\ sum = sum$
$Case2$: $If\ sum > 5\ and\ carry = 0\ , Add + 6\ to\ the\ sum\ and\ set\ carry = 1$
$Case$: $3\ If\ sum > 5\ and\ carry = 1\ add - 6\ to\ the\ sum\ and\ set\ carry = -1$

Fig 3. Decimal 3:2 VBCD compressor

In the above example each bit of the operand is passed through full adders which results in intermediate sum and carry bits. It is added with carry bits to get final sum. If final sum is greater than 5 and carry bit '0' add 6 to it and take carry bit 1.The architecture of the compressor has been implemented through binary full adders, 2x1 multiplexer and adder/subtractor circuit. The architecture was shown in figure 5.

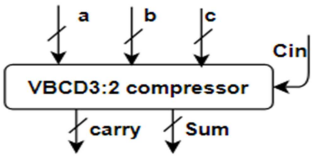

Fig 4. 3:2 VBCD Compressor

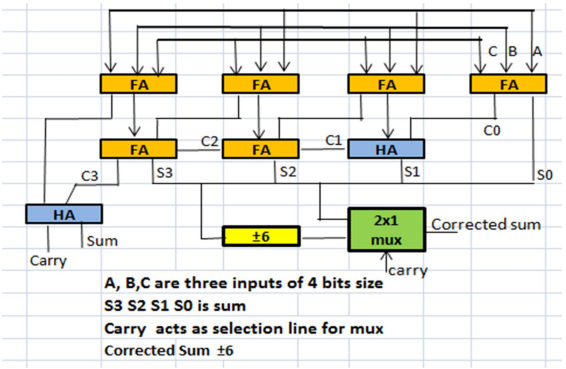

Fig 5. Basic Architecture of 3:2 Compressor

4:2 compressor consists of four operands and input carry as its inputs with two outputs Sum and carry along with intermediate carry C_{out} to the next stage as shown in the figure7 [4]. It is constructed using two 3:2 compressors where first three operands are given to 3:2 compressor1 and the output sum digit, fourth operand along with carry input is given to 2nd compressor 3:2. The output carry bit of first compressor is passed to next stage. This makes compressor faster than other adders. The weightage of the carry digit increases as the inputs increases. Same weight age of digits can be taken together for any digit compressor's inputs.

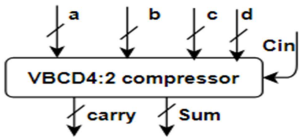

Fig 6. 4:2 VBCD Compressor

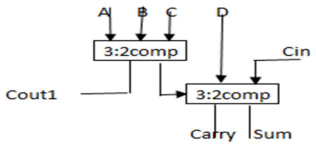

Fig 7. 4:2 Compressor using 3:2 Compressors

III. Proposed VBCD Multipliers:

3.1 Proposed Vinculum Number Representation

Vinculum is a term used in ancient (Vedas) mathematics which means bonding. It is used to represent decimal number system with less complex. Instead of using decimal digits from 0 to 9 it uses 0 to 5 to represent decimal 0 to 5 and -4 to -1 to represent digits 6 to 9 of decimal number system. Vinculum number set uses digits from $\{0, 1, 2, 3, 4, 5, \bar{4}, \bar{3}, \bar{2}, \bar{1}\}$ to represent 0 to 9[15].

3.2 Generation of Partial Products:

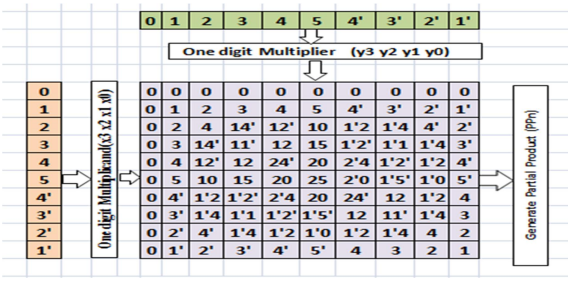

Fig 8. One digit VBCD Multiplier

LUT based one digit VBCD multiplier is implemented to reduce processing time, as shown in figure 8 where all partial products are saved in memory. The maximum value of the partial product generated by single digit is +25(5x5) where as in conventional BCD the maximum value generated is 81 (9x9).Very less combinations are available in proposed number system method which is simple and faster. This can be used as sub module while developing top module. [19]

3.3 Two Digit VBCD Multiplier:

Two digit multiplier uses vertical cross wire method (Urdhav Triyakbhyam) where it is divided in to two one bit multipliers to generate partial products as shown in example below. These partial products are added using VBCD compressors to generate partial product. Number of compressors required is equal to the number of bit multiplier.

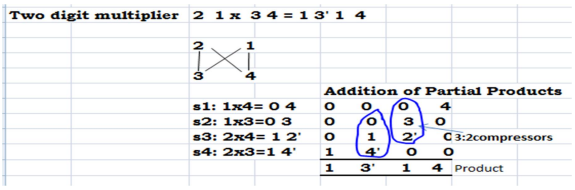

Fig 9: Example for 2 digit multiplication

Figure 9 shows the usage of Vedic multiplier, generation of partial products in terms of s1, s2, s3 and s4 and addition of partial products using 3:2 VBCD compressors. The output of these compressors provides final product. From the above example any two digit multiplier requires only two 3:2 compressors [18][19].

3.4 Four Digit Multiplication.

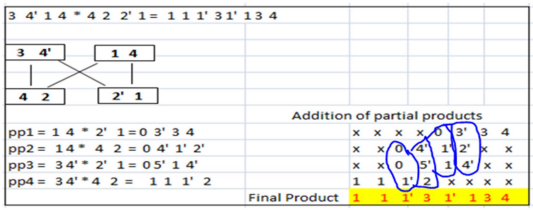

Fig 10: example for 4 digit multiplication

It is very simple to understand from figure 10 that four digits are divided into 2 halves, by using Urdhav Triyakbhyam method for generating partial products. Always for any digit number this method generates only four partial products (pp1, pp2, pp3 and pp4) and these partial products are added using

compressors as shown in figure10. In figure circle indicates compressor and for four digit multiplication we require four 3:2 compressors. Using this same logic multiplier architecture is developed which is as shown below.

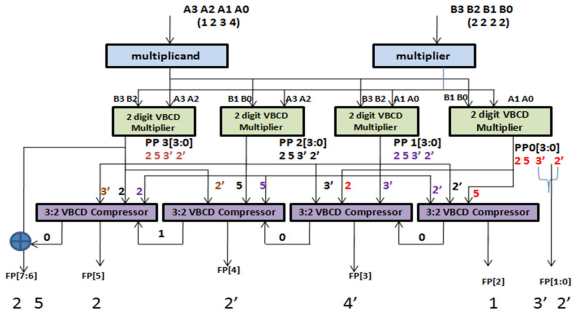

Fig 11. 4x4 digit Vedic VBCD multiplier using compressors

Using vertical and cross wire method these four digit multiplicand and multipliers are divided in to two, two digit numbers on which multiplication is performed. Two digit multipliers generates four partial products namely pp0, pp1, pp2 and pp3. Each partial product size is of 4 digit and these are given to VBCD compressors for performing addition. The output of these compressors gives final result as shown in figure 11.

3.4 Eight Digit Multiplier:

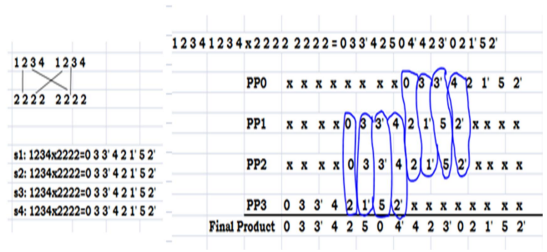

Fig 12: example for eight digit multiplication

The above example shows eight digit multiplication in which it is divided into two four digit multipliers. This Vedic method uses divide and conquer method where large module is divided into small modules for multiplication. This requires eight 3:2 compressors to get final product and all partial products can be added in parallel which is major advantage over conventional method. The maximum depth of the multiplier is only four always. For any multiplier it has only four partial products as shown in above examples. Therefore the basic 3:2 VBCD compressor is sufficient for adding partial products in Vedic method. For conventional multipliers as the number of bits increases partial products increases and depth of the column increases. So various sizes of compressors are required for conventional multiplication method.

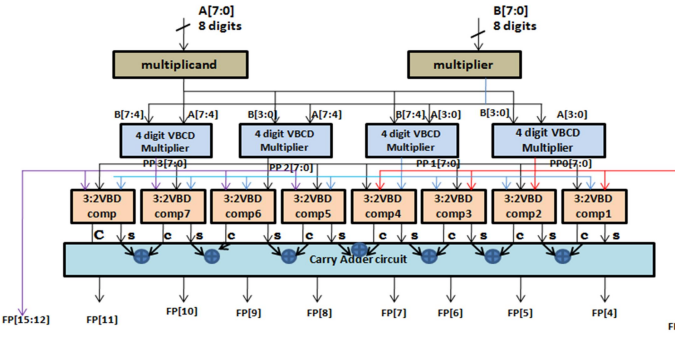

Fig 13. 8x8 digit Vedic VBCD multiplier using compressors

Figure 13 explains the hardware structure for eight digit multiplier using compressor logic. It uses four 4 digit multipliers, to generate partial products, eight 3:2 compressors and simple carry adder logic where i^{th} stage sum depends on i-1 carry. It has a delay of only one stage of carry always. The main advantage is there are no carry propagations in this method.

IV. Results:

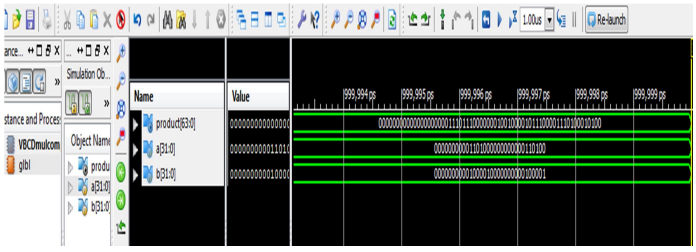

Fig 14. Simulation results for 16 digit VBCD multiplier

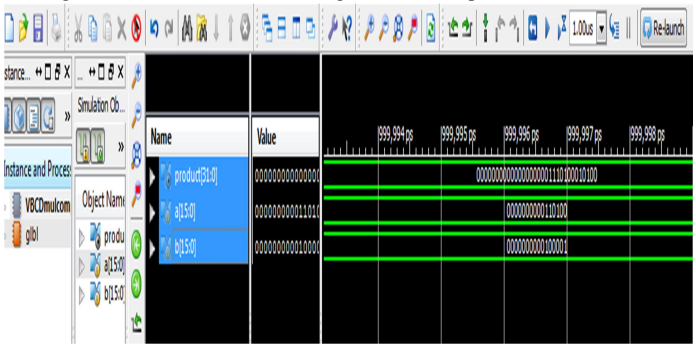

Fig 15. Simulation results for eight digit VBCD multiplier

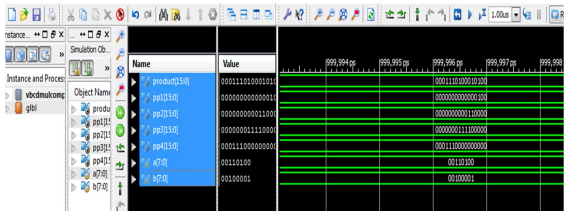

Fig 16. Simulation results for four digit VBCD multiplier

Figure 14,15 and 16 shows the simulation results of 16 digit, 8 digit and 4 digit multipliers.

Sl. No.	Type of Comp	Slice LUT's	IOB's	Delay (ns)

1 digit multiplier	1.654	27	1.654	27
2 digit multiplier	11.417	122	7.822	152
4 digit multiplier	16.69	816	10.92	869
8 digit multiplier	21.91	3405	14.87	3458

Table 2: Synthesis report of VBCD multipliers with and without compressor logic

Table 2 gives information related to various digit multipliers without compressor logic and with compressor logic in partial product generation. From table it is observed that around 7% of delay reduced with compressor logic for 8 digit (32 bit) multipliers.

Reference	Method Adopted	Delay (ns)
[4]	Conventional multiplier	58
[13]	Conventional multiplier	77
[14]	Vedic multiplier	12.42
[19]	VBCD multiplier	11.41
Proposed method	VBCD multiplier with compressor	7.822

Table 3:Comparision of Delay for 8 bit multiplier using various methods

The above table describes that multipliers with compressor logic are more efficient than normal structures for adding partial products.

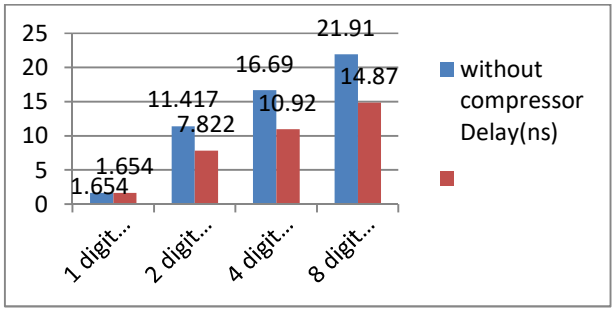

Fig. 17. Comparison of Delay with and without compressors in multipliers

From the above graph it was clear that the compressor based multipliers had less delay when compared to multiplier structures which without using compressor structures. One digit multiplier give same delay because we have chosen ROM based design and from two digit onwards delay reduces. We have checked almost for all cases and hence this architecture is efficient.

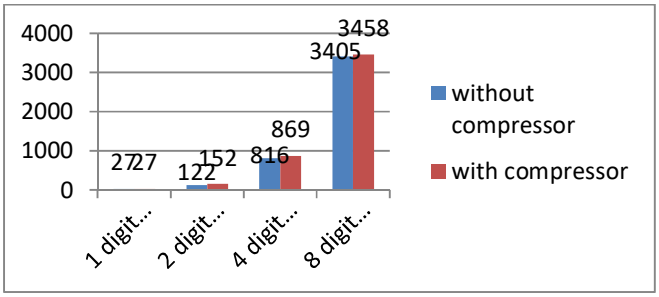

Fig 18. Comparison of LUTs between multipliers with and without compressor logic

This graph shows number of LUT's utilized for a given multiplier architecture and from this it was clear that less number of LUT's were used when compare to multipliers without compressor structures.

V. Conclusions and Future scope.

Hence we conclude that an efficient design of multipliers using VBCD compressors was designed and implemented using Xilinx 14.2i and is compared with other Vedic multipliers. It was observed that multiplier architectures using compressors are better than without compressor logic in terms of speed. In our previous work we have shown that VBCD multipliers are better than conventional multipliers. Hence in this paper we highlighted results only for VBCD architectures with and without compressor logics.

Researchers can work on decimal floating point multipliers using this concept for mantissa

multiplication and in Fused Multiply and Add Architectures.

Abstract—**This paper proposes BVLC (block variation off local correlationcoefficients) and BDIP (block difference of inverse probabilities) into covariance descriptors for image recognition and retrieval. The images in RGB is partitioned to R,G and B then BVLCs and BDIPs are computed for each channel then BVLCs and BDIPs in covariance among R,G and B is computed. The proposed BVLCs and BDIPs in covariance descriptor is extremely precious to reflect the degree of linear association among identified textures, edges and valleys. Degree of similarity among query and target images is analyzed using statistical measures of divergence namely Chernoff and Bhattacharya and results shown that Chernoff is noticeably outperform Bhattacharya measure. Comprehensive experiments on Corel- 1k, Corel- 5k and Corel-10k databases illustrates that proposed BVLCs and BDIPs in covariance descriptor is satisfactory and can attains significantly enhanced retrieval accuracies than traditional techniques.**

Keywords— BDIP, BVLC, Covariance, Chernoff distance, Bhattacharya distance.

I. INTRODUCTION

Nowdays, with the progress of image acquisition, storage and display devices, massive collection of images is being produced and images are of immense importance for a variety of realistic applications like analysis and prediction of disease and weather, classification of land, crops, galaxies and stellar spectra, monitoring the deforestation, land use change, military surveillance, finger print and iris recognition and substitute for human vision in industries because of its clear and precise depiction of information and thus researchers give more attention to image analysis, classification and matching.

The effective retrieval of images from massive image database using the visual information is coined as content based image retrieval (CBIR). The CBIR is primarily depends on excellent description of image and it has been the topic of demanding study. Hence, numerous CBIR approaches were presented by the researchers over the decade like gray level co-occurrence matrix (GLCM) reported by Haralick [1] which is co-occurrence of pixels pairs, Co-occurrence of edgels is reported in [2] and it uses prewitt operator for edge detection [2], texture and color information is jointly computed by color co-occurrence (CCM) in [3, 4], Motif co-occurrence matrix (MCM) which is quite different from CCM by including 3rd order moments is reported in [5], 3D- histogram of gradient location and orientation named as SIFT and is suggested in [6] for matching of images, robustness of SIFT is improved in [7] by incorporating log-polar location grid and coined as Gradient location and orientation histogram (GLOH), speeded-up robust (SURF) is proposed by Herbert et al, and it uses Hessian matrix and Haar wavelet responses for its computation [8], local binary pattern (LBP) based on local intensity of pixel is reported in [9], Gabor filter for texture classification and matching is suggested in [10], histogram of oriented gradients (HOG) suggested in [11] counts the gradient orientation's occurrences in sub part of an image, edge histogram direction (EHD) for capturing global and local details of edgels based on its orientation is reported in [12, 13], center-symmetric local binary pattern (CS-LBP) based on intensity of centrosymmetric pixels is introduced in [14], local intensity order pattern (LIOP) is described by Wang et al, to compute order pattern between pixels located at a fixed radius [15], local contrast and ordering (LCO) descriptor for image matching is reported in [16] and exhaustive study on CBIR are revealed in [17,18].

On other side, owing to well performance of covariance descriptor, it is extensively used in various application including face recognition using covariance matrix is suggested in [19]; Gabor-LBP based region covariance descriptor (GLRCD) computed using RGB components, spatial coordinates, LBP decimal values and Gabor features is reported in [20]; identification of objects using covariance matrix is reported in [21]; compact form of LBP is derived using local binary covariance matrix (LBCM) is proposed in [22]; texture classification using covariance matrix is described in [23-26]; human detection using covariance matrix is introduced in [27,28]; mean riemannian covariance grid (MRCG) in [29] combines gradients magnitude and orientation of each RGB channel and fire and flame identification using covariance descriptor is suggested in [30] owing to its resilient behavior to scaling and rotation and considerably resilient to uniform luminance variation [31].

Therefore, in this paper, novel feature descriptor using mean and covariance of BVLC and BDIP in RGB color space is proposed.

II. RELATED WORK

Chun et al., [32] reported BVLC and BDIP of image for retrieval and are utilizing local probabilities and variations of local correlation coefficients correspondingly to assess local brightness variation and texture smoothness respectively. The authors computed low order moments for BVLC and BDIP and are combined with color autocorrelogram for retrieval of images. Later, low order moments for BVLC and BDIP are computed from multiresolution domain and is reported in [33]. In [33], authors converted images from RGB. to HSV space then each component of HSV space is decomposed using Haar wavelet transform and the level of decomposition is 2. From the decomposed V component, first order moments for BVLC and BDIP then from H and S images, color autocorrelogram is estimated for all sub-bands and in all level of decomposition.

Later on, both low and high order statistical moments for BVLC and BDIP is introduced in [34] for retrieval of images. Subsequently, since histogram representation is resilient to noise, scaling, translation and small rotation, histogram for BVLC and BDIP is computed [35] from quantized BVLC and BDIP values. The author fixed the level of quantization to 57. Thus, histogram for BVLC and BDIP has 57 bins [35] respectively. To encompasses spatial details of textures, edges and valleys, histogram of local spatial correlations among identical BVLC and identical BDIP values are computed and are combined with color autocorrelogram for retrieval [36].

Afterwards, in [37], retrieval of histology image is reported in which wavelet Packet and Daubechies-4 transforms are utilized together with orthogonal polynomial model coefficient for histology image decomposition then authors computed BVLC and BDIP from high frequency sub-bands, and dominant color descriptor and color autocorrelogram is computed from low frequency component. Recently, BVLC and BDIP is combined with color histogram for retrieval [38].

Inspired by the efficiency of BVLC and BDIP in exploiting texture, edges and valleys respectively, we introduced novel feature representation for image retrieval in which images in RGB space are separated into R,G and, B channels and BVLC and BDIP is computed for each channel image separately then mean and covariance matrix for BVLCs and BDIPs of R, Gand B channel images are computed individually. The covariance matrices of BVLC characterizes image using correlation between identified texture within the individual channel and between the channels respectively. Similarly, covariance matrices of BDIP characterizes image using correlation between edges and valleys within the individual channel and between the channels respectively. The diagonal values of covariance matrix specify correlation among BVLCs/ BDIPs of each channel image whereas non-diagonal values specify correlation between BVLCs/ BDIPs of each pair of channel image. Thus, proposed descriptor estimates directional relationship among identified texture, edges and valleys in R, Gand B channel images more powerfully. The proposed embedding of BVLC and BDIP in covariance matrix with statistical measure of divergence is assessed experimentally on different datasets and results recommended that proposed approach enhances compactness and descriptiveness of BVLC and BDIP descriptors at locally as well globally, produces better accuracy and resilient to scaling and rotation. The remainder of this work is explained as follows. Section 3 elucidates proposed technique and recalls, BVLC, BDIP and covariance computation. Section 4 explains experiments followed by conclusions in Section 6.

III. PROPOSED IMAGE RETRIEVAL TECHNIQUE

In this section, techniques that are used in proposed image retrieval i.e., descriptor computation, measure of divergence and measure of accuracy are discussed.

The basic idea behind the proposed BDIPs inclusion in covariance is capturing the spatial dependencies of textures and BVLCs inclusion in covariance is capturing the spatial dependencies of edges and valleys. The proposed algorithm consists of three steps. First, input image in RGB is separated into R, Gand B images. Later, BDIP and BVLC is computed separately for R,G and B respectively using eq. (1) and (3). Later on, covariance among BDIPs of R, Gand B images followed by covariance among BVLCs of R, Gand B images are computed using the eq. (4) and (5). Then mean for BVLCs and BDIPs of R,G and B images are computed. Therefore, proposed descriptor has two parts: first one has BDIPs in covariance and mean of BDIPs in R,G and B images respectively, and the second part has BVLCs in covariance and mean of BVLCs in R,G and B images respectively.

Since covariance is not lie on L1 and L2 norm [39], statistical measure of divergence namely Chernoff and Bhattacharya are employed. We compared the performance of Chernoff with Bhattacharya for proposed retrieval. In our approach, distance among proposed first part of descriptors (i.e based BDIPs) of input and target image is computed then distance among proposed second part (i.e. based on BVLCs) of descriptors of input image and the target image is computed. Later, average of distance results of first and second part of proposed descriptors is computed and is considered to measure the degree of similarity in the proposed CBIR. The results on standard Corel database [40] shown that proposed approach achieve noticeably better results than conventional techniques. It also noticed that Chernoff distance outperforms Bhattacharya for our approach. The proposed approach is illustrated in Fig.1. Computation of BVLC, BDIP and covariance is expressed as follows.

A. BDIP

BDIP [32], a sketch feature consisting of edges depicted by local intensity maxima and valleys depicted by local intensity minima and is given as [32]

$$BDIP^{d}(l) = \frac{\frac{1}{B_l^d}\Sigma_{(x,y)\in B_l^d}(\max_{(x,y)\in B_l^d} f(x,y) - f(x,y))}{\max_{(x,y)\in B_l^d} f(x,y)} \quad (1)$$

Where f(x,y) designates an intensity of pixel at position (x, y) in image block B_l^k of dimension (k+l)x(k+l), k denotes the utmost distance among pixels pairs and l denotes place index. Thus, $B_l^k = (k+1)^2$. In equation (1), numerator and denominator defines maximum intensity variation and representative value in a block respectively.

B. BVLC

BVLC [33], measures texture smoothness using difference among local correlation coefficients corresponding to $0^\circ, 90^\circ, 45^\circ, -45^\circ$ orientations and is given by [33]

$$\rho(k,l) = \frac{\frac{1}{M^2}\sum_{(x,y)\in B} f(x,y) f(x+k, y+l) - \mu_{0,0}\mu_{k,l}}{\sigma_{0,0}\sigma_{k,l}} \quad (2)$$

Where B denotes image block of dimension M x M and $\mu_{0,0}\mu_{k,l}$ and $\sigma_{0,0}\sigma_{k,l}$ are local mean and standard deviation. The (k,l) denotes a pair of horizontal and vertical shift connected with orientations $0^\circ, 90^\circ, 45^\circ, -45^\circ$. Subsequent to shifting of M x M mask in each of 4 directions, *p(0,1), p(1,0), p(1,1), p(1,-1)* is calculated. After that BVLC is calculated as follows

$$BVLC^d(l) = \max_{\Delta(k)\in O_4}[\rho^k(l,\Delta(k))] - \min_{\Delta(k)\in O_4}[\rho^k(l,\Delta(k))] \quad (3)$$

Where $\Delta(k) = (\Delta_x(k), \Delta_y(k))$ denotes shift in one four directions and $O_4 = \{(-k,0), (0,-k), (0,k), (k,0)\}$

C. Covariance matrix

Let *I* be a 3D color image in RGB color space. Let $\{K_f\}_{c\,f=1,2,...,n}$ and $\{L_f\}_{c\,f=1,2,...,n}$ be a set of BVLC/ BDIP descriptors of each individual color channel images, $\bar{K}$ and $\bar{L}$ are corresponding mean vectors, *c* is either R orG or B channel image then covariance [41] between BVLC/ BDIP descriptors of two individual color channel images is given as

$$\frac{1}{n}\left(\sum_{i=1}^{n}(K_f - \bar{K})(L_f - \bar{L})\right) \quad (4)$$

The mean of feature vector of R,G and B channel images is defined as follows

$$\mu = \begin{bmatrix} \mu_r \\ \mu_g \\ \mu_b \end{bmatrix} \quad (5)$$

The covariance measures [41] spatial relation among features of two images, is low dimensional one, removes noisy textures, edges and valleys by doing averaging in its computation. The covariance matrix for BVLC and BDIP descriptors of R,G and B channel images is expressed as follows

$$\Sigma = \begin{bmatrix} \sigma_{rr} & \sigma_{rg} & \sigma_{rb} \\ \sigma_{gr} & \sigma_{gg} & \sigma_{gb} \\ \sigma_{br} & \sigma_{bg} & \sigma_{bb} \end{bmatrix} \quad (6)$$

Where Σ and σ represents spatial relation among descriptors and variance among descriptors respectively.

D. Measure of Divergence

The retrieval performance is not only depends on discriminative power of feature descriptor, it is also depends on measure of divergence. Since proposed BVLCs and BDIPs in covariance not lie in the L1 and L2 norm, we selected Chernoff and Bhattacharya measures [42]. We analyzed the competence of both measure for the presented covariance of BVLCs and BDIPs. The Chernoff distance measure [42] is given by

$$D_{p,q}(s) = \frac{s(1-s)}{2}(\mu_2 - \mu_1)^T[s\Sigma_t + (1-s)\Sigma_2]^{-1}(\mu_2 - \mu_1) + \frac{1}{2}\ln\frac{|s\Sigma_1 + (1-s)\Sigma_2|}{|\Sigma_1|^{1-s}|\Sigma_2|} \quad (7)$$

Where $D_{p,q}(s)$ is the Chernoff distance, μ_q, μ_t, Σ_q and Σ_q denotes mean and covariance of query and the target descriptors, and the optimum *s* provides maximum value for Chernoff distance and is attained by using various *s* and it falls in range $0 \le s \le 1$.

The Bhattacharya distance measure [42] is expressed as

$$D(q,t) = \frac{1}{8}[\mu_q + \mu_t]^T\frac{[\Sigma_q + \Sigma_t]^{-1}}{2}[\mu_q - \mu_t] + \frac{1}{2}\ln\left(\frac{\frac{|\Sigma_q + \Sigma_t|}{2}}{\sqrt{|\Sigma_q||\Sigma_t|}}\right) \quad (8)$$

Where μ_q, μ_t, Σ_q and Σ_q denotes mean and covariance of query and target descriptors respectively.

E. Measure of Accuracy

Each database image is used as query in the experiments. The proposed approach is assessed by precision P(N) and recall R(N) for retrieving top matched N images and are expressed as in [33, 34]

$$P(N) = \frac{I_N}{N} \quad (9)$$

$$R(N) = \frac{I_N}{M} \quad (10)$$

Where I_N, *M* and *N* denotes number of related images, total number of retrieved images and total number of images in database.

IV. EXPERIMENTS

In this section, we assessed the performance of proposed BVLCs and BDIPs in covariance with Chernoff measure then proposed BVLCs and BDIPs in covariance with Bhattacharya measure to confirm the superiority of each using the Corel- 1k, Corel-5k and. Corel-10k databases[40]. Finally, we assessed computational and storage cost of BVLCs and BDIPs in covariance and mean.

Corel datasets are widely used to assess the performance of image descriptors. The Corel 1k [40] database

(a) (b)

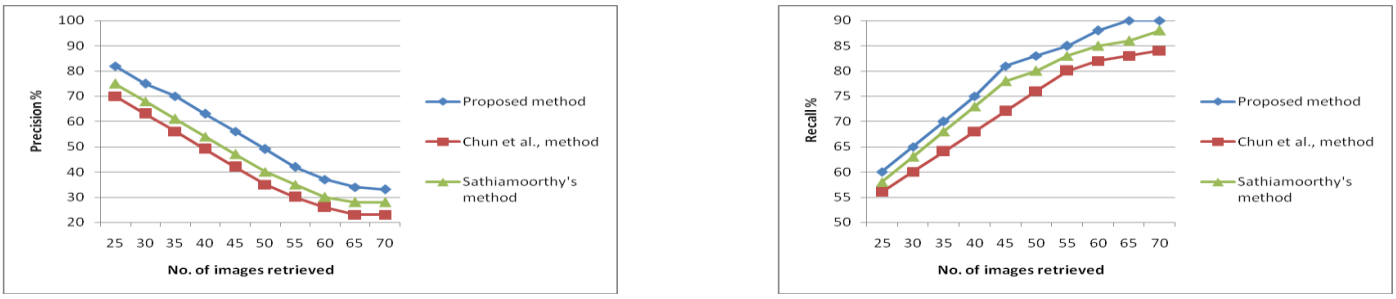
Fig.4 Precision and recall with number of images retrieved for database 2



(a) (b)

Fig.5 Precision and recall with number of images retrieved for database 3

contains 10 classes of images whereas Corel 5k [40] and Corel 10k [40] databases consists of 50 and 100 classes of images like elephants, buses, horse, lion, ship, Africans, flowers, train, waves, forest, mountain, etc. and some samples are shown in Fig.2. The images in each database are categorized into five groups in which images in one group are utilized for training and others groups for testing process. The proposed system is developed such that all five groups of images are be included in both training and testing process. We compared proposed descriptors with the descriptors of [34] and [36].

A. Database 1

In the first experiment, Corel 1k database images are used. Each image is roughly of size 120x80 or 80x120. P(N) and P(R) for BVLCs and BDIPs in covariance and conventional techniques are computed and is illustrated through graphs. In Fig. 3, plots of P(N) and P(R) are shown. Fig. 3(a) illustrates variation in P(N) with number of images retrieved and Fig. 3(b) illustrates plots among R(N) and number of images retrieved. Both the plots evidently illustrates that presented approach is better to others by means of P(N) and P(R). Average retrieval rate (ARR) of presented approach with Bhattacharya and Chernoff distances have been augmented from first order moments of BVLC and BDIP [34] and histogram representation of BVLC and BDIP [36] by 13.23%, 3.89% and 13.96% and 5.03% respectively and are presented in Table.1 and Table. 2 respectively.

B. Database 2

In the second experiment, Corel 5k database have been taken and database have 100 images for each group and approximately the dimension are 120x80 or 80x120 and images are in jpg. The results of presented approach in the form of P(N) and P(R) are depicted in graphs. Graphs for P(N) and P(R) with number of images retrieved is exemplified in Fig.4. The presented approach is more agreeable than other approaches and is obviously visible in the plots. The ARR of presented approach with Bhattacharya and Chernoff distances increases from moments of BVLC and BDIP [34] and BVLC and BDIP representation of [36] by 12.11%, 3.79% and 12.88%, 4.06% respectively and are depicted in Table. 1 and 2 which entail that additional related images are retrieved by presented one when compare to conventional approaches.

C. Database 3

In the third experiment, Corel 10k database has been taken and has roughly 100 images for each group and sizes of images are 120x80 or 80x120. Outcome for Corel 10k database is presented in Fig.5. The yields from experiments obviously illustrates that presented approach is superior then others. The ARR of presented approach with Bhattacharya and Chernoff distances improved from [34] and [36] are 12.01%, 3.83% and 13.03%, 4.17% respectively and are depicted in Table.1 and Table 2. Thus, presented approach is promising then other techniques [34, 36] in terms of accuracy. Feature descriptor length of each technique is depicted in. Table 3. The feature descriptor of presented approach is comparatively less than [34] and [36]. Even BVLC and BDIP reported in [37] performs well than [36], its computational cost is very high. Thus, the approach presented in [37] is not considered in comparative study. From the results depicted in Table.1 and Table.2, it is obvious that combination of Chernoff with BDIP in covariance and BVLC in covariance approach outperforms when compare to fusion of Bhattacharya with proposed BDIPs in covariance and BVLCs in covariance approach. Fig.6 depicts retrieval outcome of query image and top 4 retrieved images from Corel database for proposed approach with Chernoff and Bhattacharya distance measure.

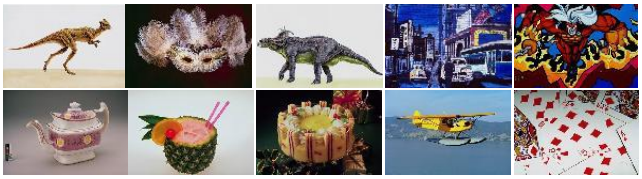


Fig.2 Example images from Corel database

Table 1. ARR of all databases using Bhattacharya Distance

Method	Corel 1k	Corel 5k	Corel 10k
Proposed method	67.23	66.32	64.56

V. CONCLUSION

A novel approach, named BVLCs and BDIPs in covariance has been suggested in this paper. The presented method computes linear association among textures using BDIPs in covariance and linear association among edges and valleys using BVLCs in covariance. In this work, first we compute the BVLC and BDIP for R,G and B components of an image in RGB space then the mean for BDIPs in R,G and B components, mean for BVLCs in R,G and B components, covariance of BDIPs among R,G and B components and covariance of BVLCs among R,G and B components are computed. The presented descriptors are combined together and compared with wavelets based moments of BVLC and BDIP and histograms of BVLC and BDIP approaches. All the approaches are tested on Corel 1k, corel5k and Corel.10k databases. Precision and recall illustrates that proposed image descriptor is proficient and suitable for image retrieval, and dimension of descriptor is also more acceptable. Outcome of presented system also reveal that Chernoff outperforms Bhattacharya distance measure for retrieval. In future,

proposed descriptors can be combined with color information of an image to increase the retrieval rate of CBIR.

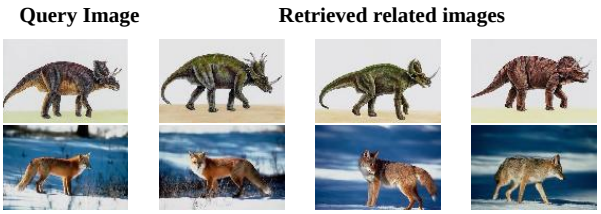

Fig.6 Query and top 4 retrieved images from Corel database for proposed approach with Chernoff (1st row) and Bhatacharya (2nd row) distance measure

***Abstract*— In this work, Multi-trend structure descriptor is suggested for retrieving images from heterogeneous medical image dataset. The multi-trend structure descriptors acquires structures in the form of large, small and equal trends along four directions at both global and local level. For the retrieval of gray-scale medical images, only the structure information computed by Multi-trend structure descriptor from the texture and edge information of an image is used while for color medical images the color information acquired by Multi-trend structure descriptor is also taken in to consideration for attaining effective retrieval rate. The fuzzy k-NN approach is incorporated to classify the feature vectors and it enhances the retrieval accuracy as well it increases the speed of retrieval. The results obviously shown that the fusion of Multi-trend structure descriptor and fuzzy k-NN outperforms the state-of-the-art approaches.**

Keywords*— Multi-trend structure, fuzzy k-NN classifier, Euclidean measure, Precision, Recall.

I. INTRODUCTION

Nowadays, rapid growth in medical imaging modalities produces gigantic quantity of medical images in hospitals and most of the medical diagnostic approaches and health monitoring are completely depends on medical images. As a result , medical image repositories serve as a very important resource for physicians for making decisions by retrieving proper medical cases from extremely enormous medical image repositories. Day to day these data stores grow massively and diversely. Beside this, representing the rich and very subtle information is more difficult. Hence, extracting the relevant medical case images and annotating the vast and diversity of medical images turn out to be more complicated task and become a hot area of research. For this reason, number of new algorithms has been developed to aid physician and to tackle the massive collections of medical images.

Today, most of the hospitals use Picture archival and communication systems (PACS) which stores and searches images based on textual keywords and the textual keywords are plagued with many drawbacks like inadequate representation of medical images which results in difficulty of identifying and locating relevant images from the vast and diverse medical image collections and it necessitates the physicians to search the desired medical images manually and is wearisome and physicians get tired [1]. Further, Mustra et al., reported that medical images in DICOM format is error-prone [2]. Thus, the troubles with PACS led to the evolution of CBMIR system, where the contents of the medical images like shape, color and texture are exploited to access the related medical images from the massive repositories. Even though CBMIR has been studied broadly, most challenging problem remains in CBMIR systems is mapping the low level visual contents with high level semantics which is still more complex one because same semantics may represents different images and visual similar images may have different semantics [3, 4]. The gap among the semantics and low-level image descriptors is defined as semantic gap and it could affect the precision of retrieval by retrieving the irrelevant images. For example, the physician wants to retrieve a particular stage of breast cancer image from the collection of mammogram images, but the system may retrieve benign cases due to the less discrimination ability of the feature vector. Thus, the researchers attempted to reduce the gap by utilizing the machine and relevance feedback learning methods [5]. But, still the gap exists. Thus, it is really important ongoing issue and most vivid study area in the purview of multimedia and medicine.

In the CBMIR approaches, image representation is modeled using feature vector which is computed from the image itself by extracting the low level visual features. Subsequently, the similarity among input and the medical images in the enormous repository is estimated in the feature space using the similarity measures. Thus, image representation and similarity measure are the core component of CBMIR systems. Further, dimensionality reduction and classification techniques are adopted to diminish the dimension of computed image descriptor and to diminish the search space respectively.

Over the decade, researchers are working towards an effective CBMIR. ASSERT, a system for lung image retrieval in which shape and texture features of region of interest is used [6]. In [7], mean and covariance are computed for

representing the color information and grey-level co-occurrence matrice is computed to represent texture information for the retrieval of skin lesion images. In [8], retrieval system for dermoscopic medical images of pigmented lesions is performed by texture and color image descriptors. The scatter-plot of R Vs G, G Vs B and B Vs R color channels are employed as color feature, and co-occurrence distribution of color ratio and variance at local level image are utilized as texture descriptor. Lan et al., used bag of words for CT images which is computed from localized texture feature obtained by applying the Gabor and Schmid filters followed by uniform and non-overlapping partitions [9]. Wei et al., introduced a retrieval system for CT images of lung nodule in which both semantic and visual similarity measures are employed [10]. Quellec et al., extracted signatures from the wavelet transformed image and is used for image retrieval instead of domain specific features [11]. MedFMI-SiR system is presented in [12] that integrate the content and metadata-based queries for effective medical image searching. Murala and Wu [13] suggested local mesh patterns which capture the association between neighboring pixels instead of neighboring pixels and a pixel at the center of the mask and they verified the efficacy of local mesh patterns on MRI and CT image databases namely VIA/I-ELCAP, OASIS-MRI and NEMA-CT.

In [14], local binary patterns are computed from the binary wavelet transform applied binary bit planes of gray-scale images and is termed as directional binary wavelet patterns which reported more efficient for CT and MR image datasets. Murala and wu presented local ternary co-occurance patterns for effectively retrieving CT and MR images and it captures co-occurrence of akin ternary edgels from the gray-levels of center pixels and neighbors of it [15]. Center symmetric local binary patterns based on local wavelet is used with random forests in [16] for annotation of medical images and the annotated keywords are used for medical image retrieval and to enhance the retrieval accuracy, relevance feedback approach is used. Local wavelet patterns suggested by Dubey et al. in [17] for CT image searching and retrieval in which local neighboring information is computed using local wavelet decomposition then the authors utilized the decomposed gray-level values and wavelet transformed center gray-level values to compute local wavelet pattern. It is described in [18] that features from deep convolutional neural networks achieved better retrieval results and localized sensitive hashing based approaches also performs well for large image datasets. Jamil Ahmad et al., computed convolutional descriptors using deep learning method and by using fast Fourier transform, convolutional descriptors are compressed to binary codes and is utilized as a descriptor for searching and retrieving the radiology and endoscopy images [18].

Bag of visual words constructed from SIFT descriptor is described in [19] for brain MRI. Zhang et al., introduced scalable retrieval approach for histopathological medical images of breast tissues utilizing supervised kernel hashing method [20]. Nowaková et al., utilized vector quantization, fuzzy signatures and fuzzy S-trees for mammogram image retrieval [21]. In [22], bag of color is computed using SIFT for CBMIR. Haas et al., suggested bag of visual words, computed from the interest points resultant from super pixels using SIFT for medical image retrieval [23]. In sequence with this, many researchers presented CBMIR based on bag of visual words [24-27]. Seetharaman and Sathiamoorthy [28] suggested a system for retrieving images from heterogeneous medical image database using the fusion of color autocorrelogram, micro-textures and enhanced edge orientation autocorrelogram which are estimated from a framework based on Full range Autoregressive Model and outperforms the conventional methods due to the ability of capturing texture, color, shape and spatial details of them at both local and global level. In the past, many researchers presented the available literature for various technologies used for medical image retrieval [30-36] and described that the existing technologies presented for medical image retrieval are not proficient.

Lately, Zhao et al., [37] suggested Multi-Trend Structure Descriptor (MTSD) for image retrieval that captures structures in the form of equal, large and small trends for texture, color and shape details separately and extensive experiments are done to demonstrate the effectiveness of MTSD on benchmark datasets namely Corel image and Caltech datasets [37], and described that MTSD is superior in performance then the existing outstanding techniques namely MSD, TCM, SSH and MTH descriptors for retrieval of an image. According to the aforementioned revealing discussion, in this paper, fusion of Multi-trend structure descriptor [37] and fuzzy k-nearest neighborhood approach is proposed for medical image retrieval from heterogeneous image dataset.

This paper is drafted as follows: The proposed MTSD and fuzzy k-NN based CBMIR approach is defined in Section 2. In the 3rd Section, experimental results and discussion is described. Section 4 presented the conclusion.

II. Proposed Medical Image Retrieval System

Herein, the feature computation using MTSD, classification of computed feature vector using fuzzy k-NN classifier and the distance and evaluation measures employed in this study are discussed.

A. Feature Extraction

In this manuscript, we employed MTSD [37]. In order to compute MTSD, an image in RGB color space is transformed to HSV [37] color space then uniform quantization is done as in [37] which results in 12, 3 and 3 quantization levels for color i.e. totally 108; 20 is the level of quantization for texture which is estimated from the V component and 9 is the quantization level for edge information which is estimated from the edge detected image using the Sobel operator on V component of an image [37].

Subsequently, Zhao et al., partitioned the image into number of 3 x 3 non overlapping blocks in order to discover the structures on local level in the method of equal, small and long trends along 0°, 45°, 90° and 135° orientations [37]. For

each color quantized value, Zhao et al., route through bottom to top and left to right direction throught the entire image to discover the number of equal, small and long trends. According to Zhao et al., pixel values from small to large, pixel values from large to small and pixel values are same along 0°, 45°, 90°0and 135° orientations for each non overlapping blocks corresponds to large, small and equal trends respectively [37]. In the same manner, large, small and equal trends are identified for each texture and edge quantized values respectively. The color, edge and texture information estimated by MTSD are concatenated for histopathological images and color information is excluded for gray-scale medical images where the role of color is not significant in distinguishing the images. Thus, the feature vector is expressed as $(N_E^{Q_c}, N_S^{Q_c}, N_L^{Q_c})$, $(N_E^{Q_t}, N_S^{Q_t}, N_L^{Q_t})$, $(N_E^{Q_e}, N_S^{Q_e}, N_L^{Q_e})$ in which N, Q_c / Q_t / Q_e, E, S and L represents the number of trends, quantized color/texture/edge value, equal, small and large trends respectively. Therefore, MTSD is feature vector of quantized color/texture/edge values versus trends. The feature matrix computed by the MTSD for color is depicted in Fig.1 where number of equal, small and large trends for quantized color value 0 to 108 is depicted. Small and large trends along 0° and 45° and equal trends along 90° and 135° is illustrated in Fig.2.

B. Fuzzy k-NN classifier

Classification of images is successfully based on low-level features and is very difficult task in CBMIR and it significantly advances the performance of CBMIR by eliminating the images that are not relevant from the search space. Thus, more familiar fuzzy k-NN classifier is incorporated in this work due to its uncertainty in the results. The fuzzy k-NN is coming under supervised learning approach and deterministic form of k-NN [38] with the benefits of fuzzy set theory [38]. Though the computation time of fuzzy k-NN is significantly higher than the k-NN, due to the consideration of unbiased weighting of instances in the decision rule nevertheless of its distance to the pattern to be categorized, fuzzy k-NN attains better classification rate [38]. In the literature, fuzzy k-NN has been employed effectively by many researchers [39-41].

Let assume that the fuzzy k-NN classifies feature vectors $F = \{F_1, F_2, \ldots F_N\}$ into C classes where $1 < C < N$ and the fuzzy membership matrix D for N number of feature vectors and C number of classes is computed and D_{ij} is the degree of fuzzy membership of feature vector F_j where j=1,2,…N and i=1,2,…C. In fuzzy membership matrice, the degree D_{ij} lies within 0 to1 for all i and j. If $D_{ij} = 1$ for class i then the D_{ij} for other classes are 0. The summation of D_{ij} of all feature vectors must be greater than 0 for class i or else the class i does not exist. In fuzzy k-NN classifier, membership of feature vector F to class i is estimated by utilizing the feature vector's distances from their k-NNs membership [38], is expressed as

$$D_i(F) = \frac{\sum_{j=1}^{k}\left(\frac{D_{ij}}{\|F-F_j\|^{\frac{2}{(w-1)}}}\right)}{\sum_{j=1}^{k}\left(\frac{1}{\|F-F_j\|^{\frac{2}{(w-1)}}}\right)} \quad (1)$$

Where k is predefined and designates the numbers of nearest neighbor, $\|F - F_j\|$ designates the Euclidean distance among F and k nearest neighbor vector F_j, w is the weight parameter of the fuzzy distance function. D_{ij} is determined a-priori from the training data and is the degree of the fuzzy membership of j^{th} neighbor to i^{th} class. The k is chosen through trail and error process.

We employed 5 fold cross validation for evading over-fitting and for attaining better generalization which occurs when the dataset is partitioned into training and testing is not adequate [28, 38]. That is, the dataset are randomly alienated into five folds without imposing any damage to the data. The size of each fold is approximately equal and for each run of five- folds cross validation, four data sub sets are utilized in training and the 5^{th} one is utilized in testing like all 5 data sub-sets are utilized in both learning and testing phase.

C. Similarity Measuremnt

The relevancy is measured among input and the dataset images using distance measure which is an essential component of CBMIR system. In this work, Euclidean distance [42] is employed to discover the distance among input and the dataset images, and is expressed as follows

$$S(Q,T) = \sqrt{\sum_{i=0}^{N}(|Q_i - T_i|)^2} \quad (2)$$

Where T and Q designate the input image and target image feature vector and N designate the number of descriptors in an image feature vector.

D. Performance Assessment

The retrieval rate of proposed CBMIR approach is evaluated using the accuracy which is estimated based on most

frequently used precision (P) and recall (R) measures [28] and is described as

$$\text{Precision (P)} = \frac{\text{Number of relevant images retrieved}}{\text{Total number of images retrieved}} \quad (3)$$

$$\text{Recall (R)} = \frac{\text{Number of relevant images retrieved}}{\text{Total number of relevant images in the database}} \quad (4)$$

III. Experimental and Results

The proposed CBMIR approach is evaluated by utilizing the heterogeneous medical image dataset [28] which has 6400 images of 83 concepts of 1510, 592, 858, 580, 1708, 663 and 489 images captured using X-ray, CT, Mammogram, MRI, Microscopy, Ultrasound, and Endoscopy modalities respectively and are collected with ground truth from the RMMCH, Annamalai University, Annamalai Nagar, India. Fig.3 depicts some examples images from the dataset.

Table. 1. The dimension of proposed MDLDPTS and state-of-art techniques

Methods	Dimension	Accuracy rate
Seetharaman and Sathiamoorthy's approach	361	64.43
MTSD (for color medical images)	137	66.12
MTSD (only considering the texture and edge information for gray-scale medical images)	29	65.87

In this work, better image retrieval can be achieved with the fusion of high discriminate feature vector, MTSD [37] and efficient fuzzy k-NN classifier [38]. Since color information extracted by MTSD is not helpful for gray-scale images, the structure information estimated by the MTSD from the edge and texture information of an image is considered and its dimension is 29 whereas histopathological images requires color information also for significant differentiation. Thus, the dimension of MTSD for color medical images is 137. The MTSD is computed as discussed in section 2.1. To validate the performance of proposed mixture of MTSD and fuzzy k-NN approach, image database used in [28] is employed and the proposed results were evaluated with the results of [28] in experiments.

In the experiment, every image is utilized as input image and for every input image, the system reacts to the user with N number of relevant images that are having shortest distance matching with the input image and are displayed in the ascending order of distance matching value. The accuracy rate of responding a query is measured by utilzing average *P* and average *R*. We compared retrieval accuracy of MTSD with the approach described in [28] and the results are summarized in Table.1. Since the MTSD captures the structures in an image for color, texture and edges at both local and global level, better results is achieved. The experimentation was conducted with N number of retrieved images and is set as 10 to evaluate the *P* of each input image and we finally attain average *P* that is *P*/M where M designates number of images in a class. In addition, recall of each retrieved image and the average *R* is estimated. The average *P* and average *R* of retrieval results is depicted in Fig.4 and 5 and it depicts the variation of *P* and *R* with respect to number of images retrieved The experimental results obviously reveal that proposed approach is notably superior to an approach in [28]. In the experiment of average *R*, image retrieval *P* raises with the number N of returned images. Thus, the proposed approach is more superior to the approach of [28]. We also used MTSD for gray-scale medical images without excluding the color information that it captures. However, there is no significant raise in the accuracy rate instead computational cost is amplified owing to an enclosure of color information which is 108 in dimension.

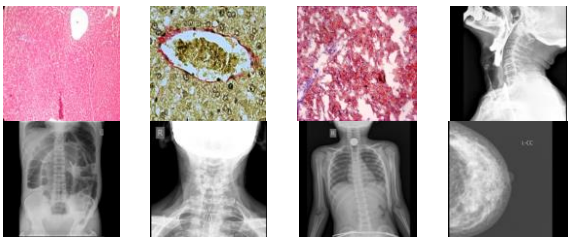

Fig.3.Some example images from the dataset

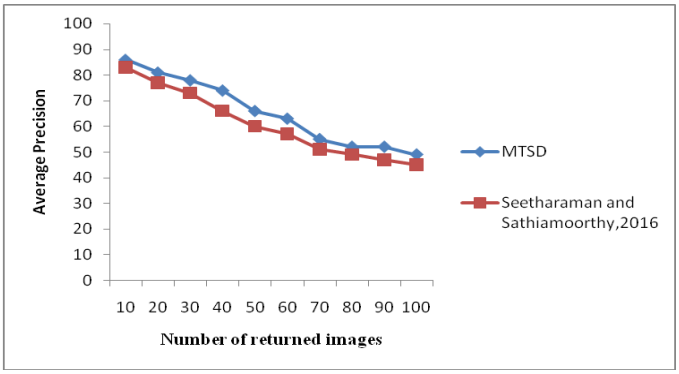

Fig.4.Average precision for proposed and existing approaches

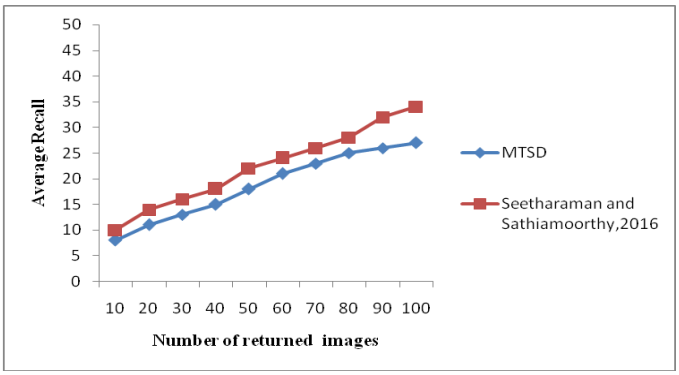

Fig.5.Average recall for proposed and existing approaches

The dimension and accuracy rate of the MTSD and the feature vector suggested in [28] is illustrated in Table.1. From the experimental results, it is obvious that fusion of MTSD and fuzzy k-NN not only attains better accuracy but can also reduced the time complexity of CBMIR. The

experiments are carried out in core i3 processor, 4 GB RAM and 64 bit Windows OS.

IV. Conclusion

We proposed a novel approach for heterogenous medical image retrieval system. Due to the diversity and very minute deformations in medical images, a feature vector with high discrimination ability is incorporated, MTSD which characterizes an image by using structures in the form of large, small and equal trends along 0°, 45°, 90° and 135° orientations. The MTSD captures texture, color and shape details at local as well global level. Fuzzy k-NN classifier is incorporated for classification task to avoid uncertainty in results. The experimental results reveal that fusion of MTSD, fuzzy k-NN classifier and Euclidean similarity measure is much better than the existing CBMIR methods. In future, proposed descriptor can be utilized in other domains

Abstract—**Shape is prominent information in the image. Commonly shape analysis approaches based on edges for image retrieval simply consider the frequency of edgels or orientation of edgels which ignores local information and spatial relation among adjacent edgels. The BDIP (Block Difference of Inverse Probabilities) computes the edges with valleys instead of edges only and it gives more shape information. By computing the co-occurrences among the neighboring gray levels, GLCM (Gray level co-occurrence matrix) computes the spatial relations. Thus, in this paper, we addressed the above said issues with the characterization of edges using histogram by integrating the GLCM with BDIP, referred as co-occurrence matrix of BDIP (CMBDIP). The proposed CMBDIP considers valleys of edges also. After computing the edges and valleys, GLCM is applied over the BDIPs of the image along four directions. The results are four co-occurrence matrices of BDIPs and are integrated to form the proposed CMBDIP. The proposed CMBDIP is extensively tested on Holiday, Corel 10k and Caltech 101 datasets and results evident its efficiency by comparing low order moments of BDIP in multiresoultion domain and histogram of BDIP approaches.**

Keywords— BDIP, GLCM, Canberra distance, CMBDIP. Co-occurrence

I. INTRODUCTION

With significant progress in imaging technology, image datasets are rapidly increasing in numbers as well in size and these encouraged researchers to centre their attention on inventing novel methodologies for retrieving images in less time span and with high accuracy rate. Normally, content based image retrieval (CBIR) incorporates information that encompasses shape, texture or color or mixture of theses to typify the image and it facilitates image retrieving. Despite noticeable advances in CBIR, image retrieval remains challenging one, particularly with diversity of images and ever raising image data.

In real world, objects are characterized predominantly by their distinct shape information. Among the commonly utilized image descriptors, shape represents essential and prominent structure information, and is more important for human perception. Thus, over the decade, shape information of an image has been explored intensively in numbers and plays central role in image retrieval. In recent years, center of interest of many researchers are on local image characterization because easy differentiation from others and its resilient against occlusion, scaling, rotation, distortions and illumination variation. Thus, dozens of local level shape descriptors were reported based on different image characteristics [1-7]. Commonly, shape descriptors are of two types: 1. Contour based 2. Region based. The former one includes approaches like Fourier descriptor [8], elastic matching [9], contour point distribution histograms [10], curvature scale space [11], edge histogram direction [12, 13], MSD [14], Edge orientation autocorrelogram [15], etc and offers characteristics of image shape. The later one includes approaches like moment invariants [16], Zernike moment descriptor [17], generic Fourier descriptor [18], etc. and are coined as global shape descriptors.

Among the aforesaid shape techniques, BDIP [19] have come out as one of the prominent shape descriptor because of its outstanding performance. The BDIP operator is well-known method for shape analysis and it characterizes image using edges and valleys. Subsequently, many of its variants also been reported in [20-24]. The BDIP descriptor has been applied successfully with other characteristics of image for image retrieval [25]. Even if BDIP has gained success in image retrieval and most of the variants of BDIP have increased the performance of BDIP, it still suffers in accuracy.

On the other side, literature reports that histogram has been utilized widely for representing the most of local descriptors [1-7, 12, 13, 15, 22]. But [28, 29] reports that histogram ignores relationship among neighborhood gray levels and any correlation between gray levels, and it reduces the retrieval rate of histogram based descriptors. It is also reveled from literature that histogram based image descriptors are computationally cost and results in large dimensionality of descriptors [30]. Since descriptors based on edges [12-15], edges and valley [20] and textures [3, 4] has limitation with histogram representation, they are to be efficient to some extent only.

Thus the researchers turned their interest from histogram representation of descriptors. One among the ending of aforesaid weakness of histogram is gray level co-

occurrence matrix (GLCM) and is reported by Haralick [31] for gray levels and it measure the texture information of the image by computing the co-relation of neighborhood pixels and gives more spatial information. Thus it is incorporated in many applications [29, 32-36] and combined with other image descriptors including co-occurrence of adjacent local binary patterns (LBP) [28], co-occurrence of Center-Symmetric LBP [37], local ternary co-occurrence patterns [38], Gabor co-occurrence [39], co-occurrence of edges [40] and color edges [41] are reported for image retrieval..

Thus, in this manuscript, to address the weakness of BDIP as aforementioned, we propose simple, effective and yet robust approach by computing the co-occurrence of edges and valleys. Since edges and valleys are identified using BDIP, the proposed co-occurrence of BDIPs (i.e. identified edges and valleys) is referred as co-occurrence matrix of BDIP (CMBDIP) which captures spatial correlation among BDIP values i.e. edges and valleys Therefore, the approach presented by us takes the benefits of both co-occurrence matrix, and edges and valleys computed by BDIP and thus proposed method considerably improving the discriminative power of BDIP. Besides, to verify the accuracy of proposed CBDIP, a detailed comparative study using co-occurrences of adjacent edges and valleys, histogram of BDIP [22] and low order moments of BDIP in multiresolution doamin [20] is performed. The experimental outcome indicates that proposed CMBDIP approach offers high accuracy in image retrieval.

The remaining of this manuscript is given as: recall of conventional descriptors is précised in Section.2 and Section 3. Section 4 and 5 deals with proposed approach and experimental evaluations and conclusion are reveled in Section 5.

II. BDIP

BDIP [20], a sketch feature consisting of edges depicted by local intensity maxima and valleys depicted by local intensity minima and is given as [32]

$$BDIP^{d}(l)=\frac{\frac{1}{B_l^d}\sum_{(x,y)\in B_l^d}(\max_{(x,y)\in B_l^d} f(x,y)-f(x,y))}{\max_{(x,y)\in B_l^d} f(x,y)} \quad (1)$$

Where f(x,y) designates an intensity of pixel at position (x, y) in image block B_l^k of dimension (k+l)x(k+l), k denotes the utmost distance among pixels pairs and l denotes the place index. Thus, $B_l^k=(k+1)^2$. In equation (1), numerator and denominator defines the maximum intensity variation and representative value in a block respectively.

III. GRAY LEVEL CO-OCCURRENCE MATRIX

GLCM [31] is second order statistical method and is described over the image to be a distribution of co-occurring of gray-levels at a specified offset. The co-occurrences are computed according to specific distance and in a specific direction. The GLCM for an image is computed as

$$G_{(\Delta x,\Delta y)}(i,j)=\sum_{p=1}^{M}\sum_{q=1}^{N}1\{I(p,q)=i\}\text{ and }1\{I(p+\Delta x,q+\Delta y)=j\} \quad (2)$$

Where *I(p,q)* denotes gray level at *p* row and *q* column, i and j are gray levels for which co-occurrence is computed, Δx and Δy are positional offsets in x and y directions, 1{} is the indicator function, M and N denotes dimension of input image. For instance the GLCM calculation is given in. Fig.1

4	4	1	2
1	2	2	1
3	1	3	2
1	2	4	4
2	1	3	3
3	4	4	2

(a)

Gray Values	1	2	3	4
1	0	0	0	0
2	0	1	0	0
3	0	0	1	0
4	0	0	0	3

(b)

Fig.1. (a).Sample image pattern (b). GLCM of image (a) at $\theta=0^{\circ}$

Therefore, the proposed CMBDIP is an average of GLCMs of BDIPs along 0°, 45°, 90°, 135° directions and is:

$$=\frac{1}{4}\left([G_{d=1,\theta=0^{\circ}}]+[G_{d=1,\theta=45^{\circ}}]+[G_{d=1,\theta=90^{\circ}}]+[G_{d=1,\theta=135^{\circ}}]\right) \quad (3)$$

IV. PROPOSED CMBDIP

We proposed an approach based on the combination of more familiar GLCM and BDIP. In this work, we used BDIP to identify the edges and valleys and the GLCM is incorporated to get the frequency of co-occurrence of neighboring BDIPs and is used as descriptor for the proposed CBIR. In our work, the GLCM is computed at distance 1 andin 0°, 45°, 90°and 135° directions. Therefore, we attained four co-occurrence matrix and are integrated together to form the proposed CMBDIP which overcomes the pitfalls of histogram characterization of BDIPs by encompassing spatial relations among the edges and valleys. The reason for choosing distance as 1 in CMBDIP is, it captures details more locally. Fig.2 illustrates the computation of proposed descriptor. Fig.3 has shown the edges and valleys computed using the BDIP for bus and cat images of Corel dataset.

A. Measure of similarity

After computing the proposed descriptor for every image in the dataset, they are stored separately, called as feature vector dataset. The descriptor matching for input and target images is performed using similarity measures. The output of the similarity measure falls in range 0 to 1 and 0 stands for similar and 1 stands for dissimilar. In our approach, we incorporated Canberra distance [41] for measuring the similarity and is:

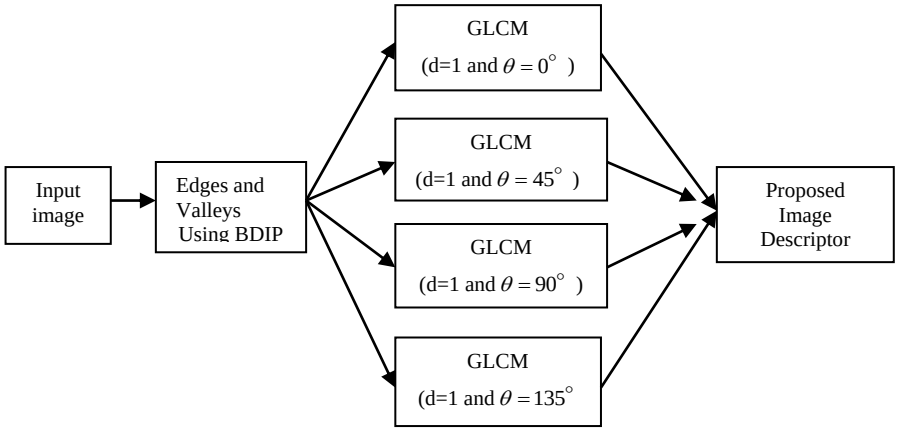

Fig.2. Proposed CMBDIP computation

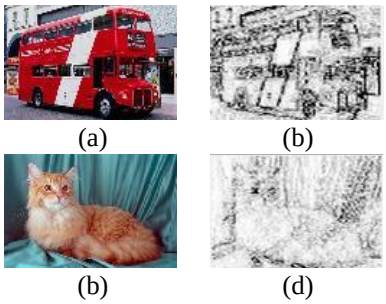

Fig.3.(a) and (b). Example image from Corel Dataset (c) and (d).BDIP of images of (a) and (b)

$$D_{Canbera}(Q,T) = \sum_{i=1}^{N} \left| \frac{T_i - Q_i}{T_i + Q} \right| \quad (4)$$

Where *Q and T* denotes input and target image descriptors and *N* denotes number of features. The computed distances among input and target image descriptors are sorted in ascending order using Bubble sort which is incredibly simple for sorting.

B. Measure of Accuracy

Each database image is used as query in the experiments. The proposed approach is assessed by precision P(N) and recall R(N) for retrieving the top matched N images and expressed as in [41]

$$\text{Precision} = \frac{I_N}{N} \quad (5)$$

$$\text{Recall} = \frac{I_N}{M} \quad (6)$$

Where I_N, *M* and *N* denotes number of relevant images, total number of retrieved images and total number of images. in database. The average P(N) and P(R) [41] for each class of images is as:

$$\text{Precision}(C_i) = \frac{1}{N_i} \sum_{k=1}^{N_i} \text{Precision}(I_k^i) \quad (7)$$

$$\text{Recall}(C_i) = \frac{1}{N_i} \sum_{k=1}^{N_i} \text{Recall}(I_k^i) \quad (8)$$

where *C* and *i* denotes the image class and number of images in each class, I_k^i is the k th image from class i. The average P(N) rate (APR) and average P(R) rate (ARR) are computed as in [41]:

$$APR = \frac{1}{N_n} \sum_{i=1}^{N_n} \text{Precision}(C_i) \quad (9)$$

$$ARR = \frac{1}{N_n} \sum_{i=1}^{N_n} \text{Recall}(C_i) \quad (10)$$

Where N_n denotes number of image classes in the dataset.

V. EXPERIMENTS

Holidays [42], Corel 10k [43] and Caltech 101[44] datasets are chosen for experiments. The Holidays dataset consists of 500 classes of images like water, natural, man-made, etc., and the numbers of images in each group differs and are in size 2448x3204. In our experiment, we resize it to 256x256. The Corel 10k dataset consist of approximately ten thousand images of 100 classes like African, cat, tiger, beach, sunset, door, waves, etc., and each class approximately has 100 images, the size of images are roughly 120 x 80 and 80 x 120 and images are in JPG format. Caltech dataset consists of 101 classes of 9,146 images and approximately image size is 300 x 200 and each class has roughly 40 to 800 images like ant, brain, chair, crab, cup, pizza, faces, panda, starfish, etc., and are in JPG format. Few example images from the experimental datasets are shown in Fig.4. In all the experiments, initially 10 images are retrieved later we increased it by 10 and it continues until number of images retrieved grows to be 100, and all the images of each class are used as query. Holidays dataset is taken in the experiment 1.The P(N) and P(R) curves for the CMBDIP [20] and [22] which obviously shown the variation in P(N) and P(R) with different number of retrieved images and shown in Fig.5 and it also obviously shown that CMBDIP is superior to the approaches presented in [20] and [22].

In Fig.8, 1st image belongs to query and remaining are the retrieved relevant images. The proposed CMBDIP has

the ARR of 57.12% for Holidays dataset and is significantly improved than others and is reported in Table.1.

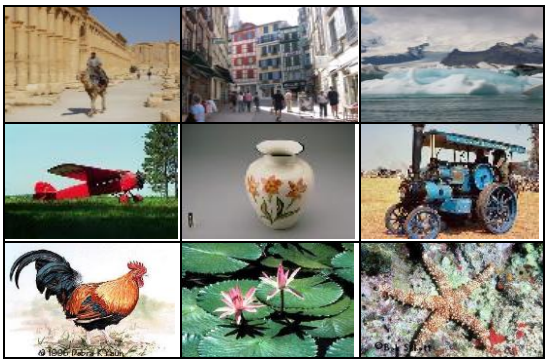

Fig. 4. Few example images of Holidays (Row 1 images), Corel 10k (Row 2 images) and Calitech 101 datasets (Row 3 images)

In the experiment 2, Corel 10k dataset is considered for evaluating proposed CMBDIP. The P(N) and P(R) is computed and performance of proposed CMBDIP is compared with histogram of BDIP [22] and low order moments of BDIP in multiresolution doamin [20]. Average P(N) Vs number of images retrieved and average P(R) Vs number of images retrieved for proposed CNBDIP, [20] and [22] is illustrated in Fig.6, which obviously reveals the dominance of proposed CMBDIP and the variations in P(N) and P(R) with respect to number of related images retrieved. The proposed CMBDIP has the ARR of 58.23% for Corel dataset and is higher than other approaches [20, 22] and is reported in Table.1. The query image and its top 4 retrieved relevant images are depicted in Fig.8.

Calitech 101 dataset is used in third experiment. The graphs for P(N) Vs P(R) of proposed CMBDIP, [20] and [22] with different number of retrieved images is illustrated in Fig.7 which obviously evident the supremacy of proposed CMBDIP and the variations in P(N) and P(R) with respect to number of related images retrieved. The proposed CMBDIP has the ARR of 61.81% for Calitech dataset and is noticeably superior to other methods [20, 22]. The query and retrieval of top 5 outcome of proposed CMBDIP for the dino, bus and sunflower images of Corel and Calitech dataset is depicted in Fig.8.

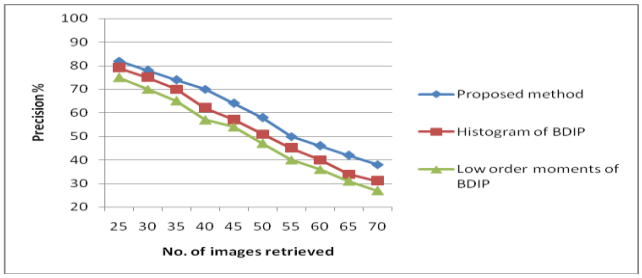

Fig.5 (a). Average precision of all the methods in Holiday dataset

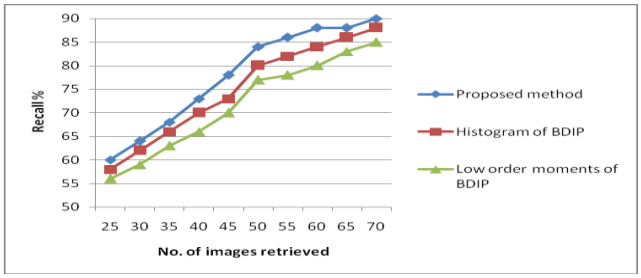

Fig.5 (b). Average recall of all the methods in Holiday dataset

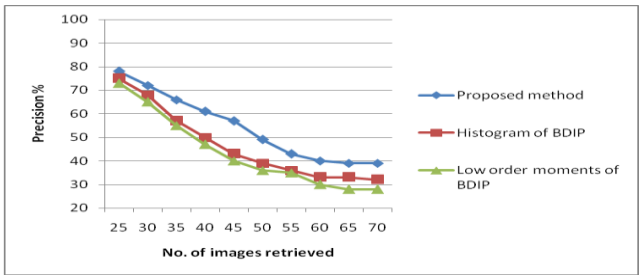

Fig.6 (a). Average precision of all the methods in Corel 10k dataset

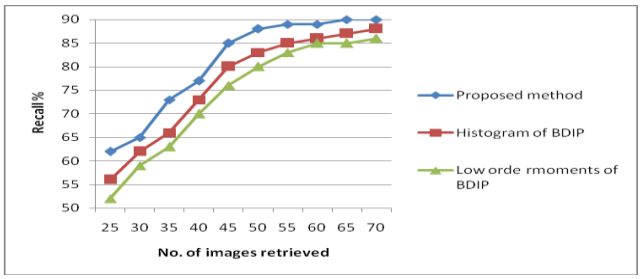

(b) Fig.6 (b). Average recall of all the methods in Corel 10k dataset

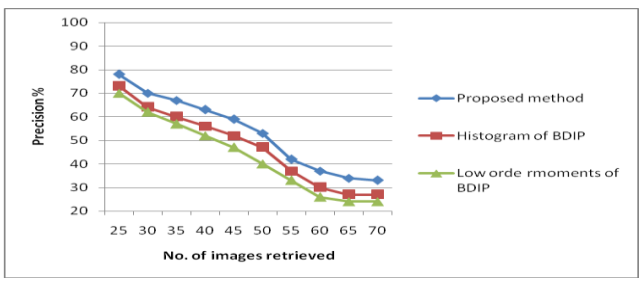

Fig.7 (a). Average precision of all the methods in Caltech dataset

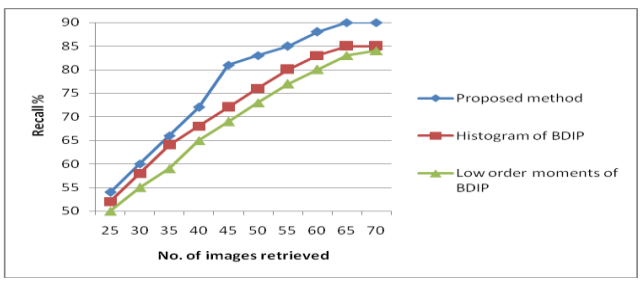

Fig.7 (b). Average recall of all the methods in Caltech dataset

Fig.8. First top 5 retrieval results for the dino, bus and sunflower images in Corel and Calitech database

Table.1. ARR for proposed and other approaches

Methods	Holiday Dataset	Corel 10k Dataset	Calitech 101 Dataset
Proposed	57.12%	58.23%	61.81%
Chun [20]	50.78%	49.23%	52.39%
Sathiamoorthy [22]	52.67%	51.45%	54.78%

In all the experiments, while we increase the number of related images retrieved above 200, the ARR remains stable and there is fluctuation in the plots of average P(N) and average P(R). The ARR values attained for proposed CMBDIP and others methods [20, 22] are reported in Table.1 and it is evidently understandable that proposed CMBDIP drastically outperforms for holiday, Corel and Calitech datasets than conventional approaches [20, 22]. In Fig.8, first two columns corresponds to the dino and bus images of Corel dataset and 3rd row had shown query and its related retrieved images for sunflower in Calitech dataset.

VI. CONCLUSION

In this paper, a novel edge based shape descriptor is proposed by combining BDIP with GLCM and named as co-occurrence matrix of BDIP (CMBDIP) which effectively computes local information and spatial information among adjacent edgels along 0°, 45°, 90°,135° directions and thus it overcomes the pitfalls of histogram of BDIP and integrates the gains of BDIP and GLCM. The proposed approach computes four CMBDIPs i.e. one for each direction and are joined together to construct the final CMBDIP. The proposed approach is verified on three image datasets namely Holiday, Corel10k and Caltech 101 and the results obviously demonstrate that proposed CMBDIP is significantly effective than conventional approaches. In future, proposed approach can be extended for various application domains.

Abstract—**In this work, an efficient multiresolution approach based geometric details of localized edgels is proposed to represent an image, called wavelet based chordiogram image descriptor. The proposed approach mainly focuses on reducing the computational cost of retrieval system with the preservation of accuracy and resilient to illumination, scaling, noise and small rotations, and is performed by deriving the geometric features from the pyramid structure of an image using Discrete Haar Wavelet Transform. The proposed multiresolution approach based chordiogram image descriptor is comprehensively tested on benchmark datasets. The experimental results proved that proposed approach is considerably better in terms of time cost and retain the accuracy of existing approach.**

.

Keywords— Chordiogram image descriptor, L1 similarity measure, Haar wavelet, Multiresolution.

I. INTRODUCTION

Nowdays, most of the services and human communication in most of the domains rely heavily on digital images owing to ease of recognition for human as a consequence of rich amount of details available in digital images. With hasty increase of digital images, the size of digital image archives and libraries are expanding day by day and it leads to the core objective of retrieving system. Since the use of image retrieval has been flourishing in speed, researchers have much attention in the advancement of proper techniques to satisfy the users of all domains in image searching and retrieval from massive image archives and turns out to be most trendy subject in the domain of pattern recognition. Generally speaking, image retrieval approaches are categorized under three labels namely text, content and semantic based approaches.

Since 1970's, more numbers of research works contributed for image retrieval based on text. But, well annotation of digital images turns into inefficient and impractical owing to the massive digital image archives and its vast diverse image gathering, and it leads to the emerging of content based image retrieval (CBIR) in 1980's and numbers of CBIR approaches including QIBC [1], Virage [2], Web seek [3], and PicToSeek [4] have reported successfully. In CBIR approach, image representation is relying on feature vector which is formed using various low-level visual descriptors including color, shape and texture. In CBIR approach, according to similarity among the feature vectors of input image and dataset images, most pertinent images are retrieved by users. Commonly, feature descriptors falls into global and local categories. The first one focuses at whole image whereas the second concentrates on prominent key points and patches in an image and it has high discriminative ability then the global one. Since the semantic gap exists among the low level image descriptors and high level image concepts perceived by human, the retrieval performance of CBIR approaches are limited and to tackle this subject, approaches including dictionary learning and relevance feedback are introduced. Besides, researchers believe that optimized and locality preserving information is suitable for increasing the retrieval performance of CBIR approach because it characterize the image content accurately and viaduct the semantic gap as much as possible. [5] suggested that representing the image descriptors using histogram based feature representation is compact one and significantly decreases the noise and compact one.

Color-based clustering descriptor (CBC) and border/interior pixel classification descriptor (BIC) is described by Stehling et al., in [6]. In BIC, border and interior pixels are characterized by two separate histograms that count the intensity and locations of border/interior pixels. In [7], edge histogram descriptor is reported by Jain and Vailya, depicted based on edges computed by canny approach. It is also described in [7] that normalization of edges reduces the problem of resilient to scale and small rotation. Afterwards, EHD is developed by MPEG-7 [8] in which Sobel approach is incorporated for edge computation.

Along this way, Liu et al., [9, 10] defined that EHD is rich in texture, shape and spatial details of texture and shape, and thus extensively incorporated in numbers of CBIR approaches [11-18]. Edge orientation autocorrelogram (EOAC) is suggested by Mahmoudi et al. [19] and it exploits shape, textures and spatial details by utilizing the correlation among neighboring edgels based on its orientation and is demonstrated that performance of EOAC is noticeably better than EHD [8] and invariant to illumination, translation,

viewing position and minute rotation. Later, Liu et al., [16] suggested micro-structure descriptor (MSD) that exploits texture, color and shape particulars of an image by utilizing the orientation resemblance of edgels with an underlying color. Toshev et al. [20] suggested chordiogram which computes the geometric details of selected set of edgels found using segmentation. The exploited geometric details are distance and orientations of pair of edgels and also the degree of the vector connecting them. Thus, chordiogram is represented using a four dimensional histogram. But, boundaries attained through segmentation include fake edgels that affects the results. In [21], Kovalev and Volmer exploited the intensity and distance among the each pair of edgels and is characterized by utilizing a three dimensional histogram. Zitnick [22] presented a binary coherent edge descriptor, illustrated using a four-dimensional histogram which characterizes the coordinates and orientation of each edgels and length of an edge passing via the edgles.

Later on, Seetharaman and Sathiamoorthy presented an enhanced variety of EHD and EOAC [23-25] in HSV color space based on Full Range Autoregressive (FRAR) model with Bayesian Approach and it exploits incredibly minute and very fine edgels, also proved that their approach considerably best than the existing EHD [8] and EOAC [19] and owing to the behavior of the FRAR model their approaches also robust to noise to some extent. [16, 23, 25] reported that edge detectors including Sobel, Prewitt, Canny and Robert are developed for the images of gray-scale even they converts the color into gray-scale images for computing the edges and thus they failed in exploiting incredibly minute and very fine edgels owing to chromatic and spectral changes. Further, it is defined in [16] that finding edgels from H or S or V channels alone failed in exploiting incredibly minute and very fine edgels owing to spectral changes and such a loss play vital task in medical color image retrieval [24].

Afterward, a novel hybrid scheme is proposed in [26] which uses the statistical approaches namely color autocorrelogram (CA) and texture autocorrelogram (TA) together with the geometric approach namely chordiogram image descriptor (CID) for each region of a image for medical image retrieval. Since the localized geometric descriptors among edgels have been treated as resilient cauterization of shapes and images, Wang et al.,[27] proposed chordiogram image descriptor (CID), a histogram of chord details. The authors divided the image into number of patches then find the edges using the edge detectors [27] for each patch. Later geometric details including the distance among the pair of edgels, orientations of each edgel and degree of angle among line segment between a pair edgels and horizontal plane is exploited for every patch and they depicted it as local edgel chordiogram (LEC) [27]. The fusion of all LECs of image, named as CID. The authors demonstrated that CID exploits spatial structure in an image and is resilient to illumination.

It is affirmed by Zhang and Lu in [5] that contour extracted from spatial domain are sensitive to noise, and are not apt to be a separate descriptors, implementation and matching is also complex and cost. Thus, in this work, we proposed discrete Haar wavelet transformation based chordiogram image descriptor (CID) using for CBIR approach, called Wavelet based chordiogram image descriptor (WCID) which depicts the shape and exploits the localized geometric details from the locations of edgels computed from Haar wavelet transformations. The implementation and matching cost of proposed WCID approach is too less than the CID and the proposed WCID preserves an accuracy and robustness against illumination as that of CID.

The proposed work is expressed as follows. The proposed image feature is introduced in Section-2. Section-3 illustrates experimental results. Section-4 concludes the work.

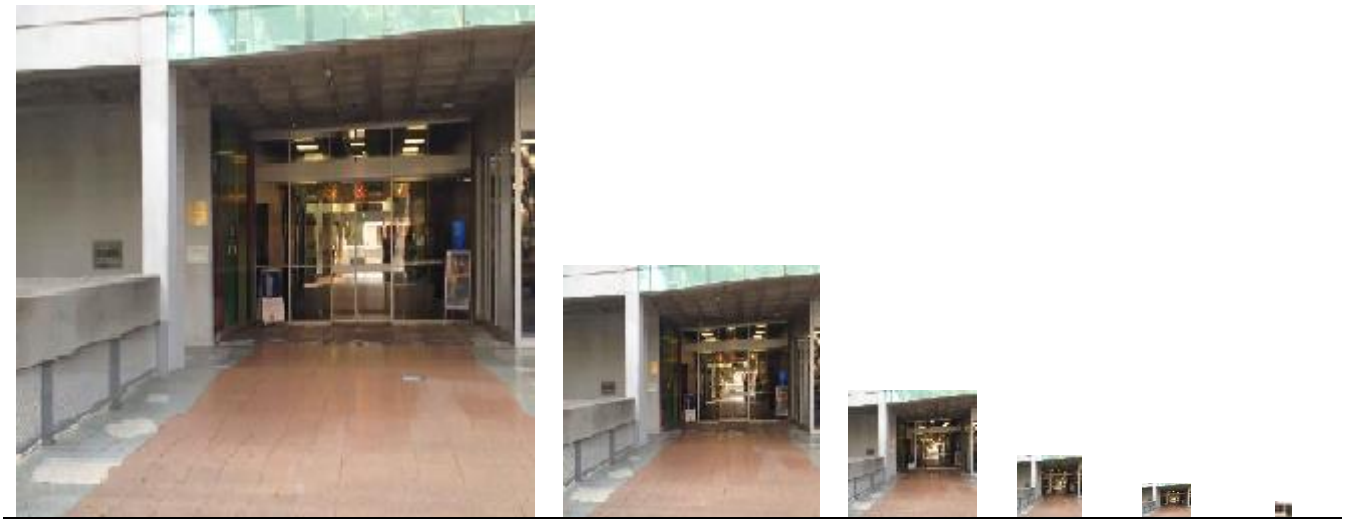
II. DISCRETE HAAR WAVELET TRANSFORM

Over the decades, researchers are working in spectral domain including Fourier [28, 29] and wavelets [30], and the descriptors computed from wavelet domain is superior to Fourier, more number of researches carried out using wavelets [31-37]. Accordingly, in this paper, discrete Haar wavelet transform [38] is incorporated and it does the decomposition by calculating the approximations and details till the fine level and provide outcome in the form of wavelet pyramid image [38].

The discrete Haar wavelet transform is incorporated to attain the multi-resolution pyramid image as reported in [38] and is expressed as

$$\begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ w_0 \\ w_1 \\ w_2 \\ w_3 \end{bmatrix} \Leftarrow \begin{bmatrix} a_0 \\ w_0 \\ a_1 \\ w_1 \\ a_2 \\ w_2 \\ a_3 \\ w_3 \end{bmatrix} = \begin{bmatrix} 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 \end{bmatrix} \cdot \begin{bmatrix} I_0 \\ I_1 \\ I_2 \\ I_3 \\ I_4 \\ I_5 \\ I_6 \\ I_7 \end{bmatrix}$$

Where $I_{0,}, I_1, ..., I_k$ are the input images and contains k coefficients in which there are k/2 approximations and k/2 wavelet coefficients and are stored in the upper $\lfloor a_{0,}, a_1, .a_3 \rfloor$ and lower $\lfloor w_{0,}, w_1, .w_3 \rfloor$ arrays respectively and this method is repeated till fine level is attained and the fine level in this work is 3, is computed on the trial and error process. Multi-resolution pyramid image is constructed by utilizing a sub-sampling rate of 2 with no overlap method as described in [38]. Fig. 1 portrays the pyramid structure of a self photographed sample image upto the level 5. The dimension of self photographed sample image is 256 x 256 in level-0, 128 x 128 in level-1, 64 x 64 in level-2, 32 x 32 in level-3, 16 x 16 in level-4 and 8x8 in level-5. For each level of decomposition, the dimension of sample image is decreases to half of sample image at previous level and image at level 4 and 5 is not clear one. In the suggested approach, we fix the fine level experimentally.



(a) (b) (c) (d) (e) (f)

Fig.1.Multi-resolution pyramid image from level-0 to 5 [(a)-(f)] using the discrete Haar wavelet transform. The input image at level 0 is of size 256 x 256 and images of succeeding level are of size 128x128, 64x64, 32x32, 16x16 and 8x8 respectively.

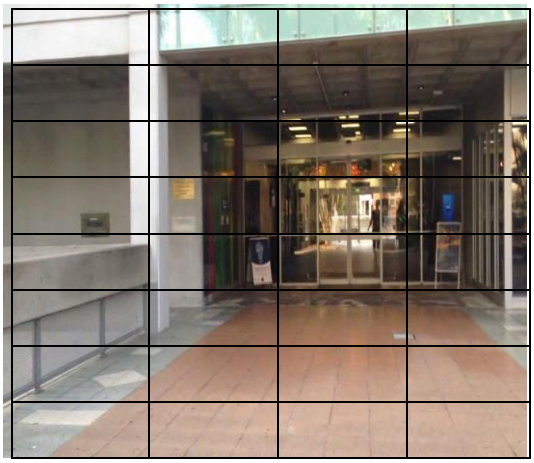


Fig.2. Image divided into 32 numbers of non-overlapping rectangular patches of size 8x8 for computing LEC

III. CHORDIOGRAM IMAGE DESCRIPTOR

Given image is partitioned into number of non-overlapping rectangular patches, numbered from 1, 2, 3, . . . , N. Each patch is characterized using LEC. In order to compute LEC, salient edgels are identified for each patch then local geometric features are computed from the salient edgels. Later, the LECs of all patches are collected in an order to construct a CID. The chord particulars of the patch image are computed from each pair of salient edgels coordinated at p and q and is described as in [27] as follows

$$C_{i_{pq}} = (\ell_{pq}, \phi_{pq}, \theta_p, \theta_q) \quad (1)$$

Where $\ell_{pq}, \phi_{pq}, \theta_p$ and θ_q designates the distance among edgels p and q, angle between line and horizontal plane, degree of orientations of edgels p and q about the normal directions respectively, and the values of ℓ_{pq} ranges from 0 to diameter of an image patch and ϕ_{pq}, θ_p and θ_q falls in between 0 and 2Π. The values of ℓ_{pq} are discretized in logarithmic space and are divided into η_d bins where d is the distance and is 4 in our work [27]. ϕ_{pq}, θ_p and θ_q are quantized into 8 bins of 50 degrees each [27]. Thus, CID is a 4D histogram and is normalized as in [27], and it encompasses chord details for every pair of salient edges in image patch.

Since CID is not sensitive to edge detector, in the experiment, Sobel operator is incorporated to compute the edges in each patch. After computing the edgels, response of each edgels are computed and are sorted. Then, proportion p of edgels having highest responses are preferred as in [27] to compute the LEC i.e. the salient edgels are preferred from the patch image with the intention of reducing the calculation cost by means of considering the less numbers of salient edgels and the selected salient edgels must exploits the shape details of patch and it must provide robustness against illumination and small rotation. Thus, the set of preferred salient edgels has two information: one is response of edgels and other is proportion p which decide the dimension of set of salient edgels and is decided experimentally as in [27] using n=pm where m and n are the amount of edgels in a patch and preferred salient edgels respectively and p is constant for all patches. Finally, the computed LECs of all patches are collected in an order to form a CID and is described as [27]

$$F = (C_1, C_2, ..., C_N) \quad (2)$$

Where $C_1, C_2, \ldots, C_N$ are the LEC of patches 1, 2, ..., N respectively.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Datasets

In the experimental study, Gardens Point Walking [39], UA Campus [27], St. Lucia [27] datasets and some self photographed images are utilized and some example images of

dataset consumed in the experiments are depicted in Fig.3. The Gardens Point Walking dataset has 3 folders namely day-left, day_right and night_right and each folder contains 200 images and are taken twice in day that is in a day and night and are roughly in 960x540 size and in JPG format. The datasets consists of images taken at varied times with sever and mild illumination changes. St. Lucia datasets consist of images taken at 5 varied times among early morning and late afternoon of a day and a day after two weeks. Thus, totally it has ten datasets. We have also used some self photographed images taken at varied time of a day in the experiments and it consists of 1140 images and are in JPG format and size of images are approximately 1280x720 and 1040 x780.

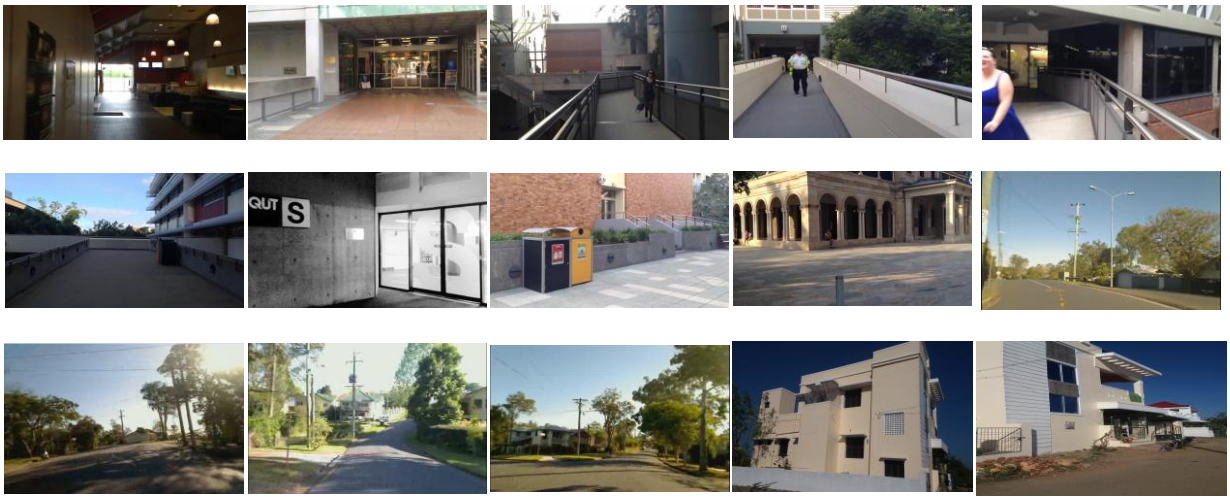

Fig.3.Few example. images of experimental datasets

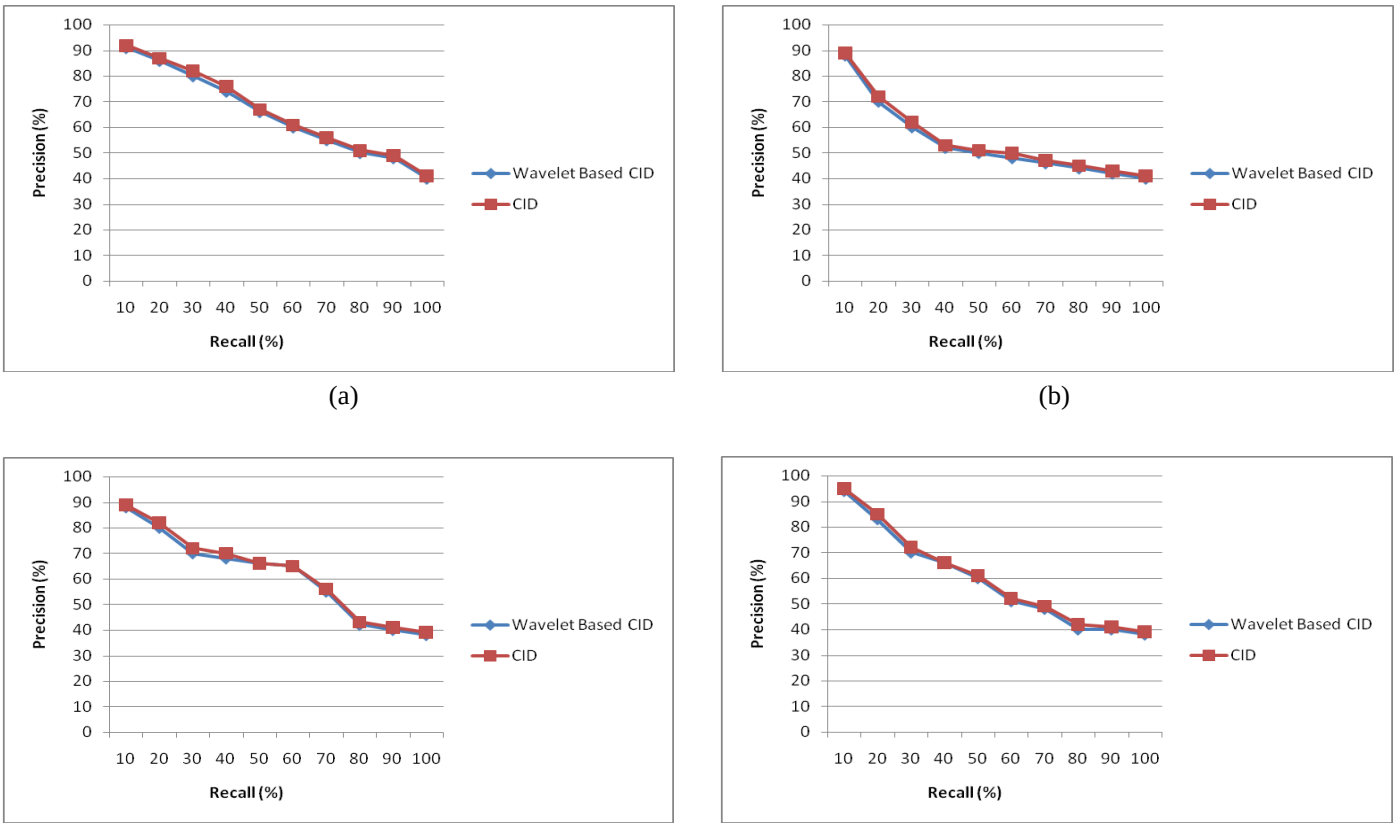

Fig.4.Precision Vs. Recall for the proposed Haar wavelet based CID and the conventional CID approaches for (a) Gardens Point Walking (b) UA Campus (c) St. Lucia (d) Self photographed image Datasets

B. Similarity Measuremnt

In the suggested work, L1 similarity measure is used and it computes sum of absolute differences of the variables [40] as a distance among 2 points in an Euclidean space with fixed Cartesian coordinate system [40]. The L1 distance among two images is given by

$$S\left(I^q, I^t\right) = \sum_{i=1}^{k}\left(I_i^q - I_i^t\right) \tag{3}$$

where, I_i^q and I_i^t are input and target image descriptor vectors respectively and k is size of the combined feature vector.

Instead of computing the similarity among query and target images based on the summation of similarity measures of all the corresponding patches, similarity measures of all the corresponding patches are computed and are ordered in ascending manner as in [27]. The higher similarity values between two images are eliminated to avoid impact of noise in the image which leads to false matching [27]. Thus, the summation of n smallest similarities computed from the corresponding patches of query and target images are summed finally to get the matching.

C. Performance Assessment

The capability of proposed wavelet based CID approach for image searching is illustrated on the basis of precision and recall. In the image retrieving process, for an input image, several images are retrieved and few of them are relevant to input image and remaining retrieved images are not relevant. The images satisfies the interest of user are known as relevant and total number of images retrieved for an input image is known as retrieved images. Precision (P) and recall (R) is calculated as [41,42]

$$P = \frac{(\text{Relevant images}) \bigcap (\text{Retrieved images})}{\text{Total number of images retrieved}} \tag{4}$$

$$R = \frac{(\text{Relevant images}) \bigcap (\text{Retrieved images})}{\text{Total number of releveant images in the database}} \tag{5}$$

The P and R associated with a class are computed as [41,42]

$$P_{avg}^{C} = \frac{1}{N}\sum_{i=1}^{N} P_i^C \tag{6}$$

$$R_{avg}^{C} = \frac{1}{N}\sum_{i=1}^{N} R_i^C \tag{7}$$

Where C designates the class number, N designates total number of images in each class. For complete dataset, the P and R is calculated as in [41,42]

$$P_{Tot}^{C} = \frac{1}{N}\sum_{s=1}^{N} P_{avg}^{C}(C) \tag{8}$$

$$R_{Tot}^{C} = \frac{1}{N}\sum_{s=1}^{N} R_{avg}^{C}(C) \tag{9}$$

Where N denotes number of classes available in the dataset. R, also named as average retrieval rate (ARR). In the suggested approach, each image in the dataset is used as query to the proposed retrieval system and for each of them, P and R is measured. For each class, P and R is measured.

D. Experimental setup

To prove the competence of the proposed WCID, input image is transformed into fine level using the discrete Haar wavelet and the level of fine is 3 which is decided experimentally. The images in the datasets are resized to 1028 x 512. The wavelet transformed image is partitioned in to number of patches of 8 x 8 sizes. Thus, for an image of size 1028 x 512, we obtained 512 x 256, 256 x 128, 128 x 64, 64 x 32 and 32 x 16 in level-1 to level-5 respectively and we have 32 numbers of 8x8 patches in the optimum level 3 and is depicted in Fig.2. According to [27], 15% of salient edgels are preferred from the patch for computing the LEC.

E. Results and Discussion

Gardens Point Walking dataset is considerd in the experiment1. P and R for the proposed WCID and conventional CID are computed and demonstrated via graphs. In Fig.4, plots for P and R are depicted. Fig.4a depicts variation in P with respect to R and very clearly it demonstrated that the suggested WCID approach is equalently performing with conventional CID and Table.1 depicts that the suggested scheme requires less time cost than the conventional CID. The P and R of presented WCID and conventional CID at level 0 and level 3 are 65.78%, 65.64% and 8.41%, 8.51% respectively. From the results it is obvious that the change in the values of precison and recall is very small from level 1 to level 3. But, from the level 4, there is drastic change in the values of both P and R.

In the second experiment, UA campus dataset have been used. The results of the proposed wavelet based CID and CID in the form of P and R is depicted in Fig.4b. The proposed approach is equally satisfying with the CID and is obviously visible in the graph. The P and R of presented and conventional techniques are 57.23%, 57.11% and 9.86%, 9.85% respectively. The outcome shown in Table 2 clearly depicted that after the 3rd level decomposition, the change in the P and R values are for above the normal.

Table 1. Computational complexity of WCID and CID

Methods	Time in seconds
Wavelet based CID	22
CID	45

In the third experiment, St.Lucia dataset has been taken for image retrieval. Results for St.Lucia dataset have been presented in Fig.4c. The results of performance measures clearly demonstrated that the proposed WCID equally outperforms the CID with leas computational time and preserves robustness capability of CID against illumination, noise scaling and small rotation. The P *and* R attain by

proposed and existing CID are 67.32%, 67.15% and 7.67% and 7.79% respectively.

In the fourth experiment, self photographed images are considered. The results of proposed WCID and CID in terms of P *and R* is depicted in Fig.4d. The precision and ARR for the WCID and CID are 66.23% and 66.05% and 6.68% and 6.79% respectively. Table 2 illustrates the average *P* and *R* for all the datasets used in the experimental study. In Fig.5 and 6, query image to the suggested system and its top five retrieval results are depicted which is similar to the results of CID. From Fig.5 and 6, it is obviously understood that the proposed WCID is illumination to invariant and for query image of day left category, the suggested system also retrieve images from day right and night right category as that of CID that is the results confirmed that proposed WCID is strongly invariant to illumination.

	Recall (%)	9.76	9.78	9.81	9.85	10.88	11.90
St. Lucia	Precision (%)	67.32	67.26	67.18	67.15	65.09	63.22
	Recall (%)	7.67	7.70	7.76	7.79	8.82	9.85
Self Photographed Images	Precision (%)	66.23	66.16	66.10	66.05	64.00	62.16
	Recall (%)	6.68	6.71	6.75	6.79	7.82	8.86

V. CONCLUSION

A shape based image descriptor called chordiogram image descriptor is computed from the multi-resolution resolution domain which captures the local geometric descriptors rather than image intensities. The pyramid structure of an image is obtained using discrete Haar wavelet transform and is used for computation of chordiogram image descriptor which reduces computation time drastically for descriptor extraction and matching and preserves the same average retrieval rate as that of CID and also resilient to sever illumination, scaling, noise and small rotation. The presented approach is extensively tested on Gardens Point Walking, UA campus, St. Lucia datasets and the presented approach depicts a excellent tradeoff between interclass separability and interclass variance. In future, the proposed scheme can be combined with other visual details of image to further improve the accuracy of retrieval.

Abstract— **We propose a novel descriptor for content based image retrieval called wavelet based multi-trend structure descriptor (WMTSD). The proposed WMTSD is an enhanced approach of multi-trend structure descriptor (MTSD). To diminish the computational cost of MTSD with the preservation of retrieval rate, WMTSD is derived. In order to diminish the time cost, an image is decomposed into optimum level using discrete Haar wavelet transform and it produces multi-resolution pyramid image. The multi-resolution pyramid image at optimum level is utilized to estimate the feature descriptor. The optimum level for the decomposition of an image is determined empirically. The proposed WMTSD is exhaustively tested on Corel 1k, Corel 5k, Corel 10k and Caltech benchmark datasets. The experimental study very clearly illustrated that the proposed WMTSD and MTSD attains almost similar retrieval accuracy. But, the time cost of WMTSD is too small then the MTSD which is required more in the era of big data. Euclidean distance measure is adopted to assess the similarity between the images. Precision and Recall are the measures used to assess the proposed approach.**

.

Keywords— Multi-Trend Structure descriptor, Euclidean similarity measure, Haar Wavelet, Wavelet based Multi-Trend Structure descriptor, Sobel operator.

I. INTRODUCTION

Today, in the domain of pattern recognition, content based image retrieval (CBIR) is an energetic area of research. Over more than three decades, more and more number of effective CBIR approaches has developed with reasonable retrieval rate and time. However, with an extensive uses of varieties of images like medical, biometric, historical archives, agriculture, media, etc over the web, the performance of existing systems for CBIR need to be enhanced.

Image retrieval system permits the end users to browse and access images more effectively from the datasets. The feature computation is the main component of retrieval system which entails an image to be characterized by high discriminative feature with high and small changes between the features of inter and intra class images, and the images are characterized either at global or local approach. The global approach disregard the local characteristics of pixels in an image and thus it endure issues related to scaling, translation, occlusion, illumination, noise etc and are overcome by the local approach which characterizes an image from local regions or partitions of an image.

It is reveled from the literature that more and more numbers of global approaches has suggested based on texture, shape and color details of an image including Tamura features [1], Gabor filtering [2], Markov random field model [3] and gray-level co-occurrence matrices [4] for texture details; contour features like circularity, eccentricity, convexity, major axis orientation [5, 6], shape signatures like curvature, cumulative angle, tangent angle, chord-length [7, 8], boundary moments [9, 10], edge histogram descriptor (EHD) [11-13] for shape details and color histogram (CH), dominant color descriptor (DCD), scalable color descriptor (SCD) and color layout descriptor (CLD) for color details [14].

Though global approach is the core of numbers of CBIR approaches, the aforesaid issues related with global approaches have required the characterization of images using local approaches including SIFT [15], SURF [16], LBP [17], HOG [18], local ternary co-occurrence patterns [19], local mesh pattern [20], multi-texton histogram [21], micro-structure descriptor [22], saliency structure histogram [23], structure element descriptor [24], texton co-occurrence matrices [25], multi-trend structure descriptor (MTSD) [26], etc. Among various local approaches MTSD has demonstrated to be the more efficient in state-of-art retrieval approaches and is successfully verified on benchmark datasets namely Corel and Caltech. The MTSD captures correlation of local structure in the form of trends for edge orientation, color and intensity details using the information variation of pixels along 0°, 45°, 90°and 135° orientations. It also found from literature that many of conventional local approaches characterizes an image using either texture or color or shape and very rare local approaches encompasses texture, color and shape and MTSD is one among them. But, we found that computational complexity of MTSD is significantly intensive. For example, consider an image of size 256 x 256 for which large, equal and small trends either for texture or color or shape details along 0°, 45°, 90° and135° orientations is computed from 7,281 non-overlapping windows of size 3 x 3. Thus, to compute texture, color and

shape details MTSD uses 21,843 non-overlapping windows of size 3 x 3. The major aim of this proposed work is developing a CBIR system that compromises between retrieval rate and computational cost. Hence, in this work., computational intensive issue of MTSD is addressed by computing the MTSD from the image which is decomposed into pyramid like multi-resolution structure utilizing discrete Haar wavelet transform [27] and the approach is named as Wavelet based multi-trend structure descriptor (WMTSD) in which an example image of size 256 x 256 is decomposed into optimum level i.e. 3, which is determined based on trial and error approach. Thus, we obtain 32 x 32 image at fine level from which we compute the MTSD. Large, equal and small trends either for texture or color or shape details along 0°, 45°, 90° and135° orientations is computed in the proposed approach (WMTSD) from 113 non-overlapping windows of size 3 x 3 and for encompassing all the three details mentioned above 339 non-overlapping windows of size 3 x 3 is used. Thus, in the proposed wavelet based approach, computational cost of MTSD is reduced without diminishing the discriminative power of MTSD and is demonstrated using the benchmark datasets.

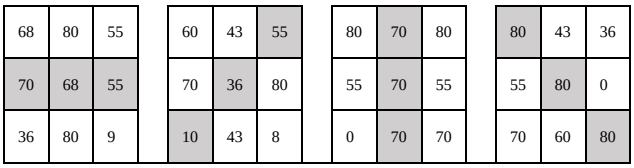

Fig.2. (a). Small trend along 0° (b). Large trend along 45° (c). Equal trend along 90° (d). Equal trend along 135°

This manuscript is structured as follows. In section II, overview of conventional MTSD is provided. The discrete Haar wavelet transform has been described in section III. Feature estimation is explained in section IV. Similarity and performance measures used in the proposed approach are explained in section.V and VI. Exhaustive experimental analysis based on retrieval rate and computational cost is reported in section VII. Conclusion is defined in section VIII.

II. MULTI-TREND STRUCTURE DESCRIPTOR

The MTSD [26] estimates the correlation of local structure in the type of trends for edge orientation, color and texture details using the information change of pixels along 0°, 45°, 90° and135° orientations. For estimating the MTSD, an image is alienated into 3 x 3 non overlapping windows. In [26], Zhao et al., defined large, small and equal trends based on quantized pixel values and are small to large, large to small and same along 0°, 45°, 90°and 135° orientations respectively.

The MTSD [26] is estimated from HSVcolor space. For estimating the local structure of color, texture and edge details based on trends, color quantization is carried out by separating the H, S andV channels into 12, 3 and 3 bins and it gives 108 colors; intensity details in V channel is quantized into 20; Sobel edge detection approach is applied on V channel image to extract edge details and the identified edges are quantized into 9 based on the orientations of edge pixels.

Accordingly, trends are estimated for quantized edge orientation, color and texture details and are integrated to form a feature vector. Fig.1 illustrates the image feature matrix estimated by the MTSD for color information where numbers of each trends for quantized colors 0 to 108 is described. Fig.2 illustrates an example for trends along 0°, 45°, 90°and 135° orientations.

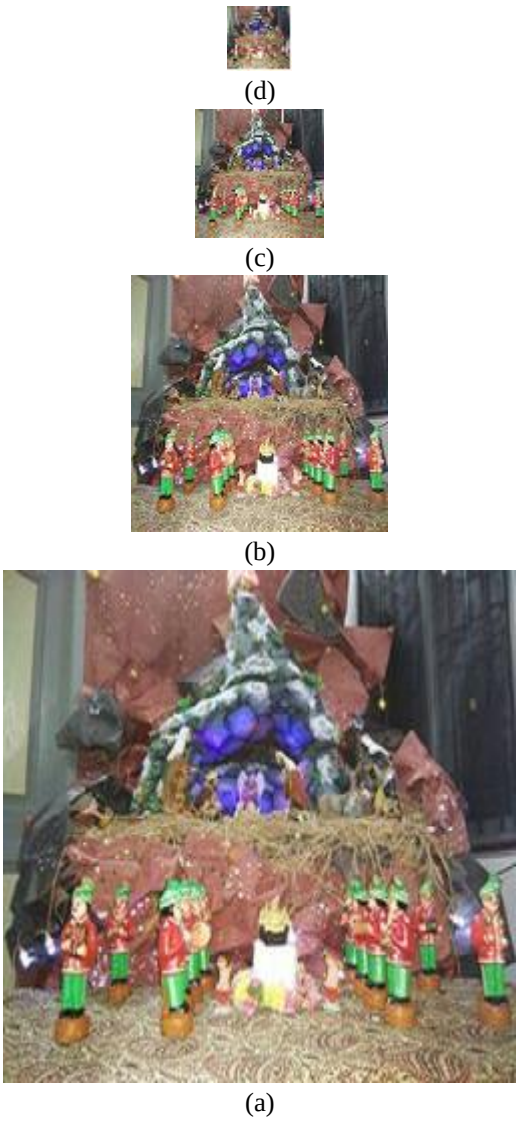
III. DISCRETE HAAR WAVELET TRANSFORM

In recent years, researchers working in CBIR, employed wavelets due to its multi-resolution ability and attained better retrieval performance [27]. Subsequently, in the proposed work, discrete Haar wavelet transform [27] is employed which performs decomposition by estimating the approximations and details till the optimum level and results in wavelet pyramid image formation [27]. The multi-resolution pyramid image is obtained using discrete Haar wavelet transform as in [27] and is described as follows

$$\begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ w_0 \\ w_1 \\ w_2 \\ w_3 \end{bmatrix} \Leftarrow \begin{bmatrix} a_0 \\ w_0 \\ a_1 \\ w_1 \\ a_2 \\ w_2 \\ a_3 \\ w_3 \end{bmatrix} = \begin{bmatrix} 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.5 & 0.5 \end{bmatrix} \begin{bmatrix} I_0 \\ I_1 \\ I_2 \\ I_3 \\ I_4 \\ I_5 \\ I_6 \\ I_7 \end{bmatrix}$$

$I_{0,}, I_1, ..., I_k$ are the input images and contains k coefficients in which there are k/2 approximations and k/2 wavelet coefficients and are stored in the upper $[a_{0,}, a_1, .a_3]$ and lower $[w_{0,}, w_1, .w_3]$ arrays respectively and this procedure is repeated till optimum level is achieved. In this work, optimum level is 3 and is determined based on trial and error approach. Multi-resolution pyramid image is framed by a sub-sampling rate of 2 with no overlap approach as in [27]. Fig. 3 illustrates the pyramid structure of an example image for the optimum level i.e. 3. The size of an example image is 256 x 256 in the first level and is

decomposed up to optimum level i.e. 3. At each level of decomposition, the size of an example image is diminishing to half of an example image at previous level. Thus, we obtained 128 x 128, 64 x 64, 32 x 32 dimensions at levels 1st, 2nd and 3rd respectively.



(d) (c) (b) (a)

Fig.3.Multi-resolution pyramid image from level-0 to level-3 [(a)-(d)] utilizing discrete Haar wavelet transform. The input image is of size 256 x 256 and images in the next level are of size 128 x 128, 64 x 64 and 32 x 32 respectively.

IV. PROPOSED WAVELET BASED MTSD ESTIMATION

The input images are in RGB color space, converted into HSV color space then for diminishing the time complexity without reducing the retrieval performance. The discrete Haar wavelet transform is utilized to form a multi-resolution pyramid image [27]. The level in which the numbers of details are very less without dropping the dominant details in an image is called fine or optimum level and is set to 4 in the proposed approach based on the trial and error process of retrieval. From the fine level of decomposed image, H, S and V channels are separated and color quantization is accomplished into 108 bins as in [26] and the WMTSD for color details are described as

$$\Gamma_c = \left(N_E^{Q_c}, N_S^{Q_c}, N_L^{Q_c}\right) \quad (1)$$

Texture details in the V channel are quantized into 20 bins as in [26] and the WMTSD for texture details are described as

$$\Gamma_t = \left(N_E^{Q_t}, N_S^{Q_t}, N_L^{Q_t}\right) \quad (2)$$

Using Sobel operator, edge information are identified and the detected edge pixels are quantized into 9 bins based on orientation details [26] and the WMTSD for edge orientation details are described as

$$\Gamma_e = \left(N_E^{Q_e}, N_S^{Q_e}, N_L^{Q_e}\right) \quad (3)$$

N, Q_c, Q_t, Q_e, E, S and L represents the number of trends, quantized color/texture/edge orientation details, equal, small and large trends respectively.

Finally, WMTSD for color, a texture and shape detail are integrated to form a combined feature vector and is defined as follows

$$\Gamma = \left(\Gamma_c, \Gamma_t, \Gamma_e\right) \quad (4)$$

The integrated WMTSD is employed for image classificaton and retrieval.

V. SIMILARITY MEASURE

Since the retrieval performance of CBIR approaches is also strongly associated with similarity measures and Euclidean distance [28] is more efficient and widely utilized in literature, we adopted it for estimating the similarity between input and the images in the benchmark dataset and is given as follows

$$S(I,T) = \sqrt{\sum_{i=0}^{N} \left(|I_i - T_i|\right)^2} \quad (5)$$

where I and T are the input and the target image feature vector and N is number of image features in image feature vector.

VI. PERFORMANCE MEASURE

In this work, each image in the benchmark dataset is utilized as an input to CBIR. The retrieval performance is estimated using precision *P(N)*, recall *P(R)*, mean average precision (*mAP*) and mean average recall (*mAR*) for top N retrieved images and are described as in [29] as follows

$$P(N) = \frac{I_N}{N} \quad (6)$$

$$R(N) = \frac{I_N}{M} \quad (7)$$

Where I_N designates number of top related images retrieved same as input image and M designates the total

number of related images in the benchmark dataset same as input image.

The average *P(N)* [29] for a given query image (*I*) is defined as an average of *P(N)* values of top N relevantly retrieved images and is given as follows

$$\mu_{P(I)} = \frac{1}{N} \sum_{i=1}^{N} P(N) \tag{8}$$

The *mAP* [29] is defined as average *P(N)* for all the input images and is expressed as follows

$$mAP = \frac{1}{N_I} \sum_{k=1}^{N_I} \mu_{P(I)} \tag{9}$$

Where N_I designates total number of input images.

VII. EXPERIMENTAL RESULTS AND DISCUSSIONS

A. Datasets

Corel dataset [22, 26, 30, 31]: Corel 10k dataset consists of 10800 natural and textural images of 80 concepts like dog, elephant, iceberg, ship, lion, flower, tier, mountain, car, ocean, fort, duck, train, fish, sunset, etc. and each concept consists of roughly 100 or more images. Corel 1k and Corel 5k datasets contains the 1st 1000 and 5000 images of Corel 10k dataset. The sizes of images are differ and are roughly in 384 x 256 or 256 x 384 or 126 x 187 or 187 x 126 or 192 x 128 or 128 x 192 sizes and the images are in JPEG format.

Caltech-101 dataset [26, 32]:

It contains 9,146 images of 101 concepts like octopus, crab, dolphin, rhino, pizza, panda, lamp, emu, cup, ant, etc and each concept consists of roughly 40 to 800 images. The size of the images is approximately 300 x 200 and are in JPG format.

B. Results and Discussions

In this section, experimental results are reported to reveal an effectiveness of proposed WMTSD and its results are compared with MTSD [26]. We carried out detailed experiments for each level of decomposition of images on benchmark datasets and the results are depicted in Table.1. From the results, it is obviously illustrated that WMTSD estimated from decomposed image at level 3 significantly provides better retrieval result than the decomposed image at level 4 and 5 despite the fact that its computational cost is less; and the retrieval results of decomposed image at level 3 and level. 0 to level. 2 are more or less similar nevertheless the computational cost of WMTSD from level 4 and 5 is too less and is shown in Table 1. As a result, in all our forgoing experiments we use optimum level as 3 for estimating the MTSD [26].

For example, in Fig.3, the size of an image at decomposed level 3 is 32 x 32 and the proposed approach estimates large, equal and small trends for texture, color and shape information along 0°, 45°, 90°and 135° orientations from 339 (i.e. 113+113+113) non-overlapping windows of size 3 x 3 as described in section 1. Whereas estimating the MTSD [26] from the level 1 image that is input image uses 21,843 non-overlapping windows of size 3 x 3. Thus, the proposed WMTSD approach preserves the accuracy of MTSD and demising the cost of computational complexity.

The retrieval performance of proposed WMTSD is compared with MTSD [26] using *mAP* and the *mAP* values attained by WMTSD and MTSD for top 10 images (*N*=10) on Corel 1k, 5k and 10k and Caltech-101 datasets are illustrated in Table 2. It is reveled from the Table 2 that proposed WMTSD maintains the *mAP* of MTSD on benchmark datasets and there is not much difference seen in between the *mAP* of MTSD and WMTSD. We also illustrated the *mAP* values for randomly selected 10 classes of Corel and Caltech datasets in Table 3 for *N*=10 which also reveal that proposed WMTSD and MTSD attains more similar results. Therefore, the proposed WMTSD maintains tradeoff between retrieval rate and computational cost. Thus, when compare to MTSD [26], WMTSD is the best choice.

Table 2. *mAP* for top 10 images retrieved by MTSD and WMTSD on Corel 1k, 5k, 10k and Caltech-101 datasets

Datasets	***mAP***	
	MTSD	**Proposed WMTSD**
Corel -1k	76.29	74.21
Corel- 5k	74.45	72.40
Corel -10k	70.19	70.11
Caltech-101	69.89	69.83

Table 3. Randomly selected class wise *mAP* for top 10 images retrieved by MTSD and WMTSD on Corel 1k, 5k, 10k and Caltech-101 datasets

Class	***mAP***	
	MTSD	**Proposed WMTSD**
Cat	82.34	82.30

Table 4. Time taken (seconds) by the MTSD and the proposed WMTSD

Methods	**Time taken for feature computation**
MTSD	39
Proposed WMTSD	15

Fig.4 illustrates the plot of precision versus recall for both MTSD and WMTSD for Corel 1k, 5k, 10k and Caltech-101 datasets. It is reveled from the graph that the proposed WMTSD consistently provides retrieval performance which is more similar to MTSD. The retrieval performance of both MTSD and WMTSD with respect to the size of the Corel1k, Corel5k, Corel 10k and Caltech-101 datasets is consistent. While the size of dataset rises, there is a fall in the *mAP* values for both MTSD and WMTSD and the fall is almost similar.

Time complexity of any CBIR system encompasses feature estimation, similarity measure between input and database image and sorting of N related retrieved images based on the result of similarity measure. In this work, we employed very simple bubble sort. We integrated the times for feature estimation, similarity measure and sorting and is referred as retrieval time and is illustrated in Table 4. It is revealed from Table 4 that the proposed WMTSD takes least time for feature extraction then the MTSD and is because of decomposition of images upto level-3 utilized Haar wavelet transform. Since, similarity measure and sorting approaches are same for proposed and existing CBIR systems, the time taken for both of them are same. For quantitative analysis, we illustrate the time analysis of both MTSD and WMTSD in graphical form and is exposed in Fig 5.

Some sample images taken from the benchmark datasets are depicted in Fig.6. An example input image and its top 5 retrieval results are depicted in Fig.7 which is common for the MTSD and the proposed WMTSD.

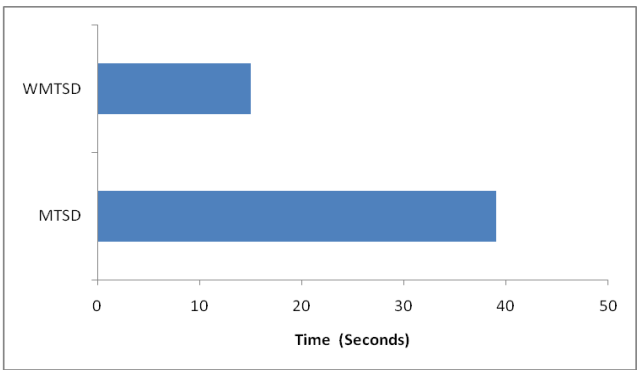

Fig.5. Time taken for MTSD and proposed WMTSD computation

VIII. CONCLUSION

The wavelet based multi-trend structure descriptor (WMTSD) is proposed in this work and is compared with multi-trend structure descriptor (MTSD). The WMTSD and MTSD provides almost similar retrieval results but the computational cost of WMTSD is too less. In the proposed work, to diminish the computational cost of MTSD, we decompose an image into level 3 utilizing discrete Haar wavelet transform, formed the multi-resolution pyramid image which in turn used to estimate the proposed WMTSD. Thus, the proposed WMTSD tradeoff between accuracy and time cost. In future, WMTSD representation may be combined with effective classifiers and implemented in the domain of medical to attain better results.

Abstract—An L-shaped double gate tunnel field effect transistor (DG L-TFET) results in better ON-current (I_{on}) due to its wider tunnelling area. Hetero dielectric Box (HDB) helps in suppressing current conduction in ambipolar region. Hetero-gate dielectric is included to improve I_{on}. To suppress ambipolar conduction further, dielectric pockets are introduced at both the drain ends. It suppresses ambipolarity by 1.5×10^8 times compared to structure without dielectric pockets. However, I_{on} remains same for both the structures. For boosting I_{on}, Germanium (Ge) source is included instead of Silicon as source. Use of Ge-source not only enhances I_{on} but also OFF-current (I_{OFF}). It enhances I_{on} by almost a decade.

Keywords—Tunnel Field Effect Transistor (TFET), L-shape, hetero-gate dielectric, hetero dielectric box (HDB), ambipolarity, dielectric pocket

I INTRODUCTION

Semiconductor devices follow Moore's law for low power applications. Devices having low power dissipation and high switching speed are in trend and demanded world widely. The regime of down scaling is difficult to carry out in devices below 32 nm as it would result in very high power consumption and large leakage currents. Tunnel Field Effect Transistor (TFET) is considered to be a potential solution in state of low power and high frequency applications. TFET is discernible from Metal Oxide Semiconductor-Field Effect Transistor (MOS-FET) as its current conduction depends on Band-to-Band Tunneling (BTBT). Owing to BTBT mechanism, TFET is highly unsusceptible to short channel effects (SCEs). TFET crosses the thermal limit of MOS-FET and results in steeper subthreshold swing (SS) of <60mV/decade. However, TFET has some setbacks in the form of low current conduction in ON-state and heavy current conduction in ambipolar region [1]. Many solutions were proposed for enhancing performance matrices of TFETs.

Ritesh et al. [2] boosted electric field at the tunnel junction by inserting a source-pocket offering higher I_{on} and steepness in SS. Saurabh et al. [3] suppressed ambipolarity by introducing a pocket at drain with high drain doping (as high as source doping). Raad et al. [4] designed and simulated dopingless TFET with a metallic layer in the oxide region at source-gate interface. This proposed solution is helpful in achieving reduced barrier width of the source-channel tunneling junction, enabling higher tunneling rate of charge carriers at this interface. Virani et al. [5] investigated that increase in the gate dielectric in dual-k spacer underlap structure degrades the performance of the device. Mallikarjunarao et al. [6] proposed a symmetric double gate n-type TFET with underlap single-k spacer structure to improve the device performance.

Abdi et al. [7] proposed gate-drain overlap structure of a TFET which exhibits suppressed conduction in ambipolar region. Sahay et al. [8] proposed a hetero dielectric box (HDB) instead of SiO_2 box above a highly doped substrate. It controls the tunnelling barrier width at the drain-channel interface and thereby suppresses ambipolar current. Upasana et al. [9] incorporated dielectric pockets at source-channel and/or drain-channel tunnelling junction for improving device performance.

Yang [10] designed a TFET with L-shaped gate. The proposed device increases the ON-current (I_{on}) by enhancing the electric field. Li et al. [11] introduced L-shaped TFET (L-TFET) with hetero-gate dielectric and lower drain doping (LDD) for improving I_{on} and suppressing ambipolar current. The L-shaped channel of L-TFET has larger tunnelling area than conventional Tunnel FET.

In our previous work, performance of L-shaped DG-TFET with HDB and hetero-gate dielectric was analyzed. It was observed that this structure had improved I_{on}, SS but not I_{ambi} [12]. Addition of dielectric pockets in DG-TFET reduces amount of carriers tunneling at drain-channel interface in negative gate bias or ambipolar state [9].

In this work, a novel L-shaped DG-TFET with dielectric pockets at drain end is proposed to improve performance metrics.

II DEVICE STRUCTURE AND SIMULATION SETUP

TCAD tool (Version J.2018) of Sentaurus is used to perform all the device simulations [13]. All regions (Source, drain, channel and substrate) are uniformly doped. Tunnelling width between source region and gate dielectric is 5nm.

The simulation results are obtained using phonon assisted tunnelling and nonlocal BTBT model. Phonon assisted tunnelling is used for indirect bandgap semiconductors like Silicon (Si) and Germanium (Ge). Enormal model with default parameters is added because of high-k dielectrics. Philips unified Mobility (PhuMob) model is

incorporated. For heavily doped source and drain regions, OldSlotboom is added as Band gap narrowing (BGN) model. Use of WKB (Wentze Kramer Brillouin) method is done for calculating tunnelling probability and their numerical solution. Auger and Shockley-Read-Hall (SRH) are incorporated as recombination models [13].

Table 1: Design parameters of L-TFET

Parameters	Value
Drain doping [cm^{-3}] [n-type]	5×10^{18}
Source doping [cm^{-3}] [p-type]	1×10^{20}
Drain length [L_d] [nm]	40
Drain height [H_d] [nm]	16
Substrate doping [cm^{-3}] [p-type]	1×10^{18}
Source length [L_s] [nm]	33
Gate length [L_g] and height [H_g] [nm]	30
Channel doping [cm^{-3}] [n-type]	1×10^{17}
Gate oxide thickness [nm] [t_{ox}]	2
Gate metal work function [eV]	4.2
Gate oxide permittivity [HfO_2]	15
Gate oxide permittivity [SiO_2]	3.9
Height of HDB [nm]	25
Source height [L_s] [nm]	24
Length of DP [nm]	2

III RESULTS AND DISCUSSIONS

L-TFET has high I_{on} and steep subthreshold swing (SS) due to vast tunnelling area at source-channel junction. However, it exhibits heavy current flow in ambipolar region which draws attention and needs to be optimized. At gate, hetero dielectric is added to boost the device characteristics. Addition of high-k gate dielectric at source is to amplify I_{on} and low-k gate dielectric at drain end to reduce ambipolarity [12].

Hetero dielectric box reduces the current flow in ambipolar state. An HDB consists of HfO_2 under drain and SiO_2 under channel and source regions. It suppresses ambipolar current (I_{ambi}) to certain extent [8]. For further suppression, dielectric pockets (DP) are introduced at drain ends. Dielectric Pocket based L-TFETs are highly advantageous and efficient with the use of high-k gate dielectric material [9]. DP increases the tunnel barrier width at drain-channel interface in ambipolar state. I_{ambi} depends on the barrier width at drain-channel junction.

It is observed that the use of high-k gate dielectric increases the device leakage and ambipolar current [9]. The usage of DP results in negligible tunneling at drain-channel junction. It turns off DP Si L-TFET during ambipolar state or negative gate bias. Fig. 1 (a)-(b) shows the device structure of conventional Si L-TFET and DP Si L-TFET.

For this device, I_{on} is calculated at gate voltage (V_{gs}) =1V and drain voltage (V_{ds}) =1V. OFF-current (I_{OFF}) is the amount of current at V_{ds} =1V and V_{gs}=0V. I_{ambi} is observed at V_{gs}= −1V and V_{ds} =1V.

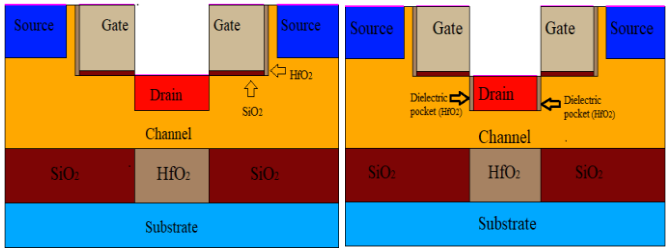

Fig.1. Schematic of (a) Conventional Si L-TFET (b) DP Si L-TFET

Calculation of threshold voltage (V_{th}) is done by constant current (CC) method assuming reference current to be 10^{-7} A/µm [14]. Average SS is the amount of V_{gs} applied to alter drain current (I_D) by a decade.

$$SS = \frac{V_{th} - V_{off}}{Log(I_{vth}) - Log(I_{Voff})} \quad (1)$$

V_{off} is the amount of applied V_{gs} at which I_D begins to take off, I_{Vth} is the I_D at $V_{gs} = V_{th}$ and I_{Voff} is the I_D when $V_{gs} = V_{off}$ [14].

The energy band diagram for conventional Si L-TFET and DP Si L-TFET in ambipolar state are shown in Fig. 2. The reduction in I_{ambi} for DP Si L-TFET is the result of increased barrier width at drain-channel junction. In ambipolar state, tunneling width for DP Si L-TFET is higher than conventional Si L-TFET structure.

Fig. 3 depicts the transfer characteristics for Conventional Si L-TFET and DP Si L-TFET. Characteristic curve plotted between I_D and V_{ds} is shown in Fig. 4.

The ON-state characteristic of DP Si L-TFET is very similar to Si L-TFET but the former has reduced I_{ambi} by a large amount. According to Fig.3, application of dielectric pockets at both drain ends in an L-TFET does not alter drive current and results in I_{on} of 6×10^{-6} A/µm. The ON-current for both L-TFETs is equal due to nearly equal amount of carrier generation rate. Ambipolar current in DP Si L-TFET is suppressed by 1.5×10^{8} compared to conventional structure. I_{OFF} and SS for Conventional Si L-TFET are 8.47×10^{-17} A/µm and 49.83 respectively whereas I_{OFF} and SS for DP Si L-TFET are 1.03×10^{-16}A/µm and 46.7 respectively.

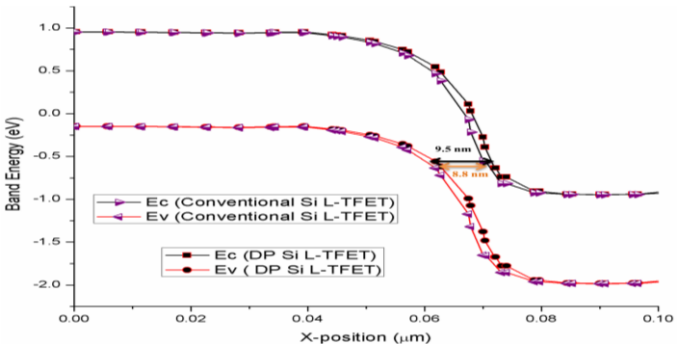

Fig.2. Conduction band (E_c) and valence band (E_v) diagrams for Conventional Si L-TFET and DP Si L-TFET in ambipolar state

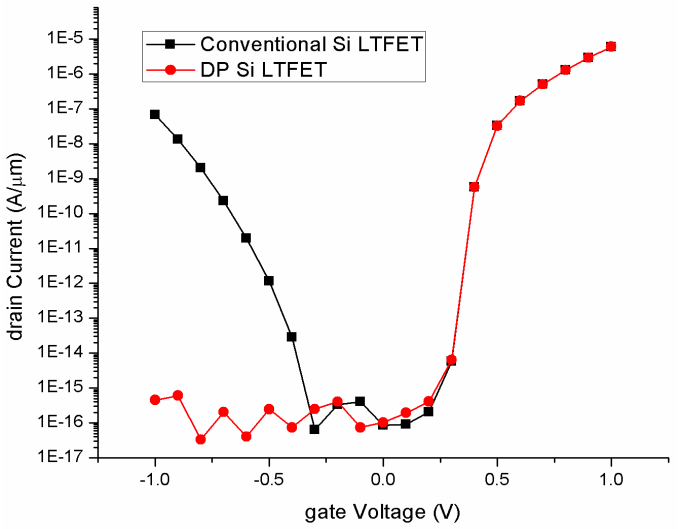

Fig.3. Plot between drain current and gate voltage (-1V≤V_{gs}≤1V) for Conventional Si L-TFET and DP Si L-TFET

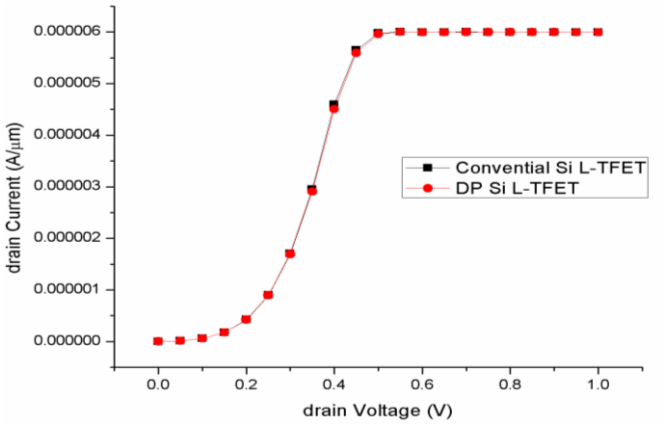

Fig.4. Plot between drain current and drain voltage (0V≤ V_{ds} ≤1V) for Conventional Si L-TFET and DP Si L-TFET

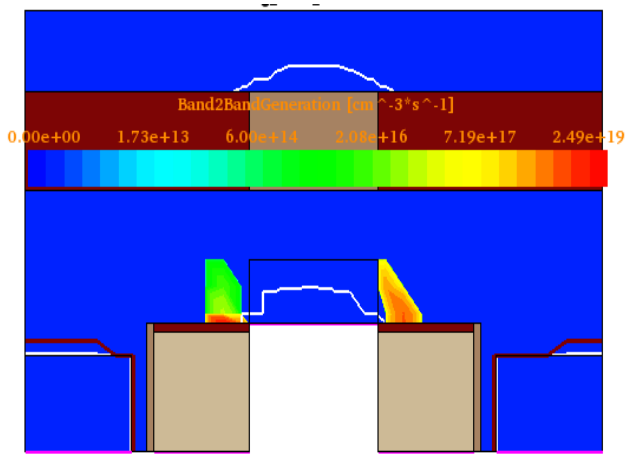

Fig.5. Band-to-band generation diagram for Conventional Si L-TFET in ambipolar state

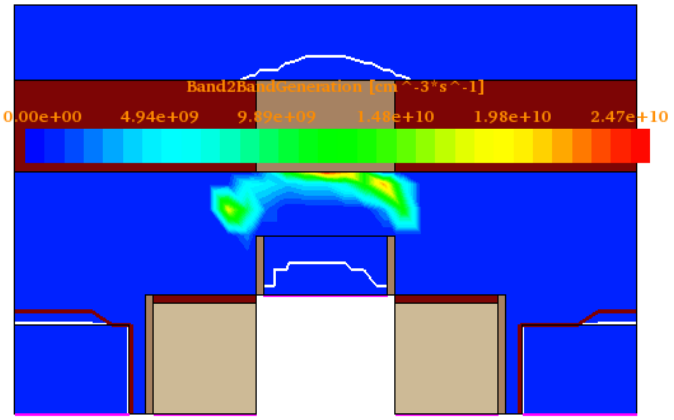

Fig.6. Band-to-band generation diagram for DP Si L-TFET in ambipolar state

Figs. 5-6 illustrate band-to-band (B2B) generation rate in ambipolar state for Conventional Si L-TFET and DP Si L-TFET. The B2B generation depicted is due to tunneling of carriers at drain-channel interface. The B2B generation is suppressed by almost 10^9 times in DP Si L-TFET resulting in reduction of I_{ambi}.

A. *BOOSTING Ion*

Current conduction in ambipolar state has been a serious concern in case of L-TFETs. DP Si L-TFETs show better characteristics in context of I_{ambi} compared to conventional L-TFETs. However, I_{on} in DP Si L-shaped TFET can be improved. Instead of Si as source material, usage of Ge-source helps in boosting I_{on} [15]. Use of low bandgap material like Ge, the tunnelling probability of carriers and I_{on} of the device are increased. However, Ge-source increases I_{on} as well as I_{OFF} as per Table. 2. Fig. 7 illustrates the DP Ge-source Si L-TFET structure.

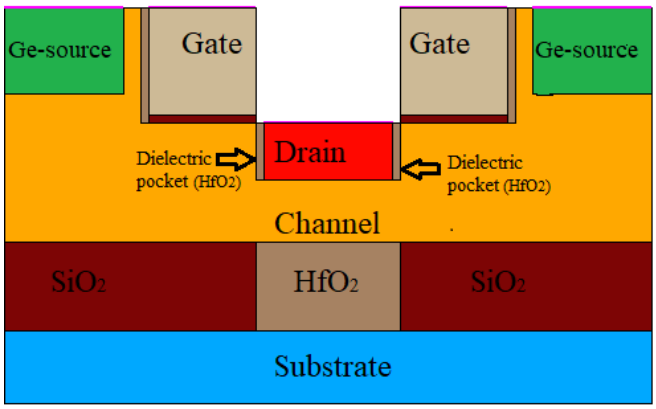

Fig.7. Schematic of DP Ge-source Si L-TFET

Owing to Ge-source, the tunneling width at source-channel interface is decreased resulting in higher I_{on} in ON-sate. ON-current in DP Ge-source Si L-TFET is incremented by a decade compared to DP Si L-TFET.

Table.2. Performance comparison between DP Si L-TFET and DP Ge-source Si L-TFET

Parameters	DP Si L-TFET	DP Ge-source Si L-TFET
I_{on} (A/μm)	6×10^{-6}	5.755×10^{-5}
I_{OFF} (A/μm)	1.027×10^{-16}	1.074×10^{-15}
I_{ambi}(A/μm)	4.52×10^{-16}	6.60×10^{-16}
V_{th} (V)	0.55	0.318
SS (mV/decade)	46.7	39

Band diagrams for DP Si L-TFET and DP Ge-source Si L-TFET in ON-state is shown in Fig.8. Ge deployed as source lowers energy bands at source region. The transfer characteristic for DP Si L-TFET and DP Ge-source Si L-TFET is depicted in Fig.9.

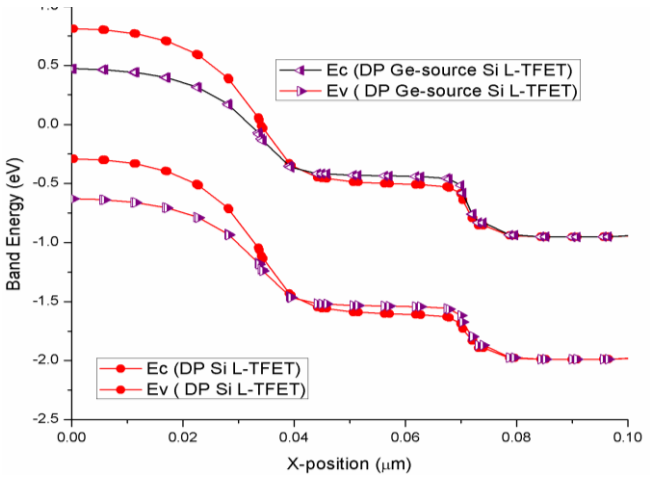

Fig.8. Conduction band (E_c) and valence band (E_v) energy diagrams for DP Si L-TFET and DP Ge-source Si L-TFET in ON-state

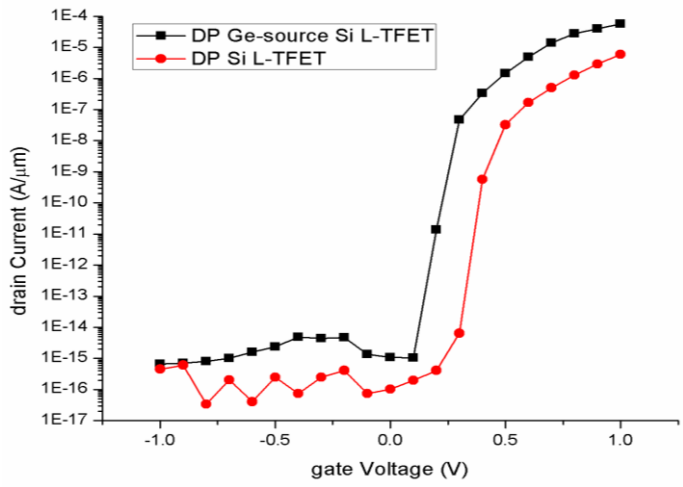

Fig.9. Plot between drain current and gate voltage (-1V ≤ V_{gs}≤ 1V) for DP Si L-TFET and DP Ge-source Si L-TFET

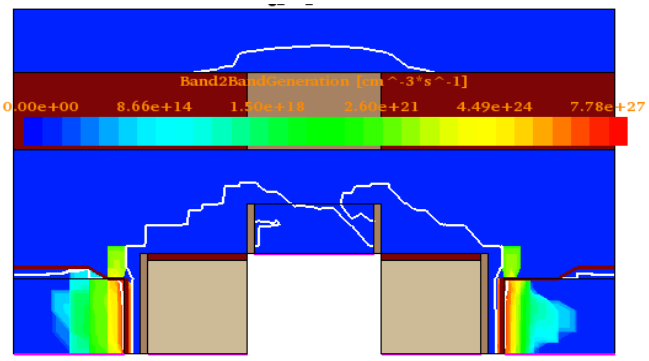

Fig.10. B2B Generation diagram for DP Si L-TFET in ON-state

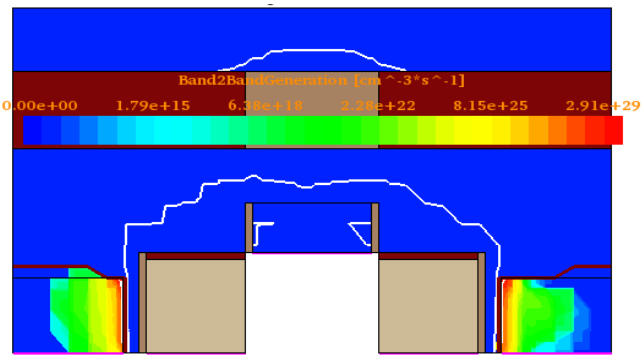

Fig.11. B2B Generation diagram for DP Ge-source Si L-TFET in ON-state

Figs. 10-11 illustrates B2B generation rate in ON-state for DP Si L-TFET and DP Ge-source Si L-TFET. The B2B generation depicted is due to tunneling of carriers at source-channel interface. The carrier generation rate is increased by 37.4 times and thus increasing I_{on}.

IV CONCLUSION

Simulation study shows that dielectric pocket Si L-shaped TFET has enhanced characteristics in context of ON-current, OFF-current, SS and ambipolar current. Dielectric pockets applied at both the drain ends help in improving ambipolar characteristics. In ambipolar-state, the carrier generation rate for dielectric pocket Si L-shaped TFET is suppressed by 10^9 times as compared to conventional Si L-shaped TFET. For boosting I_{on}, Si source is replaced by Ge. In ON-state, rate of generation of carriers for Ge-source L-TFET is improved. It enhances ON-current as well as OFF-current.

***Abstract*— The term cognition is defined as how person understand the world, how person respond, how person react to particular situation. The basic definition of Cognitive Impairment is that person may not able to think properly, has some communication and language problem. There are lots of causes for having Cognitive Impairment such as infection, vitamin deficiency, dehydration, brain injury and many more. It is necessary to identify cognitive ability of person so that further treatment can be done on person for their better health. There are many ways to identify Cognitive ability. In this paper Electroencephalogram(EEG) signal and Screening test named as Mini Mental State Examination(MMSE) are used for knowing cognitive ability of person. Lot of previous work done on detecting Cognitive Impairment. In previous work they have used traditional Electrode system for capturing EEG of brain. In this non-invasive and portable device known as Emotiv Insight is used to capture brain activity. Real time data from different person of different age groups is collected by using combination of EEG signal and MMSE. Once Data is collected it has to go through different steps for knowing cognitive ability. Different techniques such as pre-processing, feature extraction, feature selection, classification which includes algorithm such as Linear Regression, Decision Tree, Support Vector Machine are applied on data.**

Keywords—Cognition; Cognitive Impairment; Mild Cognitive Impairment; Electroencephalogram; Mini Mental State Examination.

I INTRODUCTION

The term cognition is defined as something that is relating to different intellectual activities such thinking, logical reasoning, remembering things. Cognitive ability is known as person's ability of thinking i.e. how person think or even respond to some situation. In figure1[13] it shows how psychology of cognitive covers different areas such as language, thinking and problem solving, memory, attention. Perception, human Intelligence Cognitive Impairment in simple term defined as memory problem i.e. person with cognitive impairment may not able to perform their daily tasks, lack of communication problem, poor judgment, may not able to think properly as compared to normal healthy person. So there are different causes for this cognitive impairment such as brain injury, stroke, infections and many more.

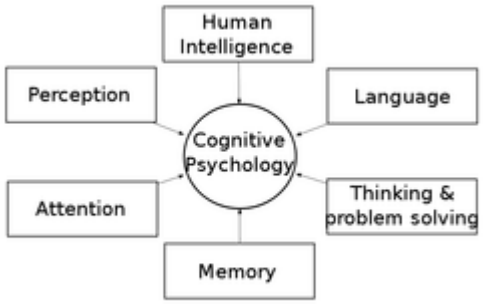

Fig. 1. Cognitive Level Of analysis

There are different stages of this cognitive impairment such as Mild, Severe and Medium. The person with mild cognitive impairment may begin with certain changes but they able to perform their daily tasks. The person having severe type of cognitive impairment include that they lose ability to talk, they can't go outside individually, understanding problem, lose the importance of something. Some of the major key facts regarding cognitive impairment are memory loss, frequently asking same questions, behaviour changes, mood

swings, difficulty in carrying out tasks, vision problem, not recognizing family members, friends, neighbours, problem in planning, taking decision.

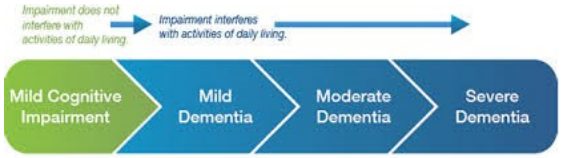

Fig. 2. MCI stages

Severe cause of Cognitive Impairment may lead to more higher type of disease such as Alzheimer's Disease(AD), Vascular Dementia(VD), Parkinson's dementia. The above figure 2[14] shows how mild cognitive impairment leads to different stages of dementia i.e. mild dementia, moderate dementia and severe dementia. Dementia is such kind of disease in which person loses memory. Such kind of disease mostly occurs at late ages i.e. may be at 60's. There are many symptoms of dementia which includes memory problem, communication and language problem i.e. problem while talking, not easily able to communicate with other person, have less ability in focus and attention, poor judgmental , short term memory, problem in performing daily activities like eating, dressing.

In hospital domain for identification of cognitive impairment lots of techniques carried out such as MRI, EEG, different blood tests. These several tests require large of amount of time and efforts. So there is need for such tools which ease in process of detection of cognitive ability. EEG and Screening Test are used for detection of cognitive ability. EEG (Electroencephalography) is used in capturing brain activity i.e. it helps in knowing functionality of brain. Screening test includes Mini Mental State Examination which helps in knowing cognitive ability of person. This test covers different areas of cognition such as language, attention and calculation, recall, orientation, memory, registration. It contains different questions which cover all above areas of cognition. It has total score of 30. Using combination of these two factors helps in giving good result for knowing cognitive ability of person.

II LITERATURE REVIEW

This section describes the previous work that has be done for detection of Cognitive Impairment of person using traditional method of collecting EEG signal of person and using device Emotiv Insight which is new and non-invasive technique to collect EEG signal of person.

In this paper[1] EEG signals and Screening test known as Montreal Cognitive Assessment(MOCA) were used in detection of Mild Cognitive Impairment(MCI). Different steps such as feature extraction, feature selection, classification and finally evaluation are used for detection of MCI. In classification different algorithms such as Support Vector Machine(SVM), Logistic Regression(LR) , Random Forest(RF) was used. At the end as a result it was proved that time frequency features are best among all other features. Classification accuracy got here was 87.9%.

In this paper[2] how EEG is used in detection of disease known as dementia is explained. EEG signal processing contains different steps such as pre-processing, features extraction, classification. Independent Component Analysis(ICA), Wavelet Transform(WT) methods was used for EEG signal processing. For classification different algorithms are used among which Support Vector Machine gives good result at detection of disease. So finally EEG is considered great biomarker for detection and classification of disease.

In this paper[3] EEG is used for detection of Alzheimer Disease(AD). Processing of EEG signal is explained in detail. EEG methodology includes Pre-processing, Feature extraction, feature selection, classification and finally Diagnosis. In classification, algorithms such as Linear Discriminant Analysis (LDA), Support Vector Machine (SVM) are used. Accuracy got with different algorithms in detection of Alzheimer Disease is compared with each other. Finally in conclusion EEG is found to be good technique in detection of Alzheimer Disease.

This paper[4] gives description about different frequencies of EEG signal which are helps in diagnosis of dementia. Different frequencies such as Dominant frequency, dominant frequency variability and dominant frequency prevalence was are used for detection and their corresponding performance is compared. The main goal is to distinguish MCI from healthy control. Finally conclusion is that EEG helps in finding dementia disease at early stage.

In this paper[5] screening test known as Mini Mental State Examination is used for

detection of Mild cognitive impairment. This MMSE test is used for knowing cognitive function which covers different areas such orientation, registration, attention and calculation, recall and language. Total MMSE score is 30. Individual score is given to each area. So as a result MMSE is good at detection of MCI and its different subtypes.

In [6][13] EEG is used in detection of dementia stage known as Mild Cognitive Impairment(MCI). Different spectral features are used and extracted for further processing. For classification k-nearest neighbour(KNN) is used. As a result it is found that EEG is great tool for detecting MCI stage.

In this paper[7] EEG signals are used in detecting Alzheimer disease(AD). EEG is great at early detection of disease. Relative Power(RP) feature of EEG signal is used in classifying healthy controls from MCI. For classification Deep Neural Network(DNN), Neural Network(NN) are used for early detection of disease. Accuracy got with these algorithm is compared for analysis purpose. Deep Neural Network(DNN) gives good result as compare to Neural Network(NN) for detection of Alzheimer Disease(AD).

In [8][12] EEG signals are used for detection of stroke related Mild Cognitive Impairment(MCI). Capturing of EEG signal is done when person performing some tasks. Wavelet Transform(WT) method is used for pre-processing of data i.e. removal of artifacts, noise. Approximation Entropy(ApEn) and permutation entropy(PerEn) features are used for detection. These feature shows less irregularity in EEG signal of MCI people as compare to normal healthy people. So in conclusion EEG is considered great technique at diagnosing MCI.

This paper[9] EEG is used for early detection of Alzheimer's Disease(AD). EEG is good at distinguishing AD from healthy control. In this EEG of Subjective Cognitive Impairment(SCI) patients, Mild Cognitive Impairment(MCI), Alzheimer's Disease(AD), and healthy control is captured. Features such as epoch based entropy and bump modelling are used for classification purpose. 91.6% accuracy is obtained while distinguishing SCI from AD patients. Sensitivity is 87.8% and specificity is 100%.

This paper[10] Mini Mental State Examination is used for knowing cognitive function. This test is very easy and takes only 5-10 minutes to complete. It covers all different areas of brain functioning. Standrad score of MMSE is 30. At conclusion it is said that MMSE is one of the great test at finding cognitive function.

In this paper[16] different EEG headset such as Emotiv Epoc, Emotiv Insight, InteraXon Muse and Imec EEG headset are explained. These device helps in knowing cognitive ability. Emotiv Insight device is used for capturing EEG of brain. Emotiv Insight helps in detecting stress or stress level of person as it helps in knowing brain functionality.

III METHODOLOGY

Use of EEG signal for detection of cognitive ability is considered one of the great technique to capture brain activity. In hospital region EEG is captured using electrodes which are placed on human brain with position specified by standard 10-20 International electrode position system. The basic flow for identification of cognitive ability contains different steps such as pre-processing, feature extraction, feature selection, classification and finally evaluation i.e. result of detection of cognitive ability. In this paper Emotiv Insight device is used to capture EEG of person of different age groups as EEG is one of the good factor for identifying cognitive impaired person. Emotiv Insight is non-invasive and portable device i.e. person need not go to hospital for recoding of EEG signal. Emotive device here used has 5 channels for capturing brain activity. When this device is connected on person head MMSE questions are asked. MMSE is used so that it covers functioning of all brain areas. Emotive pro software is used to capture this signal. Data is collecting from different people of different age groups using above two factors i.e. EEG and MMSE. After collection of data pre-processing need to perform as while capturing these signals person may perform some irrelevant movement such as eye moment or muscle moment so value may differ than original value while capturing these signal so pre-processing removes all this. After this, feature extraction is performed and then classification is performed which includes algorithms such Linear Regression(LR), Support Vector Machine(SVM), Decision Tree(DT), Naïve Bayes, K-nearest neighbour(KNN). Model is trained with these algorithms. These algorithms give different accuracy. Among this Decision Tree gives good result at detecting cognitive ability as compare to other algorithms.

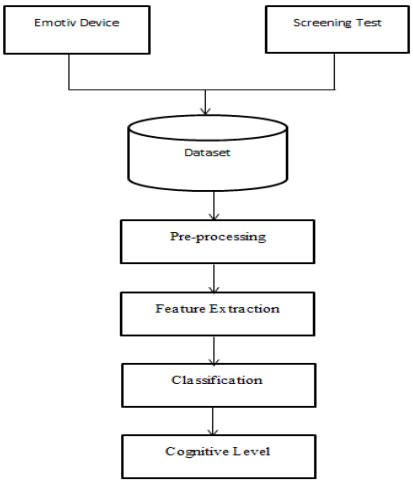

Fig. 3. System Architecture

Emotiv Device:

Fig. 4. Emotiv Insight Headset

The above figure [15] is an image of Emotiv Insight device. Emotiv Incorporation is one of the technical company which contribute in developing manufacturing wearable electroencephalography(EEG) products including other software, developing few mobile application regarding their software and some data products. Emotive Design of Emotive can be used for various purpose such as for brain-computer interface, and for research purpose also. EMOTIV device is available with different number of channel i.e. it is available with 5-channel and with 14-channel also. Emotiv basically used for producing clean, strong, robust signal of human brain irrespective of time and location of person i.e. location doesn't matter for producing signal of person brain. Emotiv is very user friendly device and its setup require hardly 2-3 minutes. Also it is wireless device and can be connected to computer. Its main goal is to produce EEG signal of human brain so that it helps in understanding brain activity of person while thinking or performing some tasks and finally it convert that EEG data into meaningful data that can be easily understood by user.

1. Pre-processing:

This is initial stage after collection of data from different people of different age groups. Pre-processing must be performed in order to remove irrelevant data. When data recording is performed there may be noise or person may perform some irrelevant tasks such as opening, closing eyes, muscle movement. So all this noisy data must be remove from original data in order to process further. For feature extraction phase data must be noise free which helps in giving good result. Method such as Independent Component Analysis(ICA) is used for pre-processing for removal of noise and artifacts.

2. Feature Extraction:

This is feature extraction phase where some of the features are extracted which are helpful in giving good result. EEG signal contains frequencies such as alpha, beta, gamma, theta and delta. When EEG test is performed on person as output of EEG signal these different waves are generated. These frequency have certain ranges. These all frequencies plays important role in detecting cognitive ability of person. So these features are extracted from original data. Techniques such as Fast Fourier Transform(FFT), is used for feature extraction.

3. Feature Selection:

This is third step of data processing. In this only some features are selected which contribute in giving cognitive ability of person. So these selected features are given to classification for further processing.

4. Classification:

This is the phase where actual model is going to build for detection by various algorithms. Features selected in earlier phase are going to use for applying algorithms. In this step algorithms such as Support Vector Machine(SVM), Linear Regression(LR), Decision Tree(DT), Naïve Bayes, K-nearest neighbour(KNN) are used in detection of cognitive ability of person.

5. Evaluation:

This is the final step where finally cognitive ability of person is detected. Accuracy obtained by various algorithms in earlier stage are going to compare for analysis purpose.

Decision Tree gives accuracy up to 90%.
Naïve Bayes gives accuracy up to 75%.
K-nearest neighbour gives accuracy up to 80%.

IV Result and Discussion

On real time dataset that I collected from different people of different age groups I applied some pre-processing techniques in order to remove noise, artifacts or any movements done by person while recording EEG of person. Pre-processing such as removal of blank fields, missing entry in some columns of CSV file i.e. data of people are removed.

Once pre-processing is done feature extraction is performed. Features such as Alpha, Theta are selected for further processing. After this Decision Tree, K-nearest neighbour, Support Vector Machine are applied on these features. Decision Tree gives highest accuracy of up to 90% among all algorithm.

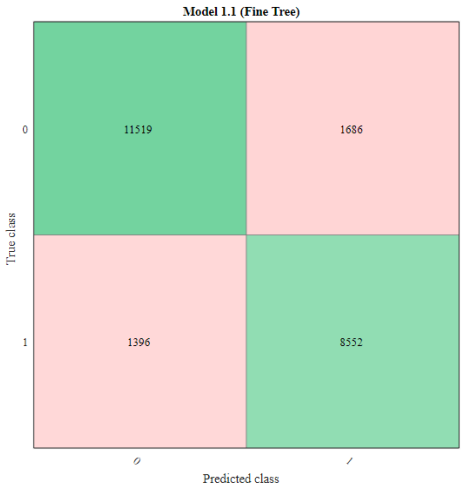

Fig. 5. Confusion Matrix For Fine Tree Algorithm

Above Figure 5 shows confusion matrix for Fine Tree Algorithm. It shows matrix of True class and Predicted class. Region in green colour should show highest value i.e. diagonal elements of matrix should contain highest value among all other values of matrix. Region in green colour shows True positive value and region in pink colour shows false negative value. True positive class contains value in which actual values and predicted values are matched. False negative class contains value in which actual values and predicted values are not matched.

Below figure 6 shows ROC curve for fine tree. ROC(Receiver Operating Characteristics) curve is a graphical plot which is used for checking performance of binary classification models. This curve plots two parameters such as true positive rate false positive rate. ROC represent probability curve.

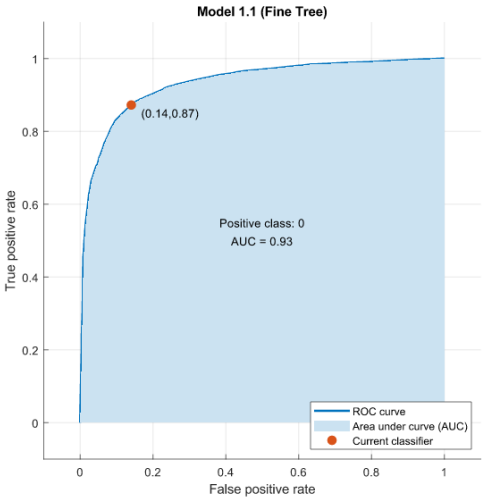

Fig. 6. ROC curve for Fine Tree

V Conclusion and Future Scope:

EEG with combination of Screening test can be consider as valid and very useful tool in finding Cognitive Ability. Use of Emotiv Insight device for capturing EEG signal helps in giving good result. Real time data from people of different age groups is collected. Data collection is done by using combination of EEG signal and MMSE test. Various abnormalities are found in data collected that are removed by pre-processing. Various feature extraction methods, classifiers helped in detection of cognitive ability. EEG and MMSE helps in identifying cognitive ability of person so that it helps in further better treatment if there any serious cause. Use of Decision Tree for classification gives accuracy up to 90%. Use of Naïve Bayes classifier gives accuracy of 75%. In this paper emotiv insight device used to capture brain activity has only 5 channels so if in future if we use 14-channel emotiv device then it may help in increasing accuracy of model as it covers more region of brain which helps in collecting very good brain activity and will give better result as compare to present result.

Impact of Imperfect Channel State Information on Downlink Sum-Rate of Two user mmWave Non Orthogonal Multiple Access

Sumathi S., Arpita Thakre
Department of Electronics and Communication Engineering
Amrita School of Engineering, Bengaluru
Amrita Vishwa Vidyapeetham, India
ssumathi_me@yahoo.co.in, arpita.thakre@ieee.org

***Abstract*—Effect of imperfect channel state information on achievable data rates of a two user downlink non orthogonal multiple access scenario is considered in this paper. The optimum antenna array weight that steers the downlink beams towards the two users has been reported earlier based upon perfect knowledge of downlink channels at the base station. This antenna weight vector is no longer optimum as soon as the channel state information available with the base station becomes outdated. The effect of wrong angle of departure information and/or wrong channel gain information reduces the advantage of above access scheme over orthogonal multiple access scheme. How reduction in achievable data rate in a non orthogonal case depends on different transceiver parameters, such as the error in angle information, the absolute value of the angle of departure, number of antenna elements at the base station is shown in this paper.**

***Index Terms*—Non Orthogonal Multiple Access, Millimeter Wave communication, Beamforming, Imperfect CSI.**

I. Introduction

Next Generation Mobile broadband network is expected to support data rate of the order of Gigabits per second. An efficient radio access technology integrated with greater spectrum availability is vital to attain the above goal [1]. Huge bandwidth available in the wave band (20 GHz to 100 GHz) prompted engineers to look into transceiver techniques suitable for use in the this band [2].

Non Orthogonal Multiple Access (NOMA) is one of the key enablers that addresses the immense data rate requirement. Existing wireless communication standard employs orthogonal access techniques in which different users are assigned orthogonal resources such as time and/or frequency to minimize inter user interference [3]. Power domain NOMA uses same radio resource for more than one user but modulates individual user's data with different power levels.Power domain NOMA employs Superposition Coding (SC) allocates different powers to the two downlink users wherein the power distribution between the two users depends on the channel gains seen by the two users. The underlying assumption is that the two users see significantly different channel gains. The user which sees a weaker channel treats the other user's data as noise and decodes his data. The user which sees a stronger channel needs to perform Successive Interference Cancellation (SIC) to recover the data meant for him [4]. In a multiple antenna wireless communication scenario, number of radio frequency (RF) chains decides the number of users to be supported simultaneously. In fact number of users that can be supported by one time or frequency or code unit per RF chain is one. Increase in number of RF chains increases the hardware cost [5]- [8]. In such a case, NOMA can be used to effectively increase the number of users served in one resource block to two or more.

Beamforming is used in mmwave MIMO communication systems to generate highly directional beams to compensate for the losses incurred in mmwave band of frequencies.Various beamforming techniques in Rayleigh fading environment are discussed in [9]. The authors of [10] have considered a random beamforming approach to maximize the achievable sum rate of two downlink NOMA users. The users experience different channel gains but are at same azimuth angle or angle of departure (AoD) with respect to antenna array in [10]. Beam Sweeping is an approach where the base station radiates multiple beams in different directions assuming an uniform distribution for AoD. The handset reports the index of beam with highest received power to the base station. The number of beams used by the base station, i.e, the codebook size, depends on available number of antenna elements [11]. Given that codebook size cannot be chosen to be very large in a practical case, and the feedback link between the handset and base station introduces delay as well as error, we will not have perfect channel knowledge at the transmitter. No doubt, the deviation from correct value also depends on the speed at which the handset is moving and the channel propagation characteristics.

We consider a downlink NOMA scenarion in mmwave channel with two users where the base station has one RF chain and multiple antenna elements connected to the ouput of the RF chain via different weights. There are two users at different distances as well as at different azimuth angles with respect to the antenna array at the base station. The aim is to design the Antenna Weight Vector (AWV) as well as power allocated to the two users' data such that achievable sum data rate gets maximized. Xiao et. al in [12] have considered the above scenario but assumed that base station has perfect channel knowledge. We study the above downlink NOMA scenario where the base station does not have perfect CSI.

In this paper we show how an error, whether an error in azimuth angle information or an error in channel gain information causes a decrease in the achievable data rates for the two users. The reduction in achievable data rates is shown to depend on number of antenna elements, error in angle information, and the absolute value of AoD as well. Section II describes the system model. Simulation results are available in section III and we conclude the paper in section IV. Bold lower case letters denote vectors, $(.)^H$ denotes Hermitian operation, $(.)^T$ denotes Transpose, $|.|$ is for absolute operation, and $(.)^*$ is used for conjugation.

II. System Model

We consider downlink mmWave NOMA for two users with *multi-beamforming* which means that base station can form multiple narrow beams with different beam gains where the beams are steered towards multiple users that are spatially located at different azimuth angles. The transceiver at the base station is assumed to have one Radio Frequency chain whose output is connected to a Uniform Linear Array (ULA) of N antenna elements via N phase shifters and N Power Amplifiers (PA). The antenna elements are assumed to be $\lambda/2$ apart from each other where λ is carrier wavelength. Proper choice of the N phase shifts or AWV, **w**, will give rise to beams in the intended directions. All the power amplifiers are assumed to have same scaling factor. Throughout the paper it is assumed that the base station forms two narrow beams with different beam gains to serve two NOMA users as shown in Fig. 1.

The underlying assumption in NOMA is that the channel gains experienced by the two downlink users are significantly different. The base station uses superposition coding to send data to the two NOMA user equipment where relatively more power is assigned to the data that will pass through the weaker channel. The sum-rate achieved by the two user downlink system depends on the power allocated to the two bit streams. The authors in [12] came up with an AWV that would maximize the downlink sum-rate with the constraints that the AWV, **w** is constant modulus and the data rate

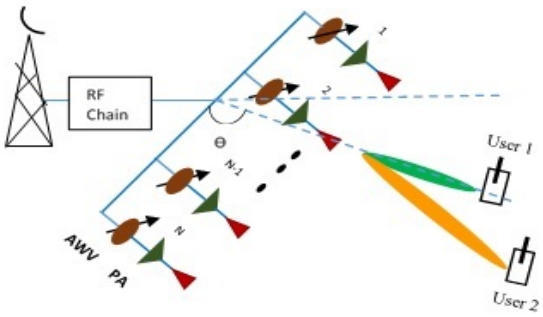

Fig. 1: Block Diagram of a two-user NOMA system with downlink beam-forming

achieved at the individual links is above a threshold value. The AWV calculation assumes that the base station knows the channel gains and the azimuth angles at which the two users are located accurately. The base station is assumed to steer the downlink beams towards the strongest multipath components of the respective users.

In a practical deployment scenario, the base station cannot have correct knowledge of channel gains and the azimuth angles of the users as explained in Introduction section. The present work aims at studying the effect of imperfect CSI on downlink user data rates. The mmWave channel between the base station and i-th user corresponding to the strongest multipath component is given by

$$\mathbf{h}_i = \lambda_i \mathbf{a}_i(N, \theta_i) \quad i = 1, 2. \tag{1}$$

where λ_i is the complex gain of the strongest multipath between base station and i-th user equipment, $\mathbf{a}_i(.)$ is antenna array response vector at the base station, and $\theta_i \in [0, \pi]$ is the azimuth angle of departure (AoD) of the strongest multipath component between base station and i-th user equipment. The antenna array response vector is given by

$$\mathbf{a}_i(N, \theta_i) = [1 \quad e^{j\pi\Omega_i} \quad e^{j\pi 2\Omega_i} \quad \ldots\ldots\ldots \quad e^{j\pi(N-1)\Omega_i}]^T \tag{2}$$

where $\Omega_i = cos(\theta_i)$.

λ_i is assumed to be Gaussian distributed and $\Omega_i \in [1, -1]$ as θ_i is uniformly distributed $\in [0, \pi]$. Throughout the paper it is assumed, without loss of generality, that $|\lambda_1| \geq |\lambda_2|$, which means that channel gain of user 1 is better than that of user 2. In mmWave frequency range of operation, the strongest multipath component is typically almost 20 dB stronger than the other multipath components. Therefore we stick to a single path model for the channel through out the paper.

Assuming s_i is the symbol meant for user i, and p_i is

the power assigned to user i, the baseband equivalent signal transmitted by the base station is given by

$$s = \sqrt{p_1}s_1 + \sqrt{p_2}s_2 \tag{3}$$

The baseband equations for the signals received by the users are respectively given by

$$\begin{aligned} y_1 &= \mathbf{h}_1^H \mathbf{w}(\sqrt{p_1}s_1 + \sqrt{p_2}s_2) + n_1 \\ y_2 &= \mathbf{h}_2^H \mathbf{w}(\sqrt{p_1}s_1 + \sqrt{p_2}s_2) + n_2 \end{aligned} \tag{4}$$

where $\mathbb{E}\{|s_i|^2\}$ = 1, n_1 and n_2 are additive noise with variance σ^2, $P = p_1 + p_2$ is the total transmit power, and P/σ^2 is the transmit Signal to Noise Ratio (tSNR). Noise is white and Gaussian distributed. The AWV, $\mathbf{w}$ should satisfy $|\mathbf{w}_k| = \frac{1}{\sqrt{N}}$ for $k = 1, 2, ..., N$.
With no loss of generality, we also assume that $|\mathbf{h}_1^H \mathbf{w}|^2 \geq |\mathbf{h}_2^H \mathbf{w}|^2$. This implies that user 1 decodes s_2 first, subtracts the signal component of s_2 from the received signal y_1 and then decodes s_1. The achievable rates of user i, for $i = 1, 2$, denoted by R_i, under the above assumption are given by

$$\begin{aligned} R_1 &= log_2\Big(1 + \frac{|\mathbf{h}_1^H \mathbf{w}|^2 p_1}{\sigma^2}\Big) \\ R_2 &= log_2\Big(1 + \frac{|\mathbf{h}_2^H \mathbf{w}|^2 p_2}{|\mathbf{h}_2^H \mathbf{w}|^2 p_1 + \sigma^2}\Big) \end{aligned} \tag{5}$$

The problem is to determine the vector $\mathbf{w}$ that makes the achievable sum rate of the two users maximum assuming that the downlink channels are known to the transmitter a priori. The constraints are that all the entries of AWV has to have same modulus and the individual data rates R_1 and R_2 should be above a predefined minimum value, say r.

$$\begin{aligned} \max_{p_1, p_2, \mathbf{w}} \ & (R_1 + R_2) \\ \text{subject to} \ & R_1, R_2 \geq r \\ & (p_1 + p_2) = P \\ |\mathbf{w}_k| = \frac{1}{\sqrt{N}}, \quad & k = 1, 2, ..., N \\ & |\mathbf{h}_1^H \mathbf{w}|^2 \geq |\mathbf{h}_2^H \mathbf{w}|^2 \end{aligned} \tag{6}$$

As described in [12] the solution to the above problem is found in three steps. In first step, the constant and equal modulus constraint on the vector $\mathbf{w}$ is relaxed. Powers p_1 and p_2 and beam gains $|\mathbf{h}_1^H \mathbf{w}|^2$ and $|\mathbf{h}_2^H \mathbf{w}|^2$ are determined that maximize the sum rate of two users while satisfying the total power avaialable and the minimum data rate requirement at the two users. In the second step, a constant modulus AWV, $\mathbf{w}$ that gives rise to beam gains equal to or more than the optimum beam gains obtained in first step is determined. In the third and final step, the $\mathbf{w}$ found in the second step is plugged into the expression for sum-rate of two users. Now the problem reduces to finding the power p_1/p_2 that makes the sum rate maximum under the minimum data rate requirements at the two users. Thereby after three steps, the optimum powers p_1, p_2, and AWV, $\mathbf{w}$ are obtained, i.e., solution to equation (6) is obtained. Please refer to [12] for further details.
In this paper we aim to study the effect on imperfect CSI on the sum-rate of two users. Imperfect CSI can be of two types. (i) The AoD θ_i can be wrong and/or (ii) the channel gain λ_i can be wrong. We first study the effect of wrong knowledge of AoD θ_i at the base station. Next we study the effect of incorrect knowledge of channel gain λ_i at the base station.

III. Impact of Imperfect AoD

We assume that $\tilde{\theta}_i$ is the correct AoD corresponding to the i-th user whereas the base station assumes θ_i to be the AoD corresponding to the i-th user equipment. We also assume that base station has correct knowledge of λ_i. In other words the channel knowledge that base station should have are given by

$$\begin{aligned} \tilde{\mathbf{h}}_1 &= \lambda_1[1 \quad e^{j\pi\tilde{\Omega}_1} \quad e^{j\pi 2\tilde{\Omega}_1} \ ..... \ e^{j\pi(N-1)\tilde{\Omega}_1}]^T \\ \tilde{\mathbf{h}}_2 &= \lambda_2[1 \quad e^{j\pi\tilde{\Omega}_2} \quad e^{j\pi 2\tilde{\Omega}_2} \ ..... \ e^{j\pi(N-1)\tilde{\Omega}_2}]^T \end{aligned} \tag{7}$$

Base station calculates optimum powers and AWV based on $\mathbf{h}_1$ and $\mathbf{h}_2$ following the three steps described in the previous section. Let us call these values as p_1, p_2 and $\mathbf{w}$. Therefore the actual downlink data rates $\tilde{R}_1$, $\tilde{R}_2$ obtained by the two users will be given by

$$\begin{aligned} \tilde{R}_1 &= log_2\Big(1 + \frac{|\tilde{\mathbf{h}}_1^H \mathbf{w}|^2 p_1}{\sigma^2}\Big) \\ \tilde{R}_2 &= log_2\Big(1 + \frac{|\tilde{\mathbf{h}}_2^H \mathbf{w}|^2 p_2}{|\tilde{\mathbf{h}}_2^H \mathbf{w}|^2 p_1 + \sigma^2}\Big) \end{aligned} \tag{8}$$

where,

$$\begin{aligned} \mathbf{h}_1 &= \lambda_1[1 \quad e^{j\pi\Omega_1} \quad e^{j\pi 2\Omega_1} \ ..... \ e^{j\pi(N-1)\Omega_1}]^T \\ \mathbf{h}_2 &= \lambda_2[1 \quad e^{j\pi\Omega_2} \quad e^{j\pi 2\Omega_2} \ ..... \ e^{j\pi(N-1)\Omega_2}]^T \end{aligned} \tag{9}$$

$$\mathbf{h}_1^H \mathbf{w} = \sum_{n=0}^{N-1} e^{-jn\pi\Omega_1} e^{j\mathbf{w}_n} = \sum_{n=0}^{N-1} \alpha_n \tag{10}$$

$$\tilde{\Omega}_1 = cos(\tilde{\theta}_1) = cos(\theta_1 + \Delta\theta_1) \approx \Omega_1 - \Delta\theta_1 sin(cos^{-1}\Omega_1) \tag{11}$$

$$\tilde{\mathbf{h}}_1^H \mathbf{w} = \sum_{n=0}^{N-1} e^{-jn\pi\tilde{\Omega}_1} e^{j\mathbf{w}_n} = \sum_{n=0}^{N-1} \alpha_n e^{jn\pi\Delta\theta_1 sin(cos^{-1}\Omega_1)} \tag{12}$$

$$|\mathbf{h}_1^H \mathbf{w}|^2 = \Big(\sum_{n=0}^{N-1} \alpha_n\Big)\Big(\sum_{k=0}^{N-1} \alpha_k^*\Big) \tag{13}$$

$$|\tilde{\mathbf{h}}_1^H \mathbf{w}|^2 = \Big(\sum_{n=0}^{N-1} \alpha_n e^{jnq}\Big)\Big(\sum_{k=0}^{N-1} \alpha_k^* e^{-jkq}\Big) \tag{14}$$

where $q = \Delta\theta_1 sin(cos^{-1}\Omega_1)$. It is clear from the above equations that for any arbitrary value of $\Delta\theta_1$ and Ω_1 $|\tilde{\mathbf{h}}_1^H \mathbf{w}|^2 < |\mathbf{h}_1^H \mathbf{w}|^2$. The sum-rate under perfect knowledge of channel gain and imperfect AoD knowledge are plotted in the paper.

IV. Impact of Imperfect Channel Gain

We assume $|\breve{\lambda}_i|$ to be the correct channel gain magnitude corresponding to the i-th user equipment. The base station, however, assumes $|\lambda_i|$ to be the channel gain magnitude. In other words the channel knowledge that base station should have are given by

$$\begin{aligned}\breve{\mathbf{h}}_1 &= \breve{\lambda}_1[1 \quad e^{j\pi\Omega_1} \quad e^{j\pi 2\Omega_1} \quad \ldots\ldots\ldots \quad e^{j\pi(N-1)\Omega_1}]^T \\ \breve{\mathbf{h}}_2 &= \breve{\lambda}_2[1 \quad e^{j\pi\Omega_2} \quad e^{j\pi 2\Omega_2} \quad \ldots\ldots\ldots \quad e^{j\pi(N-1)\Omega_2}]^T\end{aligned} \tag{15}$$

Base station calculates optimum powers and AWV based on $\mathbf{h}_1$ and $\mathbf{h}_2$. Let us call these values as p_1, p_2 and $\mathbf{w}$. However the actual downlink data rates $\breve{R}_1$, $\breve{R}_2$ obtained by the two users will be given by

$$\begin{aligned}\breve{R}_1 &= log_2\Big(1 + \frac{|\breve{\mathbf{h}}_1^H \mathbf{w}|^2 p_1}{\sigma^2}\Big) \\ \breve{R}_2 &= log_2\Big(1 + \frac{|\breve{\mathbf{h}}_2^H \mathbf{w}|^2 p_2}{|\breve{\mathbf{h}}_2^H \mathbf{w}|^2 p_1 + \sigma^2}\Big)\end{aligned} \tag{16}$$

V. Results And Discussion

Simulation has been done in matlab assuming P = 100 mW, σ^2 = 1 mW, $|\lambda_1|$ = 0.85, $|\lambda_2|$ = 0.4, $\theta_1 = 85^0$, $\theta_2 = 55^0$, N = 32. The data rates that have been plotted in the following figures are maximum achievable data rates.

Fig. 2 shows achievable sum rate vs. minimum supported data rate plot for perfect as well as imperfect AoD knowledge at the base station. The achievable sum rate decreases with increase in minimum data rate, r because data rate of near user decreases at a faster rate than the rate at which far user's data rate increases as evident from Fig. 3. The AWV, $\mathbf{w}$ changes so as to give higher data rate to far user at the expense of near user's data rate. The achievable sum rate in presence of wrong angle values available with the transmitter is always less than the perfect CSI case. The gap between sum rates for perfect and imperfect AoD increases as error in AoD increases. This behaviour is expected and explained in previous section. The power allocated to the two users' data by the base station while performing superposition coding is shown in Fig. 4. The base station transmits two users' signal with equal power at low supported data rate of 1 bps/Hz. However the gap between the powers allocated to the two users increases as the requirement for minimum supported data rate increases. Fig. 5 is a plot of beam gain as a function of angle of departure. The beam gain for near user becomes maximum at 85^0 because that is the direction along which the near user is placed. This plot also shows that as number of antenna elements at the transmitter increases, the beam becomes narrower, implying that (1) the total supported data rate would increase with number of antenna elements, N, and (2) an incorrect estimate of angle and/or channel gain at the transmitter would reduce the achievable data rates more, the higher the number of antenna elements , N. This observation is supported by simulation result shown in Fig. 6. Fig. 7 shows that incorrect knowledge of channel gain causes decrease in individual as well as sum data rate. It is to be noted that wrong channel gain information causes

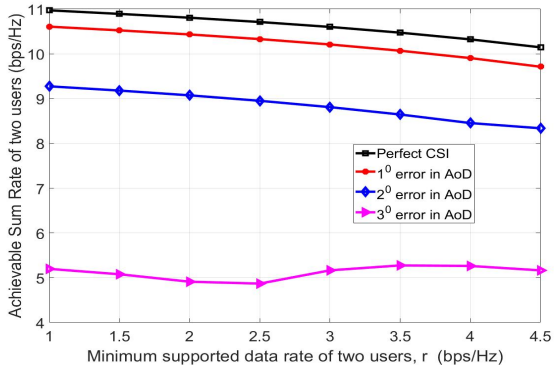

Fig. 2: Achievable sum rate vs minimum supported data rate with perfect and imperfect AoD estimates

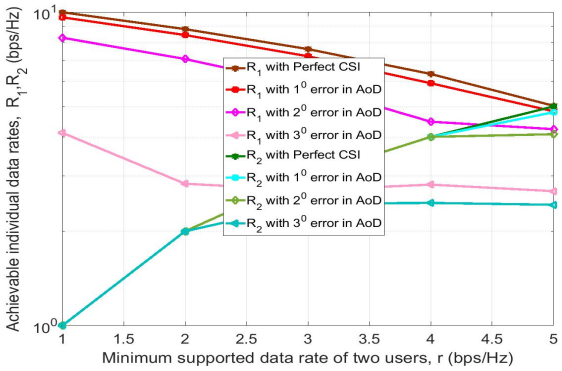

Fig. 3: Achievable data rates for Far and Near User vs minimum supported data rate with perfect and imperfect knowledge of AoD

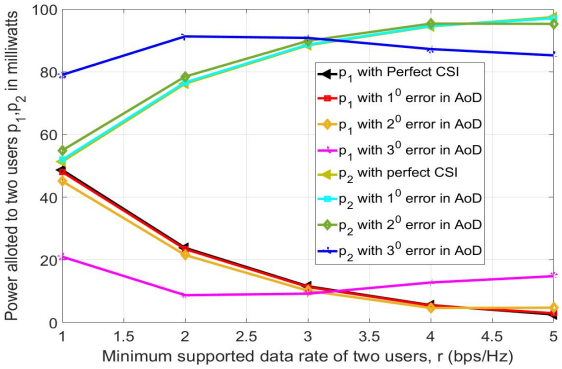

Fig. 4: Power allocated to the two users vs minimum supported data rate with perfect and imperfect AoD estimates at the base station

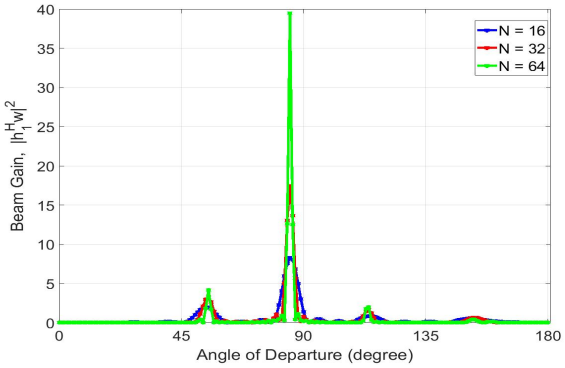

Fig. 5: Beam Gain of near user as a function of Angle of Departure for different no. of antenna elements

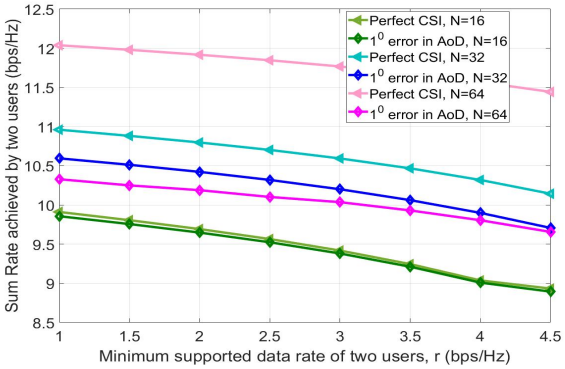

Fig. 6: Variation of achievable sum rate with number of antenna elements

a much less reduction in data rates compared to the reduction in data rate caused by imperfect knowledge of AoD. The best sum data rate achievable using TDMA with perfect CSI at transmitter has also been plotted here. The transmitter is assumed to allocate equal time to the two users. The AWV is chosen as $\mathbf{w} = \mathbf{h}_i/||\mathbf{h}_i||$ for $i = 1, 2$. Fig. 8 illustrates that absolute values of

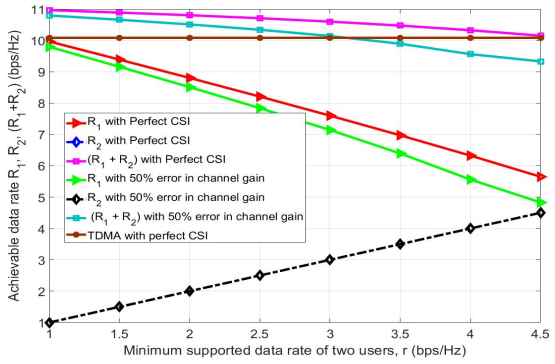

Fig. 7: Achievable data rates when the channel gain knowledge at the base station is erroneous

AoDs as well determine how much an error in AoD will affect the achievable data rates. We kept all the parameters same as before except $\theta_1 = 20^0$. Difference between Fig. 8 and Fig. 2 is clearly visible.

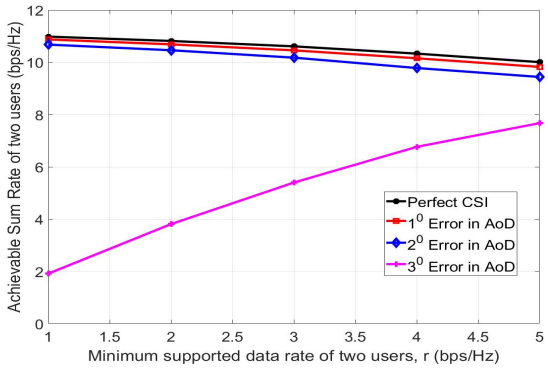

Fig. 8: Achievable sum rate vs minimum supported data rate with perfect and imperfect AoD estimates

VI. Conclusion

A two user NOMA supported on the downlink of a mmwave wireless communication system has been studied here wherein the users are assumed to be at different azimuth angles. Previous studies on NOMA assume that bases station has perfect channel state information. This paper shows how imperfect knowledge of angle of departure and/or channel gain at the base station reduces the achievable data rate for NOMA. Too much imperfection in channel knowledge may actually destroy the advantage of using non orthogonal multiple access technique compared to orthogonal multiple access techniques.

Learning the characteristics of a wireless channel is one of the most fundamental and challenging issues in the wireless communication. Many conventional signal processing techniques have been developed so far to estimate the channel state information. In this paper, we present a novel approach based on deep learning using long short term memory (LSTM) neural network to predict the fast-varying Rayleigh fading channel. Having known application of LSTM neural network in the field of time-series prediction problems, we have applied LSTM to predict the future state of the channel by providing the past channel state values. The predicted values of channel is used to recover the transmitted symbol from noisy signal received at the receiver end. We have optimized the configuration of LSTM network by correctly tuning the hyper-parameters so that we get a correct prediction of channel which is in turn used for reconstruction of signal at receiver end. The simulated Bit Error Rate vs. Signal-to-Noise ratio plot proves that LSTM based channel predictor works better than currently used interpolation based channel predictor.

Keywords— Deep Learning, Rayleigh fading channel, LSTM Neural Network, Wireless Communication, SISO system.

I. INTRODUCTION

Communication is a rich field consisting of domain knowledge regarding modelling different types of channels, signaling and detection techniques and different modulation schemes [1], [2] that ensure reliability of data transfer between transmitter and receiver [3]. Further to increase the efficiency in the performance of the wireless technologies. We need to be docile in adapting to the latest technologies, such as data-driven approaches by using machine learning and deep learning algorithms. There were different multiple access techniques like frequency division multiple access (FDMA) across frequency, time division multiple access (TDMA) across time and code division multiple access [4] schemes across different pseudo codes helped to increase the quality of service(QoS) and showed significant performance improvement but we cannot go any further with them. Now a days the data centric approach had gathered attention with huge success attained in fields as such realization of vision through computers, processing of human language and image classification [5], [6]. For a reliable data transmission to happen we need to model the channel correctly but accurate modelling of channel mathematically is almost impossible so we go for a probabilistic based approach. The core signal processing algorithms used in communications fails to improve in performance [7]. The deep learning based algorithms in the field of wireless communication [8] was used because it has the power to improve the performance in areas where it is impossible to generate mathematical models but by considering the deep learning model as a black-box we can tune hyper-parameters so that we can control the output of the system [9].

The next wave of wireless technology suffers with the problem of network latency as the number of connections over a network increases drastically in number the scope of deep learning is such that it has to automatically get tuned to the available network and increase or decrease power with respect to the corresponding receiver. In recent the machine learning which is a root class of deep learning had used in the field of communications for tasks such as recognition of modulation scheme, channel encoding techniques and decoding techniques, in estimation of channel and channel equalization [10], [11], [12], [13].

In the recent years the computing power has been drastically increased and the algorithms have been developed so far and fast that uses the data. In physical layer research, by considering the applications of deep learning we are not only trying to improve the performance of individual blocks but also we try to increase the performance of entire communication system by considering transmitter, channel and receiver as a deep learning model such type of arrangement is called as auto-encoder[14]. The channel estimation using least squares (LS) method and minimum mean square error (MMSE) method estimators have been utilized in many occasions [15]. Of that least squares estimator does not require any previous channel values. The MMSE estimator works better by considering the second order statistics of the channel. In a paper related to orthogonal frequency division multiple access (OFDM) [16] the application of deep learning which mainly focus on feed forward neural network have been studied it presents initial results in learning methods to deal with wireless channels and the removal of cyclic prefix in OFDM and usage of limited pilots and non-linear noise distortions has been discussed [17].

We, in this paper have opted for a single input single output system [18](SISO-system), modeled the channel as a fast fading channel with Rayleigh distribution and a moving receiver at 500kmph scenario is considered. Then at the receiver end we have built a LSTM neural network and trained it online using the data from the zero forcing estimation block after adding additive white Gaussian noise (AWGN). We optimized the data over the loss function between the true values of the channel and the values that were corrupted due to noise. The predicted values have been used for channel equalization and successful reconstruction of the signal at receiver end. We have fine-tuned the hyper-

parameters at a certain value of SNR and has been implemented for SNR of certain range. Finally, after the reconstruction of the transmitted bits the Bit Error Rate over different values of Signal to noise ratio has been plotted.

we will be describing about the wireless system model with the block diagram in Section II. In Section III we will be discussing about the Deep Learning basics and Deep Learning Architecture being used and how we have obtained the data and the corresponding performance metrics used in obtaining the results. That was followed by a discussion on the simulation results obtained in Section IV, Section V deals about conclusion of the topic and its future scope of the work done.

II. WIRELESS SYSTEM MODEL

We have assumed the problem of channel prediction as a supervised learning problem. Out of all the channel characteristics like attenuation, scattering, diversity, reflection and refraction we have been considering channel fading as the only phenomenon to tackle. The channel we have considered here is a Rayleigh fading channel. As *R* being its corresponding random variable and its probability density function is given by

$$f_R(r) = \frac{r}{\sigma^2} e^{\frac{-r}{2\sigma^2}}, \quad r \geq 0 \qquad (1)$$

we have been considering the case of moving receiver which introduces a Doppler shift in the receiving signal. We are considering the speed of the receiver as 500kmph in this problem. Here we have considered V as velocity and λ as wavelength and θ as the angle between the receiver and the incoming signal. The value of Doppler shift (ΔØ) affect the value of frequency of the received signal the change in frequency is calculated using Equation 2 and 3.

$$\Delta\emptyset = \frac{2\pi\Delta l}{\lambda} = \frac{2\pi v \Delta t}{\lambda} \cos\theta \qquad (2)$$

$$f_d = \frac{1}{2\pi}\frac{\Delta\emptyset}{\Delta t} = \frac{v}{\lambda}\cos\theta \qquad (3)$$

The problem we have taken is a complex optimization problem that address the time-series relationship in the data and we have modelled it as a supervised regression problem. The baseband equivalent of the bandpass SISO (single input single output) system for a faded channel of probability distribution as Rayleigh in the presence of noise will be

$$\mathbf{y = h\,x + n} \qquad (4)$$

Where y is the received complex baseband signal and h is a Rayleigh faded channel |h| is the magnitude of the fading and x is the input modulated signal to be transmitted and n is the Additive White Guassian Noise (AWGN). Where noise follows Guassian distribution. While solving the problem we have split the equations into real and imaginary parts shown in Equation 5 and 6.

$$y_{real} = h_{real} * x_{real} + n_{real} \qquad (5)$$

$$y_{img} = h_{img} * x_{img} + n_{img} \qquad (6)$$

From Fig.1, we have generated the 'N' bits where N ∈ (0, 1) and that bits has been sent to modulator block where the QPSK modulation happens on the input bits and the modulator block output symbols which are of complex in nature and they are of size N/2. Then those symbols are transmitted through wireless channel which in our case is a Rayleigh faded channel and the output of the channel is received by the receiver and adds an Additive White Gaussian Noise (AWGN) at the beginning of the receiver after the addition of noise we will consider the signal as y. 'y' is complex signal consisting of real part and imaginary part and The first 150 symbols were given as input to the zero-forcing estimator the output 150 symbols of the estimator are separated into real and imaginary values and are given to two LSTM blocks separately the LSTM block takes the input as first 150 values of h and predicts the next 600 values of h in both real and imaginary part. We call it as h' and then we collect h' and proceeds for channel equalization with the obtained values of h' and then after the channel equalization we will be demodulating the signal to reconstruct the originally transmitted information.

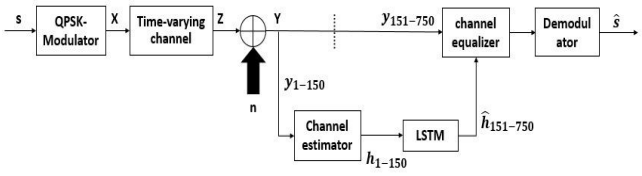

Fig.1: Signal-flow Diagram of the SISO system using LSTM neural network as channel predictor.

III. DATASET AND DEEP LEARNING ARCHITECTURE

A. Dataset

The dataset we used in this problem is a custom dataset it can be obtained by simulating the wireless communication system under specific channel conditions and the corresponding AWGN channel the data collected was the data before the noise being added to the wireless system and the data after the noise being added those two were collected and the data collected after the addition of noise is given as the input for the model to learn.

B. Deep Learning basics

Neural networks, an extension of machine learning has its own significance. Unlike, machine learning there is no need for doing feature extraction in neural networks the feature engineering is automatically done. The neural networks ideally consists of three layers. The first one is input layer, next one is hidden layer and the last one is output layer. Any neural network layer basically made up of nodes. Every node in one layer makes connection with every other node of the next layer by a weight and a bias at every node this forms the basic structure of feed-forward neural network.

Usually, the input and output nodes are common and the size of the network depends on the count of hidden layers. A neural network with one hidden layer can equally approximate any mathematical function. The Weights in the feed forward neural network are updated by an algorithm called back propagation as it updates the weights by minimizing the distance between the actual values and obtained values. The process of continuous update of weights continue until a global minima is attained on the error surface curve. The update of weights usually happen by a factor called learning rate. Generally, the output of a feed forward neural network is given by Equation 7.

C. Deep Learning Architeture

But, for our problem we need a neural network that

$$\mathbf{O} = \mathbf{Ø}\left(\sum_{i=1}^{m} \boldsymbol{W_i}.\boldsymbol{X_i} + \boldsymbol{b_i}\right) \qquad (7)$$

works a neural network that work well for time-series data. So, we have shifted our attention towards RNN (recurrent neural network). It has a same function similar to that of a feed forward neural network except for that each node in RNN consists of a feed-back which makes them efficient to deal with time-series data. RNN which is similar to feed forward net after unwrapping it in time. After unwrapping the RNN it appears like this

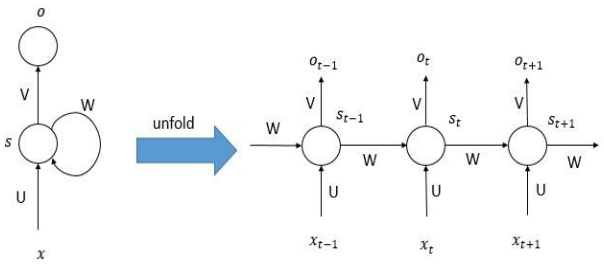

Fig.2: RNN neural network unwrapping in time.

RNN have a problem with length of time-series as the length of time-series goes on increasing the RNN suffers from a problem of disappearing gradient. The problem of disappearing gradient can be resolved by introducing a memory into RNN. This typical structure is named as LSTM (long short term memory) neural network which typically looks like this

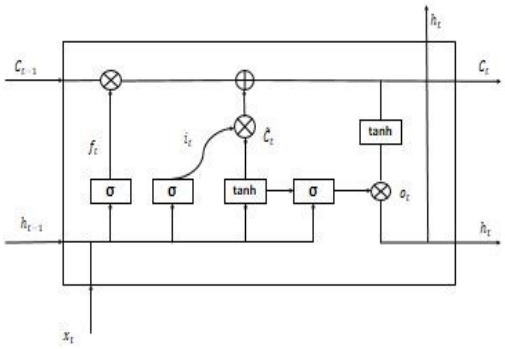

Fig. 3: LSTM memory unit structure

As in Fig.3, The LSTM memory unit consists of a three gates. These gates are responsible for the flow-control and storage of information. These functionality of these gates are used in naming them. The memory cell is responsible for the storage of current cell state which is to be applied for the future time-step. The input gate denoted by **i** responsible for the flow of fresh information into the memory cell. The forget gate which is denoted by **f** is responsible for the amount of information to be forget in the current state. The output gate which is taken as **o** is responsible for the control of amount of information to be flown into the rest of the network. The last layer in the LSTM neural network is connected to a fully connected neural network. The equations from 8 to 13 describe the functionality of LSTM.

$$\boldsymbol{i_t} = \boldsymbol{\sigma}(\boldsymbol{W_x^i}.\,\boldsymbol{x_t} + \boldsymbol{W_h^i}\,.\,\boldsymbol{h_{t-1}}) \qquad (8)$$

$$\boldsymbol{f_t} = \boldsymbol{\sigma}(\boldsymbol{W_x^f}.\,\boldsymbol{x_t} + \boldsymbol{W_h^f}\,.\,\boldsymbol{h_{t-1}}) \qquad (9)$$

$$\boldsymbol{o_t} = \boldsymbol{\sigma}(\boldsymbol{W_x^o}.\,\boldsymbol{x_t} + \boldsymbol{W_h^o}\,.\,\boldsymbol{h_{t-1}}) \qquad (10)$$

$$\tilde{\boldsymbol{C}}_t = \tanh(\boldsymbol{W_x^c}.\,\boldsymbol{x_t} + \boldsymbol{W_h^c}\,.\,\boldsymbol{h_{t-1}}) \qquad (11)$$

$$\boldsymbol{C_t} = \boldsymbol{i_t} \otimes \tilde{\boldsymbol{C}}_t + \boldsymbol{f_t} \otimes \boldsymbol{C_{t-1}} \qquad (12)$$

$$\boldsymbol{h_t} = \boldsymbol{o_t} \otimes \tanh(\boldsymbol{C_t}) \qquad (13)$$

D. Performance metrics

The predicted values of the channel are evaluated using a metric called root mean square error (RMSE) the error function upon which the weights are optimized. We will be dealing with the real component values and imaginary component values of the channel separately using two LSTM networks which are tuned differently and the result is combined to form a complex value prediction. The RMSE values are computed using a mathematical equation given by

$$\mathbf{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(y_i^{pred} - y_i^{actual}\right)} \qquad (14)$$

the problem we are solving is a regression problem so we have taken the cost function as root mean square error. There are different cost functions for different types of problems we need to choose the cost function or loss function according to the problem in hand.

IV. Results and Discussion

Experiment was carried in a simulation based environment using MATLAB 2018b and to implement neural networks in MATLAB we used neural network toolbox. A SISO wireless system was simulated and the channel was modeled as a Rayleigh fading channel and we have considered a moving receiver scenario which is offering a Doppler shift of 0.0001534 as we are modeling the channel as a fast fading channel and we have been using a predefined function to simulate Rayleigh fading channel in MATLAB with carrier frequency 2.5GHz and signal bandwidth of 5MHz and with a sampling rate of twice the signal bandwidth and we are considering Jakes spectrum. The modulation scheme used at the transmitter side was QPSK-modulation and its counterpart QPSK demodulator was used at the receiver end.

Firstly, we have generated 1500 bits and then we have passed onto a QPSK modulator so that we may get 750 symbols which are complex numbers are obtained as the output of the modulator block and those symbols were transmitted through the channel with specifications as

mentioned above and at the beginning of receiver we are adding a AWGN noise which is a byproduct due to receiver components and that is termed as 'y'. Now y which is given as input to zero forcing channel estimator and the output of that is of dimension 750x1 is separated as 150 units for training is termed as h and the rest of the values are predicted using the trained neural network model that predicted values is denoted by h'. Here the neural network model consists of 2 LSTM layers with a fully-connected layer in the end and in the LSTM layer the activation function used at the gate level was sigmoid activation function and at the cell-state level we use tanh activation function. We use two separate models that were tuned separately one to predict the real values of h' and another to predict the imaginary values of h'. For the model which predicts the real values we have taken 50 hidden units that is 50 nodes and the we have considered certain parameters like Max.epochs 200 and Mini Batch size as 64 and an Initial Learning rate as 0.05 and Learning rate drop period as 125. And for the other model which predicts the imaginary values of h uses 50 hidden units and Max.epochs of 250 and a Mini Batch size of 64 and with an Initial rate of learning as 0.05 and a Rate of Learning drop period as 125. Then the predicted values are combined to form a complex value and this is used for channel equalization and after that we give the output of this block as an input to the demodulator block and after the demodulation we will get the transmitted bits while some are corrupted due to channel impairments and the receiver noise. The hyper-parameters that were considered separately for real and imaginary were indicated in Table. I and Table. II

Table. I: Hyper parameters tuned for real channel value prediction.

Number of hidden units	50
Max. epochs	200
optimizer	Adam
Initial learning rate	0.05
Learning rate drop of period	125
Learning rate drop of factor	0.2
Mini Batch size	64

Table. II: Hyper parameters tuned for imaginary channel value prediction.

Number of hidden units	50
Max. epochs	250
Optimizer	Adam
Initial learning rate	0.05
Learning rate drop of period	125
Learning rate drop of factor	0.2
Mini Batch size	64

Fig.4, demonstrates the predicted real values of the channel at 25dB SNR. Fig.5, demonstrates the predicted

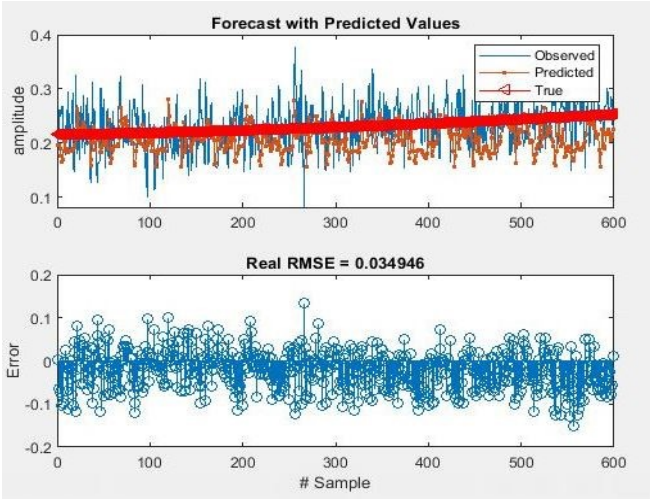

Fig. 4: predicted real values of LSTM block and Real RMSE value for sample.

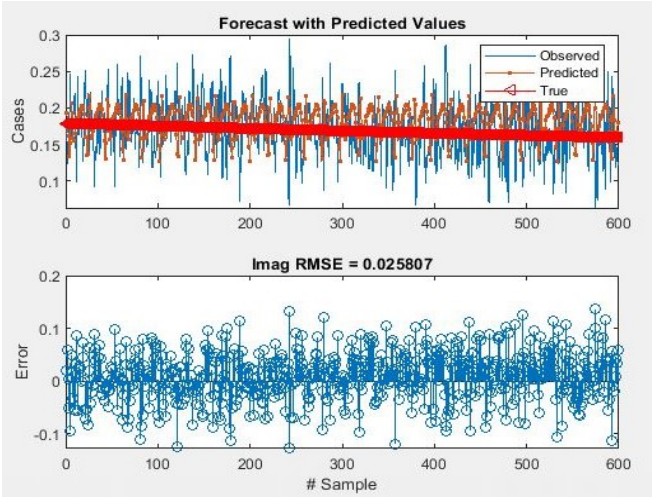

Fig. 5: predicted imaginary values of LSTM block and Imaginary RMSE value for sample.

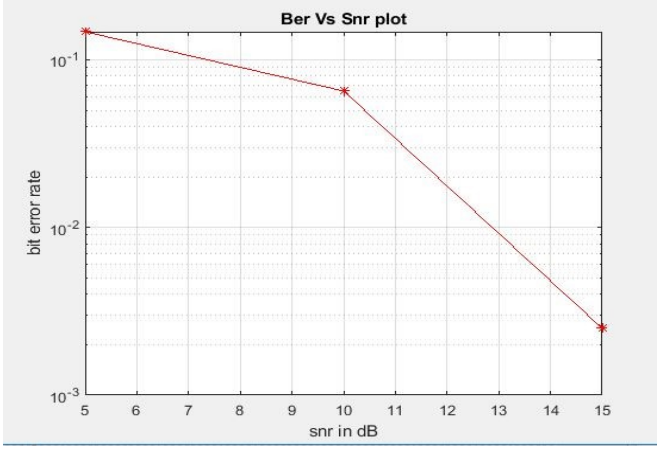

Fig. 6: BER versus SNR plot when N=1500.

imaginary values of the channel. Fig.6, indicates the Bit Error Rate (BER) versus Signal to Noise Ratio (SNR) curve for the number of bits equal to 1500. Now we will extend the concept further by extending the number of bits to 15000 and we will divide the entire 15000 bits into 10 blocks consisting of 1500 each. And then they are QPSK modulated. And these

symbols are transmitted through the channel modeled and AWGN noise was added at the beginning of receiver end. Then that symbols were collected. The symbols obtained may be represented like Fig. 7.

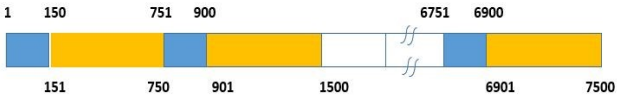

Fig .7: Representation of the symbols training and prediction.

Now the obtained symbols which have dimension of 7500x1 can be represented like the above shown figure. We consider 750 symbols as one set. Of that we will use 150 for training and the next 600 values will be predicted separately for real and imaginary values of the channel by using two different LSTM neural networks which have the hyper parameters as shown in Table. I and Table .II.

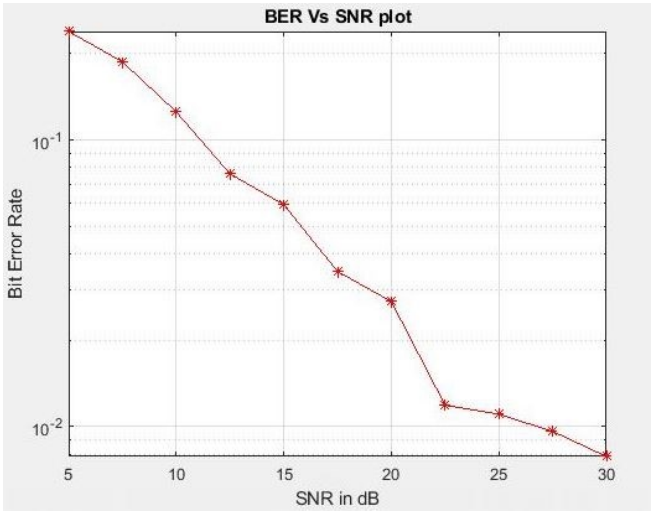

Fig. 8: BER versus SNR plot when N=15000.

We will train for every 150 symbols and predict the next 600 symbols and we will repeat this until 7500 symbols in sets of 750. The entire experiment is repeated for different values of SNR and the BER values were obtained. The BER Versus SNR plot is shown in Fig. 8. The activation function considered are for gate-level is sigmoid and cell-state level is tanh. The obtained Fig. 8, BER versus SNR plot indicates that LSTM are a good tools that can deal with time series data and can be used in application of wireless communication systems.

V. Conclusion and Future Scope

In this paper, we develop a system model that predicts the characteristics of a fast varying wireless fading channel in a moving/mobile receiver which is moving at a speed of 500kmph scenario by using a LSTM neural network and we have used that predicted channel values in order to reconstruct the message transmitted at the receiver end. For that we have tuned the hyper parameters of the LSTM neural network so that we will get a system performance better than the existing interpolation based systems. The experimental results suggested that LSTM's have the capability of predicting the time-series data i.e., getting insights from the historical data to predict the future state. we have modeled a SISO channel under the moving receiver case and trained the LSTM network online to predict the channel characteristics. LSTM's are helpful assets in building the next generation wireless technologies.

By considering this as a sub-channel in an OFDM system this concept with a little modification can be extended to multiple sub-channels in an OFDM system.

***Abstract*—A monopole antenna for multiband advanced wireless services is presented in this paper. Initially a single band antenna for 2.45 GHz is designed with Coplanar Waveguide (CPW) fed and loop ground plane. A peak gain of 3.55 dBi is observed for this configuration. Defects are introduced in the loop ground plane with the aim of obtaining dual frequency bands. Footprint of the antenna consumes same area for single and dual band configurations. The antenna characteristics – reflection and radiation properties are investigated and optimized using ANSYS HFSS. Prototype of the optimized antenna is analyzed using Vector Network Analyzer Keysight E 5080 A.**

Keywords — Coplanar waveguide (CPW), defected ground plane, dual band, Wi-Fi, WiMAX, wireless communication, monopole antenna.

I. INTRODUCTION

Wireless communication is rapidly emerging in the present day scenario. Compact gadgets which are highly efficient with large bandwidth operating in different frequency bands are preferred in the communication systems. There are variant categories of antennas that can provide these features applicable for wireless communication as they are of low profile, low price and light weight [1]. Wireless applications with multi-functional operations require multiband antennas. In recent past, multi-functionality has become a key component for many gadgets making design of compact multiband antenna need of the hour.

Different antenna configurations for dual band performance has been reported of which coplanar waveguide (CPW) fed antennas are more attractive as they can be implemented on a single plane and can easily mount active devices. A loop antenna energized with CPW can provide dual frequency band characteristics with enhanced gain [2]. Metamaterials can act as ground plane for monopole antennas providing good radiation characteristics [3]. CPW fed monopole antenna provides dual band when a planar patch with a cross slot generates two separate resonant modes [4]. A metallic strip which is of C shape etched in a rectangular slot is found to provide dual band and high bandwidth [5]. CPW fed dual-band circularly polarized antenna is discussed in [6]. CPW fed slot antenna operating for wireless applications having dual band is discussed in [7]. Small monopole antenna with inverted L-shaped and rectangular stubs can provide dual band characteristics [8]. Metamaterial-inspired antenna also provides dual frequency operation [9]. A multi-band antenna for tri-band applications using CPW is also reported [10].

A CPW fed monopole antenna which is designed at single frequency is presented in this paper, which is further modified to defected ground plane by adding stub in order to achieve dual bands. The proposed final antenna on measurement gave dual band response at 2.45 GHz and 4.59 GHz.

II. CONFIGURATION OF THE ANTENNA

The loop ground CPW fed monopole antenna is as shown in Fig. 1. To enable the antenna to radiate at 2.45 GHz, the parameters of the ground plane and monopole (Lp, Lg, Wg and d) (Fig.1) is optimized while 2g + Wp provides 50Ω impedance. The studies are carried out in a substrate with dielectric constant $\varepsilon_r = 4.4$ and a thickness h =1.6mm.

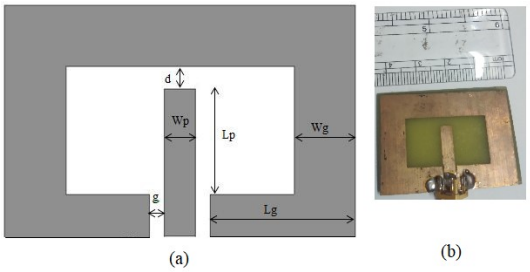

Fig. 1. Configuration of the proposed antenna
(a) Geometry (b) prototype fabricated in FR4

The antenna parameters are optimized as Lg = $\lambda_g/4$, Lp = $\lambda_g/6$, Wg = $\lambda_g/8$, Wp = $\lambda_g/14$ and d = $\lambda_g/16$, for any frequency of operation. Based on at 2.45 GHz, a prototype is fabricated and tested having a return loss as plotted in Fig.2. The antenna offers a bandwidth of 148 MHz at 2.46 GHz in simulation and 155 MHz at 2.48 GHz in measurement. The radiation performance of the antenna is studied in the bandwidth range and is presented in Fig.3. The antenna has a gain of 2 dBi in the entire bandwidth with omnidirectional characteristics.

This antenna is modified by including a stub in the ground plane to obtain dual band performance. This is discussed in the next section.

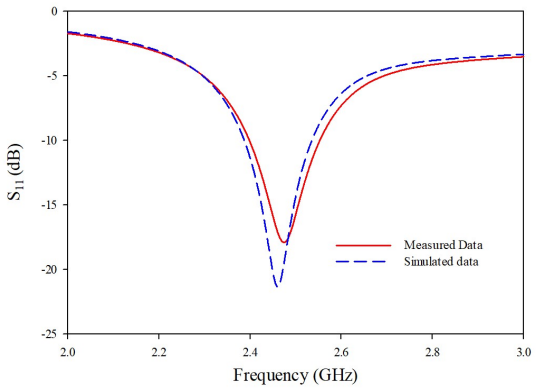

Fig. 2. Reflection Characteristics of the antenna
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm
εr = 4.4, h =1.6mm.

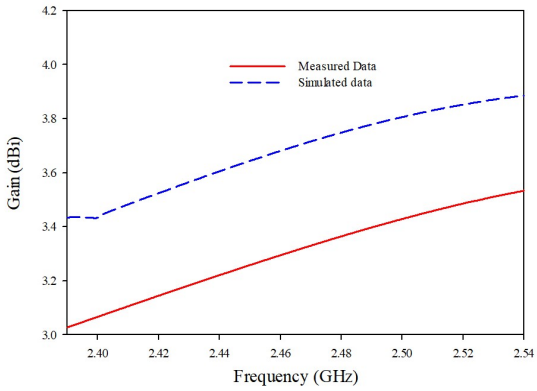

Fig. 3 (a). Gain of the antenna
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm
εr = 4.4, h =1.6mm.

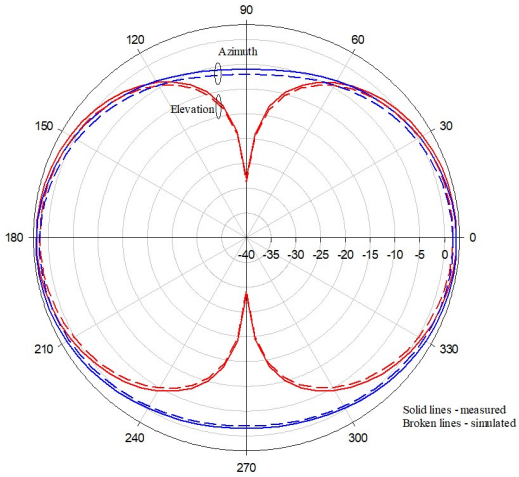

Fig. 3 (b). Radiation Pattern of the antenna at 2.46 GHz
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm
εr = 4.4, h =1.6mm.

III. ANTENNA CONFIGURATION FOR DUAL BAND PERFORMANCE

The stub loaded CPW fed loop ground monopole antenna is as shown in Fig.4. The influence of the stub l1 × sw1 in the reflection and radiation characteristics is studied in detail. Initially, the position of the stub on the ground plane is optimized. For maximum gain the stub position is fixed at top middle as in the Fig.4.

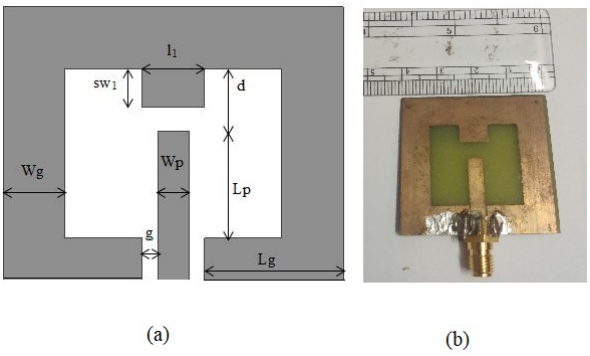

Fig. 4. Configuration of the proposed antenna for dual band performance
(a) Geometry (b) prototype fabricated in FR4

When width of the stub sw1 is increased, the first resonant frequency f1 decreases and second resonant f2 increases with decrease in gain. The stub parameters are varied in such a way that the maximum length l_1 of the stub can be varied up to 20mm ($\lambda_{g2}/2$) and width sw_1 can be varied up to 8.5mm ($\lambda_{g2}/4$) only, which gave single band response at 9.09 GHz. The stub dimension is optimized to get dual frequency bands. The frequencies f_1 and f_2 can be expressed as:

$$f_2/f_1 = \lambda_{g1}/\lambda_{g2}$$

For dual band response at 2.45 GHz and 4.59 GHz, it can be generalized as $f_2 = 1.8\ f_1$. With optimized parameters antenna is fabricated. The measured and simulated return loss is presented in Fig.5.

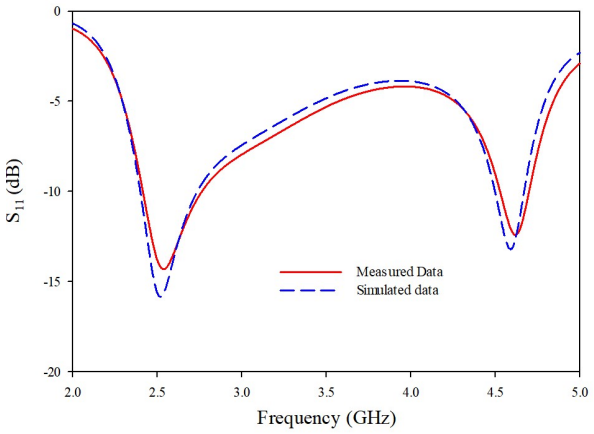

Fig. 5. Return loss characteristics of antenna with stub
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm, sw1 = 5mm, l1 = 8mm, εr = 4.4, h =1.6mm.

In anechoic chamber, the gain of the antenna is measured by gain transfer method at both the bands. The obtained gain is as in Fig.6. The radiation pattern at both frequencies is measured and is as plotted in Fig.7.

The obtained results confirm the proposed antenna as a good radiator for dual band applications. The performance of the antenna with that found in the literature is compared and presented in Table.1.

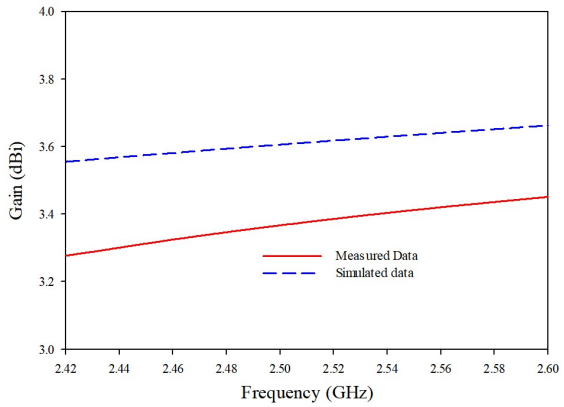

Fig. 6 (a). Gain of antenna in the first band
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm, sw1 = 5mm, l1 = 8mm, εr = 4.4, h =1.6mm.

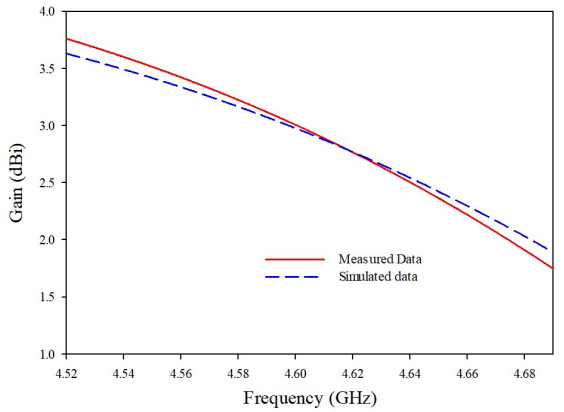

Fig. 6 (b). Gain of antenna in the second band
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm, sw1 = 5mm, l1 = 8mm, εr = 4.4, h =1.6mm.

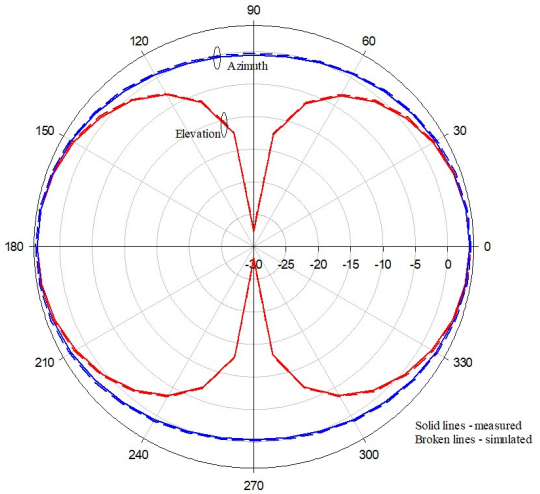

Fig. 7 (a). Radiation pattern at 2.45 GHz
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm, sw1 = 5mm, l1 = 8mm, εr = 4.4, h =1.6mm.

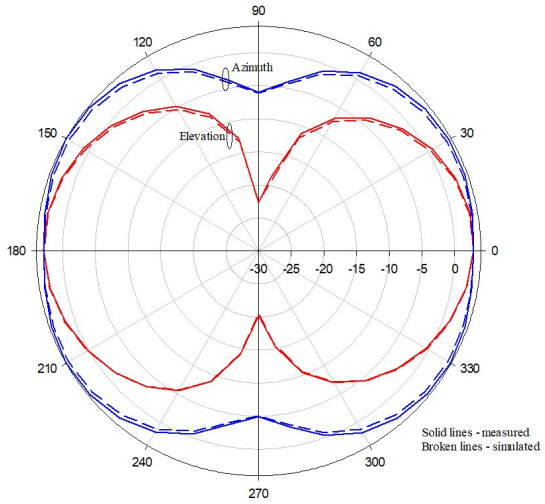

Fig. 7 (b). Radiation pattern at 4.59 GHz
Lg = 19mm, Lp = 11.8mm, Wg = 8mm, d = 3.5mm, sw1 = 5mm, l1 = 8mm, εr = 4.4, h =1.6mm.

IV. RESULTS AND DISCUSSION

A CPW fed dual band loop ground compact antenna is proposed. The antenna is simulated using Ansoft HFSS. Initial design gave response at 2.5 GHz with omnidirectional radiation pattern. The ground loop is modified by adding stub at the top of the loop, which gave dual band response at 2.45 GHz and 4.59 GHz. The stub is placed in such a position in order to obtain maximum gain.

V. CONCLUSION

Multiband antenna plays a major role in wireless communication. Multiband CPW fed monopole antenna working in Wi–Fi, WiMAX and other advanced wireless services is presented. The detailed steps of the design have been discussed in the above sections. The proposed antenna has been designed and optimized using HFSS and measurements are taken using Vector Network Analyzer (VNA). Dual bands are obtained by adding single stub to the ground loop. The stub dimension is tuned in such a way to get maximum gain at the resonant frequency. The simulated

result is validated by experiment. The effect of including more stubs to the ground plane is the work ahead.

A unified Convolutional Neural Network framework for intelligent decision making related to navigation

Khyati Marwah
CSE Deptt, IKGPTU,Jullundar
Punjab,India

Dr. Jogeshwar Singh Sohal
Director,LCET,Ludhiana,
Punjab,India

***Abstract*—Prevalent intellective systems assist the driver in the navigation errands by taking a number of simple and intricate decisions based upon on available input information. Such decisions should be astute and prompt so as to provide realistic behaviour in real life navigation scenarios decisions. Proposed unified Convolutional Neural Network framework ensembles a powerful model that could augment the predictability of the system under construction.**

The suggested work is an extension to authors previous work in which best input features for decision making neural network were obtained by shortlisting eleven texture metrics out of thirty-six metrics using state of art algorithms: Boruta Algorithm and Earth Algorithm [1]. The above said texture metrics were obtained using Spatial Gray Level Dependence Matrices (SGLDM) , the Gray Level Difference Methods (GLDM) ,First order statistics(FOS), the Fourier Power Spectrum (FPS) , the Fractal Dimension Texture Analysis (FDTA),Statistical Feature Matrix(SFM),Laws Texture Energy Measures (TEM) .

In this paper, we have proposed a unification of Best Feature Selection Method (our previous work) and Principal Component Analysis Technique so as to consummate the most pertinent neural network inputs. CNN framework has been used here to provide simple decision that is either to move or stop at a particular instant on the basis of finalized inputs. It was found that unified model inputs (based on Best Feature Selection and PCA) yield better results in comparison to their standalone performance. Furthermore, it was observed that CNN framework can perform equally well with minimal training in comparison to high order training. It implies CNN's has remarkable ability to learn from imprecise data gives it an edge over others. In nutshell, the proposed model was able to decide promptly and astutely the next move of vehicle.

Keywords— SGLDM, GLDM, FOS, FPS, FDTA, SFM, TEM, CNN

I. INTRODUCTION

While driving, the driver mind takes choices in every move. The choice can be as easy as following the track correctly or it can be difficult like finding the correct way through the junction. These decisions are dependent upon some permanent components like roads, some semi-permanent components like traffic signs and some variable components like moving vehicles etc. For taking such decisions we need an Intelligent decision-making system that should possess full-fledged knowledge within a categorical domain just like the human mind and at the same time it should be able to acclimate themselves and thereby enhance performance in a transmuting environment. The system should be able to justify the steps being followed to take a particular action or decision.

Neural networks are a mimic to biological brain. Neural Networks just like human brain have the capability to cluster and classify the data. The unlabeled data is managed into groups on the basis of similarities. A mathematical or statistical function is applied to transform data into neural network inputs. The ability of deep learning algorithms to find correlations enable it to map inputs to outputs. Approximation of the unknown functions is also done using the same technique. These abilities of Neural Network have made them the most sought choice in a number of real-world applications. These networks have found a great usage in identifying patterns, classifying them and finding out the outcomes in previously unknown situations. Thus, they can be easily tamed to take decisions in typical situations of real life.

A variant of Neural Networks, Convolutional Neural Network is powerful enough to make strong assumptions in real life navigation scenarios. If we talk about images related to navigation, the pixels within are connected to each other even if they are far off. CNN's enable to focus on particular area and provides in depth screening of the same and helps in making strong decisions. To have a limit on the input search space, the most relevant dataset is selected and the outliers are removed. The network inputs are minimized using the techniques like Feature extraction, Principal components analysis etc.

The working speed and accuracy are the grey areas in the field of neural networks. So, more attention must be paid to performance issues apart working speed during the design

and testing phases. For this we need to work upon to find appropriate ratio of training and testing datasets. Moreover, we should go for proper selection of network architecture that is the appropriate no. of participating neurons should be find out as too less neurons will result in under training and too much will result into overtraining.

This paper presents a unified CNN framework to find out next decision for a moving vehicle that is either to stop or move with better accuracy and faster response time by overcoming the shortcomings of existing systems.

II. Literature Survey

Neural Networks in conjunction with navigation systems:

Navigation Systems have been actively utilizing Neural Networks. They learn through examples and create their own representation of information received during the learning time. Thus, it acts as expert that could be habituated to provide forecast in incipient situations of interest and can provide reasoning for the decisions taken. A control system based on Neural Networks was developed for intelligent planning of the path was made in [2]. It dealt with the movement of an autonomous robot in partially structured environment. The environment involved random number of obstacles of arbitrary shape. The "free" space was found by using ultrasound range finder and this sensor information was used for the robot movement. The study lagged to find the safe path in optimal time. A dynamic artificial neural network based mobile robot motion and path planning system was proposed in [3] to navigate a robot car on flat surface among static and moving obstacles. It used extended backpropagation through time algorithm. Their algorithm worked well only for slow moving vehicles as the computation speed of their proposed model was quite less. For navigation and control of a robot movement in a semi known environment, an integrated system was developed in [4]. A path-planning algorithm was proposed in it. Here a neural network was used to automatically build up the collision penalty function. The training procedure used the information of the environment to avoid obstacles but because of its gradient character this model meets the local minima problem and thus accuracy of this model was affected. On the basis of experiences shared by human drivers, a vehicle control system was developed in [5]. The proposed system used neural networks to learn from examples in order to identify navigable and non-navigable region. A neural network based sequential machine learning technique for autonomous spacecraft navigation was proposed in [6]. It fixated on the amendment of precision of the multiple inputs used. Neural networks in [7] were tried to control the robot to reach a particular target location in urban changing scenarios. The robot had to rely on GPS and compass sensor to navigate. It was showed that neural controller with separated hidden neurons connected to specific inputs only outperformed the fully connected input-hidden networks by providing a faster response there by laying stress on importance of selecting right architecture. An architecture based on a neural network named as QMDP-net was created in paper [8] for planning under partial observability. This network had the capability to combine the strengths of model-free learning and model-based planning. It involved a deep recurrent policy network that embeds POMDP structure priors for planning under partial observability. In general, neural networks inherit the capability to map the inputs to outputs. In contrast the QMDP-net is trained in two aspects related to modeling and solving planning task. This approach had problem in handling of huge state space representation and its counter effects on the working speed of the model. On the basis of uncalibrated spherical images, a lightweight robot navigation framework was proposed in [9]. It used Convolutional Neural Network to overcome the problems in conventional algorithms, such as intense computational complexity in the testing phase and difficulty in collecting high quality labels in the training phase. The robot navigation task is formulated as a series of classification problems based on uncalibrated spherical images. A practical system related to autonomous navigation of a quadcopter was proposed in [10]. It had the feature of indoor navigation which enabled it to find any kind of target. It used a deep learning model, Convolutional Neural Network (ConvNet), to learn a controller strategy so that it can reciprocate the driving of an expert pilot.

Literature Survey revealed that though the neural networks in conjunction with other methods have been used actively in navigation systems, still the working speed and accuracy of the models have lagged the attention of researchers and need to be worked upon .Moreover the input to the neural networks play a major role in the accurate predictability/decision of the system under construction so the correct choice of input dataset is of utmost importance

III. Materials and Methods:

Any automated motion planning and navigation system needs a data collection system, a decision-making system to depict the next action of driving vehicle in real time. Decision to navigate or not depends on topological, geometric and texture features of road. Based upon these features, the decision-making system is expected to take decisions just as a real human being. For this the processing capabilities of human brain should be inseminated into it. Neural Networks, a machine learning approach comes to rescue as it is inspired by the way in which the brain performs a particular learning task. The proposed algorithm presents a unified CNN framework to take intelligent and speedy decisions by overcoming the shortcomings of existing neural network-based navigation systems. Conv Net's were chosen over other neural networks as it uses variation of multilayer perceptions designed to require minimal pre-processing. It has capability to learn even without any prior knowledge or insufficient data. Without increasing complexity, it can look into all the possible

variations before taking any decision, thus its prediction can be sought as realistic one.

The Proposed algorithm comprises steps related to database acquisition and getting the best features using a best feature selection model and further the unification of this model with Principal Component Analysis technique.

A. Database Acquisition and Selection of Best Features from Navigation Images:

- The images related to motion planning like roads, buildings, vehicles, signs etc. were collected and detailed texture analysis of images was done. A database of thirty-six metrics for hundred images was created by using SGLDM, GLDM, FOS, FPS, FDTA, SFM, and Texture Energy Measures. The extracted attributes were taken into consideration to find the next action of moving vehicle that is either "Move" or "Stop". The search space is but obviously going to be very huge and needs to be cut short.
- To get rid of irrelevant features and thereby improve the response time and reducing the costs, A Best Feature Selection Model [1] was created. This model selects out the best features having direct impact on the navigation decisions and removes the outliers.
- The features being extracted from Best Feature Selection Model namely Correlation, Sum Entropy, Entropy, Difference Entropy, Information Measures of Correlation, Kurtosis, Contrast Measure, Average Texture Energy from LE and EL kernels, Average Texture Energy from LS and SL kernels, Fractal Dimension Texture Analysis Area () are fed as input to neural networks.

B. Unified Model

Unification of both Best Feature Selection Model [1] and principal component analysis technique (PCA) is done so as to finalize the most relevant neural network inputs to be feeded into CNN framework to achieve better accuracy. A Convolutional Neural Network is a Deep Learning algorithm. It is strong enough to take decisions by assigning importance like weights and biases to various features of the images present in the image database. Furthermore, it has ability to classify and cluster the patterns on the basis of its learning during the training duration. CNN's have remarkable ability to get in depth knowledge upon a focused area and thereby it can take strong decisions. To have a limit on the input search space, the most relevant dataset is selected and the outliers are removed. The network inputs are minimized using the techniques like Feature extraction, Principal components analysis etc. PCA improves our knowledge by providing intelligent insight into the information from input features by computing covariance among them. It gives independent and different combinations of features to describe data differently and thus helps to find out important features by revealing previously unsuspected relations and thus adding more uniqueness to the proposed system. Figure 1 shows the flowchart of proposed algorithm. Here, we have extracted five features from PCA technique. Three scenarios were created using different combination of input feature sets for the CNN framework. The corresponding neural network input set for three scenarios are as follows:

- Eleven features obtained through Best Feature Selection Method
- Five features obtained from PCA
- A combination of Best Feature Selection Method and Principal Component Analysis

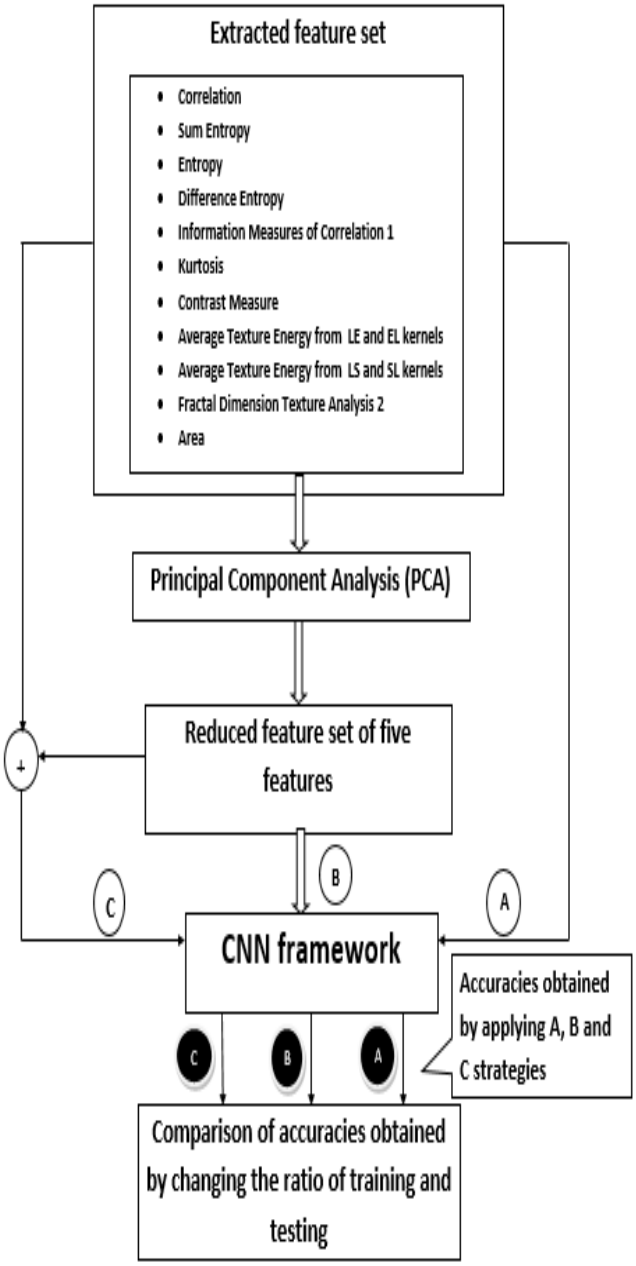

Figure 1: Flowchart of proposed Algorithm

Furthermore, we need to find the appropriate ratio of training and testing of neural networks.

Figure 1 clearly represents three approaches A, B and C to get accuracies for different ratios of training and testing for a dataset of eleven features, five features and sixteen features respectively.

The training time has direct impact on the speed of the any neural network system so we need to calculate minimum training time required by the network in such a way that it has no negative impact on accuracy of the model.

IV. Experimental Set up & Results

The algorithm was run in MATLAB for three different scenarios. Experimental Set up of CNN Framework in MATLAB tool is as follows in Figure:2. Here we have taken example of 16 input features whereas the outputs are limited to two in all the three cases. The number of hidden layers has been taken as 16 in all the scenarios. The performance metric being judged here is Mean Square Error.

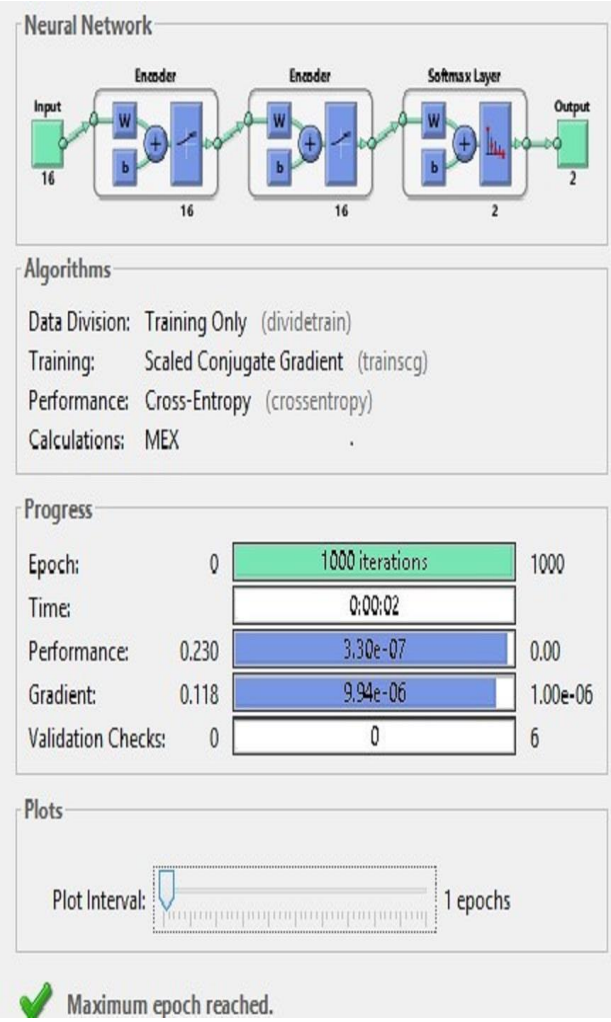

Figure 2: Experimental Set Up of CNN framework

As the training time has direct impact on processing speed so appropriate ration of training and testing needs to be calculated. Here we have assumed the training ration to be in the range of ten to seventy. Outside this range, the model will be under the effect of undertraining or overtraining.

We calculated accuracies of decision that is either to move or stop using different feature sets as inputs for convolution networks. Table 1 shows the accuracies by taking 11, 5 and 16 features as inputs for Convolutional Neural Networks. Figure 3 shows the graphical representation of change in accuracies with respect to training percentages.

Table 1: Accuracies in different scenarios

Accuracy Percentage obtained by using different input feature sets as Convolution Neural Network inputs			
Training Percentage	Case A: 11 features	Case B: 5 features	Case C: 16 features
70	66.6667	70	76.6667
60	67.5	72.5	77.53
50	68	68	80
40	73.3333	73.3333	75
30	68.5714	70	72.85
20	71.25	72.5	75
10	73.3333	73.3333	76.6667

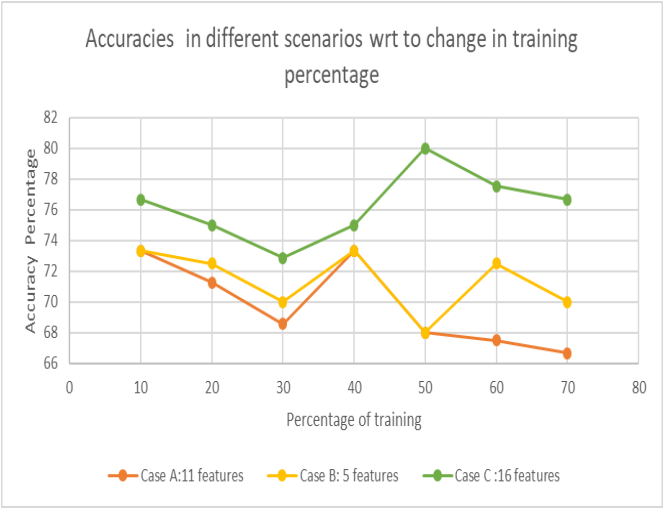

Figure 3:Accuracy graph

Furthermore, true positive rate (that is moves that are correctly identified) and false positive rate (that is moves of vehicle that were incorrectly identified) were calculated and the AUC (Area Under Curve) graphs were plotted for all the three cases

: 5 features,11 features and 16 features are shown in Figures 4, 5 and 6 respectively. The graphs further assert the previous accuracy graph and justifies that the results with sixteen features are more superior than standalone performance of CNN framework with five features and eleven features input datasets.

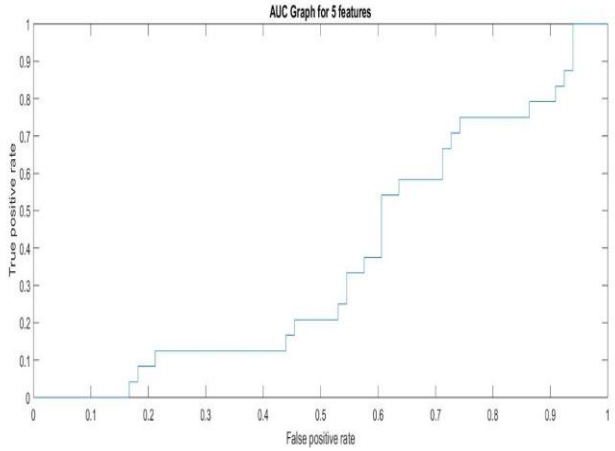

Figure 4: Area Under Curve(5 features)

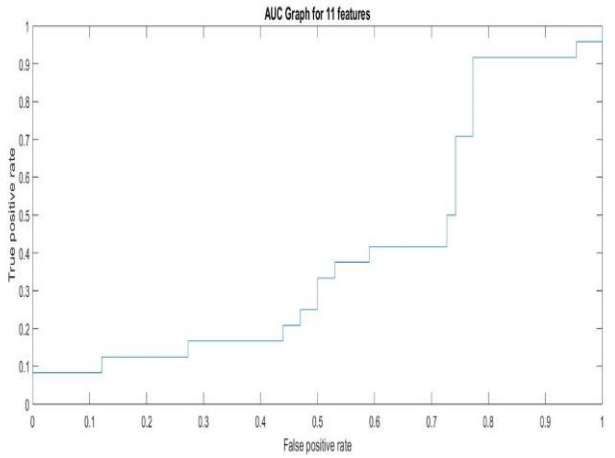

Figure 5: Area Under Curve(11 features)

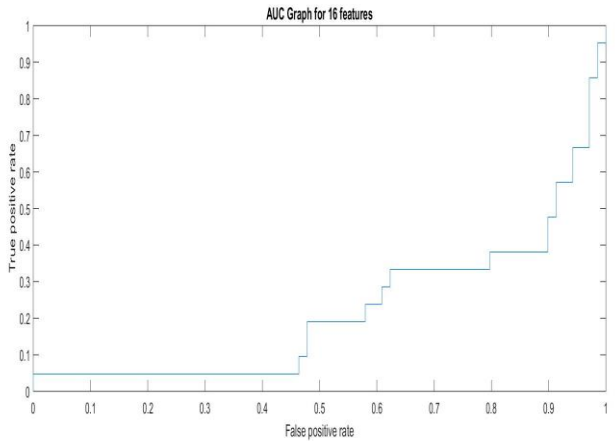

Figure 6 :Area Under Curve (16 features)

V. Discussions and Conclusions:

It was analysed that the combination of five features obtained from PCA and eleven features obtained previously from Best Feature Selection strategy have yielded better accuracies as compared to their standalone performance .This shows that PCA discovered previously unnoticed relations ,thus covering the dataset at full length .Its combination with inputs from Best Feature Selection Method provided improved information for the proposed model and paved way for better accuracies. Furthermore, it was noticed that the results for this feature set combination are same for ten percent and seventy percent training. This indicated that the ability of CNN to learn from imprecise data and finding out all variations before taking any decision makes it able to train itself well with ten percent training only. Thus, this model helps to achieve better accuracy rates even by training the model with only ten percent of dataset.

***Abstract*—Speckle alludes to the granular models that occur in ultrasound images because of wave impedance. Speckle expulsion can extraordinarily enhance the deceivability of the basic structures in an ultrasound image and upgrade resulting post-handling. A structure for speckle removal dependent on fuzzy logic algorithm. The noise present in the image can coat and diminish the visibility of specific attributes of the items present inside the images. Subsequently making it unfit for further upgrades. There has been an examination on the de-noising filters for long to expel the noise from images. In this research, we propose a unique method which beats outstanding techniques.**

Keywords—Image processing, Noise reduction, Fuzzy logic, Ultrasound images.

I. INTRODUCTION

Unique image de-noising techniques [1]–[4] using dissimilar channels recommended and executed in previous decade. A few straight and furthermore non-direct channels [5], [6] have been actualized for image de-noising reason utilized for various applications. Medicinal images [1], [7] are currently utilized for diagnosing the ailments in every single present-day clinic in regard to location of variations from the norm in human body with the help of a radiologist. Here, Medical images are accomplished using therapeutic imaging frameworks that give the data about the life systems, physical and metabolic exercises of different pieces of human body.

The discovery and expectation of imaging is getting simpler by the headway in the innovation. The snappy improvement is a result of the necessity for more quick, exact and less meddlesome treatment. Trend setting innovation in radiologic imaging rigging has also stimulated the utilization of imaging. The higher assurance comes at the expense of a consistently growing typical number of patients. The growing number and nature of the pictures cripples to overwhelm radiologist's capacities to interpret them. In various certifiable radiologic practices, automated and smart images examination and technique [8].

Ultrasound imaging is a standout amongst the most broadly utilized imaging advances in drug. This imaging methodology has accomplished incredible patient acknowledgment since it is sheltered, quick, effortless and generally modest when contrasted and the other imaging modalities. It has the extra favorable position of convey ability and might be utilized at bedside, which is exceptionally helpful for emergency unit. Ultrasound gives gritty imaging of delicate tissues that is normally clouded in X-beam images. Not at all like other tomographic methods, has ultrasound imaging offered intuitive representation of the basic life systems progressively [9]–[16].

A. Speckle Reduction Techniques

Filter has critical job in image de-noising process. Utilizing filter system, so as to choose specific estimation of pixel in yield image the neighbor pixels additionally take an interest. A few techniques have been utilized to decrease the speckle impact on ultrasound images. It comprises of a window moving over every pixel in the picture and applies a scientific count and substitutes for the estimation of the focal pixel under the window. The window moves along the picture one pixel at any given moment until it covers the whole image. The section below shows the different filtering techniques used widely in the literature.

- Mean Filter - It is a conventional technique for separating. A mean channel [14] follows up on an image by smoothing it. i.e., it decreases the variety as far as force between adjoining pixels. The mean filters are a key moving window moving filters, which replaces the middle an inspiration in the window with the common of all the neighboring pixel respects including that inside respect. It executed with a convolution shroud, which gives an outcome that is a weighted total of the estimations of a pixel and its neighbor pixels. It is known as a straight channel. The spread or bit is a square. Conventional channel approach is neighborhood average technique. The focal thought of this method is to supplant lessen scale estimation of the middle pixel by run of the mill estimation of neighborhood pixel diminish scale. It used to diminish AWGN, yet it can cause obscuring impact.
- Median Filter - The median filter is performed by taking the degree of most of the vectors inside a cloak and orchestrated by the degrees. The pixel with the center significance is then used to displace the pixel pondered the center channel is appointed an immediate channel. It works exceptionally to cover the Salt and pepper racket. A middle channel goes

under the class of nonlinear channel. It is like way looks for after the moving window standard, similar to mean channel. A 3× 3, 5× 5, or 7× 7 bit of pixels moved over the whole picture. First the focal point of the pixel respects in the window is taken care and a short time later within pixel of the window is superseded with the figured center regard. Check of Middle is done as first masterminding all the pixel regards from the incorporating neighborhood.

II. FUZZY RULES

The histogram adaptive fuzzy (HAF) filter is especially powerful to expel profoundly indiscreet noises while ensuring edge sharpness. This is rehearsed through a fluffy smoothing channel created from a ton of fluffiness In the event that made from a lot of fluffiness If rules, which substitute adaptively to control the yield mean squared goof as information histogram estimations change. A calculation is to use (debased) input histogram to pick parameters for the close-by impeccable comfortable intrigue limits. Advancement of the HAF channel incorporates three phases: (1) describe cushioned sets in the data space, (2) manufacture a ton of On the off chance that norms by combining input histogram experiences to outline the feathery support limits, and (3) assemble the channel subject to the course of action of standards. Not at all like various neuro-soft or fuzzy neuro channels, where a subjective strategy is used to pick starting enlistment capacities with respect to coming about extended getting ready, HAF can achieve close perfect execution with no preparation.

A. Technique

For the issue of excitement here, we expect an info dark image estimated 512×512 and a pixel power from 0 to 255. With flexible histogram approach for instance Histogram Versatile Channel (HAF), a fluffy method of reasoning-based procedure proposed to remove noise from innovative images. In this technique, we pick whether a pixel is disorderly or not established on the power of the pixels including the given pixel. For the said errand, we structure a fuzzy interface framework (FIS) that takes two wellsprings of information and produces one yield as showed up in Figure 1. The fundamental data taken by the FIS is qualification of within pixel and the pixel vertically on a dimension plane going before it. Second data within pixel and the pixel vertically on a dimension plane succeeding it. Figure 2. shows work publication supervisor for the FIS. Sugeno sort out is used to make the fuzzy measures.

Figure 2. demonstrates the rule editor for MATLAB tool. The pixel is viewed as an uproarious pixel whenever input 1 and information 2 i.e.; the distinctions of focus pixel with its neighboring pixels is higher. There are 49 rules executed in our work as appeared in the standard editorial manager.

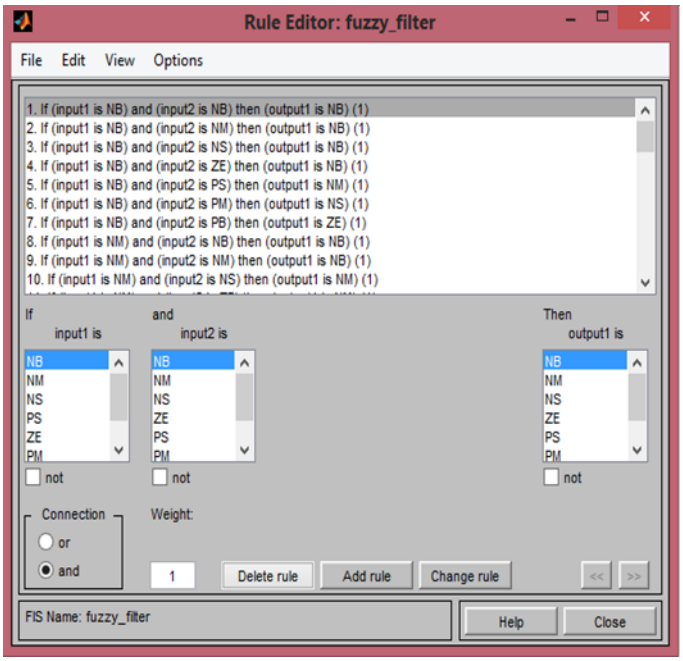

Figure 2. Rule Editor

III. PROPOSED WORK

The proposed work will give the effective filter, which expels the noises from dim scale image, and function admirably than other existing methods. To expel more than one noise from image, essential conventional that is established filters, mean filter and middle filter are joined. The proposed strategy fuses the fuzzy rationale procedures alongside the customary direct and nonlinear channels which makes it adaptable and thus ready to diminish more than one kind of noise.

The noise present in the image can coat and decrease the detectable quality of explicit characteristics of the articles present inside the image. Consequently, making it unfit for further updates. There has been an investigation on the de-noising channels for long to oust the noise from image. In our proposed the fuzzy set up channels which empties more than one kind of commotions from pictures. Traditional mean and center channels joined to empty more sorts of noises. Execution of the channel is differentiated, and various channels and the proposed technique beats existing methodologies. The

work proposed here related to the headway of a novel fluffy histogram versatile channel to diminish noise from automated images. The proposed procedure is better than other surely understood traditional strategies accessible for a similar reason. Fuzzy set is crisp sets calculated applying certain conditions corresponding to fuzzy set. This process known decussation. The field of the restorative image de-noising is extraordinary accentuation in different uses of ultrasound images. The aim of our proposed work are as follows:

- To remove the noise from an ultrasound image.
- To improve the accuracy.
- The algorithm used in proposed work are fuzzy logic alpha trim.

The proposed work is based on the fuzzy logic algorithm that works on the basis of fuzzy rules. They consist of two networks namely; mamdani and sugeno networks. With the help of these networks fuzzy rules are created. There are 49 rules IF-THEN that works based on various membership functions. The Mat lab codes works as initialize the screen and read the input image, if image is rgb convert that into gray scale and after add speckle noise to the input image. With the help of sugeno based network edges are weighted as linguistic variable and detect the resolution of the particular image. Update the mean and median values and also calculate the performance parameters. Thus, by PSNR values are compared with the existing system.

A. Step by Step Procedure

With the help of fuzzy logic algorithm, the following steps are followed:

Step-1: Input image and reads

Step-2: Adding noises in Input Image

Step-3: Create the fuzzy logic-based network

Step-4: Fuzzy Membership function is defined i.e. F(i, j)

Step-4: Calculate the weights of Edges in Image

Step-5: Restoration term for detected noise pixel is computed at Edges using Fuzzy Rules.

Step-6: Delete the d/2 largest and d/2 smallest grayscale values.

Step-7: Take Median for rest of grayscale values.

Step-8:Update the median values for every rows and columns.

Step-9: Reconstruct the de-noised Image

Step-10:Calculate the performance parameters like MSE,PSNR,SC,etc.

V. CONCLUSION

It is obvious from the outcomes area that the proposed procedure beats the outstanding de-noising channels called Mean channel and fuzzy channel. The proposed method, as it depends on fluffy rationale, is knowledgeable in dealing with the dubiousness of information contained in noisy digital images. Both quantitative and qualitative assessments on different manufactured and clinical images show that our strategy can adequately evacuate speckle and better save highlights contrasted and the cutting-edge de-spotting procedures. This procedure has improved the noises evacuation execution and reclamation systems. The proposed technique's performance is observed through computing de-noised images' PSNR value.

In future, segmentation comparison can be done different algorithm can be used to achieve better results. This work can be additionally improved to de-noise the other kind of images, too, as RGB, Indexed and Binary images.

***Abstract*—Computer vision methodologies has been predominantly used for solving number of problems related with pattern recognition, machine vision, object detection, object classification and many more. This terminology along with soft computing approaches have proven to be a solution for various complex problems. But, in recent time it has been noticed that when conventional methods incorporated with optimization methods, the result achieves higher accuracy and also lessens the computational time. These Nature inspired algorithm (NIA) or Bio-inspired methods have been espoused in the number of applications for finding an accurate solution working with real-time or complex data. Image segmentation is one of them. It is the practice of separating an image into its constituent subparts in order to extract some meaningful information from it. There are number of methods used for performing segmentation. In this paper our aim is in studying one of the optimization method named as Bacterial Foraging Optimization Algorithm (BFOA). This method is then used for initializing the weights for Artificial Neural Network (ANN) that is deployed for image segmentation. Finally, when the results are compared with the other methods shows the efficiency BFO-ANN method.**

Keywords*—*Bacterial Foraging Optimization, Image segmentation, Image processing, Nature inspired algorithms.

I. INTRODUCTION

In image processing, image segmentation or object extrcation is the preprocessing and important step frequently used in the number of applications for partitioning an image in extracting a meaningful region of interest or object from given the images. It further helps in making an image easier to analyze and interpret useful information. This process of partitioning an image is carried out based on some homogeneous characteristics of an object. The level of segmentation is the process to be carried out until the desired object has been segmented. The application of segmentation can be found in medical images for the segmentation of tumor from magnetic resonance images, pedestrian segmentation from the real-time images, land-water segmentation from satellite images, disease segmentation from the agricultural images, handwritten digit or character recognition etc.[1]-[5].

Image thresholding is the most simple and commonly used process for separating an image into its consequent parts background and foreground (i.e. object or region of interest). This process is carried out for binary images depending on the thresholding parameter known to be T. Each pixel whose values are less than to threshold value T will be assigned to black pixel (background) and pixels greater than T value will be assigned to the white pixels (foreground or object). Finding an optimal thresholding value for partitioning an image is a complicated task to perform. This threshold value is varied until the desired region of interest has been segmented [2][4]. More importantly, it is a major concern when performing multilevel image thresholding. That is when segmentation has to be carried out for partitioning an image into different regions of interest or extracting multiple objects. In this case, optimal various threshold values have to be chosen for extracting multiple objects.

Generally, bi-level or multilevel segmentation is carried out with the help of Kapur or Otsu entropy functions. These functions are depended on the

evaluation of the histogram information and objective function for generating an effective optimal value. But this process results in enhancing the computational burden when opted for multilevel thresholding values generation. Nature-inspired algorithms have shown great efficiency in providing an optimal solution in solving the number of complex problems. The heuristic algorithms like Artificial Bee Colony, Cuckoo Search, Genetic Algorithm, Firefly Algorithm, Particle Swarm Optimization, Bacterial Foraging Optimization etc. has been effectively applied in solving the thresholding problems [2][4].

Some of the work includes in [6] Artificial Bee Colony (ABC) is used for searching optimum cluster centers for Fuzzy c means algorithm, in [7] for maximizing different objective functions of methods like Kapur's entropy, Tsallis entropy, Otsu's method, Shannon entropy, Renyi entropy the optimal thresholding value is calculated by using Bat Algorithm (BA), in [8] Crow Search optimization Algorithm (CSA) is used to find out the centroid of the clusters for the Fast Fuzzy C Means algorithm, in [9] the weight of the Feed Forward Neural Network is rationalized by Genetic algorithm (GA) for stated iterations, in [10] Spider Monkey Optimization (SMO) is used for the purpose of feature selection, in [11] RBF Network is optimized for the structure selection using the GA and Particle Swarm Optimization (PSO), in [12] have used bacterial foraging optimizing algorithm for assigning the weight to the feedforward neural network, in [13] PSO is used for the training of backpropagation network, in [14] Ant colony optimization is used for selecting best discriminant features improving results using support vector machine, in [15] used Firefly Algorithm (FFA) is used for the optimal number and center selection of the Radial basis function network, in [16] Whale Optimization Algorithm (WOA) is used for dividing the image into predefined cluster, and so on.

These optimization techniques result in improving the accuracy of the results and also reducing the computational efficiency of the proposed system. Therefore, this work aims in studying and presenting various applications of one such nature-inspired algorithm known as BFOA for the segmentation of images. Followed by introduction in section 1, section 2 presents the literature review with outcomes, in the next section 3, the concept and theory behind the BFO are introduced, section 4 presents the results, and section 5 concludes this article followed by the references.

II. RELATED WORK

The various studies related with the image segmentation or object extrcation incorporated using Bacterial foraging optimization algorithm are listed in Table I.

TABLE I. LITERATURE REVIEW

Authors	Applications of Bacterial Foraging Optimization Algorithm (BFOA)	Year
Mohammad Mahdi Dehshibi et al. in [1]	For improving the accuracy of the segmentation the optimum parameters of Otsu and Kapur functions are calculated.	2017
Nandita Sanyal et al. in [5]	In this work, the BFOA has been used for optimizing the fitness function of fuzzy entropy. During the foraging of bacteria in exploration or exploitation state the algorithm varies the run length unit parameter. This causes the movement of bacteria between exploration or exploitation state during the execution phase.	2011
Ismail Ahmed A. AL-Hadi et al. in [12]	BFO is used for the learning process of the Feedforward neural network to increase the convergence rate and accuracy. The best bacterium members representing the optimum weights are used with the testing of network for calculating the errors of the weights using different data patterns.	2011
Kezong Tang et al. in [17]	Authors have worked on improving the solution by enhancing global searching ability the convergence rate of the algorithm. So, in this work for obtaining the optimal values the Tsallis thresholding functions are maximized.	2017

A. OUTCOMES

Bacterial Foraging Optimization (BFO) algorithm has been adopted in number of applications in image processing. This includes multilevel segmentation for color images, face recognition, lip segmentation, classification and identification of diseases from plant leaf images, segmentation of pedestrian and many more. It has been observed from the literature that optimizing the algorithm with the help of BFO results in better segmentation results. This confines the computational burden of the algorithm being used thus increases the efficiency of the algorithm when compared with the other optimization algorithms. Some of the features of optimization with BFO are given as under:

1. Finding the optimum parameters (thresholding values) for the functions like Otsu and Kapur results in improving segmentation performance.

2. Selection of optimum weights or initial weights helps the learning process of the neural networks, thus achieving higher convergence rates and accuracy.

3. With the help of optimization, the cluster heads or optimal cluster values are obtained for the methods like Fuzzy C Means or K-Means.

4. BFO has been used for finding the best feature subset from the database.

5. BFO has been used to find the edges of an object by the letting movement of bacteria placed at the rich nutrient location that is boundaries.

III. STANDARD BACTERIAL FORAGING OPTIMIZATION (BFO)

Animals when compared with a high sense of foraging, animals with a low sense of foraging behavior are having the high probability to extinct. *Echerichia coli* (*E.coli*) bacteria have one such imperative and captivating activity of food searching. They have the property of moving in the direction of food or nutrients without actually coming close to other cells and also avoiding the other noxious matters. Proposed by Kevin Passino (2002), BFO algorithm is a nature-inspired algorithm stimulated by the group foraging behavior of bacteria like *Echerichia coli*. The

bacteria searches for the nutrients in the search space taking small steps moving towards or away from the signal engendered. Initially, this method was developed for distributed optimization and control, but later it has confirmed to be an effective optimization solution in the number of real-time applications for improving convergence speed and accuracy [17]-[19]. BFO can be summarized in four basic steps given as [19]:

1. Search for the nutrient or food rich location.

2. Choosing whether to enter into the existing rational nutrient location or not.

3. If new nutrient location is entered then accomplishing thorough and careful foraging.

4. After consuming some nutrient or food then deciding, whether to enter into the new nutrient-rich location or continue in the same location.

These four basic steps are abridged into four stages known as 1. Chemotactic, 2. Swarming, 3. Reproduction, and 4. Elimination or Dispersal [17]-[19]. Following we will briefly describe the mentioned stages

1. Chemotaxis: This is the first phase of the algorithm. In this phase, the bacteria (*E. Coli*) starts tumbling to change its direction for period of time. After this initial step, the bacteria are moved to a step size. At this point if the bacteria finds rich nutrient location then it will keep swimming in the same direction otherwise it stops. Mathematically, if we consider that θ is the position of bacteria E.coli and $\theta^z(a,b,c)$= z^{th} bacterium in a^{th} chemotaxis, b^{th} = reproduction, c^{th} = elimination – dispersal method. Then the tumbling is given by the equation:

$$\varphi(z) = \frac{\Delta(z)}{\sqrt{\Delta(z)^T \Delta(z)}} \tag{1}$$

where $\Delta(z),\ z = 1, 2, \ldots S$ is a random vector. Each element $\Delta_m\,(z), m = 1,2, \ldots, p$ of $\Delta(z)$ is a random number between -1 to 1. S is the number of bacteria. The bacteria updating equation is given by

$$\theta^z(a+1,b,c) = \theta^z(a,b,c) + C(z)\,\Phi(z) \tag{2}$$

where $C(z), z = 1,2, \ldots, S$ is the moving step size in the swimming phase [17] [18].

2. Swarming: Swarming is the process of signaling or passing messages between cell to cell. This has two possible scenarios first if a bacteria founds nutrient rich location then it passes the signals or chemical substances attracting other bacteria and in the second case if no nutrient is found and bacteria starts dying the they release signal to repel from that bacteria or location. This behavior of the bacteria is given by the following equation.

$$J_{cc}\big(\theta,\ \theta^z(a,b,c)\big) = \sum_{z=1}^{s}\left[-d_{attract}\exp\left(-w_{attract}\sum_{f=1}^{p}(\theta_f-\theta_f^z)^2\right)\right] + \sum_{z=1}^{s}\left[h_{repellant}\exp\left(-w_{repellant}\sum_{f=1}^{p}(\theta_f-\theta_f^z)^2\right)\right] \tag{3}$$

where $\theta = [\theta_1, .., \theta_p]^T$ = bacterium optimization domain, θ_f^z = f^{th} component of the z^{th} bacterium position θ^z. $J_{cc}\big(\theta,\ \theta^z(a,b,c)\big)$ = cell to cell communication value that is to be added to the result of the fitness function in the chemotaxis phase j. p = number of problem dimension, S = number of bacteria, $d_{attract}$, $w_{attract}$, $h_{repellant}$, and $w_{repellant}$ = the different coefficients which represents the strength of attraction or repulsion. Considering the swarming effect the fitness value of z^{th} bacterium [17] [18] is given by

$$J\,(z,a,b,c) = J\,(z,a,b,c) + J_{cc}\big(\theta,\ \theta^z(a,b,c)\big) \tag{4}$$

3. Reproduction: After chemotactic steps (N_c), reproduction step is initialize. Let us assume that S be a positive even number, so S_r is the number of population that splits or reproduce into two having rich nutrient value. Given by

$$S_r = \frac{S}{2} \tag{5}$$

The accumulated cost of the bacteria is given by its health. When the accumulated cost is higher it means that the bacteria does not receive enough nutrients during its lifecycle of foraging. This means that the bacteria is unhealthy and will not get reproduce. The bacteria are then sorted according to their health in

descending order starting from the S_r least bacteria to S_r healthiest bacteria. In this process, the least bacteria dies and healthy bacteria splits into two and placed at the same location [17] [18].

4. Elimination or dispersal: Because of the abiotic factors like rise in temperature some bacteria tends to die. This process has been replicated by the elimination or dispersal of some bacteria with a probability of P_{ed}. On the other hand there is possibility of random generated bacteria for replacement [17] [18].

IV. RESULTS

The results were evaluated working on a system with 4GB RAM, i3 processor, 1TB HDD with the MATLAB 2017b environment. A real time dataset has been acquired for the images consist of about 240 images. First, the collected images has been preprocessed and divided among the training and testing dataset. Then for the segmentation work, we proposes an amalgamation of neural network with nature inspired algorithm for image segmentation. For this purpose a simple artificial neural is considered whose initial weight and training procedure has been optimized with the help of bacterial foraging algorithm. The plant leaf images are collected randomly for evaluating the performance of the proposed framework. Figure 1 shows the segmentation performance of the proposed work. The results are compared with k-means and ANN for two evaluation parameters known as Dice Similarity Coefficient (DSC) and Jaccard Coefficient (JC). Table II shows the segmentation results.

TABLE II. RESULTS FOR DIFFERENT METHODS

Images	**Image 1**		**Image 2**	
Algorithms	DSC	JC	DSC	JC
k-means	0.7579	0.7614	0.7618	0.7520
ANN	0.8012	0.8111	0.8137	0.8145
BFO-ANN	0.8679	0.8596	0.8522	0.8539

V. CONCLUSION

This work presents, the importance of optimization technique for image segmentation. Bacterial Foraging Optimization is one of the best optimization methods belongs to the family of nature-inspired algorithms. This approach of finding an optimal solution has overcome the computational overhead and also improves the performance of the algorithms or methods. This hybridization of the bio-inspired algorithm also overcomes the problem of traditional approaches in dealing with complex data. Thus for attaining higher convergence rates and accuracy, it's been noticed that an optimization phase has to be espoused.

***Abstract*— In this paper, we have proposed high speed Advanced Encryption Standard (AES) hardware architecture by using parallelism in the process. National Institute of Standards and Technology (NIST) cases are predefined inside the module will be selected by test case bits, according to test case bit selection, the key and input will be selected, and module generate corresponding output and clock cycles reduces to 44 cycles. AES Algorithm synthesized using VHDL Code and targeted into FPGA. For Synthesis and Simulation Xilinx Design Suit Version 14.7 is used. The design has been Successfully tested on ARTIX-7 FPGA.**

Keywords*— NIST, AES, VHDL, FPGA, ARTIX-7.

I. INTRODUCTION

The Advanced Encryption Standard (AES) is an authorized cryptographic algorithm which can be used to secure delicate digital information that are sensitive. AES algorithm has used for Encryption and Decryption of information. The algorithm is designed to use 128, 192, 256-bit cryptographic keys to encryption and decryption information. Before AES, the Data Encryption Standard (DES) was standard for encryption [1]. The innovative way to implement algorithm on hardware speed and resource utilization has been main concern to researchers for implementing AES design. This structure includes a looping method with 128-bit block and key size. The AES algorithm implemented using VHDL coding in Xilinx 9.2 [2], throughput reaches in this implementation up to the value of 352 Mbit/sec for both encryption and decryption process with device XCV600 of Xilinx Virtex family. Another model has been coded in Verilog and synthesized on Quartus 9.0 (Model Sim) has latency of encryption and decryption process is 51 clock cycles each, throughput reaches to 1054 Mbit/sec and 615 Mbit/sec for respective process [3].

An implementation of high-speed algorithm based on FPGA; to improve the safety of data in transmission the design used parallel processing and pipelining approach, this design targeted on VIRTEX-5 FPGA [4]. The design shows the efficient use of inter-round and intra-round pipeline [5]. The architecture not store round keys and currently calculated accordance that AES algorithm used, this design is made to reduce hardware structure and used where low throughput is required [6]. A design has been implemented on Xilinx Spartan-3 FPGA and decrypts on PC, VHDL code synthesized by using Xilinx 8.2, uses 1403 slices and operates at 2059 Mbps (throughput) [7].

In proposed work, we are using Encryption block, Decryption block and clock generating block to simulate, synthesize and implement the architecture. Clock generation block generates limited number of clock cycle to operate overall architecture and it reduces latching problem in design. The architecture uses pipeline methodology and parallel processing to reduce time cycle.

The generic design and modified design are tested with NIST cases by comparing the result we can say that the design modification not affect the behavior of the architecture. This design is simulated and synthesized on Xilinx platform and implementation on Artix-7 platform.

II. PROPOSED DESIGN ARCHITECTURE

In proposed Design, Fig.1 shows the design of AES Block which contains 128-bit registers, Mux's, Flip-flop and counter, all these digital circuits have respective uses. The final output that of 8-bit LSB of 128 bits displaying in FPGA. Fig.2,3,4 and 5 are submodules of AES Block. Fig.2 describes the clock, how to generate in proposed design. Fig.3 is basis block of Encryption that have inputs and outputs have describes in submodules section. Fig. 4 shows Encryption process in AES, how these four operations (sub bytes, shift rows, mix column and add round key) performs in AES. Fig. 5 basic block of Decryption, encrypted output is decrypted. Fig. 7 shows decryption process.

The AES-128 module consists of clock generator circuit, encryption block, decryption block and key expansion block. The overall inputs to module are clock, reset, test cases (T2, T1, T0) and output are operation_done.

In this module NIST cases are predefined in registers and selected with the help of test cases (T2, T1, T0) through MUX logic. In a test case selection, accordingly data and key are selected and pass to the data and key register respectively. Data Register available to the Encryption block and Key Register available to Key Expansion block. Firstly, process start with reset pulse to reset the block and initial mode (00) is set after the AES_START is high which start clock generator to synchronize the module and with initial mode (00) key expansion process start, it expands key to ten unique key

which are used for encryption and decryption process. When the process has completed, it has indicated by OPERATION DONE pulse and mode change to 01 with the pulse. Encryption process start with mode (01), use data and key as input and process them for ten rounds to generate output (cipher data). When the process has completed, OPERATION DONE pulse is high and mode change to 10 with the pulse. Decryption process start with mode (10), encrypted data and key given as input and generate output. When the process has completed, OPERATION DONE pulse is high. At the last, decrypted last 8 bit shown in the FPGA LED's.

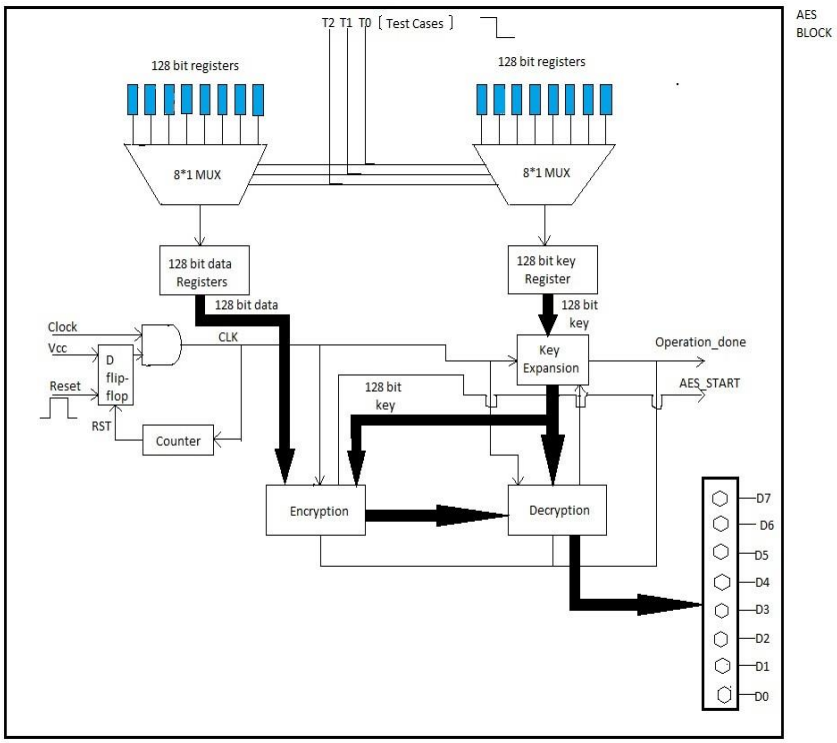

Fig. 1 – Design Architecture of Module

Above Designed Architecture to test the Encryption and Decryption module on one test bed with clock synchronization. After the modules perform Encryption and Decryption, the LSB bits (8 bits) of 128 plain text displayed on the FPGA board, to check authenticity of the architecture.

III. SUB MODULES OF ARCHITECTURE

1) *Clock Generator Circuit* :-

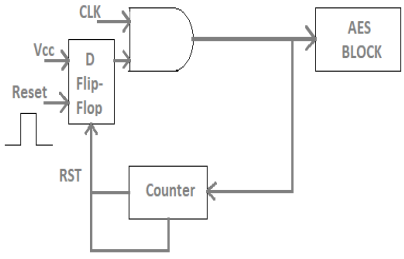

Fig.2 - Clock Generator

This circuit contains D flip-flop, AND gate and Counter. When RESET pulse high it works as Clock to D flip-flop and Set the output of flip-flop. The output of flip-flop is one of the inputs of AND gate and it allows to pass the Clock to AES Block and start the Counter. When the Counter reaches the set count it generates RESET pulse (RST) to reset the counter and flip-flop, it reset the output of flip-flop and clock to AES Block terminated.

2) *Encryption Block: -*

Number of rounds in AES process which depends on length of Key, for Key Length of 128 bit, rounds are to be 10. Key Length defined in Bytes. Using Rijndael's Key Schedule each round has separate key which is derived from Cipher Key.

In Encryption Block, Plain Text (data) and Key are given Inputs according to Control Signal. At time, when Key Load is active, Key Expansion block start processing the Key and generates Keys for 10 rounds of processing. Start

signal start the Encryption Process with synchronization of system clk

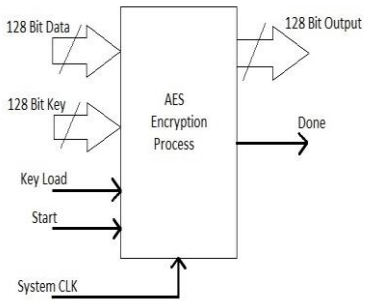

Fig.3 – Encryption Block

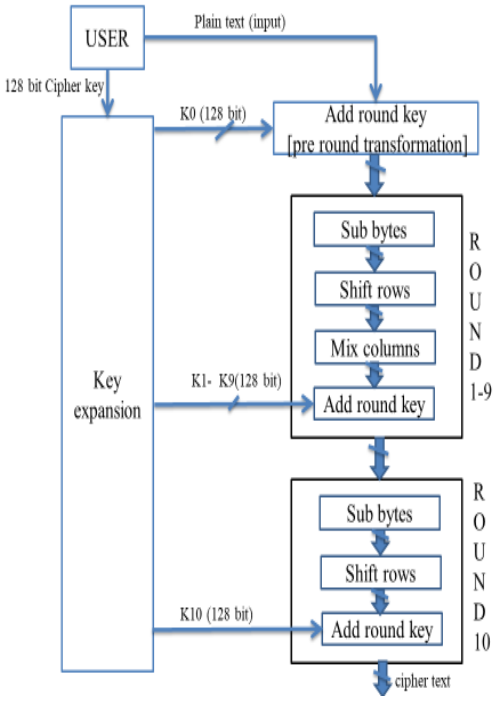

Fig.4 – Encryption Process

First Nine rounds of Encryption Algorithm consist of the following steps:

a) Add Round Key
b) Sub Byte
c) Shift Row
d) Mix Column

Tenth round of process does not have the Mix Column operation. According to Key Length Encryption Process performed by doing appropriate number of rounds.

Encryption Process run parallelly with Key Expansion block and Key Expansion block gives the current stage key to encryption block in synchronization with clk.

3) Decryption Block: -

In Decryption block, encrypted text and key are given as inputs according to control signal. When key load signal active, the Key Expansion block start processing the key and generate keys for 10 rounds of processing and start signal start the decryption process in synchronization with system clk.

There are four different operations are used in AES, out of these one is permutation and three are substitution.

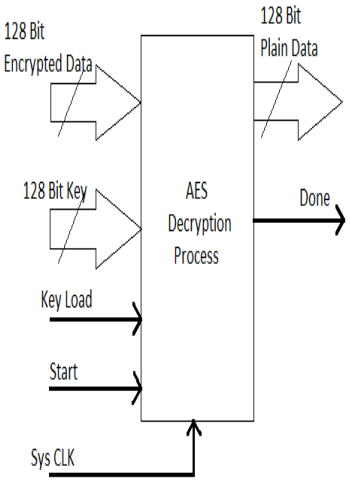

Fig.5 – Decryption Block

128-bit encrypted data and 128-bit key are inputs to decryption block, a part of that start and key load signals uses as inputs, system clock to run the overall process and timing utilization. 128-bit plain data are expected output and signal done uses as a output to complete the decryption. AES Decryption process block describes overall process in next section.

Decryption Process follows the same stages in reverse order.
The first nine rounds of Decryption Process consist of following steps:
a) Inverse Sub Bytes.
b) Inverse Shift Rows.
c) Inverse Mix Columns.
d) Inverse Add Round Key.

Tenth round does not have Inverse Mix Column Operation.

The Decryption Process run parallelly with Key Expansion block and key expansion block gives the current key to decryption block in synchronization with system clk.

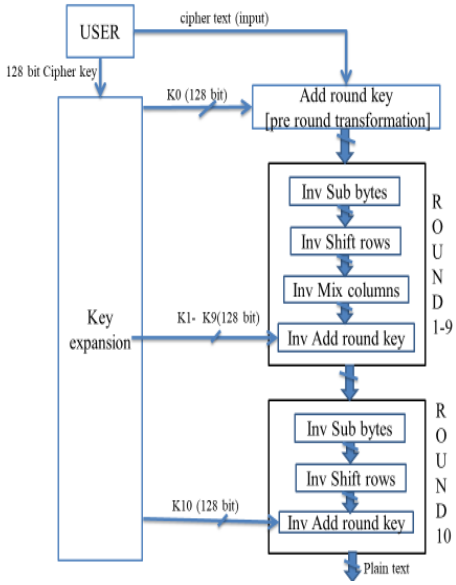

Fig.6 – Decryption Process

IV. RESULTS

FPGA Simulation results show the similarity between analysis and hardware representation. the details of Xilinx tools used tabulated below:

Family	Artix7
Device	XC7A100T
Package	CSG324
Synthesis Tool	XST (Verilog/VHDL)
Simulator	ISim (Verilog/VHDL)
Preferred Language	VHDL

Table 1 – Xilinx Tools Used

The Parallelism used in the architecture is such that the Key Expansion and Encryption block is operated in parallel with the delay of one clock cycle. Latency of Encryption and Decryption 51 clock cycle [3]. In new architecture, the latency comes down to 44 clock cycle

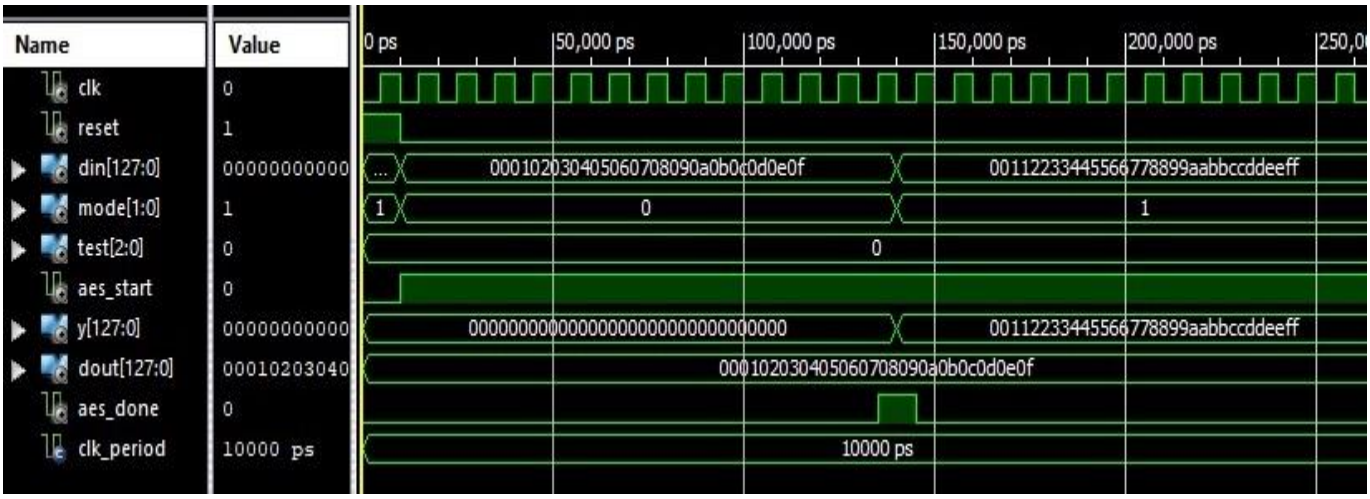

Fig.7 – Simulation Waveform of AES BLOCK

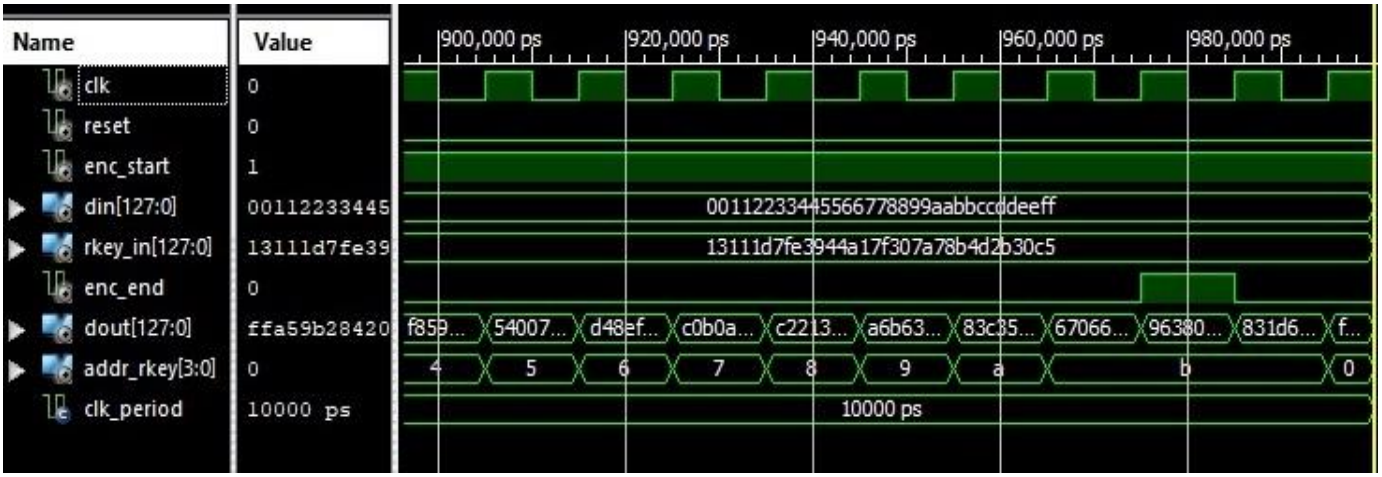

Fig.8 – Simulation Waveform of Encryption Block

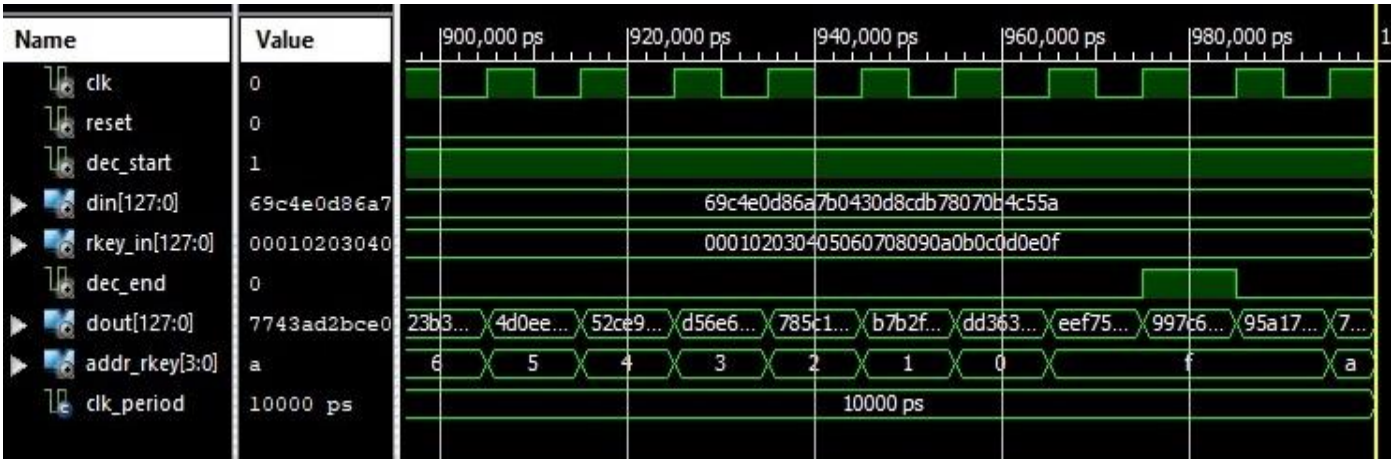

Fig.9 – Simulation Waveform of Decryption Block

Target Device: XC7A100T-3-CSG324 (ARTIX-7)
Timing Summary:

Speed Grade: -3

Minimum period: 3.659ns (Maximum Frequency: 273.289MHz)
Minimum input arrival time before clock: 4.431ns
Maximum output required time after clock: 0.668

Logic Utilization	Used Resources	Available Resources	Resource Utilization
Number of Slice Registers	811	126800	0%
Number of Slice LUT's	2814	63400	4%
Number of fully used LUT- FF pairs	718	2907	24%
Number of bonded IOB's	135	210	64%
Number of Block RAM/FIFO	2	135	1%
Number of BUFG/BUFGCTRLs	2	32	2%

Table.2 - Device utilization summary (ARTIX-7)

V. CONCLUSION

This design of AES – 128 Algorithm is Simulated and Synthesized by XILINX – ISE Software and got the expected results. This design is tested with ARTIX-7 board and device utilization summary shows maximum resources utilization, clock cycles reduces to 44, achievable frequency 273.289MHz. The main objective of paper is to reduces the clock cycles used by generic algorithm and efficient utilization of memory. In future, this algorithm can be further analyzed to make it faster by reducing clock cycles and make it more effective.

***Abstract*- There has been a rapid shift in the medical industry from the service point of view. More importance is being given to patient care and customer satisfaction than ever before. The need to keep the customers happy with the hospital's service has increased rapidly and one way they can improve a patient's experience, even more is if they integrate cloud, IoT, ML, and AI into their system. This would help the medical sector to achieve customization which would enable them to address the needs of their customers more efficiently and offering personalized solutions. In this paper, we are proposing a novel model which focuses on a smart hospital information management system that runs by using hybrid cloud, IoT, ML, and AI. This system would be beneficial not only from the hospitals perspective but also from the patient's side as well. Patients and doctors unique ID would make the entire process a lot more efficient and easier. The advances happening in the field of AI and ML due to cloud-based computing is extremely beneficial for the medical industry. By integrating these components along with IoT it is possible for multi-specialty hospitals and super specialty hospital to be able to set up a smart hospital information management system.**

***Index Terms*-Hybrid cloud, Internet of things (IoT), machine learning (ML), Artificial Intelligence (AI).**

I. INTRODUCTION

The boom of the IT sector has revolutionized the face of the entire industry ranging from retail to even our homes. The focus of this paper is on the medical field which is one of the prime sectors that transformed immensely after the implementation. With the dynamic and complex changes happening in the field of medicine it is extremely difficult to operate a multi-specialty hospital and super specialty hospital without a proper management system. Most hospitals in today's era are equipped with a hospital information system or HIS which helps it to manage the functioning of the hospital. This web-based system helps them to make the whole process paperless by integrating the data regarding the patients, staff, doctors, administrative detail, etc to one software.[1]

At present there are several hospital information systems available in the market however most of them are focused on the day to day functionality of the hospital.[2] These systems need to be updated to be more streamlined, reduce duplicate tests or procedure and automate the manual process.[3] This can be achieved with the help of our proposed system where the hybrid cloud-based system would help to link the public cloud which contains information regarding their patients to the private cloud i.e. the hospitals on-premises cloud server. This system would help the patients to have their medical records available in unique ID and as a result, reduce time-lag in providing previous records to physicians and the physicians will also be able to identify the possible problem the patient is facing faster and appropriate treatment can be given.[4]

The aim of this paper is to propose a smart hospital management system which is self-sufficient and acts as an assistant to both the administration and the patients with the help of the hybrid cloud, IoT, ML, and AI.[5] This system would focus on personalization and systemizing the entire process with the help of smart assist and unique ID of both the patient and doctor. There have been numerous attempts at setting up cloud-based systems and is being used by several hospitals at present. However, most of these systems are not being used to its maximum potential mainly because they haven't integrated AI along with IoT and used ML for furthering its scope. With the help of AI and hybrid cloud, they would be able to automize the entire administrative and management side of the hospital.[6]

It has become quite common nowadays to see doctors with hand held display devices like tablets and iPad containing patient information and treatment.[7] The data collected on these handheld devices are scattered and as a result incompatible however if this vast amount of data is combined and collected through these devices data can be cleaned and processed with AI and hybrid cloud. The system would automatically be able to detect the cleaning and filtering to be done once algorithms for machine learning are applied as well.[8] This way hospitals would be able to have access to a large database which would help them and the patients in numerous ways.[9] Mainly it will help to detect prevalent diseases in the community, virology status, and treatments for the same by using the database for running various tests and experiments.[10]

II.PRESENT SCENARIO AND RESEARCH GAP

The present scenario of this sector only focuses on the secure exchange of health information between the hospital, insurance providers and the patient.[11]

Electronic health records are starting to be viewed as an effective tool to improve safety, quality and organized health delivery system.

- Without the help of a hybrid cloud system, it is hard to expand access to healthcare in an affordable manner. [12]
- By implementing this system hospitals will be able to reduce overall healthcare cost and increase administrative efficiency.
- With the penetration rate for clouds increasing in this sector the scope is widening. Telemedicine is catching up in the market soon and this proposed model would make it, even more, user-friendly.[13]
- The volumes of data generated would be useful to have real-time figures to identify the medical challenges faced by the country as a whole.[14]
- Public cloud would prove to be a major boon to the healthcare sector. Being able to combine data from hospitals, insurance providers and other sources would make national health data readily available to carry out various analysis. [15]
- The major benefit of this system is it would help to reduce the number of medical errors and increase accuracy and productivity with the help of the unique IDs of the patients and it would also facilities to reduce the overall procedural correctness. [16]
- The proposed model focuses on these problems which can be tackled with the help of effective integration of hybrid cloud, IoT, ML, and AI.

III.PROPOSED MODEL

The proposed model is equipped with the following features- patients would be able to schedule appointments with respect to the availability of the physician, view the physicians performance rating, read previous reviews, and the physician, in turn, would be able to prescribe medicines to their patients with the help of medical inventory management, use smart assistance for analyzing test results, go through the previous medical records of the patient for a more accurate problem detection, suggest treatment plans and prescription assistance. (Fig 1.1) This has been explained in detail below:

A. Patient unique Medical ID

Each patient will be assigned to his or her own unique medical ID. This ID would comprise of the patients sleeping patterns, workout schedule, and other basic health data which would be made available through the patient's smartphones and their smart wearable devices. This would also give insights into the patient's previous doctor's prescription, appointments, diagnosis, test results, allergies and also the updated changes get automatically stored into the ID.

B. Doctor ID

Just like how every patient is assigned with a unique ID the doctors would be assigned with the same as well. Each doctor would hold a unique ID based on which a time schedule can be made which would be in accordance with the appointments being scheduled. This helps to ensure that both the doctor and the patients time is utilized effectively. The doctor's ID would also comprise of the doctor's performance records, reviews by previous patients and ratings given on the bases of the performance by both the hospital and the patients. This would give enough information to the patient in order to make the booking.

C. Scheduling and appointments

The system would go through the patient's schedule in their smartphone to check for an available date/ time slot and for the doctor it would go through the system on the bases of this recommendations would be given. The most feasible solution for both the doctor and the patient would be scheduled finally. This would ensure that the doctor is available and the patient is also free as a result leading in no clashes of schedule.

Being able to schedule and book appointments would become an easy task for both the hospital and the patients. Patients would be able to view the doctor's schedule and based on a convenient time slot for both of them and will be able to book it accordingly. If the patient is coming for a follow-up or for continuing his treatment then the patient can book an appointment or the doctor can do the same on behalf of the patient. In case the patient is up for an ultrasound scan, X-ray or a simple procedure the patient or the doctor can book the required room in accordance with the availability and the doctor's preference.

If the patient has to be hospitalized then he can check for the availability of the beds and book it online. This can be achieved by computerizing the entire scheduling system. Al and ML will help to obtain the calendar or schedule data from the patient's smartphone and cross verify with the doctor's schedule. Once this is being done it would be able and identify a slot which is comfortable for both the patient and in sync with the availability of the doctor.

D. Medical Inventory management

Smart medicine dispensers are used to get the medication prescribed by the doctor. The patients can get the medicines by entering their unique ID into the dispenser which would then vend out the medicine by identifying the ID and linking it to the prescription given by the physician. Doctors would be able to check the availability in real time if it is not available AI would provide recommendation for alternate medications and would also notify the Inventory management team with respect to the shortage. On the bases of the operation or procedure scheduled, AI will check the inventory to ensure that the required supplies and medicines are available if not an alert will be given order can be placed accordingly. It would usually done on a particular time. This would help to reduce the inventory cost exponentially.

E. Smart assistance for test results

X-ray, scan, EEG, MRI and other tests or diagnosis results are automatically saved in the private hybrid cloud of the hospital and in the patient's unique medical ID. The saved X-rays, scanned copies are then analyzed by trained AI and ML algorithms and sent to the physicians to check. The thorough analysis done by both the machine and the

doctor reduces errors in problem detection. This acts as an assistant to the doctor and helps to diagnose and rectify the problem faster.

F. Treatment and Prescription assistance

On the bases of the analysis of the test, AI will assist in detecting the possible problem in the body. After identifying the problem, it will give recommendations for treatment and medicine prescription for the doctor. The doctor can then choose the best treatment to go ahead with based on the pros and cons. On the bases of option that the doctor selects from the recommendation being given by AI, the system with the help of ML will learn which recommendations should be made for a particular treatment and as a result will be able to give more accurate and precise treatment and prescriptions.

G. Working process

The smart hospital systems operations start from the patient using his or her medical ID to schedule an appointment. This step involves the doctor's unique ID and the patient's unique ID getting connected to the network. An appropriate time slot by checking the patient's calendar in his smartphone and the doctor's availability would be selected and the appointment booked. Figure 1.2 explains the working process.

The doctor would be able to access the patient's past medical records and his basic medical information through the patient's medical ID. This would be available through the hybrid cloud server which would contain the public cloud with AI and ML-based algorithms and the private cloud which is the hospital's database management.

After the patient meets the doctor the entire process of disease identification and treatment is made easy with the help of the diagnosis assistant. This would help the doctor in analyzing the results from the various test reports obtained. With the smart assistant, the doctor would be able to run problem diagnosis far more easily and be able to detect the cause and provide a cure to the patient in no time.

The inventory management system would let the doctor know more about the availability and suitability of the medicines and based on that would provide an apt treatment method or prescription. The availability of medicines gets updated in real-time with the help of IoT and in-built sensors. This would help to maintain the required levels of stock by the hospital.

- *Example*

John a 29-year-old male has been frequently experiencing sharp and sudden abdominal pains recently and decided to do a check-up with XYZ hospital. He booked an appointment with the hospitals app and registered in it by linking his medical ID which is available on his phone and contains basic information about his health and his past records.

After going to the hospital for his appointment he gets assigned to a particular doctor and is given a unique patient ID which gets linked to the doctor's unique ID. Once John meets the doctor, he lists out the various symptoms he has been feeling. When the John is informing the doctor, the issues being faced by him the handheld device by the doctor will record and take the voice note to analyze the problems by identifying the keywords with the help of AI and ML.

This would give the doctor a series of a checklist which would enable him to narrow down to a list of possibilities and schedule a series of tests to check if it could possibly be a kidney stone. An ultrasound is scheduled on the bases of Johns preference and AI along with ML will analyze and scan the results and update the system so that the doctor can finally confirm that it is a kidney stone.

The doctor would then analyze the data from Johns smartphone to find out that it was caused due to low consumption of water and food containing high levels of calcium. He checks with the medical inventory system to look for the medicines that can be prescribed and tells John he will book an appointment for a follow up check up to see if it is gone with the help of the medication if not a procedure can be done on the same day.

John gets the medication from the dispensers by entering his unique patient ID. Once he starts the dose, he starts feeling a lot of relief and goes for a follow-up to the doctor. The doctor informs him that

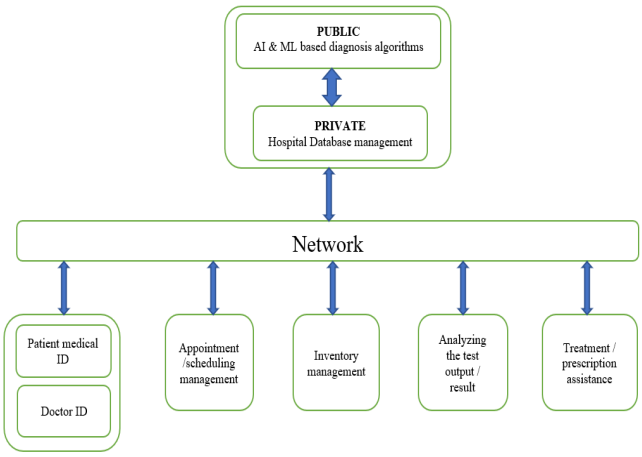

Fig 1.1 Architectural Block Diagram of Proposed system

the stone has dissolved due to the medication and he is much healthier now. After 5 years John is faced with stabbing pains again and this time he goes to a different hospital as he is out of the country. The new doctor uses Johns medical ID which was updated with the treatment he got in XYZ hospital for his kidney stone problem. The doctor is able to identify that the kidney stone has recurred and gives John the required treatment.

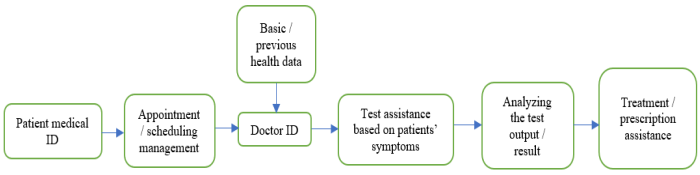

Fig 1.2 Process Flow Diagram

IV. FUTURE WORK

The implementation of this system would help to get access to large amounts of data with the help of this database AI would be able to develop an algorithm which would help to increase procedural correctness.[17] This would revolutionize the entire industry as it would help in the early detection of diseases and affordable and accurate treatment can be given. This system would help to reduce the waiting time for the test results of patients who would not have to wait for days to know the result of a particular test. It can be known just in few hours and as a result, very little time will be taken for providing a cure to the patients. In the long term this system would help to increase the efficiency of the hospital and its physicians, reduce manpower and time taken for various procedures as a result the operation cost would also decrease and would lead to automation of the entire hospital system.

V. CONCLUSION

The proposed model would change the face of healthcare IT by providing assistance to the entire hospital system by evolving its working by bringing in hybrid cloud, IoT, AI, and ML. These components when brought together would improve the entire working of hospitals. It would enable it to become more organized and efficient and focus on patient care and help to reduce the overall cost incurred by both hospitals and patients. By reducing the number of medical errors everyone would be benefited and this can be achieved with the help of this system. The diagnoses assistant would learn from the public pool made available through the hybrid cloud using ML. The system would reduce the waiting time for patients and as a result increase the number of patients treated per day. The system would eventually run on its own without manual support. In the long run, it is beneficial for both the hospital and the patient as well.

ACKNOWLEDGMENT

We thank our colleagues from the Institute of management, Christ (Deemed to be) University who provided us with insights which were a great assistance in shaping our research. We would like to express our gratitude to the faculties and colleagues of Institute of management, Christ (Deemed to be) University and Sunitha Devanand of KSMC Hospital, Riyadh for sharing their pearls of wisdom, reviewing our research and giving us key inputs.

Dual Band Monopole Antenna with a Stepped Ground Plane

Sooraj Muralidharan and *Sreedevi K. Menon
Department of Electronics and Communication Engineering,
Amrita Vishwa Vidyapeetham, Amritapuri, India
*sreedevikmenon@am.amrita.edu

***Abstract*— The paper presents a dual band monopole antenna with a defected ground plane for Wi-Fi and WLAN applications. The defect is introduced as a step in the ground plane. Initially, a single band monopole antenna is designed. This is antenna is modified with the step defect to provide dual band characteristics. The depth and width of the defect decides the second band of operation for a given monopole length. The optimized antenna in ANSYS HFSS is fabricated and tested and are in concurrence with each other.**

Keywords*— *dual band, defected ground plane, step ground plane, monopole antenna.

I. INTRODUCTION

Today, the world demand small, compact and low cost wireless systems for effective usage and utilization of resources. Antenna forms the most important part of a wireless communication system and to be integrated in wireless modules antenna has to be as compact and light weight as possible. Different type of antennas has been proposed and studied in the recent past for communication applications [1-9]. Among these, planar monopole antenna can ensure omnidirectional characteristics with compact structure. So these antennas find use in portable systems as they are light weight and can be easily manufactured [3-5].

In recent literature, lot of work has been done to implement dual band characteristics in monopole antennas. In a microstrip circular patch antenna dual band characteristics with monopole radiation pattern is achieved by the usage of double layer substrate. In this both the frequency bands have a gain better than 5 dBi and multiple periodic structures is also used in this antenna [6]. Inclusion of U-shaped metamaterials in a coplanar wave guide fed monopole antenna has also contributed to dual band characteristics [7]. Together with dual band characteristics a circular polarization is achieved for a self-complimentary antenna at Wi-Fi frequencies. This antenna provides an axial ratio better than 3 dB at both the bands [8]. Using the principle of stacking a monopole patch antenna for dual broad band has been designed and both the bands have gain better than 5dBi [9]. For MIMO system a dual band antenna has been designed using micro-metal mesh of conductive film and this also works at both WLAN/ Wi Fi frequencies and is very compact and use coplanar waveguide as feeding technique [10]. For wireless body area networks a dual band operation has been implemented using microstrip patch antenna and this antenna is also energized by CPW with a parasitic patch on the other side of the coplanar wave guide [11]. In the experimental investigation done in [12], enhanced gain with dual frequency characteristics is found by optimizing the parameters of ground plane and loop of monopole loop antenna.

This paper describes the design and of a dual band monopole antenna with a stepped ground for dual band operations. Simulations are done to analyze the effect of the dimensions of the step defect on the antenna characteristics. Using ANSYS HFSS. The optimized antenna is fabricated and the results are verified using Keysight Vector Network Analyzer (VNA).

II. PLANAR MONOPOLE ANTENNA DESIGN

Initially a microstrip line fed planar monopole antenna is designed as illustrated in Fig 1.

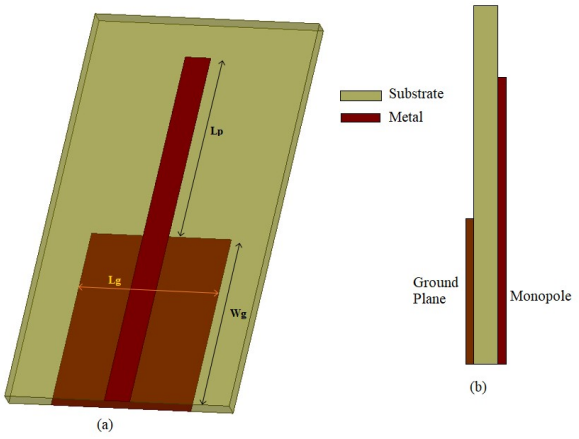

Fig.1. (a) Planar Monopole Antenna (b) cross-sectional view

When the dimensions of the antenna is taken such that the length (L_g) and width (W_g)of the ground plane is equal to the length of the monopole (L_p), the antenna offers a single band response and this is validated by simulation and the results are presented in Fig.2. The gain is found to ~ 2.4 dBi with more bandwidth at lower frequencies as presented in Table.1.

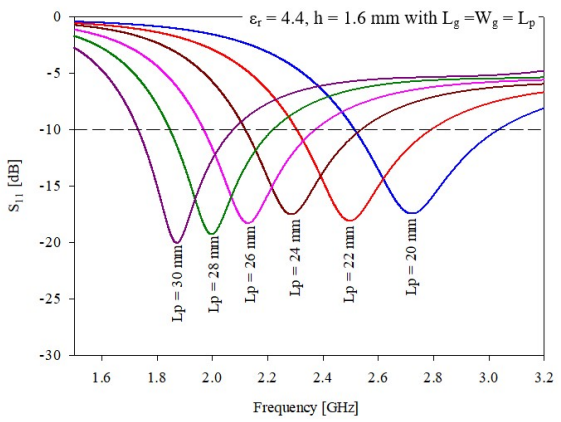

Fig.2. Variation of resonance frequency with monopole length, Lp

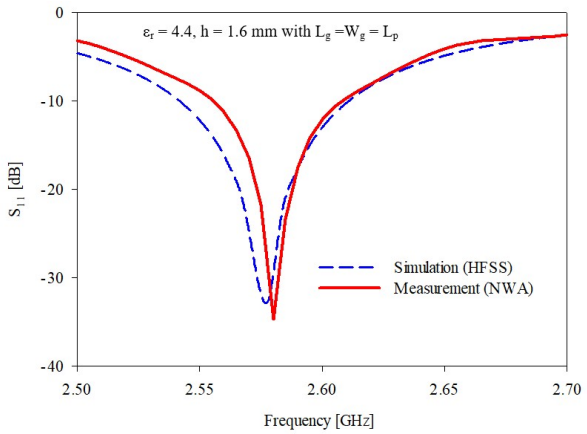

Fig.3 (a). Return Loss of the monopole antenna, Lp = 22mm

TABLE I. ANTENNA PERFORMANCE

Lp (mm)	$L_g = W_g = L_p$, $\varepsilon_r = 4.4$, h = 1.6 mm			
	Antenna Parameter			
	Frequency (GHz)	***Bandwidth (MHz)***	***Gain (dBi)***	***Radiation Pattern***
20	2.723	521	2.50	Omni – directional
22	2.503	491	2.45	
24	2.293	421	2.39	
26	2.132	411	2.41	
28	2.002	405	2.37	
30	1.872	341	2.36	

To aid the antenna to perform at Wi-Fi frequency length of the monopole L_p is taken as 22 mm for further studies. The reflection and radiation performance of this monopole is presented in Fig.3.

The ground plane of this monopole antenna is modified to provide the dual band operation by incorporating a step defect which is discussed in the next section.

III. DUAL BAND MONOPOLE ANTENNA

In the monopole operating at 2.5 GHz a step defect is introduced having a dimension, $Lg_2 \times Wg_2$. The geometry of the monopole with step defect is shown in Fig.4. In the design, Lg1 = Wg1 = Lp1 = 22mm to provide resonance at 2.5 GHz. Depending the defect dimension the second frequency can be tuned.

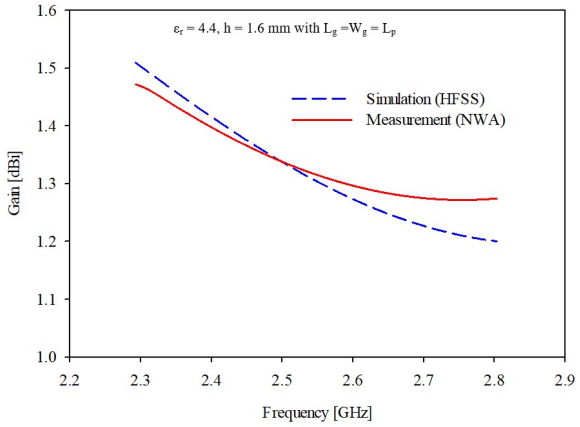

Fig.3 (b). Gain of the monopole antenna in the bandwidth of operation

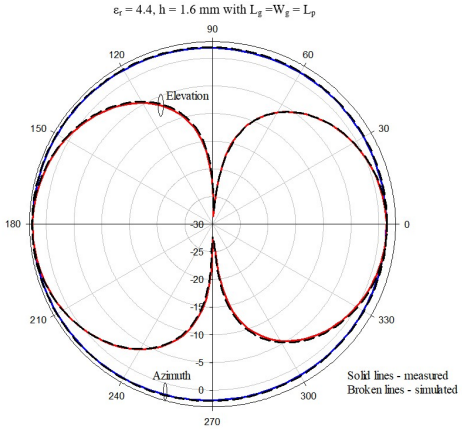

Fig.3 (c). Radiation Pattern of the monopole antenna at 2.503 GHz

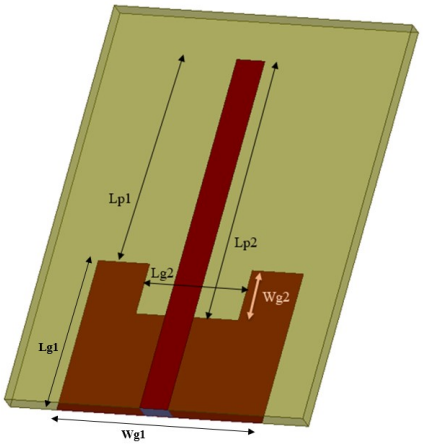

Fig.4 (a). Antenna with Defected ground plane

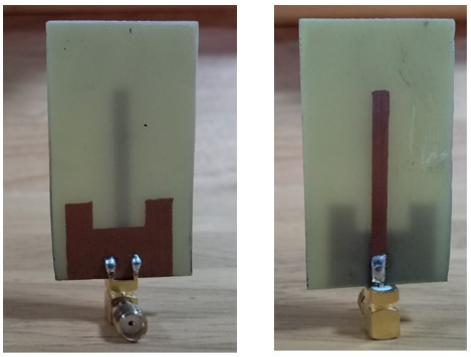

Fig.4 (b). Prototype of Planar Monopole Antenna with defected ground plane on FR4 epoxy

For the dual band performance, the defect dimension Lg2 × Wg2 is varied. The performance of the antenna based on this is presented in Fig.5.

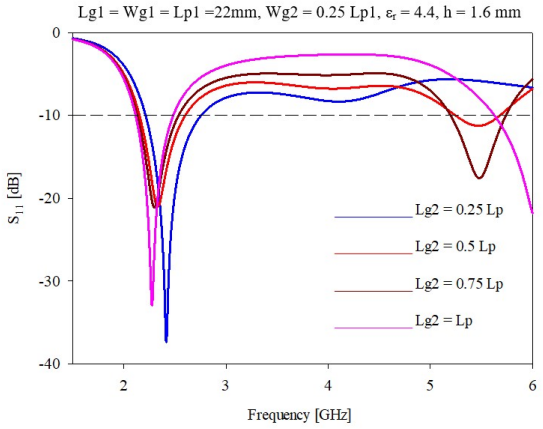

Fig.5 (a). Variation of return loss with length of the defect Lg2

For dual band performance, the defect dimension Lg2 has to be at least 0.5 Lp1 and when is same as Lp1 it is outside the band of interest. So the defect length lg2 is fixed as 0.75 Lp1. With this the depth of the defect Wg2 is optimized as 0.25Lp and the vibrational study is presented in Fig. 5(b).

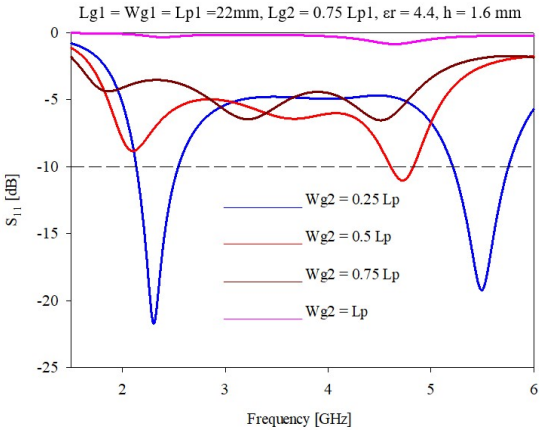

Fig.5 (b). Variation of return loss with length of the defect Wg2

The optimized defect dimension Lg2 × Wg2 is 0.75 Lp1 × 0.25 Lp1 for the dual band performance of the monopole antenna with Lp1 = 22mm. With these dimensions the antenna characteristics is analysed using ANSYS HFSS. A prototype of the optimised antenna is fabricated on FR4 epoxy as shown in Fig. 4 (b) and measured using Keysight E 5080 A Vector network Analyser. The simulated and measured results are presented as Fig.6. The defect shifts the first resonance to 2.36 GHz but 2.5 GHz is within the 2:1 VSWR bandwidth of the resonance.

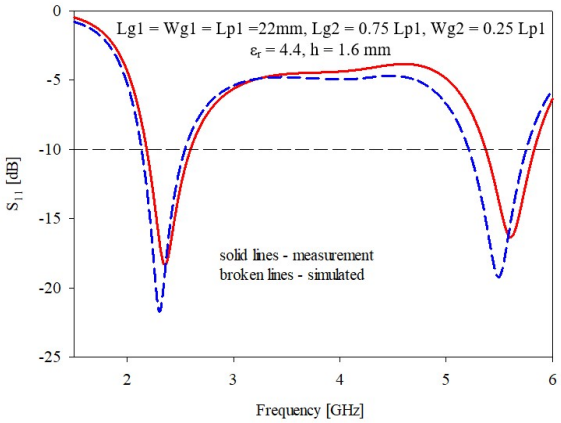

Fig.6. Variation of return loss with frequency

The simulated gain of the antenna is validated using two antenna method by measurement and is presented in Fig.7.

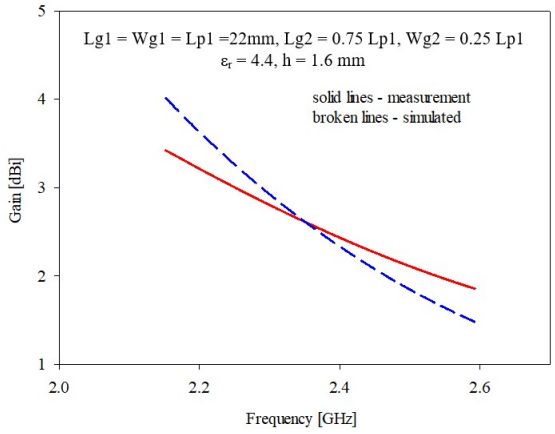

Fig.7 (a). Variation of gain with frequency at the first band

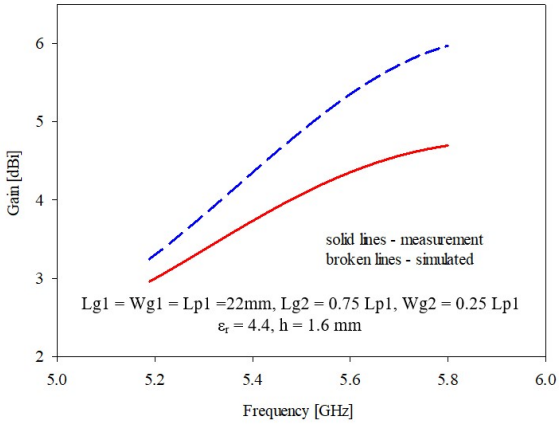

Fig.7 (b). Variation of gain with frequency at the second band

The measured and simulated radiation pattern of the antenna in the two principal planes is presented in Fig.8.

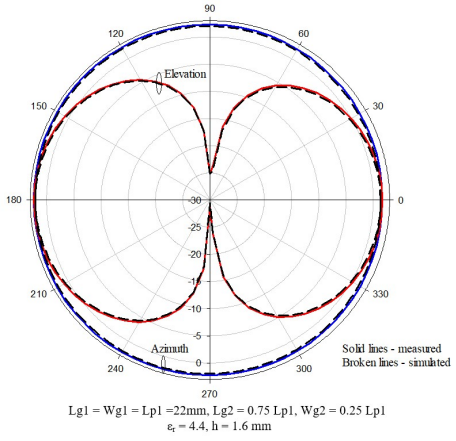

Fig.8 (a). Radiation Pattern at 2.36 GHz

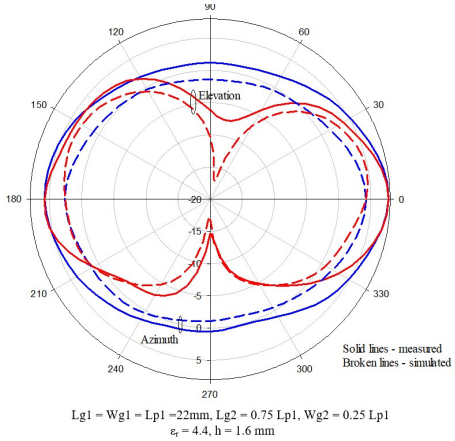

Fig.8 (b). Radiation Pattern at 5.6 GHz

The simulated and measured performance of the antenna is consolidated in Table.2. A comparison is done with the proposed antenna and that referred and is presented in Table.3.

TABLE II. DUAL BAND ANTENNA PERFORMANCE

Antenna Parameter	**Values obtained**	
	Measured	***Simulated***
First Frequency (GHz)	2.36	2.31
First Bandwidth (MHz)	410	400
Second Frequency (GHz)	5.6	5.51
Second Bandwidth (MHz)	450	520
Gain at 2.36 GHz (dBi)	2.54	2.56
Gain at 5.51 GHz (dBi)	4.13	4.97
Omni-directional in both bands		

TABLE III. PERFORMANCE OF DUAL BAND ANTENNAS COMPARED

Antenna	Frequency (GHz)	Gain (dBi)	Dimension (mm × mm × mm)
Proposed	**2.36** **5.6**	**2.54** **4.13**	**23 × 44.5 × 1.6**
Ref [4]	3.01 5.38	2.48 3.09	40 × 47 × 1.5
Ref [6]	4.01 5.24	5 5.5	84 × 84 × 1.5
Ref [7]	2.7 6.3	-1.8 -0.4	20 × 37 × 1.6
Ref [8]	2.4 5.4	Not mentioned	42 × 30 × 0.8
Ref [9]	2.415 5.525	5 6	130 × 130 × 3
Ref [10]	2.4 5.8	5 6	30 × 45 × 3.5

IV. CONCLUSION

The proposed monopole antenna exhibits dual band characteristics without the use of a dipole structure. The design is fully planar and consumes less area. The reduction in area further reduces the overall cost of the communication system. The antenna operates at the frequencies 2.45 GHz which is Wi-Fi operational frequency and at 5.45 GHz which is the WLAN operational frequency. The radiation pattern of the antenna is observed to be omnidirectional at both the frequencies making the antenna appropriate for wireless applications and portable systems.

Cooperative Hybrid Automatic Repeat Request Based on the Number of Retransmissions

Arpitha R, Chaithra B R and Usha Padma
Department of Telecommunication Engineering
RV College of Engineering
Bengaluru, India
arpithakotiyan@gmail.com

Abstract— **Cooperative communication has great potential to boost the wireless data rates by exploiting the antennas on wireless devices for spacial diversity. Since decode and forward (DF) approach eliminates noise accumulation problem, DF protocol is suitable for relay selection scheme. To improve the system performance turbo coding along with Hybrid Automatic Repeat Request (HARQ) technique is used where turbo coding adds redundant bits and HARQ minimizes the error rate in the system. The data is broadcasted over a Rayleigh fading channel. Maximal Ratio combining is used at the receiver to combine the information received from the source and the relay. If received data is found to be in error at the destination, then NACK is transmitted to the source. In this paper HARQ scheme for turbo coding is performed for different modulation order over Rayleigh channel in presence of Additive white Gaussian noise. The number of retransmissions required to clear total number of errors is calculated.**

Keywords— Cooperative communication, Decode and forward, Turbo coding, HARQ scheme, Maximal Ratio Combing.

I INTRODUCTION

The increasing number of users inspired intensive analysis in wireless communication. MIMO systems were introduced where multiple antennas were placed at the source and the destination. But usage of MIMO system in small nodes is proved to be a challenge and also it requires more number of resources.

In communication systems, wireless system is more often corrupted by the factors like fading and shadowing. In order to reduce the number of errors channel coding techniques are used. At the destination if the packet found to be in error, then retransmission is often requested by the destination. This scheme is termed as Automatic repeat request (ARQ) which ensures the low bit error rate [1]. But the efficiency of ARQ can be increased by reusing the data from the previous transmissions instead of simply discarding it. So, to improve efficiency of the system and also to reduce the number of errors, Hybrid automatic repeat request was introduced.

In order to address these challenges imposed by MIMO, Cooperative Communication concepts have been introduced. In this system relay node is introduced between source and the destination. In cooperative communication, one or multiple users can communicate with each other using relay networks [2]-[3].There are two relaying protocols in cooperative network i.e. Amplify & forward and decode & forward. At the relay, the AF protocol amplifies the data and forwards it to the destination [4]. In Decode and forward, the signal from the source is decoded and forwarded to the destination and these two protocols are commonly used [5]-[6]. But for relay selection scheme decode and forward protocol is better, since it eliminates noise accumulation problem. So DF protocol is used in this paper. The main aim of cooperative communicative is to improve the channel capacity of the wireless networks and it can be used in different applications like cellular networks, cognitive networks and also adhoc networks [7].

Adhoc network is formed by a group of communication devices where every device can communicate with each other without fixed infrastructure and without predefined organization [9].

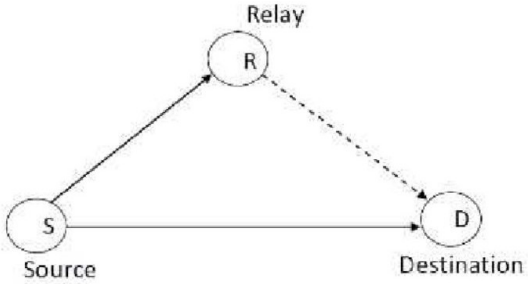

Fig 1: Scenario of Cooperative communication [8]

The channel coding techniques in a communication system can be used to reduce the number of errors. Turbo coding

plays a very important role in making the system more reliable and efficient [10].For cooperative communication, turbo codes were implemented in [16] using AWGN channel with QAM modulation.

In order to provide secure and reliable communication, error control mechanisms are essential. Hybrid automatic repeat request is the main error controlling process which is a combination of both automatic repeat request (ARQ) and forward error correction [11]. HARQ is mainly used in a communication systems like long term evolution (LTE) and High Speed Packet Access (HSPA) [12].There are mainly two types of HARQ found namely HARQ type-I and HARQ type-II. In HARQ type-I, the data packets which are broadcasted over a wireless Rayleigh channel are received at the destination. If the received data are found to be in error, then the data packets are discarded and a negative acknowledgement is sent to the transmitter. This process is continued till the maximum number of rounds is reached.

In type-II the data packets which is received at the reception is not discarded, it is stored in a buffer and combined with data of same packet which are received in the next rounds. The combined data are used in the decoding process. This process makes HARQ type-II more robust against fading and throughput will be increased [13]. There are mainly two schemes in HARQ type-II, namely HARQ with code combining (HARQ-CC) and HARQ with incremental redundancy (HARQ-IR) [14]. HARQ-IR performs better when the channel varies slowly and the retransmissions requests are responded quickly [15].

In this paper, Cooperative communication for a adhoc network is simulated with decode and forward approach. To reduce the number of errors in a system, turbo coding technique with HARQ-CC is used. To improve the performance of a system, QAM modulation technique is used. In HARQ process, if the received data bits are found to be in error then negative acknowledgement is sent to the source and SNR is for each transmission is varied till it reaches the maximum retransmissions. Multiple copies of the data bits which are received at the destination through multiple retransmissions are combined using maximal ratio combining (MRC) to obtain errorless information.

Rest of the paper is organized as follows: Section II describes the system model. Performance analysis and simulation results are explained in Section III. Section IV gives the conclusion and future scope of the proposed work.

II SYSTEM MODEL

Simulation of HARQ scheme using turbo coding technique in a cooperative adhoc network using QAM modulation is carried out in the proposed work.

Fig 2 represents the proposed work. In the above figure cooperative communication scenario is considered with a single relay. Turbo coder is used to minimize the number of errors using QAM modulation. The steps involved to implement a HARQ process is as follows:

At Source:

- The input data is encoded using turbo encoding technique**.**
- The encoded data is modulated using QAM modulation techniques and broadcasted over a Rayleigh fading channel.
- The data which is sent over Rayleigh fading channel forms two paths i.e. source to relay and source to destination.

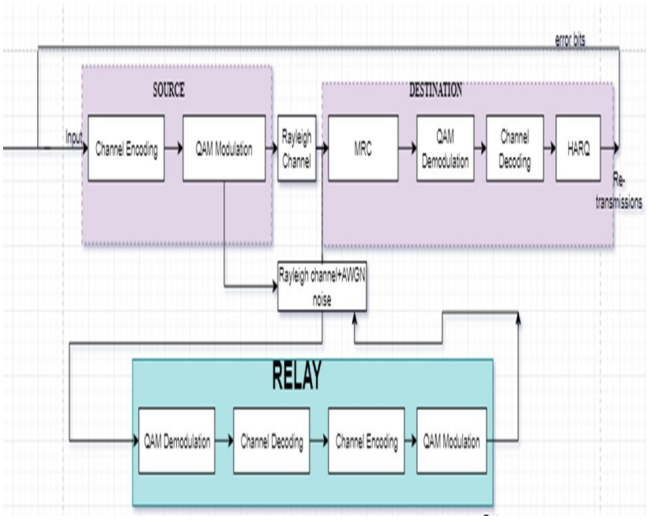

Fig 2: HARQ scheme in cooperative communication

At the relay:

- Relay is a helper node which is placed between source and the destination It uses decode and forward approach i.e. the received data is demodulated and decoded. Decoded data is again encoded and modulated.
- Then the modulated information is broadcasted over a Rayleigh channel with AWGN to the destination.

At Destination:

- The data from the source and the relay reaches the destination.
- The data received from the direct and the virtual paths are combined using maximal ratio combining (MRC).
- The combined data is demodulated and decoded using turbo decoder.
- If it found to be in error then negative acknowledgement is sent to the source.
- If the received data bits are erroneous, HARQ is used at the destination.
- To improve the performance of a system SNR is varied, and the data is combined at the destination using MRC.

Hybrid automatic repeat request (HARQ)

- Hybrid ARQ is a combination of automatic repeat request and forward error correction codes. Destination determines whether the received packet is correct or not by comparing it with the transmitted data. If the packet is correctly delivered, the destination broadcasts an acknowledge (ACK), Otherwise the destination broadcasts a NACK.
- The SNR of the system is varied, as the SNR increases, the noise spectral density (No) decreases.
- The data which is received by varying the SNR is combined using maximal ratio combining (MRC).
- If data received at the destination is erroneous, then retransmission request is sent to the source.
- For the next transmission, only the erroneous data bits are transmitted, this is continued till the data received is error free.
- Fig 3 represents the proposed work which performs HARQ mechanism.
- Channel encoding and decoding is performed using turbo coding, because in cooperative communication turbo coding scheme performs better and reduces number of errors.

III. PERFORMANCE ANALYSIS

A. Performance comparison of cooperative communication with QAM modulation with modulation order of 16 and 64.

In cooperative communication scenario, turbo coder is used to improve the performance of the system. Fig 4 shows the graph of BER vs Noise power spectral density using turbo coder. From the graph it can be noted that using turbo coding technique BER is around 33% for 16-QAM. For 64-QAM BER is almost reduced to 0.03%. By these results we can conclude that in cooperative communication scenario the performance of the network is better when turbo coding with 64-QAM is used.

B. Performance evaluation of Direct communication and decode and forward mechanism

Compared to direct communication, Cooperative Communication is better. Fig 5 shows the comparison of direct communication and decode and forward approach. When SNR increases then the number of errors decreases. 8900 bits has been transmitted from the source. In direct communication for 0db SNR, 6500 bits are found to be an error whereas in cooperative communication numbers of errors are almost reduced to 819 bits.

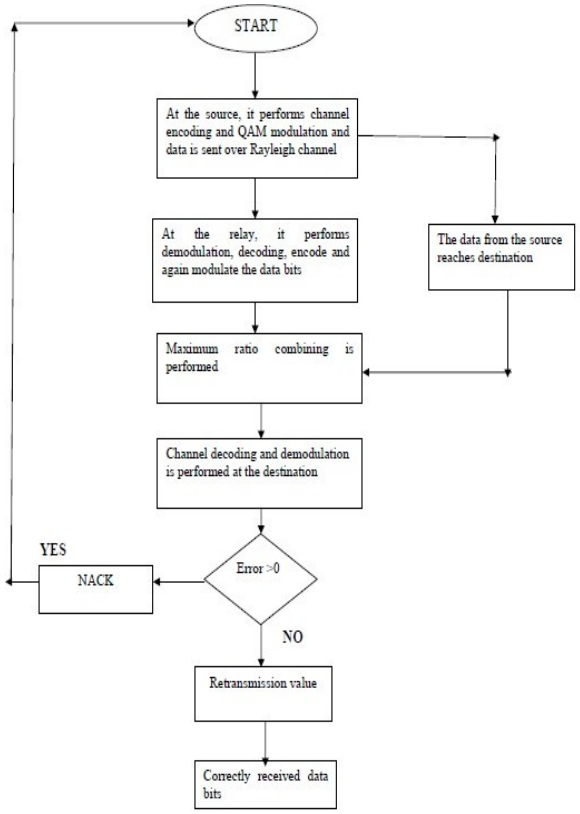

Figure 3: Flow chart of proposed work

C. Performance evaluation of Cooperative Communication when SNR is varied

The system with 64-QAM shows better performance, where BER is around 0.03% which is very less. Figure 6 shows the variation of BER vs SNR with turbo coder. This shows that when Signal to noise ratio increases then bit error rate of a system decreases.

D. Performance evaluation of HARQ scheme in decode and forward approach

With the transmission of 8900 bits for 16-QAM with cooperative HARQ, number of retransmissions required for reception of error free data are 1994. But for same number of transmitted bits, 64-QAM with cooperative HARQ provided error free data at the destination with only 165 retransmissions.

Table 1 provides the performance evaluation of HARQ scheme using QAM modulation technique.

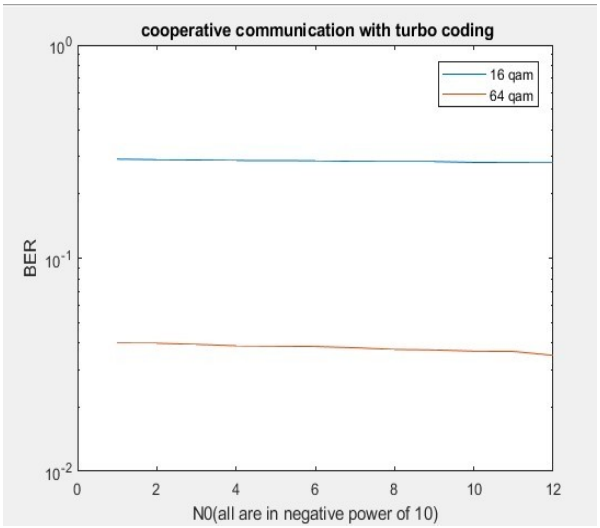

Fig 4: BER vs No using turbo coding technique for different modulation order.

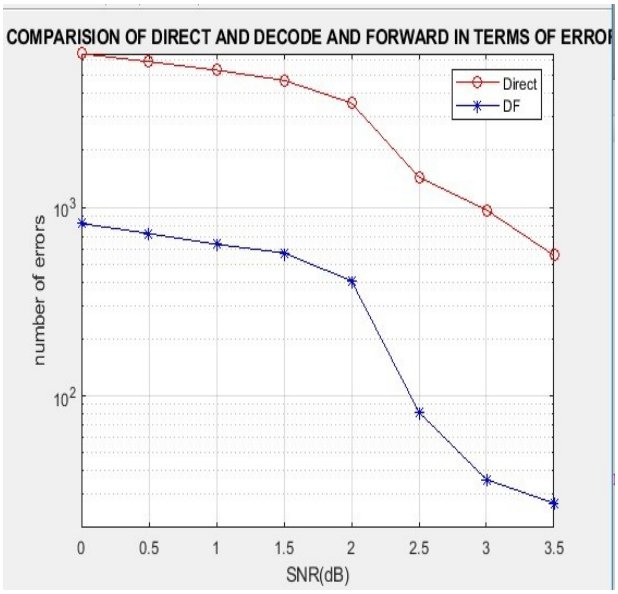

Fig 5: Performance comparisons of cooperative communication with decode and forward and direct communication

Table 1 : Performance evaluation of HARQ scheme using QAM modulation technique

Modulation order	BER	Number of errors	Number of retransmissions
16-QAM	0.3392	3019	1994
64-QAM	0.037	333	165

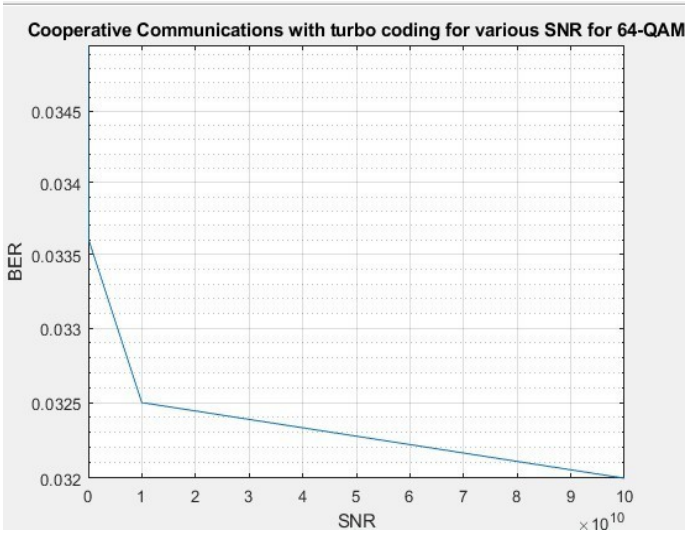

Fig 6: BER vs SNR for 64 QAM for various SNR

IV CONCLUSION

We have simulated Cooperative Adhoc Network with turbo coding technique and HARQ scheme. Performance analysis of cooperative adhoc network is carried out using 16 and 64 QAM modulation techniques. Decode and forward protocol is used at the relay to process the received data bits. Turbo coding technique is analyzed for different SNR values in cooperative adhoc network. It is shown that error rate decreases with increase in SNR. In Cooperative HARQ, 64-QAM showed better performance where only 165 retransmissions are required to correct the total number of errors, when 8900 bits are transmitted. HARQ-IR scheme can be used to reduce the total number retransmissions in future.

***Abstract*— The general day to day health of a person is vital for the efficient functioning of the human body. Taking certain prominent symptoms and their diseases to build a Machine learning model to predict common diseases based on real symptoms is the objective of this research. With the dataset of the most commonly exhibited diseases, we built a relation to predicting the possible disease based on the input of symptoms. The proposed model utilizes the capability of different Machine learning algorithms combined with text processing to achieve accurate prediction. Text processing has been implemented using Tokenization and, is combined with various algorithms to test the similarities and the outputs. In health industry, it provides several benefits such as pre-emptive detection of diseases, faster diagnosis, medical history for review of patients etc.**

Keywords—Tf-idf; Data Mining; Tokenize; Symptoms; diseases.

I. INTRODUCTION

The most common health issues among people often have some basic symptoms which are generally exhibited by a person. For example, an individual with headache may exhibit variety of other symptoms of other diseases. In such cases where we want to have instant diagnosis, we are dependent on physicians. A machine learning model can be built to predict the type of disease based on the symptoms. The model prediction can help early detection of diseases and faster diagnosis

For this purpose of our research, we used dataset which is available online to perform Machine learning based predictions to some test data. The aim of the study is to build a framework and a computational model for the prediction of diseases looking at various symptoms. For this purpose, we use a dataset which contains information about 150 most frequently occurring diseases and the associated symptoms with those diseases. The dataset used had a lot of cleaning and pre-processing needed to be done. The first step was to transpose the datasets into a form with diseases as the target column and each of the symptoms as dummy variables for the diseases, on which models were to be trained.

For the study, four different sets of algorithms were used for mapping symptoms into diseases. The first step was to split the dataset into training and testing sets, in order to effectively test the generality of the algorithms to be trained, we used 2/3rd of the dataset for training and the rest for testing purposes. However, for subsequent steps, it was seen that an over fitted model for the study was better suited and thus testing was done for the entire dataset.

II. RELATED WORK

There are several successful use cases which we come across in different predictions. Our plan was to survey various algorithms and select the most suitable one for prediction purpose.

N. Alshurafa et al.[1] used baseline questionnaires to gather labelled patient data along with real-time mobile data. The experiment revealed K-Nearest Neighbour is susceptible to noisy data. The heart disease prediction in [2] with symptoms uses a questionnaire to gather data from patients and pass it to a Support Vector Machine Algorithm. Prabakaran et al.[3] states that research shows a web system using Naïve Bayes to provide answers to complex queries to diagnose heart disease. Support Vector Machines (SVM) and Artificial Neural Networks (ANN) are the two most reused algorithms. Most commonly used methods to evaluate the classification methods accuracy are Leave-One Out and Cross-Validation. P. Chiang et al.[4] used data collected using health monitoring devices such as Fitbit and Omron for 8 people over a period of 1 month. Performed feature ranking based on RF feature selection. The study in [5] works on removing missing data and outliers using additive Least Square Support Vector Machine. The comparison between algorithms in [6] shows the use case scenarios for each algorithm with merits and demerits. An approach of sequential pattern mining is very feasible for the continuously emerging characteristics of stream data suggested in [7]. The dataset used in [8] shows how web-scraped data is useful for making predictions even without specific medical data. Open source repositories are utilized to gather updated datasets. They also implemented Naïve Bayes as one of their test algorithms. Feature engineering was done to remove outliers in the dataset such as bad data quality i.e. patients that appeared in the dataset with age less than 0 or greater than 120 and incident cases not “closed” properly. The survey in [9] provides comprehensive survey of algorithms and methods implemented in medical fields. They show Bayesian Network modelling to be one of the top used techniques in fields such as cancer and diabetes prediction.

Xin LI et al.[10] used a UCI dataset containing hospital records of diabetic patients. The records contain more than 10 years of data gathered from hospitals. It contains patient data with 50 different attributes and specifies if the patient has been re-admitted. They performed a collaborative filtering-enhanced deep learning algorithm (CFDL). For the End –User, Huang [11] proposed a health chatbot to provide recommendations such as diet and exercise , eating tips, nutrient intake and other features. The algorithms used in [12] and [13] shows implementation of Neural Networks, K-NN and Naïve Bayes. It also specifies the need to understand the importance of attributes and feature selection in the case of heart disease prediction i.e. attributes such as smoking and drinking habits.The application in [14] makes use of chatbot for medical data requests. This feature can be used for suggestive prediction with the help of NLP and integrated with general chatbot algorithms which also provide some added functionalities.

For the dataset purpose, we see [15] in which the National Health of Scotland (NHS) aided by the government provides A-Z symptom-disease data from which we manually web-scraped the dataset.

III. Data Summary And Processing

A. Dataset Preparation

The data we used was gathered from 2 sources- UMLS and NHS government websites. The web-scraped data of UMLS government database of diseases and symptoms. The Unified Medical Language System (UMLS) is a vocabulary based biomedical database of most common symptoms and disease pairs. This data was outdated, and prediction was not up to the expected outcomes. But, for the main testing and working model we curated a dataset using National Health of Scotland (NHS) data of A-Z diseases and its symptoms. This data proved to be more accurate for prediction since it was easy to gather list if most appropriate words which uniquely predict a disease or condition. We test this data with 3 main algorithms- Decision Trees, Random Forest and Naïve Bayes.

B. Text Processing

For the initial step, we consider the symptoms data and perform count-vectorization. This is done to sort the words in the corpus into a bag-of-words. The model is simple in that it ignores the order of words and relations rather focus on the occurrence of words the dataset.

For all the 3 algorithms, we use the tf-idf parameter which helps in keyword extraction to help in faster computation. The Term Frequency and Inverse Document Frequency play a major role in prediction and understanding the dispersion of symptoms. This shows how the dataset has keywords which vary in occurrences based on a certain disease.

Next, we use the above logic to perform bigram words classification of data. For example, we consider ‘abdominal pain’ as one word and check similar occurrences in dataset. This is sorted into a count vector matrix of binary matrix.

For the analysis for this data we use Term Frequency-Inverse Data Frequency (tf-idf) function which gives us the frequency of the word in each document in the corpus. It is the ratio of number of times the word appears compared to the total number of words present in the dataset. Using (1) and (2) we can get the required tf-idf mappings.

$$TF(t) = \frac{\text{(Number of word occurrences)}}{\text{(Total number of words in the dataset)}} \quad (1)$$

$$IDF(t) = \log_e \frac{\text{Total number of documents}}{\text{Number of documents with term t in it}} \quad (2)$$

IV. Methods

We test the data with 3 main classification algorithms- Decision Trees, Random Forest and Naïve Bayes. We make use of scikit-learn library and pandas data frames of the Python Programming language to process the data and implement the above algorithms.

A. Decision Trees

With the help of e Decision Tree classifier, we can derive the pairs of disease and generate a tree based on Gini index and weights of each symptom. The first step is to classify the data to fit the model of decision trees for the given dataset. We split the data into test data and training data for the model. Construct a node table to assign the different classifiers and Gini for splitting the nodes. Classify the model using Decision Tree Classifier. The value of target variable needs to be predicted using simple decision rules created using in the dataset and tf-idf features. The only extra advantage of using this is to apply it for both numerical and categorical dataset classification. This helps in reducing data cleaning based on what type of data is used for processing for each of the algorithm. Statistical testing is also easy compared to other methods. It uses 3 main criteria for determining the correct split. Gini Index, Information gain and Entropy. The Gini Index is subtracted sum of the squared probabilities of each class from one. Information Gain specifies the lowest entropy for each split and accordingly produces each node for lowest entropy calculated for each split. Figure 1 shows the section of the decision tree built with the count vector matrix after classification.

B. Random Forest

This is a more enhanced version of decision trees where we pick N random records from the dataset which contains symptoms. It is a supervised algorithm in which multiple decision trees are built with the help of bagging method. It does not rely on the most important features rather it uses random subset of features is considered while splitting a node. There is very low or no bias since it relies on the power of "the crowd". It follows 4 main steps:

1) Pick random samples from the dataset.
2) Produce decision tree using each sample and get a predicted result from each tree.
3) For each result, gain a vote to predict the result.
4) The final prediction with most overall votes gained by will be the result.

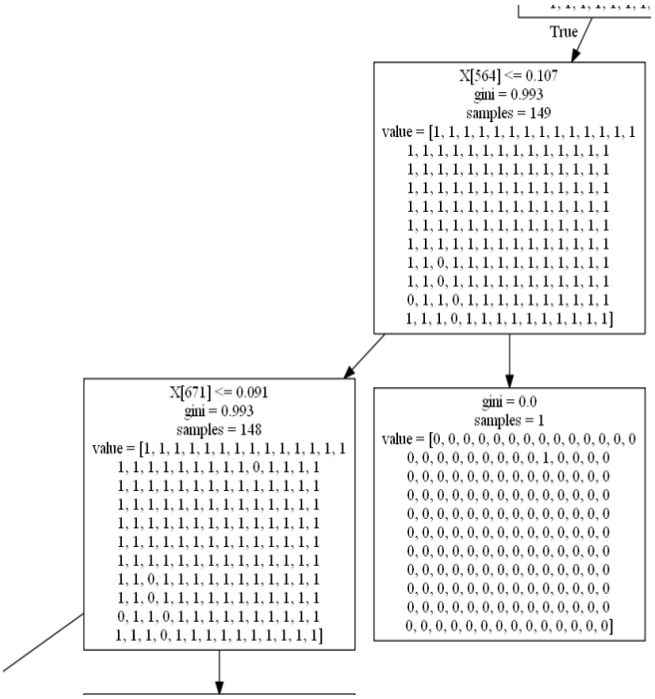

Figure 1: Section of the decision tree generated by count vector method

The general model for random forest selection and construction of tree is explained in Figure 2. The training set is randomly searched for a sample and the tree is constructed. Thus, it prevents overfitting of random subsets by creating trees on random subsets.

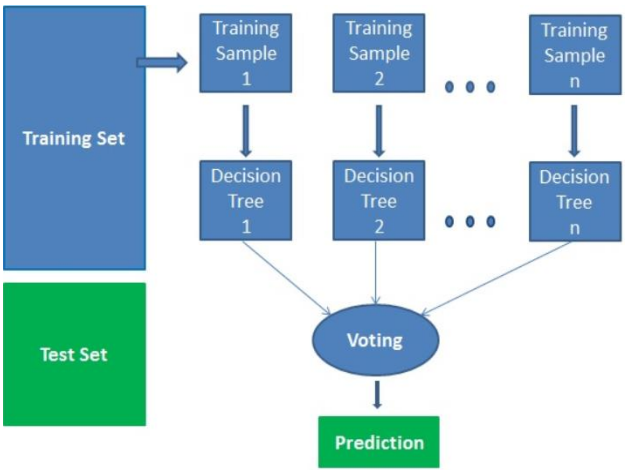

Figure 2: Random Forest Classifier Flow-chart

For our model, we use 300 n_estimators which specifies the number of trees and max_depth of 3 which specifies the maximum depth of each tree. There is an exponential increase in training time as we add more data to the existing dataset. Due to the branching and complexity it is not a viable option for future scaling, but it delivers more accurate results once it is trained compared to the other 2 algorithms.

C. Naïve Bayes

This is a conditional probability based algorithm. It is the most widely used and fastest algorithm since it uses less training data and strong independence assumptions. In our case, we use a built in function called MultinomialNaïveBayes which is mainly used for discrete features such as text classification. It requires a feature count parameter which helps in determining each class while fitting the sample with appropriate weights. For this we use the tf-idf count vector as the parameter.This experiment yielded around 99% accuracy. In text classification, the main aim is to find the best class for the given document. Figure 3 shows how text classification can be combined as a parameter to pass tf-idf vector which contains tokens and frequency data. We score the algorithm to obtain the results. It has 2 main functions. The first function is used to train the multinomial Naïve Bayes model based on the feature extraction and count vector. Each of the Count (C) of words and Document (D) can be done in a single pass through this training data. The conditional probability of Vector in each case is returned. The next step is to apply the algorithm to the tf-idf count vector (V) to assign score to each term collected as bag-of-words. The final score is obtained as the cumulative score for given document.

TRAINMULTINOMIALNB($\mathbb{C}, \mathbb{D}$)
1 $V \leftarrow$ EXTRACTVOCABULARY($\mathbb{D}$)

1 $W \leftarrow$ EXTRACTTOKENSFROMDOC(V, d)
2 **for each** $c \in \mathbb{C}$
3 **do** $score[c] \leftarrow \log prior[c]$
4 **for each** $t \in W$
5 **do** $score[c] \mathrel{+}= \log condprob[t][c]$
6 **return** $\arg\max_{c \in \mathbb{C}} score[c]$

Figure 3: Algorithm used for combining text classification with Multinomial Naïve Bayes

Test results shown in Table 1 imply that there is negligible difference between the 3 methods and the text processing plays a role in reducing the execution time. For more samples added to the same dataset, the model will function slower and the compilation time gap will increase due to variation in splitting methods and computational differences between probabilistic model and trees. As the comparison in [6] says, the tree model performs better with more data compared to Naïve Bayes.

TABLE I. TEST RESULTS

Algorithm	Accuracy
Decision Trees	98.18%
Random Forest	98.05%
Naïve Bayes	98.55%

V. RESULTS AND FUTURE WORK

Using the graphs and visualization, we can understand the trends in diseases. The prediction of diseases is also very accurate and yield fast results due to text pre-processing before any of the 3 algorithms is applied. This ensures faster execution and future scalability. The results obtained are very similar due to lack of large datasets in this field. There will be slight variations in result of each algorithm based on data processing. For the most part, they all yield the same results. The Token counts of each vector in word-count is mapped onto the graph in Figure 4 which reveals the most common disease symptom pairs which are found in any of the order as given in graph. The first 4 samples in graph represent dummy braces in the dataset.

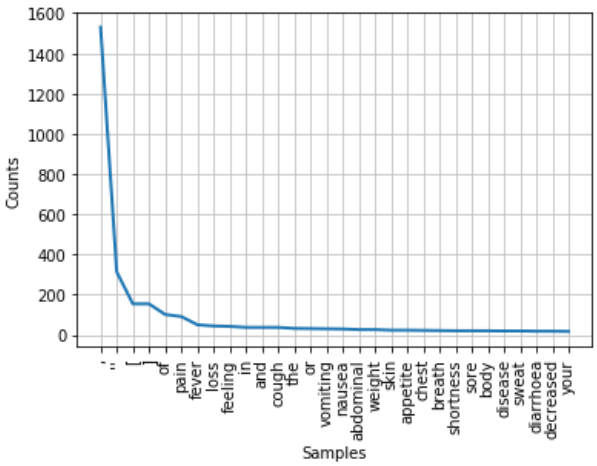

Figure 4: Counts of samples found for each disease

Figure 6 shows how words can be graphically represented from the dataset. The symptoms are arranged in accordance to font sizes i.e. the larger font size means higher frequency of occurrence and lower fonts mean the opposite. The input symptoms can be passed to get the predicted disease.Since there is only 154 most common diseases in the dataset, it is not possible to predict some diseases which may not be classified or present in dataset.It requires a minimum of 3 symptoms to predict a disease. The tests showed differences in predictions. In some cases, Naïve bayes was the only algorithm to predict the disease closest to the actual one when comparing with 3 or more of the same symptoms. In figure 6, 4 main terms stand out – pain, cough, fever and appetite loss. This helps us minimize the transaction time and predict diseases faster by adding parameters for recurring words in a corpus. All the above graphs have shown about the distribution on various symptoms which the most common irrespective of the disease and other symptoms which are occurring only for specific diseases. Figure 5 shows the T-distributed Stochastic Neighbor Embedding (t-SNE) plot which is used to visualize key data points in 3-dimensions. As specified in the graph, we show all the diseases classified as one single cluster of 154 data points. Each color represents a symptom.

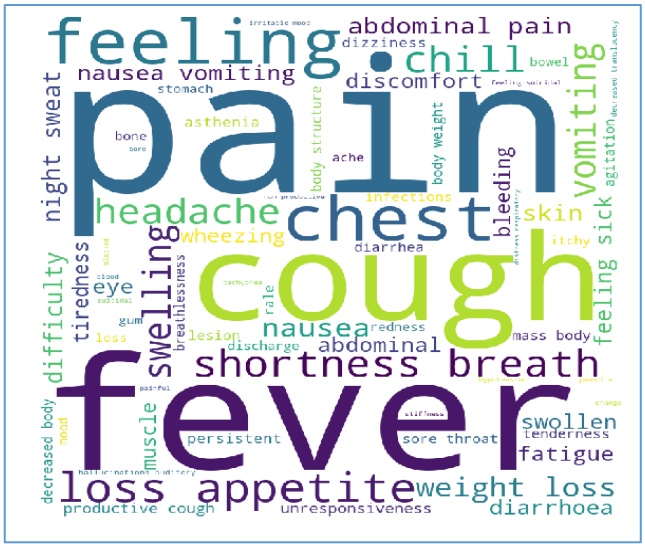

Figure 6: Visualization of words occurrence based on WordCloud

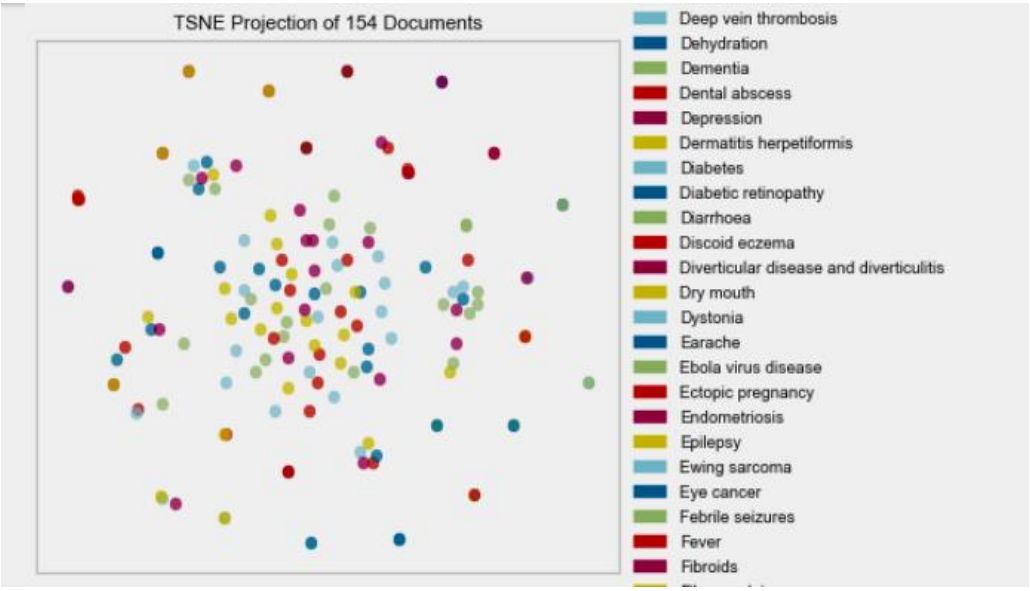

Figure 5: T-stochastic neighbor

We chose Naïve bayes model since it is the most favoured algorithm alongside text data and requires less pre-processing. It does not show all components of the Diagnosis system, but it focuses on the feature of classification. It shows how the data is web-scraped, analysed and is used to make prediction on the disease.

We propose the model in Figure 7 which uses crowd sourced and public data which can be collaborated with hospitals to feed the database of disease and symptoms, for example symptoms exhibited for new diseases like Zika Virus, help in getting data from patients such as heart rate, blood sugar etc.

The dataset can be dynamically updated for given set of attributes for better future prediction. The predictions can be linked to suggest ailments and possible causes of disease in future so the patients can understand the root causes of diseases based on symptoms. Since this model is efficient, we can parallelly add more data and run on multiple systems for faster processing. The future of data mining is more towards crowd sourced data which is gathered from wide variety of

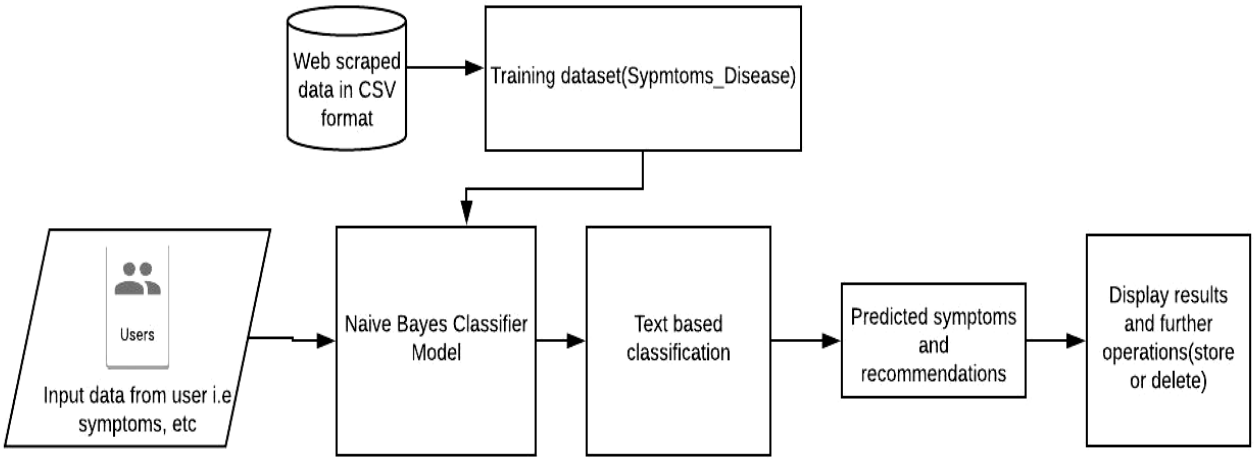

Figure 7: Proposed architecture diagram

etc.Due to lack to public data sources, we are unable to get more data. Collaborated data from hospitals can be curated accordingly for the model.

The block diagram that shows the major functional blocks that are part of the system being described, the outside entities (people and systems not part of the system being described), and the major interfaces between them. It does not show all components of the Diagnosis system, but it focuses on the feature of classification. It shows how the data is scanned, analysed and is used to make prediction on the disease.

VI. Discussion

The model trained for predicting diseases gives a very good result for the given dataset. The algorithms used are very efficient and accurate. The medical field has seen some new innovations in multi-platform availability such as smartphones and smart watch integration to predict and prevent some medical conditions. The power of Artificial Intelligence is also being integrated to Machine learning approaches to bring it closer to the human sentiment. This model can be integrated with chatbot models such as DialogFlow from Google to add some more interactions.

There is room for improving the method of delivering the results to the user by adding an intuitive UI for input of symptoms and prediction of disease. We can integrate the same code for processing on mobile devices for an easier access to healthcare. Various modern mobile sensors can also medical sources. This helps in directly integrating the models which are can process a variety of data based on the features and type of data appropriate for any specific algorithm. The dataset plays the most vital role in improving the model. The test set from UMLS open source dataset was found to be outdated. But it was a source of understanding how web-scraped data can be used to make predictions.

***Abstract*—An energy harvesting system uses Pre charge circuits. The need for designing circuits that consume low power is the need of the day. In this paper a pre charge circuit has been designed in 45nm CMOS technology and the output energy and average power consumption of the circuit has been computed. The cascaded double tail comparator and the gate driver circuits are designed. The pre charge circuit is energy efficient and harvests more energy as compared to the invested energy. The capacitance value for designing the pre charge circuit has been obtained from the capacitive pressure sensor in COMSOL Multiphysics 5.3. A plot of capacitance versus pressure gives the equivalent capacitance for the applied pressure. A value of 1pF has been chosen for an applied pressure of 22.5 to 25 KPa. In the pre charge circuit, the energy consumption during charging of the capacitor was computed to be 4.5 µ W and during discharging it was computed to be 10 µW. The invested energy was 0.281 x 10^{-9} fJ and the obtained energy was 0.781 x 10^{-9} fJ. The net energy gain was 0.5 x 10^{-9} fJ and the percentage gain was 177.94%.**

Keywords— Pre charge circuit, Energy Harvesting, Low Power VLSI Design, Energy efficient circuits

I. INTRODUCTION

Energy harvesting systems use pre charge circuits to charge the capacitor to the applied voltage. Especially in Electrostatic Energy harvesting systems the capacitor is the most important element in the circuit. If the power flow into the device is rapid it will destroy it. Therefore, to prevent this a pre charge circuit is used. Electrostatic energy works on the principle of storing charge in the capacitor. As the distance between the parallel plates increase, the capacitance decreases. As charge is given by the product of capacitance and voltage, the voltage increases, and the capacitance decreases to keep the charge constant [1]. This leads to an increase in the energy.

In [1], an Electrostatic energy harvesting IC has been designed. At 30GHz, the IC harvested 1.27, 2.14, and 2.87 nJ/cycle. The power generated was 38.1, 64.2, and 86.1 nW, respectively. The proposed IC detects C_{MAX} during reset, pre charges CVAR, connects it to the battery, during harvest C_{MIN} is detected and disconnects C_{VAR} during reset. The IC has been designed using BiCMOS logic. A 1µF capacitor takes 35s to charge from 3.5 to 3.81V. In this work a pre charge circuit consisting of a pre charge comparator, pre charge de – energize comparator, bias current generator, harvest detection subsystem and pre charge detection subsystem are designed. Errick O Torres [2], presents a self- tuning electrostatic energy harvester IC. The inductor based pre charger adapts to a constantly changing supply voltage. The pre charger and its self-tuning reference, draw enough power but dissipate minimum energy. At battery voltages of 2.7, 3.5, and 4.2 V, the harvester generates, the IC generates 1.93, 2.43, and 3.89 nJ per vibration cycle, respectively. The operating frequency is 30GHz. The power for the respective voltages is computed as 57.89, 73.02, and 116.55 nW. A 1µF capacitor is charged from 2.7 to 4.2 V in 69s. The energy harvesting is demonstrated in three phases, the pre charge phase, the harvest phase and the reset phase. B Manoj Kumar [4] proposes a low power and high-speed double tail comparator. As compared to the other proposed comparator designs i.e the dynamic comparator, double tail comparator and modified double tail comparator, the one proposed in this paper is the fastest and consumes he least power. The proposed comparator has been designed in 180nm technology. The delay is computed to be 15.32ps and the average power consumption is 13.90 µW. In [3] and [5] the design of energy efficient electrostatic transducers has been discussed. SOI-based electro-mechanical transducer has been modelled and fabricated. The use of a capacitive pressure sensor to demonstrate the energy harvesting principle is discussed in [6], [7].

The literature survey provides evidence for the use of electrostatic energy for designing an energy efficient pre charge circuit.

II. BASICS OF ELECTROSTATIC ENERGY HARVESTING

Electrostatic energy harvesters use capacitors for storing and retrieving the charge. The conversion of vibration to charge can be considered as an electromechanical conversion process. The charge stored in a capacitor is given by equation 1. Q is the charge, V is the voltage and C is the capacitance.

$$Q = CV \tag{1}$$

The distance between the paralled plates d, the capacitance C, area A and the relative permittivity ε are given by equation 2.

$$C = \frac{\varepsilon A}{d} \tag{2}$$

The relationship between the Energy E, capacitance C and voltage V is given by equation 3.

$$E = \frac{1}{2}CV^2 \tag{3}$$

III. Implementation of Pre charge Circuit

The energy harvesting circuit contains a pre charge circuit used to reduce the rapidity of power flow into the device during charging. The pre charge circuit consists of the following sub circuits.

- Capacitor – The design value has been obtained from COMSOL. For a pressure of 20kPa, the equivalent capacitance is approximately equal to 1pF.
- Comparator – Based on Domino logic
- Gate driver circuit
- Inductor – The value is taken to be 10µH.

The voltage at the inductor is compared with the reference voltage. The capacitance value is assumed to be 1p F. The DC voltage amplitude given for Vpulse is 1V. The specifications for performing the transient analysis are shown in Table I.

TABLE I Specifications for Performing Transient Analysis

Analysis	Specification
Transient	Cap = 1pF Vpulse = 1V

Table I shows the Specifications for performing Transient Analysis. The capacitance value is chosen to be 1pF and the applied voltage to the Pre charge circuit is 1V. The Pre charge circuit is shown in Fig. 1.

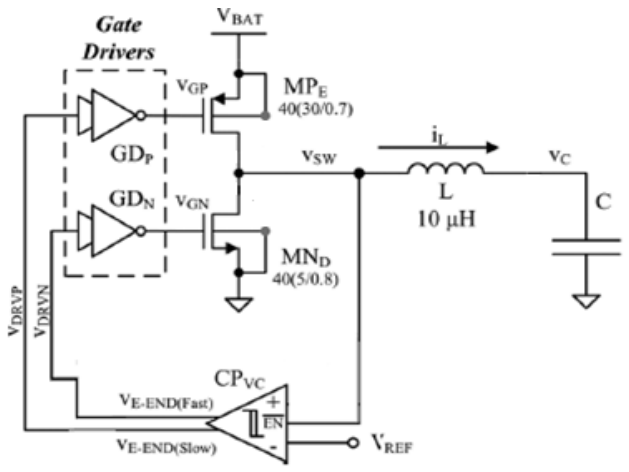

Fig. 1. Pre charge Circuit

Transistors MP_E and MN_D charge C to the supply voltage V_{BAT} by energizing and de-energizing inductor L. As L and C energize, comparator C_{PVC}

A. Obtaining the capacitance value from COMSOL

An electromechanical capacitive pressure sensor has been designed in COMSOL. The pressure from a range of 20 to 25KPa is applied. The equivalent of mechanical vibration is considered as pressure in this case. It is shown in Fig. 2. The legend on the right side of the figure indicates the displacement on the application of pressure. The displacement ranges from 0.2µm to 2µm. The pressure is maximum at the centre of the electromechanical pressure sensor i.e near the vacuum cavity. Near the vacuum cavity the displacement is around 2µm. Towards the surface of the pressure sensor is dradually decreases.

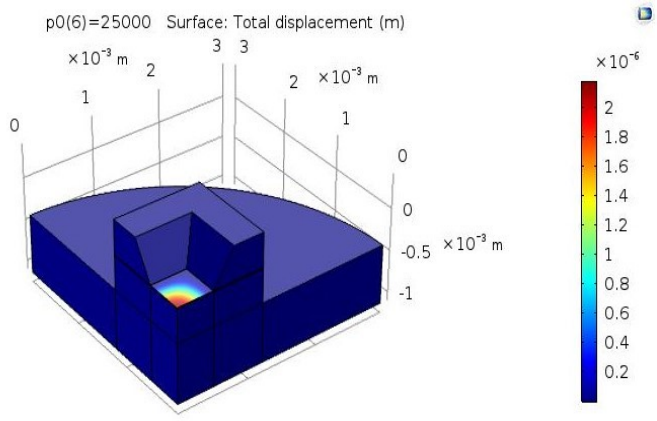

Fig. 2. Electromechanical capacitive pressure sensor

A plot of capacitance v/s pressure is shown in Fig. 3. The C value of 1pF has been considered for design for a pressure between 22.5 to 25KPa.

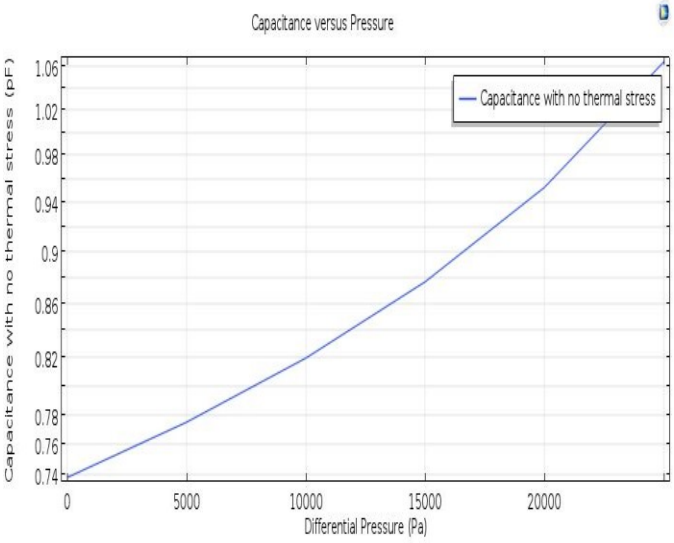

Fig. 3. Plot of capacitance v/s applied pressure.

B. Design of Gate Driver Circuit

The gate driver circuit consists of 14 transistors in total. Out of which, seven of them are PMOS and the other seven are NMOS transistors. The transistors are assigned the sizes as follows. MPP1, MPP2 and MPP3 are assigned W/L ratios of 12/0.7, 4(12/0.7) and 20(12/0.7) respectively [1]. MNP1, MNP2 and MNP3 are assigned W/L ratios of 3/0.8, 4(3/0.8) and 20(3/0.8) respectively. MNP1, MNP2 and MNP3 are assigned W/L ratios of 8/0.7, 4(8/0.7) and 20(8/0.7) respectively. MNN1, MNN2 and MNN3 are assigned W/L ratios of 2/0.8, 4(2/0.8) and 20(2/0.8) respectively. The transistors MPE and MND are

connected to GDP and GDN. The gate driver circuit is shown in Fig. 4.

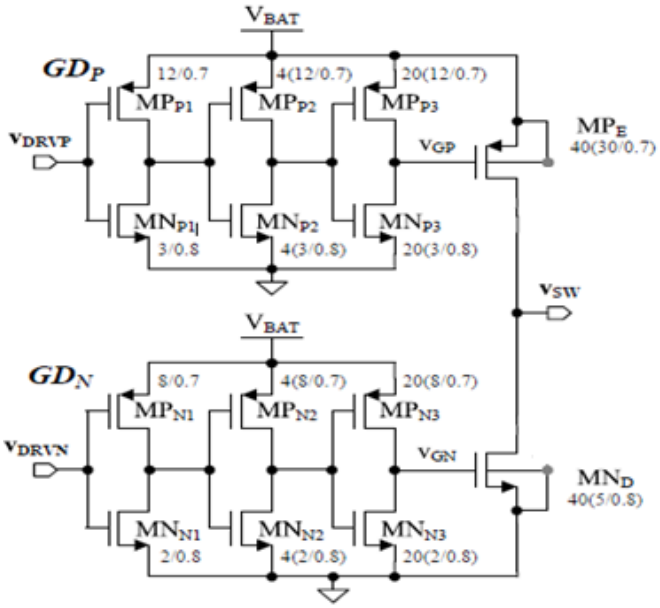

Fig. 4. Gate Driver Circuit [1]

C. *Design of Cascaded Double Tail Comparator*

Comparators form the basic building block in many Analog circuits such as Data converters and Signal Processing systems. A comparator also forms an important component of the Pre charge circuit.

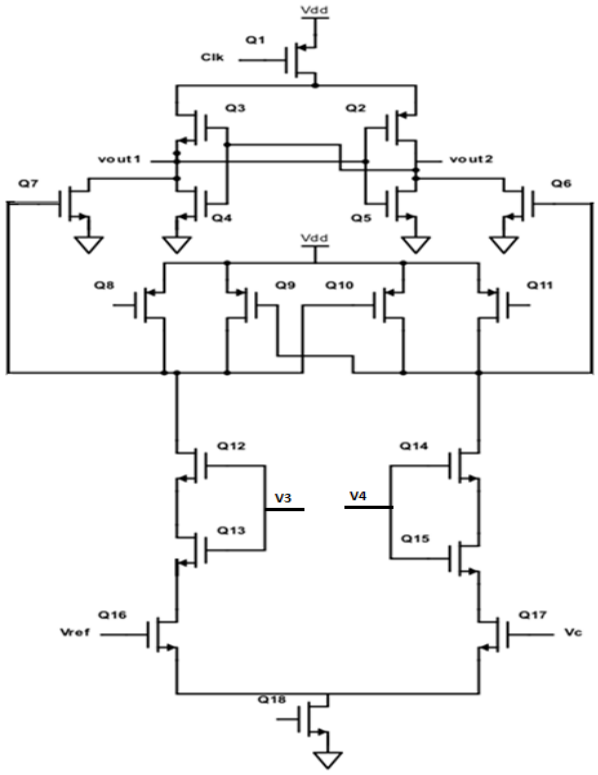

Fig. 5. Cascaded Double Tail Comparator [4]

The Cascaded Double Tail comparator is a high speed and a low power comparator and is most appropriate for the application.[4] It has been designed using the 45nm CMOS technology. The devices that are used are pmos1v and nmos1v which form a part of gpdk045. The pulse widths for V_c, V_{ref} and clk are specified. The voltages vpulse and vdc are a part of the library analogLib. The amplitude of 1V is applied to all. For V_c the period is 30ns, pulse width is 15ns and DC voltage is 0.8 V. For V_{ref} the period is 40ns, pulse width is 20ns and DC voltage is 1.1V. For clk the period is 20ns, pulse width is 10ns and DC voltage 1V. The supply voltage is 1V. The Double Tail comparator has been designed using Cadence Virtuoso Analog Design Environment and is shown in Fig. 5. The specifications for designing the pre charge circuit are shown in Table II.

TABLE II SPECIFICATIONS FOR DESIGNING COMPARATOR

Library	Model name	Pin Name	Specification
gpdk045	pmos1v, nmos1v	Vref, Vc	L = 45nm, VDD = 1V
analogLib	Vdd	Not applicable	1V
	vpulse	Not applicable	1.1 V
	gnd	Not applicable	-
analogLib	vpulse	Vref	Period = 40ns Pulse width = 20ns. DC Voltage = 1.1 V
		Vc	Period = 30ns Pulse width = 15ns DC Voltage = 0.8 V
		clk	Period = 20ns Pulse width = 10ns DC Voltage = 1V

The specification for performing transient analysis is shown in Table III. The transient analysis has been performed for the Cascaded Double tail comparator. The stop time is set to 200ns and the accuracy defaults are set to moderate.

.

TABLE III SPECIFICATIONS FOR PERFORMING TRANSIENT ANALYSIS OF THE COMPARATOR

Analysis	Specification
Transient	Analysis: tran Stop time: 200ns Accuracy defaults: Moderate

IV. RESULTS OF PRE CHARGE CIRCUIT

The pre charge circuit was designed with the Double tail comparator and a gate driver circuit. The output of the comparator was a constant DC voltage which verified it functionality and is shown in Fig. 6.

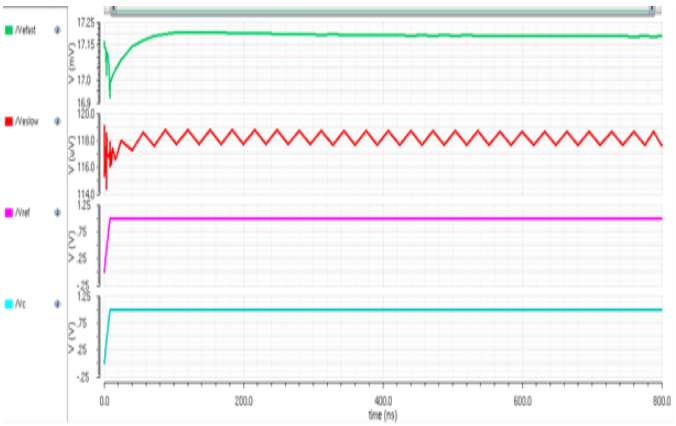

Fig. 6. Output of the comparator

The energizing and de-energizing of the capacitor is depicted in Fig. 7.

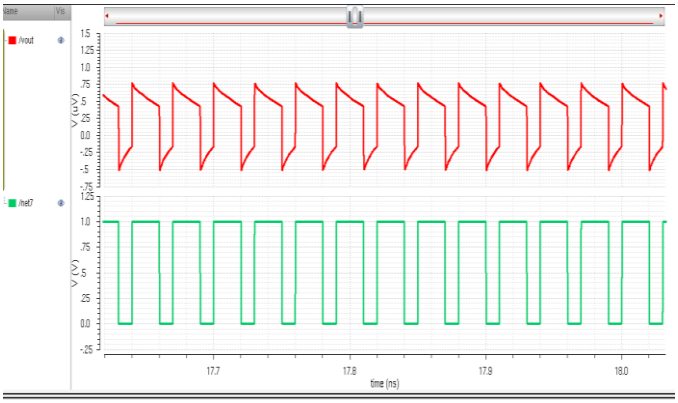

Fig. 7. Energizing and de energizing of the comparator

Vc and Vref were the two inputs and Vefast and Veslow were the two outputs. When the comparator output was 1, the gate driver sent the output to the capacitor, and it charged. When the output was 0, the capacitor de-energized. This happened when the comparator output was 0. The input voltage was 1V and the output voltage during charging was 0.75µV. This happened when the output of the comparator was high. When the output of the comparator was low, the capacitor discharged. This voltage was the difference between 0.75µV and -0.50 µV.

The energy during charging is given by

$$E = \frac{1}{2}CV^2$$
$$= \frac{1}{2} \text{x } 1\text{pF x } (0.75\mu V)^2$$
$$= 0.281 \text{ x } 10^{-9} \text{ f Joules}$$

The energy during discharging is given by

$$E = \frac{1}{2}C(V_{MAX} - V_{MIN})^2$$
$$= \frac{1}{2} \text{ X } 1\text{pF x } (0.75\mu V - (-0.50\ \mu V))^2$$
$$= 0.781 \text{ x } 10^{-9} \text{ f Joules}$$

The net energy increase by the capacitor is given by

= energy during discharging – energy during charging
= (0.781 x 10^{-9} f Joules - 0.281 x 10^{-9} f Joules)
= 0.5 x 10^{-9} f Joules

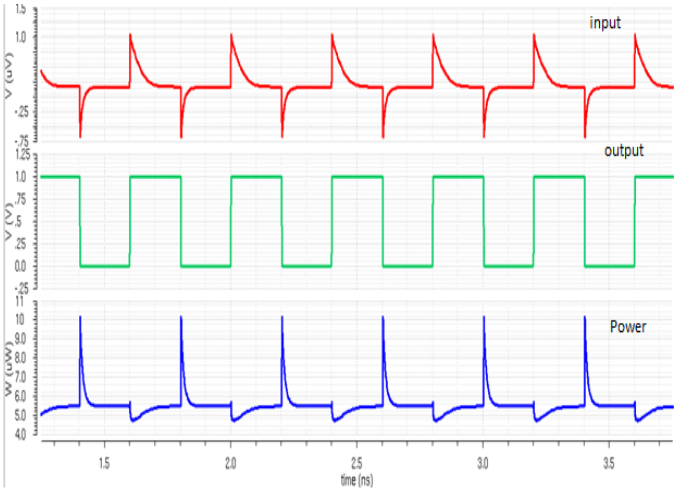

Fig. 6. Computation of power of pre charge circuit

Computation of power of the pre charge circuit is shown in Fig. 6. The applied input was 1V. During charging of the capacitor, the output peak power was 4.5µW. During discharging the power was higher which computed to 10µW. The energy consumption of the circuit is given by $E = \frac{1}{2}CV^2$. The energy and power consumption of the circuit is shown in Table IV.

TABLE IV ENERGY AND POWER CONSUMPTION OF PRE-CHARGE CIRCUIT

Power consumption		Energy consumed (fJ)	
Charging	**Discharging**	**Charging**	**Discharging**
4.5µW	10µW	0.281 x 10^{-9}	0.781 x 10^{-9}

A comparison was done with the previous works. The invested and obtained energies were compared. The energy during charging was 0.281 x 10^{-9} fJ and the energy during discharging was 0.781 x 10^{-9} fJ. Comparison of energy consumption with previous works is shown in Table V.

TABLE V ENERGY CONSUMPTION AND COMPARISON WITH PREVIOUS WORKS

Parameters	Invested Energy	Obtained Energy	Net Energy Gain	Gain in percentage
Previous work [1]	-5.629 nJ	-4.356nJ	1.273nJ	22.61%
Present work	0.281 x 10^{-9} fJ	0.781 x 10^{-9} fJ	0.5 x 10^{-9} f J	177.94%

In the previous work [1], the invested energy was -5.629 nJ and the obtained energy was -4.356nJ. The net energy gain per cycle was 1.273nJ. The gain in percentage was 22.61%. In the present design the invested energy was 0.281 x 10^{-9} fJ and the obtained energy was 0.781 x 10^{-9} fJ. The net energy gain was 0.5 x 10^{-9} f J. The net energy gain in percentage was 177.94%.

V. CONCLUSION

The capacitance value for designing the pre charge circuit has been obtained from the capacitive pressure sensor in COMSOL Multiphysics 5.3. A plot of capacitance versus pressure gave the equivalent capacitance for the applied pressure. A value of 1pF was chosen for an applied pressure of 22.5 to 25 KPa, to design the pre charge circuit. In the pre charge circuit, the energy consumption during charging of the capacitor was computed to be 4.5µW and during discharging it was computed to be 10 µW. The invested energy was 0.281 x 10^{-9} fJ and the obtained energy was 0.781 x 10^{-9} fJ. The net energy gain was 0.5 x 10^{-9} fJ and the percentage gain was 177.94%. In the previous work [1], the invested energy was -5.629 nJ and the obtained energy was -4.356nJ. The net energy gain per cycle was 1.273nJ. The gain in percentage was 22.61%.

***Abstract*— The electrocardiogram (ECG) helps to read the electrical and muscular functions of the heart. The burdensome part in Electrocardiogram (ECG) acquisition is that the signal voltage levels are typically ranging between 0.1mV and 5mV but the noise levels are in few volts. This makes the signal too weak and extraction is done by amplification of the ECG signal, rejecting noise and interference signals. The amplification levels are fixed according to its compatibility with devices such as digital storage oscilloscope (DSO). This report deals with the design and implementation of an instrumentation amplifier with appropriate filtering circuits.9th order Butterworth lowpass and high pass filters are used to reject noise. The circuit is designed and simulated using Multisim. The circuit is hardware implemented and tested in real-time and analysis of the results are presented.**

Keywords*— *ECG, Butterworth filter, Instrumentation amplifier, sallen key topology, differential amplifier

I. INTRODUCTION

ECG signal records the electrical activity of the heart. One cycle of the ECG signal consists of the P wave, QRS complex along with T wave. Each has its own importance and value. Cardiovascular diseases account for more than a million deaths per year worldwide. Information about a wide range of cardiac disorders can be pulled out from an ECG signal. ECG can also detect the presence of any damage to the heart. The main objective of this paper is to acquire the ECG signal, display the signal on a DSO and to thus understand the system used in biomedical instrumentation. The circuit is divided into three parts namely,

- Instrumentation Amplifiers
- High pass filter
- Low pass filter

This paper explains the design and hardware implementation of the ECG acquisition system. Section 2 describes the various studies related to the ECG acquisition. Section 3 describes the proposed system with circuit design. Section 4 deals with the simulation and experimental results. Section 5 gives the conclusion of the work and future work.

II. RELATED WORKS

The authors in [1] use second order Butterworth low pass and high pass filters which don't exhibit higher roll off in filter response and removal of noise is not done to the expected levels. In [4] µa741 operational amplifier is used in the circuit which produces more internal noise and has higher offset values. The authors [5] implemented filtering circuits, that doesn't help in pulling out a clear ECG signal which contains high levels of noise. In [7] fifth-order Bessel filters were implemented. Higher order filters can be used to increase the precision of the circuit.

III. OBTAINING AN ECG SIGNAL

The block diagram of the ECG acquisition system is shown in Fig. 1. The Ag-AgCl electrodes are attached as shown to the human body and connected to the instrumentation amplifier (IA). The output of IA is given to filters and thus a clean ECG signal is obtained.

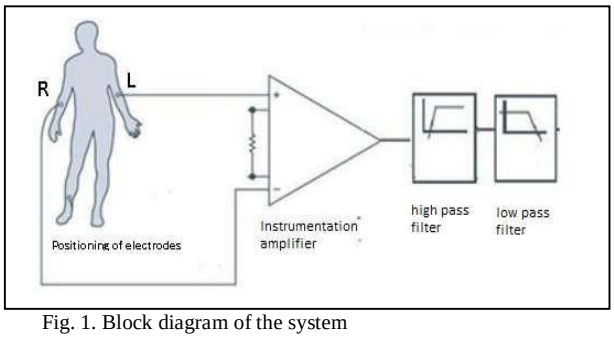

Fig. 1. Block diagram of the system

A. Instrumentation amplifier

An instrumentation amplifier (IA) as shown in Fig. 2 is a difference amplifier meeting the following specifications:

- Extremely high (ideally infinite) common-mode and differential mode input impedances.
- Very low (ideally zero) output impedance
- Accurate, stable gain and extremely high common-mode rejection ratio.

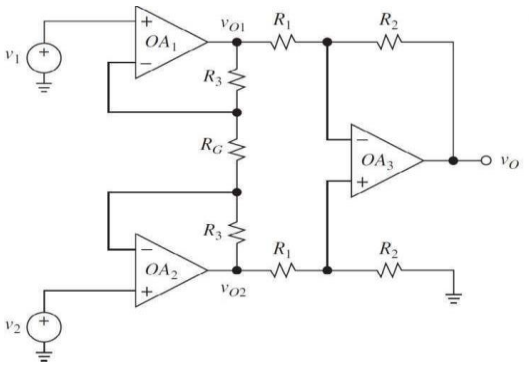

Fig. 2. Instrumentation Amplifier

The foremost function of the instrumentation amplifier is to reject common mode noise and amplify a low-level signal. This can be achieved by providing a good Common Mode Rejection Ratio (CMRR). Thus, from equation 1 it can be inferred that to increase CMRR, A_{cm} must be decreased.

$$CMRR=20*\log |A_{dm}/A_{cm}| \quad (1)$$

Normally the peak value of the ECG signal is 1mV. Thus, for further processing of the signal amplification is required. So, by using equation 2 gain is fixed.

$$gain= (1+2 R_3/R_G) *R_2/R_1 \quad (2)$$

Effect of resistance mismatches:

An instrumentation amplifier will be insensitive to common mode only as long as the resistors satisfy the balanced-bridge condition. In general, it can be said that if the bridge is unbalanced, the circuit will respond not only to differential mode but also to common mode signals. It is apparent that for high CMRRs the resistors must be very tightly matched, and this is achieved as shown in Fig. 3 by matching the values by adjusting the value of the Rpot until it is perfectly matched and lowest possible common mode gain is attained.

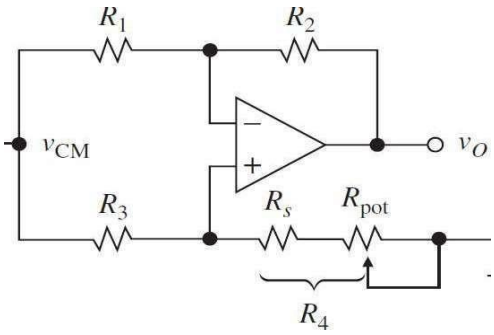

Fig. 3. CMRR Optimization

Another key aspect in IA is the choice of an operational amplifier. As the ECG signal is in very low amplitude levels an opamp with low offset voltage and low noise is required to accurately amplify the required signal. Thus, the op27 precision operational amplifier is suitable for this application.it has an offset voltage of 10 μ V and noise, en = 3.5 nV/ √ Hz, at 10 Hz. It also has Low drift: 0.2 μV/° C and High speed: 2.8 V/μs slew rate.

B. Filters

ECG signal lies in a frequency range of 0.5Hz to 40Hz. So, there is a need for a filter that allows only the ECG signal's frequency range and rejects all other frequencies. It is impossible to attain a brick wall response but the order of the filter plays an important role. Butterworth curve becomes somewhat rounded near cut off frequency and rolls off at an ultimate rate of −20 dB/Dec in the stopband.

The higher the order n, then the closer the response is to the brick-wall model. The cut off frequency is determined by equation 3.

$$fc=1/(2*\pi*R*C) \quad (3)$$

Fig. 4,5 depicts the Butterworth second order high pass and low pass filter. It serves as a building block for higher order filters. The operational amplifier used in the design is op07, which is cheap and has a low offset voltage.

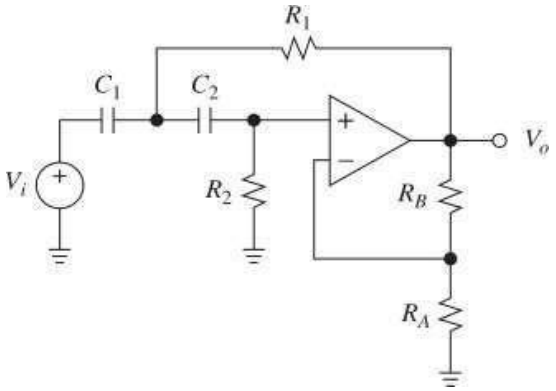

Fig. 4. Butterworth 2nd order High pass filter

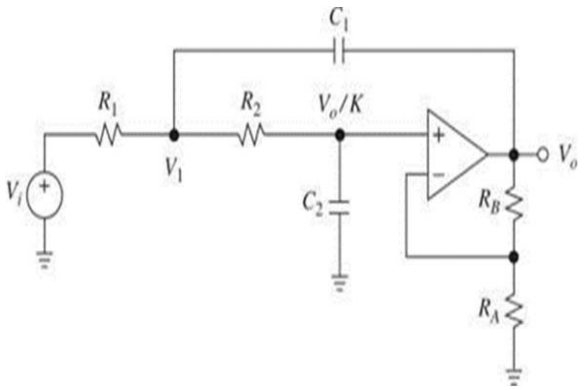

Fig. 5. Butterworth 2nd order Low pass filter

Imposing R1 = R2 = R and C1 =C2 =C we get the design equation,

$$RC=1/\omega, K=3-1/Q, RB=(K-1)RA \quad (4)$$

By using equation 4 we can design our desired nth order filter. In our case to get a 9th order filter, four 2nd order filters and one 1st order filter is cascaded. The Q values for each second order filter cascade is determined from the normalized Butterworth low pass filter table and substituted in equation 4 to get the required RA and RB values. Fig. 6 and 7 show the design for 9th order high pass and low pass filters respectively. The low pass and high pass designs are cascaded to get the desired response. Each operational amplifier circuit is a second order filter and thus four operational amplifier circuits constitute eighth order and finally, an RC is cascaded to get a desired ninth order.

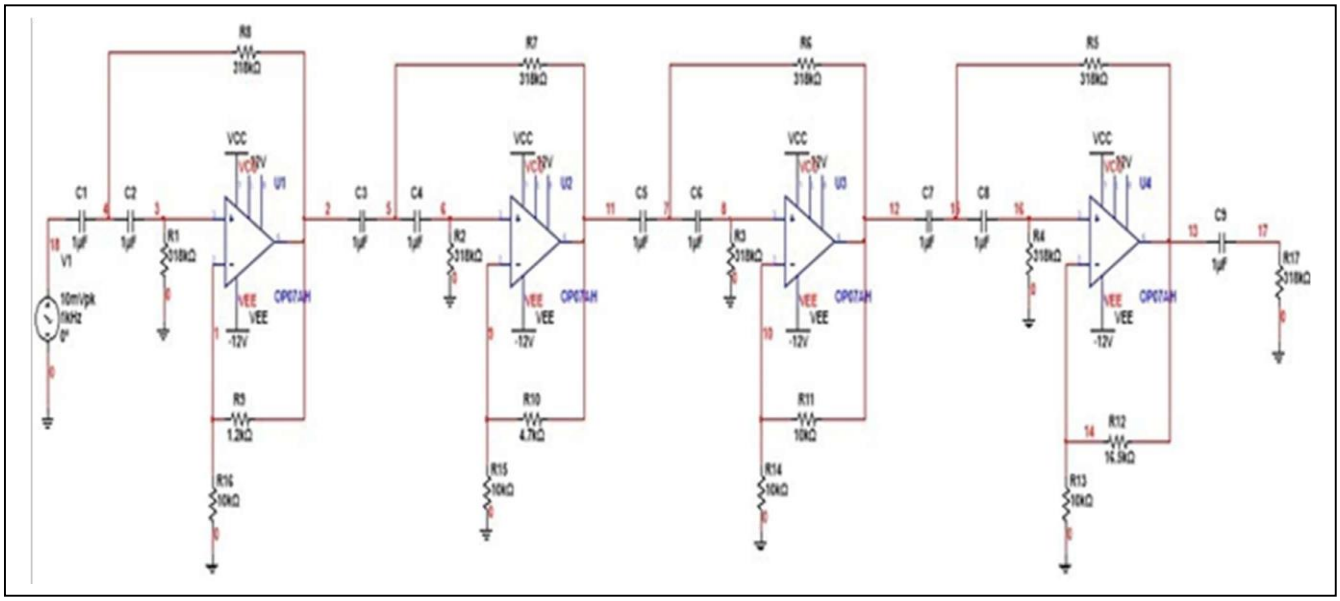

Fig. 6. Ninth order Butterworth High pass filter

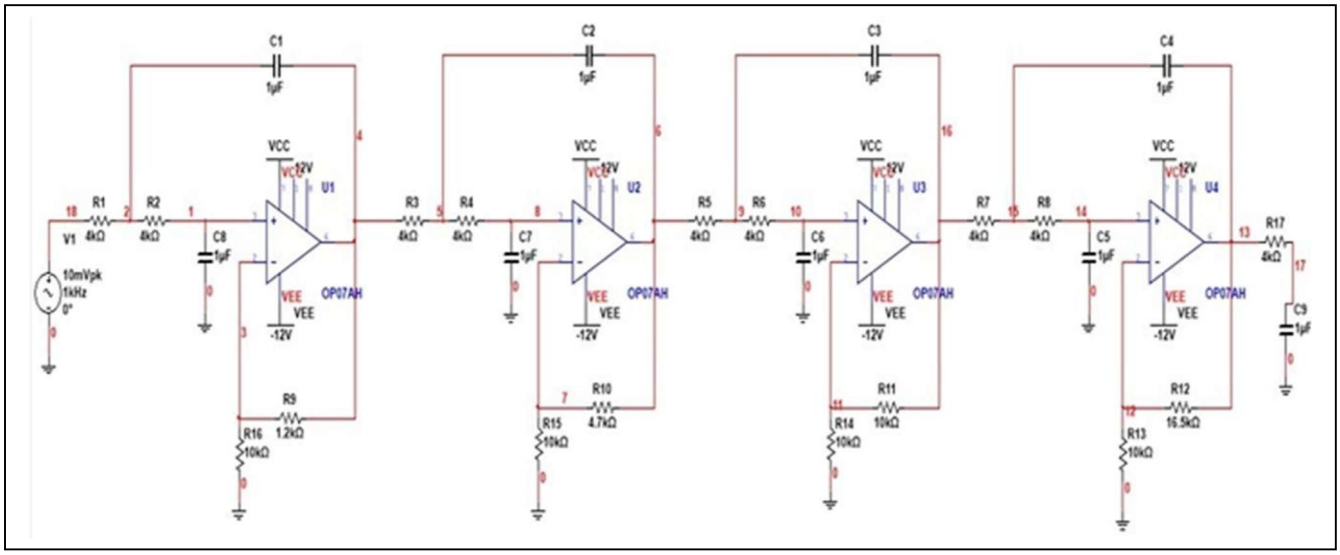

Fig. 7. Ninth order Butterworth Low pass filter

IV. RESULTS

The cascaded filter response is shown in fig. 8. The filter has a lower cutoff frequency as 0.5Hz and higher frequency cutoff of 40Hz. As it is a ninth order filter it has a roll off of -180dB/Dec. This higher roll off separates the noise and signal components. Simulations are carried out using Multisim tool and the results are verified. Fig. 9,10,11 shows the hardware implementation of the ECG acquisition system. Tolerance of the resistor plays a crucial role in our system, so 1% tolerance resistors are used throughout. Filters used in the circuit are active analog filters.

The cumulative gain of the high pass (Fig. 10) and low pass filter (Fig. 11) is 75. Thus, cascading instrumentation amplifier and the filter will yield a total gain of 750. Hence, the entire circuit amplifies the ECG signal 750 times and also filter of the noise.

Fig. 12 shows the final output of the proposed ECG acquisition system taken from a human volunteer. Thus, the system is able to reduce noise and amplify the ECG signal. It produces very efficient and continuous ECG signal that can be recorded.

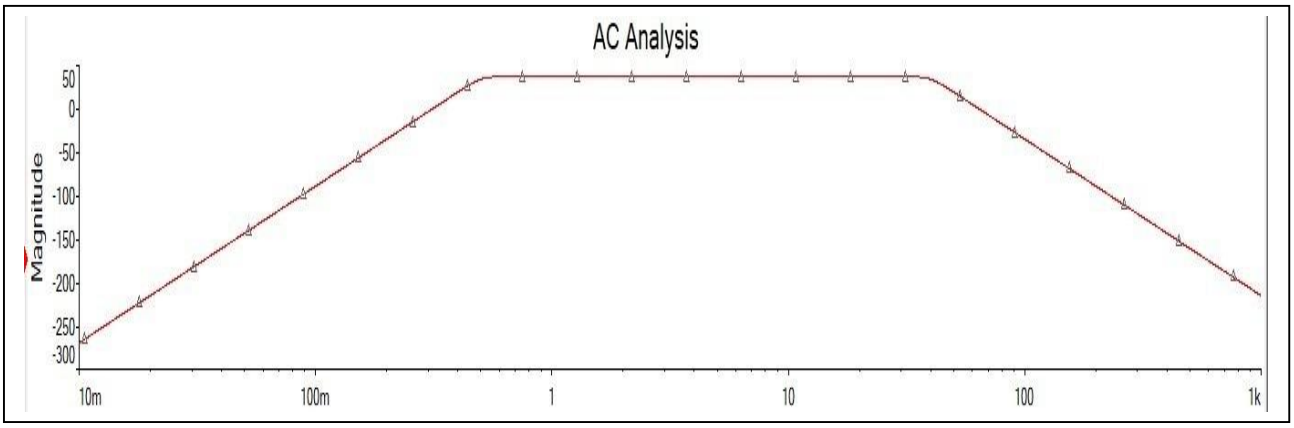

Fig. 8. Filter response

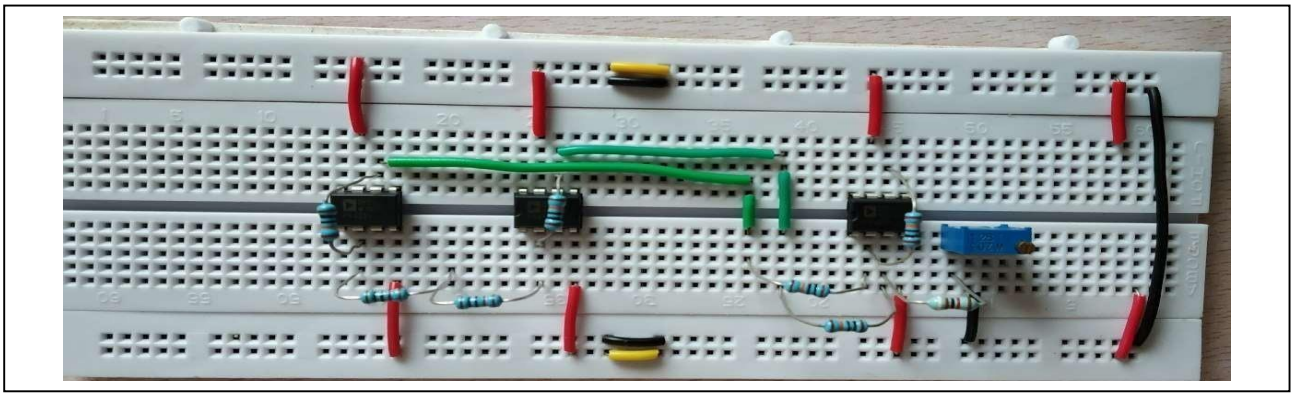

Fig. 9. Instrumentation amplifier

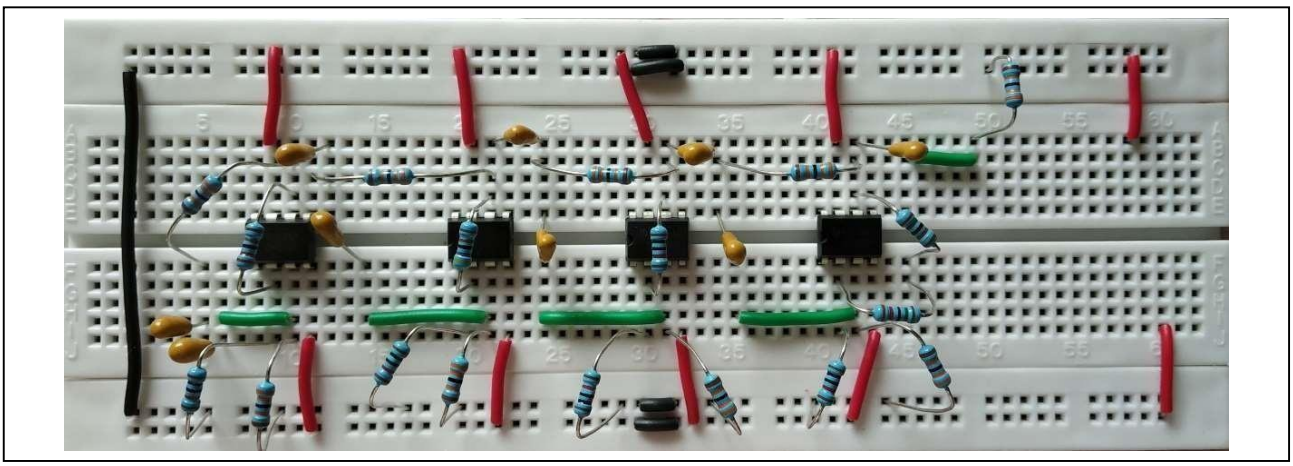

Fig. 10. Ninth order high pass filter

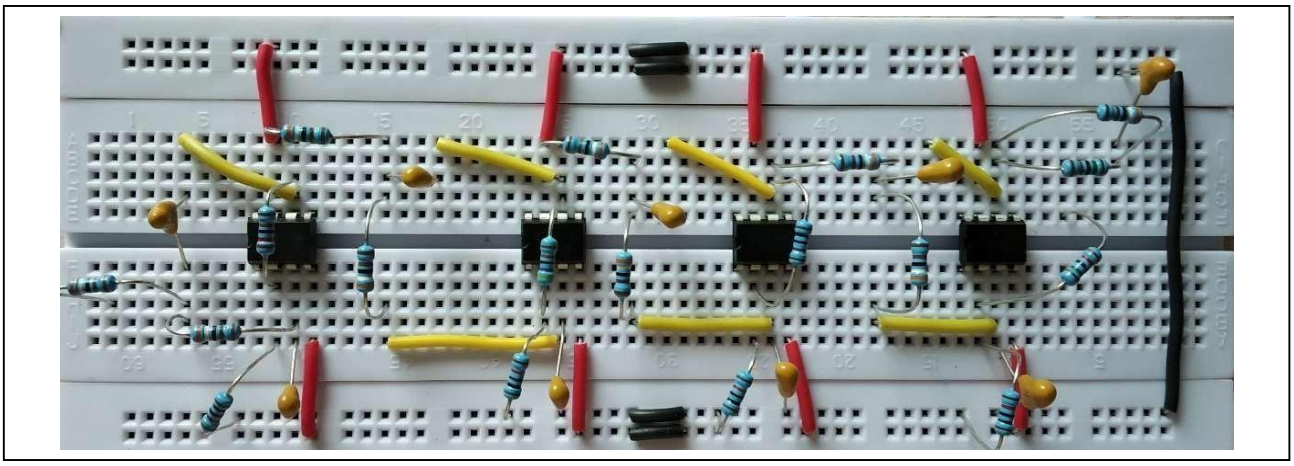

Fig. 11. Ninth order low pass filter

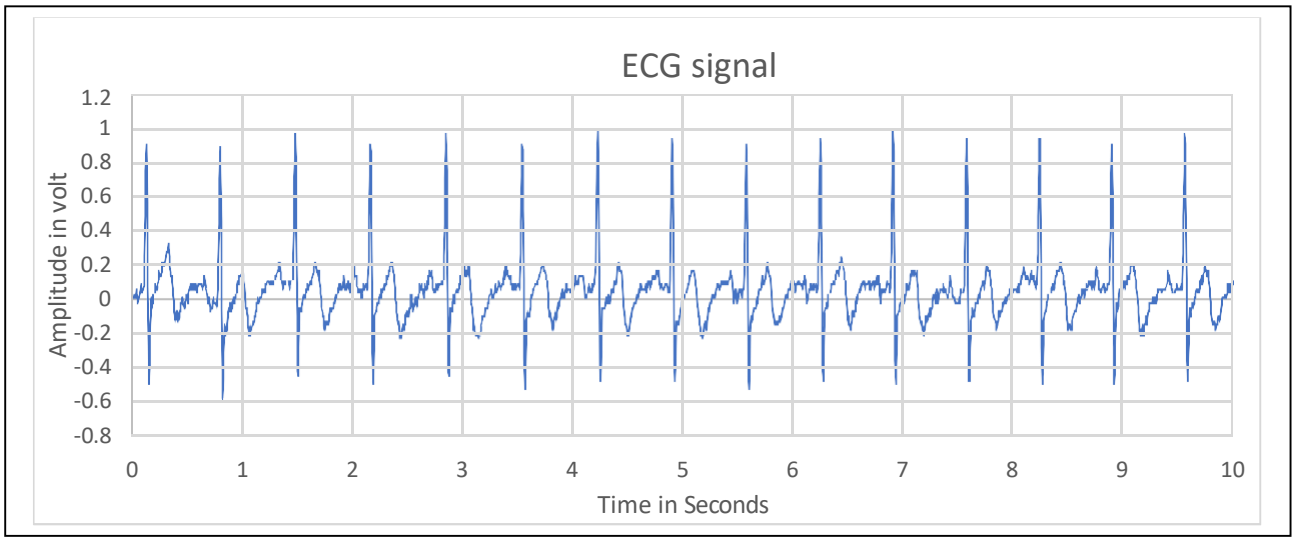

Fig. 12. The output of the system

CONCLUSION

A circuit that has a structure has been built on a breadboard. Conventional Ag/AgCl plated disposable ECG electrodes were used to get the ECG signals from the human volunteer. The output shows that successful conditioning of the raw ECG signal is performed. The system is able to remove artifacts and high-frequency noise. Ninth order filter plays a crucial role in the removal of the above-mentioned noises. Filter's sharp cutoff frequency removes the unwanted frequencies and thereby giving a smooth response of the output signal as seen in Fig. 12. Further, the system can be implemented in a printed circuit board to reduce noise to a greater extent. Also, using a Bessel filter instead of a Butterworth filter enhances the performance of the system.

Ranchi, India

***Abstract* - Facial Expression Recognition is an extremely interesting topic of research owing to the uniqueness attached to emotions of different humans. Deep Learning is a novel zone within the domain of machine learning which is exceedingly efficient in image classification problems. Methods of Deep Learning, (CNN) Convolutional Neural Networks in particular, have been used with great precision for the purpose of feature extraction. This paper categorizes each facial image into one of the seven human emotion classes by making use of a specially designed Convolutional Neural Network which employs four subsequent sets of layers and a loss function. The model has been trained and tested on the FER2013 data set from the *Kaggle Facial Expression Recognition Challenge*, which consists of 35,887, 48-by-48-pixel pictures of human faces, which are grayscale in nature, each with a label of one of the 7 emotion categories. The model gives an accuracy of about 64%.**

Keywords: Facial Emotion Recognition, Deep Learning, CNN, Convolutional Neural Network.

I. INTRODUCTION

Facial expression is a perceptible manifestation of the cerebral activity, physiology, psychology, temperament, intentions and state of mind of a person. Facial Expressions are vital for social interactions as they provide cues and guide conversations. It is also an essential mode of non-verbal communication, the study of which can make lives easier for all human beings. David Matsumoto declared that there are seven basic human emotions, namely sadness, happiness, anger, surprise, disgust, fear and neutral. and each term is a family of connected emotions. [1] It has also been seen that it is easier to differentiate between emotions which are genuine than among those that are unfelt. Facial Expression Recognition has continued to remain an inspiring and challenging problem in computer vision and continues to pique the interest of researchers because the way in which people show their expressions varies and this difference makes the objective of classification into categories exceptionally tedious. Facial Expression Recognition in computer vision because the difference in people's way of expressing Computer vision is a domain that provides computers with instincts and intelligence that is comparable to humans. It works towards training computers to perceive things in the same way as humans do, process that input and then provide the required output. However, this is a rather tedious task.

The edge between the physical and the digital world is continuously blurring. This has given rise to Human-Computer interaction. These new modes of interaction usually require the capture of the observable behaviour of the user for which artificial perception techniques like computer vision are useful. Vast strides in technology and artificial intelligence have made Human-Computer interaction very feasible and detection of human emptions by machines is one of the most trending subjects that is being researched. [2] Due to the vast applications of emotion recognition in areas of Human-Computer Interaction, various methods have been applied. Facial expression recognition usually utilizes a three-tier training involving Face Acquisition [3], Feature Extraction [4] and Classifier Construction [5,6]. In [7], the writers proposed four stages for recognition: face extraction, pre-processing, principle component analysis (PCA) and classification. Later, some works [8, 9] exhibited that combination of facial feature extraction stage and classifier construction stage can benefit the process of emotion recognition. A model to evaluate facial representation based on statistical local characteristics and binary patterns was devised in [10]. Lajevardi et al. used K-NN classifier to classify the selected features [11]. A different technique was proposed in [12], which made use of the 2-D discrete cosine transform, over the picture of the face, as a feature detector and a constructive feed forward neural network, with a concealed layer, as an emotion classifier.

However, due to a surge in the availability of computational power and increasingly huge training databases to train and test the models, the machine

learning technique has become the dominating force in the field of emotion detection in recent times. As times have evolved, Deep Learning, which is a subset of Machine Learning itself, has taken over; especially for cases which make use of image data. Deep Learning models not only work more efficiently with image datasets, but the algorithms can also self-determine whether a prediction is precise or not. Hong Wei NG et al. used a transfer learning approach for Deep CNN architectures. They pre-trained their network on the ImageNet dataset and fine-tuned their network in two stages using two different datasets. Their results verified that this cascading of fine-tuning yielded better results [13]. In [14], a face detection classification network was designed which was a collective of multiple deep CNNs. Again, the pre-trained networks were fine-tuned on SFEW 2.0 dataset and then combined to learn ensemble weights of individual networks. Heechul Jung et al. devised a double stage process. Firstly, the face was detected from image using Haar-like features. Secondly, the deep network was used for classifying the facial expression of the detected face. They also compared two types of deep networks, and the convolution neural network was found to trump the other neural network in performance [15]. In [16], Ma Xiaoxi et al. employed Deep Boltzmann Machine (DBM) and SVM (Support Vector Machine). Ali Mollahosseini et al. designed a network consisting of two convolutional layers each ensued by max pooling and then four Inception layers [17]. Abir Fathallah et al. offered a novel architecture based on CNN for facial expressions recognition. They used Visual Geometry Group model (VGG) to fine tune their architecture and acquired better results [18]. In [19], Neha Jain et al. proposed a hybrid Convolution-Recurrent Neural Network method. The architecture consisted of Convolution layers which extracted the relations and patterns in the images, subsequently followed by Recurrent Neural Network which considered the temporal dependencies in the images during classification. Bazrafkan in [20] showed that the accuracy in prediction of emotion was lower when different databases were used for training and testing.

By virtue of facial expression recognition, assistance can be lent to monitor patients in hospital or psychiatric wards. It can be used during sessions with therapists or psychiatrists. It is an excellent feedback tool whose services can be availed by banks, movie theatres, supermarkets etc. Another domain which can benefit greatly from facial expression detection is e learning where real time feedback can be supplied to online tutors or tutorial videos.

II. METHODOLOGY

The objective of this work is to correctly identify the emotion depicted on the human face by making diligent use of a Convolutional Neural Network. In this, network is configured in such a way that it has four convolutional layers, each followed by a down-sampling Pooling layer and a terminating fully connected layer as shown in fig. 1. In the Fully Connected Layer, SoftMax Activation function is used.

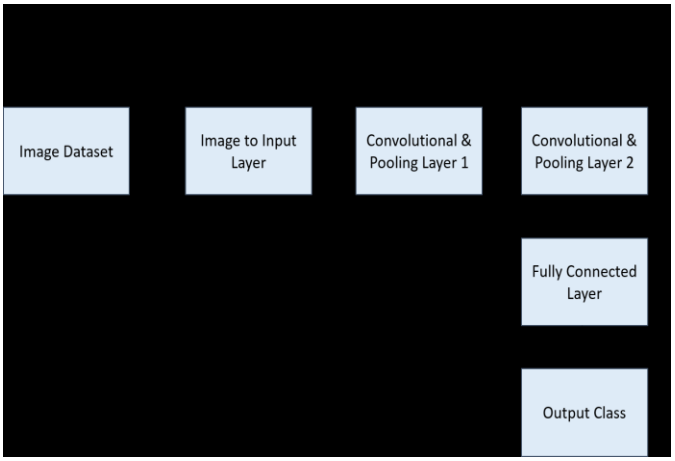

Fig 1. Flowchart

Convolutional Neural Networks fall under the domain of Deep Learning and the reasoning for choosing Deep Learning over Machine Learning is the fact that these algorithms can determine whether an estimate is accurate or not, on its own. Also, Deep Learning networks work better with large data than classical ML algorithms and image classification is one field where Deep Learning has shown immense hike in quality from Machine Learning. Convolutional Neural Networks, also known as ConvNets, aren't very different from ordinary Neural Networks. Their fundamental structure consists of neurons with weights and biases that possess the ability to learn themselves. Every neuron is provided with some input, a dot product with some weight is calculated and a non-linearity is optionally attached. From the raw input data input at one end, we get a class score at the other and this score is achieved by virtue of an activation function that succeeds the last fully connected layer. The difference from regular Neural Networks lies in the fact

that the layers of a CNN have neurons which are arranged in three dimensions: width, depth and height. This attribute is of utmost use when working with image or other visual data. We do not have to perform any operations on the images to extract features. Instead of features, the image themselves are provided as input to the network, unlike in the case of Artificial Neural Networks.

Generic Neural Networks do not scale properly to complete images. In FER2013, images are only of size 48*48*1, so a single fully connected neuron would have 48*48*1 = 2304 weights. This amount is still small enough to be managed but since the dataset has more than 35,000 images and we would most certainly be needing the use of several such neurons; the number of weights becomes unmanageable. Evidently, this full connectivity is futile, and the huge number of weights would easily cause overfitting.

The CNN layers used in the network are described below:

A. Convolutional Layer

This is the foremost layer which helps us to extract useful features from the input image. Convolution is the first layer to extract features from an image. Convolution conserves the relationship between pixels by learning features of the image using small squares of input data. This layer makes use of a set of filters which have learnable weights. The image is represented by its pixels in matrix form and a similar representation is used by the filters. The matrix extends across the three dimensions but since we have used grayscale images, the depth dimension is unity. Convolution takes place between the two matrices, where the filter slides across the height and width of the image matrix and calculates dot products, resulting in the formation of a convolved feature map. Stride is the value which tells the filter the number of pixels that need to be jumped for next convolution. When the stride is 1, every pixel is covered 1 by 1. Sometimes, padding the image with zeros around the edges helps to cover the entire image and prevent data loss. This is called zero padding.

B. Pooling Layer

Succeeding every convolutional layer is a Pooling Layer which helps us in decreasing the spatial volume of the samples, to lessen the quantity of parameters and to control computational load and overfitting. The Pooling Layer in the proposed network makes use of the MAX operation and operates independently on every depth slice of the input, ensuring that only the feature with the most prominence is protected. This results in down-sampling or resizing of the data.

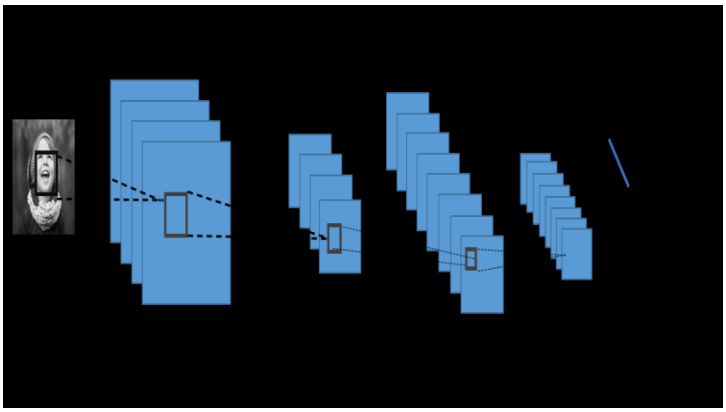

Fig 2. Representation of the network

C. Fully Connected Layer

After multiple convolutional and pooling layers, the final categorization of the images into emotion classes is performed by the Fully Connected Layer. The matrix is flattened to form a vector. All the neurons in this layer have connections to all outputs of the previous layer and the output of this can simply be calculated by matrix multiplication. The activation function used here is the SoftMax function. It is a type of sigmoid function, but it is of use when we are trying to classify data into several classes. In this work, the number of classes is 7. The SoftMax function squeezes the outputs for all these 7 classes between 0 and 1 and divides by the sum of the outputs.

III. DATASET

We have trained our model on the FER2013 data set from the *Kaggle Facial Expression Recognition Challenge*, which consists of 35,887, 48-by-48-pixel grayscale pictures of human faces, each with a label of one of the 7 emotion categories (table 2): **anger, disgust, fear, happiness, sadness, surprise, and neutral**. Training, cross validation and testing has been performed on the dataset in the ratio of 80: 10: 10.

IV. APPROACH

The CNN model that we have designed consists of three layers: 4 Convolutional, 4 Pooling and 1 Fully Connected Layer. The Convolutional Layer performs convolution of the features with the weights of the sliding filter.

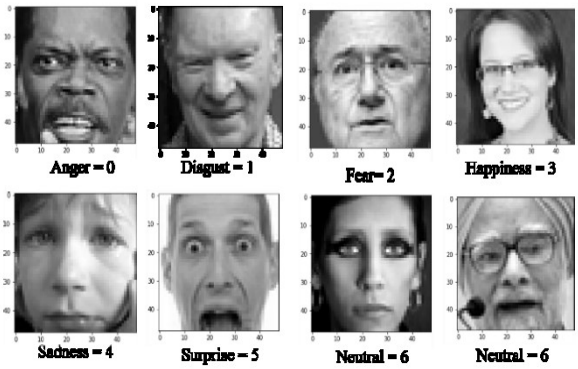

Fig 3. Sample Images from FER2013 dataset

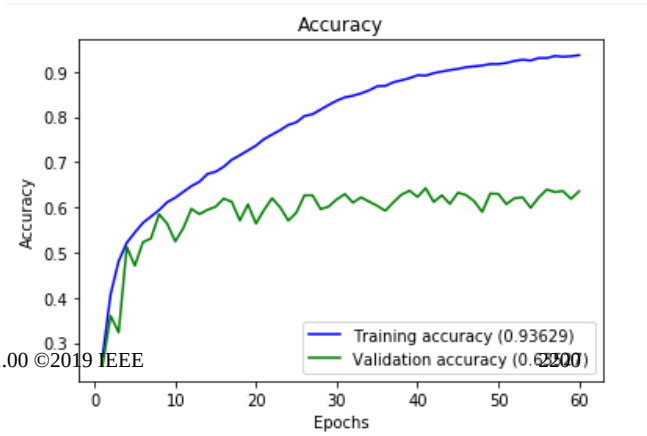
A Batch Normalization Layer follows the convolutional layers to increase the learning rate of the network. After the Activation Layer introduces nonlinearity in the network, the Pooling Layer down samples the data. Post this, some random neurons are dropped out to prevent overfitting. The training of this model has been done on



80% of the data of FER2013 dataset. The number of epochs for the training were finalised to be 60 from the following graph. Epoch is the number of iterations of the passing of the entire data through the model. Table 1 explains the model configuration of the proposed architecture. It gives the outputs of the different layers at different stages.

Fig 4. Accuracy vs Epochs graph

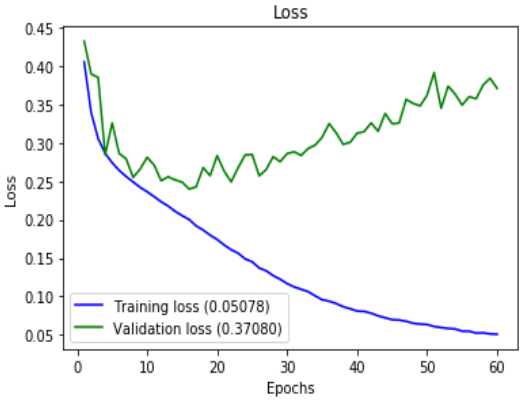


Fig 5. Normal Loss vs Epochs graph

It was observed that both the training and the validation i.e. cross-checking accuracy of the model does not increase beyond the employment of 60 epochs. After the model was trained, we tested it in two ways.

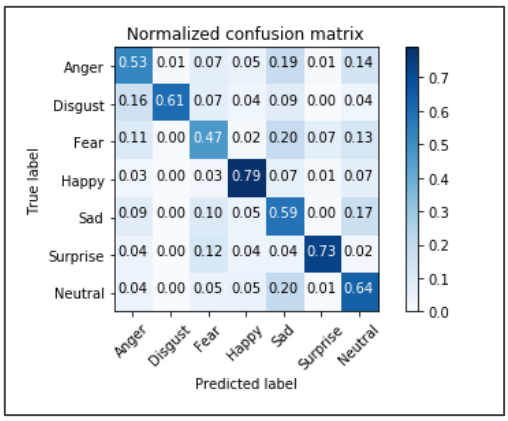
The first method of testing was the simple use of FER2013 dataset and its 10% images that had not been used for training or cross-validation. For the second method, we made use of OpenCV, a library of Python which deals with Computer Vision. By employing this, we were able to detect emotions on still images that were provided to the network as well as from images captured using a web camera.

To detect emotions on images from outside the dataset, either the image stream from our webcam or the images saved for testing, first the faces are detected using OpenCV and bounding boxes are added. Then the faces are converted to greyscale and resized so that the pre trained network can work on them. The predictions are received, and the label is added to the image. And finally, the original image stream is returned with the emotion label attached.

V. RESULTS

In our work, 28709 images from the FER2013 dataset, have been used for training and 3589 images have been used for validation and testing each. As shown in Fig. 4, the training accuracy reaches its peak at 0.93 whereas the validation accuracy comes out to be 0.64. Fig. 5 explains the normal loss. When the remaining 3589 images of the dataset are used for testing, the confusion matrix for all the seven emotions is generated. From Fig. 6, the overall accuracy for the testing images was found to be 0.6422.

The easiest emotions to detect on the dataset were Happy which had the accuracy of 0.79 and Surprise with an accuracy of 0.73. Meanwhile, Fear was a tough emotion



to

Fig 6. Confusion Matrix for FER2013 dataset

predict with the lowest accuracy of 0.47. The average of all the seven emotions is approximately 0.64.

In the case of live images (fig. 7), as has been previously mentioned, the emotion was returned as a label on top of the image.

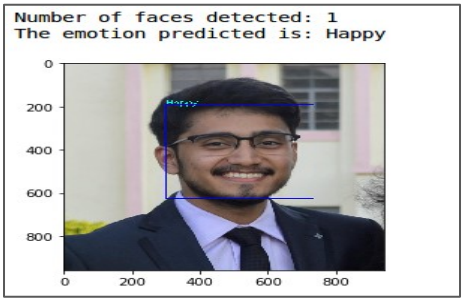


Fig 7. Emotion detection on a single stored image

The algorithm, for the extraction of faces from live or stored images, went so far as to detect multiple faces

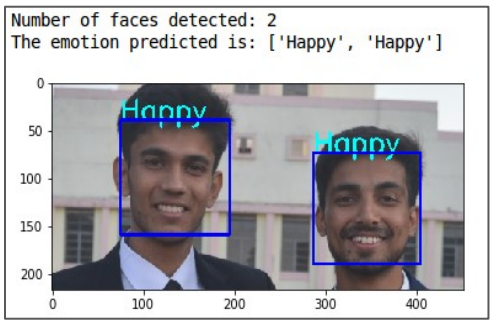

Fig 8. Stored image having multiple faces

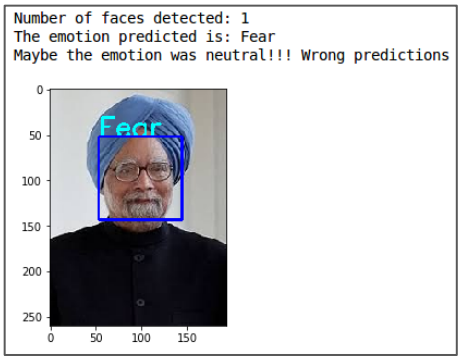
(fig. 8) in a single image and return their respective emotions. There were also some cases where the emotions were wrongly predicted (fig. 9) and most of the confusion was centered around the emotions Neutral, Anger and Fear which were repeatedly confused for Sad.



9. Wrong emotion detected

VI. CONCLUSION

Facial Emotion Recognition has been a vehemently researched topic and justifiably so owing to the innumerable applications that it allows to develop. Here, a neural network architecture is presented for the recognition of facial emotion on images. The proposed architecture consists of 4 convolutional, 4 pooling and 1 fully connected layer followed by the SoftMax activation function. After being trained on the FER2013 dataset, the model can be tested on both images from the dataset as well as on saved images or images captured from web cam. The model works for an image having a single person as well as multiple persons. The accuracy of the model turned out to be 0.64 and the emotions that were the most accurately predicted were Happy and Surprise while the emotions on the lower rungs of the accuracy leader were Fear and Anger. The proposed work can be extended for real time application by maximizing the accuracy.

Abstract— **Understanding impulse response of a buried electrode helps for designing a better grounding system under the situations of surges. In this paper, the analysis of lightning impulse current has been carried on horizontal grounding electrode by varying its length. Present study has been performed using the approximate transmission line (TL) approach. In TL approach, space-time telegrapher's equation are reformed to Finite Difference Time Domain (FDTD) equations and the same are used for calculating induced voltage and current along the length of the grounding electrode. The aim of this work is to verify the applicability of this approach in the analysis of the horizontal grounding electrode excited by high impulsive currents. The effects of the ground conductivity (σ) on the induced over voltages and current on ground electrode is analyzed and results are reported.**

Keywords—finite difference time domain (FDTD), grounding, horizontal electrode, lightning, transmission line(TL)

I. INTRODUCTION

Grounding system main objective is to provide low path impedance for flow of surge and fault current, so that we can protect power system equipment. During lightning discharge large impulse current could flow in grounding systems and induces transients, these induced voltages will cause damage or mal function of sensitive devices. Transient electromagnetic field analysis which are coupled to horizontal grounding electrode is of continuous interest in electromagnetic compatibility (EMC) [1-3]. Analysis of transient response of grounding system excited by impulsive currents is given in [4-6]. Design of grounding system for protecting power system equipment including time dependent nonlinear soil ionization are reported in [7].

Basically there are two models to find voltage and currents in grounding conductor due to transient magnetic fields (i) antenna theory model and (ii) transmission line (TL) approximation [8]. Both models can be solved either in frequency or time domain. Antenna theory approach is more rigorous one and takes more computational time and cost. Transient analysis of simple ground by using wire AT is given in [9]. TL approach is a classical and sufficient approximation for long length lines with electrically small cross sections, but for high frequency excitations of finite length line it is not precise.

Standard TL approach restrictions can be overcome by using enhanced TL models [10]. Wire antenna theory model and modified transmission line model (MTLM) in frequency domain are used to find the transient response of horizontal grounding electrode is in [10].

Using Finite Difference Time Domain (FDTD) method induced voltages and currents at every node is calculated by using the approach developed by using Taylor MTL equations and the expressions representing localized networks [11]. Direct time domain analysis of electromagnetic fields coupling to buried thin wire by antenna theory approach and by TL approach are compared in [12].

By taking the soil ionization and coupling between elements in to consideration, the transient behavior of horizontal grounding electrode when excited with lightning currents [13]. The nature of impedance of horizontal grounding electrodes which is immersed in soil of various resistivity has been studied by applying the Transmission Line Method in [14].

Space time Pocklington integrodifferential equation used in AT model, and telegrapher's equation is used in TL model are compared and reported in [15]

In this paper transient currents due to lightning on horizontal grounding electrode is calculated by space time telegrapher's equations from transmission line approach. FDTD method is used to solve the telegrapher's equation to find current and voltages at each point along the length of the electrode.

II. HORIZONTAL GROUNDING ELECTRODE

The study of impulse currents and voltages on horizontal grounding electrode is helps for getting better knowledge of power system grounding and for proper operation of sensitive devices at load side.

A. transmission line model:

Approximate transmission line (TL) approach is using for transient analysis of a horizontal grounding electrode dunked

in ground for finding impulse current and voltages. In this study ground is considered as imperfect i.e. it is having finite value of ground conductivity (σ≠∞). The schematic diagram representing the study of impulse response of the grounding electrode is shown if Fig.1. In TL approach set of solution of telegrapher's equations will give voltage and current values at every space and instant of time. Finite Difference Time Domain (FDTD) method is used for simplifying and solving set of telegrapher's equations.

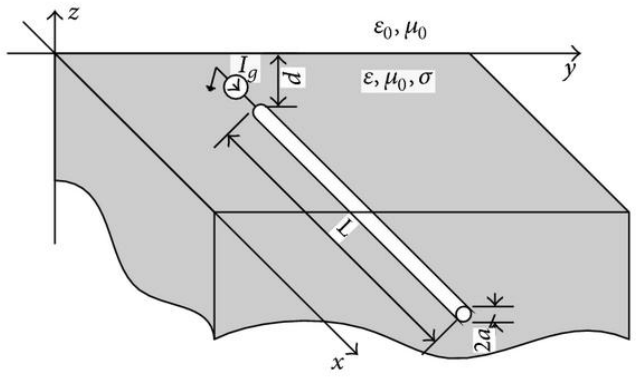

Fig. 1. Schematic diagram of horizontal grounding electrode

Lightning impulse current is the excitation or source for to examine transient behaviour of the horizontal grounding electrode buried at a certain depth of imperfect ground.

Exciting current can be theoretically represented using double exponential function (1) which is also a representation of lightning current [16]:

$$I_g(t) = I_0\left(e^{-\propto t} - e^{-\beta t}\right) \quad (1)$$

Where I_0 - is the amplitude of impulse current

$\propto$, β - constants for tail and front.

The numeric for above parameters considered in this study is as follows.

$$I_0 = 100 \times 10^3 A, \propto = 7.1622 \times 10^4 s^{-1}$$
$$\text{and} \beta = 2.0768 \times 10^7 s^{-1}.$$

The set of telegrapher's equations [17] used in this study for getting impulse voltages and current on grounding electrode is given in (2) and (3):

$$\frac{\partial v(x,t)}{\partial x} + Ri(x,t) + L\frac{\partial i(x,t)}{\partial t} = 0 \quad (2)$$

$$\frac{\partial i(x,t)}{\partial x} + Gv(x,t) + C\frac{\partial v(x,t)}{\partial t} = 0 \quad (3)$$

Consider ground electrode is a pure conductor, so resistance R=0, parameters L, G, C are calculated using (4) as follows.

$$L = \frac{\mu_0}{2\pi}\ln\left(\frac{2l}{\sqrt{2ad}} - 1\right),$$

$$G = \frac{2\pi\sigma}{\ln\left(\frac{2l}{\sqrt{2ad}} - 1\right)},$$

$$C = \frac{2\pi\varepsilon_0\varepsilon_r}{\ln\left(\frac{2l}{\sqrt{2ad}} - 1\right)}. \quad (4)$$

Here l is length, a is radius and d is depth of a horizontal electrode buried. μ_0 is permeability of air ε_0 is relative permittivity σ is conductivity of the ground.

B solution of telegrapher's equation using FDTD:

Telegrapher's equations numerical solution is done by using FDTD method [18-19]. FDTD method is proposed by YEE in 1966. It is popular numerical method for finding transient response of transmission line. The derivatives in the telegraph equations are discretized and approximated with various finite differences. In this method the position variable x is discretized to Δx and the time variable t is discretized to Δt.

FDTD method is originally used for solving the Maxwell's equation [20]. In this the differentiation is taken as difference of future and past values in time and difference of next and previous values in space differentiation. Maxwell's equations are having differentiation in terms of both time and space, and the values of magnetic field and electric fields are interdepend on each other. To find the next step electric field it is need to use present magnetic field values and similarly for finding next step magnetic needs present electric field values [21]. Fig.2. represents the Finite Difference Time Domain (FDTD) discretization used in the present study.

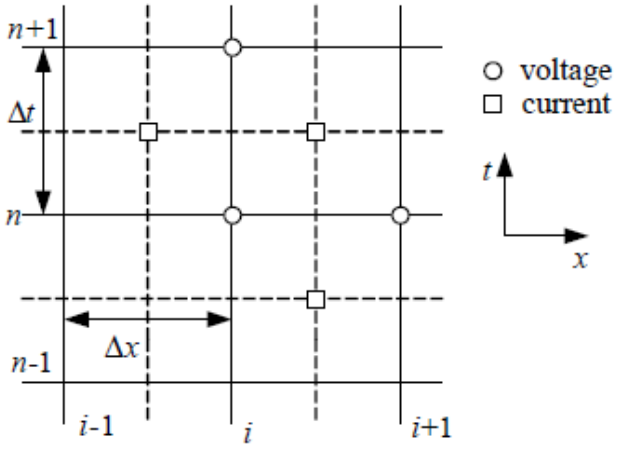

Fig. 2 Time and special discretization of line in FDTD method.

In Fig.2. shows the time and special discretization of horizontal conductor considered in this study. Taking finite differences for voltages and currents the following equation (5) is used as given in [22].

$$\frac{\partial v(x,t)}{\partial x} = \frac{v_{k+1}^{n} - v_{k}^{n}}{\Delta x}\,,$$

$$\frac{\partial i(x,t)}{\partial t} = \frac{i_{k+1/2}^{n+1/2} - i_{k+1/2}^{n-1/2}}{\Delta t} \qquad (5)$$

Substitute (5) in (2) and result is given in (6)

$$\frac{v_{k+1}^{n} - v_{k}^{n}}{\Delta x} + R\frac{i_{k+1/2}^{n+1/2} + i_{k+1/2}^{n-1/2}}{2} + L\frac{i_{k+1/2}^{n+1/2} - i_{k+1/2}^{n-1/2}}{\Delta t} = 0 \qquad (6)$$

By rearranging (6) gives (9) for finding current at every instant of time and space of conductor.

$$i_{k}^{n+\frac{3}{2}} = \left(\frac{\Delta x}{\Delta t}l + \Delta x\frac{r}{2}\right)^{-1} \cdot \left[\left(\frac{\Delta x}{\Delta t}l - \Delta x\frac{r}{2}\right)\cdot i_{k}^{n+\frac{1}{2}} - \left(v_{k+1}^{n+1} - v_{k}^{n+1}\right)\right] \text{ For k=1, 2…N} \qquad (7)$$

$$\frac{\partial i(x,t)}{\partial x} = \frac{i_{k+1/2}^{n+1/2} - i_{i-1/2}^{n+1/2}}{\Delta x}\,, \quad \frac{\partial v(x,t)}{\partial t} = \frac{v_{k}^{n+1} - v_{k}^{n}}{\Delta t} \qquad (8)$$

Substitute (8) in (3), and resultant is given in (9)

$$\frac{i_{k+1/2}^{n+1/2} - i_{i-1/2}^{n+1/2}}{\Delta x} + G\frac{v_{k}^{n+1} + v_{k}^{n}}{2} + C\frac{v_{k}^{n+1} - v_{k}^{n}}{\Delta t} = 0 \qquad (9)$$

By rearranging (9) gives (10) for finding voltage at every instant of time and space of conductor.

$$v_{k}^{n+1} = \left(\frac{\Delta x}{\Delta t}c + \Delta x\frac{g}{2}\right)^{-1} \cdot \left[\left(\frac{\Delta x}{\Delta t}c - \Delta x\frac{g}{2}\right)\cdot v_{k}^{n} - \left(i_{k}^{n+\frac{1}{2}} - i_{k-1}^{n+\frac{1}{2}}\right)\right] \text{ For k=2, 3…N} \qquad (10)$$

The following expressions are applied to evaluate the voltages at line terminations by using boundary conditions,

$$v_{1}^{n+1} = \left(\frac{\Delta x}{\Delta t}c + \Delta x\frac{g}{2}\right)^{-1} \cdot \left[\left(\frac{\Delta x}{\Delta t}c - \Delta x\frac{g}{2}\right)\cdot v_{1}^{n} - 2i_{1}^{n+\frac{1}{2}} + \left(i_{g}^{n+1} - i_{g}^{n}\right)\right] \qquad (11)$$

$$v_{nx+1}^{n+1} = \left(\frac{\Delta x}{\Delta t}c + \Delta x\frac{g}{2}\right)^{-1} \cdot \left[\left(\frac{\Delta x}{\Delta t}c - \Delta x\frac{g}{2}\right)\cdot v_{nx}^{n} + 2i_{nx}^{n+1/2}\right] \qquad (12)$$

The current excitation i_g^n at the time instant t=nΔt is given by (1). From (7) and (10) it is observed that, the current and voltages are interdependent on each other. Hence by coding (7), (10), and by taking voltage boundary condition (11), (12), results of voltage and current at each and every time instant at all spatial distances of conductor are evaluated. FDTD method gives best solution only when the spatial and temporal step are satisfying the stability condition as follows

$$\Delta t \cdot V_p < \Delta x$$

Where

$$V_p = \frac{1}{\sqrt{LC}}$$

III. RESULTS OF HORIZONTAL GROUNDING ELECTRODE

In this study a horizontal electrode which is having a length of L=10 m, and radius of a=5 mm, buried in a ground at a depth of d=0.5 m are considered. The relative permittivity of ground is ε_r =10. The source of excitation for the horizontal grounding electrode is simulated using a double exponential current function with I_0=100 kA. The numerical results are obtained by solving telegrapher's equations using FDTD method.

The excitation to the horizontal electrode for transient analysis is 0.1/1 μs pulse having parameter values are as follows,

$$\alpha = 9.4385 \cdot 10^{5} \text{ (1/s)}$$

$$\beta = 1.5 \cdot 10^{7} \text{ (1/s)}$$

Taking Δx=1 m and 10 m horizontal grounding electrode is divided into 10 equal parts. From the FDTD stability condition, the value of Δt should be less than $1 \cdot 10^{-8}$.

In this paper results shown are with

$$\Delta t = 0.4 \cdot 10^{-8}$$

Fig.3. represents the transient response at 2 m of 10 m long electrode, and Fig.4. represents the transient response at 5 m of electrode, and Fig.5. represents transient current at 8 m by taking ground conductivity of $\sigma_g = 1mS/m$.

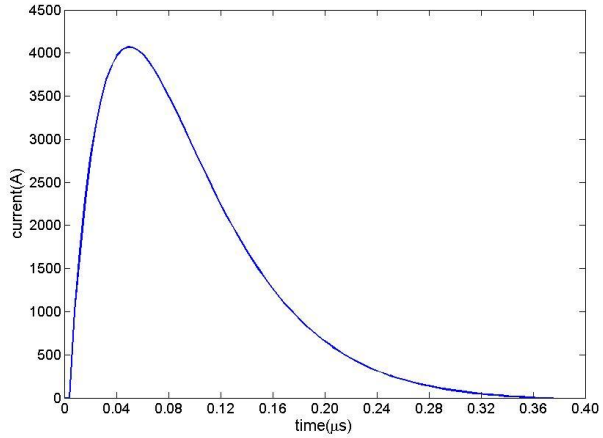

Fig. 3 current at 2 m of grounding electrode with ground conductivity of $\sigma_g = 1mS/m$

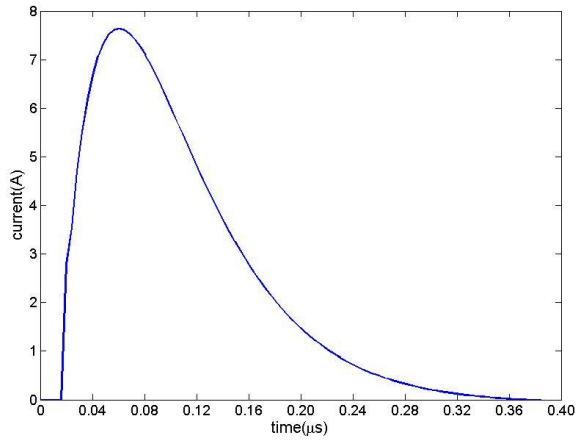

Fig. 4 current at 5 m of grounding electrode with ground conductivity of $\sigma_g = 1mS/m$

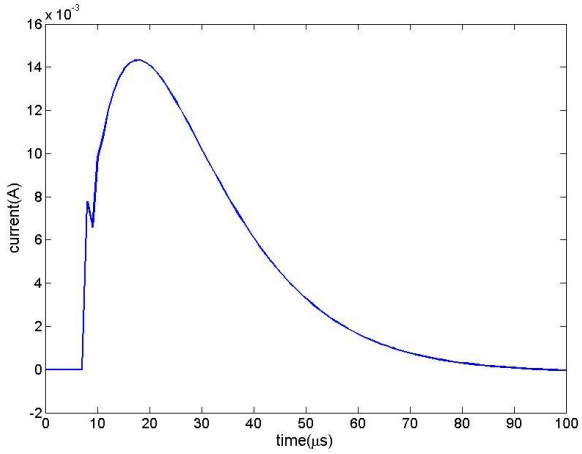

Fig. 5 current at 8 m of grounding electrode with conductivity of $\sigma_g = 1mS/m$

TABLE 1

Table.1: Peak value of impulse current at different observation point along 10 m length of horizontal electrode for different ground conductivities.

Conductivity of ground (σ_g) S/m	Peak of impulse current (A) from the injection point			
	2 m	5 m	8 m	10 m
0.0001	9186	18.15	0.03586	0.000501
0.0005	5622	10.85	0.02096	0.000288
0.001	4068	7.637	0.01432	0.000189
0.01	617	0.7851	0.001267	0.00001744

From Fig.3. and Fig.4. it observe that the peak of the impulse current at 2 m from injection point is in terms of kilo amperes. Whereas the impulse current peak is decreased to ampere at 5m and mille amperes at 8 m distance for the same injecting current.

For the same input with different conductivities of ground the peak and transient response of current changes at every observation point. Table 1 is provided peak values of current at 2 m, 5 m, 8 m and 10 m with different conductivities of ground. From the Table 1 we can observe that when the conductivity of ground is increasing peak of current is decreasing.

Impulse current at that injection point (0 m) in kA, but at the end of the conductor (10 m) is in mA. The impulse current reduces rapidly while it reaches to another end of conductor.

Fig.6, 7 and 8 shows the plots of the impulse current at the observation point 2 m, 5 m and 8 m distances from the origin, for the assumed ground conductivities varies from 0.0001S/m to 0.01S/m.

From the Fig.6. it can be observed that for a observation point close to the origin (2 m) the peak current is almost equal to 9 kA with 0.0001 S/m, were as same injecting current decreased to less than 1 kA with 0.01 S/m ground conductivity.

Hence, it can be that the ground conductivity plays as vital role to attenuate the current which is travelling on the horizontal grounding conductor.

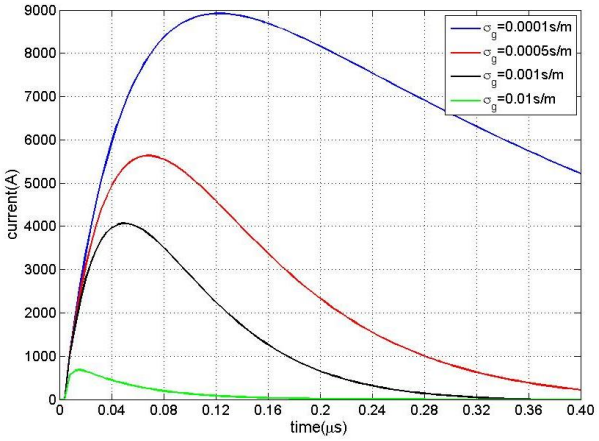

Fig. 6. impulse current at 2 m with different conductivities of ground.

In Fig.7. impulse current waveforms at 5 m distance from the starting of conductor with different conductivities of ground is given

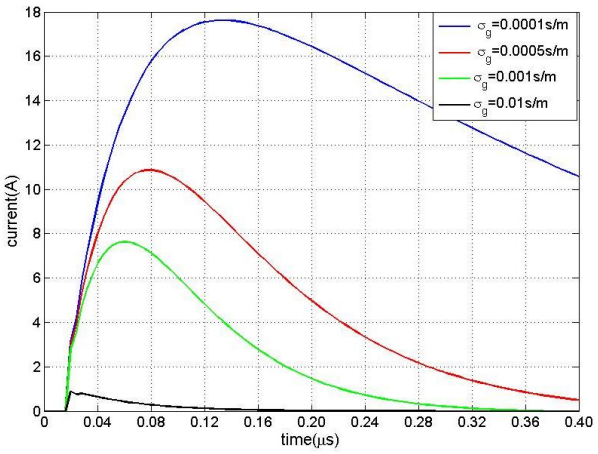

Fig.7. impulse current at 5m with different conductivities of ground.

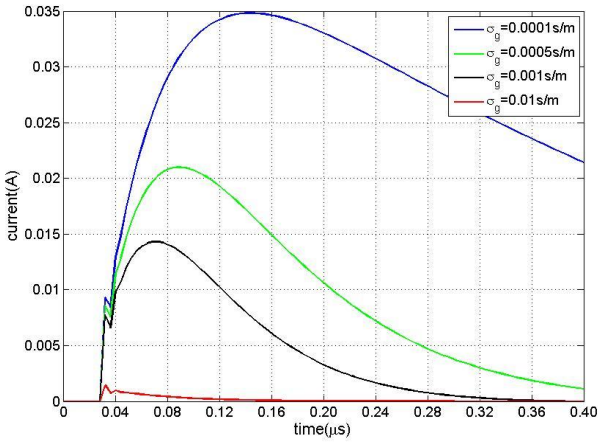

Fig. 8 impulse current at 8 m with different conductivities of ground.

From Fig.7. we can observe that impulse current having more peak value with low conductivity of ground than with the high conductivity of ground. In Fig.8 the same trend can be observe at 8 m distance from starting of the conductor. In Fig.6, 7 and 8 peak of current waveform with conductivity of 0.0001 is more than other conductivities, means the peak value is keep on reducing when conductivity of ground is increasing.

IV. CONCLUSION

The present study conducts investigation of impulse response in horizontal grounding electrode due to lightning surge. It can helps for efficient designing of grounding system under the aforementioned conditions. The transmission line (TL) model, telegrapher's equation solved by Finite Difference Time Domain (FDTD) is used for the transient analysis of the grounding system considered in in the study.

By applying double exponential impulse input to the horizontal grounding electrode we observe the transient current at 2 m and 6 m and 8 m from the source end. And from the graphs it can be observe that input impulse current magnitude is attenuating while it goes to another end of the electrode, from KA to mA. Also observe that the attenuation of the impulse is more if conductivity of earth is more.

Abstract— In recent years data security rise into a prominent area of study as there are so many threats regarding maintenance of a sensitive data. Among these threats one of the most dangerous threats is insider attack [1] where an employee of an organization leaks data to an unauthorized third party. There are so many research activities going on in this area in recent times, but the accuracy of the data leakage detection needs more accuracy level. In this paper we are going to propose an Adaptive weighted graph model where instead of content we are going to consider the context of the sensitive terms and we are going to use graphical representation method for representing the contextual information of the sensitive words. The scalability of the fresh data is improved using the label propagation algorithm. Low complexity score walk method is used to improve accuracy in determining sensitivity of sensitive terms. Exploratory outcomes demonstrate that the proposed strategy can distinguish leakage with more exactness.

Keywords— data leakage, data security, weighted graph, label propagation.

I. INTRODUCTION

There is a saying in the business world "you have to work on the business first before it works for you", it indicates that before setting up a business or before starting a new organization one must work hard and understand the needs and success rate of the business. Data analytics assists organizations identify potential opportunities to streamline operations or maximize their business and increase their profit. Associations feel that they have to accumulate tremendous potential chances to streamline activities or expand their business and increment their benefit. Associations feel that they have to accumulate colossal volumes of information before performing examination so as to produce business experiences and improve basic leadership. As the importance of data increases, data security becomes our major concern. One of the most common threats in data security is Data leakage, which indicates depiction of unenviable exposures of data. Traditional security threats are caused by the outsiders but information leakage is for the most part brought about by the insider who may leak information to the outside unapproved elements accordingly it will be of real concern.

Seriousness of data leakage does not depend on the number of records compromised, but on how much risk or damage the leakage caused for organizations or the individuals. Data Transmission mainly comprises of two components Distributor and the agents. Distributor is owner of the data and agents are the third parties who request for the data based on their requirement from the distributor. For instance the SunTrust Bank information leakage happened in April 2018. SunTrust [3] announced a representative may have released the individual information of 1.5 million clients. It is trusted that the guilty party endeavored to duplicate the information and offer it with an unapproved outsider. Correspondingly, a Tesla representative endeavored leaking information to obscure outsiders and adjusted code in the Tesla Manufacturing Operating System in 2018. It is reputed the worker, a confided in client at the time, did it for the individual advantage. These unscrupulous improvements increment the need of a productive information leakage location technique.

To address the issue of information leakage detection, a lot of research work has been finished with the utilization of hash fingerprinting, n-gram, measurable strategies etc...Because of the fast advancement of Internet, numerous new correspondence innovations have developed. Subsequently, the size of the information develops significantly and the types of information become much confused. This prompts new difficulties for information leakage identification. Accordingly, new Data Leakage Detection strategy is required with better resistance of information change and higher proficiency to manage the lot of unstructured information in long examples. Existing methods mainly focuses on the content of the data leaving behind the context which is a major drawback. There may be an issue when a document is modified by adding some contents, which leads to transform the document into a no

sensitive document results in low accuracy in detecting data leakage.

In this paper, another model named Adaptive weighted Graph Walk model is proposed to identify changed information leakage. In this technique, every one of the reports is spoken to as graphs. The delicate setting weights are spoken to as node weights and edge weights, which improve the recognition precision of the changed information. In view of the setting around the catchphrases the setting weight can evaluate the affectability of the watchwords adaptively. The proposed strategy plans to distinguish transformed information leakage precisely and productively.

II. LITERATURE SURVEY

In this area principle center is around research approaches towards information leakage detection/prevention action. Wikileaks [2] a non-benefit worldwide distributing association established by Julian Assange known for uncovering atrocities, human rights misuses, and defilement released the Afghanistan war logs (July 2010), the Iraq war logs (October 2010) .This builds the need of the exploration take a shot at information leakage detection/prevention action. The ebb and flow explore chip away at information leakage recognition/aversion can be arranged into two classes which incorporates content analysis and context analysis.

1. Content analysis

The content analysis examines any piece of writing or occurrence of record communication. The content analysis is used in the field of information retrieval. The content analysis incorporates techniques like Rule based strategy, Fingerprinting technique, Statistical technique [6].In Rule based method the tested documents are scanned with respect to predefined regular expression. Sensitivity of the report relies upon the degree to which the tested archive matches with the predefined ordinary articulation. When there is leakage detection of new data accuracy level decrease in rule based method. Fingerprinting technique utilizes hashing strategy where hash estimation of the tested report is contrasted and the hash estimation of the prepared format archive. The recognition stage turns out to be quick and accurate when the tested archive is unique record. If the document is modified (or transformed) detection becomes difficult.

The statistical strategies for the most part center on the measurable highlights of the archive like term recurrence and opposite record recurrence. Term-frequency is the portrayal of how as often as possible an articulation (term or word) happens in an archive .Inverse document-frequency is the portrayal of delicate records as for non touchy archives. AI arrangement techniques like Naive Bayes [5] and support vector machines (SVM) are utilized where content is mapped into vector space and prepares the classifier with the highlights of terms and their highlights. In this technique Statistical highlights were featured however setting of the record is overlooked which prompts less exactness in recognition stage.

By and large content analysis techniques like rule based strategies and fingerprinting strategies are wrong to manage information change, since they for the most part center on the measurable highlights of the terms in an archive by overlooking the context weight of the terms. In present world as volume of the data increases various forms of data also increases. Content analysis methods are not appropriate methods to handle these transformed data.

2. Context Analysis

Context analysis analyzes macro environment of a business, which includes both internal and external environment of a business. The recent works on context analysis considers sensitive context of terms. The word N-gram based classification [4], [8] [9] of data leakage prevention is proposed where initially only statistical features of the sensitive key words are considered as the important component. To overcome the limitations context of the keywords are considered which resulted in a more accurate result. In spite of the fact that there is an improvement in the data leakage detection accuracy still there is a scope for improvement. To achieve the improvement to a greater level graphical representation is used. The graphical representation method [11] represents the sensitive terms and their contextual relations as hub loads and edge loads of the diagram. Context based model (COBAN) [10] is proposed contains mainly two stages learning stage and detection stage. Amid learning stage the sensitive terms and their contextual correlations are used to create graphs and clusters which represents the confidential document. During detection phase these graphs and clusters are used to check whether a document is sensitive or not. But only simple transformations are considered in all the above inventions so still there is a scope of improvement in data leakage detection.

III. PROBLEM STATEMENT

In the course of expanding a business, employer must share data among trusted third parties. Let’s consider an example of a hospital management system where patient records are shared among the researchers who help the

hospital management with new treatment measures. In the same way companies maintain their collaboration with different organizations that require sharing client information. As data plays a prominent role in present day business world data leakage became prominent area of interest. Among so many types of data leakage techniques insider attack is the major one, where human mistakes are the main causes of data loss. For this type of leakage solution is obtained by monitoring the storage and transmission and providing alert when for the organization mainstream whenever required. This approach must be carried out in secrecy otherwise it can get compromised.

Figure 1: Data leakage scenario

To address the issue of data leakage detection (DLD), a ton of research work has been done with the usage of hash fingerprinting, n-gram, quantifiable systems and whatnot. With the brisk improvement of Internet, various new correspondence progresses (e.g., Device-to-Device innovation) have risen. In like manner, the volume of data grows altogether and the sorts of data end up being very ensnared. This passes on new test to DLD. Thusly, new DLD method is required with better resistance of data change and higher capability to deal with the part of unstructured data in long precedents.

IV. PROPOSED METHOD

In this paper along with the content we also focus on context of the sensitive keyword or term. In the following proposed method we mainly have two stages learning stage and detection stage. Amid learning stage, we train using sensitive keywords and then use the correlation between them to indicate the context of the keyword. In detection phase we compare the test data with respect to trained data and find data leakage.

Weighted Graph Walk Model (AGW) is proposed to recognize changed information. In this model, every one of the archives is spoken to by graph. The sensitive setting weights as hub weights and edge weights are characterized in the chart to enhance the recognition precision towards the changed information. The setting weight can evaluate the affectability of the watchwords adaptively dependent on the setting around the catchphrases. The proposed arrangement plans to recognize a lot of recently created, widely changed information precisely and productively. The fundamental commitments are as per the following.

To all the more likely endure the since quite a while ago changed information, we characterize a versatile setting weight system to evaluate the affectability of the watchword dependent on its unique circumstance. The perplexing archives are additionally spoken to by weighted setting charts, containing both key terms and important information. To adjust for the limitation of the design and augmentation the versatility, we moreover consider the data semantics. An improved mark proliferation calculation label propagation algorithm (LPA) is used to name a comparable name on the significantly noteworthy terms of the attempted graphs.

Moreover join the diagram of each record into a general one - the template graph, to ensure more relationship information between key terms and overhaul the general delicate setting. To deal with a great deal of data, we propose estimation with low-unusualness. With a weight reward and discipline framework, the count assesses the affectability of the gave documents by one walk a shot their outlines, which empowers the acknowledgment to be realized continuously.

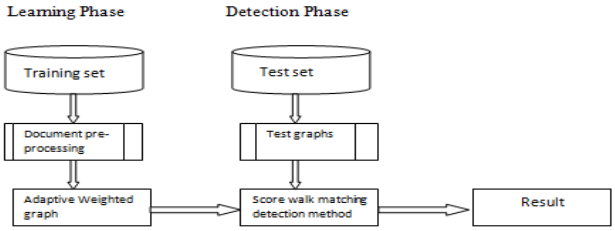

Figure 2: Overview of the model

A. Learning phase

Term frequency-inverse document frequency is utilized in the field of data recovery. Term frequency is utilized to locate the occasions an articulation (term, word) happens in a record. Inverse document frequency is the portrayal of the affectability of the report regarding non delicate archive. There TF-IDF (Term frequency-inverse document frequency) is utilized to speak to the heaviness of the delicate terms.

TF-IDF=tf(t,d) * idf (t,D) (1)

Where tf(t,d) is the term frequency and idf(t,D) is the inverse document frequency.

Term frequency can be evaluated using

$$\textbf{Term frequency (t, d)} = \frac{(n_t, d)}{\sum_{t' \epsilon d}(n_{t'}, d)} \quad (2)$$

Where $\sum_{t\prime\epsilon d}(n_{t\prime}, d)$ indicates the sum of all term in the document d.

Inverse document frequency

Idf(t,D)=log(Ds/1+{d'€Dn:t€d'}) (3)

Where Ds is the number of sensitive documents, {d'€Dn:t€d'} indicates the non sensitive documents where term t appears.

The calculated weight is used in the construction of adoptive weighted graph. Using threshold value specified for the sensitivity of the tem we are going to select N terms and those N terms are considered as the nodes and the correlation between them gives the edge weights using these Adaptive weight graph is constructed. These individual template graphs are merged to develop a generalized graph which increases detection accuracy. We cannot directly divide the graph into sub graphs which may result in incomplete or one sided graph. Therefore Label propagation method [12] [13] is used to partition the graph.

Algorithm: Pseudo Code for Sensitive Data Learning
Input: A set of documents
Output: The Adaptive Weighted graph developed for given sensitive keywords.

1. Input the sensitive keywords to be trained through a document or file.
2. Document pre-processing must be used to remove stop words.
3. Using the TF-IDF calculates the node weights and the edge weights and select the most significant N terms.
4. Using weight set of N terms, compute Weight matrix
5. N terms denote the N nodes and Using these and the weight matrix graph is constructed for each document.
6. Consolidate these individual diagrams and parcel the hubs into different classifications by utilizing label propagation algorithm.
7. Hub weights and edge weights are masked using hashing method to maintain privacy.
8. Stop

Amid Adaptive weighted graph learning phase administrator forms the touchy reports determined and extricates the delicate watchwords. As we are utilizing graphical portrayal for assessment of delicate reports, every touchy catchphrase is considered as the hub and their weight is gotten by utilizing term frequency (TF) and inverse document frequency (IDF). Considering all the touchy watchwords lead to haphazardness so an edge should be considered to constrain the quantity of delicate catchphrases. The relationship between's the touchy catchphrases is considered as edge weights and utilizing these qualities a versatile weighted graph is built for each report. Combining all these individual graphs prompts a solidified template graph which is built for assessment reason. Label propagation algorithm is utilized to order the hubs for better assessment. For safeguarding touchy catchphrases MD5 hashing technique is utilized for encryption.

B. Detection Phase

In this phase the user input the document the document is testified against the trained adaptive weighted graph if sensitive words weight exceeds the threshold the document is considered as the sensitive document. Alert message is sent to the user. It's up to user's choice to send the document or not.

Algorithm: Sensitive Data Detection Algorithm
Input: Document to be tested
Output: alert to the user if document is sensitive.

1. Input the file
2. Remove all unnecessary words, special characters from file and filter keywords from the file
3. Generate hash code for each keyword in file using MD5 Algorithm
4. Calculate weight and keyword ranking of each keyword in file
5. Calculate sensitive words data weight.
6. if sensitive weight of the words value increases threshold value, then that file is considered as sensitive file
7. Alert message is given to user whether file is sensitive or not
8. Stop

Amid detection phase the documents to be tested are pre-processed. The sensitive watchwords are removed by contrasting the substance of the record and regard to indicated touchy catchphrases. The weights of the touchy watchwords are determined utilizing TF-IDF (Term recurrence – Inverse report recurrence). The graph is built for sensitive watchwords present in the test document. Utilizing Depth first pursuit (DFS) the chart is navigated when the sensitive watchwords are experienced the weights are added. In the event that the absolute weight achieves the limit esteem, at that point the archive is proclaimed as sensitive documents.

C. Transformed Data Leakage Architecture

Information leakage happens when information is leaked or undermined by insider of an association to unapproved outsiders purposefully or coincidentally, which may make genuine harm the association. Thinking about a situation where a representative of an association releases delicate documents from authoritative neighborhood system to unapproved outsider. To maintain a strategic distance from information leakage, an identification operator must be conveyed at the outlet of the authoritative nearby system. The general design is appeared in figure 3

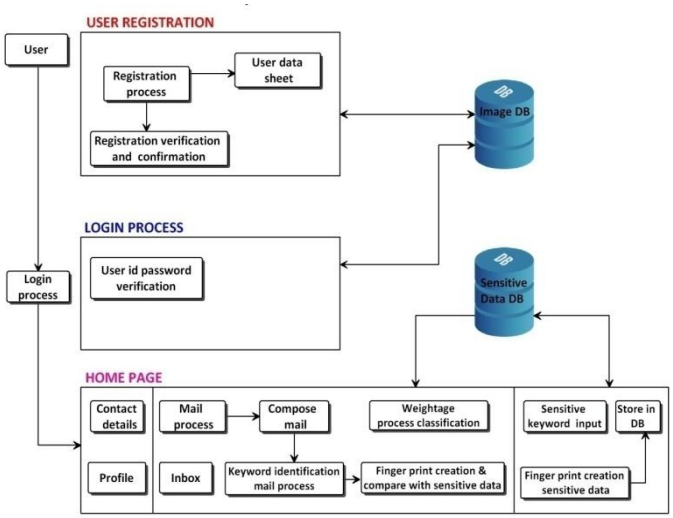

Figure 3: Transformed Data Leakage Architecture

If new user is registered, the user will be verified and confirmed then stored into the database. For User login, required credentials are username and password. Those credentials will be verified by accessing the database. User has multiple features such as Accessing inbox, composing mail, etc., Admin will manage sensitive keywords. If user composes mail, it will go through Keyword identification mail process and compares with sensitive data by accessing sensitive data DB.

V. RESULTS AND DISCUSSIONS

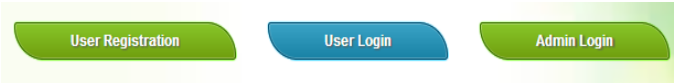

Figure 4: Home/Index page

Index page has three buttons labeled User Registration, User Login, and Admin Login. Admin has to login by submitting Admin name and Password to the application. After successful login of admin, admin can add keyword by submitting field sensitive keyword and sensitive keyword weight. Admin can see profile from view profile section. Admin can edit profile by giving valid details. To change password, admin has to input old password and then input new password and again by confirming password. Admin can see the user list by clicking user list. Admin can delete users by selecting the user admin wants to delete. Registration user has fields such as Username, UserId, UserPass, City, State, Contact No, Email then user has to submit to register.

Figure 8: Admin Login

This page allows the admin to login using their credentials. Admin has all the rights, like creating user, editing user details and deleting a user. Admin sets the roles and privacy settings. Privileges to use application will be set by admin. First time password will be set by admin, if the user forgets its username or password, they can request for reset of password or retrieve username. If the user is involved in any malicious activities admin have all the rights to take necessary actions and also admin will have access to all the data of the users and type of emails they compose and send.

Figure 9: Adding sensitive keywords using Admin credentials

User login process will take username and password as input and process the credentials provided. User will provide contact details in contact details section. In the inbox section, user will be able to view all the mails that received .User will be able to compose mail by clicking on compose

mail option. Compose mail will have fields such as to Address, Subject and Content (Body) of mail

Figure 5: User Login

Figure 6: Compose mail

While composing mail if user wants to attach file, can choose file by selecting choose file option then send the mail. After user clicks on Send, system will check for sensitive keywords in the composed mail and shows warning whether to send mail or cancel. If user still wants to send mail, can click on send option again to send mail. If cancelled, mail will not be sent and can modify the composed mail. User can view information about user by clicking on User profile option.

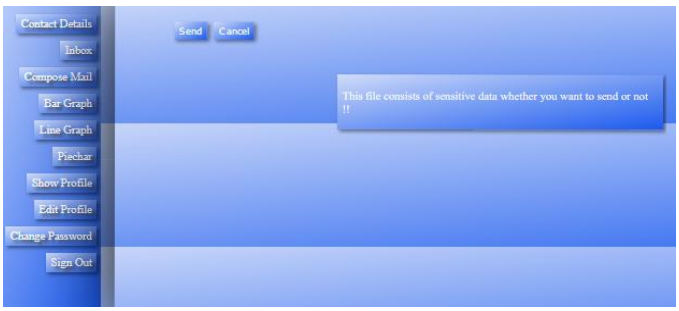

Figure 7: Alert to user regarding sensitive data in the document

If any information has to be edited, user can edit information by clicking on edit info option. User can change password by submitting current (Old) Password, then by giving new password and again confirming the password.

A. Test Cases

Test case Id	Test Input	Expected Result	Actual Result	Remarks
TC_01 User	Enter legitimate username and secret phrase click on login catch	User should be navigated to homepage with the following details as presented in figure 6 .	User should be navigated to homepage with the following details as presented in figure 6.	Pass
TC_02 Admin	Add Sensitive keyword and Sensitive keyword weight age.	Insert sensitive keyword and keyword weight age to the database.	Inserted sensitive keyword and keyword weight age to the database.	Pass
TC_03 User	View Inbox	View emails received by user.	View emails received by user.	Pass
TC_04 User	Compose Mail	Take input of To, Subject, and Body Content and if attached file and check with Fast Detection system.	Take input of To, Subject, and Body Content and if attached file and check with Fast Detection system.	Pass
TC_05 User	Fast Detection of Sensitive Keywords	Take input through Compose mail then check with Sensitive keywords from database. If found any Sensitive keywords, then Prompt	Take input through Compose mail then check with Sensitive keywords from Database. If found any Sensitive keywords, then Prompt	Pass

		user for correction.If Prompt was Yes, allow user to Edit mail.	user for correction.	
TC_06 User	Send Mail	If received prompt from Fast Detection system as No (No edit needed, proceed!) from the FD System then Send mail to Recipient.	If received prompt from Fast Detection system as No (No edit needed, proceed!) from the FD System then Send mail to Recipient.	Pass

Table 1: Test cases

CONCLUSION AND FUTURE ENHANCEMENT

In this venture, another model called Adaptive weighted graph walk model is proposed. This model comprises two stages, for example, learning stage and detection stage. Amid learning stage weighted setting charts are utilized to endure since a long time ago transformed information and to build the versatility to manage crisp arrived information improved mark engendering calculation is utilized. In detection stage weight reward and punishment system is utilized to improve the precision of information leakage detection.
